Hindawi

Retraction

Retracted: Application and Equipment of Preparation Technology of Ferroelectric Thin Film Materials in Sports Industry

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Corrigendum

Corrigendum to "Local Dimming Algorithm of Automotive LCD Instrument Based on Otsu and Maximum Entropy"

Tianfu Liu and **Chunqiu Tang**

School of Mechanical and Electrical Engineering, Wuhan University of Technology, Wuhan 430070, Hubei, China

Correspondence should be addressed to Tianfu Liu; ltf999@whut.edu.cn

In the article titled "Local Dimming Algorithm of Automotive LCD Instrument Based on Otsu and Maximum Entropy" [1], Figures 2–9 have been replaced within the article due to legal reasons. As a result of this the change to the sample figures, Table 3 has also been revised and updated within the article. This does not affect the conclusions of the article.
FIGURE 2: Block effect simulation diagram.
FIGURE 3: Effect comparison of backlight smoothing algorithm: (a) original image; (b) backlight image; (c) traditional BMA; (d) improved BMA.
FIGURE 4: Effect comparison of pixel compensation algorithm: (a) original image; (b) backlight image; (c) traditional pixel compensation; (d) improved pixel compensation.
FIGURE 5: Sample image: (a) low brightness; (b) high brightness; (c) low contrast; (d) high contrast.
FIGURE 6: Low brightness image simulation diagram: (a) max; (b) average; (c) sqrt; (d) SD; (e) ECM; (f) CDF; (g) IMF; (h) new.

Figure 7: High brightness image simulation diagram: (a) max; (b) average; (c) sqrt; (d) SD; (e) ECM; (f) CDF; (g) IMF; (h) new.

Retraction

Retracted: Relationship between Urban Landscape Design and Ecological Environment Protection in the Application of Environmental Protection and Renewable New Energy Materials

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

With the economic growth in recent years, urban construction has also developed rapidly. In developing countries, the pursuit of rapid development has also brought about huge energy consumption, energy shortage, and environmental pollution. It is urgent to find and develop renewable energy. In order to understand the role of renewable energy materials in urban landscape design and ecological environment protection, replace nonrenewable materials with renewable energy materials, and reduce urban pollution, we analyze the available energy for buildings in urban areas and optimize the allocation of various available resources. Energy, improve energy efficiency, so as to save energy, protect the environment, and coordinate the development of energy, economy, and environment. Renewable energy is also known as alternative energy, sustainable energy, or nontraditional energy. It is energy that can be obtained from nature and can be replenished naturally. Experimental results prove that the energy required for traditional material consumption is much higher than the consumption of renewable energy, and its range is more than 50%. Renewable energy can replace the role of nonrenewable energy. This article hopes to stimulate more relevant architects to think about this subject through the research and analysis of renewable energy.

1. Introduction

The rational use of renewable resources such as solar energy, geothermal energy, and bioenergy in urban buildings will contribute to the sustainable development of urban energy, economy, and environment. Through the analysis of the available energy in urban buildings, rationally optimizing the distribution of various available energies and improving energy efficiency, the goals of energy conservation, environmental protection, and coordinated development of energy, economy, and environment can be achieved. With the development of the new era, the concept of sustainability has gradually penetrated into the hearts of the people, and the design of gardens must also develop with the trend of the times. Starting with the functionality of the garden, to a certain extent, make the garden a purification system for the urban environment and play a role in buffering air pollution. Therefore, on this basis, the design of urban gardens must be highly coordinated with

the planning of related cities, and the different functions of gardens should be brought into play according to the content of urban planning. Therefore, it is necessary to study the design of urban building energy system and coordinate the available energy distribution of various buildings from the urban planning level. In this way, the sustainable use of energy can be ensured, the utilization of energy can be maximized, and the urban ecologicalization can be realized.

Renewable energy collection embedded system is a technology that uses renewable energy to have the characteristics of wide distribution, sustainable collection, and low cost, and to efficiently collect and store renewable energy while replacing a single battery as the energy supply unit of the embedded system. However, in terms of energy harvesting and storage, the technology is still affected by environmental changes and the limitations of traditional energy storage technologies, resulting in irregular and unpredictable input energy in the energy harvesting process, energy conversion, and high energy consumption

of the energy storage system. The development and utilization of new energy and renewable energy are the basic requirement for implementing the scientific development concept and building a resource-saving and environment-friendly society. It is an urgent need to adjust the energy structure, save energy and reduce emissions, and reasonably control the total energy consumption. At the same time, it is also an important way to protect the ecological environment, deal with climate change, develop the rural economy, and cultivate strategic emerging industries. This paper aims to explore the relationship between urban landscape design and ecological environmental protection in the application of environmental protection and renewable new energy materials, in order to make a certain contribution in this regard, so as to inspire more relevant architects to think about this topic.

For sustainable development, experts at home and abroad have conducted many studies. Samadi P is concerned about the load dispatching and power trading issues in systems with high penetration of renewable energy (RER). The game theory method is used to simulate the interaction and excess generation between users. The simulation results show that the proposed algorithm reduces the user's energy expenditure. The proposed algorithm also promotes the use of RER by encouraging users to consume excess power locally instead of reinjecting it into the grid [1]. Yang P formulated the cost minimization problem of storage and power generation planning, while considering the initial investment cost and operation/maintenance cost, and proposed a distributed optimization framework to overcome the difficulties caused by the large-scale optimization problem. The results will help to make decisions about energy storage and power generation capacity planning in future decentralized grids with high renewable penetration rates [2]. Rezaei R's model focuses on the unified theory of technology acceptance and use (UTAUT), which is extended to study the factors that influence the intention to use renewable energy. Using the structural equation model's multiple techniques and adding attitude variables as mediating variables in the model, it was found that the predictive ability of the model increased by 19%, providing evidence for five mediation paths in the cognitive process of renewable energy use intentions [3]. Wu Y considered cost-effective energy dispatch for residential smart grids equipped with centralized renewable energy. Quantify the best use of renewable energy to achieve a trade-off between the system-wide benefits of using renewable energy and the related costs due to its fluctuation; evaluate how the fluctuation of renewable energy affects its optimal development. A distributed algorithm with high computational efficiency is proposed to determine the best use of renewable energy and related energy scheduling decisions [4]. Rahim S conducted a comparative evaluation of the performance of home energy management controllers designed based on heuristic algorithms, introduced general demand-side management (DSM) architecture, and used a combination model of time-of-use electricity prices and inclined block rates for energy pricing. The simulation results show that all the designed energy management models have significantly achieved our goals and proved to be a cost-effective solution to improve the sustainability of the smart grid [5]. The purpose of the Athari M H study is to use an optimized fuzzy logic controller (FLC) to examine the impact of time-varying power prices on the performance of the energy storage components of the grid-connected hybrid renewable energy system (HRES). Considering that the grid electricity price has a considerable impact on the performance of the energy storage components running on the grid-connected HRES, because the weekly and daily optimized FLC results in less working hours of fuel cells and electrolyzers, and less SOC fluctuations [6]. The Dogan E empirical study analyzed the impact of actual income, renewable energy consumption, nonrenewable energy consumption, trade opening, and financial development on CO2 emissions in the first few countries listed in the EKC model. It is found that by using CADF and CIPS unit root tests, the analyzed variables become stable at the first-order difference, and the analyzed variables are cointegrated by using the LM bootstrap cointegration test. The increase in renewable energy consumption, trade opening, and financial development reduced carbon emissions, while the increase in nonrenewable energy consumption contributed to the level of emissions [7]. These studies provide a lot of reference for this article, but due to insufficient relevant research data and old research methods, the conclusions of the research cannot convince most people.

The innovations of this paper are as follows: (1) The concept, technical principles, and characteristics of regional building energy planning are analyzed. On this basis, the method of urban regional building energy planning is studied, and the basis of urban regional building energy planning is proposed. (2) Through analysis and evaluation, the available amount of conventional energy and renewable resources in urban areas can be obtained, which can provide strong data support for the comprehensive planning of urban building energy, thereby promoting energy, economic, and sustainable development. (3) Use the urban building energy planning method proposed in this paper to carry out energy planning for new urban buildings, combining theoretical research with practical engineering cases.

2. Research and Use Methods of Renewable New Energy Materials

2.1. Renewable New Energy. Renewable energy is also called alternative energy, sustainable energy, or nontraditional energy. It is energy that can be obtained from nature and can be supplemented naturally, such as wind energy, solar energy, hydro energy, geothermal energy, biological energy, and ocean energy. [8]. The main reasons why humans use renewable energy are as follows. The advancement of science and technology has made such energy more "easy to use." Fossil energy is limited, not only will its price increase day by day, but it will eventually run out. Certain renewable energy sources (e.g., wind, hydro, and solar) do not emit greenhouse gases (e.g., carbon dioxide) and therefore do not increase the risk of the greenhouse effect. To improve energy supply security, reduce reliance on imported fossil fuels, and meet the demand for sustainable energy. As a clean energy source, renewable energy is environmentally friendly and sustainable. However, along with its advantages, the use of renewable energy is still limited due to some disadvantages.

(a) Renewable resources   (b) Non-renewable resources
Figure 1: Renewable and nonrenewable resources.

First of all, one of the main disadvantages is climate dependence, because these energies continue to exist in different geographical spaces, so the available energy changes in the order of magnitude all the time [9]. The solution at this stage is to apply multiple forms of renewable energy hybrid collection technology to enable the energy collection system to continuously collect energy from the natural world. The second disadvantage is that the energy collection efficiency is low, and the energy collection cost is high. In addition to geothermal energy collection, compared with traditional energy collection technology, the cost of renewable energy collection is much higher than that of traditional energy collection systems. Therefore, reducing the cost of renewable energy collection and improving energy utilization efficiency are key issues. The third is technology development and commercialization. Nowadays, some high-efficiency, stable, and sustainable collection technologies for renewable energy are still under development [10]. Practice has proved that renewable energy can not only provide clean alternative energy, but more importantly, it can also stimulate the development of related industries such as equipment manufacturing. It is an effective way to speed up the transformation of economic development mode and the adjustment of economic structure in the post-international financial crisis period.

Renewable energy harvesting application technology mainly includes five parts: energy harvesting, electric energy conversion, electric energy transmission, electric energy storage, and electric energy use. Due to the frequent and unpredictable changes of renewable energy, the collected energy cannot be directly supplied to the load. Therefore, the collected energy needs to be rectified or stored to supply power to the load [11]. The main function of the regenerative energy storage system (ESS) and energy management system (EMS) is that in addition to efficient storage of the collected energy, it can also play a role in "shaving peaks and filling valleys" to reduce energy fluctuations and slow down the load caused by fluctuations. The energy management system includes data acquisition and monitoring system, automatic power generation control and economic dispatch control, power system state estimation, safety analysis, and dispatcher simulation training system. Renewable resources and nonrenewable resources are generally shown in Figure 1:

In the analysis of the energy storage process, the part of the object or space that is delineated in order to determine the research object is called the energy storage system. It includes energy and matter input and output, energy conversion, and storage equipment. Energy storage system (ESS) can be divided

into physical energy storage, chemical energy storage, and electromagnetic energy storage in terms of characteristics and methods. Among them, flywheel technology, pumped water energy storage, and compressed air energy storage technology belong to physical energy storage; superconducting and supercapacitors are electromagnetic energy storage technologies; lead-acid, lithium ion, sodium sulfur, and liquid batteries are electrochemical energy storage technologies [12, 13]. Small-scale low-power storage technologies are mainly lithium-ion batteries, lead-acid batteries, and super capacitors. Traditional ESS is mainly based on lead-acid batteries and lithium-ion batteries. Energy storage systems often involve multiple energies, multiple devices, multiple substances, and multiple processes. They are complex energy systems that change over time and require multiple indicators to describe their performance. Commonly used evaluation indicators include energy storage density, energy storage power, energy storage efficiency, energy storage price, and impact on the environment. With the development of ESS technology, people are paying more and more attention to supercapacitor technology. Table 1 shows the comparison of the characteristics of three energy storage devices.

The role of the EMS is to protect, detect, and control the ESS to ensure the safe and efficient operation of the ESS and to extend the service life of the ESS. The main functions of EMS include protection functions, state and parameter estimation, and energy balance and redistribution functions between single cells [14].

With the development of China and the further improvement of people's living standards, people have higher and higher requirements for the comfort of the indoor thermal environment of residential buildings, which will lead to a further increase in the energy consumption of residential buildings [15]. Currently, urban energy, economic, and environmental issues have become issues of concern to the world. How to use energy reasonably, improve the overall energy efficiency of urban buildings, optimize the energy distribution of urban buildings, and protect the urban environment on which mankind depends for survival is a long-term interest issue in the world today.

2.2. Renewable Energy Collection. We conduct research on traditional wind energy collection, solar energy collection, and storage technologies. The structure, parameters, and their mathematical models and equivalent circuits of energy conversion devices will be analyzed separately [16]. At the same time, the I-V curve and P-V curve of solar energy collection

TABLE 1: Comparison of characteristics of three energy storage devices.

	Lead-acid batteries	Lithium ion battery	Super capacitor
Energy density (Wh/kg)	25-55	85-300	5-55
Power density (W/kg)	25-55	160-500	$699 - 10^5$
Cycle life (times)	<499	499-3000	$>10^6$
Cell voltage (V)	1-2	2-3	3-5
Equivalent internal resistance (Ω)	<1	<1	<0.01
Self-discharge	High	Low	Generally
Safety	Generally	Lower	High
Environmentally destructive	Higher	Generally	Lower
Market	Saturation	Develop	Great potential

and the Cp-λ, Cp-ω characteristic curves of wind energy collection are listed for the model.

Wind energy is a kind of available energy provided to human beings due to the work done by air flow and belongs to renewable energy. The kinetic energy of air flow is called wind energy. Wind energy harvesting includes energy conversion devices (WT) and control systems. In wind energy collection technology, accurate modeling of wind energy conversion devices is particularly important. Because in order to efficiently collect and transform wind energy, MPPT is required. The MPPT technology is inseparable from an accurate wind energy conversion device model. The WT mechanical energy collection model is as follows:

$$P_m = \frac{1}{2} p\pi r^3 v^3 C_p, \tag{1}$$

where P_m is the mechanical power (W), r is the radius of the WT blade, v is the wind speed, and C_p is the power coefficient. Expressed by the tip speed ratio function C_p, the relationship between the power factor and the tip speed ratio is shown in the following formula:

$$C_p(\lambda, \beta) = c_1[c_2\partial - c_3\beta]e^{-c6\partial} + c7\lambda, \tag{2}$$

$$\partial = \left(\frac{1}{\lambda + 0.05\beta}\right) - \left(\frac{0.025}{1 + \beta^3}\right), \tag{3}$$

where λ is the tip speed ratio and β is the blade pitch angle because the constant parameters are different for different WTs. For the convenience of research, suppose the blade pitch angle β of WT is 0. Therefore, the maximum mechanical power at a given wind speed P max is:

$$P\text{ max} = \frac{1}{2} p\pi r^3 v^3 C_p(\lambda_{opt}), \tag{4}$$

$$\lambda_{opt} = \frac{rw}{v} \longrightarrow w_{opt} = \frac{\lambda_{opt} v}{r}. \tag{5}$$

The above formula can be rewritten as:

$$P_{max} = \frac{1}{2} p\pi r^5 \frac{C_{pma}x}{\lambda_{opt}^3} * \frac{\lambda_{opt}^3 v^3}{r^3}, \tag{6}$$

$$K_{opt} = \frac{0.5p\pi r^5 C_{p\text{ max}}}{\lambda_{opt}^3}. \tag{7}$$

From the above reasoning, the relationship between the power coefficient and the tip speed, as well as the relationship between the power and the angular speed of the rotor, can be obtained.

Figure 2 is a schematic block diagram of the wind energy collection system. The control system can sample the motor speed ω and output voltage, current, and power. Then, the system will calculate the maximum power point. If the output power of the WT needs to be adjusted, the control system can adjust the WT gearbox or control the DC-DC circuit to achieve MPPT.

Solar energy is produced by the fusion of hydrogen and helium atoms inside the sun to release huge nuclear energy, which is the radiation energy from the sun. The vast majority of human energy needs come directly or indirectly from the sun. Solar energy collection technology is similar to wind energy collection technology and also requires mathematical modeling of energy harvesting devices, and at the same time depicting output characteristic curves and MPPT strategy design based on mathematical models [17]. Different from wind energy harvesting, the solar energy output energy waveform changes more slowly. Therefore, the output voltage of the device can be regarded as direct current and does not require AC-DC rectification.

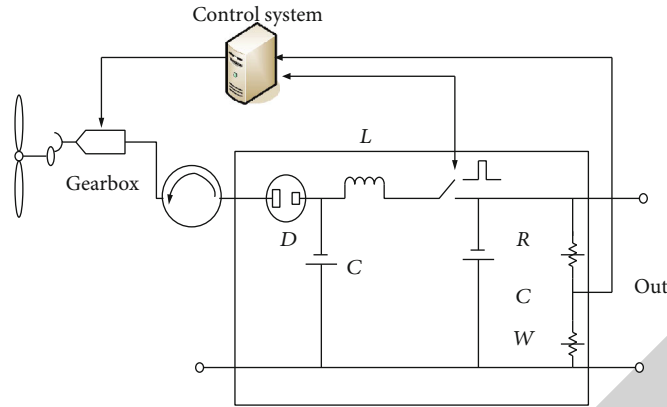
After the PV device is made, it needs to be packaged. The package structure mainly includes the front plate, solar cell, sealing layer, back plate, protective frame, and junction box [18]. The front panel can increase the mechanical strength and rigidity of the PV. It should be noted that the front panel must have good penetration and low reflectivity for light with wavelengths from 350 nm to 1200 nm; the back panel provides physical protection for the PV and can pass through the back panel. Surface reflection improves the efficiency of PV. We use the single diode model to describe the characteristics of the


Figure 2: Wind energy collection system.
Figure 3: PV equivalent circuit diagram.

photovoltaic cell, and the PV equivalent circuit is shown in Figure 3:

According to Kirchhoff's first law definition [19], the battery output current satisfies the formula:

$$I = I_{\text{ph,cell}} - I_{d,\text{cell}} - I_{R_{\text{sh,cell}}}. \tag{8}$$

In order to determine the volt-ampere relationship of the PV cell, it is necessary to determine the parameters such as the sum of the cell. The function relationship between the induced current of the PV cell equivalent circuit and the irradiance and temperature is shown in the formula.

In order to determine the volt-ampere relationship of the PV cell, it is necessary to determine the parameters such as the sum of the cell. The function relationship between the induced current of the PV cell equivalent circuit $I_{\text{ph,cell}}$ and the irradiance and temperature is shown in the formula:

$$I_{\text{ph,cell}} = \frac{G}{G_{\text{ref}}}(I_{\text{sc,ref}} + K_i \Delta T), \tag{9}$$

where V is the output voltage of the PV cell and T_{ref} is the output current of the PV cell. The current absorbed by the internal resistance of the PV cell equivalent circuit G_{ref} is as follows:

$$I_{d,\text{cell}} = I_{s,\text{cell}} \exp\left[\left(\frac{V + I_{R_{s,\text{cell}}}}{n V_{\text{th,cell}}}\right) - 1\right], \tag{10}$$

where V is the output voltage of the PV cell and I is the output current of the PV cell. The current absorbed by the internal resistance of the PV cell equivalent circuit is as follows:

$$I_{R_{\text{sh,cell}}} = \frac{\left(V + I_{R_{s,\text{cell}}}\right)}{R_{\text{sh,cell}}}, \tag{11}$$

where $I_{\text{sh,cell}}$ is the shunt resistor of the PV cell. Saturation current of PV battery diode:

$$I_{s,\text{cell}} = I_{\text{sref,cell}}\left[\frac{T}{T_{\text{ref}}}\right]^3 \exp\left(\frac{q R_q}{n K}\right). \tag{12}$$

For any given $x \in X$, there is a uniquely determined $\mu A(\text{x}) \in [0, 1]$ membership function value corresponding to it, and the fuzzy set can be expressed as:

$$\mu \tilde{A}(x): X \longrightarrow [0, 1]. \tag{13}$$

Generally, the expression of fuzzy sets is as follows:

$$\tilde{A} = \frac{\mu_{\tilde{A}}(x_1)}{x_1} + \frac{\mu_{\tilde{A}}(x_2)}{x_2} + \cdots + \frac{\mu_{\tilde{A}}(x_n)}{x_n}. \tag{14}$$

This method of representation is also called Zadeh notation. It can also be expressed in ordinal notation:

$$\tilde{A} = \{(x_1, \mu_{\tilde{A}}(x_1)), (x_2, \mu_{\tilde{A}}(x_2)), \cdots, (x_n, \mu_{\tilde{A}}(x_n))\}, \tag{15}$$

Or, use vector notation:

$$\tilde{A} = \{\mu_{\tilde{A}}(x_1), \mu_{\tilde{A}}, \cdots, \mu_{\tilde{A}}(x_n)\}. \tag{16}$$

The definition of the distance function is as follows: For all $\vec{x}_1 \in \Gamma$

$$d\left(\vec{x}\right) = \min\left(\left|\vec{x} + \vec{x}_1\right|\right). \tag{17}$$

(a) Back pressure steam turbine unit process

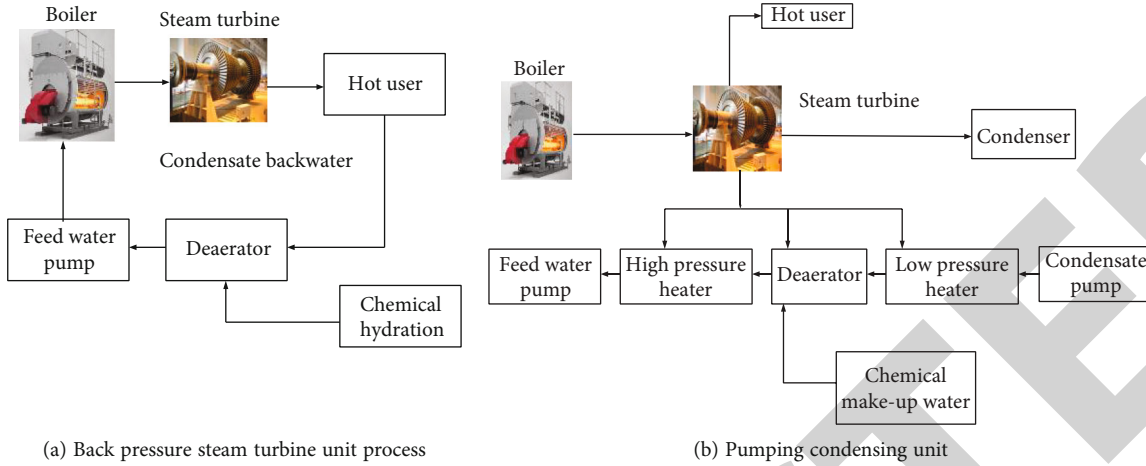
(b) Pumping condensing unit


Figure 4: Typical process of two groups of units.

From the definition, when the unknown point is on the boundary, the function value is 0. Find the nearest point on the boundary and mark the nearest point, the value of the distance function is

$$d\left(\vec{x}\right) = \left|\vec{x} - \vec{x}c\right|. \tag{18}$$

From the definition of the distance function, the specific definition of the signed distance function is:

$$\phi\left(\vec{x}\right) = d\left(-\vec{x}\right) = 0, \quad \vec{x} \in \Gamma$$
$$\phi\left(\vec{x}\right) = -d\left(\vec{x}\right) \qquad \vec{x} \in \psi. \tag{19}$$

The signed distance function is a subset of the implicit function and has all the properties of the implicit function discussed in the previous section. Using the signed distance function can simplify many level set methods for dealing with implicit functions.

$$Z_i = T^T (x_{nm} - f \notin R^n). \tag{20}$$

When solar and wind energy are sufficient, that is, the collected energy is greater than the energy consumed by the equipment, in order to avoid energy loss and maximize the use of the collected energy, it is necessary to store the excess energy [20]. Due to the irregular, unpredictable, and serious environmental impacts of the output power of solar and wind energy collection systems, the ESS of the collection system is mostly multicell cascade. This increases the difficulty of monitoring the battery module [21].

2.3. Regional Planning of Urban Landscape Design. Urban landscape is a broad, comprehensive, and difficult to define profession in architecture. A city is a complex organism, and housing and architecture should be the main body of it, complemented by a space environment other than architecture. The two together are called urban landscape.

Table 2: Changes under different voltages and currents.

Experimental parameters	Parameter value
Charge switching frequency	1 khz
Circuit PWM modulation pulse frequency	400 khz
Buck mode input voltage range	5 V-25 V
Buck mode input current range	0-1.5 A
Buck mode output voltage	5 V
Boost mode input voltage	3 V-12 V
Boost mode input current range	0-5 A
Boost mode output voltage	15 V

Landscape planning refers to the activities of comprehensively determining and arranging the nature, scale, development direction, main content, infrastructure, comprehensive spatial layout, construction staging, and investment estimation of landscape construction projects. Urban garden planning is a complex and important project. Certain principles must be followed to achieve good results. The construction of gardens on the basis of following the corresponding principles can achieve a multiplier effect with half the effort. Urban landscape refers to the natural landscape beauty inherent and created by the landscape function in the human settlement environment. It can make the city have natural landscape art and make people feel comfortable and happy in urban life. Generally speaking, urban landscape design needs to follow the following principles:

(1) The principle of function. The main function of urban gardens is to maintain the physical and mental health of residents and protect the local natural ecology. Humans and nature are the two key points of garden construction and cannot be ignored

(2) The principle of economy and efficiency. There is no doubt that economy is the foundation of garden construction, and efficiency is the driving force of

TABLE 3: Different energy harvesting classifications.

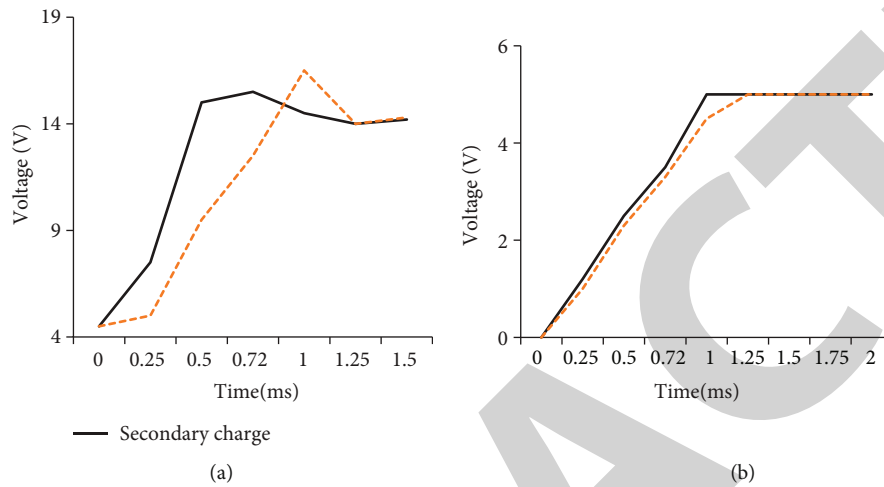
Energy harvesting technology	Equivalent internal resistance	Output voltage (V)	Output power	Conversion efficiency
Electromagnetic induction technology	25-450	0-13	0.1-0.5 W	35%-50%
Gear transmission technology	50-200	0-8	0.1-1.3 W	20%-35%
Piezoelectric ceramic technology	50-280	0-30	10 mW-30 mW	80%-85%
RF receiving technology	5 k-45 k	0-0.5	0.002 mW-0.1 mW	5%-15%


FIGURE 5: Changes in step-up and step-down.

garden construction. How to achieve economy and efficiency is a key issue that relevant departments and units should think about

(3) The principle of recycling and regeneration. As the concept of sustainable development gains roots in the hearts of the people, recycling and regeneration have become the focus of urban development. We must not only make good use of the recycling and regeneration functions of nature, but also must protect these functions. Nature's gifts to us are never infinite, and if we abuse them uncontrollably, the consequences will be disastrous

How to comprehensively utilize the energy resources available in the region is the key to the energy planning of urban buildings. It is particularly necessary to consider advanced and reasonable comprehensive utilization technologies of energy resources in the regional building energy planning and to rationally configure various resource supply systems. The back pressure steam turbine unit refers to the steam turbine unit that directly supplies the steam of the steam turbine to heat users for heating, and this unit corresponds to the condensing unit [22]. The exhaust steam condensing unit has holes in the appropriate position, and the steam turbine condensing unit that releases part of the steam for heating is called the exhaust steam condensing unit. The steam extraction method of this unit is divided into two types: adjustable exhaust and nonadjustable exhaust. Provide thermal users with adjustable output, and the system uses nonadjustable output. The typical flow of the unit is shown in Figure 4.

The heat, power, and cold cogeneration system is based on the basic idea of cascade utilization of energy, uses natural gas as fuel, and uses natural gas-burning equipment such as micro internal combustion engines, gas internal combustion engines, and small gas turbines. The waste heat generated after the high-temperature exhaust gas is used for heating in winter, cooling in summer, or supplying domestic hot water [23]. The system makes full use of high-temperature exhaust gas and increases system efficiency to 80%, thereby saving a lot of time. Compared with the central power generation-long-distance power transmission, the natural gas heat-electricity-cooling three-electric system significantly improves the overall energy efficiency. For example, the current output efficiency of large power plants is about 30%-40%. If the cogeneration system is used for waterfall energy utilization, the efficiency of the power supply system can be increased by about 40% compared with the conventional power generation system. At about 80%, there is no transmission loss problem.

District cooling technology can also use rivers and lakes, sea water, urban sewage, or steam produced by thermal power plants as cold and heat sources. Combining the actual situation of the urban area, the Dalong Lake and the hot water pipeline of the thermal power plant can be used. Therefore, the regional cooling in the urban area is suitable for heating pipelines and the surrounding areas of rivers and lakes. The application object is the density of buildings and the larger plot ratio. At the same time, with the application of a large temperature difference and a small flow energy supply system, the pipe diameter of the entire system can be reduced, and the

Table 4: Energy conservation in the region.

Type	New increment				Cumulative amount			
	Installed capacity (ten thousand KW)	Average annual power generation (100 million kWh)	Annual average emission reduction (ten thousand tCO$_2$)	Annual average standard coal quantity (ten thousand tce)	Installed capacity (ten thousand KW)	Average annual power generation (100 million kWh)	Annual average emission reduction (ten thousand tCO$_2$)	Annual average standard coal quantity (ten thousand tce)
Hydropower	195	64	407	195	799	253	1555	839
Wind power	1049	216	1521	647	1699	615	2301	863

Figure 7: Recycling ratio of different materials.

flow rate of the water pump can be reduced, thereby saving operating costs and initial equipment investment. Therefore, through the combination with district cooling technology, initial investment and operating costs can be saved [24].

3. Experiments and Results of Renewable New Energy Materials

3.1. Energy Changes. In the experiment, we first display the collected energy conversion efficiency and make statistics on the changes under different voltages and currents. The results are shown in Table 2:

It can be seen that in this experiment, the input voltage range of the step-down mode is 5 V-25 V, the output voltage is 5 V, and the output current range is 0A-1.5A; the input voltage range of the step-up mode is 3 V-12 V; and the output voltage range is 5 V-25 V.

The capability classification of different energy harvesting technologies is shown in Table 3:

We compare the two-stage charge pump with the single-stage boost. Under the same experimental conditions, when the two-stage charge pump and the single-stage boost/buck circuit rise from 4.5 V to 15 V and from 24 V to 5 V, apply

the voltage simulated by OrCAD—the time results are shown in Figure 5, where Figure 5(a) is boost and Figure 5(b) is buck:

It can be seen that when the buck/boost topology circuit is used alone for voltage regulation, as the horizontal axis voltage rises, the conversion efficiency decreases almost linearly. The secondary voltage regulating circuit added with the charge pump will slow down the decline of the conversion efficiency of the circuit at the mode switch by changing the mode of the charge pump voltage regulation [25].

3.2. Comparison before and after Transformation. The ultimate goal of developing new energy is to realize the sustainable development path of low energy consumption, high energy efficiency, less pollution, and diversified energy supply for economic and social development. We calculate the carbon emission reduction and energy saving of new energy and renewable energy in the region, and the results are shown in Table 4:

We compare new energy materials using wind and solar energy with traditional materials. By comparing their carbon dioxide emissions, recycling capacity, time cost, and energy consumption, we first make statistics on carbon emissions, and the results are shown in Figure 6:

Figure 8: Time required to produce materials.

Figure 9: Virtual city image.

As can be seen from the figure, in the time shown for the production of materials, the average time required for materials produced by traditional methods is about 0.6 h, while the average value of wind energy and solar energy is about 1 h. This is due to the requirements of solar and wind energy for climate. Higher, the display is not stable, which also causes the traditional method to produce materials faster than renewable energy. We use environmentally friendly materials to plan the city, and the virtual image is shown in Figure 9:

At present, the environment in which we live has become worse due to energy consumption, and people have gradually realized the importance of protecting the environment. Therefore, we have compared the energy consumed by different materials, and the results are shown in Figure 10.

It can be clearly seen that the energy required for the consumption of traditional materials is much higher than that of renewable energy, which is more than 50% higher. This is also due to the different production methods of the materials. Regarding the role that different materials can play in urban landscape design, we have compared the existing data and obtained relevant results. The results are shown in Figure 11.

It can be seen that in the eyes of most people, traditional materials have been more and more questioned due to their serious damage to the environment. People's pursuit of environmentally friendly materials and renewable energy has become more and more urgent. Advantages, it has become more and more people's first choice [26].

4. Discussion

Carbon dioxide and other greenhouse gas emissions are causing global climate change, posing a serious threat to human survival and sustainable economic and social development. Therefore, climate change is not only an environmental issue, but also a development issue.

By analyzing and researching the energy planning concepts, technical principles and characteristics of building regional energy planning, it is concluded that the building regional energy planning mainly includes the setting of

It can be seen from the comparison of the figure that in the comparison of the carbon emissions of different materials within one month, the carbon emissions of traditional materials are much greater than that of solar and wind energy, with an average daily emissions of about 0.4, which is twice as high as that of solar and wind energy. Many, great damage to the environment, needs to be changed.

We have carried out statistics on the recycling capacity of different materials, conducted multiple simulations, and took the average value for comparison. The results are shown in Figure 7:

It can be seen that the current recycling rate of materials is not ideal, especially in traditional materials, the recycling rate is about 35%, while for renewable energy, the recycling rate can reach about 85%, which greatly improve the protection of the environment.

We have made statistics on the time required after each piece of material is produced. Of course, due to the lack of relevant technology, our statistical time is only fuzzy time and not very accurate. The statistical results are shown in Figure 8:

Figure 10: Different materials consume energy.
Figure 11: The importance of different energy sources.

regional energy-saving strategic goals. Determine the available energy resources and the development of energy construction in the region. And forecasting the energy load of the region, select the appropriate energy system and technical route, and evaluate the energy utilization rate of the regional energy system and the possible impact on the environment.

In the field of architectural planning, how to rationally arrange the location of buildings and plants to achieve natural ventilation and natural lighting, and in a single building, how to integrate solar energy, solar cells, solar water heaters, range hoods, biogas, and geothermal heat to make rational use of ground-floor dwellings are all issues that need to be considered. In this regard, this paper proposes some technical solutions by adopting the method of software-assisted analysis. Among them, the key to passive design is to handle the relationship between the building and the environment and nature, plan and overall design in the plot, and choose the appropriate building layout and courtyard shape, and the environmental elements such as plants and ponds must be reasonably matched with the building.

For natural ventilation, the key is to organize the ventilation channels and vents; for natural lighting, the building's shading system and day lighting system must follow the angle and track of the sun. These are all used in traditional residences, especially in the planning of new residential districts, and they should be planned and laid out in detail. For the use of energy, priority is given to selecting renewable energy sources, such as solar energy, biogas energy, and geothermal energy. Solar energy is abundant, and solar power generation is now mainly used in areas where there is no grid, and it needs to be popularized due to its high cost. Solar water heaters have a big trend and can be used in engineering and construction applications, but they still face many challenges.

Generally speaking, the use of renewable energy in daily life has been very extensive, and various energy sources have their own application ranges and limitations. In order to make the effective use of renewable energy, various energy sources should complement each other in the application. This article analyzes the device and packaging structure of the PV cell and then in-depth study of the equivalent circuit model of the PV cell. According to the PV cell equivalent circuit model, the mathematical model and power-voltage output characteristic curve of the PV cell are derived. In this way, based on the output characteristic curve and mathematical model of the PV cell, the PV cell can be controlled by MPPT to obtain the maximum output power.

5. Conclusion

At present, most countries in the world have realized the importance of a good and environmentally friendly living environment to people, and have begun the ecological construction and design of modern human settlements, and have achieved some results, solving the problem of satisfying people's living conditions. Quality requirements, so in the contemporary human settlement environment, we should see the ecological philosophy and spiritual connotation of traditional residential buildings, which in many aspects show its advanced and modern concept of ecological environmental protection. Fully use and use it for reference to the modern living environment, and build a modern residential area suitable for modern people

with a good ecological environment, energy saving, and intelligent. This is also our long-term pursuit of the modern living environment. Of course, the research in this article also has its shortcomings. The article only considers the comparison of solar energy and wind energy to renewable energy, and does not give more introduction to other environmentally friendly energy sources. The design of energy harvesting does not meet the design requirements. Therefore, in future research, this paper will design a self-starting system for the energy harvesting system to further improve the efficiency of energy harvesting. According to the characteristics of wind and solar hybrid energy harvesting, a dedicated energy harvesting controller chip is designed to reduce the energy consumption of the energy harvesting circuit, reduce the circuit volume, and improve the efficiency of energy harvesting. However, due to the limitation of time and technology, we did not further discuss the design of urban garden landscape. We will also conduct in-depth discussions in the follow-up, in order to make certain contributions in this regard.

In the era of technological advancements in healthcare and medicine, monitoring of health status and treatment conditions has been made convenient by the development of various categories and forms of biomedical sensors. They have been incorporated within watches and mobile phones and can be worn as stand-alone based on user preference. However, the longevity, cost, and sustainable functionality have impeded its adoption within the population. In this review article, we have introduced a concept of bridging the textile industry and biomedical sensors to yield a self-powered biomedical system that operates on textile-based energy harvesters. Textile-based wearable systems have been compared to E-skin-based systems. The energy released by different actions in human motion has been quantified along with insights on its effective utilization in the form of energy harvesters in the subsequent sections. Information on designing such a textile-based system with schematics has been done. This review focuses on the development and connection of textile-based energy harvesters to existing models of biomedical sensors.

1. Introduction

Traditionally, hospitals with state-of-the-art instruments and patient monitoring facilities have taken precedence when an individual needs aid with diagnosis, treatment, operation, or postoperative care. Monitoring of an individual's vital organs/systems, such as heart rate, body temperature, and ECG, has been done in the presence of a doctor within a hospital or a doctor's office room. It is also well known that the treatment of certain medical conditions that necessitate intensive care units (ICU) is expensive not only for the patient but also for the hospital because they must invest in the upkeep of medical equipment such as blood pressure cuffs, oxygen saturation meters, thermometers, breathing, and urinal tubes [1, 2]. Even when the patient is shifted from an ICU room to a general care unit, the majority of the equipment is shifted as well for postoperative monitoring. However, various tubes and needles on the patient body, even after surgery for the monitoring of the vitals, cause a great deal of pain and discomfort as by this stage, the effect of anesthesia given during the operation wears off. This prompted the health-care professionals in the medical field to raise the need for an effective and less expensive setting for the patient's treatment. Consequently, the integration of nanotechnology, medical, and electronics had opened ways to develop biomedical devices with outstanding

features of drug delivery, real-time health monitoring of physiological parameters, and even the recording of nerve stimulation [3]. This gave birth to the smart health monitoring systems that possessed sensors for obtaining medical information from the patient connected to them that can sometimes wirelessly transfer real-time details to the monitor of the health-care professional were known as portable biomedical devices, which revolutionized the health-care system. With the boom of material science and miniature technology, biomedical devices could also be implanted or attached to the skin (wristwatches/smart bandages).

Medical treatments, on the other hand, can sometimes last for months, and in other cases, the patient may need to make the device a permanent part of their life. For such long-term use, biomedical devices had to be built with large batteries, which resulted in substantial models that required frequent replacement, as well as increased consumer discomfort. Moreover, this psychologically creates a negative impact on the wearer's mind reminding them of the particular medical condition, which has clinically proven to impede recovery rates. Additionally, the apparent visibility of such devices implanted or attached to the skin is hard to miss for an onlooker who quickly identifies the wearer to be a patient or sick, which no wearer finds appealing as for most people their treatment tends to be a matter of privacy. These limitations of traditional biomedical devices have undoubtedly raised the need to develop a self-sustaining power system for a biomedical device to counter the need for frequent replacement of batteries.

The progress of fabrication technology and biocompatibility has seen the textile industry contributing to the biomedical field in intensely effective ways. Due to the material advancements made, biosensors can now be integrated into textiles to make wearable clothes for people [4]. This textile-based system processes and transmits the biosystemic data with vital information directly to the health professional, thus solving the psychological impact of wearing visible biomedical devices and increasing the mental as well as emotional wellbeing, therefore overall benefitting the health of the individual. Textile-based biomedical devices also possess the ability to not only harvest but also self-generate energy.

In this review paper, we aim to emphasize the importance of these textile-based energy harvesters. We begin by highlighting the different categories of wearable health devices and elaborate on the unique features of human motion to understand the energy generated from a human body. This will be followed by the various textile-based energy harvesting systems for application in the biomedical field and an overview of self-powering textile-based wearable systems. The relevant information will be summarized in the final section of this review.

2. Different Types of Wearable Biomedical Devices [WBD]

2.1. E-Skin-Based WBD. Electronics that possess an excellent ability to stretch and showcase elasticity/flexibility with a certain extent of self-healing capabilities are referred to as electronic skin. These are popularly used in the field of prosthetics development, artificial intelligence, robotics, and now even in health monitoring systems [5–8]. E-skin-based WHC devices mimic the capabilities of the human skin and try replicating its function towards external environmental stimuli such as heat, pressure, and temperature.

E-skin, also known as artificial electronic skin, comprises sensors and actuators that receive the biosystemic information and convert it into a form of signal that can be processed, communicate the information, and self-powered. The regions of the skin on which these components are put; biocompatibility and ability to stretch in response to the demands of human mobility, as well as comfort and lightweight for the user with a reasonable shelf life, are all factors in the material selection process. Biofluid-proof materials are required in some instances. The overall device performance of such WBD pertains to the type of materials and substrates used, dimensional structures incorporated into the design, signal processing units, overall architecture, and design formed and size of the storage units. The appeal of E-skin-based WBD devices to potential wearers ultimately depends on functionality but is also more influenced by cost and esthetic appearance.

Typical substrates used for making flexible E-skin-based WBD include a wide variety of polymers segregated and chosen based on Young's modulus (for flexibility) and degradation temperature (transition temperature, T_g) in addition to the factors mentioned in the above paragraphs (refer to Table 1). These include poly-dimethyl-siloxane (PDMS), poly-ethyleneterereph-thalate (PET), poly-ethylene-napthalate (PEN), poly-ether-sulfone (PES), poly-ether-ether-ketone (PEEK), polycarbonate (PC), and polyimide (PI) [9–15]. In some cases where the transparency of the appearance of the device needs to be altered, liquid crystal polymer and eco-flex are also utilized as substrate materials that are opaque and translucent in nature [16–18]. Figure 1 illustrates the different types of such WBD devices used in the health-care system.

A key component in these WBDs is the range of sensors used. Sensors tend to make or break the entire functionality of the device [11, 12]. The different types of sensors used are demonstrated in Figure 2.

The interaction of the biotic and abiotic components, as well as a robust interface between them, is the key focus for E-skin-based or any skin-based implants [19, 20]. From a manufacturing standpoint, Ray et al. [21] emphasized the necessity of biointegrated devices for health monitoring to be user-specific. There must be excellent compatibility of the implant-/skin-based devices with the texture of the skin, size of the body part, and lifestyle of the wearer. One of many drawbacks of such an approach is the utilization of gel-based adhesive sensors in the manufacturing of skin-based biomedical devices that cause skin irritation. Moreover, large-scale manufacturing of such a technology cannot dwell into the user-specific details; thus, the end product might be of comfort to some but discomfort to others. Apart from this, the dynamic nature of the human biology system that is in continuous contact with rapidly evolving environments poses a significant challenge to the performance of

FIGURE 2: Different types of sensors applied in E-skin-based WBD.

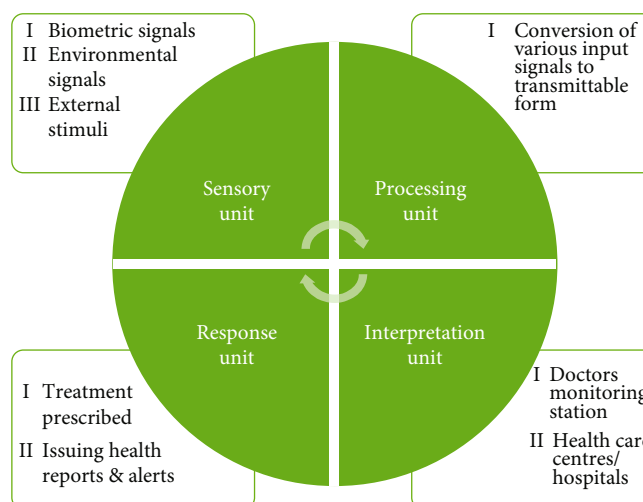
these devices. Moreover, they do not provide continuous health data (real time), making it hard for the health professional to determine the disease onset, which is attributed to the limited power from batteries requiring replacements. This naturally creates the need to develop a counter mechanism that can record and transmit continuous biosystemic data without causing discomfort and involving replacements of batteries. The interconnection between textile-based WBD (parent system) with textile-based energy harvesters as power supply unit is the proposed solution in our work.


FIGURE 3: Patient-oriented textile-based WBD.

2.2. Textile-Based WBD. Textile-based wearable biomedical devices (WBD) had been the invention that was born out of necessity on the battlefield. The concept of an "intelligent garment" was developed since people's lives depend on immediate medical attention, which is not always possible in a war zone. Primary objectives were to constantly monitor the vital organs of the soldier/wearer with additional features of military benefit including enemy weaponry knowledge by measuring the penetration of bullets on the garment. A group of doctors residing on the military base camp was sent the information directly transmitted from the garment, thus enabling constant monitoring. Smart textiles were born as a result of this concept gaining traction in the fields of material science, electronics, and medicine.

As clothes are worn at all times by people of all age groups, making these clothes, the source of medical information has gained monumental appeal from the biomedical professionals. Unlike noninvasive (electronic skin) and invasive (implants) counterparts that result in psychological stigmatization and discomfort in terms of physical wearability and technical drawbacks as highlighted in the above section, the textile-based health monitoring system provides the wearer with mental, psychological, and overall well-being. This is mainly achieved due to the easy incorporation of energy harvesters into the framework design of smart textiles.

From the customer/patient point of view, the functioning of smart textile is as simple as wearing a new shirt. The functionality of such a patient-oriented biomedical invention is summarized in Figure 3.

The sensory unit constitutes arrays of wearable sensors integrated within or onto the textile because the textile is made up of flexible fiber. This allows for the gathering of biomechanical data to be done without interruption while taking into account the natural or movement-induced deformation that occurs in humans. Based on the type of stimuli, sensors could be piezoelectric, capacitive, resistive, and triboelectric, which will be explained later in this review.

Research and development of low-dimensional electronic systems have made it possible to integrate various components onto various substrates and, more importantly, textile products. Simultaneous research into the deposition of coatings onto fibers to synthesize conductive materials/polymers has backed up the former. Further research has now enabled these conductive materials to function as actuators and transducers, which are crucial components of the processing unit shown in Figure 3.

We have taken this one step further and categorized smart textiles into three broad categories, namely, active, passive, and very active smart textiles. Passive smart textiles are believed to be the primitive of the group as these only possess the capacity to make changes to their properties based on stimuli. Optical fibers are popular inventions that come under this category.

Active materials, on the other hand, are the next generation of materials capable of making decisions about how to react to external stimuli. However, the convergence of the textile industry and biomedical field took place on the development grounds of third-generation smart textiles. These not only could sense and make decisions but also configure themselves based on the stimuli, thus opening opportunities to monitor health via apparel and clothing, known as very active smart textiles.

Furthermore, the interpretation and response unit is nearly identical to that of an E-skin-based WBD, with the exception of the level of monitoring, which is not continuous in an E-skin-based WBD due to battery and energy requirements.

Modern society is showing signs of becoming more health conscious. The demand to have a constant update on health and having control over it has pushed even the biggest telecom companies, IT industry, and brands to incorporate health applications within mobile phones and gadgets to make them more appealing. However, these are not built to provide disease onset information, postoperative care, or well-rounded health information. Many medical professionals find data from such devices unreliable due to the vulnerability of glitches.

Thus, the goal of this review is to emphasize the necessity of using the human body as a source of energy and

storing it in order to power the WBD, which can only be truly effective with a textile-based approach. The following section will comprehend this approach better by highlighting the enormous amount of energy that can be harnessed from various parts of the human body.

3. Underutilized Marvel: The Human Motion

The calculations of energy given out by the different body parts have been provided by Riemer and Shapiro [22] in their comprehensive work. Our human body per day releases energy equivalent to 20 kilograms of AA batteries with 2500 mAh each, approximately around 800-850 in number. Thermal and movement centered activities are a common outlet for such energy expenses. We can eradicate the adversities associated with modern technology that lack the convenience of long-haul usage attributed to exhaustible power sources/batteries by harvesting this unexploited energy source to power electronics.

The energy to perform human motion is gained from biomolecules such as carbohydrates, proteins, and fats. Energy converted from them by our body for utilization (specific energy) is 35 to 100 times more than the batteries used in the present day, according to Rome, L. C [23]. However, more than 70% of the energy consumed is released towards the atmosphere, thus bringing the mechanical efficiency of the body to less than 30%, validated by Vélez Día and Moreno Gutiérrez [24] in their study. Another reason why the marvel of human motion needs to be explored is to harness all the wasted energy.

According to studies, when a person moves freely, such as during running, energy is generated in various parts of the body. The data in Table 2 depicts this energy in terms of power.

Ultimately, these energies are born and released by the muscles involved in the respective motion. Therefore, to effectively harvest the energy, it is vital to consider the muscular phases—positive muscle work and negative muscle work. These phases occur during a single act of motion.

Any work done by muscles to generate motion is considered the positive phase of work of the muscle and the termination of the motion is the negative phase, in which energy is absorbed to perform this task. Eminent works of Riemer and Shapiro [25] and Alexander [26] validated that the contraction of muscle fibers due to the application of torque at the muscle joint in the same direction of the angular velocity results in motion constituting the positive phase. However, an energy harvester present at this phase to extract the energy developed here would increase the minimum energy required to perform the task, also known as metabolic cost. The body would have to exert more energy to perform the same task which would lead to a detrimental effect on health; therefore, knowing which energy to harvest is crucial. On the other hand, the negative phase involves the opposite of the former. Therefore, an energy harvester placed at this point would hamper no natural motion. Additionally, more energy harvesting can be performed in the regions where the human body gives off energy to the environment.

TABLE 2: Energy expenditure by various parts of the body.

Body movement	Energy released (W)
Elbow	0.78 W
Finger motion	6.9-19 mW
Shoulders	1.34 W
Breathing band	0.83 W
Hip	7.2 W
Knee	33.5 W
Ankle	18.9 W
Heel strike	<10 W
Blood pressure	<1 W

The heat generated from the human system, according to Carnes, if quantified, amounts to around 100 W, which is released towards the surroundings is underutilized. Thermo-electrical generators can only make use of sensible heat and not latent heat. The temperature difference is the main driving force for sensible heat, and occasions such as sweat evaporation harbor in latent heat. Consider the movement of the arms, the first motion is related to the movement of the elbow (between the forearm and upper arm), and the second motion is related to the upper arm and humorous bone involving the changes in the movement of the shoulder. It was recorded for an average male subject, and the percentage of negative work was between 35-40% for the elbows and 60-63% for the shoulders. An average of 2.2 W of power was generated just by casual walking in these regions, quantified by Winters [27] and his research team.

The most common act of carrying a heavy load on the shoulder may be a bag among children or military troupe or lifting heavy bags of groceries since the power generated as negative work is going to increase for both arm and shoulder. This concept is also called the center of mass motion. In efforts to simplify, it can be best understood as quantifying the energy from a relative motion between the bag and the person carrying it. Research has shown that for each kilogram, 1 W of energy could be available for usage. Thus, the region of shoulders could have energy harvesters, and hands could have special gloves possessing them. This energy could power up WBD that serves monitoring purposes for the upper body in addition to the energy dissipated as heat.

Heel strike, for instance, while walking, occurs each time when the heel strikes the ground. Fair to say, the higher the distance between the heel and the ground higher the energy release. This means that jumping, jogging, and other activities can provide more energy release than walking at a casual pace. Shorten [28], a researcher engaged in quantifying energy loss during heel strike, relied on a previous study [25] that showed energy loss occurs when walking towards the sole. More than 10 J of energy loss occurred based on his calculations when his heel struck the ground. This energy, if harvested, could provide power to the biosensors in WBD. The amount of energy harvested depends on the area of contact from where the loss takes place. In this case of heel strike, socks and shoes are the only two things that
Figure 4: Variations in fabric development.

provide continuous and maximum contact. Socks and soles of shoes developed with energy harvesters could be materialized through the merging of the textile industry and electronics. Not only can it harvest, but when connected to WBD can provide sustainable livelihood for the long haul as it could probably serve as an inexhaustible source of power to the biomonitoring devices, thus enlightening the importance of developing textile-based energy harvesters. As mentioned in earlier sections, textile products and apparel are the most effective since they are the only components with the most considerable contact with the skin and human body. As a result, establishing a link between textile-based energy harvesters and wearable biomedical devices is the most natural strategy for addressing contemporary difficulties and the key to revolutionizing the biomedical-electronics industry.

4. World of Smart Textile

4.1. Birth and Development of Fabrics.
The textile industry has come far from producing fabrics, polymers, and apparel merely for esthetic needs. In the age of personalized health care, personal attire has become the primary medium to deliver medical services. Textiles have been well known to outperform traditional electronics in terms of stretchability and comfort. Modernization has enabled the textile industry to enter an entirely new genre of application by utilizing various techniques to impart functional qualities to their polymers.

A textile-based monitoring system, as explained earlier, requires sensing and transducing functions; these capabilities can be built into the system either by coating it on the textile and using it as the substrate or by using a polymer that itself has transducing capabilities, thus earning itself the name of smart textile. It is essential to understand the hierarchy of processes involved in fabric development. A piece of fabric is an amalgamation of individual fibers (yarn) interconnected in various manners such as knitting, weaving, net formation, tufted, and nonwoven. Additionally, the evolution of composite fabrics enables the fabrication of multi-functional fabrics, formed when two or more types of fabric are interconnected. The following Figure 4 showcases the various forms of fabric development for a clearer understanding [29].

The coating of functional materials (sensing and transducing) can occur during the lower dimensional stage of the hierarchy and, in the final, thus being more flexible than traditional electronics. However, one must keep in mind that each fabric structure has its own properties and will serve a specific application better than others. Therefore, the choice must be based on the common ground where the application meets the properties offered by the polymer.

The geometrical properties of a fiber are its area of cross section and length; the chemical properties of a fiber are determined by its reactivity/inertness to alkaline and acidic environments; and the physical properties of a fiber are determined by the crystallography of the polymer used to make it. Tracton's [30] and Luo and Van Ooij's [31] elaborative works provide insightful light on this aspect. The final performance of the coated polymer will depend on the interfacial reaction (between the surface of coating and the surface of fiber) as the surface chemistry will also determine the nature of bonds formed between the coating layer and fiber and dictate the reversibility of the process.

4.2. Designing.
The process and approach to designing are quite different from the traditional method of printing electrical components onto a circuit board. This variation is attributed to the versatility of textiles. As explained above, it is a very application-based approach.

The first step must be to realize what is the expected function of the smart textile and the degree of wearability (ranges from static to fully wearable). Based on step one, the substrate, fabric structure, sensing, and transducer-coating materials should be decided which becomes step 2. During the coating process, it is extremely crucial to obtain a uniform layer of coating. Cover factor C and power factor (PF) must be calculated according to Equations (1) and (2). According to Tracton and colleagues' paper, the penetration of the coating into the fiber is calculated using

$$C = \left(w * d_w + f * d_f - w * f * d_w * d_f \right), \tag{1}$$

where w is the number of warp threads per inch, f is the filling threads per inch, d_w is the diameter of warp in inches, and d_f is the diameter of the filling yarn in inches.

$$\text{PF} = \frac{\text{Fabric Density}}{\text{Fiber Density}} = \frac{W * V_{\text{Fabric}}}{W * V_{\text{Fiber}}} = \frac{V_{\text{Fiber}}}{V_{\text{Fabric}}} \tag{2}$$

In the scenario of nonuniform coating, micro-cracks formation probability increases, leading to overall deformations. Moreover, the optimal functioning of the sensor is

inversely proportional to the nonuniformity of the coating. Therefore, proper adhesion of the coating, as well as its uniform thickness, plays a prime role. Mechanical, chemical, and plasma-based surface modifications can aid in ensuring the same. The research of Luo and Van Ooij is an excellent resource for learning more about surface modification techniques. In step 3, the chosen transducing material will determine the kind of power source and the system would need to function. In step 4, the data transferring system must be finalized. In addition, since the necessity for textile-based energy harvesters has been established in previous sections, step 5 is an extra step indicated by this study, which is to introduce connections between the parent system and an energy harvester that can aid in the constant supply of energy. Finally, in step 6, testing of the entire set-up must be performed.

4.3. Textile-Based Energy Harvesters. Textile-based energy harvesters provide numerous advantages over standard batteries in various biomedical devices already in use, including unlimited capacity, convenience, low maintenance, and no need for battery replacement. There are undeniably a slew of concerns at the individual, technical, and environmental levels that are driving the shift to textile-based energy harvesters. These energy harvesters make use of the energy that is wastefully released by the human body (mentioned in section III). On an average day, inclusive of all the activities performed by a normal individual, the biomechanical energy sums up to approximately 70 W. Thus, being able to utilize this and use it as a source of power for smart textiles rather than regular batteries is an intriguing, environmentally benign, and sustainable option that deserves careful consideration. Textile-based energy harvesters like smart textiles follow a similar process of fabrication. These harvesters can sense and transform energy from one form to another. They come in a variety of shapes and sizes, depending on the type of energy they convert or transform.

4.3.1. Triboelectric Energy Harvester. Mechanical energy expensed by the body is the leading source for the generation of electricity. It is an amalgamation of two processes: triboelectrification (resultant of the physical contact between two materials with varied electron affinity) and electrostatic induction (the potential difference that is created when two opposite charge carrying materials are separated). The shift towards miniature technology has shown property enhancement as the size of materials shifts from the macro-micro-nanoscale. This section will focus on energy harvesting triboelectric nanogenerators (TENGs). In 2012, Wang and his team introduced this concept and demonstrated its capabilities. Many notable research works have also showcased the advantages offered by TENGs [32–37]. TENGs can potentially harvest energy from sound, wind and vibrations. Furthermore, its fabrication involves materialistic diversity, thus aiding in choosing the material as specific as the application demands.

Zou et al. [38] have proved, and the TENGs can be made of materials such as cotton, wool, silk, artificial fiber, rubber, and polyurethane. As explained in Section 4, fabrics can be coated with various functional materials. Therefore, bridging the two concepts gives birth to a textile-based triboelectric energy harvester [39, 40]. A common concern with textile-based biomedical systems is washability. This concern was washed away by Ning et al. [41] who worked on a textile-based TENG that could generate a peak voltage of about 1050 V by measuring the friction within the clothes during everyday activities. They used nanofiber with high hydrophobic properties to impart the convenience of washing. The nanofiber was then woven into a nonwoven textile substrate via a shuttle flying process, and they have shown that a simple fabric (lab coat) can be incorporated with such a functionalized polymer fiber to generate electricity (Figure 5).

Their work intends to showcase the importance of bridging the merits of textile-based energy harvesters to solve the predicament faced by textile-based WBDs. In their work, they used electricity to power 54 LEDs. By replacing the LEDs with an inlet with a textile-based WBD system, we can have a sustainable long-lasting energy source that will ultimately enable continuous monitoring of vitals.

Zhou et al. [42] proved that using functional fiber inserted into textile could aid physiological monitoring using the power it generated in a newly published study. A combination of nylon fabric (positive) and polyester (negative) served as the source for triboelectrification with a conductive silver fiber fabric at the center. These textile-based TENGs developed by team Zhou et al. [43] were breathable, washable, and convenient, and they went on to produce alternating current by exploiting the energy expense at the arm joints during elbow movement. These composite fibers can feed in energy to textile-based WBDs, as shown in Figure 6.

When the principle behind the different forms of textile-based energy harvesting is understood, this enables the conjunction of two other energy harvesting systems as well. Interconnection between the two energy harvesting systems and material compatibility with textile manufacturing processes must be well understood before undertaking such a feat. To guide the reader towards understanding the same, we have highlighted the works of Chen et al. Chen et al. [44], in their work, explained the energy harvesting from not only mechanical sources but also solar at the same time. Another important highlight of their research was the interconnection technique used to connect the two different energy harvesters. They developed two modules, one being the module that harnesses energy from incident radiation of the sun, hence photovoltaic, and the second being the triboelectric/TENG, which harnesses power from the friction in the body motion, the action of wind blowing, vibrations, and deformations.

This was achieved using a polymer fiber-based solar cell and interlacing two polymer fibers with varied electron affinity to generate a triboelectrification effect. Another important aspect to note is that they ensured all the chosen polymer-fiber/electrodes were compatible for industrial textile processing. Figure 7 shows the interlayer distinction of one such fabric-based TENG in the form of a yarn.

Within the photovoltaic module, the ZnO/dye becomes the interface region where electrons and holes get separated due to the energy from incident sunlight, forming electron-

hole pairs. The wire-shaped counter electrode acts as a collector for holes, while electrons move through the semiconductor's conduction band. They are then collected at the photo anode, thus generating electricity from solar energy. Within the TENG module, the two PTFE strips are placed adjacently and interlaced with the copper electrode. When any deformations occur, mechanical excitation causes the two PTFE strips to come into contact, followed by deformation removal, resulting in a backflow of electrons between the electrodes, eventually leading to the current generation, as seen in Figure 8.

Both the independent modules were interconnected by counter electrodes, and copper was used as the common electrode. The interconnection procedures and materials used are explained in the same work. Moreover, the interlacing and other processes are also presented as visual aids/videos for the reader in their supplementary information. Thus, this work showcases the vast potential of such hybrid textiles possessing more than one energy harvesting system. The electricity generated from their hybrid textile was significant enough to charge a cell phone and an electronic watch under ambient conditions. If in a similar manner, this power generated could be connected to a textile-based WBD (parent system), this could lead to a fully self-powered textile-based biomedical device.

4.3.2. Piezoelectric Energy Harvesting. Piezoelectricity is the term for the generation of electricity by converting mechanical energy to electrical energy through the use of a specific material and motions involving any compression-based deformations (from the human body's perspective), whether caused by movements, the wind, or being struck/squeezed. Thus, most wearable electronics possess a piezoelectric component within their design. Textile-based piezoelectric energy harvesting similarly will possess a patch of piezoelectric material at the location of the source of mechanical energy [45–50]. Just as TENGs for triboelectric generators, here for piezoelectric energy harvesting, we have piezoelectric nanogenerators (PENGs). Polyvinylidene fluoride (PVDF) is the most commonly utilized material component for textile-based PENG because it is easy to incorporate into a fabric substrate [51, 52].

For a personalized health monitoring system, such a fabric-based patch can be directly attached or incorporated into the textile, with the help of interconnections, and the energy generated from the PENG module can be utilized to power the textile-based WBD (parent system) [53, 54]. Qin et al. [55] developed ZnO-based PENG on a Kevlar fiber by hydrothermal process. Since the fiber is coated with ZnO utilizing a fiber and twisted layer, the force created by stretching can be determined as illustrated in Figure 9. Tetraethoxysilane was utilized as a mechanical strengthening component, and the whole structure generated a voltage of 2.2 V with a current of 60-120 nA. This fabric-based PENG could be used to detect heartbeat and extract energy from it to create power under low-frequency biomechanical energy conditions.

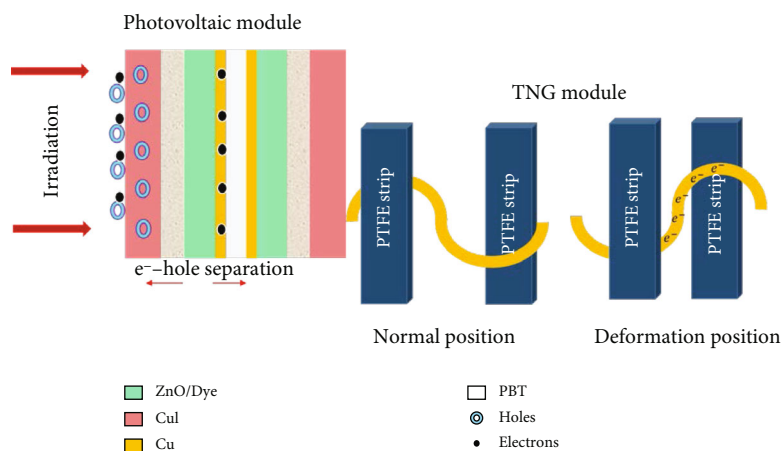
Yang et al. [56], in their works, explored a similar application of employing ZnO nanowires for textile-based PENG.


Figure 8: Electricity generation in photovoltaic module and triboelectric module.
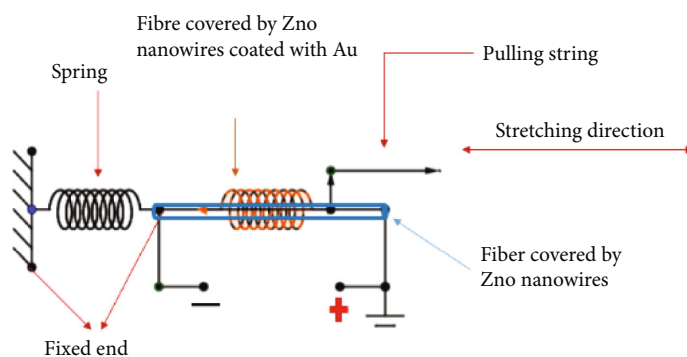

Figure 9: Fiber-based PENG.

They were able to produce an oscillating voltage up to 50 mV during the action of stretching and releasing. An ultrahigh piezoelectric voltage of 0.79 Vm $N − 1$ was developed by Chen and his team. They synthesized lead zirconate titanate (PZT) fibers via sol-gel technique, and a layer of polydimethylsiloxane (PDMS) was coated on it. On the application of pressure, the strain created flowed through the PZT fiber and passed the PDMS to generate charges during their testing. They suggested that by using more efficient piezoelectric material to coat a fiber substrate, the output voltage of 1.63 V that was observed could be improved. Further to harness the energy from a human arm, Zhang et al. developed a woven fabric generator of $BaTiO_3$-PVC composite fiber, which produced a voltage of 1.9 V. Gu et al. [57] further added to this research where they explained vertically aligned PENGs yield more voltage. In their work, a voltage of around 209 V was generated. This was a huge leap in the PENG research. Such high output, if interconnected to a textile-based WBD, could promote the shift towards a self-powering health monitoring system.

Thus, it is logical to say that in order to produce flexible textile-based PNG, the two electrodes used for PENG must be flexible and fibrous, or else attaching to the human body may not be a comfortable fit. We would like to highlight the work of Ji et al. [58] and the team, as they developed a yarn-based PENG in the form of a core-shell structure. There were two conductive threads used, an inner layer (inner electrode) and an outer layer (outer electrode). The piezoelectric nanofiber BNT-ST/PVDF was wound around the inner electrode. The core-shelled piezoelectric yarn/nanofiber was braided with two strands of conductive thread (outer electrode). For interested readers who wish to understand the synthesis process of BNT-ST/PVDF nanofibers, it has been elaborately explained in Ji et al.'s works.

This specific structural integration of components leads to improved performance and durability as it is sensitive towards bodily deformations. The core-shelled piezoelectric yarn, which was braided with the electrodes, was then directly stitched onto fabric to yield the final textile-based PENG. When this textile-based PENG was tested, the output voltage was found to be 50 kPa. Their work investigated that the voltage variation is based on the length of the PENG patch stitched, the stitching interval between the yarns and the pattern of stitching. Thus, these factors must be considered as prime factors to evaluate the voltage output with precision. They are able to introduce this patch in gloves and elbow region as a guard, and a considerable amount of power can be generated as a result of stretching and bending of these parts as illustrated in Figure 10.

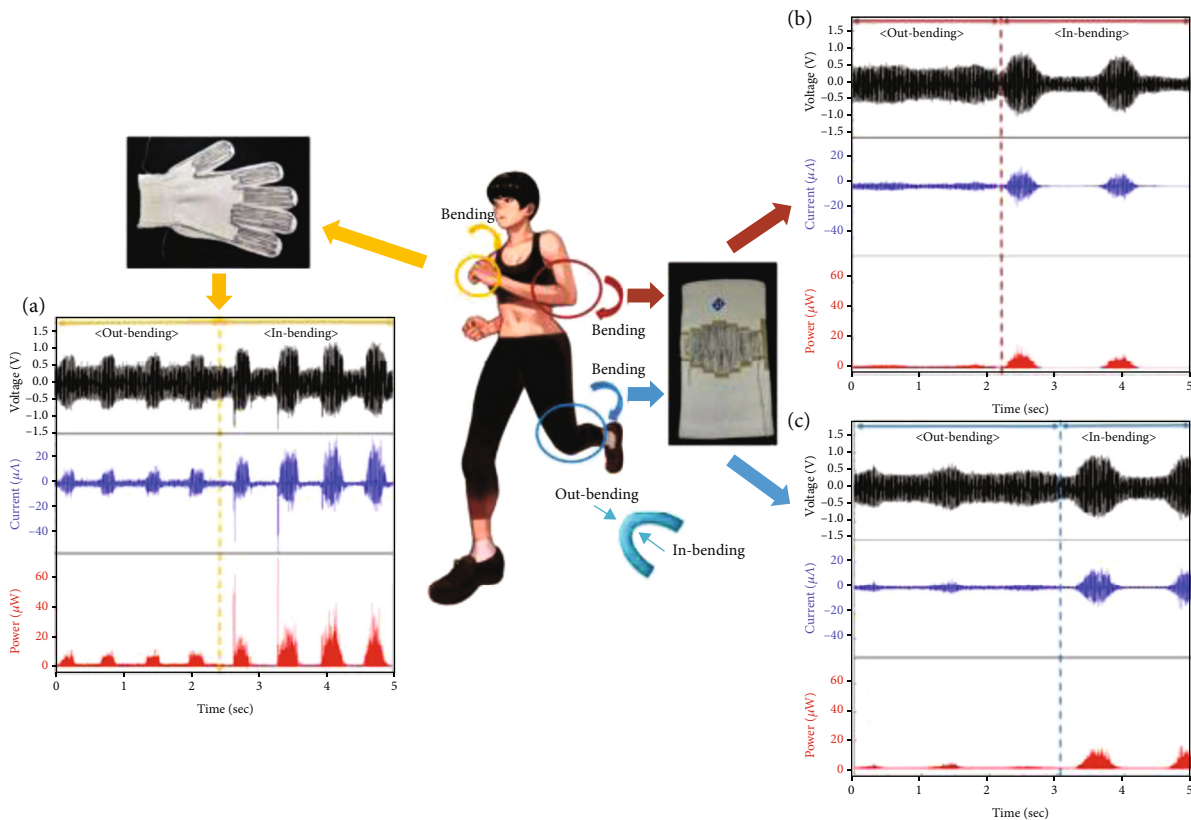
Thus, if a shirt with textile-based WBD is developed, it could incorporate these PENG patches at the source of deformations, with proper interconnections between different


FIGURE 10: Application of textile-based PENG.

modules, as shown by Chen et al. in their study. It may self-generate the power required to run the device without the need for batteries to be replaced.

4.3.3. Thermoelectric Energy Harvesters. Thermoelectric energy harvesting systems have gained attention primarily because of their working principle. It functions based on the heat released by the human body and the temperature gradient of the environment. It requires no additional deformations or body movements or external sources of energy such as sunlight. A thermoelectric energy harvester generally possesses two sides: cold and hot (refer to Figure 11). The hot side, which is between the rough skin surface and smooth thermoelectric element, generates thermal contact resistance. Subsequently, on the cold side, the heat is released via convection. Normally, this region needs to have a high surface area for higher convection. To incorporate the thermoelectric materials onto textile, a preferred polymer is poly (3, 4- ethylenedioxythiophene): poly (styrene sulfonate) (PEDOT: PSS). This is a type of conductive polymer complex. The main advantage of this polymer complex is the ease with which it can be transformed into a full-fledged textile-based system. Coating and spinning are the two main methods that facilitate this incorporation.

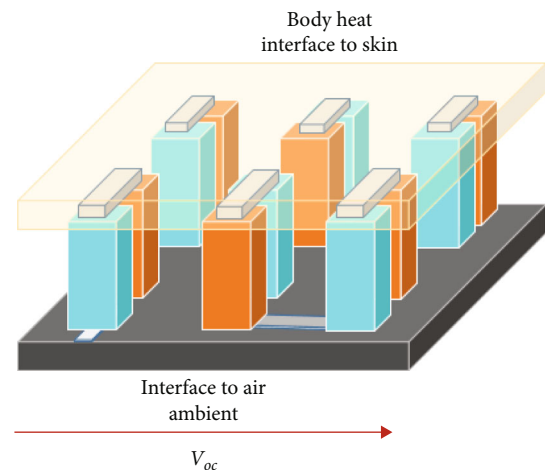
In previous research works, both in-plane and out-of-plane devices based on thermoelectric polymer-based textiles have been explored. Du et al. [59] coated cotton with PEDOT: PSS and used a silver wire. The cotton strip was


FIGURE 11: Wearable thermoelectric module.

35 mm x 5 mm, and it produced a maximum power output of 12.16 nW. Using vapor deposition, p-doped PEDOT-Cl was deposited onto cotton for an out-of-plane thermoelectric device by Allison et al. [60]. The power generated was around 4.5 nW.

In the most recent research work, Lund et al. [61] and the team have developed eight thermocouples whose each leg pair generates 2.3 nW per degree at a gradient of temperature 65 K with an overall power output of 1.2 microwatts. The highlight of this research is not only the high power
Figure 12: Embroidery into wool fabric and current generation.

output but the compatibility of their textile-based thermo-electric material with the existing textile manufacturing processes for large-scale applications. This group has also created plain and dyed conductive polymer rolls that are wash and wear-resistant and ready to be woven and sewn.

Another intriguing finding from their research is the use of conducting paste as an interface between thermocouples to lower component contact resistance. To generate the out-of-plane layout, they perform embroidery by hand to hold the different layers of wool fabric in place, as shown in Figure 12. Wool fabric was chosen for its comfort and ability to generate a temperature gradient. Therefore, when this textile-based thermoelectric energy harvesting system is worn in low-temperature conditions, the body becomes the hot region, and the external environment becomes the cold; thus, the heat will flow from hot to cold region, which results in the production of electricity, as shown in Figure 12. With such research happening, in our review, we would like to highlight once again the importance of creating a link between textile-based energy harvesters and textile-based biomedical wearable devices. This could revolutionize the field of health monitoring systems forever, as the main drawback of traditional biomedical devices can be addressed.

5. Conclusion

An increasingly health-conscious and convenience-driven culture has prompted the convergence of technology and medicine. As a result, a variety of invasive and noninvasive wearable devices that can capture biosystemic data have been developed, and they have proven to be useful in disease diagnosis and detection. However, their effective acceptance by wearers/patients has been hampered by their performance life-span, wearability, expense, and comfort. Furthermore, its psychological impact has been identified as a contributing factor in slow recovery rates. Fortunately, with the advancement in miniature technology and the textile industry, this new fusion can be the solution to the predicaments faced by traditional wearable devices. The solution lies in bridging textile-based wearable biomedical devices

with textile-based energy harvesters which can provide the continuous source of power that can be generated from the wasteful energy released by various human motions using source-specific textile-based nanogenerators. Therefore, we hope to plant a seed of thought in the minds of the readers and researchers about the importance of textile-based energy harvesters and their vast but less explored potential.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Properties and Modification of Bismuth-Layered Structure Ferroelectric Materials and Application in Sports

Guorong Jiang (ID)

School of Sports, Jiujiang University, Jiujiang, 332005 Jiangxi, China

Correspondence should be addressed to Guorong Jiang; 2021001548@poers.edu.pl

Bismuth-layered oxides are a very important class of ferroelectric materials. Due to their special structure, they have outstanding features in many aspects, such as high Curie temperature, large spontaneous polarization, polarization stability to temperature, high voltage resistance, low dielectric loss, and excellence. Due to its antifatigue properties, the system is very suitable for applications in nonvolatile random access memory and high-temperature sensors. The purpose of this paper is to study the application of the performance and modification of bismuth-layered ferroelectric materials in sports scientific research. Proposed the combination of new materials and sports scientific research projects. This article uses sample analysis and (the comparative experiment method is a method to compare the experimental group and the control group to illustrate the superiority of the experiment) comparative experiment methods, sets up an experimental group and a control group, summarizes the algorithm rules through the study of the microscopic properties of nanomaterials, and designs a numerical simulation program. The experimental results in this article show that after receiving hyperbaric oxygen recovery in the first week, the heart rate of the experimental group subjects has a significant change, which is significantly lower than the initial value ($p < 0.05$), from 58.0 to 53.0, The higher pressure oxygen had a very significant drop before recovery, from 62.9 to 53.0. In the second week and the third week, the heart rate index decreased significantly after 1 hour of hyperbaric oxygen recovery ($p < 0.01$), from 54.3 to 49.3 and 56.1 to 52.4, respectively. After the fourth week of intensity training, the heart rate increased significantly from the initial value ($p < 0.05$), from 49.6 to 55.2. After 1 hour of hyperbaric oxygen recovery, there was a significant decrease compared with before the hyperbaric oxygen recovery ($p < 0.05$), dropped from 55.2 to 53.1. Illustrate the success of the experimental results. It also completed the subject of interaction and combination of the performance and modification of bismuth-layered ferroelectric materials in sports scientific research.

1. Introduction

In a certain temperature, the ferroelectric material exhibits the characteristics of spontaneous polarization when there is no external electric field, and its polarization may have multiple directions. When an electric field is applied, the polarization direction changes with the change of the electric field. Generally, after the temperature exceeds a certain value, the spontaneous polarization of the ferroelectric material will disappear, and the ferroelectric material will become paraelectric. The transition between ferroelectricity and paraelectricity is called ferroelectric phase transition. Many physical properties of crystals at this temperature are different from usual, and the temperature of this transition is the Curie point of ferroelectrics. In addition to spontaneous polarization, the hysteresis loop is also an important way to observe whether a crystal is a ferroelectric. Research shows that the polarization intensity and direction of the crystal will exhibit a dielectric characteristic different from ordinary materials with the applied electric field. Ferroelectric materials are special electrolytes and have been extensively studied. It has a variety of polarization modes, which have different effects at different frequencies, so that the dielectric spectrum of different materials is very different. From the microscopic mechanism, it can be attributed to two different types: (1) displacement type and (2) order and disorder type. Frequency-tunable materials have potential applications in the fields of frequency selection,

absorption, imaging, and biology. Certain elements are sensitive to temperature changes. Doping these elements in ferroelectric materials can affect its dielectric properties. Ferroelectric materials are widely used in subject interaction due to their unique properties.

Multiferroic materials with ferromagnetism and ferroelectricity are mainly concentrated in transition metal (rare earth element) oxides, mainly due to their complex electronic structures and competing interactions. These competitions include charge, spin, orbital, and lattice degrees of freedom, which are more easily regulated by external means (such as electric field, magnetic field, and stress). At the same time, multiferrocity requires that the d or f orbitals of transition metals or rare earth elements must be partially filled with local electrons, and through exchange interactions between local moments, magnetic order (time reversal broken) is caused. On the other hand, for ferroelectric materials, in order to induce spontaneous polarization (spatial inversion broken), empty d orbitals are required. Few systems can meet these two requirements at the same time, so there are very few multi-iron materials in nature. According to the microscopic sources of different iron-containing properties, multicore materials can be divided into different types, and the magnetic properties of materials can generally be divided into paramagnetic, antiferromagnetic, and ferromagnetic. When the magnet is lower than the Curie temperature, it is ferromagnetic; when it is higher than the Curie temperature, it is macroscopically paramagnetic. Adjacent magnetic atoms have different magnetic coupling results, leading to different magnetic orientations, leading to different magnetic step settings. In the rectangular perovskite system, ferromagnetism (FM), the magnetic orientation of all its atoms is the same. For diamagnetism, there are four different magnetic orientations, namely, A-type diamagnetism (A-AFM): the orientation of the magnetic order of the atoms in the plane is the same, and the magnetic order of the atoms in the plane is opposite. Diamagnetic C-type (C-AFM): the magnetic order of atoms in the plane is diamagnetic order, and the magnetic order of atoms in the plane is diamagnetic. The magnetic order between the outer atoms is the same. Antimagnetic G (G-AFM): the magnetic sequence of the nearest neighbor is opposite. E-AFM: the magnetic orientation of diamagnetism is along the AC plane, and individuals with the same magnetic orientation are saw-shaped.

From 1935 to 1938, Basheer et al. discovered that the simple structure of potassium dihydrogen phosphate (KDP) and many of its isomorphic crystals are also piezoelectric, and all have high room temperature electromechanical coupling coefficients. But they did not propose the concept of piezoelectric effect [1]. The piezoelectric effect was first discovered in quartz crystal by Nie et al. in 1880. Its discovery led to the rapid development of piezoelectric devices and piezoelectric materials. However, due to time constraints, their research did not further analyze other media and materials related to the piezoelectric effect [2]. In 1954, Ketwong et al. discovered the quasihomomorphic phase boundary (MPB) of Pb $(Zr,Ti)O_3$(PZT) system solid solution. The ferroelectric near MPB has excellent dielectric and piezoelectric properties, and it is close to $BaTiO_3$

ceramics. The high electromechanical coupling coefficient has made piezoelectric materials widely used, but their research stopped here, and the ferroelectricity of subsequent perovskite structure compounds was not found [3].

The innovations of this paper are as follows: (1) in the research content, the macroscopic research method, the transfer matrix method, is selected to study the microstructure characteristics of the crystal. The characteristic matrix is used to express its interaction with electromagnetic waves. (2) The $Bi_4Ti_3O_{12}$ crystal was selected as the bismuth-layered ferroelectric material in this article. The crystal has stable properties, relatively good ferroelectricity, and convenient preparation. (3) The research and introduction of the ferroelectric polarization value have been carried out, making the concept of perfecting the text clear.

The new materials adopted in this article are combined with traditional sports scientific research to meet the needs of subject interaction.

2. Performance and Modification of Bismuth-Layered Structure Ferroelectric Materials and Application Methods in Sports Scientific

2.1. Ferroelectricity. The ferroelectric system is a substance that has spontaneous polarization after transitioning from a high-temperature phase to a low-temperature phase, and its polarization direction can be reversed by an external electric field [4]. Many properties of ferroelectric systems are similar to ferromagnets. For example, electric polarization (P) corresponds to magnetization (M), electric field (E) corresponds to magnetic field (H), and electric displacement (D) corresponds to magnetic flux density (B) [5]. At the same time, ferroelectric materials can form domains, and their polarization and electric displacement exhibit electric hysteresis loop behavior in the applied electric field. Therefore, ferroelectric materials can be used for data storage. Research has found that ferroelectric materials can also be used as capacitors, because the concentration of charge density in ferroelectric materials will cause them to have a high dielectric constant [6].

The early work of ferroelectric materials mainly focused on Rochelle salt, $KNa(C_4H_4O_6)\cdot4H_2O$. Although the research of Rochelle's salt has established many basic properties of ferroelectric materials, the complex structure and the large number of atoms in each cell make it difficult to give a microscopic theory to clarify ferroelectricity from an experimental point of view [7]. At present, the widely studied ferroelectric system is the perovskite structure oxide ABO3. The ideal perovskite structure is characterized by a cation (B) with a small particle radius, in the center composed of an anionic oxygen octahedron, and the particle radius. The larger cation (A) is at the apex of the primitive cell [8]. The relatively simple structure of perovskite allows researchers to study its ferroelectric properties in detail and have a deeper understanding of the basic principles of ferroelectricity [9].

Table 1 is an introduction to 32 crystallographic point groups.

TABLE 1: 32 crystallographic point groups.

T	Th	O	Td	Oh		
C4	S4	C4h	D4	C4v	D2d	D4h
D2	C2v	D2h				
C2	Cs	C2h				
C1	Ci					
C3	S6	D3	C3v	D3d		
C6	C3h	C6h	D6	C6v	D3h	D6h

Symmetry determines whether the system is ferroelectric. Among the 32 crystallographic point groups, 11 crystallographic point groups have a center of symmetry (centrosymmetric); that is, they do not have ferroelectricity; in the remaining 21 point groups, the O point group does not have ferroelectricity. The remaining 20 all show piezoelectric effect, but only 10 point groups have its specific polarity direction [10].

2.2. Preparation Technology. The traditional solid-phase melting process is used to manufacture bismuth-coated ceramic powder. The uniformity of the powder is low, and the melting temperature is high [11]. It is difficult to obtain ceramic samples with high density and excellent performance [12]. In recent years, some liquid chemical methods, such as sol-gel method, hydrothermal synthesis method, and other powder preparation methods, have gradually attracted the attention of scientific researchers [13]. The use of liquid chemical methods to manufacture ceramic powder can achieve molecular-level mixing between the various components of the material [14], with high product purity, large powder specific surface area, and high ceramic fusion temperature, which can also be reduced to a certain extent. The sol-gel method was used to prepare ceramic powder $(K_{0.16}Na_{0.84})_{0.5}Bi_{4.5}Ti_4O_{15}$ (KNBT) [15], and the phase structure and electrical properties were studied. Studies have found that when the composition temperature is 500°C, single-phase KNBT ceramic powder can be formed, and the Curie temperature of the ceramic sample is 659°C [16], which is higher than the Curie temperature of KNBT ceramic prepared by traditional methods. The ferroelectric ceramics of the $SrBi_4$-$xCexTi_4O_{15}$ system can also be successfully prepared by the sol-gel method. The study found that all ceramic samples formed a typical phase structure with a bismuth layer, and the Curie temperature of the samples was above 500°C [17]. In short, the use of different powder preparation techniques will definitely have different effects on the structure and performance of ceramic samples [18]. This liquid chemical method can prepare ceramic powder with uniform particle size and large specific surface area. However, the cost of raw materials used in this type of process is high, the experimental process is complicated, and the organic solvent used in the reaction process is toxic and difficult to achieve. Batches of lead-free bismuth piezoelectric ceramics have a wide range of applications in industrial production and can be used in the research of this article [19].

Lead-free dual-structure piezoelectric materials are widely used in the research of ferroelectric thin films and devices due to their fatigue resistance and high-temperature Curie characteristics [20]. However, due to the limitation of its own structure, it is difficult to effectively improve the two-level performance of ceramics, ferroelectric properties, and piezoelectric properties [21, 22]. The physical and chemical properties of materials are determined by the structure of the material, and the structure of the material is related to the composition of the material. Therefore, replacing the composition and structure of ceramic crystals with doping is an effective measure to improve the electrical properties of bismuth ceramics [23, 24]. This type of method has low preparation cost and simple process and is suitable for a wide range of applications [25]. At present, the doping modification methods of bismuth lead-free piezoelectric ceramics mainly include A-site substitution, B-site substitution, and additive modification [26].

2.3. Transfer Matrix Method. The matrix transmission method (TMM) is a method that combines the knowledge of Maxwell's equations (It is a set of partial differential equations established by British physicist James Clark Maxwell in the 19th century to describe the relationship between electric field, magnetic field, charge density, and current density.) and optical matrices to calculate the transmission and reflection propagation of electromagnetic waves in multiple layers of different media structures. The propagation of electromagnetic waves in the intermediate layer is considered to be the superposition of incident electromagnetic waves and reflected electromagnetic waves. The tangent continuous state of the electromagnetic field is satisfied at the limit of each intermediate layer, and its interaction with electromagnetic waves can be represented by a characteristic matrix. Assuming that the field vectors on both sides of the dielectric layer are EI and HI and EII and HII, the relationship between them can be linked by the characteristic matrix:

$$\begin{bmatrix} E_1 \\ H_1 \end{bmatrix} = M \begin{bmatrix} E_{11} \\ H_{11} \end{bmatrix}. \tag{1}$$

For interface I,

$$\left\{ \begin{array}{l} E_1 = E_{i1} + E_{r1} = E_{t1} + E'_{r2} \\ H_1 = H_{i1} \cos \theta_{i1} - H_{r1} \cos \theta_{i1} \end{array} \right\}. \tag{2}$$

In the same way, in interface II,

$$\left\{ \begin{array}{l} E_{II} = E_{i2} + E_{r2} = E_{r2} + E'_{r3} \\ H_{II} = H_{i2} \cos \theta_{i2} - H_{r2} \cos \theta_{i2} \end{array} \right\}. \tag{3}$$

The thickness of the medium nb is b (that is, the distance between the interfaces I and II), and the formula of

the transmission field E_{t1} on the interface I and the incident field E_{i2} of the interface II is shown in

$$\begin{cases} E_{t1} = E_{t10} e^{-i(k_x x + k_z z)} \big|_{z=0}, \\ E_{t2} = E_{t10} e^{-i(k_x x + k_z z)} \big|_{z=b} = E_{t1} e^{i\delta_b}. \end{cases} \tag{4}$$

The phase difference when the electromagnetic plane wave crosses the two interfaces perpendicularly is

$$\delta_b = -k_z h_b = -\frac{\omega}{c} n_b b \cos \theta_b. \tag{5}$$

The same goes for

$$E'_{r2} = E_{r2} e^{i\delta_b}. \tag{6}$$

Organize to get

$$\begin{cases} E_1 = \cos \delta_b E_{\mathrm{II}} - \dfrac{1}{\eta_b} \sin \delta_b H_{\mathrm{II}}, \\ H_1 = -i\eta_b \sin \delta_b E_{\mathrm{II}} + \cos \delta_b H_{\mathrm{II}}, \end{cases} \tag{7}$$

where

$$\eta_b = \sqrt{\frac{\varepsilon_0}{\mu_0}} \sqrt{\frac{\varepsilon_r}{\mu_0}} \cos \theta_b. \tag{8}$$

In matrix form, there are

$$\begin{bmatrix} E_1 \\ H_1 \end{bmatrix} = \begin{bmatrix} \cos \delta_b & -\dfrac{1}{\eta_b} \sin \delta_b \\ -i\eta_b \sin \delta_b & \cos \delta_b \end{bmatrix} \begin{bmatrix} E_{\mathrm{II}} \\ H_{\mathrm{II}} \end{bmatrix}. \tag{9}$$

The characteristic matrix of any dielectric layer j is

$$M_j = \begin{bmatrix} \cos \delta_j & -\dfrac{i}{\eta_j} \sin \delta_j \\ -i\eta_j \sin \delta_j & \cos \delta_j \end{bmatrix}. \tag{10}$$

For the case in TTE mode, where

$$\begin{cases} \delta_j = -\dfrac{\omega}{c} n_j h_j \cos \theta_j, \\ n_j = \sqrt{\dfrac{\varsigma_0}{\mu_0}} \sqrt{\dfrac{\mu_j}{\varepsilon_j}} \cos \theta_j. \end{cases} \tag{11}$$

In the case of TM mode, the other formulas are the same, but the key variables are replaced:

$$n_j = \sqrt{\frac{\mu_0}{\varepsilon_0}} \sqrt{\frac{\mu_j}{\varepsilon_j}} \cos \theta_j. \tag{12}$$

For multilayer media, it can be applied layer by layer, then:

$$\begin{bmatrix} E_1 \\ H_1 \end{bmatrix} = M_1 M_2 \cdots M_{N-1} M_N \begin{bmatrix} E_{N+1} \\ H_{N+1} \end{bmatrix} = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} E_{N+1} \\ H_{N+1} \end{bmatrix}. \tag{13}$$

The transmittance T, reflectance R, and absorptance A are

$$\begin{cases} T = |t|^2, \\ R = |r|^2, \\ A = 1 - T - R. \end{cases} \tag{14}$$

Among them,

$$\begin{cases} \delta_a = -\dfrac{\omega}{c} n_a a \cos \theta_a, \\ \delta_b = -\dfrac{\omega}{c} n_b b \cos \theta_b, \\ \eta_a = \sqrt{\dfrac{\varepsilon_0}{\mu_0}} \sqrt{\dfrac{\varepsilon_0}{\mu_0}} \cos \theta_a, \\ \eta_b = \sqrt{\dfrac{\varepsilon_0}{\mu_0}} \sqrt{\dfrac{\varepsilon_0}{\mu_0}} \cos \theta_b. \end{cases} \tag{15}$$

In summary, the introduction of the transmission matrix method is complete, and the experiment is ready to begin.

3. Performance and Modification of Bismuth-Layered Structure Ferroelectric Materials and Application Experiments in Sports Scientific

3.1. Preparation and Application of $Bi_4Ti_3O_{12}$ Powder. $Bi_4Ti_3O_{12}$ material has a low forbidden band width and photocatalytic activity, and its absorbable spectral range can be extended to the visible light range through the method of nanomaterialization or doping modification of the material. This plays an important role in improving the utilization of sunlight. In addition, it is a typical ferroelectric material with good ferroelectric and piezoelectric properties. In this chapter, $Bi_4Ti_3O_{12}$ powder is prepared by hydrothermal method, and the role of hydrothermal temperature in the preparation process is discussed. The key work of this chapter is to apply ultrasound and light to $Bi_4Ti_3O_{12}$ powder at the same time. It is expected that ultrasound can be used to activate the piezoelectric properties of bismuth titanate, to achieve polarization of bismuth titanate powder, and to improve its photocatalytic efficiency.

In this paper, $Bi_4Ti_3O_{12}$ powder is prepared by hydrothermal method. The preparation process can be divided into three steps: preparation of hydrothermal reaction precursor, hydrothermal reaction, and heat treatment of hydrothermal product. Among them, bismuth nitrate is used as

TABLE 2: The main drugs needed for the experiment.

Reagent name	Specification	Manufacturer
Bismuth nitrate	Analytically pure	Sinopharm
Tetrabutyl titanate	Analytically pure	Sinopharm

the titanium source, tetrabutyl titanate is used as the bismuth source, and 3 mol/L NaOH solution is used as the mineralizer for the hydrothermal reaction. First, 30 mL of glacial acetic acid and 30 mL of ethylene glycol methyl ether are mixed, and then, 9.7 g of bismuth nitrate is added to form solution A; then, 5.10 g of tetrabutyl titanate is dissolved in 20 mL of ethylene glycol methyl ether to form solution B. Finally, solution B was slowly added to solution A, and an appropriate amount of ethylene glycol methyl ether was added to prepare a 0.05 M bismuth titanate sol. After drying the sol, a dry gel is obtained, and the dry gel is ground and dissolved in a mineralizer to prepare a hydrothermal reaction precursor. After the preparation of the hydrothermal precursor is completed, the hydrothermal precursor solution is put into the reaction kettle and put into the oven for hydrothermal reaction. Through literature research and consideration of experimental safety, three hydrothermal temperature points of 160°C, 180°C, and 200°C that do not exceed 200°C are selected for the experiment, and the holding time is 24 h.

The main experimental drugs are shown in Table 2.

3.2. Objects of Experiments. The subjects of this study are divided into the excellent long-distance runner group (case) and the general population control group (control group).

The basic situation of the outstanding long-distance runner group is shown in Table 3.

The athletes and ordinary personnel in this experiment were taken from two classes in a major physical education department and a certain electrical engineering department

with the same basic situation, each with 130 students as samples.

The basic situation of the control group is shown in Table 4.

3.3. Test Instrument and Test Index. The equipment used in the exercise capacity test is hyperbaric oxygen equipment, 0.035 MPa, and the maximum working load is 0.05 MPa.

In the HRV test, the omega wave test and analysis system are used to collect signals, and Excel is used for index calculation. Use the SPSS24.0 software statistical package to perform statistical processing on the data. $p < 0.05$ indicates a significant difference.

4. Application of the Performance and Modification of Bismuth-Layered Ferroelectric Materials in Sports Scientific

4.1. Influence of $Bi_4Ti_3O_{12}$ on the Quiet Heart Rate of Middle and Long Distance Runners. Figure 1 shows the initial value of heart rate in the experimental group during the experimental period, before the recovery of hyperbaric oxygen, and the change of resting heart rate after 1 hour of recovery.

After receiving hyperbaric oxygen recovery in the first week, the heart rate of subjects in the experimental group changed significantly from the initial value ($p < 0.05$), from 58.0 to 53.0, before the higher oxygen pressure was restored. There has been a very significant drop, from 62.9 to 53.0. In the second week and the third week, the heart rate index decreased significantly after 1 hour of hyperbaric oxygen
Figure 1: Heart rate changes in the experimental group.
Figure 2: Changes in heart rate variability of the experimental group before and after recovery with hyperbaric oxygen in the first week.

recovery ($p < 0.01$), from 54.3 to 49.3 and 56.1 to 52.4, respectively. After the fourth week of intensity training, the heart rate increased significantly from the initial value ($p < 0.05$), from 49.6 to 55.2. After 1 hour of hyperbaric oxygen recovery, there was a significant decrease compared with before the hyperbaric oxygen recovery ($p < 0.05$), dropped from 55.2 to 53.1.

The changes in heart rate variability of the experimental group before and after recovery using hyperbaric oxygen in the first week are shown in Figure 2.

It can be seen that there is no significant change in the time domain indicators of heart rate variability.

The initial value of the experimental group in the second week, before the recovery of hyperbaric oxygen, and the change of heart rate variability index after the recovery of hyperbaric oxygen for 1 hour are shown in Figure 3.

In the second week, the time domain indicators SDNN, RMSSD, and PNN50 of the experimental group showed a
Figure 3: The initial value of the experimental group in the second week, before the recovery of hyperbaric oxygen, and the change of heart rate variability index after 1 hour of hyperbaric oxygen recovery.

slight upward trend from the initial value before the hyperbaric oxygen recovery and 1 h after receiving the hyperbaric oxygen recovery, but there was no significant difference. One hour after the recovery of hyperbaric oxygen, the change before the recovery of higher pressure oxygen was not obvious. The VLF in the frequency domain indicators of the subjects decreased sequentially, but there was no significant difference. The change of HF and LF is not obvious.

The initial value of the experimental group in the third week, before the recovery of hyperbaric oxygen, and the change of heart rate variability index after the recovery of hyperbaric oxygen for 1 hour are shown in Figure 4.

It can be seen from the above table that in the time domain index, the initial value of PNN50, the value before hyperbaric oxygen recovery, and the value after hyperbaric

oxygen recovery 1 h showed a sequential upward trend, and the initial value after 1 h hyperbaric oxygen recovery appeared compared with the initial value. There was a significant increase ($p < 0.05$), from 19.93 to 35.12, and the RMSSD value also showed an upward trend, but there was no significant change. In the frequency domain indicators, both VLF and LF showed a downward trend and then an upward trend. HF showed a sequential upward trend, but there was no significant difference. LF/HF showed a downward trend, but it did not appear significant.

The initial value of the experimental group in the fourth week, before the recovery of hyperbaric oxygen, and the change of heart rate variability index after the recovery of hyperbaric oxygen for 1 hour are shown in Figure 5:

In the time domain index, the value of RMSSD in the experimental group was higher after 1 hour of hyperbaric oxygen recovery, and there was a significant increase ($p < 0.05$), from 108.91 to 111.70, while the changes in SDNN and PNN50 were not very obvious and not significant. In the frequency domain parameters of the subjects, HF increased significantly ($p < 0.05$) from 1354 to 1683 after receiving hyperbaric oxygen treatment for 1 hour than before hyperbaric oxygen recovery. LF also increased from the initial value before hyperbaric oxygen recovery. After

receiving treatment for 1 hour, the trend of AIDS decreased, but there was no significant change.

In the fifth and sixth weeks, the experimental group stopped hyperbaric oxygen during the observation period and resumed the initial value of the heart rate on the week, as shown in Table 5.

The subjects' various time-domain indicators have declined, but there is no significant difference, and there is little change. The values of VLF and LF have a downward trend, HF does not change significantly, and LF/HF rises, but there is no significant difference. SDNN is an indicator of heart rate variability; generally, it is greater than 100.

4.2. Iron Polarization Value. The ferroelectric polarization value is zero for the antiferroelectric structure ($\lambda = 0$), and the subsequent trend shows that a nonmonotonic line increases with λ. The nonmonotonic behavior as a lambda function is common in the case of organic-inorganic hybrid compounds. At the same time, the components of the total ferroelectric polarization vector and the modulus of the vector are calculated by the first principles, as shown in Table 6.

The estimated Rashba coefficient in organic halide perovskite is shown in Table 7.

4.3. $Bi_4Ti_3O_{12}$ Microstructure and Ferroelectric Properties. Table 8 is the crystal information and refinement conditions of $Bi_4Ti_3O_{12}$ at room temperature.

It can be seen from the table that the contribution of the total spontaneous polarization of $Bi_4Ti_3O_{12}$ is better, and the ferroelectricity is increased. It shows that the phase reversal does come from signal polarization reversal and ferroelectric behavior, which is higher than 0.26 nm in OPP mode.

5. Conclusions

The experimental results show that the performance and modification research of the bismuth-layered ferroelectric material proposed in this paper is applied in sports scientific research. Compared with the current traditional sports scientific research, due to the use of a new type of bismuth-layered ferroelectric material, as a result, the effect of scientific research is better. After athletes use the material for long-distance running assistance, all data and performance have increased significantly. The observation effect is better, the data collection is more accurate, and it is more convenient for sports-assisted scientific research personnel and researchers to judge and test. In this paper, sample collection method, comparison experiment method, and transmission matrix method are used to design a method to calculate the transmittance and reflectance of electromagnetic wave propagation in multilayer different media structures by combining the knowledge of Maxwell's equation and matrix optics. And the changes in heart rate variability before and after 4-week recovery with hyperbaric oxygen in the control and experimental groups were also tested. The experimental results showed that after receiving hyperbaric oxygen recovery in the first week, the heart rate of the experimental group subjects changed significantly, which was significantly lower than the initial value ($p < 0.05$), from 58.0 to 53.0. There was a very significant drop before hyperbaric oxygen recovery, from 62.9 to 53.0. In the second week and the third week, the heart rate index decreased significantly after 1 hour of hyperbaric oxygen recovery ($p < 0.01$), from 54.3 to 49.3 and 56.1 to 52.4, respectively. After the fourth week of intensity training, the heart rate increased significantly from the initial value ($p < 0.05$), from 49.6 to 55.2. After 1 hour of

hyperbaric oxygen recovery, there was a significant decrease compared with before the hyperbaric oxygen recovery ($p < 0.05$), dropped from 55.2 to 53.1. It illustrates the success of the experiment results after the ferroelectric material is used in sports scientific research. It also completed the subject of interaction and combination of the performance and modification of bismuth-layered ferroelectric materials in sports scientific research. The shortcomings of this article are as follows: (1) use long-distance running as the basis of the subject for research and does not consider sports such as long jump and various ball sports. In future research, the research content can be gradually improved and expanded to more sports items. (2) Among the research materials in this article, due to the limitation of experimental site and funding, only the research on $Bi_4Ti_3O_{12}$, a layered bismuth ferroelectric material, has been carried out. In future research, efforts can be made to find bismuth-layered ferroelectric materials with cheaper prices, better experimental results, and ferroelectric properties more in line with experimental requirements. (3) Due to time and space constraints, this article only conducted a 4-week training for the two groups to collect heart rate indicators. In future research, the experimental time and interval length can be extended to ensure the scientific reliability of the experimental results.

Retracted: Application Effect Analysis of a Nanotube Combined with Orthopedic Exercise Rehabilitation Therapy in the Treatment of Patients with Knee Arthritis

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Knee arthritis is one of the common diseases with the highest incidence in osteoarthrosis, which seriously affects people's health, and as the patient's medical history prolongs, the pain degree becomes more and more serious. In recent years, with the rapid development of nanotechnology, its application scope has gradually been involved the medical field. The application of nanotube-targeted drugs to treat osteoarthritis can repair bone to a certain extent and relieve patient pain symptom. Sports rehabilitation therapy, as an important nursing method in orthopedic treatment, can improve the patient's body recovery ability and enhance the therapeutic effect of surgery. Based on this, this article proposes the application research of a nanotube combined with exercise rehabilitation therapy in the treatment of patients with knee arthritis. The research carried out in this article is mainly divided into three parts: the first part is the research of titanium dioxide nanotubes in orthopedic treatment, studying the diameter and drug loading of nanotubes, research on how to target the damaged bone tissue and release drugs, and discussing the tissue compatibility and safety of nanotubes to the human body; the second part is the study on exercise rehabilitation therapy in orthopedic treatment and study on how to exercise properly to enhance the patient's body recovery; the third part is clinical investigation and research, according to the observation group in contrast with the indicators of the control group to draw conclusions. The results of this experiment show that in the clinical treatment of knee arthritis surgery, in the analysis of postoperative patients, the scores of the three groups of patients before treatment were relatively low, with scores ranging from 5 to 8, but the scores of the observation group were significantly higher than those of the first and second groups. The observation group ranged from 7 to 10. The joint scores of the observation group gradually increased at 1 week and 2 weeks after treatment. The increase in functional score was more pronounced. For patients with a longer medical history, perform appropriate helping exercises. Titanium dioxide nanotubes have good antibacterial properties as an endoplant and good histocompatibility with human bones. In the observation group combined with exercise therapy, various complications such as pain, swelling, and muscle atrophy were relatively small, allowing the patient to speed up the recovery of various body functions.

1. Introduction

As one of the human organs, bones have important functions that many other organs do not have, such as maintaining body posture, exercising, and supporting muscles and organ tissues. Degenerative osteoarthritis, also known as osteoarthritis, degenerative arthritis, senile arthritis, and hypertrophic arthritis, is a degenerative disease caused by

aging, obesity, strain, trauma, congenital abnormalities of joints, joint degeneration of articular cartilage, and joint edge and subchondral bone-reactive hyperplasia caused by many factors such as deformity. Osteoarthritis [1] is a kind of synovial arthritis, which is very common in clinical treatment, and knee osteoarthritis [2, 3] has the highest incidence. It is more common in middle-aged and elderly people and occurs in weight-bearing joints and joints with

more activities (such as the cervical spine, lumbar spine, knee joint, and hip joint). Excessive weight bearing or use of these joints can promote degenerative changes. At the onset, symptoms include cartilage damage, joint pain, infection, and a prolonged medical history. Relevant investigations have shown that every year, more than one million arthritis patients undergo implant repair [4] and related knee joint surgery. Some patients undergo a series of complications such as internal infections after the surgery, which leads to implantation failure. A second operation is required. Curing OA can only slow symptoms or delay the progression of the disease. OA treatment methods are divided into surgical treatment and nonsurgical treatment. Relieving or eliminating pain and controlling the development of inflammation are the main methods for the treatment of OA at present. With the continuous development of tissue engineering and materials science, researchers have used nanoparticles as drug carriers to inhibit the inflammatory response and promote cartilage repair in OA patients. Therefore, in order to solve a series of problems that may arise, it is a common method to use therapeutic drugs to treat bone diseases. It is a common method to transport the therapeutic drugs to the damaged bone tissue through a certain carrier. Because the composition and function of bone tissue are quite different from other human tissues, especially in cases of fracture, trauma, or cancer with impaired blood supply, the effect of medication is not good.

Infection of the implant site in orthopedic treatment [5, 6] is one of the most difficult complications in orthopedic surgery, ranging from delaying the treatment cycle and increasing treatment costs to amputation or death due to infection. There are generally two reasons for orthopedic prosthesis infection: firstly, bacterial adhesion [7] forms a biofilm on the surface of the implant, which hinders the body's immune response and the killing effect of antibiotics on bacteria. Secondly, because the implant material has poor biocompatibility and cannot form a firm bond with human bone, the fiber layer of the implant osseointegration interface will reduce the local resistance of the host. Therefore, finding nanomaterials with excellent antibacterial properties [8] is of great value for reducing the infectivity of internal implants and prolonging the service life and promoting the development of high-end orthopedic implants with independent intellectual property rights. In the nursing process before and after orthopedic surgery, rehabilitation training is an important part of fracture recovery treatment and the effect of independent exercise is unmatched by other treatment methods. It can enhance the recovery effect of the patient's function, which is very conducive to the recovery of the patient's body, and greatly reduces the postoperative mortality and disability rate of the patient. Based on this, nanotubes combined with exercise rehabilitation therapy [9–11] have great application potential in the treatment of knee arthritis. As a plant medicine carrier in orthopedics, it has a good clinical effect and has great potential for improving the clinical treatment of knee arthritis. However, for the research on knee arthritis injury caused by nanotubes and exercise rehabilitation therapy, the definition and thinking of traditional

exercise therapy have not been removed, so that the two cannot be well combined.

Nanomaterials are widely used in energy, materials, biology, medicine, and other fields due to their superior physical and chemical properties. With the development of materials science, osteoarthritis has been developed and its focus is on repair and reconstruction. Finding materials with good human tissue compatibility, strong mechanical properties, and strong antibacterial ability has always been a difficult point in orthopedics. As a newly developed material, TiO_2 nanotubes [12, 13] have better human tissue compatibility and strong anti-infection performance than commonly used orthopedic materials such as stainless steel, titanium alloy, polyethylene, and ceramics. In addition, by changing the diameter of the nanotube, the thickness of the tube wall, the length of the tube, and the amount of drug loaded, the damaged bone tissue can be targeted and the drug can be released, which has a long-lasting antibacterial effect of the implant. In addition, its nanopore morphology [14] can be suitable for a variety of cell adhesion and growth, achieving good compatibility with human tissues [15]. On this basis, as an important integrated treatment, nursing staff must develop a corresponding rehabilitation exercise plan for the patient. And according to the degree of disease and medical history of orthopedic patients, the patients are arranged for corresponding preoperative and postoperative exercises. Compared with injection of DEX or CDMP-1 alone, intra-articular injection of CDMP-1 and DEX-loaded discoid lipid nanoparticle DLNPs can significantly reduce the levels of inflammatory factors in serum and synovial tissue of knee arthritis and can significantly reduce the levels of inflammatory factors in knee arthritis. Promote the repair of damaged cartilage, and delay or avoid the occurrence of joint replacement surgery. This study suggests that the discoid lipid nanoparticles loaded with synergistic drugs with sustained release have broad development space in clinical practice [16].

The research carried out in this paper is mainly divided into three parts: the first part is the research of titanium dioxide nanotubes in orthopedic treatment. Titanium dioxide nanotubes are another form of TiO_2. Because nanotube nanofilms have a relatively large surface area ratio, so, it has a high adsorption capacity and can achieve compatibility with human tissues, especially the addition of other equipment to the nanotubes for assembly into advanced nanomaterials, which will improve all aspects of the performance of titanium dioxide to a certain extent. In this paper, TiO_2 nanotubes are used as antibacterial drugs and growth factor carriers to study the application of knee arthritis; the second part is the study of sports rehabilitation therapy in orthopedic treatment. Rehabilitation exercises for orthopedic patients can reduce postoperative pain, eliminate swelling in the surgical area and surrounding areas, avoid various complications such as muscle atrophy, and enable patients to speed up the recovery of various body functions. In the orthopedic nursing process, the nursing staff should pay close attention to the various indicators of the patient's body and do a good job in the communication between the doctor and family members and the content of family care. The self-

confidence of recovery must be established for the patient, so that the patient's sports rehabilitation can be realized. The third part is the clinical investigation and research part. Investigate the therapeutic improvement degree, clinical effect, and patient satisfaction of titanium dioxide nanotubes as a new nanomaterial in the treatment of knee arthritis. This article will discuss in detail the advantages and disadvantages of nanotechnology and explore the feasibility of nanotechnology combined with sports rehabilitation therapy to treat knee arthritis. In this paper, the efficacy, clinical effect and patient satisfaction of titanium dioxide nanotubes as a new nanomaterial in the treatment of knee arthritis were investigated. This article will discuss in detail the advantages and disadvantages of nanotechnology and explore the feasibility of combining nanotechnology with the rehabilitation of knee arthritis [17].

2. Treatment of Knee Arthritis Based on Titanium Dioxide Nanotubes

The TiO_2 nanotube materials prepared in orthopedic research are often prepared using the surface layer of pure titanium or titanium alloy. Observing the TiO_2 nanotube under an electron microscope, it can be found that it is composed of a large number of uniform tubular structures. Each tubular structure is hollow in the middle, the top is open, and the bottom is closed. The specific surface area of the entire tubular structure is large and porous. This is a special structure used for drug carrier adsorption. The research of TiO_2 nanotubes in orthopedics can be divided into two aspects: one is to study the biocompatibility of TiO_2 nanotubes, that is, to study bone fusion and bone growth, and to study the application of TiO_2 nanotubes as antibacterial drug carriers, including drug load, anti-infection, and antitumor. Related studies have found that TiO_2 nanotubes can resist the adhesion of bacteria and the surface layer of nanotubes with a diameter of 80 nm can resist the adhesion of bacteria and promote the production of biofilms. Because of this feature, it can reduce the risk of infection for patients, so it is a new type of simple antibacterial nanomaterial.

2.1. Biocompatibility of TiO_2 Nanotubes

2.1.1. Research on Histocompatibility. TiO_2 nanotubes have a special structure that promotes bone formation. The frosted surface of the nanotube is conducive to cell adhesion, cell proliferation, and cell diffusion. Its structure diagram is shown in Figure 1.

It can be seen in Figure 1 that it has the following characteristics:

(1) Compared with traditional titanium, the growth capacity of osteoblasts on the surface of nanotubes is increased by 200%–300%, which can greatly improve the activity of osteoblasts and the deposition of materials on the surface of bone cells

(2) Previous studies have shown that the enhancement of bone formation ability on the surface of nanotubes is related to the diameter of nanotubes. The diameter
FIGURE 1: Structure diagram of titanium dioxide nanotubes.

of TiO_2 nanotubes can significantly promote the adhesion and proliferation of osteoblasts, thereby affecting the differentiation and proliferation of osteoblasts. When the diameter of the nozzle is about 30 nm, it is conducive to cell adhesion; when the diameter is 100 nm, the cell adhesion begins to decrease. Under this condition, the proliferation of osteoblasts and the increase of alkaline phosphatase activity begin to accelerate. When the diameter is between 30 nm and 100 nm, TiO_2 nanotubes are very suitable for osseointegration surgery

(3) The biocompatibility of titanium nanoparticles' surface layer with osteoblasts is quite good, which can cause the nanomaterials to merge with primitive bone cells, boosting the stability of the interior components [18]

(4) The special structure of nanotubes not only promotes bone fusion but also eliminates the body's immune rejection response

(5) The research on nanotubes is limited and not comprehensive enough

2.1.2. Research on Improving Biocompatibility with Growth Factors. TiO_2 nanotubes can use the combination with growth factors to enhance bone formation and promote tissue compatibility. The TiO_2 nanotube array can be used as a carrier to achieve bone cell fusion of human bone. Relevant studies have shown that the combination of TiO_2 nanotube array and bone morphogenetic protein can greatly promote the differentiation of stem cells into bone cells in the human body, resulting in better surgical results. However, although TiO_2 nanotubes can improve the adhesion and activity of fibroblasts, no studies have shown that TiO_2 nanotubes can promote the adhesion and growth of fibroblasts [19].

2.2. Application of TiO_2 Nanotubes as Drug Carriers

2.2.1. Loaded Silver (Ag). Silver has been widely used as an antibacterial substance a long time ago, and its antibacterial mechanism is more complicated. In recent years, with the production of nanosilver, silver as an antibacterial drug has become more and more popular. Due to its good electrical

conductivity, nanosilver particles occupy an extremely important position in the field of microelectronics. The surface effect and quantum size effect of nanosilver particles also make them have some special uses, such as surface-enhanced Raman applications and medical applications [20]. Silver nanoparticles have a large surface area, so they can be in contact with microorganisms. They can attack bacteria and release a substance to damage the cell wall, which can effectively kill bacteria. The study found that the antibacterial activity after loading silver was significantly higher than that of the control titanium surface and the nonsilver nanotube surface and it had no adverse effect on the adhesion and growth of bone cells. Zhao et al. found that the surface layer of titanium dioxide nanotubes containing silver nanoparticle bubbles immersed in AgNO solution can effectively kill early bacteria and effectively inhibit bacterial adhesion. However, it is worth noting that Ag+ may also cause cell toxicity in humans, especially in areas where Ag+ may accumulate. Therefore, it is necessary to deeply study the regulation of the nanotube structure and the release control of silver and other metal ions.

2.2.2. Contains Antibiotics. TiO_2 nanotubes are used as a powerful carrier to release antibacterial drugs, thereby forming a local receptor system on the bone surface. The research results of Popa et al. showed that lyophilization of gentamicin into TiO_2 nanotubes can resist the growth of bacteria to a certain extent and will not affect the adhesion, proliferation, and proliferation of osteoblasts near the nanotubes. Differentiation. Research by Gulati et al. found that a titanium rod with a diameter of 70 mm was placed in a TiO_2 nanotube in a PBS solution, and it was found that the drug was released slowly within 6 hours before the rapid release and the drug was released with zero-order kinetics. The above two-stage drug release stage shows that TiO_2 nanotubes meet the needs of targeted drug release. In addition, in order to delay the release time of the drug and achieve long-term antibacterial effect, the TiO_2 nanotube drug carrier can be covered with a polymer coating and the drug release can be controlled by a slow speed.

2.2.3. Containing Antimicrobial Peptides. Antibacterial peptides (AMPs) are a kind of peptides, composed of no more than 50 amino acids. This is an antibiotic and is unlikely to develop resistance. Related studies have shown that the use of vacuum-assisted physical adsorption technology to fill antimicrobial peptides into TiO_2 nanotubes can achieve targeted effective sterilization and inhibit bacterial adhesion and the release kinetics of nanotubes is closely related to the crystal type. Nitric oxide (NO), also known as an endothelial relaxing factor, can relieve the body's vascular tension, and by producing some substances, it destroys the bacterial cell membrane and DNA, thereby producing antibacterial effects. Smith et al.'s experimental research on animal implantation showed that the NO release system with titanium dioxide nanotubes as a carrier was discussed. The surface of titanium dioxide nanotubes can significantly reduce the surrounding NO level, fibrous tissue thickness, and macrophage concentration. Therefore, the NO release

system using titanium dioxide nanotubes as a carrier needs further research and demonstration. In addition, the combination of antibacterial drugs albumin and quaternary ammonium salts with titanium dioxide nanotubes must be further studied for verification. So far, more than 1200 antimicrobial peptides have been identified. The antibacterial peptides were loaded onto the titanium dioxide nanotubes by physical methods to study the antibacterial ability of the antibacterial peptides against Gram-positive bacteria and *Staphylococcus aureus*. After 2 hours of cultivation, the antibacterial peptides on the surface of the nanotubes can destroy bacteria and reduce the number of bacteria.

2.2.4. Antibacterial Agent. Gentamicin in the antibacterial inner plant coating is a broad-spectrum antibiotic that has been extensively studied and is more sensitive to *Staphylococcus aureus*. Related studies have found that 80 nm nanotubes loaded with gentamicin have better antistaphylococcal effects than nanotubes without gentamicin. Compared with traditional titanium sheets, TiO_2 with or without gentamicin can significantly facilitate cell adhesion, proliferation, and differentiation of adult bone. Gallium nitrate is a new type of antibacterial agent. The gallium ions formed by ionization can strongly resist the production of iron ions, thereby inhibiting the metabolic activity of bacteria. Gallium nitrate can resist the production of *E. coli* and the accumulation of *E. coli*. The titanium gallium nitrate plate was immersed in the serum and incubated at 36°C. Antibacterial activity can be maintained for up to 30 days. Therefore, implants coated with gallium nitrate can resist the reproduction of bacteria on its surface.

2.2.5. Contains Antitumor Drugs. Because of the larger specific surface area and better surface activity of TiO_2 nanotubes, a large number of researchers have studied in vitro the filling, release, and anticancer effects of doxorubicin and 5-fluorouracil on TiO_2 nanotubes. The physical adsorption method can be used to fill doxorubicin into the TiO_2 nanotubes, and the pH value can be adjusted by adjusting the release solution. Corresponding in vitro experiments show that the best loading time is 12 hours, and the total release rate of doxorubicin is greater than 75%. Nanotubes loaded with uracil have very good drug release kinetics and selective killing ability to cancer cells. In summary, TiO_2 nanotubes are promising anticancer drug carriers.

2.3. Problems with TiO_2 Nanotubes. At present, although a large number of studies have been conducted on TiO_2 nanotubes at home and abroad, there are still deficiencies in clinical application treatment, so there is no generally recognized stable application. TiO_2 nanotubes have better human histocompatibility and strong anti-infective properties. At present, the preparation of uniform and stable nanotubes requires a lot of material research. The study of TiO_2 nanotubes in knee arthritis is mainly limited to in vitro studies, so it is impossible to specifically express the specific conditions in vivo. The coating and drug loading of TiO_2 nanotubes are incomplete in terms of drug loading, targeted drug release, and stability. Based on this, although the

research on TiO_2 nanotubes is not thorough enough, the preparation process of TiO_2 nanotubes is less complicated and less harmful to the human body, has large drug loading, and has good antibacterial properties. It is a promising orthopaedic implant material with great potential value.

3. Research on Sports Rehabilitation in Knee Arthritis

In the nursing process before and after orthopedic surgery, rehabilitation training is an important part of fracture recovery treatment and the effect of independent exercise is unmatched by other treatment methods. It can enhance the recovery effect of the patient's function, which is very conducive to the recovery of the patient's body. Through postinjury rehabilitation training, the body's energy metabolism can be balanced, preventing weight gain and shortening the time required to resume exercise after injury [21].

3.1. Necessity of Sports Health Treatment in the Treatment of Knee Arthritis. Symptoms of knee stiffness usually occur after knee surgery, which will greatly affect the patient's walking posture and reduce the subjective well-being of life. Relevant studies have shown that the incidence of knee stiffness after knee surgery is 10% to 16%. However, proper exercise, light stretching, and regular walking can significantly reduce the occurrence of knee stiffness. This article studies the effect of sports rehabilitation therapy on knee stiffness. It is found that good therapeutic effects have been obtained in the early rehabilitation training investigation of patients with knee stiffness.

This study selected 60 patients with knee stiffness after surgery, including 38 males and 22 females, with an average age of 47 years. The patients were divided into three groups according to the order of admission.

3.2. Method. Group 1 uses common knee joint treatment clinical methods and conventional medical care, group 2 uses TiO_2 nanotubes to carry antibacterial drugs for knee arthritis treatment and conventional medical care, and group 3 uses TiO_2 nanotubes to carry antibacterial drugs for knee arthritis treatment and professional sports rehabilitation therapy, among which group 1 and group 2 are used as the control group and group 3 is used as the observation group. Before rehabilitative training, their body will experience different pain conditions; the specific method is as follows:

(1) Psychological counseling

In the course of rehabilitation training after knee arthritis surgery, the patient's confidence in recovery plays an important role in the recovery of the disease. Because of the stiffness of the knee, the flexion and extension of the patient are restricted to a certain extent, which greatly affects the quality of life of the patient, and the patient often feels a decrease in inner happiness. Therefore, nurses should pay close attention to the patients actively and give them a certain degree of psychological counseling, so that the patients can control their emotions and have an optimistic and confident attitude towards recovery. In addition to eliminating the patient's dependence on psychological surgery and equipment, we should also actively cooperate with nursing staff to carry out functional exercises.

(2) Pain care

Patients with stiff knees will experience pain after surgery, which is the main reason that affects the recovery of patients. Before the anesthesia effect disappears, advance recovery training is required. During exercise, an analgesic pump can be used to reduce the pain caused by exercise. After the analgesic pump is relieved, analgesic drugs can be taken immediately to reduce pain and accelerate the recovery of knee joint function.

(3) Actively exercise

From the patient's activity ability, guide and encourage the patient to exercise actively and tell the patient not to rush to achieve the immediate effect of overexercising, but to exercise patiently and confidently, so as to promote fracture recovery.

(4) Dynamic auxiliary physical therapy

For patients with a long medical history, appropriate assistance exercises should be carried out. Because the patient has not recovered well, he cannot carry out voluntary exercise training and needs to rely on others to carry out exercises within a certain range of strength. Only in this way can the health recovery of the illness be achieved. Therefore, the nurse or family member must provide some help to the patient, especially when lying down [22].

(5) Massage

For patients with stiff knee joints, caregivers should actively tell their family members to massage the biological part of the patient's muscles. Massage can promote blood circulation and increase the blood supply to the osteoarthritis surgery site, reduce muscle swelling and pain, and improve patient satisfaction with nursing. However, it is worth noting that during exercise, the strength of the massage should be adjusted to avoid secondary injuries. The intensity should not be too high; otherwise, the exercise effect will be difficult to achieve.

The observation group adopted the above nursing methods, while the control group adopted methods (1), (2), and (3). The postoperative active and assisted activity records of the control group and the observation group are shown in Table 1. The autonomous and assisted movement ranges of the two groups of patients have been expanded. However, the movement angle of the observation group was significantly higher than that of the control after recovery. ($P < 0.05$).

3.3. Evaluation Index. The range of flexion motion between the maximum flexion and the maximum elongation of the

TABLE 1: The range of physical activity of the three groups of patients.

Group	Before recovery		After recovery	
	Autonomous range of motion	Power range of motion	Autonomous range of motion	Power range of motion
Group 1	61.65	68.32	77.14	92.17
Group 2	63.47	72.16	87.42	101.42
Group 3	69.21	75.85	98.18	110.26

knee joint before and after nursing was measured, and the active and passive angles of the knee joints in the two groups were evaluated.

The simple life scale is used to assess the quality of life of patients after surgery. The indicators include physical pain, limb stretching, mental health, social activities, and overall health. 10 points in the score is the upper limit; the higher the score, the better the patient's quality of life. The quality of life scores of the observation group was higher than that of the control group in all indicators. Therefore, it can be concluded that, compared with ordinary nursing care, the addition of specialized exercise therapy intervention after surgery can effectively speed up the recovery of knee joint function and not only improve the patient's quality of life during illness but also make the patient recover better and better. At the same time, from the perspective of the patient, the communication between the doctor and the patient is increased and the patient's satisfaction with the treatment is improved. The postoperative quality of life of the patients was assessed by observing various indicators.

3.4. Statistical Methods. SPSS statistical software can analyze the relationship between single variables and multiple variables. The chi-square test was used to compare the incidence of intraoperative and postoperative complications and the rate of stone clearance. The factors with statistical significance ($P < 0.05$) were used as independent variables and whether blood transfusion treatment was used as the dependent variable. The t-test was used for comparison between groups. When $P < 0.05$, it is considered statistically significant. The chi-square test formula is as follows:

$$\chi^2 = \sum_{i=1}^{k} \frac{(f_i - np_i)^2}{np_i}. \tag{1}$$

Among them, χ^2 is the test statistic, n is the number of experiments, and f_i is the group frequency.

3.5. Advantages of Sports Health Treatment. In the course of rehabilitation training after knee arthritis, the patient's confidence in recovery plays an important role in the recovery of the condition:

(1) Because of the stiffness of the knee, the patient's flexion and extension are restricted to a certain extent, which greatly affects the patient's quality of life. The caregiver and family members massage some of the patient's muscles. Massage can promote blood circulation and improve the osteoarthritis surgery site. Blood supply can reduce muscle swelling and pain and stiffness

(2) Normal nursing includes effective methods such as psychological counseling, pain nursing, massage, and adding exercise fixation belts. The observation group's nursing involves professional sports rehabilitation and rehabilitation projects. In the process, rehabilitation training is an important part of fracture recovery treatment and the effect of independent exercise is unmatched by other treatment methods. It can enhance the recovery effect of the patient's function, which is very conducive to the recovery of the patient's body, and greatly reduces the postoperative mortality and disability rate of the patient

(3) During training, attention should be paid to alleviating the pain of the patient, such as early recovery training before the effect of anesthesia disappears. During exercise, an analgesic pump can be used to reduce the pain caused by exercise. After the analgesic pump is relieved, analgesic drugs can be taken immediately to reduce pain and accelerate the recovery of knee joint function

Because the number of research subjects in this study is small, the results of the survey have certain flaws. If the number of researchers is expanded, I believe that more valuable research results can be obtained.

4. Survey Results and Analysis

In this study, 60 patients with knee stiffness after surgery were selected as the research objects, including 38 males and 22 females, with an average age of 47 years. According to the order of admission, the patients were divided into an observation group and two control groups. Among them, age, gender, and knee stiffness are the characteristics of this experiment, which are important factors that determine the degree of nanomaterials for knee injury repair.

Group 1 adopts common knee joint treatment clinical methods and routine medical care, group 2 adopts TiO_2 nanotubes to carry antibacterial drugs for knee arthritis treatment and routine medical care, and group 3 adopts TiO_2 nanotubes to carry antibacterial drugs for knee arthritis treatment and professional sports rehabilitation therapy, among which group 1 and group 2 are used as the control group, and group 3 is used as the observation group. Specific investigation and research found that among the three groups compared, the observation group had higher scores of physical pain, physical function, mental health, social function, and overall health compared with the control group. It can be seen that rehabilitation nursing intervention is more effective than conventional nursing. Promote the recovery of knee joint function, improve the quality of daily life, and help patients return to normal home and work life better and faster.
Figure 2: Comparison of knee joint activity scores before and after treatment in the three groups.
Figure 3: Comparison of pain scores before and after treatment in the three groups.

It can be seen in Figure 2 that the knee joint activity scores of the three groups before and after treatment are significantly different. The scores of the three groups of patients before treatment were relatively low, but the scores of the observation group were significantly higher than those of groups 1 and 2. The joint scores of the observation group gradually increased one week and two weeks after treatment. The functional score increased more significantly. For patients with a long medical history, carry out appropriate help exercises. Because the patient has not recovered well, he cannot carry out voluntary exercise training and needs to rely on others to carry out exercises within a certain range of strength. Therefore, the nurse or family member must provide some help to the patient, especially when lying down. Patients with stiff knees will experience pain after surgery, which is the main reason that affects the recovery of patients. Before the anesthesia effect disappears, advance recovery training is required. During exercise, an analgesic pump can be used to reduce the pain caused by exercise. After the analgesic pump is relieved, analgesic drugs can be taken immediately to reduce the pain and accelerate the recovery of knee joint function, so the observation group can achieve a healthy recovery from the disease. Therefore, compared with patients without nanomaterials to heal knee joints and conventional treatment, patients after using nanotubes and exercise rehabilitation therapy are more effective for knee arthritis recovery.

It can be seen in Figure 3 that the pain scores of the three groups before and after treatment are significantly different. Before the treatment, the scores of the three groups of patients were relatively low but the scores of group 3 were significantly higher than those of groups 1 and 2. The pain scores of one week and two weeks after treatment were significantly reduced. Compared with the control group, the observation group's pain score decreased more obviously. The use of the sports fixation belt device is customized for patients with special conditions. The exercise fixation belt used for postoperative recovery can reduce the swelling of the patient's body, help restore the patient's muscle strength, accelerate the patient's nerve to touch recovery, and enhance the patient's ability to take care of themselves. Before the anesthesia effect disappears, advance recovery training is required. During exercise, an analgesic pump can be used to reduce the pain caused by exercise. After the analgesic pump is relieved, analgesic drugs can be taken immediately to reduce the pain and accelerate the recovery of knee joint function.

It can be seen in Figure 4 that the scores of pains, mental health, social function, and swelling of the three groups before and after treatment have obvious differences. The scores of various indicators of the observation group are significantly higher than those of the control group. In the course of rehabilitation training after knee arthritis surgery, the patient's confidence in recovery plays an important role in the recovery of the disease. Because of the stiffness of the knee, the flexion and extension of the patient are restricted to a certain extent, which greatly affects the quality of life of the patient, and the patient often feels a decrease in inner happiness. Therefore, nurses should pay close attention to the patients actively and give them a certain degree of psychological counseling, so that the patients can control their emotions and have an optimistic and confident attitude towards recovery.

It can be seen in Figure 5 that all the study subjects are very satisfied with the preoperative and postoperative care.
Figure 4: Comparison of quality of life scores before and after treatment in the three groups.
Figure 5: Patient satisfaction with surgery.

The patient's critical period is 24 hours after the operation. The nursing staff carefully observe the changes in the patient's physical signs. The patient will be tested every half an hour after the operation. If any abnormality is found, please inform the doctor for proper treatment in time. After the vital signs are stable, test once every 2 hours. When the patient was conscious, the nursing staff did the first time to tell the patient the news of the success of the operation and actively guided the family members to master some of the contents and methods of nursing, which greatly helped the patient to relieve the pressure and improve the family's understanding of nursing work. In addition, nurses observe the color and volume of the urinary tube and nephrostomy tube at regular intervals and make a record; for patients with knee stiffness, the nurse should actively tell the family to massage the patient's biological muscles, which can promote blood circulation. Increasing the blood supply to the osteoarthritis surgery site can reduce muscle swelling and pain and improve patient satisfaction with nursing care.

5. Conclusions

Osteoarthritis is a type of synovial arthritis, which is very common in clinical treatment, and knee osteoarthritis has the highest incidence. In recent years, TiO_2 nanotubes, as a newly developed material, have better human tissue compatibility and strong anti-infection performance than commonly used orthopedic materials such as stainless steel, titanium alloy, polyethylene, and ceramics. In addition, by adjusting the diameter and drug loading of the nanotubes, the damaged bone tissue can be targeted and the drug can be released and the internal implantation has a long-lasting antibacterial effect. Sports rehabilitation therapy combined with important nursing methods in orthopedic treatment can enable patients to speed up the recovery of various body functions. In this paper, the research of titanium dioxide nanotubes in orthopedic treatment is carried out and how the diameter and drug loading of TiO_2 nanotubes affect the recovery of damaged cells, as well as the tissue compatibility and safety of nanotubes to the human body. At the same time, a comprehensive analysis of the enhancement of exercise rehabilitation therapy to the patient's physical recovery ability is also carried out. Clinical investigation and analysis showed that according to the assessment of the simple life scale, the postoperative quality of life, social activities, mental health, and physical function of the observation group were higher than those of the control group. The movement of nanomaterials is of great importance in research in many fields of medicine, which are used as drug carriers, antibacterial drugs, anticancer drugs, and smart targeted drugs. In summary, in the clinical treatment of knee arthritis surgery, titanium dioxide nanotubes have good antibacterial properties as an endoplant and good histocompatibility with human bones. In the observation group combined with exercise therapy, various complications such as pain, swelling, and muscle atrophy were relatively small, allowing the patient to speed up the recovery of various body functions. At the same time, nurses should actively pay attention to patients and give patients a certain degree of

Mineral admixtures are frequently utilized as cement substitution materials in high-performance concrete (HPC), and so many studies have explored the influence of mineral admixtures on the rheological behavior of HPC. Investigations were done to examine the impact of nanosilica less than 100 nm on HPC by substituting copper slag at a fixed substitution of forty percent for fine aggregate. Concrete samples were cast by substituting cement with nanosilica at (0.5, 1, 1.5, 2, 2.5, and 3) percentages. Examinations on mechanical properties and durability were done on specimens. The above tests demonstrated an increase in water demand because of the increase in the nanosilica substitution percentage. Mechanical and durability properties were improved at a larger rate with the incorporation of nanosilica. The outcomes indicated that colloidal nanosilica is an effective material that enhances the microstructure and acts as a catalyst for pozzolanic activity. The incorporation of nanosilica improves the strength up to two percentage substitution level.

1. Introduction

HPC on the other hand is a concrete that is proved to give good strength as well as good durability. HPC has been generally utilized across the globe for the past thirty years. Compressive strength might differ from 50 to 200 MPa. Notwithstanding strength requisites, durability properties are essential in producing high-performance concrete. Consequently, it is important to utilize large amounts and worth resources to convene up above prerequisites. Aggregates comprise around 70 to 80 per cent of the volume of the concrete, and thus, there is fast growth in the utilization of normal aggregate worldwide. The industrialization has

prompted the creation of tremendous waste materials and side effects that leads to ecological issues. Hence, there is a vital requirement to discover and use substitute materials for aggregates by using waste materials and results utilizing no characteristics change that prompts a maintainable and better environment alongside specialized benefits. There is an enhancement in strength property of HPC while mineral admixtures are utilized since fractional replacement to concrete because of fortifying of the interfacial transition zone. These days, the utilization of nanomaterials in concrete is acquiring significance attributable to their improved property in the hardened and non-hardened conditions of concrete because of its particular superficial region. The

materials utilized in nanosize are nanosilica, nano-TiO_2, nano-Fe_2O_3, nano-Al_2O_3, and carbon nanotubes/strands. Among all the nanomaterials, nanosilica is the most generally used material in concrete due to pore filling impact [1]. A limited quantity of nanosilica, typically at 0 to 5 percentage substitution, is sufficient for enhancement in HPC. The addition of nanosilica speeds up the hydration cycle and responds with (CaOH2), creates more amounts of (C-S-H), and improves the mechanical properties. Cement combined with nanosilica brings a compact microstructure with a smaller quantity of calcium hydroxide crystals. Pozzolanic reactivity is faster in concrete when nanosilica is added up to three percentages. Substitution of nanosilica in concrete resulted in increased mechanical properties [2–5] and development in tensile strength [6] and improvement in abrasion resistance compared to conventional concrete to a significant stage. Research on permeability properties of nanosilica concrete proved that there is a decrease in absorption properties compared to conventional concrete [2, 6]. Substitution of nanosilica with GGBS resulted in prolonged hydration speed [7]. The increase of nanosilica content in concrete revealed decreased chloride particle entrance. Nanosilica addition worked on the compressive strength because of the speed increase of hydration [8–10]. The high amount of waste glass powder with nanosilica is made conceivable in concrete [11]. The adverse consequences of sludge inclusion in setting time and mortar strength provisions could be repaid by utilizing nanoparticles [12, 13]. The inclusion of nanoparticles could increase the strength of concrete by 15 to 20 percentages [14]. Additionally, nanosilica particles work on exhibition sludge combinations in tile creation with a decrease in water assimilation and expansion to wear [15]. The ($CaOH_2$) formed at some point in hydration to form added (C-S-H) gel. In this manner, nanosilica goes about as the focus of nucleation because of its high surface region, hence speeding up the hydration [16]. Likewise, expanding how much nanosilica brings about agglomeration forestalling the uniform appropriation of nanosilica particles inside the mortar because of its high explicit surface energies. In this manner, the enhancement of mechanical properties is diminished by increasing the nanosilica content. Nanosilica could absorb other Ca^{+2} particles and reduce the convergence of calcium particles, speeding up the disintegration of C_3S, which expands the pace of hydration successfully [17]. Adding colloidal nanosilica is more straightforward and effective than incorporating powdered content [18, 19]. The vast majority of examinations reduced the investigation of the properties of substitution of nanosilica in concrete. A couple of exploration was completed to decide concrete's mechanical properties and porousness with nanosilica. Numerous analysts announced extraordinary and incongruous ideal amounts of nanosilica alongside a few strange impacts, which need a lot of fixations in additional exploration [1, 11–17]. The ideal amount of nanosilica should show up for every material separately. The usage of waste produced from industry is the major challenge confronted today because of the removal cost and potential contamination issue. The above issue can be resolved or even disposed of alongside the accomplishment of asset protection, assuming that it is proficiently utilized. Fayalite slag is a derivative acquired during the refining process of copper. Fayalite slag tracks down its utilization in sandblasting, cutting devices, rail line counterweight, blacktop asphalt, and concrete [20]. Many kinds of exploration were done to concentrate on the conceivable outcomes of utilizing waste materials as fractional/complete substitution of concrete [21]. The utilization of copper slag as a replacement for fine aggregates further develops strength and durability parameters at similar usefulness. At the same time, superplasticizer is a vital fixing in HPC prepared by copper slag to give great functionality and better consistency. The utilization of Fayalite slag in concrete clinker formation and the impacts of copper slag on the properties of concrete have been examined by numerous analysts [22–24]. A few works detailed the mechanical properties of concrete prepared using fayalite slags substitution for sand, and crushed stones show more development than ordinary cement [25–27]. For each huge load of copper delivered, roughly 2.2 to 3 tons of slags were created according to a logical estimate. According to the review in 2010, copper slag creation was assessed by around 30 tons everywhere. Copper slag is a throwaway material that gives probable, natural, specialized, and financial advantages in concrete and cement.

Improvement of nanosilica based on HPC is relied upon to decrease cement utilization meant for environment conservation and economic benefits [1]. Even though there is not much information on adding nanoparticles in concrete, less consideration has been made on the importance of nanosilica in concrete. Additionally, it creates an interest in concrete innovation and is relied upon to work on the mechanical properties. The impact of copper slag as a partial substitution for sand on high-performance concrete was examined by different researchers [25–27]. As a primer work, an ideal amount of copper slag to be utilized in the research was examined and found as forty percentage substitutions is the perfect material for fine aggregate substitution. Here, the examination is reached out to explore the impact of the addition of nanosilica on HPC at consistent slump where copper slag is consolidated as a fractional substitution.

2. Materials

OPC 53 grade was utilized, and the specific gravity of the same is 3.15. River sand with a specific gravity of 2.67 and fineness modulus of 2.92 was utilized, and copper slag was used as a substitution material. The chemical properties of copper slag are displayed in Table 1. Polycarboxylic ether-based superplasticizer with a specific gravity of 1.09 and pH more noteworthy than 6. Chloride concentration under 0.25 percentage was utilized in this research. Colloidal nanosilica have a specific gravity 1.32, and pH 9.5 was used. Standard consistency and setting time tests were performed in concrete with nanomaterials at different substitution levels. XRD investigation of nanosilica has shown that a wide summit shifted between 15° and 30° was acquired by mixtures in nanostructure and amorphous nature shown in Figure 1.

Table 1: Chemical properties of copper slag, cement, and nanosilica.

Materials	Weight (percentage)
Silicon dioxide	26.72
Aluminum oxide	0.25
Ferric oxide	69.33
Calcium oxide	0.16
Sodium carbonate	0.6
Manganese oxide	0.25
Copper oxide	1.3
Titanium dioxide	0.5
Specific gravity (cement)	3.11
Initial setting (cement)	30 minutes
Final setting time (cement)	450 minutes
Specific surface area (m^2/gm) (nanosilica)	206
pH value (nanosilica)	4.3
Silica content (nanosilica)	99.9
Carbon content (nanosilica)	0.08
Figure 1: SEM of nanosilica.

2.1. Experimental Study. The experimental study is divided into two stages; initially, the percentage of copper slag is optimized with water-reducing admixtures. These cement matrix cubes of $70 \times 70 \times 70$ mm were cast with copper slag substitution of 0, 10, 20, 30, 40, and 50 percentages by weight of fine aggregate. Due to the lower water binder ratio, cement mortar cubes with superplasticizer results were improved than cubes without superplasticizer. Based on compressive strength, the ideal substitution of copper slag used for fine aggregate is 40%. The second stage of the study involves the study of the impact of nanosilica substitution for cement in mortar cubes. For this study, mortar cube of $70 \times 70 \times 70$ mm was cast by stable 40% of copper slag as substitution and nanosilica of 0.5, 1, 1.5, 2, and 2.5 and percentage by weight of cement with w/b 0.32 and constant rate of superplasticizer of 0.5 percentage. The cast cubes were tested for compressive strength at 3, 7, 28, 56, and 90 days.

Further, ACI [27] technique for mix proportioning was taken to show up at the orientation mix extent for M60 grade of concrete. Seven mixes of concrete at various doses of colloidal nanosilica N0, N0.5, N1, N1.5, N2, N2.5, and

N3 correspondingly (0, 0.5, 1, 1.5, 2, 2.5, and 3) weight fraction of cement were ready for workability between twenty-five to fifty mm with forty percentage substitution. The w/b proportion for all mix replacements was reserved at 0.32. The water-reducing admixture content was changed in each mix with the goal that the drop is kept up with at the required range, and details are shown in Table 2.

2.2. Casting and Testing of Specimens. The ingredients are mixed in a dry state. Later, nanosilica with water is added to get the uniform scattering of nanoparticles. The mixed matrix was filled in three layers, and compaction was done with the vibrating table. Slump properties of the concrete matrix were studied to understand the influence of nanosilica inclusion in the slag concrete. The samples were covered and were kept at room temperature until the demolding period. The samples were then demolded after twenty-four hours. The curing process is done till the required period and tested at the expected age. Cube of size $100 \times 100 \times 100$ mm were casted to determine the compressive strength of the samples at three, seven, twenty-eight, fifty-six, and ninety days. Cylinder specimens of size 150×300 mm were cast to find the split tensile strength of concrete. Rapid chloride penetration test was conducted on cylinders of size 100×50 mm, where the samples were placed in the cell, with liquid storage on every face. To perform the test, one cylinder was placed in the solution of sodium chloride with 3% concentration and the other with the solution of sodium hydroxide. The quality of electric current travelled through the concrete are measured by keeping potential variation of 60 V DC for 6 hours. Overall charges transferred (Coulomb) are closely connected to the specimen's chloride ion penetration. To perform the sorptivity test, 100×100 mm cubic samples set over the steel network in tub of water and bottom portion are submerged to five-millimeter depth. The other faces of the specimen are fixed such that it is saturated for 40 mm from the lower part such that progression of water is made from base surface.

3. Results and Discussions

3.1. Impact of Nanosilica on Strength Properties of Cement Mortars. From Figure 2, it is clear that the strength of the cement matrix with 2% nanosilica has higher strength than the control specimen. The improvement in three-day compressive strength was 26.88, 53.82, 81.54, 99.62, 96, and 85.52 percentage for N0.5, N1, N1.5, N2, N2.5, and N3 correspondingly than the control sample N0. Many outcomes have centered on the outstanding exposition in the premature strength. Moreover, the prime objective of pozzolanic material is strength advancement and decrease of pore size appropriation; based on this. The strength development is obtained up to 2% addition of nanosilica, which decreases the compressive strength [28]. The strength increase for the N2 mix is 22.9 and 14 percentages at the twenty-eight and ninety days correspondingly. In comparison, strength increases for the N3 mix diminished to 13.5 and 6.9 percentages at twenty-eight and ninety days. Samples with high nanosilica content experience excessive self-drying and

TABLE 2: Mix design properties.

Properties	Mix designation						
	N0	N0.5	N1	N1.5	N2	N2.5	N3
Cement (kg/m^3)	518	514	510	508	505	503	500
Colloidal nanosilica	0	4	8	10	13	15	18
Fine aggregate (kg/m^3)	350	350	350	350	350	350	350
Water (kg/m^3)	150	150	150	150	150	150	150
Copper slag (kg/m^3)	240	240	240	240	240	240	240
Coarse aggregate (kg/m^3)	1130	1130	1130	1130	1130	1130	1130
Super plasticizer (percentage)	0.42	0.42	0.43	0.45	0.5	0.55	0.55
FIGURE 2: Impact of nanosilica on compressive strength properties of concrete containing copper slag.

breaking, and this can be by changing water and superplasticizer content [29–32]. Development in compressive strength by adding nanosilica came about because of both densification and filler impact of interfacial transition zone [33].

3.2. Impact of Nanosilica on Workability. Incorporating copper slag enhances workability because of its shiny surface, and less water absorption is shown in Figure 3. In any case, a higher level of copper slag incorporation brings bleeding due to the incorporation of nanosilica. Water particles are promptly drawn at nanosilica because of their elevated explicit surface region and larger reactivity. In this way, the consistency of the mix was expanded, bringing about a decline in usefulness upon the substitution of nanoparticles. To prevail over this problem, the quantity of superplasticizer was altered. Research on the impact of the substitution of nanosilica on cement concluded that incorporating nanomaterials to cementitious mixes decreases workability because of timely relations between the nanomaterials and cementitious matrix [34].

3.3. Impact of Nanosilica on Strength Properties of Concrete Containing Copper Slag. Results obtained from the samples are shown in Figures 4 and 5. Differences in compressive strength are noted because of the incorporation of nanosilica in slag concrete at 3, 7, 28, 56, and 90 days. The blends N0.5, N1, N1.5, N2, N2.5, and N3 improved compressive strength of 41.2, 57.5, 76.7, 90, 76.4, and 73.6 percentages corre-

spondingly as for the control mix. A similar pattern was seen on any remaining long periods. It was seen that the compressive strength upgraded up to two percentage of nanosilica substitution and afterwards declined to some extent. The more prominent utilization of calcium hydroxide is seen in the early ages because of the improved hydration. The outcome obtained is profitable for nanosilica substitution of two percentages by weight of cement. Hydration items fill the pores between the concrete in this manner, shortcutting the penetration of water to the unhydrated particles and bringing down the strength gain beyond two percentage substitution of nanosilica. It was found that the improvement in ninety-day compressive strength was 7.1, 12.8, 22.8, 27.9, 22.2, and 18.7 percentages for N0.5, N1, N1.5, N2, N2.5, and N3 mixes correspondingly compared to the control specimen. An increase in strength is recognized in the way that calcium hydroxide liberated during the process of hydration is used by nanosilica, bringing about higher strength at early ages. Additionally, the results of hydration fill the pores and make them denser. Mix N2 shows the greatest strength obtained at the entire period, and the proportion of addition in compressive strength concerning twenty-eight days was higher.

Figure 5 shows the difference of split tensile strength owing to the incorporation of nanosilica at entire ages. Samples of N0.5, N1, N1.5, N2, N2.5, and N3 increased 4.2, 9.9, 15.6, 17.8, 14.5, and 12.1 correspondingly by reference to the control sample at three days. Seven days, strength obtained
FIGURE 3: Impact of nanosilica on cement mortar strength.
FIGURE 4: Impact of nanosilica on split tensile strength properties of concrete containing copper slag.
FIGURE 5: Relation between SQRT of compressive strength and splitting tensile strength.

was 4.8, 11.3, 17.3, 22.5, 19, and 15.4 percentages correspondingly for $N0.5$, $N1$, $N1.5$, $N2$, $N2.5$, and $N3$ compared with the control specimen. The improvement in strength was found to be 7.8 to 26.3 and 7.9 to 27.4 percentages for nanosilica mixes correspondingly than the control sample at twenty-eight and ninety days. This phenomenon is primarily due to a stronger attachment between the aggregate and cement matrix.

The reduction in mechanical properties with more prominent than two percentage of nanoparticle substitution is accredited to the explanation that the number of nanopar-

ticles is larger. On this junction, nanosilica is a replacement material for cement utilized for filling the pores yet does not engage in the hydration cycle.

3.4. Impact of Nanosilica on Chloride Ion Penetration. The capacity of concrete to oppose the access of chloride particles is an important constraint in deciding the service life of steel in concrete in marine conditions. It is likewise critical to research the conduct of cement containing substitutions like copper slag concerning protection from chloride particle infiltration. The rapid chloride penetration results of

TABLE 3: Impact of nanosilica on chloride penetration.

Parameters	Charge passed (Coulombs 28 days)	Chloride penetration	Charge passed (Coulombs 90 days)	Chloride penetration
$N0$	1140	Low	1155	Low
$N0.5$	1138	Low	990	Extremely low
$N1$	1050	Low	920	Extremely low
$N1.5$	980	Extremely low	850	Extremely low
$N2$	820	Extremely low	702	Extremely low
$N2.5$	910	Extremely low	788	Extremely low
$N3$	955	Extremely low	824	Extremely low

nanosilica with a forty percentage aggregate substitution by copper slag at twenty-eight and ninety days are shown in Table 3. It was noticed that every mix contained a small vulnerability towards chloride. Values of Coulombs were reduced by substituting nanosilica up to two percentages demonstrating that the concrete became denser—further addition of nanosilica results in small enhancement in Coulomb. The above perspective has been shown in the compressive strength result from which it very well may be presumed that concrete shows more protection from chloride ion penetration than different mixes. In this research, it was seen that concrete with nanosilica showed extremely low chloride particle penetration compared with other concretes. The decrease in chloride particle entrance might be because of the fuse of round particles like nanosilica and copper slag, which brought about the improvement of the molecule. Coulomb charges passed at ninety days are low compared to twenty-eight days due to dense microstructure.

3.5. Impact of Nanosilica on Sorptivity. The main strength of water suction is capillary pressure [35]. The sorptivity coefficient is a significant boundary to forecast the life of a structure [35]. Substitution of nanosilica quantity from zero to two percentages causes a reduction in the sorptivity esteem by 44.3 and 57.8 percentages at twenty-eight and ninety days correspondingly. Being extremely fine particles, nanomaterials fill up the pores in concrete, consequently decreasing the capillary pores.

4. Conclusions

Based on the experimental investigation on utilization of nanosilica in concrete with forty percentage of copper slag as fine aggregate substitutions, the following conclusions have arrived:

(i) As the quantity of nanosilica was raised to three percentages, the consistency was improved while the setting time was reduced because of the increased hydration rate. The nanosilica inclusion has increased the compressive strength of concrete containing forty percent copper slag as a weight fraction for fine aggregate compared to the control mix. The strength increment was observed up to

two percent of nanosilica substitution, beyond which the strength decreases

(ii) The highest strength properties were found in concrete containing copper slag in the samples containing two percentages of nanosilica. The above reaction brings about higher creation of calcium silicate hydrate gel. Further addition of nanosilica results in higher quantity than the amount of free lime and directly affects the pozzolanic activity. It very well may be acknowledged that the ideal nanosilica substitution is two percentage

(iii) Rapid chloride penetration test containing nanosilica in concrete was exceptionally low at twenty-eight and ninety days. The charges passed were not exactly aligned with the control specimens

(iv) Sorptivity results of concrete containing nanosilica and copper slag decrease with an increment in nanosilica content because of the consolidated activity of pore filling impact. The highest decrease in sorptivity values was seen in mixes with two nanosilica percentages

Data Availability

The data used to support the findings of this study are included in the article.

With the rapid development of the integrated circuit industry, ferroelectric thin film materials and technologies have become increasingly important. Ferroelectric materials have been widely used in aerospace, information storage, artificial intelligence, microelectromechanical, wearable devices, and other fields. Traditional sports is an important carrier of traditional culture. It contains the sports cultural resources created and precipitated by the Chinese nation for thousands of years, and all sectors of society are also paying great attention to this. Under the background of the market economy system and the major premise of the vigorous development of the cultural industry and sports industry, industrialization is obviously the inevitable choice for traditional sports to break through the difficulties and seek development, and it will also promote the further inheritance and promotion of traditional sports. The complex combination causes its performance to decrease or even fail. Therefore, it cannot cause foresee losses and disasters. It has important application value and significance to master the performance changes and mechanisms of ferrous film materials under different adding environments. This paper takes ferroelectric $Pb(Zr_{0.52}Ti_{0.48})O_3(PZT)Bi_{3.15}Nd_{0.85}Ti_3O_{12}(BNT)$ as the research object, proposes the preparation of sol coating for thin film materials, and studies the preparation parameters PZT of the sol electric ferroelectric method. Electrical method and BNT electrical film properties affect iron and physical experiments on the properties of iron. The influence of the best sol-iron coating method on the electrical properties of PZT and BNT films is the ferroelectric properties of the 700°C layer of high-temperature gas, 10-layer PZT films, and 8-layer BNT films. The elasticity and elastic moduli of PZT and BNT films are 66.8 MPa and 99.6 MPa and 159.3 GPa and 189 GPa, respectively; the elastic coefficients of PZT and BNT films are 15.4×10^{10} N/m^2 and 18.4×10^{10} N/m^2, and their elastic coefficients $|e31|$ decrease with accompanying increase in swallowing. And with the disease of reading and writing field strength, as the speed becomes faster and slower, the carriers have more time to move to the brain wall, so the intensity is also intuitive. It has strong practicability and feasibility to popularize the material and manufacture the equipment of the current sports equipment club.

1. Introduction

Intel and IBM jointly launched a 45-nanometer processor chip in 2007, using high-dielectric constant hafnium dioxide to replace the previous silicon dioxide gate insulating layer, which solves the leakage that occurs as the processor becomes smaller. This technological invention has brought historical changes to the IT industry, and the research on hafnium dioxide has also kicked off an upsurge. With the progress of people's research work, hafnium dioxide has been widely used in the fields of electronics, optics, and so on. In 2006, Setter mentioned in a review of ferroelectric thin film materials, characteristics, and applications that ferroelectric field effect transistors (FeFET) will be used as a fast, low-energy, and nonvolatile storage technology for a long time in the future. In these devices, information will be permanently stored in the gate insulating layer in the form of polarization state and can be read nondestructively in the form of a threshold voltage change. Although as early as 1974, Wu had put forward the concept of ferroelectric field effect transistor experimentally, but for a long time, there are still many difficulties in practical application. For

example, it is difficult to obtain materials with strong stability. This is mainly due to the thermodynamic mismatch of known ferroelectric materials such as lead zirconate titanate (PZT), strontium bismuth tantalate (SBT), and strontium titanate (STO) on silicon. In addition, because silicon has a very small band step, in order to obtain low leakage current devices, thick film and precious metal electrodes must be used. In order to improve the stability of direct contact between ferroelectric materials and silicon, many methods such as the introduction of buffer layers have been tried, but these methods have reduced the scalability of such devices. To make matters worse, when the buffer layer is introduced, the existence of a higher depolarization field will degrade the information storage capacity. Therefore, in order to obtain a highly reliable ferroelectric field effect transistor, a new ferroelectric material with semiconductor compatibility is urgently needed. The ferroelectric thin film material proposed in this paper can satisfy this point. Although, in recent years, the traditional sports industry has gradually attracted the attention of people from all walks of life and has achieved certain results, but compared with the industrialization of most modern sports events, there is still a big gap. Especially in the context of the new era, how traditional sports can seize the economic and cultural double stilts to move forward steadily and realize the real industrialization of traditional sports requires further theoretical and practical discussions.

Through the investigation of the high dielectric constant gate insulating layer material, it can be found that only a few metal oxides have both semiconductor compatibility and sufficient energy band gap, and hafnium dioxide is one of them. Hafnium dioxide is an inorganic substance and an oxide of hafnium element. It is a white solid at room temperature and pressure, insoluble in water, insoluble in hydrochloric acid and nitric acid, and soluble in concentrated sulfuric acid and hydrofluoric acid. However, for a long period of time in the past, it is generally believed that hafnium dioxide does not have a noncentrosymmetric crystal structure, so hafnium dioxide cannot be a good ferroelectric material. However, many experiments in recent years have shown that hafnium dioxide-based ferroelectric thin film materials with ferroelectric properties can be obtained by controlling the material structure by methods such as doping and stress clamping. This is of great significance for the development of the next generation of ferroelectric memory that is compatible with semiconductor processes, can be miniaturized, and has low power consumption. In addition, the anti-irradiation ability of ferroelectric materials in extreme working environments has made them always regarded as one of the choices of aerospace-grade chip materials. However, after reaching a certain radiation dose, the performance of memory based on traditional ferroelectric materials will drop sharply. Therefore, research on the anti-radiation ability of ferroelectric hafnium dioxide devices has also become very important. This research has laid the foundation for us to explore the connotation and essence of industrialization. In terms of industrialization paths, cultural industrialization paths and sports industrialization paths have always been the focus and hotspot of research, providing reference for the research on traditional sports industrialization paths.

For structures with conductive oxide (IrO_2) and metal (Pt) top electrodes, Brewer et al. studied the influence of gamma radiation on the dielectric and piezoelectric response of $Pb[Zr_{0.52}Ti_{0.48}]O_3$(PZT) thin film stacks. When exposed to 2.5 Mrad (Si)60Co gamma radiation, the sample usually shows degradation of various key dielectric, ferroelectric, and electromechanical responses. However, the low-field, relative permittivity εr is largely unaffected by the irradiation of samples with two types of electrodes. The sample with the Pt top electrode showed a significant degradation of the remanent polarization and the overall piezoelectric response, as well as the shrinkage of the polarization hysteresis curve and the generation of multiple peaks in the dielectric constant-electric field curve after radiation. However, samples with oxide electrodes are largely unaffected by the same radiation dose, and any change in functional characteristics is less than 5%. The results show the radiation-induced changes in the number of defects or defect energy in the PZT with a metal top electrode. However, they did not consider the change and particularity of the dielectric constant of the PZT film after radiation, and there are still errors in the experiment [1]. Ferroelectric perovskite oxides are a promising photosensitive layer for photovoltaic applications due to their very high stability and the solar energy conversion mechanism associated with ferroelectrics they replace, which may lead to very high efficiency. One of the biggest challenges so far is to reduce their band gap to the visible light region while maintaining ferroelectricity. In order to solve these two problems, Pamela et al. replaced Fe with Co cations to carry out the elemental composition engineering of $BiFeO_3$ as a means to adjust the characteristics of transition metal-oxygen bonds. They formed an epitaxial, pure phase, and stable $BiFe_{1-x}Co_xO_3$ film through solution treatment, $x \leq 0.3$, and the film thickness is as high as 100 nm. Importantly, the band gap can be adjusted from 2.7 eV to 2.3 eV after cobalt substitution while enhancing ferroelectricity. As a proof of concept, unoptimized vertical devices have been fabricated, and it is gratifying that the electrooptic response in the visible light region of the Co-substituted. However, his method of substituting Co cations for Fe to reduce the band gap is not of high value for enhancing ferroelectricity, and further research is needed [2]. Shin and Son deposited epitaxial Bi_2FeMnO_6 (BFMO) film on Nb-doped $SrTiO_3$ (Nb:STO) substrate by pulsed laser deposition. X-ray diffraction confirmed that the 100 nm thick BFMO film has relatively high tetragonality, with a high cla ratio of 1.04. The BFMO film has low leakage current, good ferroelectric properties and an enhanced remanent polarization of about 25.0 μC/cm~2. Compared with conventional ferroelectric films (such as $PbTiO_3$ films), BFMO films have a larger ferroelectric domain structure due to their high domain wall energy. However, they did not make a detailed study on the ferroelectric fatigue of Nb-doped BFMO film, and there are still insufficient studies on the ferroelectric properties of BFMO film [3].

The innovation of this paper is to improve the preparation method of traditional ferroelectric thin film materials.

The sol-gel method is used to prepare ferroelectric thin films. It has precise composition control, easy adjustment, low annealing temperature, and easy to produce large-area thin films. It also has good ferroelectric properties for the prepared ferroelectric thin film. In addition, the research of this paper can also put forward suggestions for improving the equipment manufacturing and equipment production in the sports industry and provide a novel research direction for the development of sports.

2. Preparation and Performance Analysis of Ferroelectric Thin Film Materials

2.1. Ferroelectric Materials. Materials, information, and energy are the three pillars of human civilization, and materials are the material basis for the improvement of human production and living standards. The research, development, and application of new materials are the cornerstone of promoting social and technological progress. Since Schmid defined multiferroic materials in 1994 [4, 5] (referring to a class of materials with more than one ferroelectric sequence parameter for single-phase materials), the definition of multiferroic materials has been continuously broadened. At present, it is considered that the four basic order parameters of multiferroic materials are electric dipole moment, magnetic moment, elastic moment, and spin pole moment [6] (see Figure 1). That is to say, a multiferroic material is a material that has two or more basic ferroelectric characteristics (including ferroelectricity, antiferroelectricity, ferromagnetism, antiferromagnetism, and ferroelasticity). Multiferroic materials have unique physical and magneto-electric application functions, such as polarization reorientation or induction of ferroelectric phase transition under the action of a magnetic field and magnetization reorientation or induction of ferromagnetic phase transition under the action of an electric field. So they have emerged in many cutting-edge technology applications, such as sensors, energy converters, signal generation and processors, filters, information storage, and microwave devices. The research of multiferroic materials continues to attract the attention of many scholars and has become one of the key subjects of condensed matter physics and material science research [7, 8].

Multiferroic materials are mainly divided into two types: one is a single-phase multiferroic material, and the other is a composite multiferroic material. Single-phase multi-iron materials are represented by $BiFeO_3$ and $TbMnO_3$. $BiFeO_3$ has ferroelectricity and antiferromagnetism at room temperature. $TbMnO_3$ has a large magnetoelectric coupling coefficient but a low Curie temperature. In 1972, Van Suchtelen et al. proposed a mixed preparation method of ferroelectric phase and ferromagnetic phase, which is composed of ferroelectric materials and ferromagnetic materials in different combinations. There are currently three types of structures of 0-3, 1-3, and 2-2 [9, 10], which are characterized by a relatively high Curie temperature, a large magnetoelectric coupling coefficient, and performance far higher than single-phase materials and are available for selection. Because of
Figure 1: Multi-iron coupling order parameter.

this, composite multiferroic materials have become one of the hotspots in the research of multiferroic materials.

The essential feature of ferroelectric materials is the existence of spontaneous polarization, and the spontaneous polarization can change with the change of electric field [11], which is why the name of ferroelectric materials comes from. There is a hysteresis relationship between the polarization intensity of the ferroelectric material and the electric field intensity. When the polarization strength of the ferroelectric material increases, the electric field strength of the material does not increase immediately but changes only after a certain period of adaptation, as shown in Figure 2:

Ferroelectric thin films have good properties, such as ferroelectricity, piezoelectricity, pyroelectricity, electro-optics, and nonlinear optics [12, 13], and can be widely used in microelectronics, optoelectronics, integrated optics, and microelectronic mechanical systems. Other fields are currently one of the frontiers and hotspots of high-tech research [14].

After nearly a century of development, ferroelectric materials have formed five major types of structural systems: perovskite type, lithium niobate type, bismuth-containing layered, pyrochlore type, and tungsten bronze type structure system [15, 16]. Perovskite-type ferroelectrics are currently the most widely used, perfect perovskite structure, usually expressed by ABO_3. At present, the main research is barium titanate ($BaTiO_3$), lead titanate ($PbTiO_3$), and other representative perovskite-type ferroelectric materials, as well as their performance research such as A/B and AB position ion substitution [17, 18].

2.2. Test and Characterization Methods of Thin Film Materials and Development Overview. In recent years, the application of ferroelectric thin film materials has gradually increased. In the aerospace, automotive, and sports industries, ferroelectric thin film materials have potential applications. With the maturity of the preparation process of ferroelectric thin film materials, the performance of this material has been greatly improved. Its piezoelectric effect, pyroelectric effect, electro-optic effect, and acousto-optic
Figure 2: Hysteresis loop diagram of ferroelectric materials.

effect have been developed relatively maturely. And the cost has been greatly reduced, so its application fields have been expanded, and it can be used to manufacture precision parts for microwave circuit plug-ins and turbocharged propulsion. There are also reports on their applications in the sports industry and electronic fields. In the sports industry, the use of nanomaterials to develop volleyballs that do not touch water and dust is more conducive to the promotion of sports activities. Performance characterization (detection and evaluation) is particularly important for the future application of materials. It is not only related to the correct evaluation of materials but also lays the foundation for the design and application of materials. The detection and evaluation of materials has a wealth of content, such as the detection and analysis of key issues such as elastic modulus, plastic strain, fracture toughness, and fatigue [19, 20]. At present, the application scope of ferroelectric thin film and magneto-electric composite thin film involves all aspects of functional thin film materials and devices. It is represented by applications in the fields of microelectromechanical systems, sensors, detectors, and information storage. It is constantly advancing social progress and changing people [21]. Therefore, it is indispensable to understand the mechanical parameters of thin film materials such as elastic modulus, Poisson's ratio, residual stress, fatigue strength, and fracture strength before designing and manufacturing new materials and devices. The mechanical properties of thin film materials directly affect the quality of new materials and devices. The traditional testing methods are mostly suitable for bulk materials, which poses great challenges to the mechanical parameter testing of microcomponents and functional thin-film devices [22, 23].

2.3. Application of Ferroelectric Thin Film. In previous studies, significant progress has been made in the preparation of ferroelectric thin films, the synthesis of multilayer films, performance, testing, microstructure, and the integration of ferroelectric thin films into heterostructures [24]. The discovery of $SrBi_2Ta_2O_9$ (SBT) makes FRAM very suitable for its excellent fatigue resistance, excellent storage perfor-

mance, and low leakage current. However, the use of ferroelectric thin films is not limited to ferroelectric memories [25]. Utilizing the dielectric, ferroelectric, piezoelectric, electrostatic, pyroelectric, optical, electro-optical, and other properties of ferroelectric film, its application is extended to separation devices [26]. In this way, the main application of ferroelectric film in the memory of multilayer capacitors, nonvolatile ferroelectric dynamic random access memory (NVFRAM), smart cards, infrared detectors, infrared sensors and inverters, etc., will be extended. According to the physical results, the application of ferroelectric thin film can be classified as shown in Table 1.

New applications of ferroelectric thin films are still being proposed, such as the use of iron thin films such as laser disks, microwave waveguides, solar cell energy storage capacitors compatible with solar cells, and powerful electron emission sources [27].

2.4. Methods of Fatigue Characteristics of Ferroelectric Capacitors. The relationship between temperature and fatigue rate, when the temperature rises, the fatigue rate also rises rapidly. It can be expressed as

$$T(A) = T_0 \times [1 - R(S) \times \log A]. \tag{1}$$

Among them, T_0 is the initial residual polarization, $T(A)$ is the residual polarization after reading and writing, and $R(S)$ is a temperature-dependent phase.

$$\varepsilon_d \mu R(S) = A \times \exp\left[-\frac{B_a}{k_b T}\right]. \tag{2}$$

Among them, B_a is the activation energy, T is the temperature in Kelvin, K_B is the Boltzmann constant, and A is a proportional coefficient.

In this study, similar electrical performance characterization was performed on the devices before and after fatigue, and the modified SE model was used to fit the measured current under low field. The following can be drawn:

$$\text{In}\left(\frac{R_{SE}}{T^{2/3}}\right) = \text{In}(D(S)) - \frac{A}{\text{DT}}\left[\left(\sqrt{\frac{AB}{4\pi\varepsilon_0^2\varepsilon_d\varepsilon_{st}}}\right) - b\sqrt{V}\right], \tag{3}$$

$$D(S) = 2a\left(\frac{2\pi m_{\text{eff}} d}{h^2}\right)^{3/2}\mu E, \tag{4}$$

$$b = \sqrt{\frac{a^2 N_{\text{eff}}}{8\pi\varepsilon_0\varepsilon_d B}}, \tag{5}$$

$$\log\left(\frac{R_{\text{PF}}}{E}\right) = \frac{\left[-a\left[\varphi_t - (aE/\pi\varepsilon_d\varepsilon_0)^{1/2}\right]\right]}{D_B T \ln 10} + \log(B), \tag{6}$$

where m_{eff} is the effective mass of electrons, D_B is Boltzmann's constant, h is Planck's constant, μ is the mobility of carriers in the film, E is the applied field strength, φ_B is the barrier height at the interface, φ_t is the bound energy

TABLE 1: Application of ferroelectric thin film.

Performance	Main components
Dielectric	Capacitors, dynamic random access memory (DRAM)
Piezoelectricity	Surface acoustic wave (SAW) devices, miniature piezoelectric motors, miniature piezoelectric actuators
Pyroelectricity	Pyroelectric detector and array
Ferroelectricity	Ferroelectric random access memory (FRAM)
Electro-optic effect	Optical modulator, optical waveguide

Photorefractive effect	Optical modulator, optical holographic memory
Nonlinear optical effect	Optical frequency doubler

level in the material, ε_0 is the dielectric constant in vacuum, ε_d is the dynamic dielectric constant of the ferroelectric material in the infrared region, ε_{st} is the static dielectric constant of the ferroelectric material, and N_{eff} is the depletion layer at the cross section charge density, including bound charge and shallow ions. B is the remanent polarization of the ferroelectric material, S is the applied voltage, and A is the unit point charge. The improved SE model takes into account the influence of polarization at the metal-ferroelectric-metal interface on the maximum field strength. If the ferroelectric polarization is not taken into account, the calculated Schottky barrier will be much lower than the actual one.

The next step will be to discuss the situation in the low field. According to the improved SE model, the magnitude of the tunneling current mainly depends on the free carriers of the injected metal passing through the Schottky barrier of the ferroelectric layer interface. The larger the actual value of the Schottky barrier, the smaller the value of the tunneling current. Here, first define the "significant" barrier 6:

$$\sigma_{ie} = \sigma_b - \sqrt{\frac{aB}{4\pi\varepsilon_0^2\varepsilon_d\varepsilon_{st}}}. \tag{7}$$

The value at each voltage can be obtained by fitting the slope of the straight line.

The Seebeck effect, as the most basic theoretical basis for ferroelectric performance, was first discovered by Seebeck in 1821. When two different materials are connected end to end into a closed loop, two connection points are formed. The two connection points are made by certain means. If the temperature difference is formed at the position, then an electric current is formed in the closed circuit. It can be expressed by a formula:

$$G_{iu} = \alpha_{ab}(C_1 - C_2), \tag{8}$$

where α_{ab} is the thermoelectromotive force rate. For the same material, when it approaches zero, α_{ab} can be regarded as a constant, which is named Seebeck coefficient, namely,

$$\alpha_{ab} = \lim_{\nabla C} \frac{G_{iu}}{\nabla C} = \frac{d\nu_{iu}}{dc}. \tag{9}$$

In a certain period of time, the change in heat at the connection point in the entire closed loop, that is, the transfer of heat is proportional to the current, and the ratio of the change in heat at the connection point Rt to the current I in unit time R_d is

$$\frac{R_d}{Rt} = \pi I, \tag{10}$$

where π is the Peltier coefficient, the unit is V, and its magnitude is related to the material and voltage of the closed loop.

The Thomson effect, which is a secondary thermal effect, when a current flows through a uniform conductor with a temperature gradient, in addition to generating Joule heat related to resistance, the conductor also absorbs or releases heat. This effect of absorbing or releasing heat is called the Thomson effect. It has a small heat absorption and release and is reversible, so it is very difficult to measure and easily confused with Joule heating.

$$\frac{R_d}{Rt} = \tau I\left(\frac{R_t}{t}\right). \tag{11}$$

The three do not exist independently of each other but are inseparable from the mutual influence of the three of the same substance. The relationship between them is

$$\pi_{ab} = \alpha_{ab}C, \tag{12}$$

$$\frac{d\alpha_{ab}}{dC} = \frac{\gamma_a - \gamma_b}{C}. \tag{13}$$

It can be seen that the three-point iron effect is reversible, and the Joule heat generated by the internal resistance of the material corresponding to it is irreversible.

The thermoelectric conversion device can directly convert heat energy and electric energy, and it provides a scalable, reliable, and environment-friendly energy conversion method. The conversion efficiency of the thermoelectric conversion device can be determined:

$$\lambda = \frac{P_e - P_o}{P_e} \times \frac{\sqrt{1 + ZP} - 1}{\sqrt{1 + ZP} + (P_e/P_o)}, \tag{14}$$

where P_e and P_o are the temperature of the hot and cold ends of the ferroelectric material and the ZP value is a dimensionless thermoelectric figure of merit. It is the decisive factor that determines whether the thermoelectric material can be widely used. Its size can be defined as

$$ZP = \frac{\delta^2}{d},\tag{15}$$

where P is the average temperature, which reflects the electrical transport characteristics of the thermoelectric material, and d is the thermal conductivity, which reflects the heat transport characteristics of the material.

2.5. Ferroelectric Thin Film Materials in Sports. At present, ferroelectric thin film materials are widely used in sports measurement sensors. It has both piezoelectricity and mechanical properties of soft film. Pressure sensors made with it can be used to detect human body signals such as pulse and heart sounds. The pulse and heart sound signal carries important physiological parameter information of the human body. Through effective processing of the signal, the waveform and the number of heart rate can be accurately obtained, which can provide a reliable basis for physical fitness measurement. In addition, sensors made of ferroelectric thin-film materials have a large frequency response range, pyroelectric effect, and other characteristics and have great application potential. In terms of vibration detection, it is mainly used in music pickup, machine condition monitoring, bearing wear, fan airflow, rope breakage, etc., as an accelerometer in acceleration detection and in nondestructive testing. When it appears in the form of a sensor array, it can also be used to monitor human movement, sports scoring, switches, and microphones. With the improvement of the production process of ferroelectric thin film materials, the continuous decline of production costs, and the continuous development and in-depth research in various aspects, it is reasonable to believe that the application prospects of ferroelectric thin film materials in the sports industry must be very broad.

3. Preparation of Ferroelectric Thin Film

3.1. Film Preparation Method. Although the pulsed laser deposition (PLD) film-making technology has only a history of more than 50 years, it is a promising manufacturing technology with distinct advantages and disadvantages. The main advantages are as follows: (1) the element measurement ratio of the film material and the target material can be consistent under appropriate conditions. (2) It can prepare many inorganic thin film materials such as refractory materials, metals, semiconductors, insulators, and some organic thin film materials. (3) Multilayer films, heterogeneous films, etc., can be prepared, and the target change is convenient and flexible. (4) It is convenient to adjust the deposition parameters and growth rate, the deposition temperature is low, and the film quality is high. The disadvantages are also obvious: the uniformity of the film formation is poor, the formation of a large area film is difficult, and mass production and preparation cannot be carried out.

The sputtering method started in 1940 and developed rapidly with the rise of the semiconductor industry and was officially born in the 1970s. Its advantages are mainly reflected in the following: (1) the film-forming temperature is usually lower than 500°C; it is compatible with microelectronics technology and can be used to make devices. (2) The prepared film is of good quality without pinholes and cracks. (3) The crystallization performance is good, and an epitaxial single crystal film can be obtained. The main disadvantages are slow film growth rate, long preparation time, deviation of film composition and target material, etc.

Metal organic chemical meteorological deposition (MOCVD) uses metal organic compounds as the material source for chemical vapor deposition. After more than 30 years of development, it has been relatively perfect. The method can precisely control the composition and thickness of the thin film; it is easy to produce a large-area film, the deposition temperature is low, and the uniformity and repeatability of the prepared thin film are high. However, due to the high toxicity of raw materials and the high cost of materials and equipment, the application scope of MOCVD is limited.

The sol-gel method uses inorganic metal salts or metal alkoxides prepared with liquid chemical reagents as solvents and alcohol solutions as solvents, and the two are mixed. After a series of hydrolysis, carbonization, and carbonization reactions, they are transparent and uniform. Use different methods. The precursor solution is aged; then, the precursor solution matures to polymerize and gel the solute; finally, the gel is dried and baked to remove organic compounds and obtain a thin film material. The processing equipment requirements are simple and easy to apply. The chemical uniformity is good and can reach the molecular level. The stoichiometry is accurate, quantitative and uniform doping can be achieved, the doping range is wide, the manufacturing temperature is low, and it is compatible with semiconductors. The sol-gel method also has certain limitations. The alkoxides that can be selected are limited, expensive, and easy to pollute the environment; during the drying process, organic matter volatilizes and cracks occur; when different materials are prepared, it is difficult to control the changes in process parameters. The above four methods for preparing ferroelectric thin films have their own advantages and disadvantages, and they need to be selected according to different needs. The bulging sample is a self-clamping free film, which is prepared by chemical etching in the later stage. At the same time, it is necessary to quickly prepare a film sample with good uniformity and stable performance. These differences indicate that the preparation method also has a certain impact on the performance of the material.

In Table 2, various properties under different preparation processes are compared. It can be seen that the film prepared by the sol-gel method has higher remanent polarization, and it also has the smallest coercive field and the largest dielectric constant. It reached 0.8 and 46, respectively. These indicators are important because a higher

TABLE 2: Comparison of film properties under different preparation methods.

	PLD	Sputtering	MOCVD	Sol-gel
2Pr (C/cm^2)	49	23	27	29
Rectify the field (MV/cm)	1.2	0.9	2.1	0.8
Dielectric constant	44	31	24	46

residual polarization means a larger read and write window, a smaller coercive field means lower power consumption, and a higher dielectric constant means smaller leakage. Therefore, this paper chooses the sol-gel method as the method of preparing the film.

3.2. Preparation of Sol-Gel Film

3.2.1. Experimental Supplies. The chemicals used in the experiment are shown in Table 3.

During the reaction process, a certain chelating agent (acetylacetone) is added to the solution to control the polycondensation rate and hydrolysis rate of the alkoxide while also keeping the titanium and zirconium ions in a stable state to obtain a uniform gel. After adding a certain amount of acetic acid, it can not only adjust the pH of the solution but also act as a catalyst.

Pt metal has stable properties and low diffusion performance and can prevent mutual diffusion between interfaces. The atomic weight of platinum is 195.078, which is slightly smaller than that of gold, and the atomic number is 78, which belongs to the transition metal. Therefore, Pt thin film is selected as the bottom electrode of the substrate. At the same time, the Ti film is selected as the buffer layer connecting SiO_2/Si to enhance the bonding strength of the Pt layer. The substrate used in the experiment was provided by Peking University Microelectronics, and the structure from top to bottom was $Pt/Ti/SiO_2/Si/SiO_2$, as shown in Figure 3. The total thickness is 500 μm, the thickness of the Pt layer is 150 nm, the thickness of the Ti layer is 20 nm, the thickness of the SiO_2 layer is 20 μm, and the preferred orientation of the Pt layer is (111).

3.2.2. PZT Film Preparation. For the preparation of PZT film precursor, the selected composition ratio is Pb:Zr:Ti $= 1.15 : 0.52 : 0.48$, which is near the quasihomotype phase boundary. An excess of 15% of lead is used to suppress the formation of oxygen vacancies caused by lead volatilization during annealing. The preparation steps of the PZT precursor solution are as follows:

(1) Use an electronic balance to weigh out 3.774 g lead acetate, 2.009 g zirconium nitrate, and 1.500 g butyl titanate. Dissolve zirconium nitrate and butyl titanate in ethylene glycol methyl ether solution and stir evenly. Add 3 to 5 drops of acetylacetone to the butyl titanate solution as a stabilizer

(2) Lead acetate is relatively insoluble, so after it is dissolved in ethylene glycol methyl ether, it is heated in a hot water bath while stirring on a magnetic stir-

rer. The temperature is set to 60°C, and it is completely dissolved and placed at 120°C. Dry in a vacuum drying oven (model DZF-6020) for 5~10 min to remove crystal water, and then add a little glacial acetic acid after cooling to room temperature

(3) Slowly dissolve the zirconium nitrate solution in the lead acetate solution, stir it evenly, and then add the butyl titanate solution to the mixed solution to form a light yellow precursor solution

(4) Add a proper amount of ethylene glycol methyl ether to adjust the concentration of the precursor solution to 0.3 mol/L, and add a proper amount of formamide to prevent the prepared film from cracking. After continuous stirring for 8-10 h, aging for 4-7 days, the solution is a light yellow transparent liquid without precipitation, and the preparation is complete. The flow chart is shown in Figure 3

3.2.3. Preparation of BNT Film. The preparation of BNT film precursors is relatively simple, and the preparation steps are as follows:

(1) According to the stoichiometric ratio of $Bi_{3.15}Nd_{0.85}Ti_3O_{12}$, weigh appropriate amounts of nitric acid ($Bi(NO_3)_3 \cdot 5H_2O$) and neodymium nitrate ($Nd(NO_3)_3 \cdot 6H_2O$), of which bismuth nitrate is weighed 10% more to make up Bi element volatilization loss during subsequent processing

(2) Place the weighed sample in a clean beaker, add 5 mL of glacial acetic acid and 4 mL of ethylene glycol methyl ether to the beaker, respectively, and place it on a magnetic stirrer and stir (the solution is purple), which is the A solution

(3) In another clean beaker, add 4 mL of ethylene glycol methyl ether and 4 drops of acetylacetone, stir appropriately to make the mixture even. After peeling the skin on the electronic balance, add a certain weight of butyl titanate ($C_{16}H_{36}O_4Ti$) solution to the beaker to form solution B

(4) After stirring the A and B solutions for 5-10 minutes, slowly add the A solution to the B solution to obtain a mixed solution (wine red), and adjust the concentration to 0.01 mol/L. Stir on a magnetic stirrer for 5 to 8 hours, and a light yellow BNT precursor will be obtained. Let it stand for 4 to 7 days to age the solution. If no precipitation appears, the preparation is complete. The schematic diagram of the process is shown in Figure 4

After the preparation of the precursor solution is completed, the preparation of the film can be carried out. The spin-coating preparation process is carried out in an ultraclean room, which has a grade of 10,000. The homogenizer is a KW-4B homogenizer produced by Beijing Saidecase Electronics Co., Ltd. When the film is prepared by the spin

TABLE 3: Summary of experimental drugs.

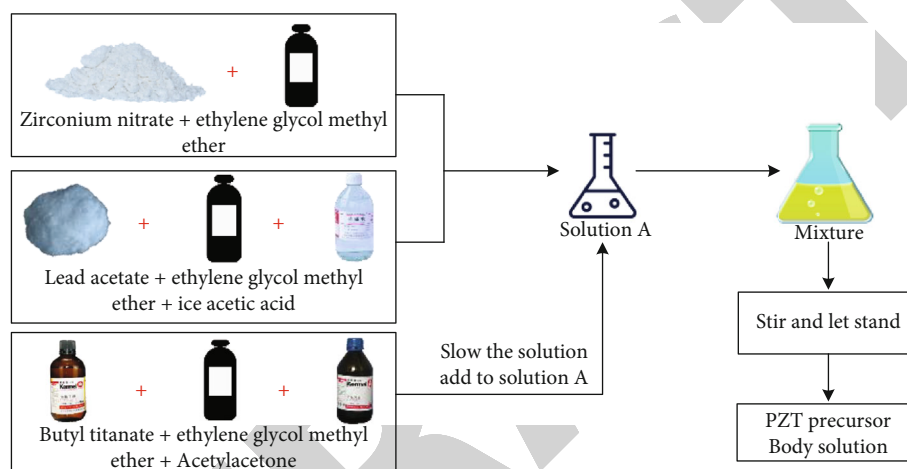
Drug name	Molecular formula	Purity	Molar mass (g/mol)
Zirconium nitrate	$Zr(NO_3)_4 \cdot 5H_2O$	Analytically pure	425.16
Lead acetate	$(CH_3COO)_2Pb \cdot 3H_2O$	99.1%	383.25
Butyl phthalate	$C_{16}H_{36}O_4Ti$	98.7%	351.67
Neodymium nitrate	$Nd(NO_3)_3 \cdot 6H_2O$	98.5%	328.16
Bismuth nitrate	$Bi(NO_3)_3 \cdot 5H_2O$	99.3%	491.38
Ethylene glycol monomethyl ether	$C_3H_8O_2$	99%	77.41
Acetylacetone	$C_5H_8O_2$	98%	101.79
Formamid	CH_3NO	Analytically pure	48.35
Acetic acid	CH_3COOH	Analytically pure	62.83


FIGURE 3: Schematic diagram of the preparation process of PZT precursor solution.
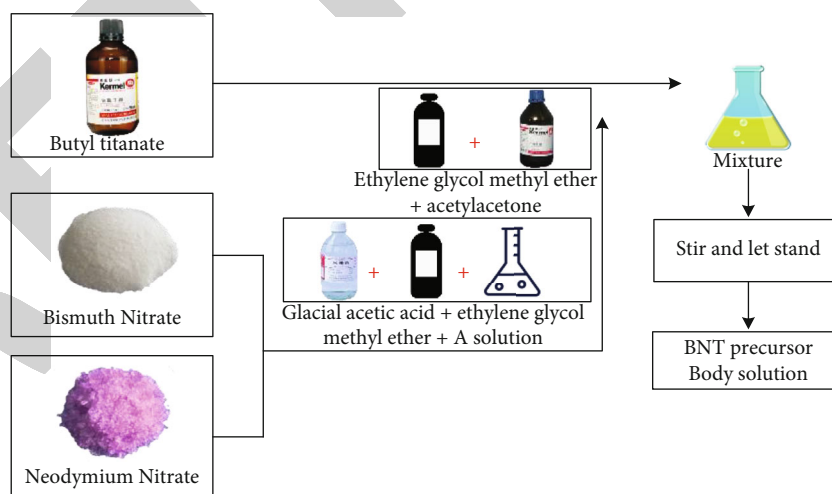

FIGURE 4: Schematic diagram of the preparation process of BNT precursor solution.

coating method, the effect of the parameter setting of the homogenizer on the performance of the film is mainly reflected in the uniformity of the film, and the annealing process mainly controls the ferroelectric properties of the film, such as the size and orientation of the crystal grains, and the defects in the film.

After many experiments and comparisons with other documents, the spin coating process parameters are set to low speed 400 r/s and high speed 4000 r/s, and the spin coating time is 10 s and 40 s, respectively. The air humidity in the ultraclean room is controlled between 39% and 48%, the temperature is changed between 17.4 and 22.2°C, and the
Figure 5: XRD pattern of PZT film under air and oxygen annealing atmosphere.

Figure 6: Ferroelectric thin film C-V test.

humidity and temperature remain basically unchanged during a single spin coating. The rapid annealing process is divided into three small stages: the first stage is drying, and 18 s is heated from room temperature to 180°C and maintained for 300 s; the second stage is pyrolysis, and 20 s is heated from 180°C to 400°C and maintained for 300 s; the third stage is annealing, and 20 s is heated from 400°C to 700°C and kept for 600 s; that is, a complete annealing is completed.

When the spin coating reaches the desired thickness, the annealing process is completed, and the film preparation is completed. The Ni layer in the Ni/PZT composite film is sputtered by the MIS800 multifunctional ion beam magnetron sputtering composite coating equipment. The sputtering voltage is 2 kV, the current is 50 mA, and the sputtering time is 20 min. The thickness is about 100 nm, and then, a 5-10 nm Ag layer is covered on the surface of the nickel layer as a protective layer to prevent oxidation of the nickel layer.

4. Influence of Preparation Parameters on the Ferroelectric Properties of PZT Thin Films

4.1. Effect of Annealing Environment on the Ferroelectric Properties of PZT Thin Films. When annealing at the same temperature, the environment of the sample can also affect the intrinsic properties of the film, and the difference in oxygen partial pressure will produce different effects. Figure 5 shows the XRD pattern of the PZT film under annealing environment.

Annealing in air has a low oxygen partial pressure, and there are usually more oxygen vacancies generated during annealing, resulting in more defects in the film; the existence of defects will increase the leakage current of the film, reduce the polarization of the film, and reduce the residual polariza-
Figure 7: PUND test displacement current result.

tion. The value becomes smaller; at the same time, the increase of defects makes the clamping effect more significant and inhibits the reversal of the ferroelectric domain, and the electrical domain reversal is difficult; that is, the electric coercive field of the ferroelectric film becomes larger. Annealing in an oxygen atmosphere significantly increases the oxygen partial pressure ratio, inhibits the generation of oxygen vacancies, and reduces the number of internal defects in the film, making the film denser and improving the ferroelectric properties.

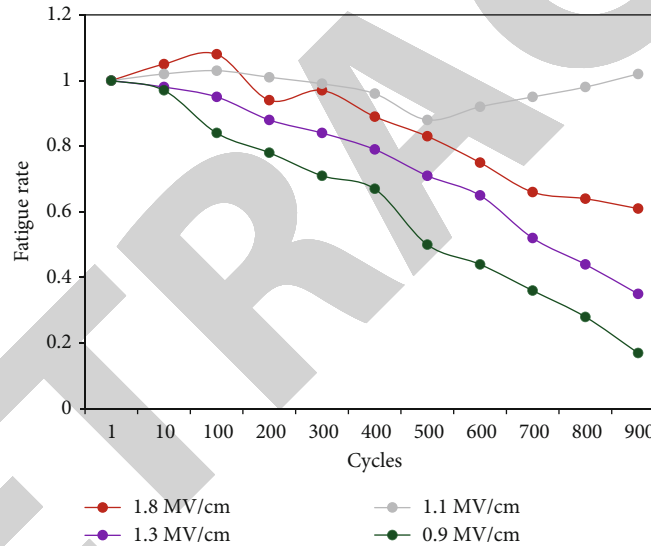
4.2. Structure and Conductivity of Ferroelectric Thin Films. First, the structure and ferroelectric properties of the prepared ferroelectric thin film were characterized.
FIGURE 8: The relationship between the residual polarization intensity and the number of reads and writes under different pulse amplitudes.


FIGURE 9: Normalized results of fatigue rate under each pulse amplitude.

Figure 6 shows the capacitance-voltage test of the prepared 15 nm thick sample. The electrode area of the test device is $30\,\mu$m $\times 30\,\mu$m, the applied field strength range is ± 3 MV/cm, and the test frequency is 50 kHz. From the figure, you can see a "butterfly-shaped" CV curve unique to ferroelectric materials. Two obvious "bulges" can be observed around ± 0.8 MV/cm, which is a characteristic of ferroelectric capacitors. The reason is that the movement of the domain wall near the coercive field will increase significantly.

Figure 7 shows the displacement current during the PUND (positive up, negative down) test. A polarization current of about 0.1 A cm^{-2} can be observed at the rising edge of the first positive pulse and the falling edge of the third pulse, which is also one of the current characteristics of ferroelectric materials.

4.3. Fatigue Characteristics Analysis of Ferroelectric Capacitors.
In PZT-based ferroelectric capacitors, there have been many reports that the rate of device fatigue is closely related to pulse width, pulse amplitude, and temperature. These characteristics are related to various fatigue mechanisms such as domain wall pinning, redistribution, and injection of oxygen vacancies.

In this experiment, the fatigue characteristics of the device were also characterized under these different experimental conditions. The first research is the relationship between fatigue characteristics and pulse amplitude. The frequency of the pulse is fixed at 0.91 MHz, as shown in the inset in Figure 8; the amplitude of the pulse varies from 0.8 MV·cm^{-1} to 1.8 MV·cm^{-1}, as shown in Figure 8. In the literature, hafnium dioxide-based ferroelectric materials will have the characteristic of "wake-up" in the polarization

TABLE 4: Comparison of device performance indicators under different irradiation doses.

Dose(ions/cm^2)	Dielectric constant	Coercive field (MV/cm)	2Pr (μC/cm^2) (at 2.5 MV/cm)	2Pr (μC/cm^2) (at 1.3 MV/cm)	2Pr after cycling (μC/cm^2) (at 1.3 MV/cm)		
					Mean values	Range	Percentage
Initial state	39.4	1.12/-0.68	24.9	13.9	1.5 ~ 5.5	2.75	23%
5×10^{13}				12.6	2.1 ~ 8.8	4.66	36%
10^{14}	39.2	1.19/-0.56	24.4	11.4	3.6 ~ 10	4.78	54%
$5 * 10^{14}$				10.7	1.6 ~ 8.4	5.52	43%
10^{15}	38.8	1.07/-0.59	23.6	9.8	1.2 ~ 6.6	3.24	26%

intensity during the first 200 reads and writes; that is, the polarization intensity will first increase with the increase in the number of reads and writes. This phenomenon has also been observed in this experiment. When the reading and writing field strength is 1.8 MV·cm^{-1}, the residual polarization intensity increases from 12 μC·cm^{-2} to 13 μC·cm^{-2} after reading and writing 200. It was also at this moment that fatigue began to occur. When the reading and writing field strength is reduced to below 1.3 MV·cm^{-1}, the "wake up" phenomenon disappears, and the device shows fatigue characteristics directly from the beginning of reading and writing. When the reading and writing field strength decreases from 1.8 MV·cm^{-1} to near 0.9 MV·cm^{-1} of the material coercive field, the fatigue rate increases significantly.

Figure 9 normalizes the fatigue rate under various field strengths ($P(N)/P0$, where $P(N)$ represents the residual polarization after reading and writing N times and $P0$ represents the initial residual polarization of the device). It can be seen very clearly that as the reading and writing field strength decreases, the fatigue rate of the device is gradually increasing.

In this paper, the fatigue characteristics are studied, and it can be seen that the device is more likely to exhibit fatigue characteristics at a voltage close to the coercive field. Therefore, in order to better study the characteristics of fatigue characteristics under proton irradiation, in this chapter, we have carried out fatigue tests on the device near the coercive field, and we can see that the fatigue has a tendency to first improve and then decrease.

Table 4 summarizes the changes of various ferroelectric properties under irradiation. It can be seen that the dielectric constant, the coercive field, and the residual polarization under 2.5 MV·cm^{-1} only slightly changed. Irradiation even has an inhibitory effect on fatigue. In general, the performance of devices based on ferroelectric thin films does not change significantly under proton irradiation.

5. Conclusions

Ferroelectric thin film materials can greatly improve the overall performance of sports facilities, improve sports equipment, improve the quality of new equipment, and promote athletes to obtain excellent results. Therefore, the application of ferroelectric thin film materials to sports will have a lasting high-quality impact on the sports industry. Ferroelectric thin film materials have great potential and can improve all aspects of sports. Sports activities require

specific equipment and equipment, as well as the material texture and design of the equipment, which play a vital role in the development of sports. The application of ferroelectric thin film materials in the sports industry is mainly reflected in two aspects: one is the application in sports infrastructure, such as the construction of sports venues, sports equipment, sports clothing, and sports biology. The second is the application in sports equipment, such as enhanced golf, tennis, swimming, racing, and cycling. The core part of sports industrialization refers to the industrial phenomenon that a certain sports event takes competition activities as the leader, achieves a high degree of marketization, and forms a considerable economy of scale, thus presenting an industrial phenomenon. Such industrialization has played a decisive role in the development of sports. The extension of sports industrialization refers to the industrialization of all sports-related departments. They will promote the development of sports, but they are not decisive. The industrialization of sports is the same as the socialist modernization construction in China. Its foothold can only be based on the national conditions. The industrialization of sports can only give full play to its own advantages and adapt to the requirements of the socialist market economy only if it conforms to the national conditions. Its basic feature is that the industrialization of sports is a direction for China to deepen the reform of sports. It is the process of sports from a closed system run by the state to an open system run by the state and society. What needs to be emphasized is the social and economic benefits of sports. In this paper, PZT and BNT ferroelectric films were prepared by sol-gel method, and PZT and BNT were used as the research objects to study the influence of sol-gel method preparation parameters on the properties of PZT and BZT ferroelectric films. When the annealing temperature increases, the degree of crystallization of the film increases. When the film is annealed in an oxygen atmosphere, the oxygen partial pressure increases, reduces the oxygen vacancy concentration, suppresses the occurrence of defects, and improves its ferroelectric properties. The increase of film thickness can increase the average size of crystal grains, reduce the internal stress of the film, and also improve the ferroelectric properties of the film. When annealed in an oxygen atmosphere at 700°C and a thickness of 10 layers, the ferroelectric properties of the PZT film are the best. The BNT film has the best ferroelectric performance when it is annealed in an oxygen atmosphere at 700°C, and the thickness is 8 layers. Then, using electrical characterization and other methods to study its fatigue

mechanism and anti-irradiation performance, it is concluded that the occurrence of the ferroelectric film fatigue process is closely related to the magnitude of the applied field strength, the frequency of read and write pulses, and the temperature, and these characteristics all point to the main fatigue mechanism caused by charged carrier injection. The performance of the device is stable under proton irradiation, and the fatigue characteristics are even improved. This paper studies the excellent performance characteristics of ferroelectric thin films that can be used in the optical and sensing sports industry. Sensors made of ferroelectric thin film materials have sufficient sensitivity and accuracy to perform online in-body monitoring and are widely used in the sports industry. However, there are still some shortcomings in the research of this paper. Although the mechanism of ferroelectric thin film fatigue is proposed in this paper, the improvement of fatigue has not been achieved. It is hoped that this problem that hinders commercial application can be completely solved in future work. And in future research work, I will propose methods for ferroelectric material optimization from more perspectives based on existing technologies and methods and continuously improve the quality and efficiency of research work.

3D printing, known as the "new industrial revolution," has set off an upsurge in the scientific and technological field in recent years, and 3D printing of digital light processing technology has even improved the performance and efficiency of 3D printing. This technology uses the projection principle to form; no matter the size of the workpiece, the forming speed is not affected. It uses very cheap lamp radiation, the system has no injection-molded components, there is no nozzle clogging problem of traditional molding systems, and maintenance costs are greatly reduced. In this paper, based on digital light processing 3D printing technology, light-curing reactive functional materials commonly used in digital light processing 3D printing are prepared. In the past, most of these materials were imported. In this paper, by adjusting the DLP technology, a water-soluble photocurable reflection material is constructed, a method for shaping the reaction material. It conducts experiments on the preparation and performance research of water-soluble photocurable reaction materials through formulation and process optimization. It prepared a water-soluble photocurable reactive functional material and compared it with traditional imported materials. Due to the characteristics of UV curing and good mechanical properties and water solubility, it provides a new idea for the preparation of 3D printing-related functional materials.

1. Introduction

Digital light processing (DLP) refers to digitally processing an image signal and then projecting it to the desired point. In 3D printing, because of its high-precision casting technology, it can achieve excellent performance in material, detail, and surface material casting.

Nowadays, there are many types of 3D printing materials, the common ones are ABS, PLA, and Nylon. There are many more, such as resins under DLP/SLA molding technology and metals (such as aluminum, iron, steel, silver, gold, and titanium) for industrial-grade models, ceramics, etc. There are also various materials with special properties, such as magnetic materials, conductive materials, wood-like materials, elastic materials, and hard materials like concrete,

special inks for bio-3D printing. These materials are suitable for different application fields and show their own characteristics, and 3D printing of functional materials is also included in this category.

Functional materials refer to materials with excellent electrical, magnetic, optical, thermal, and other functions and special physical, chemical, and biological effects, which can complete the mutual transformation of functions, and are mainly used to construct various functions. Because 3D printing has the advantages of short manufacturing cycle, high molding precision, and customization, the technology is widely used in many aspects, and printing materials are the key. Among them, the vacancy of photocurable reactive functional materials as supporting materials has affected the development of digital light

processing 3D printing technology in China. In this paper, with digital light processing technology as the core, a water-soluble photocurable 3D printing reactive material was prepared and studied. This is of great significance for the development of digital light processing technology 3D printing and related functional materials. The innovation is that it can make up for the current situation of relying on imports of this material and play a certain reference role in promoting the development of related materials in China.

2. Related Work

Due to the increasing popularity of 3D printing, 3D printing-related technologies are becoming an emerging core competitiveness. Huang and Lin combined the "Conceive, Design, Implement, Operate" (CDIO) framework with 3D printing tangible to propose a novel technical thinking [1]. Xu et al. developed a framework to study the innovation capabilities of multilayer innovation ecosystems involving science, technology, and business subecosystems. They selected China's 3D printing ecosystem as a case study, in addition to analyzing the interplay between the science, technology, and business layers [2]. Vanderburgh et al. highlighted recent advances in 3D printing of tissue-engineered structures. They defined it as the layer-by-layer fabrication of a part guided by digital information in a 3D computer-aided design file. In this structure, they recapitulated the physical and cellular properties of the tissue microenvironment and it was used to study disease progression mechanisms and screen drugs [3]. Xu et al. proposed a combination of 3D scanning and cement mortar-based 3D printing for developing a new process for replicating decorative parts of historic buildings. The process was traditionally labor-intensive and expensive to build, but they developed and presented a layered algorithm for model slicing and an improved scanline algorithm for nozzle paths [4]. Ho et al. prepared stereolithography (STL) format computer models and contrast-enhanced CT of 3D printed models for 3D printing in the medical field. Their proposed 3D-printed model, generated from a strong and flexible plastic material, successfully replicated the anatomical details of the aortic structure and pathology [5]. The printability of the materials used in extrusion-based 3D printing was one of the most important properties, especially when manufacturing objects of architectural complexity. However, this parameter is affected by several factors (temperature, composition, and additives), which makes comprehensive evaluation and classification challenging. Kim et al. evaluated the printability of food inks for 3D food printing applications by systematically adjusting dimensional stability testing, handling performance evaluation, and shear rheology testing using edible hydrocolloids as reference materials. Thus, a high-quality solution is proposed [6]. To date, most printable thermoset materials suffer from complex processes, poor thermodynamic properties, and slow printing speeds. Wang et al. developed a photosensitive composite ink for fast photocuring printing, which has a good auxiliary role for 3D printing under digital light processing [7].

However, the photosensitive composite ink they developed is lacking in the accuracy of 3D printing and is prone to errors in more complex model processing tasks, so it still needs to be improved before it is widely used.

3. Technical Setup and Material Preparation Method of 3D Printing Based on Digital Light Processing

DLP 3D printing based on digital light processing mainly uses DMD chips developed by TI. It uses a high-pixel digital light processor (DMD) optomechanical to project model slices to solidify liquid photopolymer layer by layer [8]. In a DLP projection system, the core element is its DMD chip. The DMD chip can deflect the microscope to different angles to complete the light modulation [9]. The size of the DMD micromirror is generally $7.6\,\mu m$, the minimum is $5.4\,\mu m$, and the maximum is $13.6\,\mu m$. There are two types of arrangement: square arrangement and rhombus arrangement. In order to facilitate the deflection of the mirror, there is a certain gap between the arrays, so the actual size of the chip and the projection size are not only determined by the size of the mirror [10]. Figure 1 shows the layout of the lower exposure 3D printing system and DMD chip lens.

3.1. DLP Technology Adjustment. When DLP technology is applied to 3D printing, the reflectivity and diffraction performance of the DMD chip microprocessor can be affected due to the higher photoresponse of the photoinitiator in the photosensitive material to higher energy light. The energy rate of the system also has an effect [11]. Excessive use of light energy can cause excessive system losses, fail to reach projection targets, or even damage equipment. Therefore, the reflectivity of the DMD chip in different light zones, as well as in the DMD window, will be the main estimate.

According to the DMD chip guidance given by TI, DMD chips suitable for visible light, ultraviolet light, and near-infrared wavelengths also have different energy utilization rates for different light wavelengths under different human radiation angles, as shown in Figure 2.

The DMD window is optimized by coating for the wavelength of 420~700 nm in the visible light band to improve the transmission efficiency. The ultraviolet band is optimized for the light wavelength of 355~400 nm, and the optimized effect is shown in Figure 3.

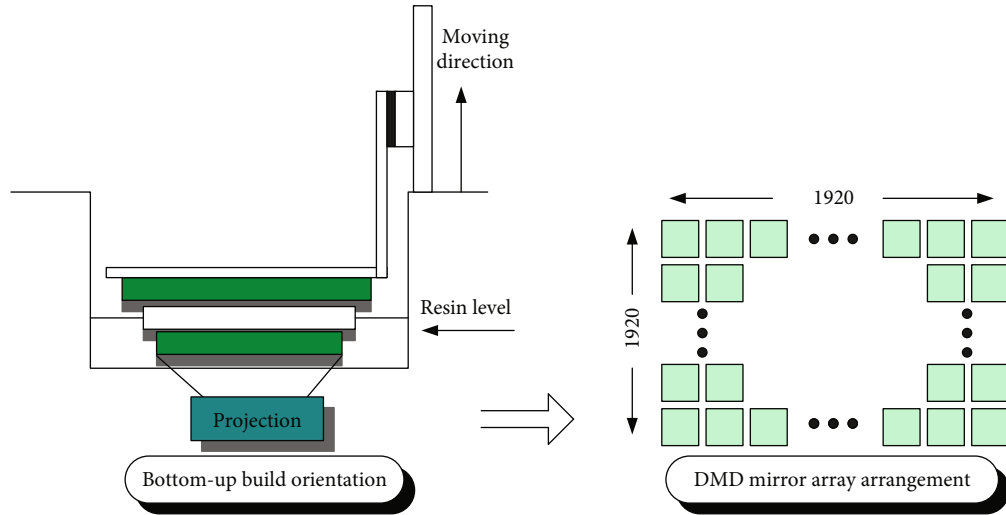
In 3D printing applications, the typical wavelengths used by DLP technology are 355 nm and 405 nm, mainly determined by the light source [12]. The optimization effect of visible light band and ultraviolet light band in Figure 3 shows that the DMD chip for ultraviolet band should be used as the core of the system. It ensures that the system has a high light energy consumption rate. If the visible light region DMD chip is used, the system loss will increase. If the wavelength of the light source is 355 nm, the utilization rate is only 70%, and the waste of system energy is huge [13]. After completing the above settings, it can print the material. The specific process is shown in Figure 4.


FIGURE 1: Layout of the lower exposure 3D printing system and DMD chip lens.
FIGURE 2: Energy utilization curve of DMD chip at different wavelengths.

After understanding the working principle and operation process of DLP technology, the next article will introduce the curing and molding mechanism of the functional materials to be prepared. It studies the effect of process conditions on the properties of the material before and after curing to determine the optimal formulation of the material. This provides a certain theoretical basis and practical methods for the localization of digital light processing 3D printing materials.

3.2. Construction Principle of Water-Soluble Photoreactive Materials. Light-curing 3D printing materials are composed of a solid material and a support material. The material

responsible for building the solid part of the part is called the solid material. It directly affects the molding accuracy and surface quality of solid parts and is a key functional material for photocuring 3D printing [14]. The composition of the material includes prepolymer, monomer, and photoinitiator, as shown in the following formula. The polymerization cross-linking reaction allows the liquid resin to form a cured product in a very short time:

$$
\begin{aligned}
X - Y &\xrightarrow{\text{hv}} \left(\frac{X}{Y}\right), \\
\left(\frac{X}{Y}\right) \cdot &\longrightarrow X \cdot + Y.
\end{aligned}
\tag{1}
$$
It abstracts hydrogen atoms from hydrogen atom donors such as prepolymers and active monomers, such as photoinitiator ITX, to make them active free radicals. After the previous step is completed, as shown in the following formula, the polymerization and cross-linking reaction is further initiated.

$$
\begin{aligned}
X &\xrightarrow{\text{hv}} X, \\
X \cdot &\xrightarrow{RH} XH + R.
\end{aligned}
\tag{2}
$$
The photocurable reactive materials mainly include three stages of chain initiation, chain growth, and chain termination [15].

(1) Chain initiation

The photoinitiator (I) absorbs light energy under the irradiation of a UV lamp. It transitions from the ground state to the excited state, forming active radicals (R). The active free radical then undergoes an addition reaction with the monomer (M) to form a monomer free radical, as shown
FIGURE 3: Optimization effect diagram of visible light band and ultraviolet light band.

in the formula:

$$I \xrightarrow{\text{hv}} R,$$
$$R \cdot + M \xrightarrow{\text{hv}} (R - M). \tag{3}$$
(2) Chain growth

The above process is repeated continuously, so that active radicals and monomers are rapidly added to form macromolecules. Light-curing printing materials change from liquid to solid:

$$(R\text{-}M)_n \cdot + M \xrightarrow{\text{hv}} (R - M - M)_n \cdot \tag{4}$$
(3) Chain termination

Common chain terminations include disproportionation termination and coupling termination. With the continuous progress of the chain growth reaction, the content of free radicals in the chain increases continuously, and the photo-curing reaction ends [16].

3.3. Curing and Characterization of Reactive Materials

(1) Viscosity

The viscosity of the reactive material is measured according to the specified standard. It puts an appropriate amount of liquid reaction material into the barrel of the digital viscometer and then puts the barrel into a constant temperature water tank. It uses a No. 21 rotor to measure the viscosity of the reaction material at different temperatures [17].

Viscosity is an important process parameter characterizing the jetting properties of photocurable 3D printing support materials, which determines whether the reactive material can be smoothly and steadily ejected from the noz-

FIGURE 4: DLP printing process.

zle [18]. It is subjected to shearing force. It simplifies the injection process, and the viscosity of the reaction material is shown in the formula:

$$\tau = F|A,$$
$$D = \left(\frac{dx}{dz}\right)|dt, \tag{5}$$
$$\eta = \tau|D.$$

τ is the shear stress, F is the shear force, A is the area where the shear force acts, and D is the shear rate. dx/dz is the shear deformation, dt is the shear force action time, and η is the viscosity of the reaction material.

(2) Surface tension

It measures the surface tension of the reactive material. It puts an appropriate amount of liquid temperature-sensitive reactive material sample into the barrel of the automatic surface tensiometer and then puts the barrel into a constant temperature water tank. It chooses the platinum plate method to test the surface tension of the reaction material at different temperatures. The specific process is as follows:

$$P = \text{mg} + L\gamma(\cos\theta) - sh\rho g. \tag{6}$$

(3) Volatilization rate

It adds the reaction material to the beaker. The mass of the beaker is M_0, and the total mass after adding the reaction material is M_1. After being placed at different temperatures for different times, it measured a total mass of M_2. The volatilization rate α of the reaction material is calculated as follows:

$$\alpha = \frac{M_1 - M_2}{M_1 - M_0}. \tag{7}$$

(4) Curing shrinkage

Under the condition of 25°C, it uses the ZMD-2 electronic densitometer to measure the density of the reaction material before curing and the density of the cured product, and the curing shrinkage can be calculated by the formula:

$$\Delta = \frac{\rho_1 - \rho_0}{\rho_0}. \tag{8}$$

(5) Solubility

It cuts the cured product of the reaction material to obtain a sample with a size of $10 \times 10 \times 4\,\text{mm}^3$. The mass of the sample is called M_0, and the sample is soaked in distilled water of different temperatures for a certain period of time. It takes a filter paper with a quality of M_1 for filtration and puts the filter paper and the sample into a vacuum drying oven for drying, and the quality after drying is M_2. Then, the reaction material solubility S is calculated by the following formula:

$$S = \frac{M_0 - (M_2 - M_1)}{M_0}. \tag{9}$$
FIGURE 5: 1H NMR spectrum of single-end hydroxyl PEGmA.

The photocuring reaction process of the photocurable monomer is as follows:

$$R \xrightarrow{\text{violetray}} R,$$
$$R\cdot + mPEG400DA \longrightarrow R - PEG400DA_m,$$
$$R\cdot + R - PEG400DA_m \cdot \longrightarrow R - PEG400DA_m - R,$$
$$R - PEG400DA_m \cdot + R - PEG400DA_m \cdot \longrightarrow R - PEG400DA_m - R. \tag{10}$$
R is a photoinitiator, R is a free radical, and PEG400DA is polyethylene glycol 400 diacrylate.

Surface tension is also an important process parameter for light-cured 3D printing reaction materials, which determines whether the reaction materials can be smoothly and stably ejected from the nozzle [19]. During jet printing, the reactive material droplets have a tendency to automatically shrink into spherical shapes. The air resistance and the change of the mass of the reaction material droplets are ignored, and the force of the reaction material is simplified. The surface tension of the reactive material is shown in the formula:

$$\alpha = \frac{\omega}{\gamma}. \tag{11}$$

In the formula, α is the surface area of the new surface, ω is the work done when the new surface is generated, and γ is the surface tension coefficient.

3.3.1. Experiments on the Preparation and Performance of Water-Soluble Photocurable Reactive Materials. Before the experiment, the water-soluble photocurable monomer must first be provided for the preparation of the water-soluble photocurable 3D printing reaction material. Single-ended hydroxyl PEGmA, also known as polyethylene glycol acrylate monoester, has good UV curing properties. Because of its special molecular structure, PEGmA and its cured products have good water solubility and can be easily removed by water gun [20]. In addition, PEGmA has the advantages of nontoxicity and low volatilization rate. Therefore,

TABLE 1: Basic formula of water-soluble photocurable 3D reactive materials.

Materials	PEGmA	Polyethylene glycol	369	ITX	Other agents
Proportion of the 1st blend/wt%	75	12	2	2	9
Proportion of the 2nd blend/wt%	65	12	2	2	8
Proportion of the 3rd blend/wt%	43	6	2	1	7
Proportion of the 4th blend/wt%	22	6	1	1	6
Proportion of the 5th blend/wt%	15	3	1	1	4
FIGURE 6: Schematic diagram of the structure of photoinitiator 369.
FIGURE 7: Schematic diagram of the structure of the photoinitiator ITX.

PEGmA provides a new idea for the preparation of water-soluble photocurable reactive materials. However, it is currently difficult to purchase pure PEGmA in the market, and the domestic synthesis process and purification method of PEGmA are not mature, and there is no commercial PEGmA, so it is necessary to make PEGmA.

3.4. Synthesis and Purification of Single-Ended Hydroxyl PEGmA. It firstly adds a certain amount of reactant polyethylene glycol into a 250 ml container equipped with a thermometer, a constant pressure dropping funnel, a water separator, and a condenser. In the flask, it heated the mixture to 60°C with magnetic stirring. After the p-toluenesulfonic acid and hydroquinone were completely dissolved, the temperature was raised to 120°C. It continues to magnetically stir for 10 to 15 minutes, and after no bubbles are produced, it filters. The filtered product was added to a rotary evaporator, distilled under reduced pressure, and toluene was removed to obtain a crude product of PEGmA.

It uses a pipette to, respectively, measure a certain amount of reaction solution and distilled water (mass ratio 1 : 10) into a conical flask, add indicator phenolphthalein, and mix evenly. It is titrated to a reddish color with standard NaOH solution, shaken, and the end point of the titration is that the red color does not fade within 30 seconds. It records the amount of NaOH solution consumed and calculates the acidity and esterification of the sample.

The formula for calculating acidity is as follows:

$$AV = \frac{CVMr}{m_s}. \tag{12}$$

In the formula, AV is the acidity value of the sample; C is the mass concentration of the standard NaOH solution; V is the volume of the NaOH solution consumed when the titration reaches the end point; Mr is the relative molecular mass of NaOH; m_s is the mass of the sample taken.

The calculation of the degree of esterification of the esterification reaction is as follows:

$$DE = \frac{A_i - A_t}{A_i}. \tag{13}$$

Among them, DE is the esterification degree of the sample; A_i is the initial acidity value of the sample; A_t is the acidity value of the sample measured at a certain time.

Figure 5 is the 1H NMR spectrum of single-ended hydroxyl PEGmA. It can be seen from Figure 5 that, compared with pure polyethylene glycol, characteristic peaks appear at the chemical shifts of 5.8-6.5 in the hydrogen spectrum of single-end hydroxyl PEGmA, corresponding to the 3 Hs of the terminal alkenyl group. The characteristic peaks at chemical shifts 4.2-4.4 correspond to the 2 Hs on the carbon atom of the ester group and the 2 Hs on the methylene group connected to the terminal hydroxyl group. It has characteristic peaks at chemical shifts of 3.6-3.8. The characteristic peaks at chemical shifts of 3.5 to 3.6 correspond to 82 Hs in the oxyethane structure of the monoester, which indicates that the oxyethane structure (ether chain structure) of polyethylene glycol is not destroyed. In conclusion, the esterification reaction of polyethylene glycol and acrylic acid occurred to generate single-end hydroxyl PEGmA. The peak shape in the figure is sharp, and there are few impurity peaks, which proves that the purity of the monoester is high.

3.5. Preparation of Reactive Photocurable 3D Printing Materials. Single-end hydroxyl PEGmA has excellent UV curability and can be cured quickly under the action of photoinitiator. And its cured product has good water solubility and mechanical properties, which can support the molding of solid materials [21]. After it has been formed, the PEGmA cured product can be removed by flushing with a water gun. Therefore, PEGmA meets the performance of water-soluble functional materials, which provides a new idea for the preparation of water-soluble photocurable 3D printing materials. In this section, on the basis of the synthesized water-soluble PEGmA as the photocurable monomer, a new type of water-soluble functional material, reactive photocurable 3D printing functional material, was prepared. It analyzes the influence of monomers, types, and contents

Table 2: The volatilization rate of reaction materials containing 75 wt% PEGmA in different environments.

Storing time	8	16	24	32	40	48	56	64	72
Wet environment	0.18	0.24	0.29	0.33	0.48	0.40	0.59	0.60	0.69
Dry environment	0.15	0.23	0.26	0.29	0.38	0.39	0.49	0.56	0.68
Hot environment	0.28	0.33	0.39	0.47	0.51	0.55	0.62	0.68	0.72
Cold environment	0.01	0.12	0.2	0.35	0.38	0.52	0.64	0.65	0.68
Figure 8: Effect of temperature and monomer content on viscosity of reaction material.

of photoinitiators on the properties of the material, studies the preparation process of the material, and analyzes its curing and forming mechanism. It finalizes the optimal formulation of water-soluble photocurable 3D reactive materials. The basic formula is shown in Table 1.

It formulates photoinitiator 369 and ITX, polyethylene glycol, and photocurable monomer PEGmA into a clean beaker. It was stirred with a magnetic stirrer until the photoinitiator 369 and ITX were completely dissolved. It is then added with the inhibitor according to the formula, and stirring is continued until the inhibitor is completely dissolved. When it forms a transparent and uniform solution 1, it needs to be sealed for later use. 369 is a photoinitiator with high sensitivity range and high UV absorption, which belongs to the cleavage type photoinitiator [22].

369 is often used to initiate free radical photopolymerization and is light yellow powdery crystal. Its structural formula is shown in Figure 6.

ITX is a highly efficient hydrogen abstraction photoinitiator, which is light yellow crystalline powder. Its pseudonym is isopropylthioxanthone, and its structural formula is shown in Figure 7.

369 is not only a cleavage free radical photoinitiator, but also a hydrogen-donating polymer photoinitiator, which can donate hydrogen to the hydrogen abstraction initiator ITX. Therefore, 369 is often compounded with ITX as a coinitiator, which can improve the initiation efficiency [23]. The volatilization of some components in the reaction material not only affects the performance of the reaction material but also causes pollution to the environment and harm to

the human body. Therefore, the volatilization rate is also a factor that must be considered for the reaction material.

Table 2 shows the volatilization rates of the reacted materials with a monomer concentration of 75 wt% stored at 55°C in different environments for different times. It can be seen from Table 2 that after the reaction material was stored at 55°C for 72 h, the volatilization rate was only 0.72% in the highest case. Therefore, the reactive functional material has good long-term spraying stability and can meet the requirements of long-term spraying.

3.6. Properties of Water-Soluble Photocurable Reactive Materials before Curing. As mentioned above, viscosity is an important process parameter that determines whether the reaction material can be smoothly and stably ejected from the nozzle. If the viscosity is too high, the required shear force is too large, and the reaction material will not be ejected from the nozzle smoothly. If the viscosity is too low, it is easy to cause ink leakage, thus affecting the molding quality and accuracy [24]. Therefore, the reactive material should have a suitable viscosity to ensure the smooth progress of photocuring 3D printing. The suitable viscosity range in this experiment is 10~25 mPa·s. There are many factors that affect viscosity, but the most important are temperature and monomer content.

A photocurable reaction material with a monomer content of 75 wt% was prepared, and the effect of temperature on the viscosity of the reaction material was studied. At the same time, the photocurable monomer PEGmA was prepared into reaction materials with contents of 60 wt%,

The influence temperature has on viscosity

● Tendency of the surface tension

The influence monomer content has on viscosity

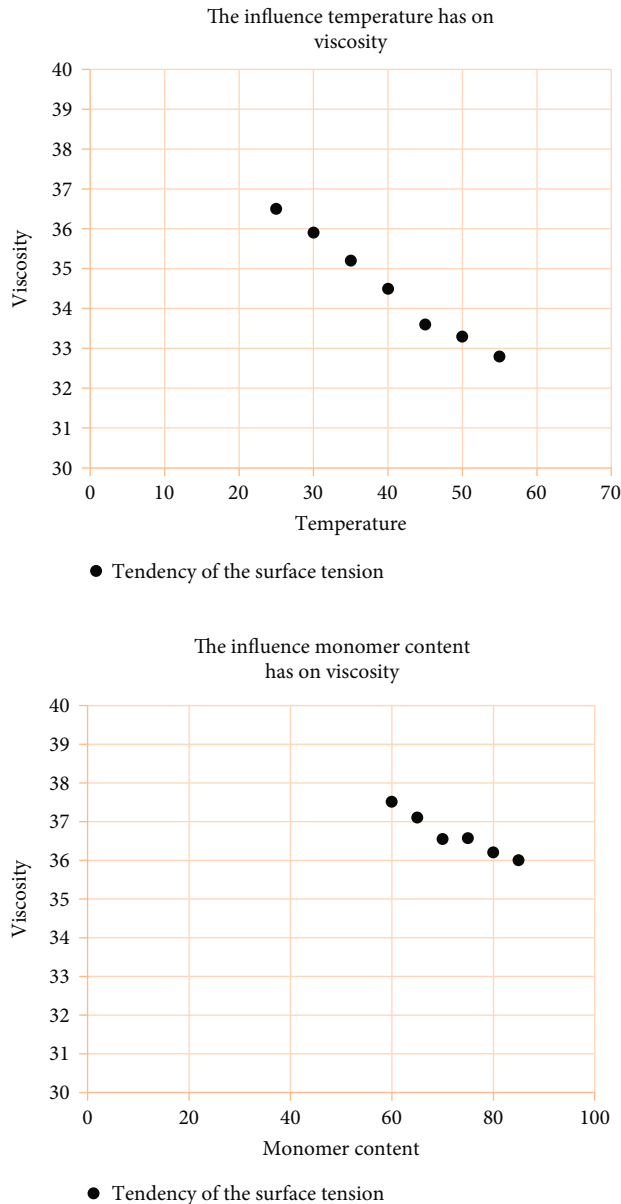
● Tendency of the surface tension


FIGURE 9: Effect of temperature and monomer content on the surface tension of reactive materials.

65 wt%, 70 wt%, 75 wt%, 80 wt%, and 85 wt%, respectively, and the effect of monomer content on the viscosity of the reaction material was studied. The results are shown in Figure 8.

It can be seen from Figure 8(a) that describing the effect of temperature on the reaction material, as the temperature increases, the viscosity of the reaction material gradually decreases, but the decreasing range gradually decreases. When the temperature reaches the interval of 45-60 degrees, the viscosity tends to be stable around 30. This is because the temperature increases, the intermolecular distance in the reaction material solution increases, the interaction force weakens, the resistance decreases, and the viscosity decreases. However, when the temperature is too high, the activity of the monomers in the reaction material solution increases, and a curing reaction is likely to occur. This causes the viscosity of the reaction material to rise sharply, and the solidified product of the reaction material is likely to cause clogging of the nozzle and damage the nozzle.

At the same time, Figure 8(b) shows that the viscosity of the reaction material increases gradually with the increase of the content of photocurable monomers. This is because when the content of the photocurable monomer is low, the effect of monomer molecules is weak. Each monomer molecule can be considered to exist individually, so the viscosity of the reactive material is low. However, when the monomer content is high, the intermolecular interactions of the monomers also increase significantly. At this time, the monomers no longer exist alone but exist in the solution in the form of aggregates. This in turn increases the viscosity of the solution, affecting the jetting process and part quality. Therefore, the content of monomers should be controlled to ensure the working stability of light-curing 3D printing.

Surface tension is also an important process parameter that determines whether the reaction material can be smoothly and stably ejected from the nozzle. The surface tension of the reactive material is too high, the required voltage exceeds the upper limit, and the reactive material cannot be ejected. If the surface tension is too low, the reactive material cannot form effective droplets, which affects the molding quality and accuracy. Therefore, the reaction material should have a suitable surface tension to ensure stable ejection of the reaction material. The suitable surface tension range in this experiment is 25~35 mN/m. It mainly studies the effect of temperature, monomer content, and leveling agent content on the surface tension of reactive materials [25, 26].

It prepares reactive materials with a monomer content of 75 wt% and studies the effect of temperature on the surface tension of reactive materials. It prepared the photocurable monomer PEGmA into reactive materials with contents of 60 wt%, 65 wt%, 70 wt%, 75 wt%, 80 wt%, and 85 wt%, respectively. It studies the effect of monomer content on the surface tension of reactive materials. The results are shown in Figure 9.

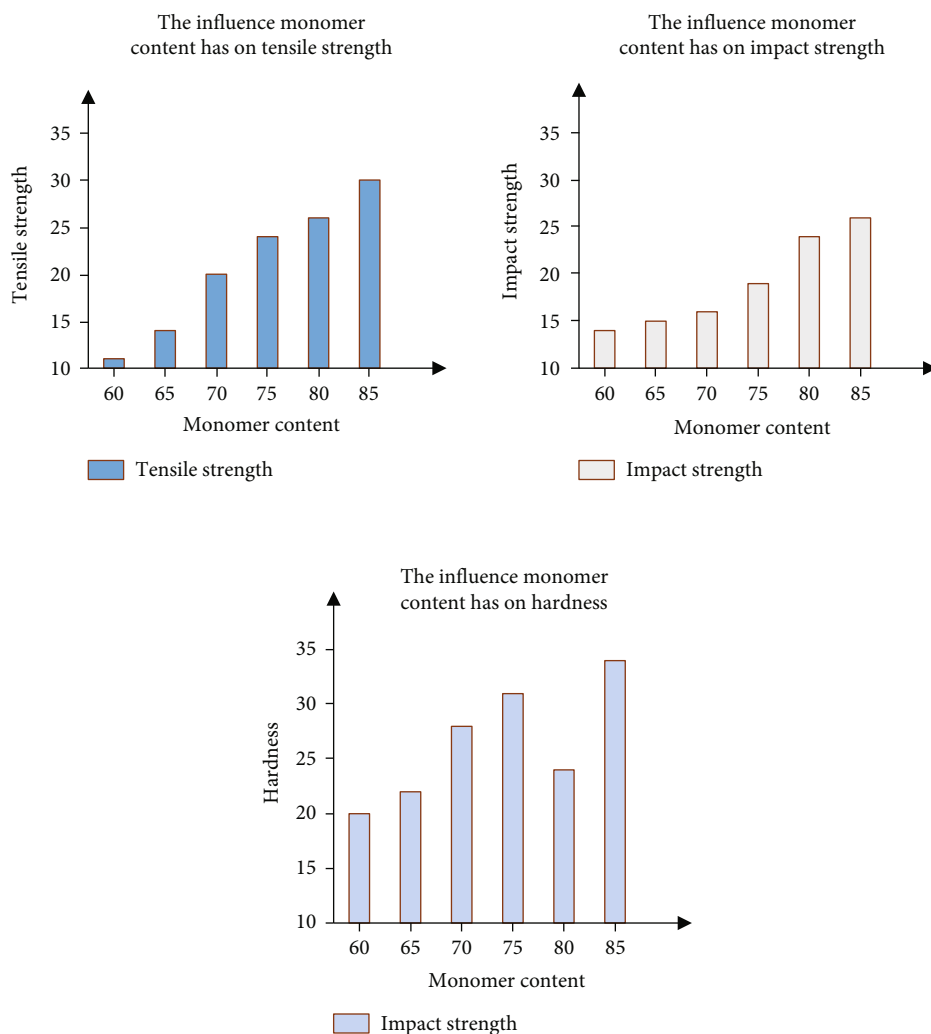
It can be seen from Figure 9 that with the increase of temperature, the surface tension of the reaction material gradually decreases. When the temperature exceeds 80, the surface tension drops below 36. This is because as the temperature increases, the intermolecular distance in the solution increases, the intermolecular interaction force weakens, and the surface tension decreases accordingly. But when the temperature is too high, the monomer is easy to solidify and block the nozzle. Therefore, a suitable working temperature can reduce the surface tension of the reaction material and ensure stable work. It can be seen from Figure 9 that with the increase of the content of the photocurable monomer, the surface tension of the reaction material decreases, but the decrease is smaller. This is because the pure PEGmA monomer has a low surface tension of only 32.667 mN/m. The surface tension of the solvent polyethylene glycol is as high as 57.13 mN/m. The higher the monomer content, the higher the viscosity of the reaction material. The lower the thermal stability, the easier it is to


FIGURE 10: Effect of monomer content on surface tension, impact strength, and hardness of reactive materials.

TABLE 3: Effect of monomer content on hardness under different conditions.

Photocurable monomer content/wt%	60	65	70	75	80	85
Hard/HA	29	33	38	42	48	53
Soft/SA	14	18	20	29	30	39
Medium/MA	23	20	25	34	32	43

cure in advance and block the nozzle. Therefore, the higher the monomer content, the lower the solvent content, which is more conducive to the reduction of surface tension. The surface tension of the reactive material cannot be lowered by substantially increasing the monomer content [27].

3.7. Properties of Water-Soluble Photocurable Reactive Materials after Curing. There are many factors that affect the curing shrinkage of reactive materials. In this section, the effects of the content of photocurable monomers on the curing shrinkage and mechanical properties (tensile strength, impact strength, and hardness) of reactive materials are studied. It was prepared as reactive materials with monomer contents of 60 wt%, 65 wt%, 70 wt%, 75 wt%,

80 wt%, and 85 wt%, respectively. At 25°C, it studies the effect of photocurable monomer content on curing shrinkage of reactive materials.

It can be seen from Figure 10 that the higher the content of the photocurable monomer, the higher the tensile strength, impact strength, and hardness of the reaction material. This is because the photocurable monomer forms a three-dimensional space network structure after curing, which has higher mechanical properties and greater hardness. This in turn gives the reactive material suitable mechanical properties to aid in solid material shaping. Therefore, the higher the monomer content, the highest mechanical properties of the reactive material. In addition, under the influence of different environments, the reactive

stig3	70.49	30.88	0.51	0.66	31	69

materials are still stable. Table 3 shows the effect of monomer content on hardness under different conditions.

3.8. Performance Comparison of Water-Soluble Photocurable 3D Printing Reactive Materials and Traditionally Used Foreign Materials. In this section, the performance data of the water-soluble light-curing 3D printing materials obtained by the experiment are compared with the performance of the traditional imported commonly used materials Fullcure705 and stig3, as shown in Table 4.

It can be seen from Table 4 that the viscosity of the water-soluble photocurable reactive materials prepared in this paper is the lowest compared with the imported photocurable reactive materials Fullcure705 and stig3. It is only 49.85 mPa·s, which is beneficial to the stable ejection of the reaction material. Moreover, the surface tension is high, reaching 37.64 mN/m, which is beneficial to assist the molding of solid materials. In other properties, the solubility is as high as 80.12%, which is beneficial to the water washing and removal of the reaction material, which is also the key performance of the reaction material. And its volatilization rate is low, only 0.2%, and its mechanical properties are as high as 41HA. This is beneficial to ensure the ejection stability of the reaction material and assist the molding of the solid material. Compared with all key data, the reaction materials prepared in this paper have better comprehensive properties and are more suitable as functional materials for digital light processing 3D printing.

4. Conclusions

In this chapter, using the synthesized single-end hydroxyl PEGmA as a photocurable monomer, using its UV-curing properties and the water solubility of the cured product, and using polyethylene glycol, 369, and ITX coinitiators as raw materials, a kind of PEGmA was prepared. In addition, the curing molding mechanism and water-solubility characteristics of the material were also analyzed, the influence of each component of the material and the molding process conditions on the properties before and after curing were studied, and the optimal formulation of the water-soluble light-curing reactive material was optimized and determined. Finally, by comparing the prepared functional materials with the traditional imported materials, it is found that the materials prepared in this paper have better performance in various key indicators. In the future, the author hopes to optimize the formulation of this material through more experiments, so that it can be prepared in batches and can be used in more places.

At present, the world-wide heavy-haul transportation technology of cargo trains has developed rapidly. Heavy-haul railway transportation has received extensive attention due to its large capacity, high efficiency, and low transportation costs. In order to understand the role that ferroelectric materials can play in the dynamic response of a heavy-duty railway surrounding rock structures in crosstunnels, this article introduces the domain structure of ferroelectric materials, derives the calculation method of the dynamic response of the surrounding rock structure, simulates the dynamic response characteristics through the corresponding formula, and analyzes the changes of the heavy-duty railway in the presence and absence of water. The situation was analyzed. The research results found that the increase of axle load will increase the bending moment of the invert structure. When the axle load is 30 t, the V-class surrounding rock is the most unfavorable working condition and the bending moment value of the invert structure is the largest at this time. When the added value of contact pressure is generally around 6.5 kPa, the railway as a whole can maintain a stable state.

1. Introduction

With the continuous improvement of my country's railway network, "passenger high speed" and "freight heavy duty" have become the two important directions of today's railway development. The structural stress forms and disease characteristics of heavy-duty railway tunnels are very different from those of ordinary railway tunnels. The bottom of the tunnel is the foundation that bears the load of trains and structures. Coupled with the effect of geological factors such as groundwater, the diseases at the bottom of the tunnel are particularly prominent, manifesting as lining cracks, venting and sinking of the basement, external squeezing of the side ditch, and mud and mud. Damage to the tunnel bottom causes a decrease in the safety reserve of the tunnel structure in terms of strength, rigidity, and stability. These diseases not only endanger driving safety and deteriorate driving conditions but also increase tunnel maintenance costs and shorten tunnel service life.

Ferroelectric materials have some very excellent properties, such as dielectric properties. Ferroelectric materials include layered ferroelectric ceramics, relaxor ferroelectric ceramics, and antiferroelectric ceramics. When there is an external electric field, the positive and negative charges inside the ferroelectric material will shift to a certain extent, which will cause the charge centers to no longer overlap, and the so-called dipoles will appear. The applied electric field can drive the polarization direction of the dipole to move in the direction of the applied electric field, resulting in dielectric polarization. If we place a uniform dielectric

between the two poles of a capacitor, under the polarization of this dielectric, the capacitance value of the capacitor will increase several times compared with the capacitance value of the vacuum medium. This property is called dielectric. Ferroelectrics have the characteristics of large dielectric constant and obvious nonlinear effects. The spontaneous polarization of ferroelectric materials originates from the electric dipole generated by the noncoincidence of the positive and negative charge centers inside the unit cell. Perovskite structure ferroelectrics are currently the most widely studied, simplest, and most representative ferroelectric materials.

For the related applications of ferroelectric materials and the characteristics of railway dynamic response, experts at home and abroad have done a lot of research. In order to study the mechanism behind the collapse evolution, Xiao et al. conducted in situ microseismic (MS) monitoring in the left main/auxiliary power house. The temporal and spatial characteristics of stress-structure-controlled collapse are summarized and introduced. These methods provide a consistent set of results, that is, tensile fracturing is the most active rock mass fracturing mechanism in the evolution of stress-structure-controlled collapse. In addition, the evolution of microseismic activity during the development of the study collapse was also obtained. The results provide a direct case history, which will help predict and support stress-structure-controlled collapse disasters and help excavate deep-buried caves on site [1]. He et al. proposed an innovative roof-cutting and pressure-relief technology in response to the complex construction technology and high roadway construction costs in the traditional technology of retaining lanes along the goaf. A number of mechanical models of the "surrounding rock structure-roadside support" were established, and the design formulas for the support resistance of each roadway were obtained. The results show that through presplitting blasting, the lower foundation roof falls enough to better support the upper roof, thereby limiting the rotation deformation of the upper roof and reducing the impact load of the roof fracture [2]. Yan et al. deal with several types of inclination rail defects by simulating the acceleration system installed on the locomotive and theoretically study the feasibility of monitoring the inclination rail joint defects. The quantitative relationship between the axle box acceleration characteristics (peak) and the rail defects was determined by simulation. Therefore, the proposed method combines defect analysis and comparison with theoretical results, will enhance the ability of long-term monitoring and evaluation of the track system, and provide a more sensible preventive track maintenance strategy [3]. Cai et al. comprehensively studied the new track dynamics behavior of a polyurethane foam-cured ball in heavy-duty railway tunnels. First, based on the multibody system dynamics theory and finite element method, a dynamic model of the vehicle-track-tunnel interaction system is established. Then, the dynamic effect of the polyurethane foam-cured road ast track on the train and surrounding infrastructure is calculated and compared with the dynamic effect of the traditional road ast track [4]. In order to study the adaptability of cement-modified expansive soil as a filling material for heavy-duty railway subgrades, Cai et al. carried out different

axle loads, trains, speeds, and service environmental conditions based on the test section of the cement-modified expansive soil subgrade of the Menggan Railway. The results show that the dynamic parameters decay linearly along the depth and lateral direction of the subgrade in the same infill structure layer. The dynamic stress attenuation at the bottom of the subgrade surface is about 49%, and the dynamic stress attenuation at the bottom of the lowest subgrade is 76% [5]. Based on the train longitudinal dynamics theory and the vehicle-track coupling dynamics theory, Liu et al. established a heavy-duty train-track coupling dynamics model considering the longitudinal, lateral, and vertical forces of the coupler and traction system. The inspection conditions and mechanical properties of the locomotive under traction and braking conditions are analyzed, and the process and extent of the influence of traction, braking force, and coupler force on the locomotive performance are studied, and the theoretical model is verified by train [6]. The focus of Holder et al.'s research is the laboratory characterization of the lateral load path through the Skl-type fastening system using new instrument technologies that are subjected to heavy freight rail loading conditions. The investigation of the performance of the fastener system includes the evaluation of the lateral load distribution through the superstructure of the track and the evaluation of the single fastener system. The observations of this study will help the railway industry to improve the design of fastener systems and develop mechanical track structure design methods [7]. These studies have provided some references for this article, but due to certain problems in related research methods and data, the results of the experiment have not been accepted by the public.

The innovation of this article is that the article puts forward the theoretical calculation method of the surface load of the ballast bed based on the measured data combined with the existing specifications and the research results at home and abroad according to the characteristics of the ballast bed and the wheel-rail action mode. The elastic layered system is used to derive the elastic mechanics analytical solution of the surface load of the invert structure, which is an elastic foundation beam. The model and the load structure model provide the initial conditions of the load.

2. Response Characteristic Analysis Method

2.1. Ferroelectric Materials. A ferroelectric material is a kind of dielectric material. It has spontaneous polarization in two or more directions within a certain temperature range, and its spontaneous polarization will occur with the direction and magnitude of the external field (common electric field, temperature field). When the ferroelectric is below the critical temperature, it will transform from the paraelectric phase to the ferroelectric phase. This critical temperature is the Curie temperature (CT) [8, 9]. Figure 1 shows the change in the crystal structure of a ferroelectric material with a perovskite structure from a paraelectric phase to a ferroelectric phase. The general formula of perovskite is ABO_3: A and B are metal ions, and O is oxygen ion. Above the Curie temperature, the perovskite ferroelectric material has a cubic
FIGURE 1: The crystal structure from the paraelectric phase to the ferroelectric phase of the perovskite structure.

FIGURE 2: Schematic diagram of hysteresis loop of ferroelectric material.

crystal structure. At this time, the positive and negative charge centers coincide and the ferroelectric material is in a nonpolarized state, that is, the paraelectric phase; when the temperature drops below the Curie temperature, the atoms in the unit cell will move the ferroelectric material. Due to the different displacements of the positive and negative ions, the positive and negative charge centers no longer overlap, resulting in an electric dipole moment. Polarization refers to the electric dipole moment per unit volume, that is, at the Curie temperature. The following ferroelectric materials exhibit ferroelectricity in the macroscopic view [10].

As a kind of dielectric material, a ferroelectric material has other characteristics besides showing ferroelectricity, such as dielectric, piezoelectricity, pyroelectricity, photoelectric effect, acousto-optic effect, and optical transition effect [11]. These different characteristics also make ferroelectric materials have a wide range of applications. In the application of ferroelectric materials, ferroelectric memory uses the polarized bistable state for information storage, so it has the advantages of nonvolatile, fast reading and writing, fatigue resistance, radiation resistance, etc. and is considered to be one of the most potential new types of memory at present; ferroelectric memory has been commercialized [12]. The hysteresis loop of ferroelectric materials is shown in Figure 2.

Important parameters such as spontaneous polarization CP, remanent polarization OP, coercive field BG, and ferroelectric loss can be obtained by measuring the hysteresis loop. It is precisely because of these advantages that ferroelectric memory has been widely used in both civilian and military fields [13, 14]. Ferroelectric memory is currently the only new-generation memory that has been widely used, and its advantages and application areas are shown in Figure 3.

Ferroelectric memory allows designers to write data to nonvolatile memory faster and more frequently and at a lower price. The failure of the ferroelectric thin film is caused by the abnormal evolution of the ferroelectric single domain. The essential reasons for determining ferroelectric domains and domain flipping are the microstructure of ferroelectric thin films such as lattice defects, interface terminal types, and oxygen vacancies [15]. With the miniaturization and high integration of ferroelectric memory, the size of ferroelectric thin films in the thickness direction is close to
the nanometer scale and the polarization/domain structure and evolution are increasingly restricted by the abovementioned factors.

2.2. Heavy-Duty Railway Tunnel Structure. The tunnel bottom structure is the main load-bearing structure of heavy-duty railway tunnels, and the load size is mostly determined based on the experience of ordinary railway tunnels. The accurate theoretical calculation method can quickly calculate the dynamic load on the surface of each structural layer and determine the initial load conditions of the calculation model, which has important guiding significance for the design of heavy-duty railway tunnels [16].

Based on the force mode of the track bed structure of the heavy-duty railway tunnel under the action of sleepers, a calculation method for the dynamic load on the sleeper bottom surface is proposed, that is, the static axle load/wheel weight is converted to the dynamic axle load/wheel load according to the train speed, combined with the contact area of the sleeper bottom surface. The additional value threshold of the dynamic load caused by the train is calculated.

$$\sigma = \frac{P * (1 + \beta v)}{BL}, \tag{1}$$

where σ is the stress, P is the static axle load, and β is the dynamic impact coefficient, also known as the velocity influence coefficient.

The dynamic load on the surface of the track bed structure is calculated according to formula (1), which is different from the actual "saddle-shaped" or "triangular" load distribution on the surface of the track bed structure. The error is compensated [17]. Table 1 compares the calculated results of formula (1) with the measured dynamic load threshold on the surface of the track bed structure.

According to D'Alembert's principle, the dynamic differential equation of the structure can be obtained as follows:

$$[M]\{\ddot{\phi}\} + [C]\{\dot{\phi}\} + [K]\{\phi\} = [F(t)]. \tag{2}$$

Among them, M stands for the mass matrix, C stands for the damping matrix, K stands for the stiffness matrix, and ϕ stands for displacement.

Regarding the formula as a constant coefficient differential equation, the displacement of the structure can be used
Figure 3: Ferroelectric memory application.

Table 1: Comparison of calculation results and formulas.

Surrounding rock level	Train axle weight (ton)	Tunnel form	Cumulative dynamic load threshold	Formula calculated value
III	26	Single-line ballastless	81.6	425.44
		Double-line ballast	143.2	425.44
			125.6	425.44
IV	26		129.5	425.44
	29	Two-wire ballastless	163.3	532.74
V	26		120.1	425.44
	29		164.1	532.74

to approximate the velocity and acceleration of the structure through a finite difference expression. One of the most effective solutions is the central difference method. The method assumes

$$\{\phi\} = \frac{1}{\Delta t^2}\left(\{\phi_{t-\Delta t}\} - 2\{\phi\} + \{\phi_{t+\Delta t}\}\right),$$
$$\{\phi_t\} = \frac{1}{2\Delta t}\left(\{-\phi_{t-\Delta t}\} + \{\phi_{t+\Delta t}\}\right). \tag{3}$$

Based on the abovementioned formula, we can get

$$\left(\frac{1}{\Delta t^2}[M] + \frac{1}{2\Delta t}\right)\{\phi_{t+\Delta t}\} = [F(t)] - \left([K] - \frac{2}{\Delta t^2}M\right). \tag{4}$$

The theoretical basis of the finite element method is the

weighted residual method and the variational method. The weighted margin method commonly used is the configuration method, the least square method, the moment method, and the Galerkin method, among which the Galerkin method is the most widely used. The variational method is aimed at solving the continuum problem. For the function of the unknown function, there are

$$\Pi = \int_\gamma F\left(u, \frac{\partial u}{\partial k}\right)d\gamma + \int_\gamma E\left(u, \frac{\partial u}{\partial x}\right)d\Gamma. \tag{5}$$

In the formula, u is an unknown function, F is a specific operator, and E is a specific operator.

Next, the discrete unit is determined, the finite element is divided, and the displacement interpolation function is determined. The matrix form is generally

$$u = \begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} N_i \, 0 \\ 0 \qquad N_i \end{pmatrix} \begin{bmatrix} Ni & 0 & Nj \\ 0 & Ni & 0 \end{bmatrix} = [Ni, Nj, Nm] a^c. \tag{6}$$

In the formula, N is the interpolation function matrix and a^c is the nodal displacement matrix.

According to the element displacement obtained in the previous step, the stress-strain equation of each element can be solved according to the geometric and physical equations and the stress-strain matrix is obtained as follows:

$$\varepsilon = \begin{pmatrix} \varepsilon_x \\ \varepsilon_y \\ \varepsilon_{xy} \end{pmatrix} = Lu = LN a^e = [Bi, Bj, Bm] a^e = B a^e,$$

$$\sigma = \begin{pmatrix} \sigma_x \\ \sigma_y \\ \sigma_{xy} \end{pmatrix} = D\varepsilon = DB a^e = S a^e, \tag{7}$$

$$S = DB = D[B_i, B_j, B_m] = [S_i, S_j, S_m].$$

In the formula, B is the strain matrix, L is the differential operator, S is the stress matrix, and D is the elastic matrix.

Based on the principle of virtual work, the stiffness matrix equation is established as follows:

$$\{F\}^e = [K]^e \{u\}^e. \tag{8}$$

In the formula, $\{F\}^e$ is the vector of the concentrated force on the nodes of the element, $[K]^e$ is the element stiffness matrix, and $\{u\}^e$ is the displacement vector of the element nodes.

The stepwise integration method is a kind of direct integration method. It uses finite difference instead of the derivative of displacement γ'' with γ'' respect to time and expresses the sum with the combination of displacements to obtain the recurrence formula of each time interval and then obtain the response of the entire time history. The content of the method is as follows:

γ' and γ'' can be expressed by displacement γ:

$$\gamma'' = \frac{1}{\Delta t^2} (\delta_{t-\Delta t} - 2\delta_t + \delta_{t+\Delta t}),$$

$$\gamma' = \frac{1}{2\Delta t} (-\delta_{t-\Delta t} + \delta_{t+\Delta t}). \tag{9}$$

The recurrence formula of the stepwise integration method is as follows:

$$\left(\frac{1}{\Delta t^2} M + \frac{1}{2\Delta t} C \right) \delta_{t+\Delta t} = Qt - \left(K - \frac{2}{\Delta t^2} M \right) \delta_t. \tag{10}$$

The definition of the distance function is as follows for all $\vec{x}_1 \in \Gamma$:

$$d(\vec{x}) = \min \left(\left| \vec{x} + \vec{x}_1 \right| \right). \tag{11}$$

From the definition, when the unknown point is on the boundary, the function value is 0. Find the closest point on the boundary and mark the closest point and the value of the distance function is

$$d(\vec{x}) = \left| \vec{x} - \vec{x}c \right|. \tag{12}$$

From the definition of the distance function, the specific definition of the signed distance function is

$$\phi(\vec{x}) = d(-\vec{x}) = 0, \quad \vec{x} \in \Gamma,$$

$$\phi(\vec{x}) = -d(\vec{x}), \quad \vec{x} \in \psi. \tag{13}$$

The signed distance function is a subset of the implicit function and has all the properties of the implicit function discussed in the previous section [18]. Using the signed distance function can simplify many level set methods for dealing with implicit functions.

$$Z_i = T^T (x_{nm} - f \notin R^n. \tag{14}$$

Meet the orthogonal normalization condition, namely,

$$b_j^T b_k = \delta_{jk}, \tag{15}$$

in which, at the time, $j = k$, $\delta_{jk} = 1$; otherwise, $\delta_{jk} = 0$.

$$X'_{ij} = d + BB^T (X_{ij} - d) = d + BZ_j. \tag{16}$$

The formula is inverse transformation. In actual operation, due to the influence of noise data or different transformation methods, there are errors between them, as shown as follows:

$$\varepsilon_j = X_{ij} - X'_{ij} = X_{ij} - d - BB^T (X_{ij} - d). \tag{17}$$

The vibration load caused by train operation is generally a small amplitude load, and the shield tunnel lining and surrounding rock generally only undergo elastic deformation under the action of the train vibration load [19].

2.3. Heavy-Duty Railway. Chloride ions corrode the steel bars, resulting in the continuous loss of the effective cross-sectional area of the steel bars, and the load-bearing capacity is obviously reduced. The corrosion of the steel bars causes the rust expansion effect, causing the concrete protective layer to crack. The continuous development of the cracks also accelerates the corrosion of chloride salts and reduces the bearing capacity of the concrete. Chloride ions invade the reinforced concrete structure and severely reduce the bonding force between the steel bar and concrete, which will cause the steel bar and concrete to not work together normally [20, 21]. Therefore, the corrosive effect of chloride

ions is one of the main reasons that affect the service life of reinforced concrete structures.

Among the diseases of heavy-duty railway tunnels, the most frequent occurrence is water seepage diseases. Water leakage is the most common disease in well-known railway tunnels and has less harm to the tunnel structure. Therefore, the number of diseases at the bottom of the tunnel is ranked second, which is sufficient to explain the heavy-duty railway tunnels. The problem of the disease at the bottom of the tunnel is particularly prominent, which indicates that the bottom of the tunnel is the main place where the disease of the heavy-duty railway tunnel occurs. The conditions of the disease at the bottom of the tunnel are shown in Figure 4.

From the point of view of the location of the disease, different diseases occurred in the upper arch wall structure and the lower tunnel bottom structure of the heavy-duty railway tunnel [22]. Comparing the disease rates of passenger-cargo railway tunnels and heavy-duty railway tunnels, the disease rate of heavy-duty railway tunnels is much higher than the average disease rate of the whole road tunnel, indicating that the high disease rate of heavy-duty railway tunnels is its primary feature [23].

Because the heavy-duty train runs on continuous rails, the train vibration load generated by the interaction between the heavy-duty train and the rail is continuous in space and time. Then, the discrete fastener system distributed at a certain interval in the track structure converts the continuous excitation load on the upper part into multiple vertical excitation loads that act on specific positions of the track structure and then transfer them to the concrete track bed, and then, the track bed is transferred to the shield segment tunnel, and finally, the load is transferred to the soil layer [24]. Among them, under the action of the vibration load of the heavy-duty train, the vibration load curve of each fastener system can be obtained from the actual measurement situation [25].

Based on the vertical dynamics analysis model of the subway train in the shield tunnel, the vibration load of the subway train required for the similar model test is realized by applying a vertical excitation load on the position of the fastener on the concrete track bed and through multiple excitations. The device applies the fastener load at a certain time interval to simulate the effect of the train.

3. Response Characteristic Experiment and Results

3.1. Foundation Beam Calculation. Single-track heavy-duty railway tunnels and double-track heavy-duty railway tunnels are usually only equipped with the floor structure under the condition of level II surrounding rock. Therefore, this example is based on the Winkel foundation beam theory to analyze the single-track and double-track heavy-duty railways of level II surrounding rock. The internal force calculation of the tunnel was the floor structure. The internal force solution of the calculation model for the slab structure of the class II surrounding rock single-track tunnel under the action of 27 t axle load is shown in Table 2.

The theoretical calculation of the bending moment and shear force of the calculation model of the elastic foundation beam bottom plate of the single-track tunnel is shown in Table 3.

We list the converted concentrated loads corresponding to the characteristic points on the surface of the invert structure of the single-track tunnel under the condition of the 27 t axial load of the III-level surrounding rock. The boundary constraint conditions of the invert structure are considered in accordance with the consolidation, and the internal forces of the invert structure under different concentrated loads are solved. The overlay is shown in Table 4.

Then, the internal force of the invert structure under the action of concentrated force is solved and listed in Table 5.

It can be seen that the concentrated load of F1~F5 will cause the bending moment value of the corresponding characteristic point to increase. After the internal force is superimposed, it is found that the bending moment value of the single-track tunnel invert structure under the symmetrical load is also symmetrically distributed and the bending moment value at the center of the line maximum.

3.2. Dynamic Response Characteristic Analysis. Since the left amplitude of the surface load of the invert structure is larger than the right amplitude as a whole, the structural bending moments show the same regularity. The bending moment theory of the invert structure is obtained by summing the bending moments under the action of the equivalent 7 concentrated loads of the 27 t axle load calculated. We compare the theoretical calculation solution of the bending moment of the invert structure corresponding to different working conditions with the measured data, and the results are shown in Figures 5 and 6.

The measured data show that the decrease of surrounding rock conditions and the increase of axle load will increase the bending moment of the invert structure. When the axle load is 30 t, the V-level surrounding rock is the most unfavorable working condition and the bending moment value of the invert structure is the largest at this time. For the lateral distribution of the bending moment of the inverted arch structure, the value of the bending moment of the heavy-duty line, that is, the left line and the right rail position, is the largest and gradually decreases with the increase of the lateral distance. There is a certain error in the analysis of the bending moment under the most unfavorable conditions. According to the most unfavorable principle, it is considered that the calculation method of the curved elastic foundation beam can be applied to the design of the invert structure of the double-track heavy-duty railway tunnel.

The change curve of the additional value $\triangle P$ of the contact pressure of the no. 1 measuring point at the bottom left of the center line and the no. 2 measuring point below the center line with and without water is shown in Figure 7.

It can be seen that when the surrounding rock at the bottom of the tunnel is in anhydrous conditions, the additional value of contact pressure $\triangle P$ below the center line fluctuates at about 6.5 kPa and the additional value of contact pressure on the left and right side $\triangle P$ is stable at about 5.8 kPa but the

overall situation is relatively stable. The additional value of the contact pressure below the center line is slightly reduced compared with that below the center line, indicating that the effect of the excited vibration load below the center line is more obvious than that of other positions.

In order to understand the role of the domain structure of ferroelectric materials, we compare the elastic energy, depolarization energy, and various abilities of the ferroelectric material domain structure and the railway surrounding rock structure under traditional materials. The comparison result is shown in Figure 8.

It can be seen in Figure 8 that after comparing the elastic properties of different materials, it can be seen that the elastic properties of traditional materials vary greatly, and as the number of uses increases, their elastic properties must show a certain degree. In the case of ferroelectric materials, the elastic performance is much better than that of traditional materials and the increase rate is about 30%.

We compare the depolarization energies of the two materials, and the results are shown in Figure 9.

As can be seen, in the comparison of the depolarization energy of traditional materials and ferroelectric materials, the depolarization energy of traditional materials is much higher than that of ferroelectric materials and as the number of tests increases. The depolarization energy of traditional materials shows an upward trend, while the trend of ferroelectric materials shows a downward trend.

We compare the various abilities of the two materials, and the results obtained are shown in Figure 10.

It can be seen that for the supernatural power of materials, the difference between ferroelectric materials and traditional materials is not much. In this simulation test, there is no obvious difference between the values obtained by the two. This shows that ferroelectric materials have no special advantage over traditional materials in terms of abilities.

4. Discuss

4.1. Surrounding Rock Structure.
Based on a variety of research methods such as the on-site large-scale in situ vibration test, long-term remote monitoring, theoretical derivation, numerical simulation, and data investigation, the dynamic characteristics, load theoretical calculation methods, calculation models, and fatigue damage evolution laws of heavy-duty railway tunnel structures are carried out. The dynamic response and stress distribution characteristics of different structural parts of heavy-duty railway tunnels are clarified.

The heavy-duty railway tunnel is divided into two major structural parts, the upper arch wall structure and the lower tunnel bottom structure, to analyze the dynamic response and stress distribution characteristics, respectively. The increase of the axle load of the heavy-duty train, the decrease of the surrounding rock conditions, and the decrease of the

(a) V-class surrounding rock 27 t axle load

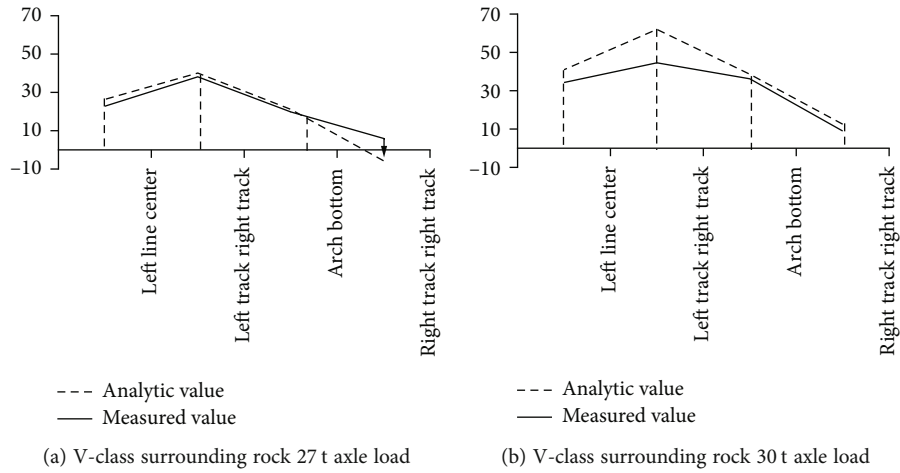
(b) V-class surrounding rock 30 t axle load


FIGURE 6: Bending moment of invert structure of V-class surrounding rock heavy-duty railway tunnel.
FIGURE 7: Pressure changes at the measuring point below the center line.

distance from the train load acting position will increase the dynamic load increment on the surface of the structure and the internal force of the structure.

The dynamic response and stress distribution characteristics of the arch wall structure are clarified: single- and double-line tunnels and ballastless and ballasted tunnel arch wall structures have similar dynamic load distribution laws under various working conditions and under the most unfavorable working conditions (class V) (surrounding rock, 30 t axle load). The maximum power increment does not exceed 5%, which is less affected by the power of heavy-duty trains.

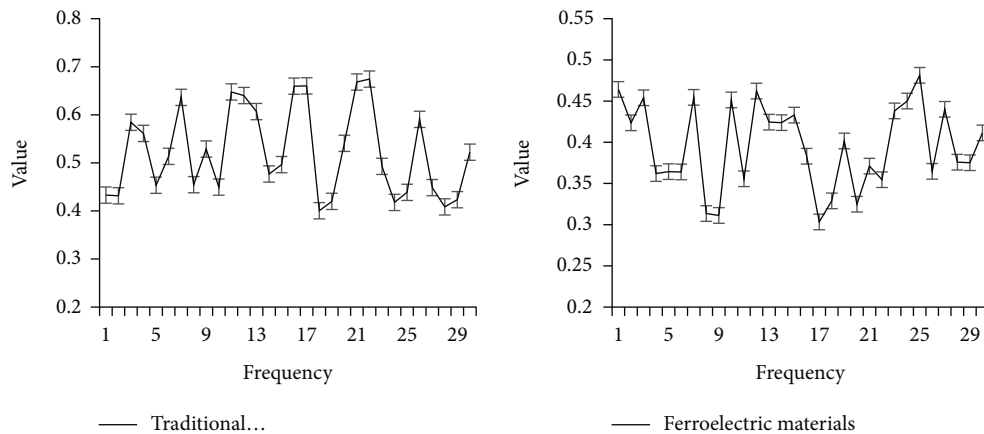
The surface load distribution and vertical transmission laws of the various structural layers of the heavy-duty railway tunnel bottom structure are clarified: (1) the heavy-duty train load gradually decreases with the increase of the vertical depth during the transmission of the tunnel bottom structure, and the track bed structure has a large rigidity and a filling layer. The large thickness has a buffer effect on the dynamic load. When the dynamic load is transmitted to the surface of the surrounding rock, there has been a significant attenuation but the maximum power increase of the single-track tunnel is still 38.26% and 9.6% of the double-
FIGURE 8: Comparison of elastic properties of different materials.
FIGURE 9: Comparison of depolarization energy.


FIGURE 10: Comparison of various abilities.

track tunnel is much higher than the arch wall structure. Therefore, the dynamic impact of the heavy-duty train on the tunnel structure is mainly focused on the structure at the bottom of the tunnel. (2) In the single-track heavy-duty railway tunnel, due to the symmetry of the structure, the lateral distribution of the additional train load on the surface of each structural layer at the bottom of the tunnel is in a "triangular" distribution, which is represented by the largest line center and gradually attenuates with the increase of the lateral distance. (3) In double-track ballasted and unballasted heavy-duty railway tunnels, the dynamic load distribution on the surface of the track bed, the surface

of the invert, and the surface of the surrounding rock shows that the dynamic effect of the train is mainly concentrated on the position of the track of the heavy-duty line. There is a difference in the dynamic load distribution on the surface of the two types of ballast beds. The surface of the filled layer of the ballastless bed is "saddle shaped," and the ballast bed has a "triangular" load, and the dynamic load value of the ballast bed is higher than that of the ballastless bed. (4) The influence rate of the axle load on the dynamic increase of the tunnel bottom structure is up to 33.5%~48.2%, and the influence rate of surrounding rock conditions is up to 19.7%~24.3%. Therefore, axle load is the main factor affecting the dynamic response of the tunnel bottom structure.

4.2. Ferroelectric Materials. Ferroelectric materials are widely used in the manufacture of modern electronic devices due to their excellent dielectric properties, piezoelectric properties, and polarization reversibility. The microstructure of ferroelectric materials determines the macroscopic properties of ferroelectric materials to a certain extent, and the simulation of their microstructure is of great significance in material design. At present, the traditional phase field method used to calculate and simulate ferroelectric materials has limitations such as many material parameters, energy potential wells, and unobvious symmetry, which seriously hinder ferroelectric materials, especially the microstructure of new ferroelectric materials.

This paper establishes a theoretical framework for nontraditional phase field simulation of tetragonal and orthogonal ferroelectric phases. Based on the characteristic function of the ferroelectric material variant, use it as the phase field simulation sequence parameter to construct the anisotropic properties of the ferroelectric variant, which presents a multipotential well structure, and use it to replace the traditional phase field method to describe higher-order polynomials in ferroelectric materials. Using the anisotropic properties of ferroelectric variants to replace the polynomial of the internal energy of the traditional phase field method, an unconventional phase field method suitable for tetragonal and orthogonal phase ferroelectric domain structures has been developed. The nontraditional phase field method requires few parameters and can also describe the multipotential well structure of the ferroelectric material variant, and the potential well structure is obvious and the symmetry is obvious.

5. Conclusion

This study found that under different axle loads and surrounding rock conditions, the fatigue damage of the tunnel bottom structure of the single- and double-track heavy-duty railway tunnel is significantly higher than that of the arch wall structure and it is mainly concentrated in the position of the heavy-duty line track and decreases with the increase of depth. The track position of the infill structure began to show damage after 50 years of operation and developed downward; when the operation time exceeds 100 years, the fatigue damage of the inverted structure and the damage of the infill structure are connected. The fatigue damage of the single-track tunnel is always symmetrical, while the

double-track tunnel expands to the bottom of the side trench structure half of the heavy-duty line. Of course, there are some shortcomings in the research of this paper. The data studied in this paper are basically based on simulation results, and no real field investigation has been carried out. In the collected data, the factors that may damage the track in the tunnel are not considered. Completely, the experiments in this article cannot draw very perfect conclusions. This also requires that in today's research, we need to increase the scope of data and conduct real data investigations in order to obtain better research results.

In the rapid development of urban traffic, the small clearance interchange tunnel has always been a difficult problem for heavy-duty railways, so special requirements are also put forward for materials. Bainite steel with excellent comprehensive mechanical properties is considered to replace traditional high manganese, the best material for steel. This article first improves the process of the material and analyzes the structural dynamics of the material through different isothermal cooling to analyze the different performances of the material on the heavy-duty railway. Using traditional theoretical data analysis, theoretical data calculation, numerical analysis simulation, and on-site engineering monitoring technical means is to complement the construction of the soft rock underground tunnel in the subway section at the intersection of the small clear distance line to the existing surrounding rock tunnel wall in the section. The degree of deformation affects the change law, and the related technical issues of engineering control are analyzed. Finally, the control measures of full-face grouting reinforcement with steel flower pipes and the final construction plan of constructing the left line, right line, and undercut section in sequence are proposed. FLAC numerical simulation software was used to complete the feasibility evaluation of the control measures for the deformation of the ground and lining induced by the construction of the cross tunnel. The results show that the maximum deformation of the ground surface is reduced by 35.4% compared with no control measures, and the longitudinal deformation range of the ground surface and the vault is reduced by 28.9%.

1. Introduction

Throughout the world of underground cities, the smooth utilization, development, and comprehensive utilization of public space in underground cities have been rapidly developed and gradually become an effective and important way to effectively solve the serious crisis of underground resources and local soil ecological environment pollution in various underground cities. After our country has entered the 21st century, our country's underground and aboveground urban rail transportation vehicle transportation system infrastructure has initially entered a new stage of rapid, healthy, and orderly development. According to statistics, as of the end of 2016, a total of 30 major large- and medium-sized cities in northern mainland China have completed and opened underground and aboveground urban rail transit automobile public transportation, a total of 133 operating subway lines, and a total of annual operating subway line mileage. The maximum length is 4152.8 kilometers, of which the cumulative operating mileage of Beijing Metro in 2016 was 3168.7 kilometers, accounting for 76.3%. Construction of Nanning Metro began in 2011, and Line 1 was opened

for operation in September 2016. Up to now, Nanning has planned 8 lines, including 187 stations, 22 transfer stations, and 4 vehicle lines.

With the continuous increase in the depth of underground space excavation and planned mileage, the number of stations and transfer stations will also continue to increase, and the cross construction of two or more tunnels will become increasingly apparent. In addition, due to the dense high-rise buildings in the urban areas of our country and the developed subway underground tunnel transportation network, the building pile foundations, municipal tunnel pipelines, underground tunnel structures, and other ancient buildings during the construction of subway underground tunnels have formed the use of space in the urban newly built subway tunnels. Large space restrictions cannot be avoided by design. Therefore, the probability of overlap between new tunnels and existing tunnels is greatly increased. However, the continuous construction of the existing new building tunnels will cause great disturbance to the surrounding building stratum structure, causing three or even four times of large stress between the existing new tunnel and the structural stratum, causing the existing new tunnel and steel structure stratum to occur the stress adds a large internal force and stratum deformation, causing sudden surface deformation values, and there is a major construction risk. Excessive deformation of the tunnel may directly cause the main structure of the existing domestic road tunnels to fail to fully meet the road operation safety requirements, and the ground will also have depressions. When severely damaged, road operations and traffic safety accidents will occur directly and cause great operational safety hazards. In order to ensure the safe and smooth operation of our country's urban rail network transportation, how to effectively supervise, control, and accurately evaluate the direct impact of the delayed construction of urban new railway tunnels on the existing urban new tunnels has gradually become a key academic research topic today.

At present, the research on the influence of new energy materials on the dynamic interaction between the surrounding rock and structure of the heavy-duty railway tunnel with a small clear interval is mainly in these directions. Yanowitz et al. layered the dolomite and rock limestone together and performed a separate downgrading modulus treatment. There was a problem that the dolomite rock surrounding rock model hierarchical modulus was low. According to the surrounding rock model ED (China Dynamics Yang) for tunnel engineering along the Chengdu-Chongqing Railway Modulus classification and quantitative model classification processing system, the dolomite surrounding rock is separately downgraded, which solves the problem of low dolomite surrounding rock model classification modulus, but the materials targeted in this direction are relatively limited [1]. Correa et al. established a three-dimensional numerical prototype virtual statistical model of the length of the subway tunnel based on the various geological surrounding rock deformation risk conditions in the domestic subway tunnel site engineering design and the results of this research, and calculated the collapse of the base layer of the domestic subway exit tunnel through the tunnel numerical prototype

simulation, the design process of the surrounding rock deformation during the construction, and the analysis of the deformation process of the base layer of the subway tunnel. After the design is completed, the exit tunnel of the existing domestic subway tunnel station exit tunnel and the newly built foreign existing domestic expressway Yangtze River Bridge station tunnel subway base collapsed surrounding rock statistics on the relatively large risk of construction deformation due to the collapse of the arch bottom. It is concluded that there may be a high-strength plasticity metro tunnel arch underneath part of the area under the subway arch of the newly built domestic existing expressway station tunnel, and there may be a greater risk of deformation of the surrounding rock when the base of the subway tunnel collapses. There is a certain amount of simulated data [2]. In the actual construction design stage of the railway elevated tunnel project, Yamada et al. formulated practical and feasible overall construction technology according to the actual construction situation of the weak layer and the horizontal hard rock layer in the railway tunnel, in order to effectively ensure the entire tunnel construction design project. Quality and safety are effectively guaranteed, and a detailed discussion of how the overall construction technology of the horizontal hard rock layer of the tunnel should be applied in the actual railway tunnel engineering construction design process is given, but the research is too theoretical [3]. Liu et al. conducted a comprehensive analysis of the movement measurement of the local stress and deformation of the surrounding rock structure of 8 underground tunnels located in 12 shallow and deep buried sections of the underground tunnel, and analyzed the tunnel surroundings of each section of the shallow tunnel under the shallow and deep buried section of the underground tunnel. The research and analysis results of the local movement and deformation of the rock structure's overall movement law are compared and analyzed in depth. The research and analysis of the overall local deformation movement law of the surrounding rock structure of each section of the underground tunnel is divided into the first rapid movement displacement of the surrounding rock of the underground tunnel-rapid movement displacement stable deformation—slow motion displacement stabilizes deformation—fast displacement stabilizes four different process stages. Through the simulation of the statistical numerical comprehensive analysis of the tunnel FLAC3D, the method of supporting treatment of the advanced and late construction conditions and the supporting method of the advanced and late construction treatment and the supporting method of the advanced construction support and the advanced construction treatment method of the underground tunnel are analyzed in depth. The overall local deformation of the rock structure is directly affected by the movement, and this analysis has not kept up with the background of the times [4]. Rynning et al. take the tunnel underneath the surrounding rock of the railway bridge section as an example. It conducts on-site monitoring through the deformation of the surrounding rock and performs necessary numerical simulations. Through statistical analysis of the experimental results, it can be seen that in the process of randomly excavating objects, the displacement of the object

section near the face of the object changes greatly, the maximum and minimum of the vertical square displacement are at an arch, and the maximum and minimum horizontal displacements are it is in an arched waist, and the material requirements of this research are too low [5]. Sonntag, Based on the situation of a large-scale railway branch tunnel in the planning, construction and design stage, Sonntag D studied the classification of surrounding rock and analyzed and guided the construction design and planning of the railway tunnel in combination with the thickness variation of the tunnel surrounding rock and the influence of related factors. At the same time, it provides an important reference and evaluation basis for the construction evaluation of similar tunnel projects, but the data used is not representative [6]. Sorgenfrei and Tsatsaronis take the railway sandy tunnel deep-buried railway single-track tunnel railway surrounding rock tunnel as the key object of the subject research; through the numerical statistical measurement and analysis of the measured railway load data of the railway surrounding rock tunnel, the research establishes the railway based on the BQ numerical calculation index. The numerical calculation and analysis method of the measured load of the surrounding rock, but the application range of this method for calculating the measured load of surrounding rock is too narrow [7].

The two materials used in the main test materials in this paper are the new Si-Mn-Cr series low- and medium-sized carbon fiber low-alloy steel developed by Xihua University. The low-alloy steel is heated under air-cooled and high-pressure conditions. Bainite without activated carbonized substance, through the contact fatigue strength test of the roller rolling gear, the direct influence of the smooth difference between the roller load and the gear rolling on the rolling contact fatigue test performance of the alloy steel used in the switch fork machine of the heavy-duty high-speed railway in China is studied. And further analyze the structure, phase, fracture morphology, and hardness change law and explore the fatigue damage mechanism and fatigue performance of heavy-duty railway frog steel. Using traditional theoretical data analysis, theoretical data calculation, numerical analysis simulation and on-site engineering monitoring combined technical means is to construct the soft rock underground tunnel in the subway section at the intersection of the small clear distance line to the existing soft rock tunnel wall in the section. The degree of deformation affects the change law, and the related technical issues of engineering control are studied in depth.

2. Overview of the Close Construction of Subway Tunnels

2.1. Classification of Close Construction of Subway Tunnels. The primary technical problem that the direct technical construction of underground construction projects must face in the near future is that the close construction of new underground constructions may have a certain impact on the original air stability performance of the underground construction structure, breaking the original balance mode. The main reason for the impact of this change is closest to the essence. The continuous construction of the new sur-rounding rock project may cause the stress system in the solid surrounding rock to redistribute again and again, which directly leads to a series of surrounding rock mechanical and physical behaviors. This force characteristic is related to many factors such as engineering and hydrogeological conditions, engineering construction sequence, spatial position relationship, and construction method, such as loading, unloading, horizontal, vertical, and spatial different effects under different conditions [8, 9].

Generally, the construction when the new construction is adjacent to the existing construction and the construction of the new construction may adversely affect the normal function use of the existing construction is called the near construction. When the new construction and the existing construction are both tunnel constructions, those that meet the above conditions can be defined as the adjacent construction of the tunnel construction. From the perspective of the construction location relationship of the grounding space, the construction location of the short-distance grounding of the tunnel can be divided into three kinds of construction location spatial relations: one-way parallel, overlapping, and two-way crossing [10, 11].

2.1.1. Side Wear. When a new tunnel passes through an existing tunnel, the surrounding rock and stratum are disturbed due to the construction of the new tunnel, and the surrounding rock of the existing tunnel will also relax. Therefore, the load on the lining of the existing tunnel will increase. The lining structure will undergo a certain tensile deformation to the new tunnel side, and biased pressure may occur. In subway engineering, the side-crossing problem mostly belongs to section crossing or the foundation pit crossing existing tunnel.

2.1.2. Underwear. When the newly built tunnels on both sides pass through the lower intersection of the existing tunnels on both sides, the two tunnels are in a downward crossing relationship. With the continuous excavation of the two newly built line tunnels, the interlayer lining space structure of the existing line tunnels may also continue to sink. At the same time, due to the excessive settlement of the tunnel, it is very likely that the gradient is unevenly distributed. The main reason is the change in the positional relationship of the interlayer space structure of the two tunnels. If the location is different, the excessive settlement may cause the track structure variation. The settlement value is too large to exceed the tunnel management standard, resulting in the temporary suspension of trains along the line.

2.1.3. Put on. When the new tunnel crosses the upper part of the existing tunnel, the two tunnels are in an upward pass relationship. With the excavation of new tunnels, due to the unloading effect of the soil, the existing tunnels will undergo vertical uplift deformation, which may be unevenly distributed. If the deformation is too large, it will also bring safety hazards to the safe operation of the train.

According to the way of crossing, it can be divided into three types: up, down, and side. Underpass mainly refers to crossing the existing sections, stations, buildings, bridges,

pipelines, railways, highways, etc.; upward crossing mainly refers to new projects crossing existing sections and underground pipelines; side crossing can refer to new projects crossing pile foundations or parallel tunnels, and their structural relationships are shown in Figure 1.

Here is a basic classification according to the characteristics of the tunnel force conditions under different force elements of the remote connection time, space, and remote connection construction method, which can be roughly divided into two newly built simultaneous tunnels in the short-distance and long-distance period. Two or more new tunnels are short-distance close to each other during the construction of two basic force types [12, 13].

The highway design requires that the new construction of the existing highway tunnel is connected with the new existing tunnel and the new highway tunnel is connected in coordination with the new construction of the existing highway tunnel according to the highway design requirements. The connection of the newly built highway tunnel also occupies the relationship between the space distance and the location of the tunnel as well as the mobile rate. It is subdivided into three cases: parallel tunnels, overlapped tunnels, and interlaced tunnels, as shown in Table 1.

Two or more new tunnels will be constructed at the same time at a close distance. According to the spatial position relationship between the new tunnel and the neighboring existing tunnels, Table 2 further subdivides them into three cases: parallel tunnels, overlapping tunnels, and intersecting tunnels [14, 15].

2.2. Zoning of the Impact Degree of Close-Up Construction. According to different classifications of close-range construction of subway tunnels, the influence degree of construction is also different. The extent of the impact of the construction of a new project in the underground project on the surrounding existing projects varies depending on the spatial position and can be expressed by the degree of proximity. At present, there are few researches on the adjacent tunnel engineering at home and abroad, and most of them are based on a scattered specific project summary, lacking systematic rules. The earliest method to study the construction of short-distance connection engineering is Japan. Due to the small land area in Japan, in order to make full use of the existing underground resources, there are many application cases of new tunnel connection engineering in the construction of short-distance connection engineering. Promulgated the "Guidelines for the Close-up Construction of Existing Railway Tunnels", which has carried out a more comprehensive and systematic theoretical explanation of the research on the problems of the construction of the short-distance connection engineering tunnels, and has directness in solving the construction problems of the existing underground railway tunnels. This paper comprehensively analyzes and considers various factors such as the building scale, construction design plan, geological space movement relationship between the structures, engineering, and ground hydrogeological objective conditions of different newly built tunnel projects, so that the construction of different newly built projects can be compared to the different

existing railways. The direct impact caused by the performance of the structure is of different severity and can be divided into four categories: the more specific and intangible impact consideration scope, the attention consideration scope, the consideration scope of measures taken when necessary, and the careful consideration scope, as shown in Table 3.

When a new line traverses an existing line, the division of its proximity is shown in Figure 2.

For the construction of two or more crossing tunnels, it is necessary to consider both the lateral impact range of the new tunnel construction on the existing tunnel and the longitudinal impact range that may be affected. The vertical and horizontal impact range of the existing tunnel by the new tunnel is shown in Figure 3.

When the longitudinal oblique line of the new tunnel in the existing tunnel overlaps with the area where the weak damage of the existing tunnel is weakly damaged and the damage is doubled, the intensity of the tunnel longitudinal oblique line overlaps again. If the landslide strength of the existing newly built new tunnel is weak and the damage affects the damage hazard again and the longitudinal slash of the tunnel overlaps again, then the strength of the newly built longitudinal landslide of the existing tunnel is the weak damage effect. The area of damage hazard is divided into the intensity range, and at the same time, the part of the intensity influence range is still not necessary to separately focus on the comprehensive consideration of the strength rupture effect of the newly built transverse landslide of the existing tunnel [16, 17].

Regarding the new longitudinal landslide, it can be divided according to the range of damage intensity. The format of the strength impact division criteria can be redetermined according to the Moore-Coulomb strength division criteria format and the potential longitudinal landslide strength fracture cross section of the newly built longitudinal landslide. The oblique angle of the fracture cross section is generally $45° + \varphi/2$. Among them, the division scope of the hazard zone for the strength damage of the newly built longitudinal tunnel can be divided according to the longitudinal oblique line of the newly built tunnel and the existing tunnel in which the transverse oblique line of the new tunnel overlaps the longitudinal oblique line on the main axis. The line position is redivided to increase the 2D intensity influence division range (D is the equivalent diameter of the newly built tunnel). Among them, 2D is the depth range involved in the oblique line deformation of the ground outside the included angle of the tunnel fracture [18, 19]. In the same way, the $45° + \varphi/2$ stratum oblique line from the top of the existing domestic newly built tunnel intersects the longitudinal and horizontal axis of the domestic newly built existing tunnel structure, which can be used to determine that the existing domestic tunnel structure of the affected vertical axis intersects the construction scope of the new tunnel, as shown in Figure 4.

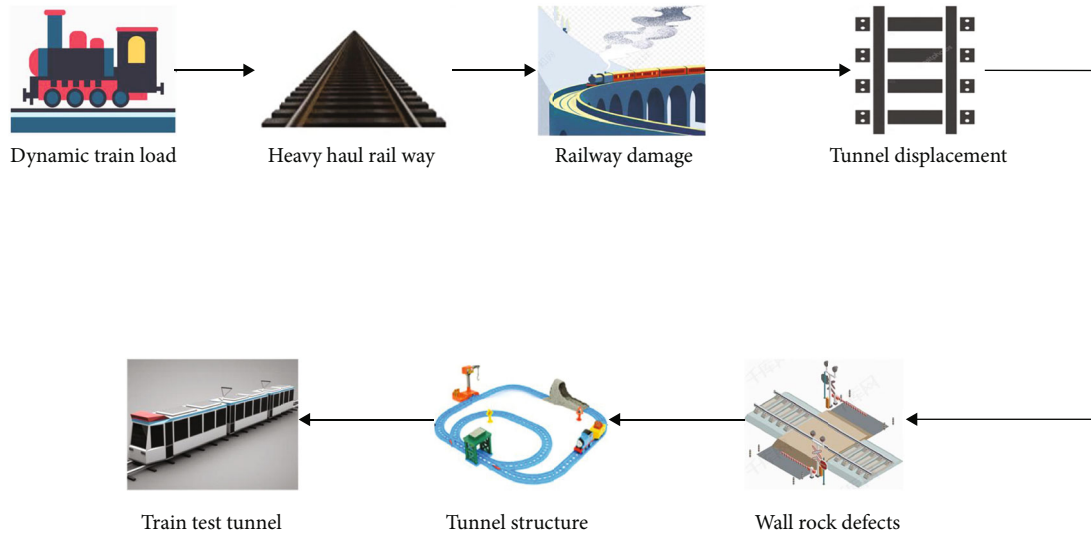
For the specific nearby construction of underground engineering, the size of the existing tunnel and the newly built tunnel and the design distance between the two are known. According to the Moore-Coulomb failure criterion,


FIGURE 1: Analysis of the relationship between the various structures of the railway tunnel.

TABLE 1: Construction classification and engineering application of new tunnels adjacent to the existing tunnels.

Engineering applications	Type
When constructing new tunnels in parallel with the existing tunnels and planning new subway lines	Tunnel side by side
Due to the space conditions, the two tunnels must be built on top of each other	Tunnel overlap
Due to space constraints, the two tunnels must be constructed in a staggered way	Tunnel staggered
Pass through the existing tunnel from the upper or lower part of the existing tunnel. It is a transfer node for multiple lines	Tunnel crossing

TABLE 2: Construction classification and engineering application of two or more new tunnels at the same time.

Engineering applications	Type
Due to conditions, the two tunnels were constructed in parallel to the left and right at a short distance. Usually, the two tunnels are mostly uplink and downlink	Side by side tunnel
Due to conditions, the two tunnels were constructed in close distance and overlapped with the upper and lower ones, which are more common in the upper and lower lines of the tunnel	Tunnels overlap up and down
Due to conditions, the two tunnels were built diagonally and staggered at close distances.	Tunnel diagonally staggered
Due to conditions, the space of the two tunnels is twisted and cross-constructed, which is mostly seen in the simultaneous construction of two subway lines or the positional relationship between the main line and the vehicle line	Tunnel space cross torsion

TABLE 3: Division and measures of proximity.

Proximity division	Divide content	Measure content
No influence	Do not consider the scope of the impact of new construction on the existing structure	Generally do not take corresponding measures
Pay attention to the scope	Usually no adverse effects but a certain range	Usually by adopting appropriate construction methods, based on the monitoring data during construction combined with the allowable values of displacement and deformation of the existing structure, comprehensively determine whether to take other measures

the impact range of the nearby construction can be determined. The close construction of shield tunnels and general undercut tunnels has similar rules [20, 21].

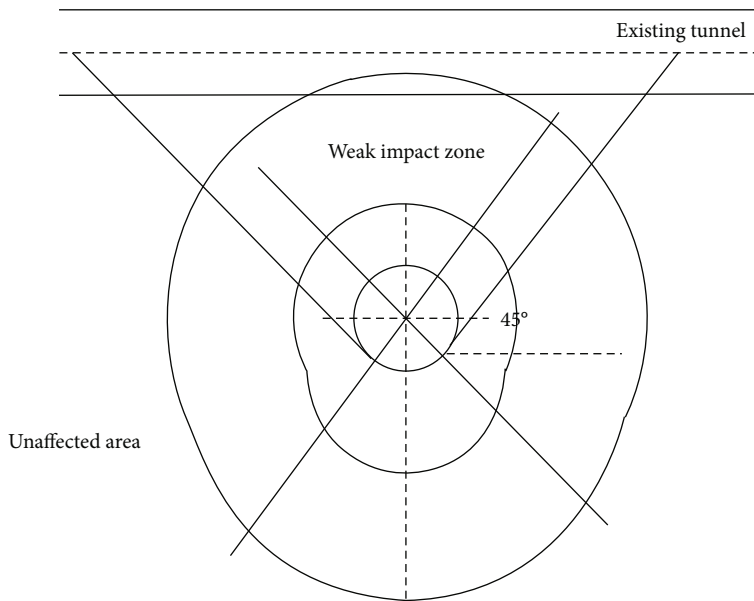
For a shield tunnel, along tunneling direction, the cutterhead pushing pressure and cutterhead excavation have a disturbance influence zone on the front soil. When there are
FIGURE 2: Dividing the proximity of a new tunnel through an existing tunnel.


FIGURE 3: The existing tunnels affected by the construction of new tunnels.

existing structures in this influence zone, it is the approach construction. This process is the shield which passes through the affected zone. At this time, the main moving soil body in front is generally set to the pressure control state of the compressed moving soil, and it can directly face the direction of the upper shield tunnel construction area to introduce another shield tunnel that is tangent to the existing shield tunnel of the upper shield. The longitudinal shear of $45° - \varphi/2$ with the height of the tunnel horizontal plane passes through the line of the failure zone. At this time, when the existing tunnel of the upper shield machine intersects with the shear failure zone in a straight line, it can be directly considered that the existing tunnel of the upper shield machine

has entered a larger area that passes through the influence zone [22, 23]. In the same way, introduce a horizontal shear line that is tangent to the existing shield tunnel passing downward and is $45° - \varphi/2$ to the horizontal plane of the tunnel to pass through the failure zone. When the lower shield tunnel has an existing shield tunnel and when the tunnel and this line have not been sheared and intersected, it can be directly considered that the existing tunnel of the upper shield has entered a larger area that passes through the influence zone, as shown in Figure 5.

2.3. Analysis of Risk Factors in the Existing Tunnel Engineering. Urban subway tunnel construction has a great
Figure 4: Construction scope of new tunnels affecting the existing tunnels.

impact on the surrounding environment. The deformation of the existing tunnels mainly depends on the engineering and hydrogeological conditions of the tunnel, the characteristics of the new tunnel, the characteristics of the existing tunnel, and the spatial relationship between the new tunnel and the existing tunnel. Among them, engineering hydrogeology is particularly important, which is an uncontrollable factor. The spatial position relationship between new tunnels and the existing tunnels is extremely sensitive to the deformation of the ground and lining [24, 25].

Whether it is a new underground tunnel project or an existing tunnel project, it is in a complex hydrogeological environment. Taking Nanning as an example, the Quaternary stratum in Nanning area mainly includes fill, silty clay, silt, silt sand, medium-coarse sand, round gravel, and pebbles; the lower bedrock is mostly soft rock, such as mudstone and siltstone . The cohesive force of silty clay is 20~65 kPa, the internal friction angle is 5~15°, and the characteristic value of foundation bearing capacity is 90~220 kPa; the cohesive force of silt clay is 15 kPa, the internal friction angle is 10°, and the characteristic value of foundation bearing capacity is 120 kPa. Among them, the characteristic value of foundation bearing capacity indicates the maximum allowable foundation pressure of the building foundation, and if the pressure exerted by the foundation on the foundation is greater than this value, excessive deformation may occur [26].

In this paper, the length of the shield machine is considered to be 9 m. Considering the larger model, the excavation distance is 3 m each time, that is, two ring segments. In the process of shield tunneling, in order to maintain the stability of the excavation surface, it is necessary to adjust the soil pressure inside the shield machine's soil bin from time to time. In the actual construction process, the supporting pressure is 0.25 MPa. During the excavation of the soil of each section of the tunnel, a supporting force of 0.25 MPa was added to the face of the tunnel at the same time. When the shield machine enters the hole completely, the relevant commands are compiled according to the process shown in Figure 6 until the shield machine exits the hole [27].

On the one hand, the impact of the construction of the new project on the existing subway tunnel is mainly trans-mitted through the deformation of the interlayer soil. On the other hand, the physical and mechanical properties of the stratum in which the existing subway structure is located also have a greater impact on the stratum deformation induced by construction disturbance, and the deformation will be transferred to the existing structure. Therefore, the deformation of the soil between the newly built tunnel and the existing tunnel during continuous failure is directly related to the deformation value of the existing structure. In areas with better stratum conditions, the structural deformation of the existing subway tunnels induced by the construction of new tunnels is small, while in areas with poor soil mechanical properties, rich water content, and high groundwater levels, due to the self-excavation of the new tunnel construction, poor stability, resulting in increased stratum deformation, and due to poor stratum mechanical properties, the existing subway structure will deform even more [28].

3. The Impact of New Energy Materials on the Dynamics Analysis of Heavy-Haul Railways

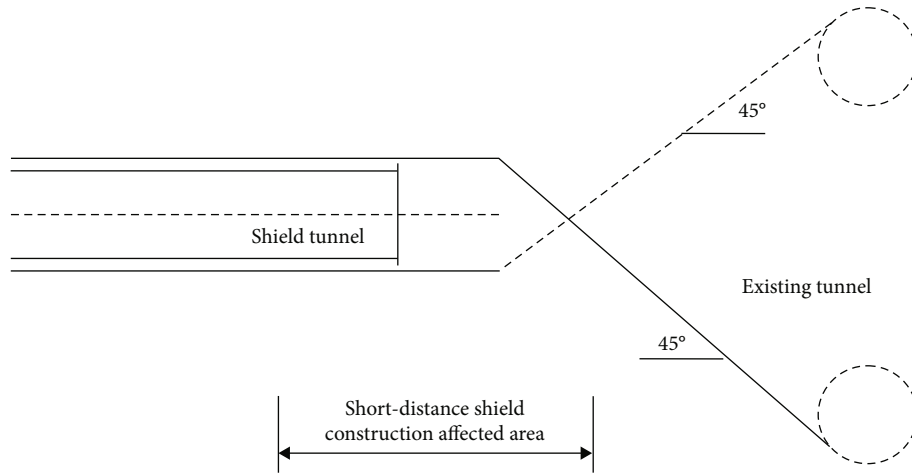
3.1. Changes in the Performance of Steel Used in Heavy-Duty Railway Frogs. After different heat treatment processes, the hardness of steel used on the plosive of heavy-duty railway is improved to some extent compared with that of the original sample. At the same temperature of austenite steel integrated treatment, the maximum hardness of the iron alloy steel used on the frog of heavy-duty high-speed railway train after air cooling is about 47.4 HRC, the highest hardness of the steel used after heat treatment of isothermal boiler is next, and the lowest iron hardness of the steel used after furnace cooling is about 42.3 HRC. This is mainly because the iron alloys used in China's high-speed railways cannot be rapidly cooled, and the heat dissipation is slow, and the heat dissipation performance of metal alloys and metal elements such as carbon atoms and iron is poor. The rich carbon sulphide austenite will rapidly diffuse and transform to other carbon-rich alloy martensite, which will increase the super-heated and undercooled saturation of the structure of the rich carbon alloy martensite, and improve the solid activity and insolubility of the carbon contained in the steel during


FIGURE 5: Schematic diagram of shield tunneling through adjacent affected area.
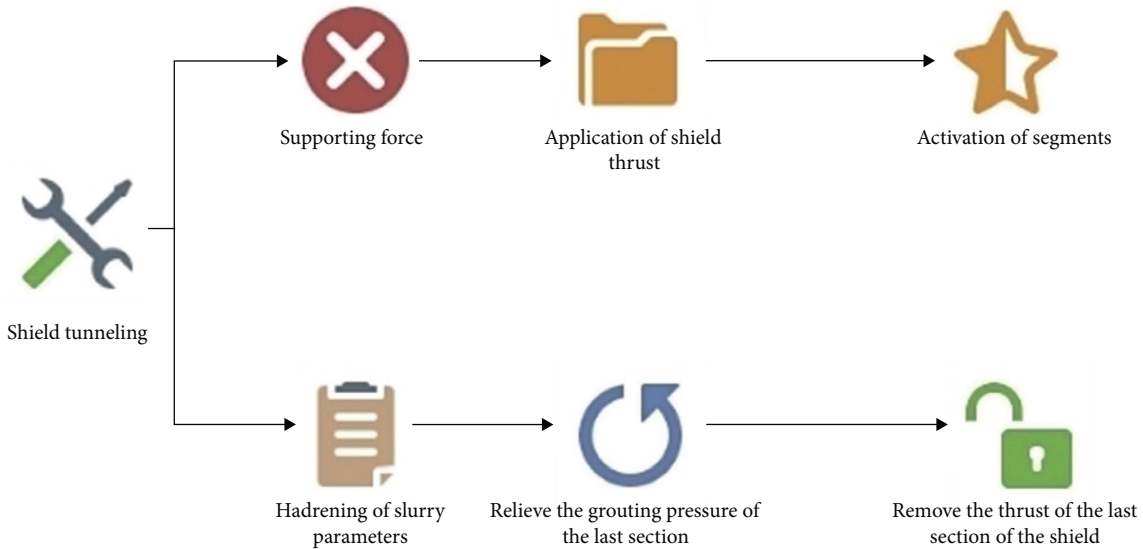

FIGURE 6: Shield tunnel simulation method.

the reaction of the main carbon-generating martensite heating process. In addition, the supercooling diffusion rate of the iron and steel used on all types of train vehicle frog of heavy-duty China high-speed railway is larger in air cooling, and the steel generated by carbon mixture in steel species has more understrip bainite, so the supercooling hardness of steel is the highest. Since the steel in China's high-speed railway has the slowest cooling diffusion rate in the furnace, the cooling diffusion of carbon and other metal alloys is insufficient, and the steel stays in the high-temperature environment for a long time during the cooling process, so the hardness is extremely small. The change rule of hardness of steel sample used on heavy-duty railway frog after heat treatment is shown in Figure 7.

When heat treatment is performed under isothermal conditions, some metal alloys and nonmetallic carbons in iron and steel used in frog vehicles for heavy-duty China high-speed railway frog vehicles and train-mounted iron

and steel have low thermal diffusivity and heat dissipation reaction capacity under isothermal conditions. It is not possible to directly carry out high-temperature thermal diffusion for a long period of time or short distance in the residual undercooled and overheated austenite. Bainite will grow in the carbon-depleted zone containing a small amount of residual undercooled or warm and overheated high-temperature austenite at the grain boundary temperature. In nucleus, with the growth of bainite, the content of metal elements such as Si hinders the rapid precipitation of metal carbides in the grain boundary temperature, which is more conducive to the continuity of the high-temperature cold-hot reaction of the grain boundary. The metal steel of steel has better compression resistance and impact toughness; however, when heat treatment is performed at a higher grain boundary temperature isothermally or heat treatment at a temperature, the heavy load capacity of China's high-speed rail will vary. The carbon content of some steel with
FIGURE 7: The effect of heat treatment on the hardness of heavy rail frog steel.

a small amount of residual supercooled and superheated austenite metal elements may also increase significantly, so its impact toughness can be improved. For the same cooling method, increasing the austenitizing temperature will increase the impact toughness value of heavy-duty railway bainitic steel. This is mainly because they increase the temperature of the two-austenite carbon gas compound, the energy diffusion between the two elements of carbon and metal alloys is more complete, the carbon content in the austenite increases and the stability is enhanced, and the final amount retained austenite. The increase makes the impact toughness increase to a certain extent. Compared with the traditional high manganese steel, the steel used in heavy-haul railway has to go through more processes and be made more complex, so its performance will be stronger. Figure 8 shows the influence of heat treatment on the impact toughness of bainitic steel used in heavy-duty railway frogs.

3.2. Dynamic Analysis of Heavy-Duty Trains. Heavy-haul train generally refers to a kind of a super-long and overweight freight train which is organized by large special trucks and pulled by two or more machines on the transportation line where the freight volume is concentrated. Heavy-haul trains have large load capacity. There are a large number of trains. The primary task of high-speed railway bridge research is to determine the impact of train operation on the substructure. This has always been the focus and difficulty of engineering research. At present, there are two main methods. The first is to use structural dynamics to establish train and substructure and the overall coupled dynamic equation of the track, but due to the many factors involved in the train-track coupled dynamic equation, it is difficult to solve the equation and it is difficult to apply it to practical engineering. The second is to directly fit the train load expression considering factors such as vehicles and tracks. However, there are many factors that affect the operation of high-speed trains, so it is difficult to determine an accurate expression that considers all influencing factors, but it is possible to obtain simplified expressions that can be applied to engineering problems. At present, there are mainly two train load simulation methods: the first kind of

track vibration acceleration is regarded as a random process, and the acceleration data is transformed into a force model by a data transformation method; the other is based on the excitation caused by track irregularity and a comprehensive consideration of vehicle and track factors for load fitting.

The differential equation of vehicle dynamic balance can be expressed as follows:

$$
\begin{aligned}
m_2 y_1 + c(y_1 - y_0) + k(y_1 - y_0) &= 0, \\
y_r &= y_1 - y_0, \\
m_2 y_r + c y_2 + k y_r &= -m_2 y_0.
\end{aligned}
\tag{1}
$$

Using the D'Alembert principle, the interaction force between the wheel and rail is as follows:

$$
P(t) = (m_1 + m_2)g + (m_1 + m_2)y_0 + m_2 y_r.
\tag{2}
$$

The idea of the track measured acceleration method is mainly based on the random vibration load model. By treating the environmental vibration induced by the train as a random process, the track measured acceleration data can be expressed in the following complex series:

$$
\begin{aligned}
x(t) &= 2 \sum_{k=1}^{(N/2)-1} |C_K| \cos (k w_0 t + \beta_k), \\
C_K &= \frac{1}{N} \sum_{n=0}^{N-1} x(t_k) \exp \left(-i \frac{nk\pi}{N} \right).
\end{aligned}
\tag{3}
$$

Assuming that the orbital vibration is a Gaussian stochastic process with a zero mean value, the following trigonometric expression of acceleration can be obtained through numerical changes:

$$
x(t) = 2 \sum_{k=1}^{(N/2)-1} a_k \cos (k w_0 t) + b_n \sin (k w_0 t).
\tag{4}
$$
FIGURE 8: The effect of heat treatment on the impact toughness of steel used in heavy-duty railway frogs.

In the above formula,

$$a_k = C_K + \overrightarrow{C_K},$$
$$b_n = i\left(C_K + \overrightarrow{C_K}\right), \quad (5)$$
$$w_0 = \frac{2\pi}{N\Delta t},$$

where a_k represents the change amplitude of a numerical value, b_n represents the acceleration, and w_0 represents the period of track vibration.

Incorporating Equation (4) into the dynamic balance differential equation, ignoring the influence of transient response, the following load excitation model can be obtained as follows:

$$P(t) = (m_1 + m_2) + \sum_{k=1}^{(N/2)-1} \left[(m_1 + m_2)A_K - k^2 w_0^2 m_2 P_2\right]. \quad (6)$$

At present, the main method of statistics is to accurately analyze and describe the unevenness of the electric locomotive running track at the same time through the high-frequency density function statistics of the random power sequence amplitude of the electric locomotive running track irregularity and the random density power spectrum high-frequency density function statistical method. Electric locomotive running track uneven smooth random density power sequence spectrum high-frequency amplitude value density function calculation in the function of the statistical method is a general high-frequency spectrum random power amplitude density calculation function statistics that can use uniform value and square value to be accurate. Analyzing and describing the data characteristics of the random power sequence spectrum and the mathematical structure of the random frequency spectrum, many developed countries have preliminarily determined the functions in the calculation of the high-frequency density function of the random power sequence spectrum along with the uneven running track of their electric locomotives.

$$w_1 = D(i,j), w_{k-1} = D(O,P), I - O \le 1, J - P \le 1,$$
$$I - O \le 1, J - P \le 1. \quad (7)$$

The main constraint optimization problem is defined as the following formula:

$$\text{minLPELM} = \frac{1}{2}\|\alpha\|^2 + C\frac{1}{2}\sum_{i=1}^{n}\|\gamma_i\|^2. \quad (8)$$

The constraints are as follows:

$$h(x_i)\alpha = t_i^T - \gamma_i^T, \quad i = 1, \cdots, n. \quad (9)$$

The optimization problem encountered can be transformed into the following equation:

$$\alpha = H^T\varphi, \varphi_i = C\gamma_I, h(x_i)\alpha - t_i^T + \gamma_i^T = 0, \quad i = 1, \cdots, n, \quad (10)$$

where T is the Lagrange multiplier matrix. The final output weight α is calculated as the following formula:

$$\alpha = H^T\left(\frac{I}{C} + HH^T\right)^{-1}T. \quad (11)$$

Therefore, the output function of the extreme learning machine can be defined as the following formula:

$$f(x_j) = h(x_i)H^T\left(\frac{I}{C} + HH^T\right)^{-1}T, \quad j = 1, \cdots, n. \quad (12)$$

It is fitting to obtain the following power spectra of track irregularity:

$$S_V(\Omega) = \frac{KA_\alpha\Omega_c^2}{\Omega^2(\Omega^2 + \Omega_c^2)},$$
$$S_c(\Omega) = \frac{4KA_v\Omega_c^2}{\Omega^2(\Omega^2 + \Omega_c^2)(\Omega^2 + \Omega_s^2)}. \quad (13)$$

3.3. Forces on the Structure of the Tunnel Bottom under the State of Vacant Surrounding Rock. In underground rock engineering, the surrounding rock mass whose stress state changes due to excavation is called surrounding rock. There are roughly two kinds of relationships between ore bodies and surrounding rocks: there are significant differences in fabric and content of useful components between ore bodies and surrounding rocks, and the contact boundary is clear, such as the relationship between vein filling ore bodies and surrounding rocks. In this study, indoor model tests and finite element numerical simulations are used to study the process of underground water erosion on the surrounding rock at the bottom of the heavy-duty railway tunnel during the operation period due to the dynamic load of heavy-duty trains, and quantitatively analyze the voids. The change law of contact pressure and the transmission characteristics of earth pressure under the condition of the tunnel excavation process were monitored for the clearance convergence of the lining structure of the typical section of the left and right shield tunnels, as shown in Table 4.

The above research is based on indoor model tests to qualitatively study the process of underground water erosion on the surrounding rock at the bottom of the heavy-duty railway tunnel structure due to the dynamic load of heavy-duty trains during the operation period. The following quantitative analysis of the contact pressure during the erosion process and the transmission characteristics of earth pressure is as follows: the change curve of the additional value ΔP of the contact pressure at the bottom left of the center line, the bottom left of the center line, the bottom of the center line, the second point, and the bottom right of the center line, the point 3, when there is water and no water, and the additional value ΔP change curve.

The following can be seen from Figure 9:

(1) When the surrounding rock at the bottom of the tunnel is in anhydrous conditions, the additional value of contact pressure ΔP below the centerline fluctuates around 6.5 kPa, and the additional value of contact pressure on the left and right sides ΔP is stable at around 5.8 kPa, but the overall situation is relatively stable. The additional value of the contact pressure below the left and right sides of the center line is slightly reduced compared with that below the center line, indicating that the effect of the excited vibration load below the center line is more obvious than other positions

(2) When the surrounding rock at the bottom of the tunnel is in a water-rich condition, the additional value ΔP of the contact pressure at the three measuring points under the floor is lower than the ΔP when there is no water, which indicates that the water body between the structure and the surrounding rock is to a certain extent play a role in buffering the excitation load. After 100 s of excitation, ΔP began to rise and gradually stabilized at about 5.5 kPa at 100 s. The initial contact pressure value ΔP on the left and right sides of the center line is about 4.5 kPa, and after a period of excitation, it starts to increase and finally stabilizes at about 5.0 kPa, with a change value of about 0.5 kPa

Therefore, on the whole, the stress of the tunnel bottom structure in the state of empty surrounding rock is relatively stable, although there are different pressures in different positions. But the overall fluctuation is not big.

4. Experimental Results and Analysis

4.1. Comparative Analysis of Ground Surface Measurement and FLAC Simulation Data. FLAC (Fast Lagrangian Analysis of Continua) is a continuum mechanics analysis software developed by Itasca Company. It is an internationally used professional analysis software for geotechnical engineering. It has powerful calculation functions and extensive simulation capabilities, especially in the analysis of large deformation problems. Combining the layout of the measuring points, this paper selects four sections of 172, 175, 178, and 182 to analyze the measured data on the surface. The specific data is shown in Figure 10.

It can be seen from Figure 10 that the measured data has 2 to 3 large settlements depending on the time. Taking section 182 as an example, the tunnel face of the left-line shield tunnel reaches the measuring point, and a large area of settlement occurs on the ground surface with the largest settlement. The value is located directly above the center of the tunnel, and the surface settlement value is still increasing the next day, which is mainly due to the disturbance of the surrounding soil by the construction gap and the shield machine. On July 15th, the right-line shield tunnel was excavated to the location of the measurement point. At this time, the measurement point directly above the center of the left-line shield was still growing. After 7 days, the shield machine was far away from the measurement point, and the maximum surface settlement was at above the center of the right-line shield tunnel, and its value is 26.1 mm. On October 21, the face of the undercut tunnel has completely passed through the section of the measurement point. Since the left and right shield tunnels are both within the affected area of the undercut tunnel, the ground surface around the left and right shield tunnels has changed again. Settlement occurred again. As the net distance between the left-line tunnel and the right-line tunnel is slightly smaller than that of the undercut tunnel, the increase at this stage is not large.

The final maximum surface settlement is located directly above the center of the excavated tunnel, its value is 46.8 mm, and the maximum value obtained by simulation is 42.05 mm. Because of the damage of the measuring point of the 178 sections, only the surface settlement induced during the construction of the tunnel is shown in the figure, so the deformation value is much smaller than the final simulated settlement value. The development law of the ground surface in the simulation has been verified in the actual measurement, but its value still has a certain deviation compared with the actual measurement. The actual measurement data is slightly larger than the simulated value. The main reasons for the difference are as follows:

TABLE 4: Convergence and deformation of the overpass tunnel to the existing left-line shield tunnel.

Section position (m)	$y = 12$	$y = 27$	$y = 51$	$y = 75$	$y = 87$
After the left-line shield is completed (mm)	7.59	7.85	8.12	9.12	12.52
After the right-line shield is completed (mm)	8.02	8.15	8.23	9.23	11.52
After digging is completed (mm)	7.56	7.86	8.62	7.99	12.56
FIGURE 9: The change curve of the additional value ΔP of the contact pressure below the center line and the left side.
FIGURE 10: Surface deformation law of cross section.

(i) The problem of groundwater was not considered in the simulation. For undercut tunnels, water-free operation must be ensured, and the ground settlement induced by the lowering of the water level is very large

(ii) The creep effect of rock and soil is not considered in the simulation

(iii) The uncertainty of the load on the upper part of the ground. The dynamic load of vehicles has a greater impact on the deformation of the ground. In the simulation, the ground load is considered as a uniform load, and the operation of heavy-duty vehicles will inevitably increase the settlement of the ground

(iv) The rock and soil are heterogeneous, because the thickness and mechanical parameters of the rock and soil body at each section will have a certain difference, and the rock and soil are treated according to the same thickness of each section during the simulation

In the simulation, the soil layer is considered as waiting for homogeneity, and the ground load is simplified as a heap load, so the simulation results in the uniform and smooth

curve. The measured data are all nonsmooth broken line segments. The measured value is slightly larger than the simulated value on the whole, and the error is about 20%. The measured data of individual points is smaller than the simulated value. However, the deformation development law of the simulated curve and the measured curve is more consistent. For surface subsidence, the maximum value is not directly above the intersection, but at the almost parallel position of the three tunnels. The measured maximum value is 46.8 mm. The excavation of three tunnels is disturbed, so the surface deformation is relatively large.

4.2. Experimental Data Analysis

(1) Based on the results of numerical simulation of this project, reasonable construction methods and supporting measures for this project are given. That is, within the affected area of the upper and lower crossing sections, the left and right main line shield tunnels shall be constructed first, and then, the construction of the crossing section of the outbound line shall be continued. The undercut tunnel adopts a horseshoe-shaped composite lining structure, a comprehensively advanced small pipe presupport, and a step (reserved core soil) method for tunnel construction. Three control methods are put forward through advanced geological exploration, full-face grouting of steel flower pipes, stratum reinforcement, and strengthened inspection and monitoring, and the grouting range and grouting parameters of steel flower pipes are given

(2) Lagrange algorithm is very suitable for simulating large deformation problems. FLAC adopts the explicit finite difference scheme to solve the governing differential equation of the field and applies the mixed element discrete model, which can accurately simulate the yield, plastic flow, and softening to large deformation of materials, especially in the fields of elastic-plastic analysis of materials, large deformation analysis, and simulation of construction process. The FLAC analysis results show that the use of steel flower pipe grouting reinforcement is more obvious for controlling surface deformation than tunnel vaults and convergence. Among them, the maximum deformation of the ground surface is 35.4% less than that without reinforcement measures. The longitudinal deformation range of the ground surface and the vault is reduced by 28.9% compared with no reinforcement measures

5. Conclusion

This paper systematically analyzes and summarizes the large degree of risk impact, the characteristics of the stress conditions, and the degree of deformation of the tunnel through the construction of the subway and railway tunnels under different construction methods. It focuses on the analysis of various factors that affect the safety risks of the new subway tunnel project crossing the new existing subway tunnel

proximity project. The main factors are the existing railway engineering and the tunnel hydrogeological environmental conditions, the existing subway tunnel engineering status, and the new subway tunnel engineering status. There are four main aspects of the relationship between crossing the newly built subway tunnel and the three-dimensional space connection position of the existing subway tunnel. The steel of the railway tunnel frog bainite plate in the heavy load engineering of the tunnel is in the process of material compression processing due to the continuous change of dislocations and the combination and entanglement to form multiple dislocation cells, which hinder the slippage of dislocation cells. The steel processing hardness of the bainite plate gradually doubled from 450 HV to 608 HV, showing obvious work hardening and smoothness. The FLAC analysis results show that the use of steel flower tube grouting reinforcement is particularly obvious for controlling the surface and the tunnel vault. After the reinforcement measures were taken, the maximum deformation of the ground surface was reduced by 35.4%, and the influence of the deformation of the ground surface and the vault along the axial direction of the tunnel was reduced by 28.9%. Finally, the method is used to carry out dynamic numerical simulation during the construction phase of the tunnel with a small clear distance to analyze the stability of the surrounding rock of the tunnel. Due to the complex construction process of the small clear distance tunnel, in the numerical simulation modeling process, the boundary between the upper and lower steps is regarded as the boundary layer of soil and rock, and the grouting of the leading small pipe is equivalent to the entity, without considering the groundwater and actual working conditions. The impact of this coupling on the model in this paper can be further considered in future research.

Retracted: Health Screening and Promotion System Based on Disease Prevention

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

With the rapid development of modern medical technology, more and more clinicians use computerized medical images as the main diagnostic basis. At the same time, the generation of massive medical image information promotes the development of medical image management. Aiming at the above two problems, a medical image reporting system based on physical examination is designed and implemented, in which the medical image reporting system is an independent and complete system including login, registration, appointment, triage and doctor workstation (inquiry, report editing, and report printing), and other modules. Using the methods of literature review, expert interview, case analysis, and rational analysis, combined with nanotechnology research, this paper takes urban population health as the starting point and health promotion as the background. As the basis of systematic comparison, the theory, position, and function of health promotion are discussed in detail. Among them, Chinese Center for Disease Control and Prevention, World Health Organization, and Subscriber Data Center are the collection sites for the literature data mentioned in this article. With the construction of healthy towns and the development of social movements, the establishment of healthy sports to improve health promotion system aims to help sports play an important role in promoting healthy development. The results show that the average scores of step test for boys and girls in the test are 72.97 and 68.77, respectively, while the average scores of distance running in the national physique monitoring are 66 and 63. Therefore, in the newly established scoring standard, the step test scores of boys with 66 points are 72, while those of girls with 66 points are 68.

1. Introduction

Health promotion is a global strategy initiated by the World Health Organization (WHO), aiming at solving major challenges related to human health due to the speed of action. Using health promotion in urban planning is about creating a healthy city. The concept of health promotion aims to raise public awareness, encourage citizens to cooperate with local governments and social organizations, and create a series of effective health and environmental support, services, and interventions that affect human health, so as to achieve the purpose of health promotion. Urbanization is the general trend of the development of modern human society and the objective and inevitable result of the development of social productive forces. In the 2015 edition of the World Population Situation Report, it is estimated that in 2015, the urban population of the world will reach 54.4%, and that of developed countries will reach 81.6%. Today, when building a well-off society in an all-round way, China has entered a period of rapid urbanization, and it is estimated that the

level of urbanization will reach 50% in 2010. Rapid urbanization has brought about a series of changes. On the one hand, with the rapid development of urban construction, especially industrial towns, it is faced with overcrowding, homelessness, water shortage, and food insecurity, as well as many social, health, environmental, and other problems. Social problems such as environmental pollution are more and more important problems affecting human health. On the other hand, in the era of urban development, with the emergence of modern science and technology, the working and living conditions of urban residents have undergone earth-shaking changes. The intensification of social competition, the quickening pace of life, the improvement of intelligence, and the reduction of physical labor, the low grain output, and food shortage make people more vulnerable.

In view of the severe challenges brought by the urbanization process to human health, in order to ensure the sustainable development of cities and embody the concept of "people-oriented" urban development, the World Health Organization recommends that people in cities live a healthy life on a global scale. At present, many cities are building health promotion systems to build a healthy and harmonious affluent society, while the economy is growing rapidly. According to the concept of the World Health Organization, the importance of a healthy city means "ensuring the development of healthy life and work" to serve the broad masses of the people. To become an organic combination of healthy people, healthy environment, and society necessary for development, it must be suitable for the healthy development, growth, and enjoyment of human life.

Traditionally, health check-ups are usually done manually. Heavy business, insufficient statistics, poor management, and many other shortcomings are the result of human activities or complete lack of goal setting. Because of the extensive use of computer technology in disease management, the use of environment becomes more and more difficult for health promotion management. In the past, medical records and medical certificates were all paper, and many other medical records contained the results of medical examinations. This kind of storage system takes up a lot of space, and data is easy to be decomposed and lost. Importantly, it is difficult for Chinese Center for Disease Control and Prevention (CDC) to make statistical analysis and make effective use of medical information. The results of statistical analysis provide information for CDC's decision-making. Due to the rich experience in management follow-up and management and the rapid development and progress of network and computer technology, the use of advanced network and computer technology in medical care has become the inevitable status quo of the development of physical research methods. Using computer software for medical research can save a lot of people and property. It is necessary to know the authenticity of medical records, functional test results, other diagnostic criteria, and medical evidence of professionals, as well as the principles, information, and conditions of managing physical examination. The document is being worked out and will continue to study the medical information physical examination work. It is meaningful to build this part of Subscriber Data Center (SDC) knowledge.

2. Related Work

In the related fields of nanotechnology and health promotion, experts at home and abroad also have many research achievements. Mihail et al. discussed the progress of nanotechnology development since 2000, the achievements in the past ten years, and the global opportunities in research, education, innovation, and social achievements by 2020 [1]. Reis and Damgé thought that only through nanoparticles or biochips can nanoparticle-mediated materials be delivered to plants and advanced biosensors for precision agriculture [2]. The research of Falagan-Lotsch et al. introduced a new method of breast cancer nanodrugs based on active targeting. This method uses a multifunctional inorganic nanoplatform with biomedical relevance [3]. The research goal of Lee et al. was to provide a comprehensive overview of oil-water separation by nanotechnology and organic chemistry and to raise awareness of the environmental problems of water purification by nanotechnology [4]. Lisa et al. thought that although the side effects of medical interventions are well known and widely investigated, the possible unexpected effects of health promotion interventions are rarely discussed in the research [5]. These systems studied by Hors-Fraile et al. can be used to create tailor-made health interventions, thus reducing the cost of health care and fostering a healthier lifestyle among people [6]. However, due to the incomplete data of nanoanalysis, there are some controversies about the methods used in these studies, resulting in the related results not being recognized by the public.

3. Nanotechnology-Based Medical Examination Reporting System

This topic is a series of medical examination management system software developed based on Microsoft data. The software needs to be implemented in several stages, from registration to medical certificate issuance, changing the way of completing some work ahead of schedule, improving work efficiency, and simplifying workflow and product distribution [7]. Through large-scale data analysis, extensive analysis, and investigation, it is easy to generate reports such as quality statistics, turn data into useful information in decision-making, and provide faster decision-making suggestions for decision makers [8].

Individual nanoparticles such as nanotubes and nanorods have only one direction of electron motion left in it. Individual nanoparticles include nanoparticles, nanotubes, nanorods, and nanoviruses. Two-dimensional nanomaterials and three-dimensional nanoparticles are represented by nanoparticles, nanostructures, nanoceramics, and nanobodies. Nanocomposites are the most widely used materials today. From the point of view of morphology and structure analysis, nanoscale materials with one or more dimensions are called nanoparticles [9]. When nanoparticles are reduced
FIGURE 1: Timing diagram of graphene application in displays and electronics.
FIGURE 2: FT-IR spectra of PEG, HO-PEG-OTs, and HO-PEG-N3.

to the atomic or molecular level, materials show many specific effects, such as topological effect, dielectric reduction, large size, small size, and macroscopic quantum tunneling effect. Among the core materials, nanoparticles exhibit special physical and chemical properties such as optics, electricity, magnetism, mechanics, and heat. Different from the conventional properties in nanobelts and chemical converters, it can open the energy gap of graphene and increase the transmission current management ratio. Graphene is expected to be used in more industries in the near future [10]. Figure 1 shows the application schedule of graphene in displays and electronic devices.

In this paper, the change of PEG structure was detected and characterized by FT-IR spectra. The analysis of PEG, HO-PEG-OTs, and HO-PEG-N3 in this paper can help to understand the structure and display process of medical imaging system. Figure 2 shows the FT-IR spectra of PEG, HO-PEG-OTs, and HO-PEG-N3, respectively. Among them, 3440 cm-1, 2887 cm-1, and 1108 cm-1 are the O-H telescopic vibration absorption peaks of PEG, C-H telescopic vibration absorption peaks of methylene, and C-O telescopic vibration absorption peaks, respectively [11, 12]. In contrast, the FT-IR spectrum of HO-PEG-Ts not only has the characteristic absorption peak of PEG but also has two characteristic peaks of benzene ring skeleton vibration at 1648 cm-1 and 1594 cm-1. At the same time, the absorption peak of O-H stretching vibration at 3440 cm-1 obviously weakened, which indicated that the hydroxyl group at one end of

PEG successfully reacted with p-toluenesulfonyl chloride to form p-toluenesulfonate. In the FT-IR spectrum of HO-PEG-N3, two peaks at 1648 cm-1 and 1594 cm-1 disappeared, but the characteristic absorption peak of azide group appeared at 2106 cm-1. It shows that the tosyl group of HO-PEG-Ts is replaced by azide group [13].

The amino group at the end of DSPE reacts with PEG modified by chloroformate to obtain DSPE-PEG conjugate. Its characterization was mainly carried out by FT-IR and nuclear magnetic resonance. Infrared contrast is shown in Figure 3. In the infrared spectrum of DSPE-PEG, the characteristic peaks of DSPE (2887 cm-1 and 2851 cm-1) and PEG (1111 cm-1) appeared. Therefore, we can judge that DSPE-PEG long-acting phospholipid was successfully synthesized, and its nuclear magnetic resonance further proved the structure of the compound. Among them, the peak at the chemical shift of 0.86 ppm is the methyl peak of DSPE, 1.23 ppm is the methylene peak of DSPE alkyl chain, and 3.51 ppm is the characteristic peak of polyethylene glycol.

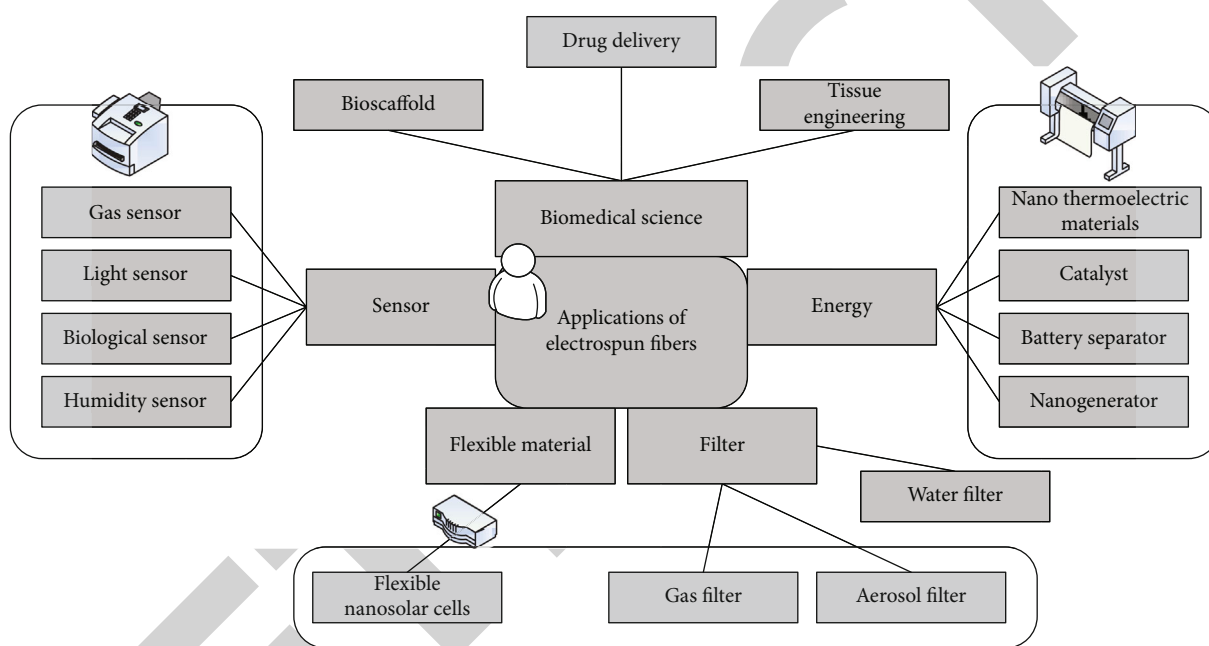
Up to now, micronanomaterials can be derived from fiber structures such as ceramics and polymers, spherical structures, and tubular structures. However, the most common product of electrospinning is fiber structures. At present, there are two shortcomings in electrospinning technology: most fibers are nonwoven fabrics. The voltage required for the electrospinning process is very high. To expand the application of fiber in microelectronic devices, people have invented and developed many methods,
FIGURE 3: FT-IR spectra of PEG, DSPE, and DSPE-PEG.


FIGURE 4: Various application areas for electrospun fibers.

including parallel double-electrode collection method and magnetic field electrospinning, to prepare micronanofibers [14]. By controlling the above experimental parameters, fibers with different morphologies such as coaxial structure, beaded structure, porous structure, red blood cell structure, ribbon structure, patterned fiber structure, spider web structure, and array structure can also be obtained [15]. Nonwoven fabric fiber is the most common fiber morphology. Electrospun fibers play an important role in the fields of sensors, filtering devices, tissue scaffolds, implant coating films, and wound dressings. As shown in Figure 4, there are many application fields of electrospun fibers [16].

Up to now, there are many methods to prepare nanomaterials, such as vacuum condensation method, ball milling method, chemical vapor deposition method, hydrothermal method, sol-gel method, spraying magnetron method, nanoprinting method, electrostatic spinning method, and template method. Sequential or random nanostructures can be

obtained by these methods. These electrothermal technologies can produce long-sized nanofibers with uniform diameters and different compositions. Fibers can be organic or inorganic [17, 18]. The method has the characteristics of simple operation process and wide application. According to the physical state of nanomaterials, it can be divided into gas phase method, liquid phase method, and solid phase method. In recent years, hydrothermal method, magnetron spraying method, chemical vapor deposition method, and electric drying method have been adopted. Nanotechnology has attracted much attention because of its simple tools, low cost, high efficiency, and convenience. With the progress of science and technology, people have a deeper understanding of nanomaterials, and the application of nanomaterials in people's lives is also more extensive [19].

In today's society, which has stepped into the post-Moore era, devices are gradually developing towards the fields of multifunction, miniaturization, and flexible

wearable. As a representative, ZnO (ZnO) is a semiconductor material of group II-IV direct band gap compounds. It can be used as a display interface module for medical imaging systems. It is an ideal material for developing ultraviolet detectors, blue-ultraviolet light emitting devices, and blue laser. In addition, compared with Si, GaAs, and InP, ZnO has higher breakdown electric field, thermal conductivity, electron saturation rate, and radiation resistance due to its unique wide bandgap structure [20]. It is ZnO that has these excellent properties at the same time, which has aroused extensive research by researchers. ZnO fiber has special crystal structure, wide band gap, high breakdown electric field, high thermal conductivity, high electron saturation rate, high radiation resistance, and so on and has many excellent properties, which can emit blue-violet light. As a typical representative of the third generation semiconductor, ZnO has a very wide application prospect. For example, it can be used in blue LED, photodetector, flexible nanosolar cell, nanopiezoelectric material, ZnO arrester, and tester and can also be used to prepare ZnO carriers. In addition, it can also be used to make facial masks. Figure 5 shows the application picture of ZnO [21].

However, these methods can only prepare ZnO thin films and short nanowires, which greatly limits the preparation of ZnO-based devices. Compared with other technologies, electrospinning technology has its unique advantages. For example, the device is simple, the cost is low, the applicable materials are wide, the modification is strong, the fiber morphology is diverse, and the specific surface area is large. In addition, it can prepare ultrathin fibers and long continuous fibers. Ce-ZnO prepared by electrospinning is spun. Long filiform ones have the advantages of large specific surface area, especially suitable for sensing applications and so on. In the literature on the properties and applications of electrostatically woven nanofibers, the application of electrospinning ZnO nanofibers is also very extensive, among which the representative applications are shown in Table 1.

PVDF has five different crystal phases, of which β phase has the best piezoelectric properties. In the process of electrospinning, the parameters such as voltage, polymer solution pushing speed, and boiling point of solvent are closely related to the formation of β phase PVDF. In order to study the influence of PVDF nanofiber membranes on the output performance of devices, it prepared a series of PVDF nanofiber membranes with different parameters and assembled them into devices for performance testing. Table 2 summarizes the parameters of these different samples. The definitions and dimensions of ZnO and PVDF are explained in the texts of Tables 1 and 2, and the display modules in the subsequent system architecture design are better constructed. Among these parameters, it changed the voltage and spinning time of electrospinning, and other constant parameters can be seen in the experimental part. When the spinning voltage is 12 KV, the α phase peak at 18.4° and 26.7° shifts to the β phase peak at 20.6°, showing an obvious broad peak at 20.1. This shows the transformation of PVDF from α phase to β phase during spinning. The output voltage results also show that when the voltage is 12 KV, the output
FIGURE 5: Application picture of ZnO.

value is the largest. In addition, the film thickness is also an important parameter that affects its output performance. As we know, for friction nanogenerators, the smaller the film thickness, the better the device output performance, while for piezoelectric devices, the increase of film thickness in a certain range is beneficial to the device output performance. Therefore, it is very important to find an optimal film thickness for PVDF film used as both friction material and piezoelectric material. PVDF nanofiber membranes with different thicknesses were prepared by controlling the spinning time. The thickness of PVDF film increases with the extension of spinning time. When the PVDF thickness is 145.3 μm, the maximum output voltage of 98 V is obtained. Therefore, the best preparation conditions are as follows: spinning voltage 12 KV and spinning time 2 h.

Figure 6 shows the XRD patterns of the prepared pure ZnO and cerium-doped ZnO nanofibers, which reflect the crystalline characteristics of pure ZnO and cerium-doped ZnO nanofibers. The clear diffraction pattern has higher peak position and narrower half-peak width, which indicates that pure ZnO and cerium doped ZnO have good crystallinity. XRD spectrum shows that pure ZnO nanofibers have hexagonal wurtzite structure (observed by JCPDS36-1451); the 2θ values of the strong diffraction peaks are 31.77°, 34.42°, and 36.26°, respectively; and the corresponding diffraction planes are (100), (002), and (101), respectively. Compared with pure ZnO, the diffraction peak of CeO2 (JCPDS34-0394) appears at the crystal plane (111) of 2θ = 28.55° after cerium doping. Moreover, by comparing the XRD profiles of pure ZnO and cerium-doped ZnO, it can be seen that the peak position of cerium-doped ZnO has a small angle (~0.31degree) shift. The radius of cerium atom is larger than that of zinc atom, which will make the crystal lattice of ZnO larger. According to Bragg formula, the lattice parameters are related to the interplanar spacing d. With the increase of atomic radius, the diffraction peak shifts to a small angle. It shows that cerium ions are successfully doped into the crystal lattice of ZnO. XRD results show that the synthesized nanofibers are the mixed phase of hexagonal ZnO and cubic cerium oxide. In XRD pattern, except Ce element, there are no other peaks. Therefore, the prepared sample is a combination of high-purity hexagonal ZnO and cubic ceria.

TABLE 1: Diameters, properties, and applications of electrospun ZnO-based nanofibers.

Material	Fiber diameter/nm	Performance	Application
Cu-ZnO	100	HRP2 protein detection limit is 10 μg/ml	Biological sensor
ZnSe/ZnO	200	Short circuit current density 6.60 mA/cm^2. Maximum power conversion efficiency of 1.24%	Solar battery
ZnO/CNFs-PA	150	At a current density of 200 mAg-1, the capacity is 702 mAhg-1	Lithium ion battery
CuO-ZnO	312 183	The maximum adsorption capacity of Congo red dye is 126.4 mg/g	Shows significant antibacterial activity against Staphylococcus aureus
ZnO/PVA	200	Detection limit for NO2 is 10 ppm	Sensor
PVDF-HFP/Co-ZnO	300	Maximum output voltage 2.8 V	Nanogenerator
ZnO/Al2O3/AuNPs	200	Detection limits of 0.19 μM and 15.0 μM for tea phenol and hydroquinone, respectively	New sensor (detection of tea phenol and hydroquinone)
TMCNF/ZnO	200	Ultrafast cycling stability (452 mA hg−1 after 500 cycles)	Lithium ion battery
PA6/PPy/ZnO	80	Urea detection limit is 0.011 mg DL−1	Biological sensor
ZnO/PU	250	Improve photocatalytic efficiency	Organic pollutant degradation and wastewater purification

TABLE 2: Dimensions of PVDF nanofibers electrospun with different process parameters.

Sample	Applied voltage (KV)	Applied time (h)	Diameters of nanofibers (nm)	Thickness of the film (μm)
1	10	1	180	68
2	12	1	160	68
3	14	1	152	68
4	16	1	122	68
5	18	1	123	68
6	12	0.5	160	37
7	12	1.5	160	97
8	12	2	160	145
9	12	3	160	189

Although the physical conditions of different materials are different, the thermal conduction modes are different due to different compounds. There are also significant differences in thermal conductivity. However, in different states of matter, one thing is similar, that is, heat in matter is transferred by collision and particles. The thermal conductivity κ of all solids can be directly expressed as the thermal conductivity of atomic gas as a thermal conductor, namely,

$$K = \frac{1}{3} Cv\Lambda. \tag{1}$$

Among them, C represents thermal conductivity of the solid per unit volume. V represents the average velocity of hot carrier movement per unit volume. Λ represents the mean free path of hot carrier movement per unit volume.

$$f = \frac{1}{e^{hwIk} - 1}, \tag{2}$$

$$U = \sum_{i=1}^{3N} \frac{hw}{e^{hwIK_BT} - 1}. \tag{3}$$

Assuming that the number of vibration modes of the crystal with a given polarization mode is $D(\omega)d\omega$ in the frequency range of $\omega + d\omega$, the formula can be changed into integral form:

$$U = \int \frac{hw}{e^{hwIk_BT} - 1} D(w)dw, \tag{4}$$

$$C = \frac{dU}{dT} = \frac{3Vh^2}{2\pi^2 v^3 k_B T^2} \int_0^{wD} \frac{w^4 e^{hw/r}}{(e^{hw/r} - 1)^2} dw. \tag{5}$$

The relaxation time of phonon scattering is a function $\tau(\omega)$ related to phonon frequency. According to the empirical formula of scattering probability of inverse scattering between phonons, impurity scattering, and boundary scattering, the relaxation time of inverse scattering can be obtained as follows:

$$\tau_{umkl}^{-1} = B_1 w^2 T \exp\left(\frac{-B_2}{T}\right), \tag{6}$$

$$\tau_{imp}^{-1} = A_1 w^4, \tag{7}$$
FIGURE 6: XRD patterns of pure ZnO and Ce-ZnO nanofibers, the inset is an enlarged view of the (101) diffraction plane.

$$\tau_{bdy}^{-1} = \frac{v_g}{L}, \tag{8}$$

$$\tau_{tol}^{-1}(w, T, L) = \tau_{umkl}^{-1}(w, T) + \tau_{imp}^{-1}(w) + \tau_{bdy}^{-1}(L), \tag{9}$$

$$\Lambda_{eff}^{-1}(w, T, L) = \Lambda_{umkl}^{-1}(w, T) + \Lambda_{imp}^{-1}(w) + \Lambda_{bdy}^{-1}(L). \tag{10}$$

The longitudinal acoustic lattice wave (LA) and the transverse acoustic lattice wave (TA) are not distinguished, and the thermal conductivity of germanium at low temperature is well predicted. Callaway model considers isotope impurity scattering, inverse scattering, normal scattering, and boundary scattering, respectively; and the expression of relaxation time is

$$\tau_C^{-1} = \tau_I^{-1} + \tau_U^{-1} + \tau_N^{-1} + \tau_b^{-1}, \tag{11}$$

$$Aw^4 + B_U T^3 w^2 + B_N T^3 w^2 + \frac{c}{L}, \tag{12}$$

$$Aw^4 + (B_U + B_N) T^3 w^2 + \frac{c}{L}. \tag{13}$$

Holland model is an extension of Callaway model. Different relaxation time approximations are adopted, so that the calculated results can accord with the experimental results at high temperature. The formula for calculating the thermal conductivity of Holland mode is

$$K_H = K_L + K_T, \tag{14}$$

$$KL = \frac{1}{3} \int_0^{\theta r/T} \frac{C_L T^3 x^4 e^x (e^x - 1) dx}{\tau_L^{-1}}, \tag{15}$$

$$KT = \frac{2}{3} \int_0^{\theta r/T} \frac{C_L T^3 x^4 e^x (e^x - 1)^{-2} dx}{\tau_L^{-1}}. \tag{16}$$

This indicates the contribution of the two transverse acoustic lattice waves TA to the thermal conductivity. When Holland model calculates the relaxation time, the thermal conductivity of LA is integrated in the whole frequency range:

$$\tau_L^{-1} = \frac{v_b}{FL + Aw^4 + B_L w^2 T^3}, \tag{17}$$

$$\tau_T^{-1} = \frac{v_b}{FL + Aw^4 + B_T w T^4 (w < w_1)}, \tag{18}$$

$$\tau_T^{-1} = \frac{v_b}{FL} + Aw^4 + B_T w T^4 + \frac{B_{TU} w^2}{\sinh x(w1 < w < w2)}. \tag{19}$$

The SW potential of silicon contains a two-body potential term and a three-body potential term, and the specific expression is

$$u_3(r_i, r_j, r_k) = \varepsilon \lfloor h(r_{ij}, r_{ik}, \theta_{jik}) + h(r_{ji}, r_{jk}, \theta_{jik}) + h(r_{ki}, r_{kj}, \theta_{ikj}) \rfloor. \tag{20}$$

It can be seen from the above that such formulas related to thermal conductivity can help the construction of the LCD display interface in the health promotion system.

4. Health Promotion System Experiment

Two common items, football and yoga, were selected in the experiment. Through nanotechnology, health promotion and health examination decision-making are studied. The former focuses on the quality of endurance and strength, while the latter focuses on the quality of practicing soft keys. The subjects were 137 males and 90 females. The hypothesis of this study is that students with higher endurance and strength qualities are more likely to get high scores in football matches, while students with flexible choice qualities are more likely to get good results in yoga activities. The main purpose of the experiment in this section is to establish the performance prediction model of health promotion and predict the results of these two items for the theme experiment to verify the accuracy of the hypothesis. It randomly selects the historical data of 136 men and 77 women in a football project and 66 men and 138 women in a yoga project to build the performance prediction models of the two projects. Through correlation analysis, it is found that the test indexes with higher correlation coefficient with football performance are step test and long standing jump. The test index with higher performance correlation coefficient of yoga is forward flexion, which is consistent with the results of the questionnaire. When building the partition model, the four data sets are divided into 4, 4, 4, and 5 subsets, respectively. To verify the health promotion model, Table 3 shows the division of the subdivision model.

On this basis, a performance prediction model is established for each subset of men's soccer, women's soccer, yoga men, and yoga women. The physical fitness data of these students have been used to verify the model. Of the four data sets, only one, two, and three made accurate predictions, with the accuracy rates of 99.2, 95.5, and 97.8%, respectively. The physical health data of 37 males and 90 females were included in the prediction model with the same degree to predict the performance of each student in health promotion activities. The results are shown in Figure 7. Therefore, the result of achievement prediction is consistent with the level of students' physical quality.

From the comparison of events, the expected performance of yoga events is higher than that of football events, because students' soft back quality is better than endurance and strength quality. From the comparison of men and women, the performance of women's football is better than that of men's football. Although men are usually less flexible than women, their yoga performance is not inferior to that of women. The reason may be that the gender orientation in football and yoga is obvious. Teachers will take care of disadvantaged gender groups and give them higher scores. This has a certain influence on the results of the health promotion system under nanotechnology. The results of data standardization are shown in Figure 8 and Table 4.

There are 1, 2, 3, and 4 categories. In terms of male or female, the degree of similarity is similar to normal distribution. The more equal the classification of boys, the greater
Figure 8: Sample data normalization.

the difference between girls. The figure clearly shows the number of each type and the difference between the sexes. This is important because the classification and analysis of the variable table can be used to evaluate whether the type is reasonable. After the differential function is detected, the formula $Xi = (X1i, X2i, X3i, X4i, X5i, X6)$ is normalized. To obtain the required difference, it is necessary to compare it with the value of Y and classify the scores according to the rules. In this study, boys are used as case studies. According to the boys of four classes, five data sets of 20 people were selected, and the first data was normalized (Figure 9).

Then discriminate and predict the data (as shown in Figure 10).

First of all, according to the different data units of the training samples, this paper is dedimensioning, that is, stan-

dardization. Then, SPSS software is used to quickly cluster the standardized data. Finally, Fisher linear discriminant function is obtained, and the classification model is constructed. In Figures 9 and 10, the probability of dividing men and women is 99.3% and 99.2%, respectively, which indicates that the distribution model has a high probability of distribution results. Finally, according to the existing samples' 1, 2, 3, and 4 categories, this cycle is obtained, and a total of 20 model cycles are tested by the difference program. The correct rate was 99.5%. As long as the six types of information and their corresponding numerical values are standardized and modeled, the model can be inspected. Moreover, the six indicators proposed in this study have not been combined with the research. Samples measure the internal characteristics of the human body. Based on the
Figure 9: Standardization of sample data to be tested.
Figure 10: Sample prediction results.

intelligent health promotion service system, the corresponding index data of human body can be measured by simple instrument operation. It not only simplifies the process of obtaining test data but also reduces human error, which provides important scientific and technological support for studying physical health. Through the above data analysis, it can know that the physical health of boys is evenly distributed, which accords with normal distribution, while that of girls is unevenly distributed, showing a trend of two-level differentiation. As the social rhythm continues to accelerate, the pressure on students becomes more and more. For a long time, it has formed bad living habits, such as excessive intake of fat and calories. In addition, the structure of food is not very reasonable, and there is a lack of adequate physical exercise, which leads to physical deterioration, great influence on physical health and polarization. This needs attention. Therefore, it must pay more attention to the problems of physical health and adopt practical and feasible countermeasures to further improve the physical health in the actual process. This model can be used to comprehen-

sively evaluate the physical health of individuals and groups. In the process of applying this model, it is only necessary to standardize all kinds of index values actually measured by each individual into the corresponding model for calculation, so that the physical health level of an individual or a group can be obtained. The establishment of the grading model avoids the score according to each item in the standard. It then uses the weight to calculate the total score in this complicated process. To some extent, this simplifies the operation procedures, achieves the goal of simplicity, and then makes the evaluation results very clear and effective.

5. Discussion

Through the analysis of the model of the article, the article constructs the health promotion system from the aspects of physical quality, skills, and shape; tests the physical health data; realizes real-time analysis; and gives warnings. The early warning mechanism accurately provides health

information and is supplemented by early warning statement. This kind of early warning statement is predictive, and if individuals are allowed to develop continuously, physical health may be damaged. According to the warning statement, targeted prevention and exercise can effectively avoid this kind of future harm. The health examination management system introduced in this paper is based on the actual application requirements of the physical examination institute of the Center for Disease Control and Prevention. It is developed by Delphi and SQL server 2000. Through the comprehensive application of data analysis, data encryption, software reuse and other technologies, and information maintenance, it perfectly shows the modular design idea, and at the same time, it integrates the management mode of modern CDC physical examination center into it. The system has the characteristics of strong practicability, good real-time, high work efficiency, and easy data maintenance, which has brought higher economic benefits and good social reflection to the physical examination of center for disease control.

This paper designs the input module and physical examination and perspective module. The result is automatically judged. Single-particle imaging and single-particle spectroscopy based on the optical properties of metal nanoparticles, with nanoscale spatial resolution and millisecond temporal resolution, have become important tools for studying the behavior and function of biomolecules at the single-cell level. It uses bar code to scan and input the whole process, which simplifies unnecessary time in work. It provides users with a variety of flexible access methods. Customized human search object function, powerful demand function, and statistical analysis function help users easily understand daily tasks and problems and calculate relevant information. Data from the health screening system have been analyzed and evaluated by nanotechnology and medical promotion verification data, providing detailed data of disease prevention. The advantages of this system include developing a suitable C/S search engine, which is convenient and fast to use, improving the efficiency, improving the running speed of SDC, and realizing the verification data to test the physical form. It improves the speed and efficiency of data retrieval, the sorting of selection and record results, the sorting of people and laboratories, and the combination of physical screening software and verification tools to ensure that data will not be lost. It simplifies the workflow of SDC, improves performance, and provides detailed information during data analysis. Due to the limitation of resources, time, hardware, or other conditions and the standardization of medical information disclosure, there is no integration between the standardization of CDC management model and the standardization of information system model, and the system still has a lot of room for development. Even if there is relatively complete physical examination data, more detailed data mining research is needed. The system design should also fully consider the future upgrade and expansion of the system to promote the integration of the existing system and the proposed system. This system only realizes the interface with some inspection instruments, and it needs to reserve interfaces for other system equipment.

In view of vital capacity and cardiovascular index, according to relevant research, the vital capacity and maximum oxygen uptake of human body are closely related to body weight, height, body surface area, chest circumference, and sitting height. Therefore, according to different gender, age, race, region, and different types of sports groups or individuals, comparing and analyzing this index of vital capacity, and carrying out quantitative analysis on it, it can objectively reflect the differences among different individuals and carry out evaluation. Body mass index, the individual's fatness, and thinness directly affect the level of physical health. One of the criteria to measure the individual's weight is the height and body mass index (BMI). According to the BMI value, it can know the fat and thin level of individual figure. Therefore, the new early warning indicators in this paper still retain the height and weight indicators, body composition, and balance index. Body composition includes internal indexes related to physical health level, such as bone density and muscle. It can reflect the existing level of each index inside the body of the tested person and the ability of balance and coordination. Balance ability is to analyze the individual balance ability through the completion result of a given action. If the two indexes of body composition and balance ability are too low, early warning is needed so as to exercise pertinently and improve the physical health level.

6. Conclusion

Health promotion is the process of improving the health status of different groups of people. It improves people's lifestyle by means of sports intervention. It promotes the formation of healthy sports knowledge, improves the sports environment, and improves the quality of life. Health promotion system is a service and safety system that can provide sports health services for people, improve sports health, promote environmental conditions, meet the scientific needs of human health, and improve people's quality of life and health level. The goal system of sports promotion is to form healthy sports knowledge, including the formation of sports positive attitude, sports true values, and emotional sports positive experience. Sports lifestyle includes reasonable sports lifestyle, colorful sports activities, and sports content. The formation of a healthy sports environment includes the development of sports facilities, the formation of a strong institutional network, the formation of a good sports atmosphere, and other components. Health promotion action system includes raising residents' awareness of sports, encouraging residents to improve sports, shaping sports lifestyle, and improving sports environment. The safety system of sports promotion includes organizational guarantee, talent guarantee, fund guarantee, and facility guarantee. This is the guarantee for the smooth operation of the sports health promotion operation system and the realization of the sports health promotion purpose. Community organization network is an organization and operation organization that cooperates with sports health promotion association, individual community sports association, and community sports associations led by various committees

to promote community health. This paper basically realizes the medical image transmission and storage system based on ultrasonic equipment. However, there are still some problems in this system due to various reasons such as short development time and insufficient manpower. Therefore, in order to become a mature and stable system and put it into hospital use, it should continue to improve the problems existing in the system. The following aspects need to be completed. The encryption algorithm involved in the system only refers to the method of regular expression matching when the user logs in. Therefore, there are not many encryption algorithms used in the system, which leads to the low security performance of the system. Therefore, the following work needs to study the knowledge related to software encryption. The encryption algorithm is used in the programming that the system needs to be encrypted to improve the security of the system to prevent malicious damage by illegal personnel. The system needs to generate standard DICOM files for the transmission and storage of medical images, such as images collected by video acquisition card, patient basic information, examination information, and diagnosis information. The analysis and format conversions of DICOM files are involved when the patient history examination needs to consult DICOM files. In order to realize the above two aspects, this paper uses the executable file in DCMKT. However, the files in DCMKT are not flexible enough to realize the system functions accurately. Therefore, in the following work, it is necessary to reduce the reference to the executable files in DCMTK and fully grasp the DICOM protocol. Using c++ programming language to develop DICOM can accurately realize the functions required by the system. The actual use of the hospital needs to be integrated with the hospital information system, health examination information management system, and other information systems. Due to the lack of actual installation test in the hospital, this system has poor compatibility and can only be used as an independent system. Therefore, in the following work, according to the HIS system and health examination information management system of the hospital, the data interface between medical image reporting system and HIS system and health examination information management system is designed and implemented, so that the medical image reporting system can exchange data with HIS system and health examination information management system.

Swarm intelligence algorithm is an emerging evolutionary computing technology, which has become the focus of more and more researchers. It has a very special connection with artificial life, especially evolutionary strategies and genetic algorithms. The swarm intelligence algorithms you see include genetic algorithm, particle swarm optimization algorithm, and ant colony algorithm. This part of the content has been supplemented in the article. Evolutionary computing is a group-oriented random search technology and method produced by simulating the evolutionary process of organisms in nature. Evolutionary computing is based on natural selection strategy: survival of the fittest, elimination of the unfit, and individuals with large fitness values have a higher survival probability than individuals with small fitness values. The purpose of this paper is to study the structure optimization of carbon nanotubes based on swarm intelligence algorithm and evolutionary computation. It is expected to optimize the structure of carbon nanotube materials with the help of intelligent evolution algorithm, so that it can be used in more fields. In this paper, the preparation process and principle of carbon nanotube-based gas sensors are studied, and the preparation process of the side-heated gas sensor is selected. This paper focuses on the strain sensing performance of carbon nanotubes, analyzes various parameters that characterize the sensing performance, and proposes feasible technical routes for improvement, optimization and improvement. The experimental results in this paper show that when different proportions of oxides are added, the tensile strength of carbon nanotube materials is increased by about 8%, and the elastic modulus is increased by up to 40%. After adding CNFs, the tensile strength increased by up to 18%, and the elastic modulus increased by up to 50%.

1. Introduction

With the continuous advancement of science and technology, polymer materials are more and more widely used in daily life, and with the high requirements for the performance of polymer materials, this problem was not solved until the emergence of nanopolymers. Polymer materials are materials based on polymer compounds, materials composed of compounds with relatively high molecular weight, including rubber, plastics, fibers, and polymer-based composite materials. Polymers are the form of life. In fact, every advance of human society is closely related to the development of new materials. In the 21st century, with the continuous development of science and technology, the understanding of human beings is constantly expanding, and the exploration of nanomaterials has promoted the development of human beings in a deeper direction. Since the end of World War II, optimization computing has been widely introduced and used in the scientific community. Since optimization algorithms already have the advantage of effectively dealing with complex problems that are difficult to solve by traditional methods, these algorithms and designs are sought after as soon as they are published. The optimization algorithm can use the mathematical modeling method to convert the actual problem into an optimization problem and convert the optimization problem into a standard optimization model. It has a simple structure and flexible calculation and can solve many complex problems.

How to combine the swarm intelligence algorithm with evolutionary computing and carbon nanotube structure optimization is the problem to be explored in this paper.

With the increase of function dimension, traditional optimization methods cannot solve complex function optimization problems well. The evolutionary algorithm that simulates the biological evolution process can get a set of solutions in one run. This main advantage is introduced into the optimization problem, which effectively solves many complex optimization problems. The swarm intelligence optimization algorithm has good heuristics, parallelism, and distribution and can solve complex function optimization problems well, save resources, and improve efficiency.

Based on the work of genetic operator impact analysis, this paper proposes GPs based on edit distance 1 and 2 population diversity control, respectively. The influence of genetic operators in GP on the population and its diversity is analyzed and compared, and the correlation between population diversity and individual fitness is explored.

2. Related Work

With the development of the times, more and more people conduct research on optimization calculation. Bhattacharjee and Sarmah attempt algorithmic advantage to solve combinatorial problems. In the improved version of CSA, the local randomized wandering repair operator is used. And in the improved version of FA, variable distance shifts for local search are applied. The firefly algorithm is proposed by simulating the natural phenomenon of firefly swarming activities in nature at night. In the swarming activities of fireflies, each firefly communicates with its companions for food and courtship by emitting fluorescein. The efficiency of the proposed algorithm is demonstrated through experiments using a large number of benchmark problem examples [1]. Ntouni et al. proposed a robust iterative optimization algorithm based on standard particle swarm optimization (PSO) techniques called acceleration-assisted PSO (A-APSO). He implemented the A-APSO algorithm to evaluate the detector weights. The results show that the error performance is better than the weight values evaluated by the PSO algorithm when A-APSO weights are used [2]. Gao et al. proposed a protein structure prediction method. He used three different structural evolution methods, including an improved particle swarm optimization (PSO) algorithm, random perturbation, and fragment replacement, to update the protein structure while keeping the secondary structure unchanged. The high success rate and the accuracy of the results demonstrate the reliability of the method [3]. Zhong et al. proposed to extend the multidimensional similarity space region with group similarity and firstly used the optimal value of the iterative clustering function as the clustering quality index. In addition, he also proposed the fuzzy high-order hybrid clustering (F-HOHC-SIS) algorithm, which can effectively control the convergence speed and reduce the computation time, while improving the anti-interference capability [4]. In cloud environments, various meta-heuristics can be used to solve scheduling problems that fall under the NP-complete problem. Two of the funda-

mental goals of computer science are to discover algorithms that can be shown to perform well and yield optimal or suboptimal solutions. Heuristics, on the other hand, try to provide one or all goals at a time. Tabaghchi proposes task scheduling algorithms to reduce the idle time of virtual machines while achieving load balancing and reducing the running time. According to the results obtained, he reduced the manufacturing time and energy consumption using the proposed algorithm [5]. Son et al. proposed an optimization method to design radar absorbing structures made of fiber-reinforced plastic structures. In the optimized design, the objective function is set to maximize the absorption bandwidth of the X-band stealth. The results confirmed that using the S-FSM not only the electromagnetic performance of the samples could be detected but also the defects caused by the manufacturing process [6]. Ahmadi et al. describe the optimization of parameters involved in the production of nanofibers. Single-walled carbon nanotubes were used to improve the mechanical properties. The results show that the concentration has a greater effect on the fiber diameter than other parameters in PAN and PAN/CNT nanofibers. However, excessive CNTs have a negative effect on elongation and modulus due to the aggregation of CNTs within the nanofibers. The results showed that the PAN nanofibers have an amorphous structure compared to the conventional PAN nanofibers [7]. Lu et al. proposed carbon nanotube bucky paper as a sensing layer in composite materials. Bucky paper is a special kind of carbon nanotube thin layer, which looks very similar to ordinary carbon fiber paper. People also call it "Bucky paper." It is made of only one-fifty thousandth of a human hair, made of molecular weight. The experimental results show that the resistance temperature coefficient of the bucky paper is related to the curing behavior of the resin, and a critical value of the resistance temperature coefficient is determined. In addition, by monitoring and optimizing the curing parameters, the properties of the composites can indeed be improved [8]. Although these theories have analyzed the optimization calculation and carbon nanotube structure to a certain extent, the combination of the two is insufficient and not practical.

3. Swarm Intelligence Algorithm and Evolutionary Computation for Carbon Nanotube Structure Optimization Methods

3.1. Overview of Carbon Nanotubes. Since the 1990s, carbon nanotubes have been paid attention to by scientists. Unlike other materials, carbon nanotubes have two different structures, so carbon nanotubes have many applications in many fields. Carbon nanotubes have two structures, single-walled carbon nanotubes, and multiwalled carbon nanotubes. Single-walled carbon nanotubes can be regarded as hollow cylinders made of a layer of graphite curled, while multiwalled carbon nanotubes are composed of a group of coaxial graphene. In the development of carbon nanometers, its electrical properties have received extensive attention [9, 10]. Nanomaterials are materials with nanoscale structures, which can be divided into zero-dimensional

nanomaterials and one-dimensional nanomaterials according to their specific dimensions. It has been asserted that when people can arrange and combine substances on a very small scale, they will obtain various novel materials [11, 12]. The change in properties caused by the ratio of the number of atoms on the surface of the particle to the total number of atoms increases sharply as the particle size decreases. For example, when the particle diameter is 10 nm, the particle contains 4000 atoms, and the surface atoms account for 40%; when the particle diameter is 1 nm, the particle contains 30 atoms, and the surface atoms account for 99%. Nanomaterials have attracted attention as a potential dielectric material, and most of the current research on this material focuses on the effect of nanoceramic doping on the dielectric properties of ceramics [13]. The electronic properties of metallic carbon nanotubes are not sensitive to the chemical environment, but its electrical conductivity is very superior. It can be used as a wire, and its electrical conductivity far exceeds that of copper, while the internal electronic properties of semiconducting carbon nanotubes are affected by the environment and other substances. In the traditional manufacturing process, the oxide surface is usually coated on the ceramic surface by chemical means. This method can reduce the loss and increase the energy storage density, but since the oxide is a nonferroelectric, the ferroelectric properties of the ceramic itself will interfere [14, 15]. In order to meet the use of nanomaterials in defense and communication, we usually incorporate dopants into the original materials to modify their defects. This method has a good effect and has been widely used in the storage field. In use, it is found that when the doping substances reach a certain limit, the dielectric and ferroelectric properties of ceramics will exhibit relaxation ferroelectric phenomena [16, 17]. The application of nanoceramic materials in capacitors requires a stable dielectric temperature. This is achieved by adding rare earth elements. This method can inhibit the growth of crystal grains and can also obtain dense and fine powders. Figure 1 is an image of nanopowders. This material can be fired into high-density ceramics [18, 19].

Until the end of the last century, the first International Conference on Nanoscience and Technology was held in the United States, which formally combined theoretical research with contemporary science and technology, marking the official birth of nanotechnology [20]. When the size of the material is at the nanometer level, the number of atoms on the surface of the material will increase dramatically, which will far exceed the number of ordinary materials, and the chemical activity of the material will be greatly increased at this time. At the same time, nanomaterials are equal to or smaller than the wavelength of light wave, de Broglie wavelength, and coherence length of superconducting state, and the periodic boundary of the material is destroyed, resulting in "novel" optical, electrical, magnetic, acoustic, and thermodynamic properties. In addition, nanomaterials also have quantum size effects and macroscopic quantum tunneling effects. These unique characteristics provide conditions for the wide-scale application of nanomaterials. With the continuous and in-depth development of theory and practice, nanostructures that are not called sys-

tems have been established. With the maturity of application, the uniqueness of nanomaterials plays a pivotal role in the fields of biotechnology and advanced manufacturing. Figure 2 is a schematic diagram of common nanomaterials.

3.2. Overview of Optimization Calculations. With the continuous development of the production economy, the scale of computation involved is increasing, especially in the fields of management and engineering. With the continuous development of computer technology, and in order to reduce the complexity of the calculation, the optimization calculation came into being. In essence, optimization refers to the use of certain rules to meet the needs of users.

Evolutionary computing is a stochastic optimization method that simulates the genetic mechanism of the animal kingdom. It has the idea of "survival of the fittest." Therefore, when using evolutionary thinking to solve target optimization problems, genetic operations and natural selection become its important components. Evolutionary algorithms iteratively generate multiple solutions to each problem during the optimization process and continue to generate better solutions. The optimization function is called the fitness function. Each solution is called an individual, and all individuals in each generation form a group. The fitness value of individuals in each group is different. With iteration, better individuals are obtained through certain evolutionary strategies, such as crossover and mutation. When the algorithm terminates, the individual with the best fitness value in the entire population is selected as the solution to the problem. Figure 3 shows the basic structure of the optimization calculation.

Evolutionary algorithm is a random search method. Compared with other enumeration techniques and heuristic search techniques, the global optimal solution probability of this problem is higher. The evaluation information of the objective function is used to make it actionable and general. It is concise in form, can be operated with massively parallel computers, and can be easily combined with other methods. At present, evolutionary computing mainly includes genetic algorithm, evolutionary strategy, and evolutionary planning. Genetic algorithm refers to the population of solution sets, and the population is composed of several individuals encoded by genes. In essence, genetic algorithm is an optimization algorithm, which is a random search algorithm that uses the idea of natural selection and biological evolution to search for the optimal solution in the search space.

$$\min \{g(a)|a \in Q\}. \tag{1}$$

Formula (1) represents the function expression of the function optimization model, where a represents the decision variable, $g(a)$ represents the objective function, and Q represents the spatial subset.

$$\min g(a).\text{st} * p(a) \geq 0. \tag{2}$$

Formula (2) represents the decision variable inequality.

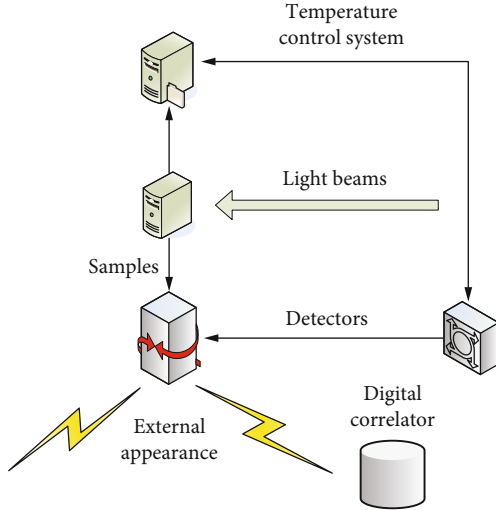
$$Q = \{a \in W^s | p(a) \geq 0\}. \tag{3}$$
Figure 1: Nanopowder image.


Figure 2: Common nanomaterial quiz structure.

Formula (3) represents the feasible region of the decision solution, which is the set of all solutions in layman's terms.

In order to get the optimal solution for the region, we need to optimize the model.

$$\forall a \in QI \left\{ a \in W^s \middle| \sqrt{\sum (a_1 - a*)^2} < a \right\}. \tag{4}$$

When formula (4) is satisfied $g(a*) \leq g(a)$, we say that the model has an optimal solution. Figure 4 shows the basic flow structure of the algorithm.

$$\beta = \frac{T_{\max} - T_{\min}}{2^p - 1}. \tag{5}$$

Formula (5) represents the precision of binary encoding, among them, T represents the range of values, and p represents the length of the encoded symbol.

$$k = T_{\min} + \left(\sum_{o=1}^{p} w_o * 2^{o-2} \right) * \frac{T_{\max} - T_{\min}}{2^p - 1}. \tag{6}$$

Formula (6) represents the decoding function expression when the encoded length is k.

$$\begin{cases} f_p = w_p, \\ f_p = w_{p+1} \oplus w_p, \end{cases} \tag{7}$$

$$\begin{cases} w_p = f_p, \\ w_p = w_{p+1} \oplus f_p. \end{cases} \tag{8}$$

Formulas (7) and (8) represent binary codes under different Gray codes.

In the genetic algorithm, we usually use the fitness function to judge the situation of the individual. The fitness function satisfies the generality, so the calculation steps can be reduced in the actual use process.

$$\text{Fitness}(g(a)) = g(a). \tag{9}$$

Formula (9) represents the functional expression of the maximal optimization problem.

$$\text{Fitness}(g(a)) = -g(a). \tag{10}$$

Formula (10) represents the functional expression for the minimal optimization problem.

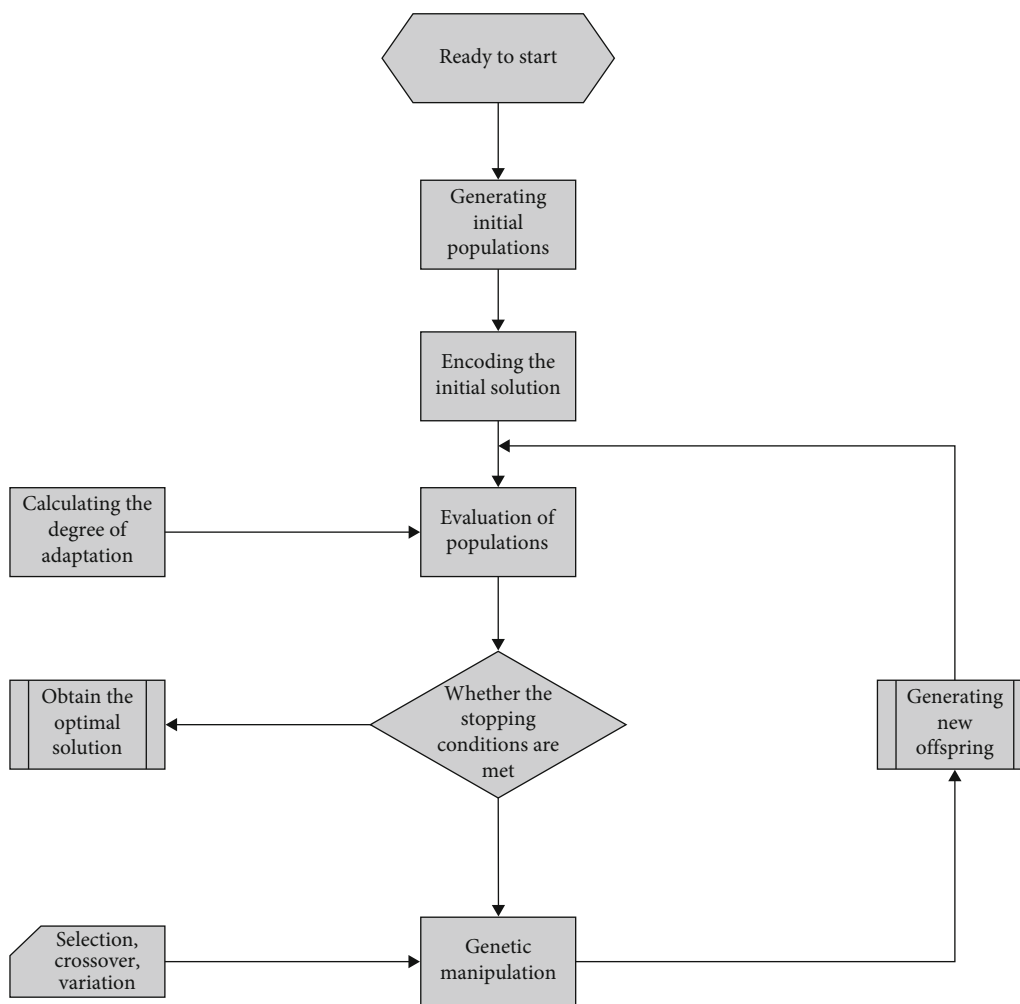
Computers have been developing and progressing continuously since their appearance in 1946 and have been fully used in various fields of social production. Although the development is very rapid, the production needs of human beings are also expanding, and the traditional computing performance cannot meet the current development needs, so high-performance computing came into being. With the ever-increasing demand for computing power, high-performance computing is also evolving. The current research directions of high-performance computing include cluster computing, network computing, cloud computing, and FPGA-based reconfigurable heterogeneous computing [21]. The initial high-performance computing focused on the computing field, but with the continuous improvement of high-performance computing, high-performance computing has basically become an essential means of research, and high-performance computing can be seen in various fields. From computers, minicomputers to mainframes, the development and replacement of computers are fast, but they still cannot meet the needs of computing. Scientific computing, network computing, terminal computing, cloud computing, supercomputing, intelligent computing, GPU computing


FIGURE 3: Basic framework of genetic algorithm.
FIGURE 4: Model algorithm flow demonstration

and other computing modes, concepts, technologies, and applications dominate the progress and development of science and technology. Quantum computing, brain-like computing, borderless computing, human-machine-object ternary fusion computing, data-intensive computing, etc. have brought computing into the era of diversity. Although high performance computing has many advantages, the issues affecting the development of high performance computing are power consumption, energy efficiency ratio, energy saving, ecological environment and industrialization, performance and scalability, reliability and fault tolerance, application efficiency and applicability, efficient management, and low threshold operation [22, 23].

Figure 5 is a schematic diagram of a high-performance scientific computing cluster architecture.

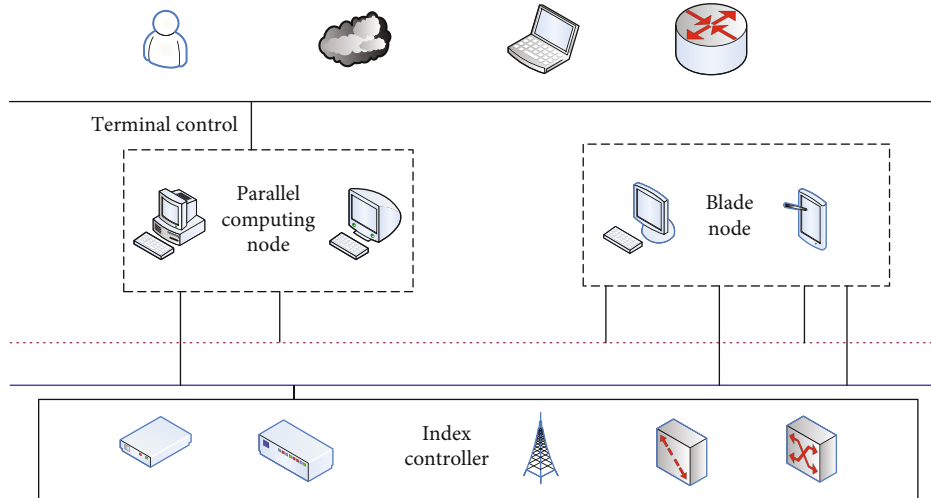
China's research on high-performance computing is relatively late, and the pace of research has been officially started since the advent of China's first shared storage multiprocessor system. The Dawning 400A, developed in 2004, has entered the top ten in the world in computing power. In 2017, the world's first optical quantum computer that surpassed the early classical computers was born. The successful


FIGURE 5: High-performance scientific computing cluster architecture.
FIGURE 6: High-performance computing architecture.

development of the E-class system in 2018 shows that China's computing level has entered the forefront of the world and occupies a very important position in the field of high-performance computing. Figure 6 is a schematic diagram of a high performance computing architecture.

GC-MS is an analytical instrument that can obtain a set of chronological data during the experiment. During the experiment, the target object is composed of t parts, then each component is 1, 2, 3 ... n; the specific function expression is as follows:

$$W_1 = W_{11}, W_{12}, \Lambda W_{1M}, \tag{11}$$

$$W_2 = W_{21}, W_{22}, \Lambda W_{2M}, \tag{12}$$

$$W_N = W_{N1}, W_{N2}, \Lambda, W_{NM}. \tag{13}$$

Among them, W stands for different components.

Introducing the above formula into a matrix, it can be simplified to

$$W = \begin{pmatrix} W_{11}, & W_{12}, & \Lambda & W_{1M} \\ W_{21}, & W_{22}, & \Lambda & W_{2M} \\ \Lambda & \Lambda & \Lambda & \Lambda \\ W_{N1}, & W_{N2}, & \Lambda & W_{NM} \end{pmatrix}. \tag{14}$$

If the matrix is the distribution of n mixtures during the experiment; then, it can be represented by a two-

dimensional matrix. Each row represents a time point, and each column represents the distribution status. The specific function expression is as follows:

$$E = \begin{pmatrix} E_{11}, & E_{12}, & \Lambda & E_{1N} \\ E_{21}, & E_{22}, & \Lambda & E_{2N} \\ \Lambda & \Lambda & \Lambda & \Lambda \\ E_{U1}, & E_{U2}, & \Lambda & E_{UN} \end{pmatrix}. \tag{15}$$

Among them, E represents a two-dimensional matrix.

$$Q_K(C) = \frac{2}{R(c)} \sum_{k=1}^{n} N_{uk} * Y_{uk}. \tag{16}$$

Among them, Q represents the set of indicators, and $Q_K(C)$ represents the indicators under point C.

$$\alpha(C) = \int_M^1 \left(Q_K(C) - \frac{1}{m} \sum_{k=1}^{m} Q_K(C) \right)^3. \tag{17}$$

Among them, according to $0 < Q_K(C) \leq 1$, $0 \leq \alpha(C) < 0.57$ can be obtained.

$$\beta(C) = 1 - 2 * \alpha(C). \tag{18}$$

Among them, according to $0 \leq \alpha(C) < 0.57$, $0 \leq \beta(C) \leq 1$ can be obtained.

$$QW_j(c,r) = \frac{1}{\sqrt{c}} \int_{-\infty}^{+\infty} j(r)\chi * \left(\frac{w-t}{c} \right) dw. \tag{19}$$

Among them, $QW_j(c,r)$ is the wavelet coefficient, $\chi(w)$ is the wavelet basis function, and $j(r)$ is the analysis signal.

$$L_V = W \, \mathrm{diag}\left(s_{(v)} \right) D^U + Q_v, \quad v = 1, 2, \Lambda, V. \tag{20}$$

Among them, L stands for cubic matrix, W stands for pure chromatogram, and D stands for pure mass spectrum.

4. Swarm Intelligence Algorithm and Evolutionary Computation for Carbon Nanotube Structure Optimization Experiment

4.1. Experimental Material Parameters. Materials are the material basis for human survival and the symbol of human material civilization. Materials are the backbone of modern science and technology. At the same time, the progress of science and technology has put forward higher requirements for materials. The structural optimization of carbon nanotube materials explored in this paper is expected to bring infinite possibilities for development through the optimization of material structure. The material parameters involved in this paper are as follows.

TABLE 1: Mechanical parameters of composite materials.

Grain size	Volumetric fraction 6%			Volumetric fraction 10%		
	A (GPa)	B (GPa)	c	A (GPa)	B (GPa)	c
10	4.52	1.68	0.32	5.23	1.93	0.35
11.3	4.47	1.65	0.31	5.22	1.9	0.35
12.4	4.45	1.65	0.32	5.2	1.87	0.33
13.24	4.43	1.63	0.32	5.17	1.85	0.34
14.8	4.4	1.61	0.31	5.13	1.83	0.33

TABLE 2: Nanoparticle unit cell elastic stiffness matrix.

Z (GPa)	1	2	3	4	5
1	6.98	5.32	5.01	-0.31	-0.05
2	7.63	6.31	5.21	-0.04	1.37
3	6.31	4.74	6.97	1.43	0.39
4	5.02	5.25	3.28	0.41	1.39
5	-0.41	-0.03	-0.15	0.039	0.52

TABLE 3: Matrix action energy.

Grain size	Volume	Energy is 5%	Energy is 10%	5% energy per unit volume	10% energy per unit volume
10	4258	-304	-402	-0.09	-0.015
11.27	6512	-501	-456	-0.08	-0.06
12.3	7365	-536	-526	-0.07	-0.03
13.2	8964	-648	-614	0.06	-0.054
14.1	10254	-712	-715	-0.043	0.048

TABLE 4: Single cell model and single cell mechanical properties.

Performance	PI	Volumetric fraction 5%	Volumetric fraction 10%
Young's modulus	4.15	4.6	4.79
Volume	5.4	5.87	7.43
Lamé constant	4.62	4.71	6.25
Shear modulus	1.53	1.63	1.71
Poisson's ratio	0.35	0.36	0.37

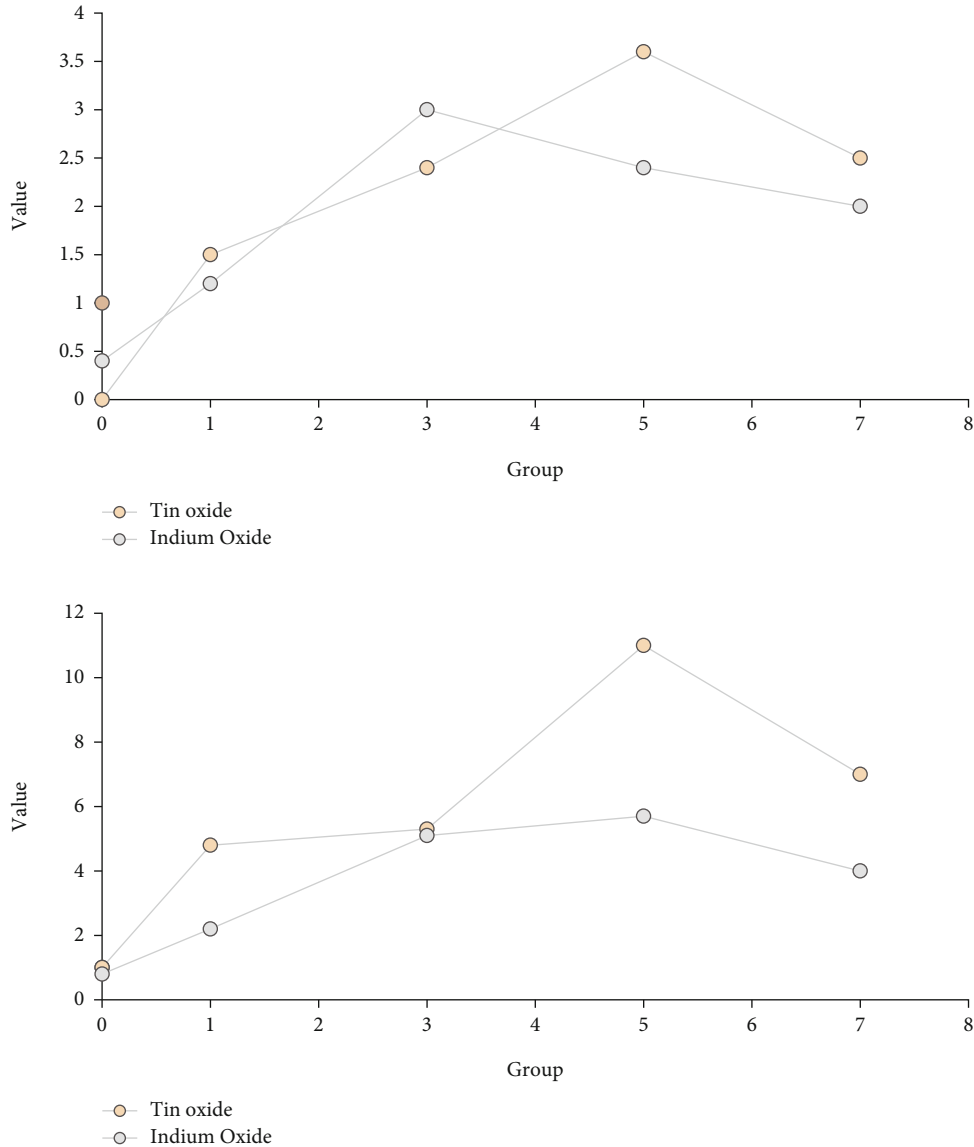
As can be seen from the data in Table 1, assuming that the diameter of the nanoparticles is 10 nm and the thickness of the interface layer is 10 nm, when the volume of the nanoparticles increases continuously, the elastic modulus of the material will also change and show a certain linear law. When the diameter of the nanoparticle is 11.3 nm and the volume fraction is 6%, its elastic modulus is 0.31, and when the volume fraction is 10%, its elastic modulus is 0.35. When the diameter of the nanoparticle is 12.4 nm and the volume fraction is 6%, its elastic modulus is 0.32, and when the volume fraction is 10%, its elastic modulus is 0.33. When the diameter of the nanoparticle is 13.24 nm and the volume


FIGURE 7: Doping concentration vs. sensitivity curve of carbon nanotubes.

fraction is 6%, its elastic modulus is 0.32, and when the volume fraction is 10%, its elastic modulus is 0.34. When the diameter of the nanoparticle is 14.8 nm and the volume fraction is 6%, its elastic modulus is 0.31, and when the volume fraction is 10%, its elastic modulus is 0.33. According to the data, when the particle diameter increases, the elastic modulus decreases and the change trend is relatively gentle.

According to the data in Table 2, there are many factors that affect carbon nanomaterials, and anisotropic materials are used in the experiment. However, according to the data in Table 2, the values of many materials can be regarded as zero, and there are also many materials whose values are relatively close under certain conditions. In fact, when determining the range of particle variation, the number of atoms increases at a certain rate, and when the volume fraction of nanoparticles is 6%, the number of unit cells

surges, and the number of filled molecular chains also increases rapidly.

4.2. Correlation between Material Structure and Matrix. Nanocomposites consist of filler particles, a polymer matrix, and an interface between the two. In order to explore the relationship between the properties and energy of nanomaterial structures, it is necessary to perform single-point energy calculations to obtain the interaction energy between the two.

According to the data in Table 3, when the nanoparticles embedded in the unit cell are enlarged, the number of atoms around them will also increase, and the number of nonbonded pairs between the nanomaterial structure and the matrix will also increase, so the interaction between the two also increases. When the diameter of the material is 10 nm and the volume is 4285, the energy ratios are -0.09
FIGURE 8: Curves of operating temperature versus sensitivity.

and -0.015 in different cases, respectively. When the diameter of the material is 11.27 nm and the volume is 6512, its energy ratios are -0.08 and -0.06 under different conditions, respectively. When the material has a diameter of 12.3 nm and a volume of 7365, its energy ratios are -0.07 and -0.03 under different conditions, respectively. When the diameter of the material is 13.2 nm and the volume is 8964, its energy ratios are 0.06 and -0.054 under different conditions, respectively. When the diameter of the material is 14.1 nm and the volume is 10254, its energy ratios are -0.043 and 0.048 under different conditions, respectively. According to this data, the qualitative correlation between the elastic properties of nanomaterials and the action energy is also related to the volume of nanoparticles. When the diameter of nanoparticles increases, the body-to-surface ratio decreases, resulting in a decrease in the number of nonbonded pairs, weakening the interaction energy, and reducing the elastic modulus of the composite.

4.3. Single-Cell Model and Single-Cell Mechanical Properties. Combined with molecular dynamics, this experiment simu-lates the mechanical properties of nanomaterials, explores the effects of nanoparticles and volume, and explores the relationship between the number of nanoparticles and the properties of composite materials.

According to the data in Table 4, when the PI of the nanomaterial is 4.15 and the volume fraction is 5%, the Young's modulus of the material is 4.6, and when the volume fraction is 10%, the Young's modulus of the material is 4.79. When the PI of the nanomaterial is 5.4 and the volume fraction is 5%, the Lame constant of the material is 4.71, and when the volume fraction is 10%, the Lame constant of the material is 6.25. When the PI of the nanomaterial is 1.53 and the volume fraction is 5%, the shear modulus of the material is 1.63, and when the volume fraction is 10%, the shear modulus of the material is 1.71. When the PI of the nanomaterial is 0.35 and the volume fraction is 5%, the Poisson's ratio of the material is 0.36, and when the volume fraction is 10%, the Poisson's ratio of the material is 0.37. According to this data, the Young's modulus, shear modulus, Lame constant, and volume of the composites all increased when nanoparticles were added to the material.
FIGURE 9: Schematic diagram of the secondary mechanical properties of the composite material.

And the data show that the difference becomes more obvious with the increasing volume, but the Poisson's ratio does not change much.

5. Swarm Intelligence Algorithm and Evolutionary Computation for Structure Optimization of Carbon Nanotubes

5.1. Gas Sensitivity of Carbon Nanotubes. Sensors are an important tool in modern technology. Gas sensitivity is an important branch of sensors that can detect different gases. Therefore, gas sensors are widely used in food and medical fields. Based on this, in order to find out the optimal doping concentration of carbon nanotubes for the two metal oxides, we analyzed them as follows.

According to the data in Figure 7, in order to explore the doping concentration of carbon nanotubes to different oxides, we analyzed the nanomaterials at different tempera-

tures. When the experimental temperature is 150 degrees Celsius, the sensitivity of tin oxide is 0, and the sensitivity of indium oxide is 0.4 in the case of dopant. When the doping content of tin oxide is 1%, the sensitivity of the sensor is 1.5, and when the doping content of indium oxide is 1%, the sensitivity of the sensor is 1.2. When the doping content of tin oxide is 3%, the sensitivity of the sensor is 2.4, and when the doping content of indium oxide is 3%, the sensitivity of the sensor is 3. When the doping content of tin oxide is 5%, the sensitivity of the sensor is 3.6, and when the doping content of indium oxide is 5%, the sensitivity of the sensor is 2.4. When the doping content of tin oxide is 7%, the sensitivity of the sensor is 2.5, and when the doping content of indium oxide is 7%, the sensitivity of the sensor is 2. According to the data, when the doping content of tin oxide is 5%, the sensitivity of the sensor is the best, and when the doping content of indium oxide is 3%, the sensitivity of the sensor is the best.
Figure 10: Schematic diagram of the relationship between composite material modulus and particle size.

When the experimental temperature is 250 degrees Celsius, in the case of dopant, the sensitivity of tin oxide is 1, and the sensitivity of indium oxide is 0.8. When the doping content of tin oxide is 1%, the sensitivity of the sensor is 4.8, and when the doping content of indium oxide is 1%, the sensitivity of the sensor is 2.2. When the doping content of tin oxide is 3%, the sensitivity of the sensor is 5.3, and when the doping content of indium oxide is 3%, the sensitivity of the sensor is 5.1. When the doping content of tin oxide is 5%, the sensitivity of the sensor is 11, and when the doping content of indium oxide is 5%, the sensitivity of the sensor is 5.7. When the doping content of tin oxide is 7%, the sensitivity of the sensor is 7, and when the doping content of indium oxide is 7%, the sensitivity of the sensor is 4. According to the data, when the doping content of tin oxide is 5%, the sensitivity of the sensor is the best, and when the doping content of indium oxide is 5%, the sensitivity of the sensor is the best.

According to the data in Figure 8, when the experimental temperature is 350 degrees Celsius, in the case of dopant, the sensitivity of tin oxide is 3.2, and the sensitivity of indium oxide is 2.1. When the doping content of tin oxide is 1%, the sensitivity of the sensor is 3.7, and when the doping content of indium oxide is 1%, the sensitivity of the sensor is 3.4. When the doping content of tin oxide is 3%, the sensitivity of the sensor is 4, and when the doping content of indium oxide is 3%, the sensitivity of the sensor is 6.2. When the doping content of tin oxide is 5%, the sensitivity of the sensor is 7, and when the doping content of indium oxide is 5%, the sensitivity of the sensor is 4.3. When the doping content of tin oxide is 7%, the sensitivity of the sensor is 4.2, and when the doping content of indium oxide is 7%, the sensitivity of the sensor is 3. According to the data, when the doping content of tin oxide is 5%, the sensitivity of the sensor is the best, and when the doping content of indium oxide is 3%, the sensitivity of the sensor is the best.

According to the experimental data, the sensitivity of carbon nanotubes changes differently at different temperatures. The sensitivity of tin oxide is the best at 350 degrees Celsius, and the sensitivity of indium oxide is the best at 300 degrees Celsius.

5.2. Performance of Carbon Nanotube Materials. According to Figure 9, the tensile strength, elongation, and Young's scale of the original nanomaterials all decreased to varying degrees, mainly due to the structural defects induced by the agglomerates in the matrix, resulting in a decrease in the mechanical energy of the nanomaterials. The improved agglomerates show an initial decrease in energy, allowing them to be more uniformly dispersed in the matrix, while improving the interfacial interaction with the matrix. From a macroscopic point of view, the elastic modulus is a measure of the resistance of an object to elastic deformation. From a microscopic level, as long as it is a factor that can interfere with the strength of the inspection, it can affect the elastic modulus.

According to the data in Figure 10, after the nanoparticles are modified, the Young's modulus and shear modulus of the composite have increased to varying degrees. And according to Figure 10, it can be seen that with the increase of the graft ratio, there will be an increasing trend, and at the same time, the performance of the composite material will decrease with the increase of the drop of nanoparticles.

6. Conclusions

With the development of science and technology, people's production needs are increasing, and traditional computing power cannot meet the needs of production. Therefore, optimal computing has become a current research hotspot. With the gradual deepening of people's understanding of natural science, more and more materials are produced. The purpose of this paper is to study the structure optimization of carbon nanotubes based on swarm intelligence algorithm and evolutionary calculation. Although this paper discusses the structure and optimization calculation of carbon nanotubes, there are still shortcomings: when the single-objective particle swarm optimization algorithm solves high-dimensional complex problems, it is still easy to fall into the local optimal solution, and the convergence accuracy still has a large room for improvement.

High dimensionality of the feature space is one of the problems in the field of text classification. Identification of optimal subset of features can optimize text classification process in terms of processing time and performance. In this paper, we propose a novel Relevant-Based Feature Ranking (RBFR) algorithm which identifies and selects smaller subsets of more relevant features in the feature space. We compared the performance of the RBFR against other existing feature selection methods such as balanced accuracy measure, information gain, Gini index, and odds ratio on 3 datasets, namely, 20 newsgroup, Reuters, and WAP datasets. We have used 5 machine learning models (SVM, NB, kNN, RF, and LR) to test and evaluate the proposed feature selection method. We found that the performance of the proposed feature selection method is 25.4305% times more effective than the existing feature selection methods in terms of accuracy.

1. Introduction

Massive amount of information is generated and pushed into the digital world every second through various sources such as web pages, blog contents, eBooks, social media contents, and review documents. As the content is increasing day by day, it becomes difficult to convert the content into an organized form which causes many problems such as difficult in searching and lack of summarization. Automatic text classification is one of the way to efficiently organize the documents. Supervised machine learning models such as support vector machines (SVM) [1], Naïve Bayes (NB) [2], k nearest neighbor (kNN) [3], random forest (RF) [4],

and logistic regression (LR) [5] are very efficient in organizing content into one or more topics (or classes). There are wide applications of machine learning in the field of text classification such as spam detection [6], sentimental analysis [7], and topic classification [8].

There are three stages in text classification known as preprocessing, feature selection, and final classification. The preprocessing stage is responsible for formatting and removing useless words. Stop word removal, stemming, and text representations are few task performed in the preprocessing stage. Stop word removal eliminates useless symbols such as "is," "was," "that," and punctuation marks. Stemming is responsible for converting all the derived words into its root

form (e.g., "running" is converted to "run," and "walked" is converted to "walk"). Word representing formats the document into usable text. Features are identified in this stage. There are many text representations such as Bag-of-Words (BoW) [9] and n-gram [10].

A feature is the indivisible atomic unit in a text document. A text corpus may contain many documents $D = \{d_1, d_2, d_n\}$. Each document contains m number of unique features, and the entire text corpus contains k number of unique features such as $F = \{f_1, f_2, \cdots, f_k\}$. As the number of documents increases, the corresponding feature size also increases which increases the classification complexity, increases time, and decreases the accuracy. Hence, an optimal subset of F should be found to represent the document much better and increase the classification performance. The total number of subset possibility is $2^k - 1$ (excluding the null set), so it is not practically possible to brute force all the combinations; thus, there are various feature selection algorithms which are aimed at finding out the optimal combinations in much easier way.

There are three types of feature selection methods known as filter based, wrapper based, and embedded based [11]. Filter-based methods are model independent which picks the features based on statistical methods like correlation and chi-square. Filter-based methods are faster than the other two types but it cannot identify the dependency between the features. Wrapper-based methods are model dependent that means for each model, separate sets of features are selected. Wrapper-based methods use an evaluation strategy to pick the optimal subset. The embedded-based method combines both the filter based and wrapper based. Wrapper-based methods inherit both the positives and negatives of filter and wrapper based.

In this paper, we propose a filter-based feature selection method called as Relevant-Based Feature Ranking (RBFR) algorithm which identifies the most important features and removes irrelevant features from the feature space. The proposed method first ranks all the features according to two metrics known as true positive rate (TPR) and false positive rate (FPR). Then, the features from top TPR are picked; within the chosen list, the features with high FPR are removed. The list is appended by the common features selected by odds ratio (OR), information gain (IG), and chi-square feature selection methods. We have compared the proposed method with well-known standard feature selection methods such as balanced accuracy, OR, IG, and Pearson correlation. The main contributions are listed as follows:

(i) To develop a filter-based feature selection method which is able to pick the most important features that could describe the target class better

(ii) To identify and eliminate overlapping or weak features that poorly represent the target class

(iii) To utilize the merits of other filter-based methods to pick correct features

The above-mentioned contributions are aimed at picking the high rich features that could represent the target class

better than the other features; additionally, the error in the selected features should be identified and removed to increase the performance. Moreover, the high features selected by other filter-based methods are also utilized in the feature selection process.

The rest of the paper is organized as follows. Section 2 briefs the literature related to feature selection. Section 3 contains the working of the proposed algorithms. Section 4 presents the experimental results and the comparison with existing machine learning models and with other existing works. Finally, the conclusion is present in Section 5.

2. Related Works

In this section, we brief the recent works in the field of feature selection in text classification and list out the comparison, merits, and limitations.

A research work done by [12] proposes a feature selection method that uses correlation between each feature to the class. They have strengthened the positive features and weakened the negative features. A margin-based feature selection is implemented to increase the performance of the classification. They have evaluated their proposed filter-based method in thirteen datasets and showed the superiority over existing feature selection methods.

Feature selection can also be done in many stages. A work by [13] proposes a three-stage feature selection. In the first stage, they have incorporated particle swarm optimization to search for optimal features in the feature space. The second stage, the redundant features are found and removed from the selected features. The last stage is used to measure each feature for their significance; if the measure is too low, they are deleted from the feature space. Thus, one stage for selecting the features and two stages for removing irrelevant features are used.

The feature selection proposed by [14] focuses on selecting features in two decision levels. In the first level, they have used learners to find the relevant features. The filtration of learners is done to find the high confident learners. The elected learners are allowed to vote in the second level to pick the most relevant features among the feature space.

Clustering is used for grouping features and picking the relevant features in a work proposed by [15]. The redundancy and relevancy problems are solved by the clustering algorithm. A sorting algorithm is used which arranges all the features in the clustering space. Correlation is the main metric used in the sorting algorithm to rank all the features.

An embedded based feature selection was proposed by [16] for classification on Twitter review. As it combines both filter and wrapper methods, it eliminates the semantic problem. Transfer learning is used along with filter-based methods such as information gain, Pearson's correlation, and wrapper-based methods such as expectation maximization. A weight-based deep learning model is implemented to test the performance of the proposed method.

The irrelevant and redundant features present in the text corpus create a negative impact in text classification. A hybrid filter-based feature selection introduced by [17] combines principal component analysis and information gain. In

their experiment, they found that their proposed feature selection method reduces the dimension of data significantly by picking the correct feature subset thus reducing the training time.

A comparison of feature selection was done by [18]; they have used seven filter-based methods, two wrapped-based methods, and one embedded-based method to test the significance of the classification. Three models artificial neural network, support vector machine, and random forest were used in their experiment. Several combinations of feature selection and classifiers are made, and the most appropriate subset is found based on the training performance.

Instance selection is the method of selecting/removing instance. Reducing the number of instances is also one of the methods to increase the performance of the classification. Ensemble methods are also popular in feature selection such as in [19] where the authors have used both feature selection and instance selection. Three-feature selection algorithms along with instance selection are used in their experiment. Two ensemble-based techniques are used in the experiment.

Redundancy and dependency identification is generally good in filter-based methods [20]; a work [21] shows that mutual information feature selection is effective in finding correlation between the features and the target class. When it comes to the fuzzy-based environment, the mutual information like other filter-based methods is weak in calculating correlation and dependencies. They adopted a fuzzy independent classification on a fuzzy-based data space; then, based on the proportion of classification error, they adjust the fuzzy-based feature selection.

Feature selection is optimized by using genetic programming as mentioned in [22]. A hybrid feature selection is done by merging multiple filter-based feature selection methods. A feature construction algorithm is utilized to optimize the selected features. Nine datasets were used in their experiment, and the comparison shows that the feature construction algorithm is effective (Table 1).

From the above-mentioned literature, the feature selection needs lots of improvement, especially when considering the relevancy. Thus, we propose a feature selection which is able to extract the relevant features which improves the efficiency of the text classification.

2.1. Few Existing Feature Selection Methods.
This section presents an overview of three popular feature selection filter-based methods.

2.1.1. Information Gain.
Information gain [28] is a supervised feature selection methods which is used to rank the feature according to the word's contribution based on its presence or absence in a particular set of text inputs [29]. IG is calculated as

$$IG = -\sum_{i=1}^{m} P(c_i) \log P(c_i) + P(t) \sum_{i=1}^{m} P(c_i|t) \log P(c_i|t) P(\bar{t})$$
$$\cdot \sum_{i=1}^{m} P(c_i|\bar{t}) \log P(c_i|\bar{t}), \tag{1}$$

where m represents the total number of target classes. If binary classification is used then m value is 2. $P(C_i)$ denotes the probability of class i. $P(t)$ is the probability of the word t when t is present in the document, and similarly, $P(\bar{t})$ represents the probability of the word t when t is absent in the document. $P(c_i|t)$ and $P(c_i|\bar{t})$ are the conditional probabilities.

2.1.2. Chi-Square.
Chi-square [30] is the test of independence of a feature with the target class. It is used to measure how much a term is diverged from its dependent class [31]. CHI is calculated using the formula shown as follows:

$$CHI = t\big(tp, (tp + fp) + ve_{prob} + t\big(fn, (fn + tn) + ve_{prob}\big)$$
$$+ t\big(fp, (tp + fp) - ve_{prob)} + t(tn, fn + tn) - ve_{prob}\big). \tag{2}$$

The symbols $+ve_{prob}$ and $-ve_{prob}$ represent the probability of the positive class and the negative class, respectively.

2.1.3. Pearson Correlation.
Pearson correlation is one of the good statistical measures to test the dependence of a feature towards the target class [32]. It is unaffected by overfitting [33]. It is calculated by the formula as described as follows:

$$PC = \frac{Cov(X, Y)}{\sigma X \sigma Y}. \tag{3}$$

The existing feature selections have lots of problems such as lack of representation of class unique features, problems in removing the unless and common features, and unable to perform negativity test.

2.2. Overall Drawbacks in Existing Feature Selection Methods.
Feature selection is done to reduce the dimensionality of features in the dataset. Good features need to be identified to separate the classes. As the number of features increases, the complexity of the classifier is also increased; this creates a need for better feature selection methods [34].

Most existing feature selection methods use a weighted method such as frequency and distribution; these feature selection methods fail to pick the class unique features; that is, when one feature is very specific to one class or few classes, that feature is very important for a classifier to determine the class as the classifier feels very easy to identify the class.

Another problem in the feature selection is many methods rely on positive test; that is, if a feature is present, then an appropriate class can be identified; however, negativity test is also one of the powerful methods to eliminate weak candidates in the classification. There are only limited methods for the negativity test.

Combining two or more feature selection methods lets the classifier enjoys the advantages of multiple feature selection methods. The existing methods are least focused on ensembling. Hence, by the use of ensemble technique, the performance of feature selection can be improved.

TABLE 1: Comparison of recent works related to imbalanced classification.

Reference	Technique	Methodology	Comments
[23]	Extreme gradient boosting	Time-, frequency-, and spatial-based features were extracted by the proposed algorithm. Random forest is used for classification.	Correlation in time-based features can be improved. Embedded FS can be incorporated.
[24]	Orthogonal least squares	The authors have improved the speed of fetching the best features using orthogonal least squares. They have compared mutual information and other embedded methods.	Multiple correlation coefficient and the canonical correlation coefficient can be improved when feature generation and instance generation methods are used.
[25]	Centroid mutation-based search	A set of features which can represent a strong convergence to a set of classes is identified. This increases the position of classification margin and reduces the error.	The noisy features can be identified and removed before finding the strong convergence.
[26]	Balanced pointwise mutual information	A deep learning model is employed in Twitter text classification. Special characters like emoji are used as features to classify tweets.	Spam detection can be implemented to increase the accuracy.
[27]	Term weighting	Most of the feature selection methods just use frequency. The authors used category information as additional metric to select features for classification.	Semantics information can degrade the performance of the classification.

3. Relevant-Based Feature Ranking Algorithms

Feature selection is one of the important steps in text classification. The existing problem in ranking features is lack of identification of dependence. A good feature is identified by the following characteristics:

(i) A feature present in only one class is uniqueness, and it helps to identify the class correctly

(ii) A feature present in all the classes is not a good sign to identify a class

(iii) A feature is absent in one or more classes is also uniqueness, and it helps in negativity test

Consider a sample dataset as described in Table 2. There are two classes; one class is representing the topic astronomy, and other class is representing the topic society. Let us take the feature "planet" which is a unique feature in the topic 1; similarly, the feature "marriage" is a unique feature for the topic 2. The words "people" and "life" are present in both the topics. The ACC2 ratings are displayed in the last column; it is noted that for the unique feature "planet" and the nonsignificant feature "life" have the same rating, which is not a good sign for the classification. Hence, the rating methodology should be optimized to select the rich features.

The proposed feature selection algorithm takes this ranking problem in consideration and is aimed at assigning a rank based on its relevance towards the target class. If the feature represents the class fully, then high weight is given; similarly, when the feature is present in almost all the classes, then it is less likely that the proposed algorithm will pick this particular feature. The RBFR algorithm works in the following steps:

(1) Rank the features based on TPR-FPR

TABLE 2: Problems in feature selection.

Feature	Class 1	Class 2	TRP	FPR	Accuracy measure (ACC2)
Planet	5	0	0.5	0	0.5
People	1	2	0.1	0.2	0.1
Life	9	4	0.9	0.4	0.5
Marriage	0	9	0	0.9	0.9

(2) Within the list, remove the features with low FPR

(3) Merge three filter-based FS algorithm selected features

(4) Rank the features based on class unique weights

The feature ranks are given based on four metrics known as true positive (TP), true negative (TN), false positive (FP), and false negative (FN), which are defined as follows:

(i) TP: if a feature is present in the positive class

(ii) TN: if a feature is absent in the positive class

(iii) FP: if the feature is present in the negative class

(iv) FN: if the feature is absent in the negative class

The rich features for each class are determined by the ACC2 (TPR-FPR) [35], but there are high chances that the negative features are also selected alone with the rich features. Hence, a second level filtration on the basis of FPR could remove the weakly represented features.

3.1. Feature Selection Methods. To increase the rate of representation, three popular feature selection methods, namely, information gain, chi-square, and Pearson correlation, are

---

Input: F= set of features in the text corpus
Output: S – top N rich features
Begin:
1 **For each** f **in** F
2   TPR score = $TP/TP + FN$
3   FPR score = $FP/TN + FP$
4   L = {top k_1 features with high TPR-FPR score}
5 **For each** f **in** L
6   **If** FPR(f)<TH **then**
7   Remove f from L
8   F1 = top N features from IG = $-\sum_{i=1}^{m} P(c_i) \log P(c_i) + P(t) \sum_{i=1}^{m} P(c_i|t) \log P(c_i|t) + P(\bar{t}) \sum_{i=1}^{m} P(c_i|\bar{t}) \log P(c_i|\bar{t})$
9   F2 = top N features from CHI = $t(tp, (tp + fp) + ve_{prob}) + t(fn, (fn + tn) + ve_{prob}) + t(fp, (tp + fp) - ve_{prob)} + t(tn, fn + tn) - ve_{prob}$
10   F3 = top N features from Pearson Correlation
11   Common Features = $(F1 \cap F2) \cup (F1 \cap F3) \cup (F2 \cap F3)$
Return $L \cup Common\ Features$

ALGORITHM 1: RBFR.

used to extract features. If a feature is selected by at least two of the feature selection methods, then that feature is also selected as per equation (4) for classification.

$$F = (F1 \cap F2) \cup (F1 \cap F3) \cup (F2 \cap F3). \qquad (4)$$

$F1$, $F2$, and $F3$ in equation (4) represent the features selected by information gain, chi-square, and Pearson correlation, respectively. The details of the feature selection algorithms are briefed in the following subsections.

3.2. Class Unique Features. A feature is important based on how it represents the class. If a feature is present in only one class, then the feature is very important because it is very unique to a class. Similarly, if a feature is present across many classes, then it is very less important. After the second level of filtrations, a unique weight is calculated for each feature. This weight is based on the occurrence of a feature across various classes. Consider Table 3 which displays feature wise and class wise frequency, where $F_{i,j}$ represents the frequency of feature i in the class j. The first step is to remove the less class wise frequent term as per the condition in

$$\sum_i \sum_j F_{i,j} > \frac{\sigma}{n}. \qquad (5)$$

The average of all frequency count is calculated, and the first step is to remove all the entries which have the frequency less than the average frequency. Then, an inverse class frequency is calculated to find out whether a feature is common or rare. A term which is very important is then filtered using a threshold value as described in equation (6), where $|C|$ is the total number of classes in the classification. $F(c)$ represents the number of classes the feature f represent.

$$Threshold(f) = TF * \log \left(\frac{|C|}{|F(c)|} \right). \qquad (6)$$

TABLE 3: Feature weights.

Feature	Class 1	Class 2	Class 3	Class 4
1	$F_{1,1}$	$F_{1,2}$	$F_{1,3}$	$F_{1,4}$
2	$F_{2,1}$	$F_{2,2}$	$F_{2,3}$	$F_{2,4}$
3	$F_{3,1}$	$F_{3,2}$	$F_{3,3}$	$F_{3,4}$

3.3. Machine Learning Models. The proposed feature selection algorithm is tested using five machine learning models which are briefed in the following subsections.

3.3.1. k Nearest Neighbor. kNN is the machine learning models that finds distances between each instance. When a new sample or instance needs to be classified, the kNN finds the k closest neighbors from the instance, and the target class is found by majority voting. Some statistical methods are used to fix the value of K before starting the classification. It is better to fix the value of K as odd number. kNN is called as lazy classifier because it does nothing in the training phase; the distance calculation and the majority voting are done only in the classification phase.

3.3.2. Naïve Bayes. One of the most used classifiers in the field of text classification is Naïve Bayes. This model works with the probability concept of Bayes theorem. NB groups the instances based on similarity and determines the class of the new sample based on how much it is related with each class.

3.3.3. Support Vector Machines. Support vector machines are the most used classifier in the text classification domain.

SVM can classify both linear as well as nonlinear data. A support vector is an end point in each class. The SVM model fixes a linearly separatable margin between the class; this margin is used to classify the instances.

3.3.4. Random Forest.
RF is an ensemble-based classifier. The RF uses multiple decision tree. The number of DT is fixed before the start of classification. Each decision tree receives unique set of input and trained separately. Then, the output of each DT is used in majority voting to determine the final class.

3.3.5. Logistic Regression.
LR is a special type of classifier that is used to classify linear data. LR constructs a margin which separates the classes. The new instances are assigned a class based on the position where it resides with respect to the margin.

4. Results and Discussion

We have used three benchmark datasets for evaluating our proposed feature selection algorithm. Table 3 contains the descriptions of all datasets.

4.1. Dataset Description. The three datasets contain different instances, number of classes, and number of features as shown in Table 4. We have taken random 2500 features from each dataset for our experiment.

4.2. Performance Evaluation. In order to test the performance of our proposed feature selection algorithm, we have used four standard metrics: accuracy, precision, recall, and F1-score. The formulas for calculating all the metrics are shown as follows:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN},$$

$$\text{Precision} = \frac{TP}{TP + FP},$$

$$\text{Recall} = \frac{TP}{TP + TN},$$

$$\text{F1-Score} = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}}.$$

(7)

All the documents are preprocessed; stemming and stop word removal are done before the classification; also, a

second level of filtering is done by identifying the frequent words. The frequent words are features that are present in almost every document. The datasets are divided as per 10-fold validation.

The characteristics of the features that are selected by a feature selection algorithm can be analyzed to test the effectiveness of the feature selection algorithm. If unique features are selected and high rank is given to those features, then it is more likely that the performance of the classification will be good. Similarly, if irrelevant features are assigned higher ranks, then that will cause very poor performance in classification. The proposed feature selection method removes the high false rates thus provides a way to rank good feature. This is one of the reasons for the good performance of each classifier. Along with the ranking, the RBFR also considers top selected features from three well-known filter-based methods, and the common features present in them were selected. The precision, recall, and F1 comparison are shown in the Tables 5–7 for the datasets Reuters, WAP, and 20 newsgroups, respectively.

From the performance comparison tables, it is clear that the RBFR method identifies the rich features present in the corpus and ranks them higher than the irrelevant features. Precision is one of the good measures to judge a classification. It indicates the quality of positive predictions. The RBFR has higher precision in majority cases while compared with other feature selection methods.

The ensemble of three filter-based feature selection increases the chance of selecting high rich features. As the selected features contain high level features, the classification using RBFR method is much higher than the classification done by other feature selection algorithms. Figures 1–3 display the accuracy of kNN in the three datasets. We have compared our proposed feature selection algorithm with other two works, and Table 8 shows the comparison.

The participation of multiple number of features in the process of classification is one of the important stages as it is not only responsible for increasing the efficiency of classification but also reduces the presence of simultaneous information redundancy. To solve the problems which affect the classification performance, the number of features should be selected optimally. If the feature size is very high, it increases the time of training rapidly; also if the size is too small, the accuracy becomes very low. Hence, the optimal number of features is determined by linearly increasing the number of features and stop when the performance degradation is observed.

In our experiment, we noticed that the optimal feature size is 600; after that, the accuracy of the classifiers seems to reduce. Among the classifiers, random forest seems to have increased accuracy even after 600; this is because the random forest can reduce the dimensionality by branching over the data. Up to 1400, the random forest classifier produces acceptable accuracy.

From Figure 4, it can be seen that among the existing feature selection methods, our proposed method outputs better performance in terms of accuracy, and SVM classifier produces the best accuracy when the number of features is 600. From the analysis, it can be found that as the number of features increases, there is a positive fluctuation in the classification performance. This is because, more sufficient knowledge can be derived in the training stage to improve the accuracy of the classification. Information duplication may arise when the number of features is increased too much; hence, an optimal count is preferred.

The number of neighbors plays a critical role in classification. From Figure 5, it can be observed that as the number of

neighbor's increases, the performance also increases, but after 75, the classifier stabilizes. The proposed feature selection produces better results than the other feature selection methods because the removal of noise and redundant features.

5. Conclusions

Feature selection is one of the important stages in improving the performance of text classification. The existing feature selection methods can identify rich features present in the text corpus, but still lots of irrelevant features are also selected which degrades the performance of the text classification. In this work, we propose a ranking-based feature selection model which can identify and eliminate the irrelevant features from the selection set. We have implemented the proposed feature selection model in three datasets and compared with five existing filter-based feature selection methods, namely, ACC2, NDM, CHI, GI, and IG. The machine learning models used for classification were kNN, SVM, NB, LR, and RF. The experiment result shows that NB outperforms the classification task with 93.96% accuracy. In future work, we aim to rank the features based on its semantics and implement deep learning-based classification.

Preparation of SnO₂-Based Composite Gas-Sensitive Material and Its Effect on the Membrane Treatment Process of Volatile Organic Compounds

Youping Shou, Junjie Zhao ⓘ, and Jianzhe Qiao

Tianjin Research Institute for Water Transport Engineering, M.O.T., 300000 Tianjin, China

Correspondence should be addressed to Junjie Zhao; 631406010214@mails.cqjtu.edu.cn

Semiconductor oxide-sensitive materials can be divided into n-type materials and p-type materials according to this characteristic. The carriers in n-type materials are mainly electrons, which are formed by the existence of a large number of oxygen vacancies in the material's crystal lattice. Common n-type materials include SnO_2, In_2O_3, and ZnO. This article is aimed at studying the effect of SnO_2-based composite gas-sensitive materials on the treatment process of volatile organic compounds. In this paper, the biomembrane method, the ultrafiltration membrane transmembrane pressure difference method, and the chemical reaction activity analysis method in the membrane treatment detection method are proposed, and then, the empirical kinetic model for the preparation of SnO_2-based composite gas-sensitive materials is established, and the TPU nanometer is analyzed. The cross-sectional scanning of the composite material explored the effect of the curing agent content on the SnO_2-based composite gas-sensitive material and analyzed the mechanical properties of the material. The experiment in this article uses 15 orders of magnitude of mechanics, which improves the scientific nature of the article. The experimental results show that the material modification has a better improvement effect on the film treatment process of volatile organic compounds.

1. Introduction

1.1. Background. With the development and progress of society, the population of urban areas has expanded, the flow of motor vehicles has increased, and chemical products have increased, but they have strong chemical activity. Some VOCs are also highly toxic and have certain hazards to the atmospheric environment and organisms. Affected by changes in the intensity of emission sources and traffic activities, VOCs exhibit regular daily and seasonal changes. The literature shows that there is a significant seasonal variation in the concentration of VOCs, which reaches the highest value in winter and drops to the lowest value in summer. Due to the low temperature in winter and the increase in coal consumption for heating, the increased VOC emissions increase the concentration level in the atmosphere, and the high temperature in summer reduces the consumption of coal and other energy sources. At the same time, high temperature promotes the elimination of some VOCs in the

atmosphere and reduces the level. In addition, in the chemical plant area, VOCs are greatly affected by changes in temperature. Olefin compounds such as isoprene are mainly derived from the natural emissions of plants, and their changes show significant characteristics of plant emissions. However, none of these methods can fundamentally solve the volatility problem of volatile organic compounds such as styrene.

1.2. Significance. For the detection of harmful gases, there are currently two methods: large analytical instruments and gas sensors. Although large-scale analytical instruments have the advantages of accurate and high-precision gas detection, they cannot be the main method for gas detection due to their high price, inconvenience to carry, and inability to complete rapid detection. For more than half a century, through the continuous efforts of scientists, the application of semiconductor oxide sensors in real life has become more and more extensive. At the same time, the nanofiber

material has the advantages of uniform thickness and good morphology consistency, which reduces the influence of the morphology on the gas-sensing properties and facilitates the comparison of the gas-sensing properties of different materials. However, semiconductor gas sensors still have a series of problems such as inaccurate gas detection and poor accuracy. Therefore, it is necessary to develop high-performance gas sensors to complete the detection of the types and concentrations of harmful gases.

1.3. Related Work. Volatile organic compounds are an important air pollutant and have a huge destructive effect on the human living environment. Zheng et al.'s research is aimed at evaluating the efficiency of removing volatile organic compounds (VOC) from process gases in the eastern Polish food industry plant, which produces high-quality animals (geese, ducks, and pigs) and vegetable fats using two phases: method combined with biological purification and membrane separation. The research was conducted on a semitechnical scale and compared the effects of traditional and two-stage biological filtration under the same process conditions. The concentration of VOC in the process gas is measured by a multigas detector. In addition, the temperature and humidity of the gas are determined by a thermal anemometer under the filter bed, followed by two different types of filling materials (a mixture of stumps and bark, and a mixture of stumps, bark, and compost: European Union and Poland national standard methods) and two kinds of membranes (using three-layer semipermeable membrane fabrics with different air permeability and water tightness) were analyzed [1]. VOC (volatile organic compounds) are mainly produced in workplaces or laundry shops using spray paint processes or organic solvents. Large-scale plasma treatment of exhaust gas under industrial or municipal conditions requires a high-efficiency plasma conversion process at a high processing speed, that is, a large volume flow. Due to the use of plasma processing steps, the integration of the plasma unit into the existing system puts forward requirements for pipeline system compatibility and minimum pressure drop. The innovative rotating electrode sliding arc plasma device described in this article can meet these conditions. The system consists of propeller-shaped high-voltage electrodes in a grounded metal pipe. The design of the high-voltage electrode eliminates the pressure drop inside the air system. In contrast, the plasma device itself can drive exhaust gas with a tube diameter of 20 cm at a volume flow rate of up to 300 cubic meters per hour. They are composed of various forms of hydrocarbons. Because of their low concentration, they are diluted in the atmosphere, so it is difficult to burn directly with traditional burners. In this research, Sun et al. proposed a new form of VMDC (volume matrix dump) burner to process this low-calorie VOC gas. The burner configuration combines the characteristics of a plasma burner, dump burner, and volume matrix burner. Therefore, VMDC is configured to ensure sufficient decomposition temperature and residence time for stable flame formation and VOC decomposition. [2]. Although wood-based panels release harmful formaldehyde, they are still widely used. In order to protect humans

from exposure to formaldehyde, we have successfully produced particle board by surface treatment of wood fibers and the use of unsaturated polyester resin (UP) as a formaldehyde-free binder. Phenolic (PF) aqueous solutions are used to treat wood particles to make them more compatible. Wan et al. inspected whether the mechanical properties of particleboard meet the national standard and M-1 level (ANSI A208.1-1999). The water absorption test confirmed the dimensional stability of FF particleboard. The performance of PF-treated FF particleboard is several times better than that of untreated FF particleboard. In addition, the effect of PF treatment on the adhesion of wood particles and UP interface was also studied by SEM, DMTA, and contact angle measurement. The results confirmed that PF treatment improved the interfacial adhesion between UP and wood particles [3]. Although his experimental studies have improved the interfacial adhesion between UP and wood particles, the adhesion is still insufficient.

1.4. Innovation. This paper introduces the curing kinetic parameter algorithm of unsaturated polyester resin, membrane processing detection method, chemical reaction activity analysis method, and other methods and then constructs the empirical kinetic model of unsaturated polyester resin, the preparation of cellulose nanocrystals, and study on the apparent kinetics of curing of unsaturated polyester resin and finally analyze the cross-sectional scan of the TPU nanocomposite, explore the effect of curing agent content on the gel time of unsaturated polyester resin, and analyze the mechanical properties of the material. According to the conclusions obtained after the comparison, the mechanism of the enhanced gas sensing properties of the composites and the mechanism of the conductivity type transition were analyzed.

2. Experimental Method

2.1. Gas Sensor Production. The experiment mainly uses hollow ceramic tubes to prepare indirectly heated gas sensors for gas sensitivity testing [4]. There are two ring electrodes in the middle of the ceramic tube, and each ring electrode leads out two pins. Put the metal oxide sensitive material prepared after the experiment into a mortar, add an appropriate amount of deionized water to it, and grind for 15-20 minutes, so that the sensitive material and deionized water are fully mixed to obtain a paste with good uniformity material [5, 6]. Use a brush to evenly coat the polished material on the middle part of the two electrodes of the ceramic tube, and the thickness should cover the electrodes. After drying at room temperature, put the coated ceramic tube in the muffle furnace, raise it to 300°C at a rate of 2°C/min, keep it for 120 minutes, and then lower it to room temperature at a rate of 3°C/min to ensure that the material is firmly attached to the electrode surface [7]. Pass the heating wire in the middle of the processed ceramic tube, weld the heating wire and the ceramic tube to the hexagonal base, aging in the air at a temperature of 300°C for 1 week, and then obtain a gas sensor that can be tested [8].

The static test system consists of air distribution box, DC power supply, A/D data acquisition card, and computer. The volume of the gas distribution box is 50 l, which is mainly used to prepare the required concentration of gas. The DC power supply is used to provide stable voltage, test voltage, and heating voltage for the gas sensor. The A/D data acquisition card (model USB7360B) is mainly used to convert the analog signal obtained by measuring the voltage of the sensitive element into a digital signal and then upload it to the computer for analysis by the software in the computer.

Since the VOC gas in this experiment is obtained through the vaporization of the corresponding organic solution, a heating crucible is equipped in the gas distribution box, which is to accelerate the evaporation of organic gas, and it is equipped with a gas exchange device and a test circuit [9]. During the test, the relationship between the volume V of the organic liquid to be injected and the gas concentration c in the gas distribution box is as shown in the formula:

$$\frac{p * w\% * v}{M} = \frac{V * c}{22.4 * (273 + T)/273}. \tag{1}$$

After simplification, you can get

$$v = \frac{V * c * M * 273}{(273 + T) * 22.4 * p * w\%}. \tag{2}$$

In the formula, M represents the molar mass of the gas to be tested, p represents the density of the organic liquid, $w\%$ represents the mass fraction of the component to be tested in the organic liquid, V represents the volume of the test chamber, and T is the temperature of the test chamber. For p-type materials, the expression of the response value S of the gas

$$S = \frac{Rg}{Ra} = \frac{Ug(10 - Ua)}{Ua(10 - Ug)}. \tag{3}$$

For n-type materials, the gas response value S can be expressed as

$$S = \frac{Ra}{Rg} = \frac{Ua(10 - Ug)}{Ug(10 - Ua)}. \tag{4}$$

In the formula, Ua and Ug are the voltage values of the tested component measured by the static test system in air and organic gas, respectively.

2.2. Membrane Treatment and Detection Method

2.2.1. Ultrafiltration Membrane Transmembrane Pressure Difference Method.
The experiment uses the change of transmembrane pressure difference as the basis for evaluating the fouling rate of the ultrafiltration membrane, and the transmembrane pressure difference is monitored online by a pressure gauge [10]. The detected water quality data includes the turbidity, SDI, and CODMn of the incoming and outgoing water of each processing unit. The surface morphology

changes of ultrafiltration membranes under different operation modes are analyzed.

In order to explore the pollution mechanism of ultrafiltration under different pretreatment conditions, the experiment refers to the Darcy resistance model [11] and analyzes each part of the resistance generated during the ultrafiltration process. The formula is as follows:

$$J = \frac{\Delta p}{\mu (R_m + R_f + R_c)} = \frac{\Delta p}{\mu R_t}. \tag{5}$$

Each resistance can be calculated by the following formula:

$$R_m = \frac{\Delta p}{\mu j_{iw}}, \tag{6}$$

$$R_f = \frac{\Delta p}{\mu j_{iw}} - R_m, \tag{7}$$

$$R_c = \frac{\Delta p}{\mu j} - (R_m + R_f), \tag{8}$$

where j_{iw} is the initial membrane water flux, $m^3/(m^2 \cdot h)$ and j is the membrane water flux after pollution, $m^3/(m^2 \cdot h)$.

Membrane treatment ultrafiltration technology has broad prospects in the treatment of volatile gases, sewage, drinking water, and surface water due to its own advantages. Based on the current problems of ultrafiltration, this research studies the pollution mechanism of ultrafiltration membranes to alleviate membrane pollution and reduce the cost of ultrafiltration. It also compares and analyzes the current commonly used pretreatment methods to find out suitable pretreatment methods such as Figure 1 shows the ultrafiltration device and its simple schematic diagram.

2.3. Chemical Reaction Activity Analysis Method.
Although the content of VOCs in the atmosphere is small, they can undergo a series of chemical reactions with oxidants such as OH radicals, HO_2 radicals, and O_3 in the atmosphere and play an important role in the elimination of atmospheric oxidants, thereby affecting the global OH radicals Distribution. On the other hand, VOCs can interact with NOx in the atmosphere and have an important impact on the formation of tropospheric ozone on a regional or even global scale. VOCs and ozone and other photochemical oxidation products can endanger the health of exposed people. VOCs have high volatility and also have characteristics such as permeability and lipophilicity. Most of the aromatic compounds are toxic and harmful substances. Due to the high lipophilicity, these compounds will enter the human body through respiration and be enriched. People who are exposed to these low-concentration toxic and harmful pollutants for a long time will produce chronic hazards. This hazard is often difficult to attract people's attention. These pollutants mainly irritate the eyes and nasal mucosa through contact with the respiratory mucosa, resulting in chronic bronchitis and asthma. Physiological dysfunctions such as lung cancer and

lung cancer aggravate the condition of hypertension and heart disease.

At present, there are two main methods used to measure the reactivity of VOCs and their contribution to ozone production: First, the reactivity of VOCs species is expressed as

$$L_i^{\text{OH}} = [\text{VOCs}]_i \times K_i^{\text{OH}}. \tag{9}$$

Calculate the reactivity of each component of VOCs and then add the LiOH of each species in the component:

$$L^{\text{OH}} = \sum [\text{VOCs}]_i \times K_i^{\text{OH}}, \tag{10}$$

$$\Phi_{\text{ofp}} = \xi_{\text{MIR}} \times \rho(c_2 - c_{12}). \tag{11}$$

2.4. Performance Indicators of Gas Sensors. The performance of the gas sensor is mainly judged by the following aspects: the response value of the gas sensor, the working temperature, the selectivity, the response-recovery time, the stability, etc.

The response of the gas sensor to the gas to be measured will be affected by temperature, because the gas to be measured requires a certain amount of energy to react on the surface of the gas sensor [12, 13]. When the temperature is too low, the energy provided is too little, which will result in too little gas to be measured on the surface of the sensor, resulting in a relatively low response value; when the temperature is too high, it will lead to waste of energy and even damage to the device [14]. At a specific temperature, the sensitive element will show the maximum response value of the gas to be measured, and this temperature is usually called the optimal working temperature of the element. A lower optimal working temperature or even room temperature operation is one of the necessary conditions for a sensor with good performance [15, 16].

Selectivity is obtained by comparing the response value of the sensor to a specific gas with the response value of other gases [17]. It is known that the sensitive element will respond to a variety of gases when working at the optimal operating temperature, which will cause errors in the measurement. Therefore, it is necessary to prepare components with good selectivity.

B (°C/min)	Ti (°C)	Tp (°C)	Tf (°C)
2	46.8	54.5	62.5
5	65.1	73.1	81.2
10	76.9	91.0	107.2
20	82.6	100.8	125.7

TABLE 2: Composite gas-sensitive material curing kinetics data.

B (°C/min)	Tp (°C)	Tp (K)	$1/Tp$	$-\ln \beta/T^2_P$	$\ln \beta$
2	54.5	327.6	$3.053 * 10^{-3}$	10.890	0.693
5	73.1	346.3	$2.888 * 10^{-3}$	10.085	1.609
10	91.0	364.2	$2.746 * 10^{-3}$	9.493	2.303
20	100.8	374.0	$2.671 * 10^{-3}$	8.853	2.996

When it comes into contact with the gas to be measured, it takes a certain time for the sensitive element to reach the maximum response value [18]. The time when the initial state reaches 90% of the maximum response value is usually defined as the response time; similarly, when it is separated from the gas to be measured, the sensitive element needs to be restored. It takes a certain time to restore to the original state. Usually, the time from the maximum response value to 10% of the maximum response value is defined as the recovery time. Shortening the response-recovery time is helpful for continuous detection, so the response-recovery time is also an important parameter of the gas sensor.
FIGURE 4: ln $(\beta/T^2_p) \sim 1/Tp$ and ln $\beta \sim 1/Tp$ of the curing reaction of composite gas-sensitive materials.
FIGURE 5: The relationship between T and β.

If the gas sensor is used for a long time or stored for a long time, its internal structure will change, causing the resistance to drift when measuring gas [19]. This will cause problems such as a decrease in the response value, which will affect the accuracy of the measurement. Therefore, stability is the decisive factor for whether the gas sensor can be applied in real life. The performance of these sensors is mainly determined by the characteristics of sensitive materials. Therefore, in order to make a gas sensor with good performance, it is necessary to prepare a sensitive material with good characteristics.

For gas sensors, sensitive materials with good characteristics must be prepared. The gas-sensing characteristics of

sensitive materials are mainly determined by factors such as the composition of the material, the morphology of the material, the porosity of the material, the size of the grain size of the material, and the specific surface area of the material. Therefore, improving the gas-sensing properties of sensitive materials can be achieved through physical modification and chemical modification.

3. Experimental Inquiry

3.1. Establishment of an Empirical Kinetic Model of Unsaturated Polyester Resin. The curing kinetics of unsaturated polyester resins can be roughly divided into two
FIGURE 6: (a) GO/TPU, (b) GOE/TPU, (c) GOS/TPU, and (d) cross-sectional SEM image.

categories: empirical kinetic models and mechanism kinetic models [20]. The former does not consider the specific reaction process between the reactants, but a curing kinetic model equation established by mathematical simulation of a series of kinetic parameters measured through experiments during the curing reaction process. The latter is a curing kinetic model based on the principle of free radical polymerization. Unsaturated polyester resins include chain initiation, chain extension, and chain termination during the curing process, which are related to each other, and the reaction is difficult to stay in a certain way. In the first stage, with many parameters, it is difficult to get a suitable model. Therefore, empirical kinetic models are more commonly used to analyze the curing kinetics of unsaturated polyester resins.

The kinetic model of the n-order reaction model of unsaturated polyester resin is expressed as

$$\frac{d_a}{d_t} = kn(1-a)^n. \tag{12}$$

Curing reaction rate equation:

$$\frac{d_a}{d_t} = An(1-a)^n \exp\left[-\frac{E}{RT}\right]. \tag{13}$$

The expression of the autocatalytic model is

$$\frac{d_a}{d_t} = (_1 + k_2 a^m)(1-a)^n, \tag{14}$$

where k_1 is the reaction rate constant when $t = 0$ and k_2 is the reaction rate constant when $t > 0$, and both conform to the Arrheriu formula. m and n are the reaction order. Generally, it is assumed that the reaction order is 2 (i.e., $m + n = 2$). Equation (14) is widely used to describe the autocatalytic model of isothermal curing behavior of epoxy resin; afterwards, Ahmed et al. [21] did further research on Equa-

tion (14) and found that when $k_1 = 0$, it can be better used to study the isothermal curing kinetics of unsaturated polyester resin; the equation is as follows:

$$\frac{d_a}{d_t} = k_2 a^m (1-a)^n. \tag{15}$$

For this equation, there are also many application examples. Researchers have studied the curing kinetics of unsaturated polyester resin/composite initiation system and BMC materials and found that the selection of Equations (9)–(15) can well describe the curing reaction of unsaturated polyester resin.

3.2. Preparation of Cellulose Nanocrystals

3.2.1. Extraction of Cellulose Nanocrystals. According to related literature, cellulose nanocrystals (CNs) are extracted from cotton linters by sulfuric acid acidolysis. The specific steps are as follows: disperse 20 g of cotton linters in 175 ml with a concentration of 30% (*v/v*) sulfuric acid solution. The stirring was continued for 6 hours at a speed of 100 rpm at 60°C. After the reaction, the residual sulfonic acid groups on the surface of CNs were removed. Finally, freeze-dry at a low temperature of -50°C for more than 3 days. The CNs from which the distilled water has been removed are ground to obtain a white powder.

3.2.2. The Acetylation Process of Cellulose Nanocrystals. Weigh 5 g of CNs in 100 ml of anhydrous pyridine to ultrasonically disperse for 15 min to obtain a CNs suspension. Place it in a three-necked flask. Then, prepare a mixed solution of 25 ml of acetic anhydride and 20 ml of anhydrous pyridine. Add the acetic anhydride pyridine solution dropwise to the CN pyridine suspension through a separatory funnel to carry out the acetylation reaction. The acetylation process is carried out in a three-necked flask by condensing reflux. React at 400 rpm for 5 h at °C. After the reaction, the product in the three-necked flask was poured into 1 l of
FIGURE 7: The effect of the amount of curing agent on the time of the composite gas-sensitive material was studied.
FIGURE 8: Comparison of elongation at break of graphene oxide/hydroxylated carbon nanotubes synergistically modified composite gas-sensitive materials.

TABLE 3: Mechanical properties of the composites.

Sample	Tensile strength (MPa)	Flexural modulus of elasticity (MPa)	Elongation at break (%)
0	38.42	2020.95	2.117
0.1	57.05	1678.46	4.189
0.25	53.31	1547.16	3.983
0.5	44.68	1721.01	2.896
0.75	45.96	1843.57	2.774
1	34.69	1931.86	1.951

distilled water to terminate the reaction, and the cellulose nanocrystals were precipitated, washed three times with acetone centrifugal precipitation, and then washed three times with distilled water. Then, it was dialyzed in distilled water

for 12 hours, and finally, the acetylated cellulose nanocrystals were freeze-dried, and the freeze-dried acetylated cellulose nanocrystals were ground to obtain a white powdery product (ACN).

Figure 2 shows a transmission electron microscopy (TEM) image of cellulose nanocrystals (CNs), using sulfuric acid hydrolysis to remove the amorphous areas in the linters cellulose and successfully extract CNs. After observation, the extracted CNs have a rod-like nanomorphology structure. The length of CNs was measured with the Image-Pro software to measure the average size length: length $L = 310.1 \pm 47.8$ nm and width $D = 18.9 \pm 6.2$ nm.

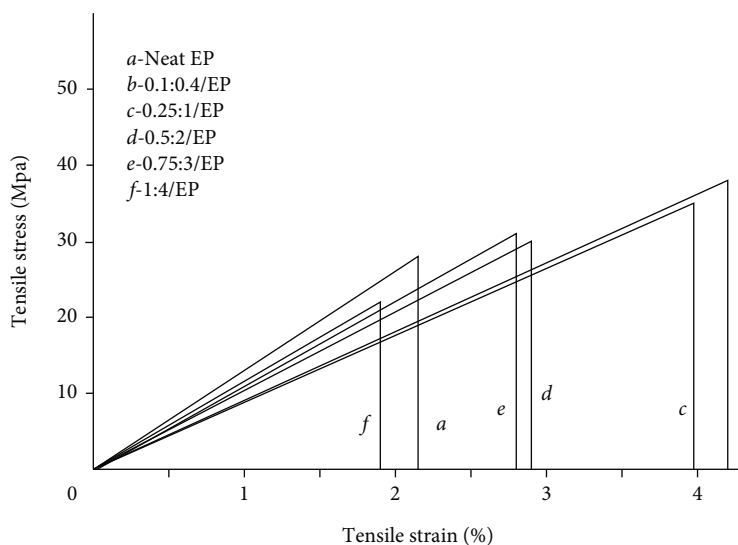
3.3. Study on the Apparent Kinetics of Curing of Unsaturated Polyester Resin. When using the DSC method to solve the curing kinetic parameters of the SnO_2-based composite


FIGURE 9: Stress-strain curve of graphene oxide/hydroxylated carbon nanotubes synergistically modified composite gas-sensitive material.

gas-sensitive material, it is necessary to test the DSC curves at different heating rates. The test result is shown in Figure 3.

In order to study the curing reaction kinetics of SnO_2-based composite gas-sensitive materials, it is necessary to solve the kinetic parameters such as the apparent activation energy (E) and reaction order (n) of the gas-sensitive materials and use the curing kinetic equation to describe the parameters and curing conditions. Table 1 shows the characteristic temperature (°C) of the DSC curve. Table 2 shows the curing kinetics data of the gas-sensitive material.

As shown in Figure 4, in order to achieve the above goal, linear fitting of the above known points can be obtained: $-\ln \beta/T^2_P \sim 1/Tp$ has a slope of $5.111 * 10^3$ and an intercept of -4.683, then $E/R = 5.111 * 10^3$, $\ln (AR/E) = 4.683$, so that the activation energy of DHEM50-1 resin system $E = 42.48$ kJ/mol, frequency factor $A = 5.523 * 10^5$. By linear fitting, it can be known that the slope of $\ln \beta \sim 1/Tp$ is $-5.81 * 10^3$, then $E/nR = 5.81 * 10^3$, since E has been obtained, substituting can be obtained $n = 0.880$.

Using the DSC method to solve the kinetics of composite gas-sensitive materials , the curing characteristic temperature of composite gas-sensitive materials can be preliminarily estimated. The relationship between temperature T and heating rate β is $T = C + B\beta$ (°C).

Use T-β to plot and get three different straight lines through linear fitting. As shown in Figure 5, when $\beta = 0$, the temperature of the composite gas-sensitive material is 51.5°C, the curing temperature is 57.8°C, and the postcuring temperature is 62.8°C. The above experiment test has no other fillers, and the dosage is small. Therefore, in actual production, it needs to be adjusted according to different situations.

4. Material Performance Analysis

4.1. Sectional Scanning Analysis of TPU Nanocomposite.
The fracture surface morphology of TPU and its composites was analyzed. Figure 6 shows the fracture SEM images of GO/TPU, GOE/TPU, GOS/TPU, and GOES/TPU composites with a filler content of 2 wt%. From Figures 6(a) to 6(d), it can be seen to varying degrees that the fracture surface has begun to become rough, with wrinkles and gullies appearing, which indicates that there is a strong interface interaction between the nanoparticles and the matrix. In addition, the composite material in Figure 6(d) is the roughest, and it is magnified to observe that GOES nanoparticles prepared by the stitching effect of EDA and SiO2 coating can effectively improve the mechanical properties of TPU. This shows that this unique stitched and multisize graphene-based material helps to enhance the interface interaction between the filler and the matrix.

4.2. The Effect of Curing Agent Content on the Time of Composite Gas-Sensitive Materials.
Figure 7 shows the effect of curing agent content on the time of the composite gas-sensitive material. It can be seen from Figure 7 that when the composition ratio, temperature, and other conditions of the composite gas-sensitive material remain unchanged, with the increase of the initiator MEKP and the accelerator TZ-9, the time of the composite gas-sensitive material gradually shortens, and the time decreases gradually. This is because the amount of initiator methyl ethyl ketone peroxide added is greater than the amount of accelerator cobalt salt added, so the greater the amount of initiator added, the more initial free radicals generated per unit time of methyl ethyl ketone peroxide, and the increase of initial free radicals can be accelerated resin free radical reactions; these reactions are exothermic reactions, which will increase the temperature of the system and accelerate the reaction rate again; however, the reaction rate of the composite gas-sensitive material cannot be increased indefinitely. This is mainly because the content of double bonds in the composite gas-sensitive material is limited, and these double bonds can only react with a limited number of free radicals. Therefore, when the initiator content increases again, the

composite gas-sensitive material time will be shortened, but the downward trend will decrease. When the initiator MEKP in the DHEM50-1 composite gas-sensitive material is added in the amount of 0.8-2 wt%, the time of the DHEM50-1 composite gas-sensitive material is in the range of 19-28 min.

4.3. Mechanical Properties. As shown in Figure 8 in conjunction with Table 3, the elongation at break and tensile strength of the material first increase and then decrease.

Figure 9 shows the tensile strength curve of GO-MWCNTs/EP material. Combined with the data in Table 3, it can be seen.

As shown in Figure 9, on the other hand, in the GO/EP system, when the GO content is 0.25 wt%, the mechanical properties of the material are the best, while in the GO-MWCNTs/EP system, when our GO content is reduced from 0.25 wt%. When it reaches 0.1 wt%, it can be seen from the graph that MWCNTs decreases with the decrease of GO content. The above experiments all show that the content of GO will enhance the material to a certain extent and is beneficial to the performance of the material.

5. Conclusions

The environmental effects of volatile organic compounds in the atmosphere are mainly manifested in their strong chemical activity. These active substances can participate in atmospheric chemical reactions, change the chemical properties of the atmosphere, and then change the air quality. This article mainly discusses the influence of composite gas-sensitive materials on the treatment process of volatile organic compounds exhaust gas membrane. It is hoped that effective treatment methods can be explored to reduce the emission and absorption of volatile organic compounds, so as to achieve the purpose of protecting the environment and improving human health. The double bond of the composite gas-sensitive material can undergo free radical polymerization with the double bond in the double bond monomer molecule as the crosslinking component under light conditions and form a more complex three-dimensional network structure under thermal initiation conditions. Combination of volatile organic compounds reduces pollution emissions. However, as far as the current situation is concerned, the technology is not perfect enough, and further research and development are needed. There are many ways to improve the gas sensing properties. The influence of the composite materials formed by doping on the gas sensing mechanism is relatively complicated. The relationship between the heterostructures composed of different materials and the gas sensing properties needs to be further studied.

Nanotechnology is an alternative material manufacturing technology, and the research field involves a broad field of modern technology, especially in the field of high-end manufacturing. Nanotechnology is a technique for studying the properties and applications of materials with structural dimensions in the range of 1 nanometer to 100 nanometers. Medical imaging refers to the technology and processing process of obtaining internal tissue images of the human body or a certain part of the human body in a noninvasive way for medical treatment or medical research; the acquired image can be further processed to restore the original image that was not clear enough to highlight some characteristic information in the image. The appearance of medical imaging has promoted the development of the medical field. The purpose of this paper is to study the application of nanoscale microparticle technology in medical imaging diagnosis and treatment. It is expected that the combination of nanotechnology and medical imaging will improve the accuracy of medical imaging diagnosis. This paper mainly introduces the general methods and technologies of technical development of medical imaging instruments and briefly shows the process of data and image analysis. The experimental results in this paper show that when other conditions remain unchanged, the image quality will change when the quality factor of the image changes. When the image quality is 60%, the image transmission rate is about 5.5FPS, which is relatively stable and can be used in the medical field.

1. Introduction

With the continuous rise of science, all fields of society have developed rapidly, and scientific research has reached the level of microscopic molecules, providing new possibilities for scientific research. The development and popularization of medical imaging technology and the substantial improvement of computer computing power have greatly promoted the development of medical image processing technology. With the continuous development of nanotechnology, a large number of nanomaterials appear in the field of social production and are widely used in the biological field. When nanobiology develops to a certain technology, nanomaterials can be used to make nanobiological cells with recognition ability, and the biomedicine of cancer cells can be absorbed and injected into the human body, which can be used for targeted killing of cancer cells. With the improvement of living standards, people pay more and more attention to their own health. How to combine nanotechnology and medical imaging technology to improve the level of medical diagnosis is a problem that should be considered at present. Since the development of medical imaging, in addition to X-ray, there are other imaging technologies. In terms of information application, image files and image digitized files can be exchanged and viewed, and the medical digital image transmission protocol technology has been developed.

The combination of medical imaging and nanotechnology can accurately extract images of lesions, reduce manual workload, improve image extraction speed, and make diagnosis results more accurate. Combining multiple imaging modes to achieve complementary advantages of each imaging mode is of great significance in biomedical imaging.

The combination of the two further enhances the digitization of hospitals and drives the development of the biomedical industry.

In this paper, an evaluation version of the X-ray medical imaging diagnostic instrument is designed, which provides the conditions for the secondary development to realize the digital acquisition and diagnosis of medical imaging data. In this paper, an image compression algorithm based on adaptive truncation coding is proposed, which solves the problem that excessive coding of unimportant coefficients brings workload to image compression.

2. Related Work

The broad application of nanotechnology in the biological field provides the possibility for the development of the medical field. Image-guided core needle biopsy is an important tool in the treatment of musculoskeletal tumors. Although the diagnostic yield and accuracy of this procedure are high, nondiagnostic results may occur. Nondiagnostic CNB results can cause unnecessary anxiety and can lead to repeat biopsies and delays in treatment. The Chinese name of CNB is fine needle biopsy, which refers to taking biopsies from the body for pathological examination, that is, observing cell morphology and the relationship between cells under a microscope. Lin et al. believe that understanding the radiological and histological factors that affect the diagnostic rate of CNB in musculoskeletal lesions can help radiologists select lesion sites for biopsy and help manage physician and patient expectations for biopsy results. Informing radiologists about the factors associated with low diagnostic rates during CNB of musculoskeletal lesions can improve diagnostic rates, demonstrating that this technique can be used in diagnosis [1]. Medical imaging is the foundation of child care, and much of the field of medical imaging relies on ionizing radiation: radiography, fluoroscopy, CT, and nuclear imaging. Frush and Sorantin believe that many considerations for this imaging of children differ in terms of appropriate radiation use, other factors that determine examination quality, opportunities for participation and education through the Internet, and translation of research work. Given these needs, it is imperative to explore the contribution of the pediatric radiology community and its impact, especially in improving the value of children's care [2]. Exposure to low-dose radiation has increased exponentially due to the influx of diagnostic imaging and medical procedures that use radiation, and this set dose limit essentially limits the use of medical radiation for diagnosis due to public health concerns. Low-dose radiation refers to ionizing radiation with a low energy transfer linear density at a dose of 100 mSv and below, and its main health risk is random effects. Rpsgt investigated radiation exposure concerns in the form of a retrospective review of previous experimental studies and an observational evaluation of the health effects of low-dose radiation. These studies show that high doses of ionizing radiation have toxic effects and increase cancer risk. Furthermore, the limitations of radiation in medical imaging are based on the assumption that the health risk of low-dose radiation is a linear extrapolation of high-

dose radiation [3]. Mobile devices and software now have sufficient computing power, speed, and complexity to interpret radiology examinations in real time. Venson et al. conducted a multivariate user study exploring image-based diagnostic capabilities using mobile devices and traditional workstations. Using CT, MRI, and radiographic datasets, they performed a task analysis between subjects, showing that for images from emergency mode, a mobile interface can provide accurate interpretation and rapid response, which may benefit patient healthcare [4]. As technology nodes shrink below 45 nm, high power issues have become a major disadvantage of CMOS logic circuits. Emerging spintronic nanodevice-based hybrid memory logic architectures have recently been investigated to overcome these issues. Deng et al. conducted a research on the architecture design of multicontext hybrid STT-MTJ/CMOS logic structure. Experimental results show that their advantages and disadvantages depend on the application being addressed. Finally, they also propose some design considerations and strategies to further optimize its reliability performance [5]. Breast cancer is a leading cause of suffering and death in women. The limitations of current diagnostic and therapeutic approaches have led to new strategies that positively impact survival and quality of life in breast cancer patients. Falagan-Lotsch et al. present an emerging approach based on actively targeted breast cancer nanomedicines. This approach uses a multifunctional inorganic nanoplatform with biomedical relevance, and nanotechnology offers real possibilities for reducing breast cancer mortality through early cancer detection, more precise diagnosis, and more effective treatment with minimal side effects [6]. The spread of antibiotic resistance and the growing prevalence of biofilm-associated infections are driving the need for new approaches to treating bacterial infections. Nanotechnology offers an innovative platform for addressing this challenge and even has the potential to manage infections involving multidrug-resistant (MDR) bacteria. Michal and Ehud summarize recent advances in the field of antimicrobial nanomedicines over the past few years and describes their unique properties, modes of action, and activities against MDR bacteria and biofilms and discusses biocompatibility and commercialization [7]. With the development of nanotechnology, there has been great interest in using nanomedicine strategies to enhance the radiation response of tumors. Nanomaterials containing high-Z elements to absorb radiation rays (such as X-rays) can act as radiosensitizers, depositing radiant energy within tumors and enhancing therapeutic efficacy. Song et al. believe that nanoscale carriers are capable of delivering therapeutic radioisotopes into tumors for internal RIT or delivering chemotherapeutic drugs to synergistically combined chemoradiotherapy. As revealed by recent studies, the tumor microenvironment can be modulated by various nanomedicine approaches to overcome hypoxia-related radioresistance. The tumor microenvironment means that the occurrence, growth, and metastasis of tumors are closely related to the internal and external environment of tumor cells. It not only includes the structure, function, and metabolism of the tumor tissue but also is related to the internal environment (nuclear and
FIGURE 1: Nanomaterial structure.

cytoplasmic) of the tumor cell itself [8]. Although these theories describe nanotechnology and medical imaging, they are rarely combined and are not practical.

3. Nanotechnology and Medical Imaging Diagnostic Methods

3.1. Overview of Nanotechnology. Nanomaterials are materials with nanoscale structures, which can be divided into zero-dimensional nanomaterials and one-dimensional nanomaterials according to their specific dimensions. It has been asserted that when people can arrange and combine substances on a very small scale, they will obtain various novel materials [9, 10]. The change in properties caused by the ratio of the number of atoms on the surface of the nanocrystal particles to the total number of atoms increases sharply with the decrease of the particle size. For example, when the particle diameter is 10 nm, the particle contains 4000 atoms, and the surface atoms account for 40%; when the particle diameter is 1 nm, the particle contains 30 atoms, and the surface atoms account for 99%. Until the end of the last century, the first International Conference on Nanoscience and Technology was held in the United States, which formally combined theoretical research with contemporary science and technology, marking the official birth of nanotechnology [11]. When the size of the material is in the nanometer level, the number of atoms on the surface of the material will increase dramatically, which will far exceed the number of ordinary materials, and the chemical activity of the material will be greatly increased [12]. At the same time, nanomaterials are equal to or smaller than the wavelength of light wave, de Broglie wavelength and coherence length of superconducting state, and the periodic

boundary of the material is destroyed, resulting in "novel" optical, electrical, magnetic, acoustic, and thermodynamic properties. In addition, nanomaterials also have quantum size effects and macroscopic quantum tunneling effects. These unique characteristics provide conditions for the wide-scale application of nanomaterials [13, 14]. Macroscopic quantum tunneling is one of the fundamental quantum phenomena, that is, when the total energy of a microscopic particle is less than the height of the potential barrier, the particle can still pass through the potential barrier. With the continuous and in-depth development of theory and practice, relatively systematic nanostructures have been established at present. With the maturity of application, the uniqueness of nanomaterials plays a pivotal role in the fields of biotechnology and advanced manufacturing [15, 16]. Nanorobots are the most tempting content in the application of nanotechnology in the medical field. They can act as miniature doctors in biomedical engineering and solve problems that are difficult for doctors to solve with traditional techniques. Figure 1 shows the nanomaterial structure.

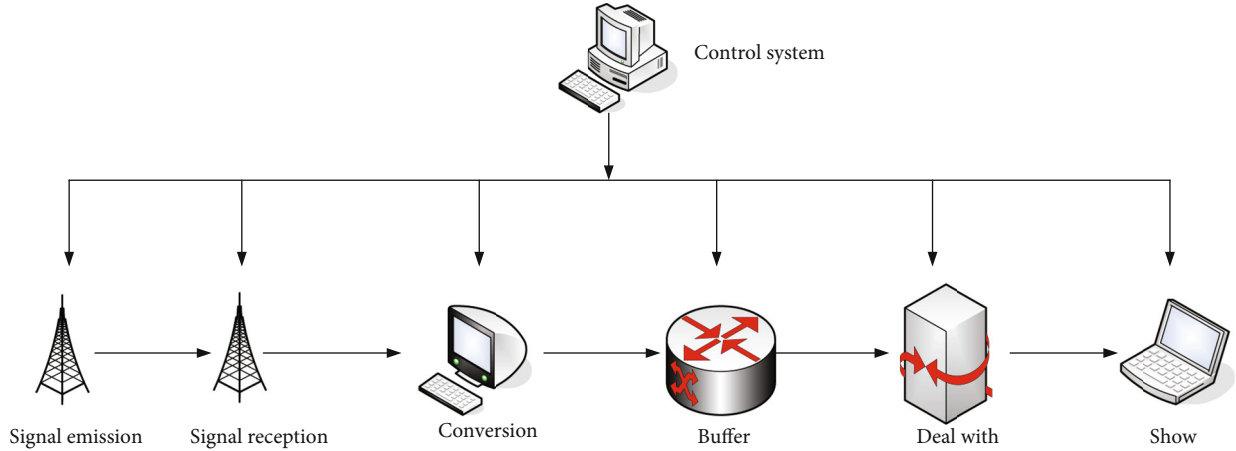
Since the introduction of carbon fiber in the 1960s, it has become one of the widely used materials for composite materials due to its excellent characteristics such as high strength and high modulus and is widely used in the fields of structural materials and high-temperature materials, and it has the effect that other materials cannot match [17]. With the development of nanotechnology, researchers have applied nanotechnology to composite materials, specifically carbon fibers, and made them into new nanoreinforced materials. The material plays a pivotal role in the modification of polymer-based materials. In terms of specific functions, polymer-based materials have the advantages of two


FIGURE 2: Ultrasonic flaw detector structure.

types of polymer materials, so they are nanocomposite materials with special performance materials [18, 19].

In the middle of the last century, the emergence of new substances made nanomaterials develop by leaps and bounds. In the subsequent gradual development, with the continuous exploration of theories by researchers, the scope of application of nanomaterials has become more and more extensive [20]. In recent years, the continuous improvement of science and technology has forced the upgrading of traditional materials. Traditional scientific and technological materials have been unable to meet the requirements of modern technology due to various functional limitations. New nanomaterials have a lot of room for development. From the offline situation, the entire nanomaterials are still in their infancy, and the follow-up development is still very violent. The focus of the first stage of development is to accurately control the number of atoms below 100. The second stage is the production of nanostructured substances, in which nanostructured substances and nanocomposites reach practical levels. In the third stage, it will be possible to mass-produce complex nanostructured substances. At this stage, although researchers choose different nanomaterials for experiments, so far there is no satisfactory result. In short, nanomaterials are very important functional materials, and the research and application of their properties still require continuous research and exploration [21, 22].

3.2. Image Processing Technology. Image processing refers to the process of analyzing images using computer technology [23]. Images are the basic tools for perception of the world and an important source of information for us. The subject of this article is the diagnosis and treatment of medical imaging. In the medical field, we often use imaging techniques, such as common B-ultrasound images and electrocardiograms [24, 25]. Therefore, it is necessary to focus on the research of image processing technology. Figure 2 shows the structure of the common ultrasound system.

In order to understand the information conveyed by the image, we need to collect data on the entire image. For the images collected by B-ultrasound, we need to process the

B-ultrasound images because of external environmental interference during the acquisition process.

$$h(a) = k(a) * g_q + f_s. \tag{1}$$

Formula (1) represents the noise model, $k(a)$ represents the original image, $h(a)$ represents the actual image, and f_s represents the noise.

$$h(a) = k(a) * g_q. \tag{2}$$

In the process of image processing, if the various points of the image are connected, the diagnostic information can be more accurate. In this case, we define the functional expression of the digital image as

$$g(a, b) = \begin{bmatrix} g(1, 1) & g(1, 2) & \cdots & g(1, n) \\ g(1, 2) & g(2, 2) & \cdots & g(2, n) \\ & & \vdots & \\ g(n, 1) & g(n, 2) & g(n, n) \end{bmatrix}, \tag{3}$$

where (a, b) represents a floating image point.

$$S_g(a, b) = y\big(S_g(g(a, b))\big). \tag{4}$$

$S_g(a, b)$ represents the gray value of the target point, g represents the displacement function of the image, and y represents the change function of the pixel value. The premise of pixel value transformation is spatial transformation, but this transformation does not occur in all cases. Figure 3 is a schematic diagram of image space conversion. When it changes, the function expression can be described as

$$S_g(a, b) = S_g(g(a, b)). \tag{5}$$

When formally transforming the image space, we need to determine the transformation process, especially the parameter transformation. We need to find the corresponding relationship
FIGURE 3: Principle of spatial transformation.
FIGURE 4: Image conversion process.

between the parameters. The main operation process is shown in Figure 4.

Entropy was originally used to represent the energy distribution in thermodynamics, and it has also made some progress in the medical field in recent years. We define its function expression as

$$F(a) = -q \sum_{i=1}^{m} k_i, \ln(k_i) \qquad (6)$$

Among them, $\sum_{i=1}^{m} k_i = 1$, when $k1 = k2 = k3 = \cdots km$, F takes the maximum value.

$$Q(a) = \int_0^1 \left(Q_{\text{int}}(a) + Q_{\text{image}}(a) \right) dc, \qquad (7)$$

where $Q_{\text{int}}(a)$ represents the internal energy, and its form is as follows:

$$Q_{\text{int}}(a) = \frac{1}{4} \left(\chi(c) |a'(c)|^3 + \eta(c) |a''(c)|^3 \right). \qquad (8)$$

Among them, $\chi(c)$ and $\eta(c)$ represent the weight coefficient.

In the process of image processing, entropy is mainly used to distinguish the foreground color and the background color. The main basis for distinguishing the foreground color and the background color is the gray value, and there is a big difference in the distribution of the gray value between the two. We express the expression of gray value as follows:

$$D_1(a) = -q \sum_{i=0}^{q-1} k_i \ln(k_i), \qquad (9)$$

$$k(i) = \frac{g(i)}{\sum_{j=0}^{q-1} g(i)}. \qquad (10)$$

Among them, $g(i)$ is the gray value function, q is a constant, and $k(i)$ represents the gray value range of 0–1.
FIGURE 5: "X-ray" working principle.
FIGURE 6: Image processing and diagnosis process.

The entropy of the part greater than the threshold q is expressed as

$$D_2(a) = -q \sum_{i=q}^{255} k_i \ln (k_i), \tag{11}$$

$$k(i) = \frac{g(i)}{\sum_{j=q}^{255} g(j)}. \tag{12}$$

Among them, $g(i)$ represents the gray value function, q is a constant, and $k(i)$ represents the gray value range in q-255.

The sum of the two entropies is

$$D(a) = D_1(a) + D_2(a). \tag{13}$$

When $D(a)$ is the largest, the threshold a is the maximum entropy threshold, that is, the threshold that distinguishes the foreground color from the background color.

$$\hat{Q} = s * \bar{Q} + d * Q. \tag{14}$$

Formula (14) represents a filtering algorithm, which can suppress the formation of noise. $\hat{Q}$ represents the image gray value, and Q represents the pixel gray value.

$$h(a, b) = \frac{\sum_{cd} t(c, d) u(a, b, c, d)}{\sum_{cd} u(a, b, c, d)}, \tag{15}$$

$$u(a, b, c, d) = \exp \left[-\left(\frac{(a-c)^3 + (j-d)^3}{\chi} + \frac{\|t(a, b) - u(c, d)\|}{\chi} \right) \right], \tag{16}$$

where χ represents the standard deviation of the intensity of the Gaussian function and formulas (15) and (16) represent the double filtering algorithm.

$$WY(a)(b) = \sum_p t(b, k) a(k) \tag{17}$$

Among them, $t(b, k)$ represents the weight coefficient, and a and b represent the pixels.

$$f(o, p) = \sum \|t(o) - u(p)\|_i^3, \tag{18}$$

$$f(o, p) = \sum k(j) \left(t(o_j) - u\left(p_j\right) \right). \tag{19}$$

i represents the standard deviation of the Gaussian function, and the value of $k(j)$ is determined according to the specific Gaussian function.

Smoothing the image is a very common technique. The gray value is calculated by calculating the weighted average value of the pixel points. The weighted average value is its core content, which is defined as

$$y(a) = \frac{u}{\partial \sqrt{2\pi}} e^{-(a-\varepsilon)^2 / 2\partial^2}. \tag{20}$$

Among them, the expected value of the Gaussian distribution is ε, the standard deviation is ∂, and the standard Gaussian distribution is $\varepsilon = 0, \partial = 1$.

In practical processing, we often use Gaussian blurred two-dimensional Gaussian distribution density distribution function, and its expression is expressed as

TABLE 1: Comparison of simulation results of PSNR image processing.

$$H(a, b) = \frac{1}{2\pi\lambda^2} e^{-\left(a^2 + b^2\right)/2\lambda^2}, \tag{21}$$

where λ represents the standard deviation.

3.3. Overview of Medical Imaging Equipment. Science benefits the world. With the continuous development of science and technology, medical technology is also constantly improving, and various medical imaging equipment has begun to be used in the medical field [26]. The "X-ray" we often hear is a typical imaging device. Due to the difference in tissue density and thickness of the human body, the X-ray measurement that passes through the inspected part will be absorbed to different degrees due to the difference in tissue density and thickness, and the final effect on the screen or film will be displayed as images with different degrees of blackening due to different measurement. In the mid-1890s, scientists discovered a ray that was invisible to the naked eye but had strong penetrating power during experiments. After continuous exploration, it is found that the ray can examine the internal mechanism of the object and display the outline of the internal organs. We can analyze and judge its health status through images [27, 28]. The working principle of "X-ray" is shown in Figure 5.

In order to save the image for a long time and use it more conveniently, we transmit the medical image information to the monitor, and the doctor can use the network to share the image resources and improve the work efficiency. At the same time, doctors can compare different imaging data of patients on the same device to improve the accuracy of diagnosis [29, 30]. When the image resources can be extracted on the device, the main purpose is to perform feature extraction; the purpose is to quantitatively analyze the lesion characteristics extracted in the first step, such as the size, density, and morphological characteristics of the lesion. At this time, we abandon the way of storing image data in the past, which saves management expenses to a certain extent, and at the same time facilitates access. Figure 6 shows the image processing and diagnosis flow [31].

4. Application Experiments in Medical Imaging Diagnosis and Treatment

4.1. Image Processing Data. The image examination performed by the patient in the hospital must be processed to obtain the information transmitted by the image, and the doctor can prescribe the right medicine according to the information. The most important thing in image processing is to remove noise and signal effects. In fact, different thresholding will give different results, so I was able to experiment with images for different threshold ranges.

According to the data in Table 1, we have conducted experiments with different threshold processing schemes. First, we set the compression index as PSNR. When the noise parameter is 1.2, the Bayes threshold is 52.93, the hard threshold is 41.56, and the soft threshold is 37.01. When the noise parameter is 0.9, the Bayes threshold is 52.03, the hard threshold is 39.74, and the soft threshold is 36.28. When the noise parameter is 0.6, the Bayes threshold is 48.72, the hard threshold is 32.74, and the soft threshold is 34.71. When the noise parameter is 0.3, the Bayes threshold is 37.22, the hard threshold is 35.19, and the soft threshold is 32.47. When the noise parameter is 0.1, the Bayes threshold is 42.63, the hard threshold is 31.29, and the soft threshold is 28.31. According to the data, when different noise parameters are selected, the obtained image effects are different. Generally speaking, the larger the set range, the higher the threshold simulation index.

According to the data in Table 2, we set the compression index as MMSIM to conduct experiments with different threshold processing schemes. When the noise parameter is 1.2, the Bayes threshold is 0.998, the hard threshold is 0.993, and the soft threshold is 0.982. When the noise parameter is 0.9, the Bayes threshold is 0.995, the hard threshold is 0.984, and the soft threshold is 0.982. When the noise parameter is 0.6, the Bayes threshold is 0.992, the hard threshold is 0.977, and the soft threshold is 0.973. When the noise parameter is 0.3, the Bayes threshold is 0.989, the hard threshold is 0.964, and the soft threshold is 0.947. When the noise parameter is 0.1, the Bayes threshold
FIGURE 7: Different transmission image quality factor-MPR frame rate test results.

is 0.984, the hard threshold is 0.943, and the soft threshold is 0.921. According to the data, the optimal parameters can be selected according to different requirements during image noise reduction.

4.2. Imaging-Related Indicators. With the continuous development of science and technology, medical technology is also constantly improving. The development of imaging technology has promoted the progress of medical level. Based on this, we have briefly analyzed the relevant indicators of imaging. The details are as follows.

According to the data in Table 3, the abduction angle of the first group is 41°, the proportion in the safe area is 85%, the anteversion angle is 22°, and the proportion in the safe area is 76%. The second group had an abduction angle of 38°, 90% in the safe zone, and an anteversion angle of 18°, which was 88% in the safe zone. The third group had an abduction angle of 42°, 88% in the safe zone, and an anteversion angle of 17°, which was 87% in the

safe zone. The fourth group had an abduction angle of 39°, 89% in the safe zone, and an anteversion angle of 19°, which was 89% in the safe zone.

4.3. Image Evaluation Metrics. After image processing, it needs to be evaluated; we usually use resolution and sharpness. In order to explore the effect of image processing, we compare and analyze the indicators of the processed image and the original image. The details are as follows.

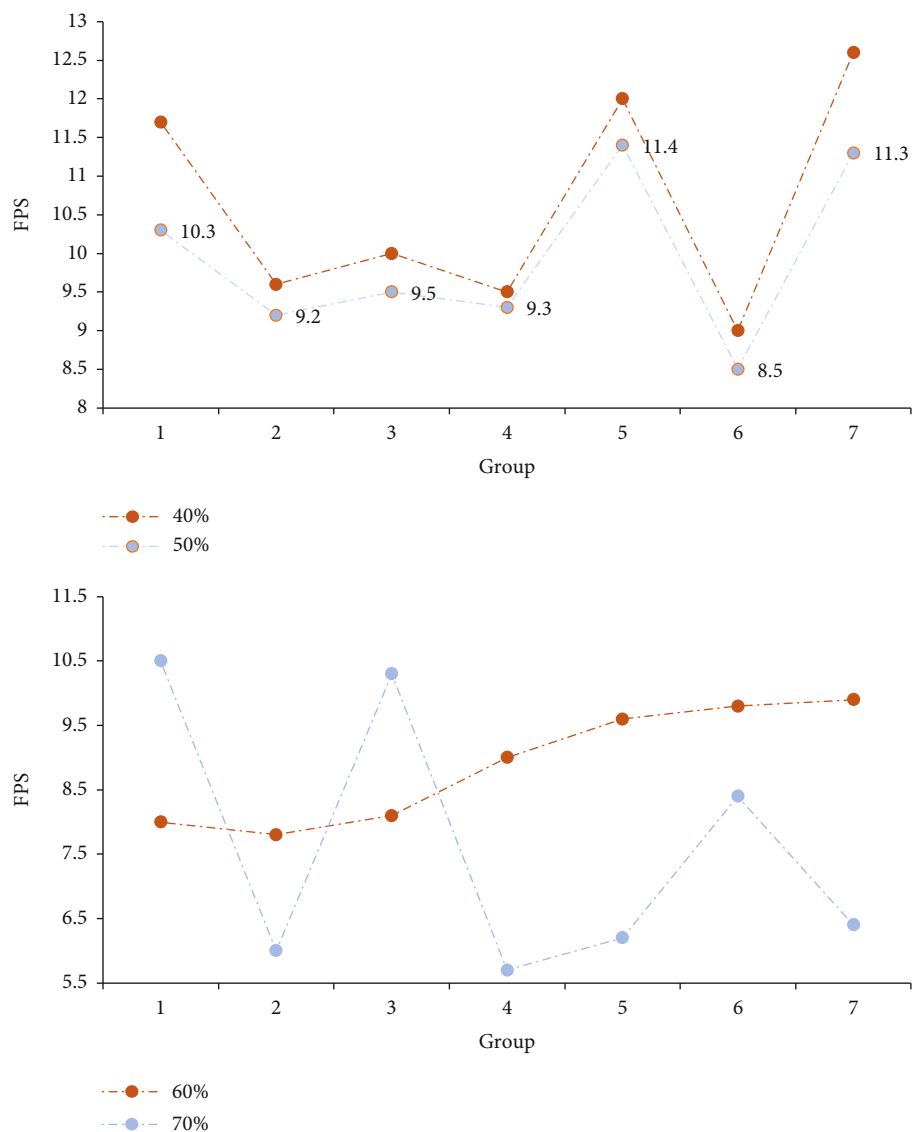
According to the data in Table 4, we have conducted two sets of experiments when evaluating the image quality, and the clarity of the original image has reached level 11, and its resolution is 0.9. The first group of processed images has a sharpness of 17 levels and a resolution of 0.9. The second group of processed images has a sharpness of 16 levels and a resolution of 0.9. According to the data, the sharpness of the processed image is obviously improved, but the resolution is decreased, but in actual situation, it does not affect the diagnosis result. It can be


FIGURE 8: Different transmission image quality factor-DVR frame rate test results.

seen that the processed image is helpful for medical diagnosis [32].

5. Application Analysis of Medical Imaging Diagnosis and Treatment

5.1. Transmission Image Quality Factor System Performance Evaluation. Image quality is an important factor affecting doctors' diagnosis results, and the dynamic adjustment of image quality factors during image transmission has an important impact on image quality. When the user zooms and rotates the image, the original quality of the image will be reduced. For this reason, we briefly analyze the quality factor of image transmission. The details are as follows.

According to the data in Figure 7, we have carried out experimental analysis on the quality factor MPR frame rate in different ranges. At this time, the network environment of image transmission, network morbidity and image output device are all the same. In this case, we found that

when the quality factor is 40%, the image transfer rate is 7.6FPS for the first time, 5.1FPS for the second time, and 7.5FPS for the third time. The image transmission rate of the fourth time is 6.4FPS, the image transmission rate of the fifth time is 7.2FPS, the image transmission rate of the sixth time is 7.7FPS, and the image transmission rate of the seventh time is 4.2FPS. When the quality factor is 50%, the first image transfer rate is 5.9FPS, the second image transfer rate is 4.6FPS, and the third image transfer rate is 7FPS. The image transmission rate of the fourth time is 5.4FPS, the image transmission rate of the fifth time is 6.6FPS, the image transmission rate of the sixth time is 7.2FPS, and the image transmission rate of the seventh time is 4.1FPS. According to the data, the smaller the image quality factor is, the larger the image transmission rate is generally, but the image transmission rate will fluctuate during the same type of transmission process.

In order to prevent the chance of the experimental data, we used different quality factors to carry out the comparison
FIGURE 9: Image performance analysis.

experiment again. According to the trend of the experimental data, when the quality factor is 70%, the first image transmission rate is as high as 6.2FPS, and the subsequent transmission rate drops sharply. When the quality factor is 60%, its image transfer rate remains the same as in the previous experiment. It can be seen that the smaller the image quality factor is, the larger the image transmission rate is generally, but when the quality factor is 60%, the level is relatively middle [33].

According to the data in Figure 8, we have conducted experimental analysis on the quality factor of DVR frame rate in different ranges. At this time, the network environment of image transmission, network morbidity and image output device are all the same. In this case, we found that when the quality factor is 40%, the image transfer rate is 11.7FPS for the first time, 9.6FPS for the second time, and 10FPS for the third time. The image transmission rate of the fourth time is 9.5FPS, the image transmission rate of

the fifth time is 12FPS, the image transmission rate of the sixth time is 9FPS, and the image transmission rate of the seventh time is 12.6FPS. When the quality factor is 50%, the first image transfer rate is 10.3FPS, the second image transfer rate is 9.2FPS, and the third image transfer rate is 9.5FPS. The image transmission rate of the fourth time is 9.3FPS, the image transmission rate of the fifth time is 11.4FPS, the image transmission rate of the sixth time is 8.5FPS, and the image transmission rate of the seventh time is 11.3FPS. According to the data, the smaller the image quality factor, the larger the image transmission rate, but the image transmission rate will fluctuate during the same type of transmission, which is the same as the MPR frame rate test result.

Similar to the DVR frame rate experiment, we conducted a second experimental comparison of DVR frame rate measurements. According to the data results, when the quality factor is 70%, the fluctuation of the image transmission rate
Figure 10: Image size data evaluation.

is too large, which is not suitable for image transmission. Secondly, according to the data, it can be found that when the quality factor is 60%, the fluctuation of the image transmission rate is small, which is suitable for image transmission.

5.2. Image Processing Performance Analysis. With the continuous development of imaging technology, medical imaging examination has become an indispensable inspection method in hospitals, providing strong support for clinical diagnosis and diagnosis. In order to explore the performance of image processing, we analyzed different situations of the image, as follows.

According to the data in Figure 9, this experiment retrieves the validity of medical images. When the usage rate of Fc1 was 22%, the image efficiency rate was 70%, and when the usage rate was 25%, the image efficiency rate was 69%. When the usage rate is 28%, the image efficiency rate is

68%, and when the usage rate is 31%, the image efficiency rate is 67.3%. When the usage rate is 34%, the image efficiency rate is 67%, and when the usage rate is 37%, the image efficiency rate is 60%. When the usage rate of Fc2 was 22%, the image efficiency rate was 68%, and when the usage rate was 25%, the image efficiency rate was 68.3%. When the usage rate is 28%, the image efficiency rate is 68.1%, and when the usage rate is 31%, the image efficiency rate is 67%. When the usage rate is 34%, the image efficiency rate is 66.5%, and when the usage rate is 37%, the image efficiency rate is 60%. According to this data, there is no significant difference in the imaging efficiency between Fc1 and Fc2.

When the usage rate of Fc3 was 22%, the image efficiency rate was 68%, and when the usage rate was 25%, the image efficiency rate was 65.7%. When the usage rate is 28%, the image efficiency rate is 65.6%, and when the usage rate is 31%, the image efficiency rate is 65%. When the usage

rate is 34%, the image efficiency rate is 64.5%, and when the usage rate is 37%, the image efficiency rate is 64.1%. When the combined use rate of Fc1 and Fc3 was 22%, the imaging efficiency rate was 73%, and when the utilization rate was 25%, the imaging efficiency rate was 74.6%. When the usage rate is 28%, the image efficiency rate is 72%, and when the usage rate is 31%, the image efficiency rate is 71%. When the usage rate is 34%, the image efficiency rate is 70.7%, and when the usage rate is 37%, the image efficiency rate is 68.3%. From this data, it can be seen that when Fc1 and Fc3 are used in combination, the imaging efficiency is greatly improved.

5.3. Image Size Data Evaluation. In addition to the transmission rate and the image quality factor, the image quality is also related to the size of the image itself. For this reason, we have analyzed images of different sizes. The details are as follows.

According to the data in Figure 10, we have conducted quality assessment on images of different data sizes. When the image is 110 M, the frame rate of the first test of the image is 13.2FPS, and the frame rate of the second test of the image is 12.7FPS. The frame rate of the third test of the image is 14.2FPS, and the frame rate of the fourth test of the image is 14FPS. When the image is 200 M, the frame rate of the first test of the image is 8FPS, and the frame rate of the second test of the image is 7.8FPS. The frame rate for the third test of the image was 8.2FPS, and the frame rate for the fourth test of the image was 8.8FPS. When the image is 300 M, the frame rate of the first test of the image is 6.4FPS, and the frame rate of the second test of the image is 6FPS. The frame rate for the third test of the image was 5.7FPS, and the frame rate for the fourth test of the image was 6.2FPS. When the size of the image data is the same, the DVR and MPR transmission rates of the images are quite different. According to the data, the size of the image data has a great influence on the image quality.

6. Conclusions

With the continuous progress of science and technology, the combination of science and technology and medical treatment has become the general trend. The continuous development of nanotechnology provides conditions for the development of the medical field. The purpose of this paper is to study the application of nanoscale microparticle technology in medical imaging diagnosis and treatment. It is expected that the combination of nanotechnology and medical imaging will improve the accuracy of medical imaging diagnosis. Although this paper has carried out some research on this basis, there are still some problems: the image processing method is very successful in the edge detection of the low-frequency part of the image, and the scale factor can be accurately calculated, but the sensitivity to the high-frequency part of the image is weak.

With the development of people's living standards, the growing prosperity of the motherland, the traditional culture has been paid more and more attention, and traditional martial arts as a part of traditional culture is not only good for viewing but also strengthens the body, so it has been loved by many people. Traditional martial arts training is a high-collision, injury-prone sport, and making a good buffer protector can improve the safety of martial arts trainers and reduce the concept or degree of injury to athletes. Nanomaterials are materials produced by nanotechnology that are extremely small in one-dimensional, two-dimensional, or even three-dimensional directions, and are several nanometers long in at least one direction. The purpose of this paper is to study a new type of nanomaterial with buffering effect, so as to understand the actual protective effect of body protectors made of this material on martial arts trainers. In this paper, a net-like plant fiber nanobuffer material is proposed, and the relevant mechanical experimental tests are carried out on the material. According to static tensile experiments, the mesh nanofiber material can withstand a pressure of 1.2 million Pa under 90% strain, while ordinary fiber materials can only withstand a pressure of 700 thousand Pa under 80% strain. And the resilience of the mesh nanofiber material reaches 1.8 mm/s, while the maximum of ordinary fiber material is only 0.6 mm/s, which means that the protective gear made of mesh nanofiber material can significantly improve the stress bearing capacity of the protective gear and improve the rebound effect.

1. Introduction

With the development of science, technology, and industry, nanomaterials have become important materials used in many fields, and the protective ability of nanomaterials has become a concern in all kinds of intense sports or training venues. Especially in the training of martial arts, trainers will be subjected to various shocks, and the degree of shock is also different. These shocks will lead to changes in the trainer's athletic state, and serious injuries will lead to fractures of athletes. In order to minimize the injury of personnel during the training process, it is necessary to select appropriate buffer nanomaterials as body protectors to achieve the effect of buffering and antiseismic, so as to protect the trainers and avoid serious injuries to the trainers during the training process. Generally, an appropriate buffer pad is added to the protective gear to absorb the impact energy of the outside world on the product, so as to achieve the buffer effect and protect the trainer. The foam material used

to reduce shock and vibration during martial arts training is the buffer. The whole product and package are called protective gear, and the buffer material in the buffer system plays a decisive role. The function of martial arts is not only limited to fighting but also has dance, art, technology, maintenance, health, governance, and other categories. However, due to historical reasons and social development factors, traditional martial arts have developed to today, and its functions have included fitness, health preservation, competition, and fighting. The most common ones are performance and display [1].

In martial arts training, the buffer material plays a very important role in protecting the human body and can greatly avoid personal injury. Therefore, it is very necessary to conduct in-depth research on buffer materials. For the research on protective gear of nanomaterials, some scholars have published relevant academic articles on it. Among them, Jung et al. identified potential nucleophiles that could be incorporated into PIMs by quantitatively comparing the

reactivity of multiple small-molecule nucleophile scaffolds as organophosphate scavengers. Jung et al. provided new insights into PIM as a reactive material for CWA decontamination and its potential use in protective gear [2]. Heinze and Carastan investigated the effects of fumed silica content, ultrasonic energy used during silica particle dispersion, and humidity during storage to analyze the performance changes of STF. In stable samples, water uptake results in a substantial loss of maximum viscosity. Humidity on the sample reduces the overall viscosity but does not prevent the sample from turning into a gel if the parameters used cause the STF to become unstable. Shearing STF reduces its maximum viscosity, more so in higher viscosity samples [3]. Cerium oxide nanoparticles (CeNPs) have been shown to have antioxidant capacity. However, their efficiency in scavenging reactive oxygen species (ROS) and their underlying mechanisms remain unclear. Filippi et al.'s study found that ceria nanoparticles (CeNPs) and nanorods (CeNRs) exhibited stronger scavenging activity than OH generation in phosphate-buffered saline (PBS) and alternative lung fluid (SLF). These insights are important for understanding the redox activity of cerium nanomaterials and providing clues to the role of CeNPs in biological and environmental processes [4]. Rzayev highlighted the ability of molecular bottle brushes as highly tunable building blocks for the creation of nanostructured materials through molecular templating, solution polymerization, and melt self-assembly. Rzayev also highlighted recent achievements in the synthesis of discrete nano-objects, micellar structures, and periodic nanomaterials from bottlebrush copolymers and briefly discussed future opportunities in this field of polymer science [5]. Zheng et al. first described the mode of action of silver nanoparticles (Ag NPs) in disrupting bacterial cell outer membranes and their intracellular components, then allowing them to exhibit broad-spectrum antibacterial effects. Zheng et al. next invented an emerging high-efficiency antibacterial agent, ultrasmall silver nanoclusters (Ag NCs). Ag NCs are ultrasmall NPs with core size less than 2 nm, and they contain 'countable' Ag atoms as cores and protected by a certain number of organic ligands. The atomically precise properties of Ag NCs provide a good platform for designing and manipulating Ag NCs at the atomic level to achieve optimized antibacterial efficacy, which is also beneficial for antibacterial mechanism research [6]. The effects of adding anatase nano-TiO_2, nano-SiO_2, etc. on the crystallization and morphology of C-S-H were systematically studied by Li H experiments. Further characterization was carried out by microscopy to investigate the effect of nanomaterials on the C-S-H morphology. Different nanomaterials have different C-S-H morphologies. Pure CSH is sheet-like structure, nano-TiO_2 is CSH and rod-like structure, nano-SiO_2 is CSH and particle agglomeration, and C-S-H and GO or CNT form a C-S-H structure grown on a template [7]. Although the above studies have promoted the research and application of nanomaterials to a certain extent, most of them are in the field of theoretical chemical reactions, and there are relatively few physical analyses of the buffering properties of nanomaterials. Therefore, this paper has important value and significance for the research on the body protector of buffer type nanomaterials.

The innovations of this paper are as follows: A new type of mesh plant fiber nanomaterial is proposed as a buffer protector, which has better buffer performance and can protect the key body parts of traditional martial arts trainers. And the relevant mechanical experiments were carried out on the nanomaterials, and the specific data obtained were used as the basis to make the results more credible.

2. Based on Buffered Nanomaterials

2.1. Buffered Nanomaterials

2.1.1. Nanotechnology and Nanomaterials

(1) Definition

The so-called nanotechnology refers to the general term of the manufacturing technology whose processing accuracy or processing size is one order of magnitude. The lattice spacing of metal crystal lattices is about 1 to 100 nanometers, so the precision of nanofabrication has reached the limit. Nanotechnology includes a variety of advanced science and technology, such as nanomaterials, nanofabrication, nanotribology, nanometer measurement, nanocontrol, nanoelectronics, nanomicroscopy, nanobiology, and a number of high-tech groups. Among them, bionanotechnology is a bottom-up molecular self-assembly strategy, and molecular components will spontaneously organize into stable structures [8, 9]. A schematic diagram of nanotechnology is shown in Figure 1.

Nanomaterials are materials that have at least one dimension in three-dimensional space on the nanometer scale (1-100 nm), nanomaterials are the basic units built around them. This corresponds to a dense scale of about 10 to 1000 atoms [10, 11].

(2) Characteristics of nanomaterials

Nanomaterials are some low-dimensional materials, and nanomaterials can be single crystal, polycrystalline, crystal structure, quasicrystalline or amorphous phase, glassy, metal, ceramic, oxide, or composite material [12, 13]. The manufacturing methods of nanomaterials include general artificial methods, artificial nanomaterials, reduction of single-phase products, heat treatment, and natural nanomaterials. Table 1 shows the characteristics of nanomaterials with different diameters.

(3) Classification

Nanomaterials can be mainly divided into nanoceramics, bulk, fibers, and powder materials according to their properties, as shown in Figure 2.

There is also a particularly familiar nanomaterial: nanomembranes, which are often used in cellphone screens or filters. Nanofilms are divided into particle films and dense films. Particle films are thin films of nanoparticles with very small gaps between them [14, 15]. The dense film is a thin film having a dense film layer with a particle size of nanometer scale. Nanomembrane can be used for gas catalysis (such
Nanotechnology

TABLE 1: Characteristics of nanomaterials with different diameters.

Diameter/ nm	Total number of atoms N	Percentage of the surface atoms
1	30	100
5	4000	40
10	30000	20
100	3000000	2

as automobile exhaust gas treatment) materials, filter materials, high-density magnetic recording materials, photosensitive materials, flat panel display materials, superconducting materials, etc. [16], as shown in Figure 3.

(4) Application fields of nanotechnology

At present, nanotechnology is widely used in many industrial, medical, energy, environmental protection, home and military fields, as shown in Figure 4.

2.1.2. Buffer Material. Buffer materials, as the name suggests, are elastic materials with a cushioning effect. At present, most of the research on cushioning materials is in the aspects of colloid, cotton, wool, leather, plant fibers, and mixed cushioning materials. The more typical ones are foamed polyethylene, foamed aluminum, cardboard fibers, etc., as shown in Figure 5. As a new type of environmental protection material, foamed polyethylene is more and more widely used in many fields, which has attracted the attention of many researchers on its cushioning, protection, and other properties. Due to its special electromagnetic shielding performance, sound insulation performance, sound absorption performance, energy absorption performance, vibration isolation, and damping performance, foamed aluminum materials are widely used in military equipment, shipbuilding, trains, automobiles, tunnel engineering, construction, and other industries. Waste paper fiber belongs to plant fiber,

so the basic principle of using it as the main raw material to prepare buffer material is the same as the current domestic and foreign researchers using plant fiber to prepare buffer material. In both of them, the fiber material is mixed with other additives, and foaming is formed by the action of the foaming agent [17, 18].

The chemical theory of a plant fiber, the concept of liquid foaming, and the associated theory of surface chemistry are used to produce the network structure of the reticulated plant fiber material [19]. The key is to first use the pressure difference between the inside and outside of the bubble to form a cavity inside the material, that is, to "squeeze" the space out of the solution, while "squeezing" the space, let the fibers adsorb around the bubble and gather into "arches." In order to make the material have the necessary physical and mechanical properties, the fibers should be connected, and before this, the "arch" fibers must be "oriented." Under the combined action of hydrogen bonds and adhesives, an effective and stable connection between fibers is formed. When the solution is excluded, it becomes an ultralightweight material with a plant fiber network structure that meets various properties. Figure 6 is a schematic diagram of the internal structure of the material similar to the "truss structure." The truss in the truss structure refers to the truss beam, which is a latticed beam structure. The truss structure is often used in public buildings such as large-span workshops, exhibition halls, gymnasiums, and bridges. Since most of them are used in the roof structure of buildings, trusses are usually also called roof trusses [20]. Plant fibers constitute "truss members," and the connection points between fibers with rubber compound constitute "truss nodes" [21].

2.2. Traditional Martial Arts. Traditional martial arts is a wonderful flower in Chinese history. It is deeply rooted in the fertile soil of Chinese culture. After thousands of years of development and precipitation, it is an important part of Chinese culture. Chinese martial arts can survive for thousands of years and maintain an active development trend. It is

Nano powder also known as ultrafine powder, generally refers to powder or particles with particle size below 100 nanometers

Nanofibers refers to a wire-like material with a diameter on the nanometer scale and a large length

(a)

Nano-block a nano-grain material obtained by high-pressure molding of nano-powder or controlled crystallization of metal liquid

Nano ceramics using nano-powder to modify existing ceramics, by adding or generating nano-scale particles, whiskers, wafer fibers, etc. into the ceramics, the grains, grain boundaries and the combination between them all reach the nano-level

fundamentally because it has rich traditional cultural connotations inside. However, in modern times, with the emergence and rapid development of Chinese competitive martial arts, the traditional connotation of martial arts has gradually become blurred, and especially the fighting ability, which is the essence of martial arts, has gradually faded out of people's
FIGURE 6: Schematic diagram of the internal structure of the mesh fiber material of the "truss structure."

attention, which has greatly misled people's understanding of martial arts. Due to the requirements of "high, difficult, new, and beautiful" put forward by competitive sports, in order to pursue the ranking and performance of the competition, traditional martial arts also excessively pursue the elegant movements and ignore the cultivation of its exercises, which has led to the fading of the cultural connotation of traditional martial arts. Figure 7 shows two traditional martial arts well known in China [22].

Tradition is to standardize and model a certain materialized spirit, so that living life can be condensed into rigid concept. It also restricts the life and practice of future generations, and becomes an example of their words and deeds. A "tradition" must have the following characteristics to be called a tradition. First, it has a long time span (time characteristics), and secondly, it has strong spatial binding force (regional characteristics), and thirdly, there are specific audiences (population characteristics). Traditional martial arts can be defined as follows: Chinese national fighting sports with a long history of development before modern China, with certain regional characteristics and practice crowds. Martial arts is a national sports event produced under the background of Chinese farming society, with tactical movements as the main content, routines, exercises, and fighting as forms of expression, focusing on both internal and external training. In terms of its time logic, traditional martial arts mainly refers to the martial arts before the old China, and it is the folk martial arts in the cold weapon era of ancient China. However, people only define traditional martial arts by time, which largely confuses the value and function characteristics of traditional and nontraditional martial arts. According to the value of martial arts, traditional martial arts and competitive martial arts correspond, but this ignores the existence of military martial arts, and only distinguishes them from the perspective of Western sports, and limits the value of traditional martial arts to the category of sports. Therefore, traditional martial arts exist not only in ancient times but also in modern times. It is developed by working people's long-term practice and accumulation. It has far-reaching implications and a long history. It takes traditional Chinese culture as the theoretical basis and takes offensive and defensive skills as the main purpose of activities. It combines physical fitness, self-defense, entertainment, and aesthetics, and it is a physical exercise with strong national traditional characteristics

[23]. Table 2 is a comparison of the force methods of different types of boxing in traditional martial arts, and Table 3 is a comparison of the force methods of different boxing methods of the same type.

From Tables 2 and 3, it can be seen that for different martial arts, their moves are different, the force is also different, and the parts of the force used in battle and the strength and parts of the blow are different. Therefore, it is necessary to wear protective gear for important parts of the human body to prevent serious injury.

2.3. Body Protector. According to the relevant regulations of the General Administration of Sports of the People's Republic of China, the national and provincial competition rules for traditional martial arts include head guards, clothing, leg guards, guards, thin belts, and mouth guards. When these basic protective gears are used, none of them can participate in the competition, and they must pass the security check before the competition and stamped with the seal before they can be used during the competition. However, judging from the current domestic competition scene, protective gear and other equipment are rarely used. One team member believes that the protective gear will affect the performance and when the level of confrontation reaches a certain level, the protective gear basically cannot protect the participants, and the protective gear does not really play its role. At the same time, female martial arts athletes will use some protective gears in the competition process and daily training of athletes in order not to damage the body. Figure 8 shows several common body protective gears.

3. Static Tensile Experiments of Nanobuffer Materials

3.1. Mechanical Model of Nanobuffer Material. According to the compression characteristics of the buffer material, a set of modulus can be used to characterize its linear elastic properties, that is,

$$\frac{E^*}{E_s} = C_1 \left(\frac{\rho^*}{\rho_s}\right)^2. \tag{1}$$

Among them, E^* is the elastic mode of the cushioning material, E_s is the elastic mode of the matrix, ρ^* is the density of the cushioning material, and ρ_s is the density of the matrix. C_1 is the scale factor.

$$\frac{G^*}{E_s} = C_2 \left(\frac{\rho^*}{\rho_s}\right)^2. \tag{2}$$

Among them, G^* is the shearing die of the buffer material and C_2 is the proportional coefficient.

In the nonbombing phase,

$$\frac{\sigma_{e1}{}^*}{E_s} = C_3 \left(\frac{\rho^*}{\rho_s}\right)^2. \tag{3}$$

FIGURE 7: Traditional martial arts. Image source: http://www.changjunwenhua.com/pic_detail.php?cid=2&id=48.

TABLE 2: Comparison of different types of force in traditional martial arts.

Fist name	Fist for example	Fist boxing method for example	Hard way
Straight-line boxing	Forward punch	South boxing: lunge step double punch boxing	Straight impact strength
Long curve boxing	Swing	Split boxing: a lotus hand	Curve whip
Short curve boxing	Hook	Fanzi fist: a wild horse running groove	Short-range impact

TABLE 3: Comparison of force methods of the same type of traditional martial arts and different styles of punches.

Boxing	Example action (punch punch)	Hard way
Eight extremes boxing	Hold the fist	In the storage of strength, cross-strength, a word to support strength
Taijiquan	Cover hands and punch with arm	Long storage strength, wrapped silk strength, elastic strength
Nanquan	Single butterfly step punch	Short storage strength, long inch strength, drill strength

FIGURE 8: Several common body protectors. Image source: https://shi222.sm160.com/Company/OfferDetail/1-000-7754-861.html.

Among them, σ_{e1}^* is the elastic limit of the buffer material and C_3 is the proportional coefficient.

For plastic buffer materials, the ultimate strength is

$$\frac{\sigma_{p1}^*}{\sigma_{ys}} = C_4 \left(\frac{\rho^*}{\rho_s}\right)^{3/2}. \tag{4}$$

Among them, σ_{p1}^* is the collapse limit of the buffer material and σ_{ys} is the yield strength of the matrix.

For a two-dimensional closed-cell buffer material, when it is compressed, its stress is:

$$\sigma = \sigma_{ys} \left[C_1 \left(\frac{\rho^*}{\rho_s}\right)^{3/2} + C_2 \frac{\rho^*}{\rho_s} \right]. \tag{5}$$

Equipment name	Model	Performance
Electronic balance	MP200-II	Capacity 180 g/0.02 g
Oven	Universal	$1 m^3$ 5 kw
Digital microscope	US MOTICDMEB5	1.3 million pixel objective lens: oil lens 100x eyepiece 5x
Environmental scanning electron microscopy	Netherlands XL30 ESEM-TMP	The resolution is 25 cm under 1KV voltage
Fourier infrared spectrometer	American Nicoli 360 intelligent	4000-400 cm^{-1}
Compression box	2	According to packing cushion material creep characteristics
Blender	7312-I	Manufactured by experimental method

The relationship between porosity and density is

$$P = \left(1 - \frac{\rho^*}{\rho_s}\right) \times 100\%. \tag{6}$$

Substitute into the previous formula to get

$$\sigma = \sigma_{ys}\left[C_1(1-P)^{3/2} + C_2(1-P)\right]. \tag{7}$$

That is to say, the porosity is inversely proportional to the strength of the buffer material.

For a buffer material, its ability to absorb energy can be expressed as

$$W = \int_0^\varepsilon \sigma d\varepsilon. \tag{8}$$

In formula, W is the absorption force per unit volume and ε is the strain.

Its ideal energy absorption efficiency is

$$I = \frac{1}{\sigma_{\max}} \int_0^\varepsilon \sigma d\varepsilon. \tag{9}$$

For the constitutive formula of the nanobuffer material, the constitutive relation of ben'gou materials mentioned in this paper is a mathematical model, which is an abstract reflection of the macroscopic properties of materials. One of the core tasks of studying the mechanical properties of materials is to establish constitutive equations that can describe the mechanical responses of materials under various loads. The parameters of the material constitutive equation are determined by a certain range of strain rate and temperature experiments, and the correctness of the constitutive equation can be verified by comparing the predicted value of the constitutive equation with the experimental results; it can be expressed as

$$\sigma = f(\varepsilon, \varepsilon^*, T). \tag{10}$$

For its mechanical properties, it can be expressed as

$$\sigma = (A + B\varepsilon^n)(1 + Cln\varepsilon^*)(1 - T^m). \tag{11}$$

The compressive stress-strain constitutive relation for the buffer material is

$$\sigma = E_0 f(\varepsilon). \tag{12}$$

In formula, E_0 is the initial modulus, $f(\varepsilon)$ is the shape function, and it has

$$f(\varepsilon) = \varepsilon\varphi(\varepsilon) = \varepsilon(a\varepsilon^{-p} + b\varepsilon^q). \tag{13}$$

If the factor of strain rate is introduced, and $f(\varepsilon)$ is regarded as the series, the constitutive relation is

$$\sigma_c = E_0(\varepsilon^*)f(\varepsilon). \tag{14}$$

In formula,

$$E_0\,\varepsilon^*) = k\varepsilon^*,$$
$$f(\varepsilon) = \sum_{i=0}^{10} A_i\varepsilon^i. \tag{15}$$

Considering that the strain rate factor is related to the strain, the more complete constitutive formula is obtained as

$$\sigma_c = M(\varepsilon, \varepsilon^*)f(\varepsilon),$$
$$M(\varepsilon, \varepsilon^*) = \left(\frac{\varepsilon^*}{\varepsilon_0^*}\right)^{n(\varepsilon)}. \tag{16}$$

In formula, ε_0^* is the static strain rate and $n(\varepsilon)$ is a linear function:

$$n(\varepsilon) = a\varepsilon + b. \tag{17}$$

3.2. Static Tensile Test. In this paper, the nanobuffer material within a certain density range is selected for stress testing at different strain rates. The density range is between 1 and 20 nanometers. The test conditions are as follows: temperature $T = 20°C$, relative humidity 75%, and the load is gradually increased to the limit on the test sample along the thickness direction at a speed of 10 mm/min. The experimental equipment is shown in Table 4.
FIGURE 9: Stress comparison of buffer materials.
FIGURE 10: Comparison of resilience performance of cushioning materials.

The basic process of this paper is first to stretch and test the test sample according to the experimental equipment in Table 4. The stretching method is to gradually increase the load and record the stretched length of the buffer material in the process and then calculate the strain diagram according to the equation and then slowly withdraw the recovery length of the material and then calculate the rebound curve of the material according to the equation.

The strain curve is obtained according to the previous constitutive formula, and compared with the common fiber material, the results are shown in Figures 9 and 10.

According to Figure 9, it can be seen that the mesh nanofiber material can withstand a pressure of 1.2 million Pa under 90% strain, while the ordinary fiber material can only withstand a pressure of 700 kPa under 80% strain. It can be seen that the use of mesh nanofiber materials can significantly improve the bearing capacity of stress. According to Figure 10, it can be seen that the resilience of the meshed nanofiber material is significantly higher than that of ordinary fiber materials. Under 90% strain, its resilience reaches 1.8 mm/s, while the maximum of ordinary fiber materials is only 0.6 mm/s. It can be seen that the mesh nanofiber

material can significantly improve the stress bearing capacity of the protective gear and improve the rebound effect.

4. Discussion

Although the experiments in this paper have specific evidence that the mesh nanofiber material can significantly improve the stress bearing capacity of the protective gear and improve the rebound effect. However, there are still some shortcomings:

(1) In practice, some buffer materials will rupture due to too fast drying or excessive external force during the drying process, or due to too slow drying, small bubbles will merge into large bubbles, which will affect the shape of the space inside the material. And it will cause internal stress defects and thus affect the strength of the sample, which should be strengthened on the drying process

(2) It is recommended to conduct further research on the microscale of the pores of the buffer material and the size of the truss structure

(3) The recovery performance and compressive stress performance of cushioning materials with different densities will be different. Further experiments are needed to analyze the cushioning and resilience performance of materials under different densities, and verification tests should be carried out for this material

(4) In this paper, only the resilience and compressive stress of the buffer material are tested, and some characteristics of the buffer material need to be further discussed and studied

5. Conclusions

In the abstract, this paper first gives an overview of the overall content of the full text and then introduces the background of traditional martial arts in the introduction and introduces the protective effect of buffered nanomaterial protective gear on martial arts trainers. Then, the innovation points of this paper are summarized, and some related researches are listed in the related work part, so as to understand the current situation of the related content of this paper. Then, in the theoretical research part, the definition, characteristics, classification, and application fields of buffer nanomaterials are first introduced, and then, the relevant content of buffer materials is introduced, and the characteristics of traditional martial arts and the force application methods of different martial arts are introduced. Then, introduce the related content of body protector. Finally, the stress bearing performance and resilience performance of the mesh nanofiber material and ordinary fiber material are tested by mechanical experiments. It is concluded that the mesh nanofiber material can significantly improve the stress bearing capacity of the protective gear and improve the rebound effect, which can better provide safety protec-

tion for traditional martial arts trainers. In the future development, nanomaterials will be more and more widely used, such as the addition of nanoparticles to the martial arts protective ware of textile and chemical fiber products, which can remove flavor and sterilization. Although the chemical fiber material is strong, but there are annoying electrostatic phenomenon, adding a small amount of metal nanometer particles can eliminate the electrostatic phenomenon.

The damage self-diagnosis function puts forward higher requirements for the research and development of intelligent structural health monitoring, and in most cases, it is necessary to monitor the load first, especially the monitoring of the impact load. The development of smart materials and structures is based on advanced sensing systems. In order to achieve this purpose, a high-speed demodulation system based on fiber grating with double long period grating is studied, and then, a damage self-diagnosis system based on fiber grating is constructed. The system can realize the strain distribution and impact load monitoring of the structure. After quantitative analysis of the signal, an advanced information identification method is used to realize the impact load location. This paper focuses on the data preprocessing process of bridge health monitoring. In view of the characteristics of high data complexity, large amount of data, and many noise components in the process of structural monitoring, this paper adopts basic data cleaning for the original data set, including data dimensionless and missing value processing. Based on the digital twin technology, the composition of the digital twin KNN model of bridge swivel construction monitoring and management is analyzed, and the digital twin system architecture of bridge swivel construction monitoring and management is built. The function display of the monitoring platform, including setting a variety of permission login modes, displaying BIM model, geographic information, and weather environment; monitoring data entry and addition, deletion, and modification; data chart analysis and export; and email warning, to verify the feasibility of the application of digital twin technology in bridge monitoring, and the advantages of the intelligent monitoring system are obtained. The strain error is found to be less than $15.48\,\mu\varepsilon$ in the research, which is within the range of the fiber grating. This method can effectively monitor and forecast these distributed, nonlinear, strongly coupled, multivariable, and time-varying complex structures. By monitoring bridges, the original monitoring data of bridges can be obtained, and scientific research data and analysis services can be provided. In particular, the damage caused by shock and vibration is monitored, so that the accumulation of damage can be detected before it threatens the safety of the structure, so that the damaged structure can be repaired in time to ensure the safe operation of the structure.

1. Introduction

With the development and progress of technology, a complete digital twin system is built from the perspective of bridge swivel construction monitoring and management and interacts with other digital twin systems to realize the interconnection of everything. The digital twin system of bridge swivel construction monitoring and management includes five levels: user domain, digital twin, measurement and control entity, real physical domain, and cross-domain functional entity. Digital twin is a simulation process integrating multidisciplinary, multiphysics, multiscale and multiprobability by making full use of physical model, sensor update, operation history, and other data to complete the mapping of physical entities

in virtual space, so as to reflect the whole life cycle process of physical entities.

A structural health monitoring system is an important application direction of intelligent structure, which has attracted more and more people's attention. In the process of bridge swivel construction, monitoring technology is used to ensure the smooth progress of the swivel process and the safety of the swivel construction, and to provide data support for decision-making at each stage. At the same time, it can detect the bridge structure, compare the monitoring data with the previous calculation results, and check each other to ensure the quality of the structure. According to the monitoring results, the design and construction process of the swivel bridge can be optimized. In addition, the data obtained from the construction monitoring can supplement the bridge construction data, improve the bridge life cycle data, and provide an important basis for the later bridge operation and maintenance [1].

In this paper, the sensing model of the uniform period fiber grating and its Fourier transform demodulation theory are studied, and the transmission response characteristics of the uniform period fiber grating are deduced according to the coupled mode theory. In the process of bridge operation, in order to ensure the safety performance and durability of long-span bridges, we need to monitor the health of bridge structures, establish a real-time and smooth network monitoring system, understand the health status of bridge structures, and ensure their normal work and operation. According to the calculation results and monitoring element analysis, sensor model, and using BIM technology, the measurement point layout and early warning mechanism design of the background swivel bridge monitoring scheme are carried out. According to the characteristics of bridges spanning high-speed railways when rotating, a bridge-building comprehensive information model is established. According to the characteristics of the swivel construction of the bridge spanning high-speed railway, combined with the background engineering, the swivel balance system is studied, which is used to adjust the unbalance of the cantilever end during the bridge swivel process, ensure the stability of the swivel process, and improve the construction safety.

2. Related Work

Digital twins are increasingly being introduced into the fields of Internet technology and industrial technology. Fiber Bragg grating (FBG) sensors and extrinsic fiber Fa-Per (EFPI) sensors are two very promising fiber optic sensors in the field of structural health monitoring. Xiaodan designed a virtual training platform for carrier-based aircraft approach and landing based on virtual reality technology. He adopts a distributed architecture, introduces each node of the system in detail, then gives a method for real-time communication using reflective memory technology, and introduces the logical relationship and integration of three dynamic modules [2]. Ye et al.'s accurate assessment of wind characteristics and wind-induced structural responses during typhoons is of great significance for bridge design and safety assessment. He proposed an angular linear approach based on the expectation maximization (EM) algorithm for probabilistic modeling of field-measured

wind properties [3]. Sarmadi et al. believe that environmental changes are a major challenge in bridge health monitoring because bridges are more prone to such changes than other civil structures. To address this challenge, they propose a new machine learning approach for early damage detection under environmental changes through clustering, a new damage metric, and an innovative method for selecting an appropriate number of clusters. Estimating reliable alert thresholds is another important challenge for early damage detection by most machine learning methods. On this basis, they propose a new probabilistic method for estimating alarm thresholds using extreme value theory and goodness-of-fit measures. Their major contributions include proposing a new damage metric suitable for clustering-based algorithms for decision making, an innovative cluster selection algorithm for dealing with environmental variability and improving damage detectability, and a new probabilistic method for threshold estimation [4]. Nguyen et al. introduced a new method for diagnosing structural damage based on changes in the mechanical parameters of materials. First, they integrated viscoelastic models into structural damage detection and diagnosis. Therefore, the model defines the mechanical properties of the material by two parameters, the elastic modulus and the coefficient of viscosity. Hooke's model is linear, while viscoelasticity is nonlinear and therefore more accurately reflects reality. Second, they exploited the amplitude and frequency of the vibrational signals and determined their relationship to mechanical parameters that detect structural changes. Based on theoretical analysis and experimental results, their research is more effective and general than previous studies. Simultaneous monitoring of structural changes using different parameters enabled the study to collect more appropriate data compared to previous studies [5]. A structural health monitoring system is one of the important application methods of intelligent structure. The digital twin will have an unignorable impact on the construction industry, and it will become the core engine for the transformation and development of the construction industry. The combination of digital twin and BIM technology will provide a digital model of the city for the government cloud platform based on image scanning, which will cover all high-voltage power grid lines, sewage systems, water supply and drainage systems, highways, traffic control systems, and all interconnected locations in the city. BIM is a building information modeling technology, which is a data-based tool used in engineering design, construction, and management. It is used to describe computer-aided design based on three-dimensional graphics, object-oriented, and architecture.

3. Fiber Bragg Grating Smart Materials and Structural Health Monitoring System Method

3.1. Fiber Bragg Grating Sensor Configuration. The grating sensor refers to a sensor that uses the principle of grating moire to measure displacement. The configuration of fiber Bragg grating sensors can be studied in terms of the number of sensors and the spatial layout of sensors. The spatial distribution of the sensors can adopt various sensor distribution

methods such as equidistant distribution, proportional distribution, and mixed distribution, which should be comprehensively determined in combination with various factors such as specific test objects, clamping methods, and loading methods. Therefore, in the subsequent test process, different sensor distribution designs will be adopted for specific test objects.

Regarding the configuration of the number of sensors, the number of sensors that can achieve wavelength division multiplexing for a single channel mainly depends on the bandwidth of the light source and the dynamic range of the measured parameters. Therefore, when determining the number of grating points on a single fiber string, the demodulation limit of the fiber grating demodulator and the actual strain of the measured object should be considered. The specific ideas are as follows.

First, the wavelength variation range of a single grating is calculated according to the strain variation range and grating strain sensitivity of a single grating monitoring point:

$$\Delta\lambda = K_\varepsilon \cdot \varepsilon. \tag{1}$$

In the formula, ε is the strain value of the ith grating point and K_ε is the strain sensitivity of the ith grating point.

Assuming that there are n grating points to be measured on a single-fiber grating string, on this basis, the wavelength variation range of all grating points on the channel of the fiber grating string is calculated [6]:

$$\Delta\lambda = \Delta\lambda_1 + \Delta\lambda_2 + \cdots + \Delta\lambda_n = \sum (K_\varepsilon \cdot \varepsilon). \tag{2}$$

In order to prevent the wavelength signals from aliasing during the measurement of grating points of adjacent wavelengths, the working range of a single grating measured point can be expressed as [7]:

$$\Delta\lambda = K_\varepsilon \cdot \varepsilon + \lambda \tag{3}$$

If n measured grating point on a single-fiber grating string can work normally without wavelength aliasing, then [8]

$$\Delta\lambda = \Delta\lambda_1 + \Delta\lambda_2 + \cdots + \Delta\lambda_n = \sum (K_\varepsilon \cdot \varepsilon + \lambda). \tag{4}$$

Then, the measurement range λ_n of the n sensors is [9]

$$\lambda_n = \Delta\lambda = \sum (K_\varepsilon \cdot \varepsilon + \lambda). \tag{5}$$

If the maximum measurement range of a single channel of the fiber grating demodulator is $\lambda_{\max}$.

$$\lambda_n \leq \lambda_{\max}, \tag{6}$$

$$n \leq \frac{[\lambda_{\max} - \sum (K_\varepsilon \cdot \varepsilon + \lambda)]}{\lambda_h}. \tag{7}$$

Assuming that the strain range measured by each grating sensor is ε, the above formula can be further simplified as [10]

$$n \leq (K_\varepsilon \cdot \varepsilon + \lambda). \tag{8}$$

Therefore, the maximum number of grating sensors that can be connected in series on each channel of the fiber grating demodulator can be calculated by the above formula [11].

3.2. KNN Algorithm. The mechanism of the KNN algorithm applied to the analysis of bridge monitoring data can be summarized as follows: when the model obtains a new detection data sample point, KNN can classify it according to the nearest known sample points of the sample point. Due to such classification characteristics, this paper uses this as a theoretical basis to design a bridge loss judgment model to classify the monitoring data of the bridge, so as to indicate the monitoring data of the bridge in a healthy state and a damaged state [12].

The basic steps of the KNN algorithm:

Input data set:

$$T = \{(x_1, y_1), (x_2, y_2), (x_3, y_3), \cdots, (x_n, y_n)\}, \tag{9}$$

where x_n represents a feature vector of the instance [13].

Output: the category to which instance x belongs.

According to the selected distance metric formula, find the k instance points closest to x in the data set, and the set of these K points is called the k neighborhood $N(x)$ of x.

According to the classification rule in the k neighborhood of x, the majority votes the classification category y of x:

$$y = \mathrm{argmax}_c \sum x \in N(x) I(y = c). \tag{10}$$

In the above formula, I is the indicator function, that is, when $y = c$, $I = 1$; otherwise, it is 0 [14].

At time t, the input layer inputs the bridge high-finesse time series data, and the state of each unit of the input layer at this time [15]:

$$U(t) = [u_1(t), u_2(t), \cdots, u_m(t)]^T. \tag{11}$$

When new data is input, the algorithm will update the state $x(t)$ of the storage layer and the update rule [16]:

$$x(t + 1) = wx(t) + w^{\mathrm{in}} u(t + 1). \tag{12}$$

After the node state update of the storage layer is completed, the node state matrix is obtained [17]

$$y = f^{\mathrm{out}} \left(\int w^{\mathrm{out}}(t) dt \right), \tag{13}$$

where w^{out} is the weight matrix of the output layer, and f^{out} is the activation function of the output layer.

Let

$$K_1 = \frac{L_0}{L_1},$$
$$K_2 = \frac{A_0}{A_1}. \tag{14}$$

It can get [18]

$$\varphi_1 = \frac{K_1 K_2}{K_1 + K_2 - 1},$$
$$\varphi_0 = K_\varphi \varphi_0.$$

(15)

Bridge construction monitoring is a general term for all the work that provides technical support for the realization of bridge design requirements through construction process simulation analysis, on-site monitoring and error identification and prediction, and feedback control. Bridge construction monitoring should include monitoring calculation, construction monitoring and data analysis, and feedback mechanism. The monitoring calculation includes design compliance calculation, presimulation calculation, and real-time simulation calculation. Construction monitoring includes stress (internal force) monitoring, linear monitoring, temperature monitoring, and monitoring of necessary environmental factors.

3.3. Structural Design of Digital Twin Bridge Health Structure Safety Monitoring System.
The digital twin bridge health structure safety monitoring system roughly includes two parts:

(1) Sensor and demodulation equipment system: sensors are divided into preembedded sensors from the installation stage, such as concrete embedded strain gauges, embedded crack gauges, and earth pressure gauges. Surface sensors, such as beam surface strain sensors, expansion joint displacement sensors, accelerometers, and inclinometers, were used. The demodulation equipment system is basically divided into static and dynamic monitoring. The static monitoring is second-level monitoring, which is collected at a certain interval, and the dynamic monitoring is about 100 Hz, the vibration data of the bridge is collected in real time

(2) Monitoring center system: the monitoring center is mainly to improve the efficiency, scientificity, rationality, and traceability of management, to achieve rational allocation of resources, and to reduce human errors. The system can be divided into two parts, data acquisition and transmission system and system integration. The data acquisition and transmission system integrates the sensor data in a unified manner, collects it centrally, and completes the software protocol connection with the system integration system. The system integration system is mainly used to assist the bridge management center, which roughly includes the following functional modules, manual inspection and maintenance management module, comprehensive early warning safety assessment module, and management center database management module

3.4. Hardware System Design of Digital Twin Bridge Health Structure Safety Monitoring System.
The hardware part of the digital twin bridge health structure safety monitoring system mainly consists of three parts:

(1) Sensor system: it consists of sensors with various functions and special components distributed on the bridge structure. The sensors are divided into embedded sensors and surface-mounted sensors

(2) Data acquisition system: the data acquisition system is divided into data acquisition and auxiliary devices. The data acquisition system is composed of demodulation equipment, acquisition equipment, acquisition computer, sensor optical cable, cable network, etc., which are arranged inside the bridge junction or on the bridge deck. At present, there are about a dozen types of sensors, and it also indicates that there are more than a dozen different types of demodulators. The auxiliary system consists of the equipment in the field and the monitoring center to assist the normal operation of the above system, including the cabinet, the chassis, the power supply module, the uninterruptible power supply system, and the lightning protection system

(3) Data processing system: process various sensors into digital signals for easy identification, package data, and connect to the system integration module. The hardware system design of the digital twin bridge health structure safety monitoring system is shown in Figure 1

3.5. Software Module Design of Digital Twin Bridge Health Structure Safety Monitoring System.
The overall architecture diagram of the software part of the digital twin bridge health structure safety monitoring system mainly covers the following contents:

(1) The sensor data acquisition, protocol transmission, and other related support services involved in each sensor measurement subsystem

(2) The centralized acquisition function of each sensor subsystem

(3) The relationship between the central database subsystem and other systems and the flow of related data

(4) The functional connection between the user interface subsystem, the structural warning and evaluation subsystem, the manual inspection auxiliary subsystem, and the user terminal. The system of the digital twin bridge health structure safety monitoring system software is shown in Figure 2

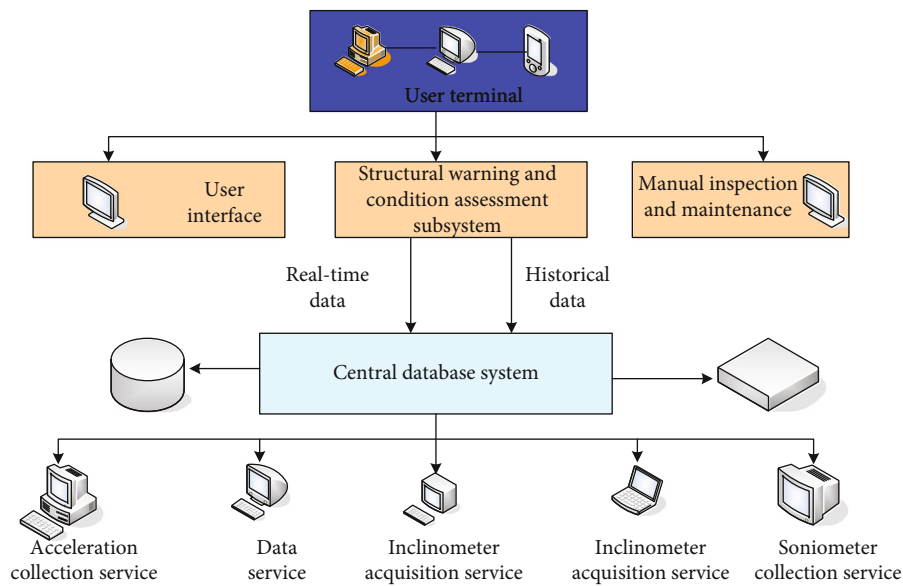
3.6. Bonding Process of Fiber Grating Sensor and Measured Structure.
The surface-mount packaging method is usually based on the preset optical fiber sensing layout, and the corresponding fiber grating sensing points are arranged on the surface of the monitored point of the structure, and the grating sensor is fixed with the help of a protective adhesive layer. The operation is convenient and simple, and it will not destroy the initial structural state of the measured object and will not cause too much influence on the strain transmission efficiency and sensitivity of the fiber grating sensor. In the actual
FIGURE 1: Hardware system design of digital twin bridge health structure safety monitoring system.


FIGURE 2: Software modules of the digital twin bridge health and structural safety monitoring system.

operation process, on the one hand, it is necessary to select an appropriate bonding method to fix the fiber grating to ensure its fit with the monitored point on the surface of the structure, and at the same time to protect the fiber grating from being damaged. On the other hand, it is necessary to select a reasonable amount of bonding material to reduce the influence on the strain transfer efficiency of the sensor after the fiber grating sensor is bonded to the structure. Based on the above discussion, the bonding process of the fiber grating sensor and the structure can be carried out according to the following steps: first, according to the preset optical fiber hybrid multiplexing network, the number and layout of the sensors required for

the test are planned. Grating sensors with different center wavelengths are selected and connected in series to form a fiber grating string, the connection is spliced by an optical fiber fusion splicer, and a metal sleeve is added at the fusion connection to protect the fusion point from breaking. Secondly, in order to ensure more sufficient contact between the grating sensor grid area and the structure, the grating sensor with the coating layer removed is selected, the grating grid area is laid on the monitored point corresponding to the structure, and a certain prestress is preapplied before gluing, to remove the residual stress that may be introduced in the process of fabrication and coating layer filtering in the grating gate
FIGURE 3: Application scene of digital twin of Hebei North University Gymnasium (the picture comes from the author's own drawing).

region. The gate area is preliminarily fixed by using a curing adhesive, and the bubbles that may be generated by the adhesive layer are extruded to ensure that the gate area and the surface of the structure are fully attached. Again, after the cured adhesive layer is air-dried (about 1 h), epoxy resin is applied to the fixed part of the gate area. Its purpose is to shield the crosstalk caused by external stress and, at the same time, protect the cured adhesive on the inside from the influence of the external corrosive environment. Finally, after all the adhesive layers are fully cured (about 24 h), follow-up tests are carried out. Since the strain transfer efficiency of the grating sensor is closely related to the properties of the adhesive layer, during the bonding process, the adhesive layer should be smeared evenly and the thickness is moderate to reduce the influence of the adhesive layer on the strain transfer efficiency of the sensor. Based on the above discussions on sensor network layout, sensor configuration, sensor bonding method, etc., the sensor system and structure integration are designed. For example, the digital twin application scenario of Hebei North University Gymnasium is shown in Figure 3.

3.7. Quality Control Measures in the Installation Stage of Embedded Sensors

(1) The on-site organization is as follows:

Because the sensor preembedding stage needs to follow the bridge construction progress, it has high construction requirements, which can neither delay the normal construction period nor affect the installation quality. The flow-type construction method is adopted, combined with the parallel construction

method to speed up the progress when necessary, that is, the work flow of forecasting installation in advance, compact installation process, and quick departure after installation. Since the sensor is installed in stages with the progress of the bridge construction, the bridge construction unit should be reported to the bridge construction unit 3 days before the installation is required, and the preparations before the installation should be done. The installation process should be compact and regular, and the installation should be carried out when the construction and installation team changes shifts as much as possible. After installation, only the engineer who recorded the installation data is left, and the rest can leave the site to ensure that the progress of the bridge construction is not affected.

(2) To control the installation quality, first of all, we can classify all the sensors that need to be embedded and installed according to the installation location according to the needs of the project. The area is divided according to the range of 500 meters, and a technical support person from a fiber grating sensor supplier company is arranged for each area to conduct real-time technical control. The main points of control are as follows:

(a) Recording the wavelength data of the fiber grating sensor in real time (monitor the initial value)

(b) Compiling record files of fiber grating sensor burial, including points, on-site pictures, sensor types, etc.

(c) Marking and recording the position of the optical fiber outgoing fiber, and report it to the construction unit, emphasizing that the optical cable should not be broken or buried in the later bridge construction process

(3) The main task of the construction team is to carry out the equipment according to the requirements of the technical personnel of the equipment supply company, which are classified into:

(a) Preparatory work before burying such as drilling and binding

(b) The sensor is buried

(c) Cable and traction of optical cable

The formula for covariance is as follows [19]:

$$X_F(X, Y) = E[(X - u_x)(X - u_y)], \tag{16}$$

where X and Y represent two random variables.

Data anomalies in bridge health monitoring belong to time series anomalies, that is, data anomalies are related to time. If the value of a subsequence in the time series deviates greatly from the values of other parts, and such deviation is not generated randomly, but in a way that is completely different from other subsequences, that is, this subsequence may be an abnormal subsequence. There are mainly three types of anomalies in bridge data: point anomaly, pattern anomaly, and sequence anomaly. A general point anomaly refers to a data point whose data value at a certain time point is significantly different from the threshold or abrupt change caused by the degradation of sensor performance or the mutation of external influence factors. The pattern anomaly refers to the existence of small continuous anomalies in the data sequence of a sensor. Such anomalies mostly occur when the sensor fails during continuous acquisition or the transmission line has faults, or it may be an anomaly displayed by obvious changes in the data caused by the gradual aging of the bridge, and there is a significant pattern difference with the continuous data in other time periods. Point exceptions can be thought of as pattern exceptions of length 1. Sequence anomaly is a time series that is significantly different from other time series and originates from different mechanisms. For eigenvalue decomposition,

$$A\eta = \lambda\eta, \tag{17}$$

$$A = Q \sum Q^{-1}. \tag{18}$$

The wave formula for light waves propagating in an optical fiber [20]:

$$\nabla^2 E + KNE + \nabla^2 \left(E \cdot \frac{\nabla\varepsilon}{\varepsilon} \right) = 0, \tag{19}$$

TABLE 1: Corresponding strain errors.

Actual strain ($\mu\varepsilon$)	Wavelength change (nm)	Sensitivity relative error (%)	Strain error ($\mu\varepsilon$)
100	0.12	0.008	0.08
1000	1.2	0.077	0.77
10000	12	0.774	7.74
20000	24	1.548	15.48

$$\nabla^2 h + KNh + \nabla^2 \left(h \cdot \frac{\nabla\varepsilon}{\varepsilon} \right) = 0, \tag{20}$$

where E, h are the electric field strength and the magnetic field strength.

4. Health Monitoring System Results

Taking the initial center wavelength of the fiber grating as 1550 nm, its strain sensitivity is 1.2 pm/$\mu\varepsilon$. Assuming that the actual strains generated are 100, 1000, and 10000, the corresponding strain errors are shown in Table 1. It can be seen from Table 1 that within the range of the fiber grating, the strain error is also within 15.48 $\mu\varepsilon$, that is, the influence of the center wavelength change of the fiber grating on the strain sensitivity coefficient is extremely small, which can be completely ignored in engineering applications.

According to the introduction of the sensitivity adjustment principle of the sensor, the sensitivity of the cable force sensor is affected by its main key parameters $K1$ and $K2$. The two parameters $K1$ and $K2$ have the same trend of influence on sensitivity and the same degree of influence [21, 22]. Among them, when the two parameters of $K1$ and $K2$ are in the range of 0-10, respectively, the sensitivity changes more sharply. After more than 10, the sensitivity change tends to be gentle with the increase of the parameters. Therefore, we are designing the variable diameter part of the sensor, considering that the two parameters of $K1$ and $K2$ are controlled within 10. The effect of sensor parameters on sensitivity is shown in Figure 4.

The analysis model is used to analyze the accident, find the cause of the accident, and predict and analyze the technical performance of the bridge project. Combining BIM technology with finite element technology, the bridge structure and the key parts of the bridge structure can be analyzed by finite element, and the safety of the structure can be monitored and evaluated. Combining BIM technology with finite element technology is shown in Figure 5.

When the monitoring result finds that the single pile load reaches 95% of the allowable value, the system will alarm, and the platform operator must stop the operation of the bridge and conduct an appropriate load shedding test on the area of the bridge until the alarm is cancelled and then gradually resume the bridge operation. The bridge column loads and alarm indicators are shown in Table 2.

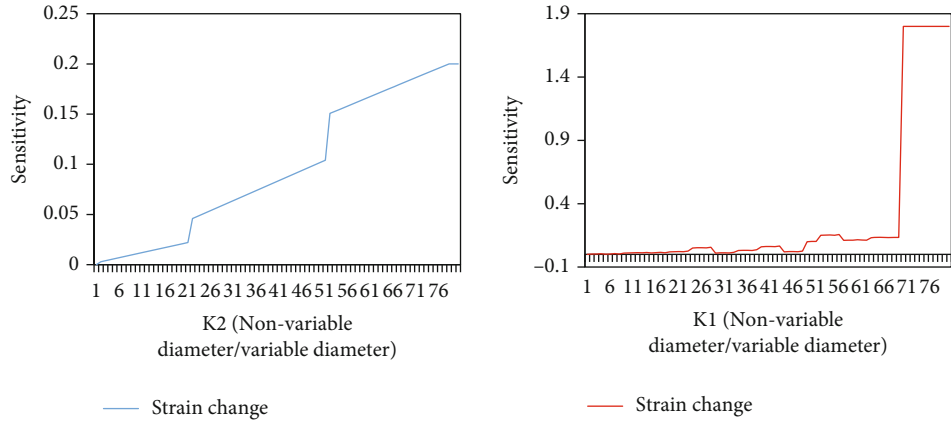
According to various problems in the commissioning stage of the digital twin bridge health structure safety monitoring system, the site is investigated and probability statistics are


FIGURE 4: Effect of sensor parameters on sensitivity.
FIGURE 5: Combining BIM technology with finite element technology (the picture comes from the author's own drawing).

carried out, and the defects and frequencies are found in Table 3.

After adopting the standard data protocol, some manufacturers of niche products, such as fiber grating equipment suppliers, have difficulty in clear data protocol, difficult development, and problems in data debugging after development [23]. The problems of fiber grating equipment are shown in Table 4.

Under the two excitation methods, the accuracy rate of KNN varies with the K value. In the environmental excitation data set, the accuracy rate will gradually increase with the increase of the K value. When the K value is about 210, the accuracy rate reaches the highest 99.95%. When the K value continues to increase, the accuracy rate will slowly decrease

TABLE 2: Bridge column loads and alarm indicators.

Part of the bridge column serial number	Carrying capacity	Current stigma force (kN)	Residual stigma force (kN)
1	2059.07	1028.78	1030.88

FIGURE 6: KNN parameter adjustment results in the environmental and electric excitation data sets.

highest and the evaluation result is the best. The parameter adjustment results of KNN in the environmental and electric excitation data sets are shown in Figure 6.

Acceleration sensor data were collected for a total of 12 days, and the sampling frequency of acceleration information was 100 Hz, which showed the process of bridge condition from healthy to damaged. The research center increased the number of accelerometers to monitor the acceleration information of the bridge structure again from 8.7 to 8.10. The acceleration sampling information on August 7 was 32 Hz, and the sampling information on 8.8-8.10 was 20 Hz. Some sampling dates and sampling frequencies are shown in Table 5.

In the experiment of single-variable pattern anomaly detection based on KNN distance, the compressed segmentation of the data sequence is first done. For the convenience of operation, the method uses the data in the form of text derived from the database. The selected data of each sensor is controlled at about 8000 data values.

First, taking deflection sensor data as an example, the fitting degree of the time series formed by the original data and the time series after segmentation is shown in Figure 7. When the segmentation error in the segmentation algorithm is set to 0.8 d, the number of original data is 8597, and the data

TABLE 5: Some sampling dates and sampling frequencies.

Date of data collection	Sampling frequency	Assessment of damage status
2018.1.1	100 Hz	Healthy
2018.5.5	100 Hz	Minor injury
2018.7.31	100 Hz	Severe injury

after compression is 1860, so the compression ratio is about 21.7%. At this time, the data before and after the segmentation can basically match, and the compression segmentation error can be adjusted reasonably according to the calculation requirements. The smaller the error, the closer to the original sequence, and the more data values.

The data set records the real-time linear acceleration response of the bridge at 4:20 p.m. local time on June 12, 2018 and the component changes of the gravitational acceleration in all directions. The acceleration time thread is shown in Figure 8.

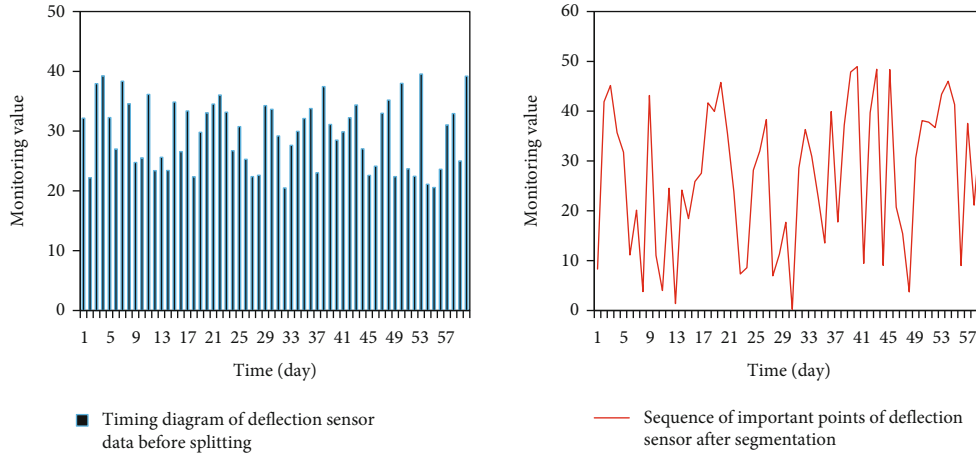
The silhouette coefficients corresponding to different numbers of clusters, in general, with the increase of the number of clusters, the silhouette coefficient has a downward trend,


FIGURE 7: The fit of the time series formed from the original data and the time series after segmentation.
FIGURE 8: Acceleration time thread.

but this does not mean that the fewer the number of clusters, the better. Because with the increase of the number of clusters, the difficulty of model learning gradually increases, and the corresponding silhouette coefficient will decrease accordingly. The contour coefficients are set as shown in Table 6.

The initial value of K of the KNN model is set to 3, that is, the judgment of the new data point is based on the categories of the 3 "nearest neighbors" closest to it. When $K = 3$, the accuracy of the model on the training set is 95.31%, and the accuracy on the test set reaches 91.63%. Its ROC curve is shown in Figure 9, and the AUC area reaches 0.982.

5. Discussion

The main components of the bridge monitoring system are as follows: data acquisition module, data transmission module, data analysis and processing module, data management module, and user interface module. The data acquisition module is the bottom part of the whole monitoring system. According to the characteristics of different bridges, the

TABLE 6: Profile factor settings.

Number of clusters	Silhouette score (silhouette score)
2	0.1932
4	0.1712
5	0.1655

types and quantities of sensors used are different. The data transmission module uses a network constructed by a large number of hubs and routers to transmit the sensor signal data to the monitoring center. The data processing and analysis module preprocesses the data, eliminates data noise and data anomalies, and uses data analysis software to analyze and diagnose bridge health data for damage, the degree and location of damage, pay attention to and study the overall behavior and structural state changes of bridges, and the long-term development trend of bridge bearing capacity and durability. The data management module manages all related bridge structure information, health status monitoring information,
Figure 9: ROC curve.

data processing, and analysis results of the entire bridge. The user interface module presents the bridge-related information to the relevant staff through the visualization program.

The modern spatial structure is developing towards a large and complex direction. These large structures such as space shuttles, high-rise structures, new bridges, and long-span grid structures will be affected by design loads and various unexpected external factors (foreign object shock, vibration, earthquake, explosion, etc.) in complex service environments, and the severe vibration or shock can cause structural damage to varying degrees. The designed service life of large bridge structures can generally reach about one hundred years, and the working life of most bridges needs to last for decades or even hundreds of years. During the service period of bridges, different types of structural damages occur to bridges due to environmental factors, load states, human activity factors, performance variations of building materials, and natural disasters. When the damage accumulates to a certain extent, the accident of sudden structural damage will occur, and the safety of people's lives and properties will be greatly threatened, resulting in significant economic losses. There are many reasons for bridge accidents: engineering quality problems, insufficient postmaintenance of bridges, bridge damage, and functional degradation caused by natural causes, etc.

The traditional bridge monitoring technology generally conducts manual testing under the condition of interrupting bridge traffic. Through regular and nonregular onsite inspection and testing, the actual data is obtained and the test results are obtained by calculation and analysis. The traditional method is limited by time, manpower, measurement conditions, etc., cannot timely feedback evaluation results, is inefficient, has discontinuity, and needs to rely on engineers with rich experience. At the same time, the data collected by traditional methods are relatively not timely enough, are intermittent, and cannot fully and truly reflect the health status of bridges.

The application of BIM in the construction stage realizes the combination of personnel, machinery, materials, documents, etc. with the BIM model in construction, which makes the project schedule easy to control and adjust, improve project quality, control construction safety, and save construction costs. In the process of rotating construction, although the bridge is in a statically indeterminate cantilever state and the force is simple, the bridge is in a state of motion and force when it rotates, and it may be subject to unmeasurable and uncontrollable factors such as wind load, temperature, traction, and friction when it rotates. Therefore, it is necessary to carry out strict construction monitoring on the construction safety and quality of this stage, so as to avoid the phenomenon that the bridge cannot rotate normally or even the bridge overturns during the rotation.

Based on the application of the above BIM technology, more in-depth application research can be carried out on some information, such as regular inspection and rating, preventive screening technology, etc. For example, in the later operation and maintenance of bridges, the operation and maintenance information is transmitted to the BIM model information resource library to realize the transmission of model, coding, data, and file information from the construction period to the operation period, and carry out the whole process management of data monitoring, technical evaluation, comparison and tracking, and auxiliary decision-making.

BIM is widely used in construction, and it can simulate construction plans, carry out special construction, and make construction disclosures. Digital photogrammetry and panoramic technology are used to quickly obtain the original and real-time image data of the project, establish a panoramic system during the construction period, monitor the construction progress, facilitate onsite online management and project live query, and compare and analyze the planned and actual construction. Managing materials, construction data, responsible persons, etc., check the hidden dangers of construction quality and safety, and ensure construction quality and safety. Associating drawings with components, automatically nesting materials, using cloud technology for dimensional inspection, and combining 3D laser scanning to obtain 3D deviation values for the production and design of each component, assisting component quality control, and accurately controlling construction, etc.

Based on Web and digital twin technology, the research on monitoring and management of bridge swivel is carried out. The B/S architecture is used to build a bridge swivel monitoring platform, which integrates animation, BIM model, pictures, and monitoring data into the same interface. Digital twin technology is used to establish a five-dimensional model (physical bridge, virtual bridge model, connection, twin data, and application service) for monitoring and management of bridge swivel construction across high-speed railways and build a digital twin system architecture based on bridge swivel construction monitoring and management. Combined with the background engineering, the operation feasibility of the digital twin system is demonstrated, and the intelligent and automatic management of bridge rotation monitoring and control is realized.

The real swivel bridge and the virtual bridge exchange data through the twin data platform, and the twin data two-way drive the real swivel bridge object and the virtual swivel bridge. The twin data it contains include real-time monitoring data, computational simulation data, rotating body precontrol data, error analysis data, regulation rule data, feedback control data, and personnel construction management data. The monitoring data obtained by the monitoring sensors of the real bridge is transmitted to the virtual bridge through the digital twin platform to simulate the real bridge state and perform real-time monitoring and calculation simulation. The feedback control data generated in the virtual bridge is transmitted to the real bridge through the digital twin platform to control the construction of the bridge swivel. Judging from the operation of the current bridge health monitoring system, the difficulty is often not the collection of monitoring data, but how to process the massive monitoring data accumulated over time, extract the health status information of the bridge with effective data processing and analysis methods, and diagnose and evaluate the bridge. In various monitoring systems, the data processing module is usually the core component. Whether it is damage identification, safety assessment, or change prediction, only good data processing and analysis methods can ensure the meaning and value of the system [24].

6. Conclusion

Aiming at the inconsistency in the dimension of structural output response information and the time-consuming data analysis, this paper uses KNN to extract effective data features, thereby reducing the computational complexity of the algorithm and greatly reducing the learning difficulty of the damage assessment model, improving the accuracy and efficiency of evaluating models. Combined with the work content of swivel construction monitoring, a bridge swivel construction monitoring system is established, the composition and mutual relationship of the monitoring system are analyzed, and the partial composition of the system is reflected in combination with engineering examples. In this paper, design check calculation, monitoring prediction calculation, and key structural analysis are carried out for the background engineering, and the monitoring elements are analyzed for the calculation results of the swivel bridge. This paper proposes to establish a monitoring sensor family library and establish a representative monitoring sensor BIM model according to the monitoring requirements. In the field of engineering, the application of BIM technology should be further explored, such as digital twin reverse modeling technology and automatic identification technology of safety hazards.

With the acceleration of China's aging trend, the physical health of the elderly needs more attention and research from us. In particular, many elderly people are prone to accidental injuries during exercise, so how to protect the health of the elderly through high-tech is worthy of more in-depth research. This measure can promote the establishment of a health system for the elderly. This article is mainly based on the research on the health promotion system of the elderly's daily body functions based on nanoprotective gear technology. It uses the literature method to read a lot of literature to understand the current research status of the elderly's daily body function and health and the application status of nanotechnology, through the questionnaire and survey method for testing the blood pressure, heart rate, pulse wave velocity, bone density, and other physical indicators of the surveyed elderly population, and organize and analyze the relevant data. In this survey, 28.8% of the elderly who regularly participate in physical exercise have high systolic blood pressure, 33.3% of the elderly who do not participate in exercise regularly have high systolic blood pressure, and most of them are in the low bone density stage. Therefore, nanocare technology can effectively protect the health of the elderly and provide protection during exercise. The research in this article is aimed at illustrating the establishment and improvement of the physical function and health promotion system of the elderly through the impact data on physical indicators and providing a factual basis for the elderly to better participate in physical exercise and improve the health quality of the elderly.

1. Introduction

The number of elderly people is increasing year by year, and the aging trend of the world population is becoming increasingly obvious. With the increase of age, the physical function of the elderly declines, the aging rate and incidence of internal organs also increase, and psychological problems gradually occur. The health problem of the elderly population is the most obvious problem in an aging society, so finding effective ways to improve the health of the elderly is the key. The World Health Organization's survey results also confirm the importance of improving healthy behaviors on the quality of life of the elderly, and it is essential to conduct surveys on improving the health of the elderly.

Universities and research institutions in various countries have increased their investment and research on nanotechnology. The development of nanotechnology has a certain socioeconomic and political background. The development of nanotechnology is inseparable from people's area of life. From physics to chemistry, from power to aviation, nanotechnology that integrates the strengths of multiple disciplines has been rapidly developed. Among them, nanoprotective technology is also under continuous research and development.

The intake of protein in the Isanejad M diet may be beneficial to the physical function (PF) of the elderly. They examined the cross-sectional and prospective associations of g/kg body weight (BW), fat mass (FM), and lean body mass (LM) with PF in 554 women aged 65.3–71.6 years

old. Research on osteoporosis risk factors and fracture prevention was carried out. Participants filled out questionnaires about lifestyle factors and 3 d food records in 2002. Body composition was measured by dual-energy X-ray absorption method, and PF was measured at baseline and 3-year follow-up. The definition of sarcopenia is based on the standards of the European Working Group on Elderly Sarcopenia. At baseline, women with higher protein intake (≥ 1.2 g/kg body weight) had grip strength/weight (GS/BM) ($P = 0.001$), knee extension/BM ($P = 0.003$), and single-leg posture ($P = 0.047$), when the chair rises ($P = 0.043$), squats ($P = 0.019$), squats on the ground ($P = 0.001$), and walks faster at 10 m ($P = 0.005$), the short-term physical performance battery score is better ($P = 0.004$). However, while recording the factors related to osteoporosis, this experiment does not account for the controllable variables [1]. Grimm B wearable sensors, especially the inertial measurement unit (IMU), can perform objective, effective, differentiated, and responsive physical function assessment during functional tests such as gait, climbing stairs, or sitting and standing. The most suitable method is to apply to each body part to accurately capture task completion time, spatiotemporal gait, and harshly testing or kinematic parameters specific to the affected limb. In activity monitoring (AM), the accelerometer is mainly used to derive energy consumption or parameters related to overall health (such as total steps). In older adults, it is most effective by studying specific events, such as stairs or high-intensity activities. By looking at qualitative parameters at the "micro" level of activity, such as rhythm or standing time, low cost and ease of use allow routine clinical applications, but there are many options for sensors, algorithms, tests, and parameter definitions. Selection and comparability are still difficult and require consensus or standardization [2]. Lin and Lin's existing health promotion system (HPS) has some shortcomings, such as lack of the ability to automatically plan exercise prescriptions (EP) for individuals, difficulty in obtaining physiological signals of users who are exercising, and lack of effective mechanisms for medical notification emergency situations for personnel users. To solve these shortcomings, in this research, they use wireless sensor network (WSN), mobile communication, and cloud computing technology to develop cloud-based HPS. HPS includes a health promotion cloud service platform that can build a user's physical health model and then generate appropriate EPs for users to perform various exercises. On the user side, in this study, they designed a motion-sensing device that can obtain the physiological signals and global positioning system (GPS) positioning information of users who exercise through WSN in time. Some sensors are designed in motion-sensing devices, such as GPS sensors. However, this technology can only provide location services and cannot provide more types of services related to healthy life [3].

The innovations of this article are as follows: (1) the combination of qualitative analysis and quantitative analysis is fully based on the analysis of data; (2) the combination of theoretical research and empirical research, and the in-depth study of nanotechnology and other theoretical foundations on the above, e is carried out in combination with the specific conditions of physical function and health of the elderly.

2. Promoting Research Methodology Based on Daily Physical Function in Healthy Elderly Nanotechnology Protective Gear

2.1. Nanoprotective Gear Technology. In the late 1980s, a new high-tech science and technology emerged in human society, which is nanotechnology [4]. The emergence of nanotechnology has played a leading role in the development of today's science and technology. This effect has changed the process of technological development to a certain extent and at the same time has changed the scope of research on the philosophy of technology [5]. The emergence of nanotechnology has opened up a brand-new research field, and the scope of its research and discussion is basically between nonmacro and nonmicro, which is what people have rarely paid attention to before [6]. In short, the development of nanotechnology has changed the traditional concept of human understanding and use of technology. It has not only changed the real life of human beings but also profoundly affected the ethics and morals of traditional human society. "Double-edged sword" is the proposition of the philosophy of technology [7, 8].

Through this understanding, we can feel that it is not easy to accurately define nanotechnology. On this basis, the foreign academic circles define nanotechnology as follows: "First, the research on the microcosm of 1-100 nm and the microcosm of molecules [9] can be used to conduct technical analysis and research on the molecules and atoms of materials. Second, research has the possibility of changing a certain characteristic of nanometers. [10]. Third, the ability to control and use the substance is within a personal range [11]."

Nanoprotective technology is a tool made of nanomaterials designed to provide protection for the elderly. By changing the size of nanobuilding units to design the properties and functions of materials [12], the internal and surface chemical properties and their combinations can be controlled. Nanotechnology is known as one of the three pillar industries in the 21st century [13]. Artificial nanomaterials are the foundation and core of nanotechnology [14, 15]. Due to the small size of the structure of artificial nanomaterials, it has special physical and chemical properties, such as small effects and complex structures, with large surface effects, very high reactivity, quantum results, etc. These characteristics bring unique characteristics to nanotechnology. Nanoresearch is highly unique, comprehensive, and social [16]. The disciplines it involves are a multidisciplinary synthesis, involving a number of research areas of emerging disciplines, and countries have also invested large funds in nanotechnology [17, 18].

The success of nanoprotective technology is a brand-new experience for the elderly, which not only provides comprehensive protection measures for the elderly but also reduces the burden on adult children. The development of the field of nanotechnology, on the one hand, can promote

the innovation of production methods. Nanotechnology can change the traditional production methods, guide human beings to produce necessary direct products on a personal level, and use existing materials to fully produce products needed for life [19]. The products produced in this way have improved performance, but the price has not increased much, so they have greater competitiveness. On the other hand, it can promote the improvement of cognitive style. Its appearance indicates that the level of human understanding of nature has reached a new level and has risen to a new height, allowing humans to understand the world from a new perspective, thereby improving human cognitive methods [20, 21]. The biggest problem with the development and application of nanoprotective gear technology at present is how protective its application is and the high cost, whether the elderly and their children can afford this price, and whether nanoprotective gear can be used.

2.2. Methods to Promote the Health of the Elderly's Daily Body Functions.

With the development of economy, the progress of science and technology, the improvement of living standards, and the improvement of medical and health conditions, the proportion of aging of the population in our country is increasing year by year [22]. We also found that while the overall level of public fitness exercise in my country is on the rise, the elderly's fitness exercise is still in the initial stage, and the overall poor health of the elderly is a general trend in the development of human life [23]. Regular exercise can resist the age effect of dysfunction and health disorders and can also reduce mortality and morbidity [24]. With the increase in the incidence of the elderly, through research and analysis, older people have the potential to improve both structure and function [25]. Moderate exercise, appropriate load, exercise time, exercise methods, etc. can promote blood circulation throughout the body, increase metabolism, improve bone, and improve adaptability to various organs and system functional loads. The elderly can also enrich their spare time through the above methods, satisfy people's spiritual needs, increase their sense of joy, establish good interpersonal relationships, improve people's body and mind, achieve their goals [26], delay aging, and improve health. The research results further confirmed that physical exercise has a good impact on the health of the elderly, and increasingly, people have clearly realized that physical exercise has a good effect on improving health and antiaging. The elderly are increasingly participating in physical exercise and at the same time enhance the national health. It provides a factual basis for people to better participate in physical exercise, to further promote the national fitness program and promote the active participation of the elderly in sports, and it provides a scientific and useful foundation. Improve people's and society's interest in older people's participation in sports and encourage them to actively participate in sports.

2.2.1. Physical Exercise.
Taking exercise as a means, using fitness, entertainment, health care, rehabilitation, and mental and intellectual training activities, according to the formation of growth and development and human skills, consciously and orderly promotes people's overall development, improves people's physical condition, improves physical strength, improves athletic ability, improves physical function, improves and maintains physical and mental health, improves lifestyle, and improves quality of life. Sport is not only a physical exercise but also a spiritual activity. Therefore, exercise not only affects physical health but also has a positive effect on mental health.

2.3. Health Promotion Model

2.3.1. Origin of Health Promotion Model.
In 1987, Pan De proposed a health promotion model, an action to improve health to achieve self-fulfillment and personal achievement. Everyone must maintain action to maintain and enhance peace and happiness. He believes that actions to improve health are for self-realization and personal achievement, and everyone will use actions to maintain and improve peace and happiness. This is a positive attitude. Through this healthy behavior, the individual can achieve the greatest potential to achieve the best state of health. The determinants of health promotion actions are divided into specific personal characteristics and experiences (the above actions, personal factors), specific action knowledge and feelings (action feelings, action disorders, self-efficacy, and action-related), and influences on actions (many have future action plans and urgent competition needs and preferences), three categories. The determinants of health promotion actions in the health promotion model can be used to evaluate patients' health awareness and enthusiasm for participating in health promotion activities. In action to improve health to achieve self-fulfillment and personal achievement, everyone must maintain action to maintain and enhance peace and happiness.

In 1987, American nursing expert Pan De first proposed the Health Promotion Lifestyle Scale, which was revised by Walker in 1996 and formulated HPLP-II. The scale contains six dimensions. Promoting a healthy lifestyle refers to all actions taken by individuals, families, communities, and society to improve peace, happiness, and the possibility of health. Based on the health promotion model, various forms have been developed to measure health status. Iran is using the scale of health-improving lifestyles to measure the health actions of Iranian elderly. It has good reliability and validity and good applicability.

2.3.2. Application of the Health Promotion Model in Nursing Practice.
Research on health promotion models has been applied to nursing practice in many countries. The health promotion model was first used in nursing practice abroad. The health promotion model can improve the dietary behavior of diabetic patients. In addition, it can also improve the loneliness symptoms of the elderly. Health education based on the health promotion model has a positive impact on improving social and mental health, delaying the aging process, improving the quality of life and physical health,

improving daily activities, and reducing the risk of disability. In this way, it can activate the essential motivation and beliefs of personal health, turn it into a healthy action, and promote the development of a healthy lifestyle at any level. To achieve a full recovery, reduce the recurrence rate and readmission rate. With the improvement of living standards, unhealthy behaviors, lifestyles, and living environments are more likely to increase the burden of disease.

3. Promote Research Experimental System Based on Daily Body Functions of Healthy Elderly Nanotechnology Protective Gear

3.1. The Establishment of a Model of Influencing Factors of the Physical Function and Health Promotion System of the Elderly

3.1.1. Build the Model Equation. The structural equation model consists of a measurement model and a structural model. In this study, the model equation can be represented by three matrix equations:

$$M = \Gamma_x \xi + \vartheta, \tag{1}$$

$$N = \Gamma_y \eta + \psi, \tag{2}$$

$$\eta = R\eta + \tau\xi + \omega. \tag{3}$$

Table 1 shows the meaning of the letters in the above formula. Equations (1) and (2) are the formulas of the measurement model, which, respectively, determine the position of the relationship between the external observation variable X and the external latent variable and the internal observation variable Y and the internal latent variable. Equation (3) is a structural model equation that determines the relationship between external latent variables and inherent latent variables.

3.1.2. Parameter Estimation Method. Establish an initial structural equation model, and verify the suitability of the model through data analysis. In the SEM analysis, 7 parameter estimation methods are provided, including ML, IV, TSLS, ULS, GLS, GWLS, and DWLS. In this paper, the maximum likelihood method (ML method) is used for parameter estimation.

3.1.3. Construction of the Theoretical Model of the Factors Affecting the Health of the Elderly. The theoretical construction of the structural equation model needs to be based on a certain theoretical foundation and practical experience. Previous literature studies have found that socioeconomic status affects the elderly's social support, family relationships, health status, and health-promoting lifestyle. For example, according to the research, high age, low education, and low income are important risk factors affecting the elderly. The main sources of living expenses, the existence of children, gender, and average monthly income are important factors that affect the level of social support for the empty-nest elderly. Family support also affects the elderly's social support, health status, and health-promoting lifestyle. Having

TABLE 1: The meaning of the letters in the above formula.

Letter	Meaning
M	Observed variables of exogenous latent variables
N	Observed variables of endogenous latent variables
η	Endogenous latent variables
Γ_x	X path coefficient of exogenous latent variables
Γ_y	Y path coefficient of endogenous latent variables
ξ	Exogenous latent variables
ϑ	Error of exogenous latent variable
ψ	Error of endogenous latent variable
ω	Staggered term

a spouse, children's filial piety, and living with children contributes to the mental health of the elderly, and the lack of timely care for spouses and children is easier for the elderly. Perceive loneliness and so on. The main factors affecting social support for the elderly in nursing facilities for the elderly are age, family status, number of visits, and the presence or absence of children.

Health status will also affect the social support of the elderly. In China, participation in social activities is causally related to the health of the elderly. If you are in good health, your chances of participating in cultural group activities and personal family activities will increase. At the same time, combined with the results of single factor analysis, on the basis of theoretical foundation and repeated verification, this study constructed a theoretical model of factors affecting the health and lifestyle of the elderly.

Construct a structural equation model based on the latent variables and observed variables extracted by exploratory factor analysis, and use the Amos22.0 software to fit the constructed model.

3.2. Monitoring System Model of Basic Health Parameters of the Elderly. The health parameter sensor is used to extract human physiological information. It is the basis of the monitoring system. The detection accuracy of the sensor is related to the effectiveness of the monitoring system, and its power consumption and wearing comfort are related to the actual application value of the monitoring system. This chapter considers the characteristics of the dynamic monitoring device, from the perspective of low power consumption, designing the detection circuit and signal processing algorithm of health parameters.

3.2.1. Design of ECG Signal Processing Algorithm. For systems used for long-term signal monitoring, due to limited resources and sensitive to power consumption, signal processing algorithms should have the characteristics of low computational complexity and high real-time performance. Smoothing filtering is a simple and practical filtering algorithm, which is widely used in medical monitoring systems and has a good filtering effect on power frequency interference.

The power frequency signal is a sine wave with a frequency of 50 Hz. We divide a period of the signal into N equal parts, and the sum of the signal values corresponding to each equal point is 0, namely

$$\sum_{i=1}^{n} \sin\left(i\frac{2\pi}{n} + \theta\right) = 0. \tag{4}$$

To achieve power frequency filtering, you only need to set the ECG signal sampling frequency to an integer multiple of 50 Hz. We assume that the ECG signal sampling frequency is 500 Hz, which is 10 times the power frequency. In other words, there are exactly 10 sampling points in a power frequency cycle, that is, $n = 10$, which is equivalent to dividing a power frequency signal cycle into 10 equal parts, and averaging 10 samples can theoretically eliminate the power frequency interference. Then, the difference equation is

$$t(n) = [x(n) + x(n-1) + x(n-2) + \cdots + x(n-9)]/10. \tag{5}$$

In the formula, $x(n), x(n-1) \cdots x(n-9)$ is the sampled signal, and $t(n)$ is the filtered ECG signal.

Performing the Z transformation on the above formula, we get

$$T(z) = \left[\left(X(z) + X(z) \cdot z^{-1} + X(z) \cdot z^{-2} \cdots + X(z) \cdot z^{-9}\right)/10\right]. \tag{6}$$

The transfer function is

$$Q(z) = \left(1 + z^{-1} + z^{-2} + \cdots + z^{-9}\right)/10. \tag{7}$$

3.2.2. Design of the Heart Rate Extraction Algorithm. Heart rate refers to the number of times the heart beats per minute, which is the reciprocal of the cardiac cycle. Every time the heart beats, a QRS complex is generated. Therefore, we can detect the heart rate by counting the number of times the R wave appears per unit time. The differential threshold method is the most widely used ECG signal R wave detection algorithm. It is a fast algorithm and is suitable for systems with high real-time requirements.

In the waveform electrocardiogram, the rise and fall of the edge of the R wave are the areas with the most dramatic changes in the trend. In this area, using the zero crossing point of the dominant number and the end point of the second derivative, the first or second derivative of the filtered ECC signal is performed to determine the position of the R wave that passes the threshold.

The first-order difference and the second-order difference of the electrocardiogram signal are obtained, and the total of the second-order differences is used as the detection standard of the R wave. The quadratic waveform uses the infinite order of the square of the center difference. Since the value of the center difference is an error, the first-order difference is as follows. The form is as follows.

$$h'(n) = \frac{(h(n+1) - h(n-1))}{2}. \tag{8}$$

The second-order difference form is

$$h''(n) = (2h(n+1) + h(n+2) - h(n-2) - 2h(n-1))/8. \tag{9}$$

In the formula, $h(n)$ is the filtered ECG signal sequence.

Then the first-order and second-order differences are squared and the square sum sequence $H(n)$ is obtained, which is equivalent to a nonlinear amplification of the signal, which significantly increases the proportion of high-frequency signals in the original signal. The calculation process is as follows:

$$H(n) = \left(h'(n)\right)^2 + \left(h''(n)\right)^2. \tag{10}$$

The square sum sequence $H(n)$ is combined with an appropriate threshold to detect the R wave and the signal difference calculation processing effect.

3.2.3. ECG Signal Detection Circuit. Only by improving the input impedance of the circuit and the common-mode interference suppression capability of the instrumentation amplifier itself, satisfactory results cannot be obtained. To further suppress the common-mode interference and improve the quality of ECG signal detection, a common-mode interference suppression circuit is designed on the basis of the above circuit. Its function is equivalent to inverting an amplifier, inverting and amplifying the detected common-mode signal before returning it to the human body to further eliminate common-mode signal interference.

We assume that the common-mode voltage of the human body is L_u, and the gain of the amplifiers U1A and U1B is 1, so the amplifier output voltage L_u can be regarded as equal to Lu. Among them are as follows:

$$L_u = i_{db} \times R6 + L_\circ, \tag{11}$$

$$L_u = i_{db} \times R6 - \frac{2R9}{R5} \times L_u'. \tag{12}$$

Thereby

$$L_u = \frac{i_{db} \times R6}{1 + 2R9/R5}. \tag{13}$$

If the right leg is directly grounded, then

$$L_u = i_{db} \times R6. \tag{14}$$

The gain of the circuit is

$$A_3 = R_{14}/(R_{12} + R_{13} + R_{14}). \tag{15}$$

TABLE 2: Elderly health promotion, lifestyle, and its score levels in various dimensions.

Dimension	Individual score	Total score	Behavior level	Sequence number
Self-actualization	2.65 ± 0.35	36.98 ± 0.28	Medium level	2
Health responsibility	2.22 ± 0.19	19.92 ± 0.12	Medium level	6
Movement	2.28 ± 0.06	6.83 ± 0.12	Medium level	5
Nutrition	2.86 ± 0.25	14.36 ± 0.05	Medium level	1
Interpersonal support	2.57 ± 0.29	12.89 ± 0.34	Medium level	3
Stress management	2.55 ± 0.37	15.35 ± 0.28	Medium level	4

4. A Health Promotion System for the Elderly's Daily Body Functions Based on Nanoprotective Technology

4.1. Elderly Health Promotion Lifestyle Physical Function and Its Analysis of the Scores.
It can be seen from Table 2 and Figure 1 that the total score for the health promotion lifestyle of the elderly in Province A in this survey is 105.98 ± 19.61 points, and the average score for each item is 2.53 ± 0.47 points. According to the evaluation criteria of the health-improving lifestyle scale, a healthy lifestyle and all aspects related to the promotion of the elderly are at a medium level. According to the average score of each dimension, the nutrition score (2.86 points) is the highest, and the rest are self-actualization (2.65 points), interpersonal support (2.55 points), stress management (2.53 points) and exercise (2.28 points), and health responsibility (2.22 points), among which the scores of nutrition, self-realization, interpersonal support, and stress management are higher than the total average score of health promotion lifestyle. The results suggest that the elderly have poor health responsibilities and exercise behaviors, and nutritional behaviors are the best.

4.2. Various Indicators of Physical Function of the Elderly.
BMI (body mass index) is an international standard used to measure body fat, weight, and health. It is mainly divided into the following: BMI < 18 is thin, 18.5-24.9 is normal (standard weight), 25-30.0 is overweight, 30.0-34.9 is grade I obesity, and 35.0-39.9 is grade II obesity.

According to the research data, as shown in Table 3 and Figure 2, the number of standard-weight elderly people who exercise regularly is 45, accounting for 50% of the total number, which is higher than the proportion of standard-weight elderly people who do not regularly participate in physical exercise. 41 obese elderly people regularly participate in sports, accounting for 45.5% of the total, far exceeding the proportion of obese people who do not regularly participate in sports. The proportion of elderly people who do not exercise regularly is higher than the proportion of elderly people who exercise regularly. Compared with men and women, the proportion of men who exercise regularly is higher than that of women, and the proportion of women who are too fat is 46.1% higher than that of women who hardly exercise. With the increase of age, body function gradually declines, and the elderly are prone to obesity. Through the body mass index test, people can judge their own health status, actively, participate in sports, control and prevent weight, and reduce the appearance of related diseases.

The blood pressure level is not only closely related to heart function, vascular resistance, and blood volume but also affected by factors such as nerves and body fluids. Blood pressure changes according to age, time, and climate. A happy mood and proper exercise can lower blood pressure, and large mood swings, high exercise intensity, and high work pressure can cause blood pressure to rise.

As shown in Table 4 and Figure 3, the blood pressure of most elderly people is in the normal range. The systolic blood pressure of the elderly who regularly participate in physical exercise reaches the normal range in 71.1%, and the diastolic blood pressure reaches the normal range in 85.5%. The systolic blood pressure of the elderly who did not regularly participate in physical exercise reached the normal range in 66.6%, and the diastolic blood pressure reached the normal range in 77.7%. 28.8% of the elderly who regularly participate in physical exercise are beyond the normal range of systolic blood pressure, and 12.2% of the elderly are higher than the maximum diastolic blood pressure. Health requires active participation in physical exercise to prevent disease and promote health. Compared

TABLE 3: BMI ratio analysis table for the elderly.

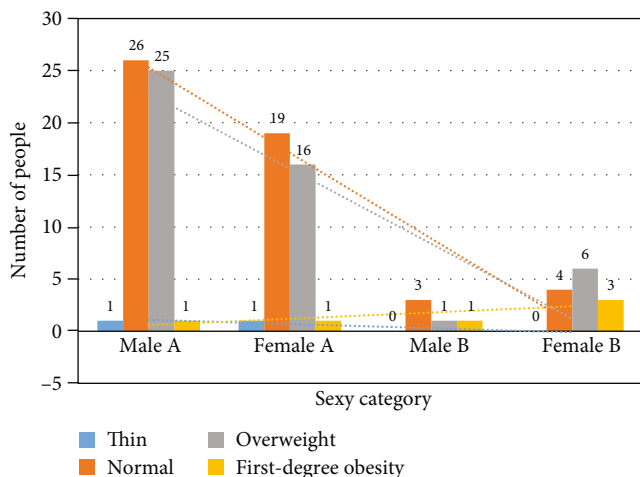
BMI classification	Participate in physical exercise regularly		Total	Participate in physical exercise infrequently		Total
	Male	Female		Male	Female	
<18, thin	1	1	2	—	—	—
18.5-24.9, normal	26	19	45	3	4	7
>25, overweight	25	16	41	1	6	7
30.0-34.9, first-degree obesity	1	1	2	1	3	4
35.0-39.9, second-degree obesity	—	—	—	—	—	—


FIGURE 2: BMI ratio analysis for the elderly.

with the blood pressure of older men and women who regularly participate in physical exercise or infrequently participate in physical exercise, the proportion of men with high blood pressure is higher than that of women.

Blood pressure is an important indicator that reflects the state of cardiovascular function. With the increase of age, the physical function of the elderly decreases, the elasticity of the blood vessels decreases, and the blood pressure rises, which is prone to hypertension. Exercise can reduce high blood pressure, increase cholesterol levels, reduce harmful cholesterol levels, reduce weight, and prevent thrombosis. The elderly should choose appropriate exercise methods according to their health conditions, actively participate in exercise, maintain normal blood pressure, and effectively prevent the occurrence of cardiovascular diseases.

The size of the heart rate can reflect the functional state of the body and the changes of the cardiovascular system function to a certain extent, and it is a reference index for evaluating the cardiovascular function state and exercise effect. The heart rate of a normal person is 60-100 beats per minute. Less than 60 times is called slow heartbeat, and more than 100 times is called fast heartbeat (less than 160 times). The heart rate of women will be faster than the heart rate of men. The heart rate of the elderly increases between physical activity and mental excitement, and the heart rate decreases. Most patients with heart disease have a heartbeat rate of more than 160 beats per minute, or less than 40 beats per minute, and they have heartbeats, chest

pressure, and initial discomfort. People who regularly participate in sports and physical labor have a very low heart rate, less than 60 beats per minute. As long as there is no discomfort, this is normal.

As shown in Table 5 and Figure 4, 87.8% of the elderly who regularly participate in physical exercise maintain the normal heart rate range, 77.8% of the elderly who do not participate in physical exercise regularly reach the normal heart rate range, and 12.2% of the elderly who regularly participate in physical exercise are in the normal heart rate range. 50-60 times/min, which is also in the normal range, indicating that the health status of the elderly who regularly participate in physical exercise is higher than that of the elderly who do not regularly participate in physical exercise. Appropriate physical exercise can keep the heart rate stable. A small number of elderly people with low or high heart rates can improve their heart rate and promote their health by participating regularly. Elderly men and women who regularly take part in physical exercise have relatively good effects on participating in exercise, and there is not much difference in heart rate changes between the two. Appropriate exercise, maintaining a normal weight, and reasonable eating habits are all effective ways to improve heart rate.

As shown in Table 6 and Figure 5, nearly 70% of elderly men and women who regularly participate in physical exercise are in a normal state. Most elderly men and women who take part in physical exercise infrequently have abnormal phenomena, and the abnormality rate of men is much higher than that of women, which may be affected by daily life habits and eating habits.

Under normal circumstances, all blood vessels change with age, the elasticity of the large arteries decreases, the rigidity increases, the inner diameter of the blood vessels increases, the thickness of the internal medium increases, the blood vessels narrow, and the brain and physical strength decline. Arteriosclerosis refers to arterial wall hypertrophy, texture hardening, rough inner wall, and passage of grooves. The pathology is based on deep steatosis and cholesterol deposition in the arterial intestine to form a nonepithelial plate. These plaques stand out and cause blockage. Atherosclerosis is the general form of arteriosclerosis. That is the main cause of myocardial infarction and cerebral infarction. Arterial vascular disease will increase the damage to the heart, brain, kidney, and other organs, causing high mortality and high obstacles. Experts suggest that atherosclerosis-tonic thrombosis is a persistent overall disease and a systemic disease that needs to be prevented

TABLE 4: Analysis table of the influence of physical exercise on the blood pressure of the elderly.

Blood pressure test	Pressure classification, mmHg	Participate in physical exercise regularly		Participate in physical exercise infrequently	
		Male	Female	Male	Female
Systolic blood pressure	90-140	69.8	72.9	60.0	69.2
	>140	30.1	27.2	40.1	30.8
	<60	5.4	2.2	—	7.6

in advance. At present, pulse wave velocity (PWV) (which refers to the speed at which the blood pumped from the heart reaches the hands and feet through the blood vessels) is used internationally. It is an index to predict the degree of atherosclerosis and the risk of coronary artery disease. The PWV of the aorta can also be used to predict the heart and an effective indicator of vascular disease to reflect the degree of arteriosclerosis. When blood vessel elasticity decreases, the blood vessel becomes hard, the speed of pulse conduction becomes faster, and PWV increases.

As shown in Table 7 and Figure 6, the average value of the pulse conduction velocity of men and women on the left and right sides of the elderly who regularly participate in physical exercise is less than 1700 m/s. Above 1800 m/s, the health status of the elderly who regularly participate in phys-

ical exercise is significantly better than that of the elderly who do not regularly participate in physical exercise. Through the T of the relevant data, there is a significant difference in pulse conduction velocity between male elderly who regularly participate in physical exercise and male elderly who do not regularly participate in physical exercise and female elderly who regularly participate in physical exercise and those who do not regularly participate in

TABLE 6: PWV statistical table of pulse wave velocity in the elderly.

TABLE 7: Analysis of the influence of physical exercise on the pulse conduction velocity PWV of the elderly.

Gender	Group	Number of samples	Left	Right
Male	Test group B	55	1692.8	1649.3
	Control group B	6	1893.1	1932.9
Female	Test group G	47	1661.5	1668.7
	Control group G	15	1843.2	1854.5

physical exercise There is a significant difference in pulse conduction velocity among elderly women. Through regular physical exercise, blood supply to tissues and organs (heart, kidney, other important organs, etc.) is increased, tissue hypoxia is reduced, lipid metabolism is improve, plasma activity is increased, body weight is reduced, and blood coagulation is reduce, which helps increase the activity of the anticoagulant system in the blood and reduce the possibility of myocardial infarction. It helps to improve mood, divert patients' attention to the disease, mobilize patients' positive causes, and eliminate negative fears.

Bone density is an important indicator of bone quality, reflects the degree of osteoporosis, and is an important basis for predicting fracture risk. The bone content of minerals is closely related to the resistance of bone and the stability of the internal environment. This is not only an important indicator for evaluating human health but also an important indicator for evaluating and studying bone physiology,

human pathology and aging, and the diagnosis of various diseases of the body. The bone mineral density, in BND and normal youth and standard deviation (SD) high (+) or low (-) comparison T value, is the most important value in the diagnosis of osteoporosis.

As shown in Table 8 and Figure 7, the bone density of the elderly who regularly participate in physical exercise is 28.8% in the normal range, which is higher than that of the elderly who participate in physical exercise infrequently; -2.5 to -1 belong to the low bone density stage. And osteoporosis, the proportion of elderly people who regularly participate in physical exercise, is 48.9%, and the proportion of elderly people who hardly participate in sports is 55.6%. Compared with the proportion of elderly people who regularly participate in sports, the proportion of elderly people who hardly participate in sports is even higher. 16.7% of the elderly who exercise regularly suffer from osteoporosis, and 22.2% of the elderly who do not exercise suffer from osteoporosis. Combined with the above analysis, it can be seen that regular participation in physical exercise can strengthen bone. Muscles and bone are inseparable. Continuous, regular, and appropriate exercise can alleviate the degree of osteoporosis. In the elderly, muscle strength is weakened, mechanical stimulation is relatively reduced, and bone turnover tends to be negatively balanced, which will accelerate the development of osteoporosis. According to these data, the ratio of osteoporosis among elderly women

TABLE 8: Analysis table of the influence of physical exercise on bone mineral density of the elderly.

	Total	22.4	55.8	16.8	6.6
FIGURE 7: The influence of physical exercise on bone mineral density of the elderly.

who regularly participate in physical exercise and those who do not participate in physical exercise is much higher than that of men. The bone mineral content of normal people is closely related to gender and age, and there are differences between different genders in the same age group. Females are lower than males. The elderly women who often take part in physical exercise are also lower than men, which is related to the body structure of men and women.

Especially for the elderly with osteoporosis, the use of nanoprotective gear can better protect the bone health of the elderly. It can also avoid accidents while exercising and provide good protection for the elderly. The research of nanoprotective gear technology is exclusively customized for the elderly. Of course, it can also be applied to the sports of many young people. The purpose is to bring a better healthy lifestyle and improve the quality of healthy life.

5. Conclusion

This article is mainly based on the research of the elderly's daily body function and health promotion system based on nanoprotective technology. Using a variety of research methods, the model of the influence factors of the elderly body function and health promotion system was established, and the elderly body function and health status from the influencing factors was analyzed. And the role and effect of nanoprotective technology in the daily exercise of the elderly were highlighted.

The innovations of this article are as follows. First, qualitative analysis is combined with quantitative analysis, and qualitative analysis is fully based on the analysis of data; second, theoretical research is combined with empirical research and in-depth study of nanotechnology, etc. On the basis of the theory, empirical research is carried out in combination with the specific conditions of the physical function and health of the elderly.

There are still shortcomings in this article. Firstly, the amount of data in the questionnaire survey is not enough, the number of interviewers is not large enough, and the representativeness of the data is not strong enough; secondly, the nanoprotective technology is still immature, and more in-depth research and more extensive research are needed. In application experiment, in the future, the development of nanotechnology will bring increasingly convenient life to people, and at the same time, it will also bring better protection to the health of the elderly.

In a narrow sense, polymer composites refer to multiphase materials composed of polymers and other substances with different compositions, shapes, and properties. They can be divided into structural composites and functional composites. In a broad sense, polymer composite materials also include polymer blend systems, collectively referred to as "polymer alloys." The purpose of this paper is at studying how to study the impact of polymer composite materials on the adaptation and comfort of sports and fitness facilities. This paper puts forward the problem of comfort, which is based on the construction materials of sports equipment, and then elaborates on the polymer composite materials and makes a case design and analysis of the applicability of polymer composite materials in sports equipment being carried out. The experimental results show that 34.81% of the people are very satisfied and relatively satisfied with the quality identification of sports equipment and only 41.99% of the people are very satisfied and relatively satisfied with the feeling of sports equipment when exercising. Both are less than half of the total sample size, which shows that the current state of sports facilities is worrying.

1. Introduction

With the rapid development of the society, under the dual pressure of work and life, people pay more and more attention to healthy life. However, the current sports equipment and fitness facilities as a whole still cannot meet the people's fitness needs, which not only limits the public's participation in physical exercise but also exacerbates the contradiction between the public's growing fitness needs and the unbalanced and insufficient supply of fitness facilities. The wide application of polymer functional composite materials in sports equipment improves the comprehensive performance of sports equipment and fitness facilities and promotes the vigorous development of sports enterprises. In view of this, it is particularly important to discuss the design research of sports equipment and facilities in sports and fitness venues.

The improvement of the comfort of sports facilities will help alleviate the contradiction between the growing demand for sports activities and the lack of sports facilities, and it can help people improve people's comfort in sports activities. Convenient transportation, good sports environment, excellent sports equipment, and comfortable sports atmosphere can not only stimulate people's desire to engage in sports activities to a certain extent but also help them improve their physical condition and enjoy physical and mental health during exercise. Likewise, it helps extend the lifespan of sports facilities.

The innovation of this paper is that (1) this paper combines polymer composite materials with deep learning and introduces the theory and related methods of the neural network in detail and (2) in the face of the comfort of sports facilities, using questionnaires and analyzing the performance of polymer composite materials to analyze come in handy. Through the evaluation of the experimental results, in the selection of materials for sports equipment, materials and comfort should be given top priority and suitable materials will improve the comfort and experience of athletes.

2. Related Work

Since the 19th century, humans have used naturally modified polymer materials. After entering the 20th century, polymer materials entered a huge development stage. Atci E presented atomic models for the transport of single-component gases (CH_4, CO_2, H_2, and N_2) and binary gas mixtures (H_2/CO_2, H_2/N_2, and H_2/CH_4) in zeolitic imidazole framework (ZIF) membranes and ZIF/polymer composite membranes. The atomic model predictions are validated by comparison with available experimental data for ZIF-90 films. However, his experimental data was less [1]. Xin et al. reported a convenient and versatile strategy to prepare cesium lead bromide or organic lead halide methyl ammonium bromide polymer composites. They verified it by using methyl methacrylate, butyl methacrylate, and polystyrene and successfully built a prototype white light-emitting diode with viable color properties and narrow bandwidth. However, its application scope was limited [2]. Vaisanen et al. conducted a critical review of the impact of multiple types of waste, residues, or process by-products on NFPC and assessed their potential as NFPC components. However, his content was relatively brief [3]. Dang et al. investigated anisotropic aluminum nitride (AlN) whiskers and isotropic spheres as mixed fillers in the epoxy resin and polyvinylidene fluoride (PVDF) matrix to improve thermal conductivity of polymer composites. And polymer composites with mixed fillers of AlN whiskers and spheres with different volume ratios were prepared. However, his results were not comprehensive enough [4]. Moura et al. reported on the production and characterization of composites for wound healing applications, investigating bioactive glasses obtained by a sol-gel method and doped with two different metal ions. However, his performance was lower [5]. Khan A used chemical vapor deposition (CVD) technology to extract two different morphologies of carbon nanomaterials (CNM), namely carbon nanobeads (P1) and a mixture of carbon nanotubes and carbon nanobeads (P2). The morphology of the composites was analyzed by FESEM to study the interaction of fillers with the matrix to improve performance. However, his influence factors were more [6]. Zhang and Goekce summarized in situ and ex situ laser prototyping methods and downstream batch processing techniques for nanoparticle-polymer composites (LaNPCs) and discussed determining factors of polymer-solvent-laser parameterization on the target physical and chemical properties of composites. The advantageous features of this technique were demonstrated by highlighting representative works related to various promising applications. Finally, it described the challenges and prospects facing LaNPC, as well as perspectives on how recent research results are changing the direction of research in this field. However, their focus was not enough [7]. Li et al. investigated polymer composites reinforced by pristine and functionalized graphene to determine the improvement of the tribological properties of polymer composites. A molecular layer model with Fe atoms as the top nanolayer was established, and the tribological properties of the polymer composites were improved by sliding the top Fe nanolayer on the surface of the polymer matrix.
Figure 1: Architecture of an artificial neural network.

The simulation results show that the average friction coefficient and wear rate of the functionalized graphene/polymer composites are reduced by about 13% and 42.3%, respectively. However, their data were not accurate enough [8].

3. Classification Method of Polymer Composite Materials

3.1. Introduction to Deep Learning Based on Polymer Composite Material Classification. In recent years, deep learning technology has been successfully applied to speech recognition, handwriting recognition, and computer vision and achieved remarkable results in the fields of natural language self-processing [9]. The classification of polymer composites can also be carried out with the help of deep learning techniques.

The artificial neural network is an information processing system, which has some characteristics of ordinary BNN. In short, the artificial neural network can be regarded as an integrated system of the mathematical model of the human brain. The structure is shown in Figure 1. A large number of interconnected neurons constitute an ANN, and each neuron is interconnected with other neurons by having corresponding weights. In this, the knowledge to solve the problem can be represented by the weights. The structure of artificial neural network is composed of the feedforward network, feedback network, and mutual combination network. A neural network is an operational model that consists of interconnected connections between a large number of nodes (or neurons).

Deep learning is a very popular method in machine learning, covering theoretical viewpoints in many fields. It is to learn the inherent laws and representation levels of sample data. In order to realize more intelligent human-
Figure 2: Deep neural network.

computer interaction, researchers imitate the human brain and thinking and establish various neural network models. Deep learning is one of them [10]. Deep learning is a multi-level representation learning method, learning data features by creating models, and finding a better data representation is the primary purpose of representation learning, as shown in Figure 2.

The convolutional neural network was first proposed in the 1980s. The idea of the CNN was inspired by human research on the cat visual system, but due to the limitations of computer resources at that time and other resource-limited problems, it could only stop there. The three major deep learning giants proposed a standard LeNet-5 network structure, using gradient descent for training, and achieved good experimental results, making it possible to train deep neural networks. The essence of the convolutional neural network is to construct multiple interconnected kernel convolution kernels, which can output data features and topological features. A structure is hidden between data by performing layer merging function on the data input side [11, 12], as shown in Figure 3.

As the number of layers continues to increase, the derived features become more and more abstract and these abstract features are finally merged through a fully connected hierarchy and classification problem. Feedback is resolved through Softmax or Sigmoid activation functions.

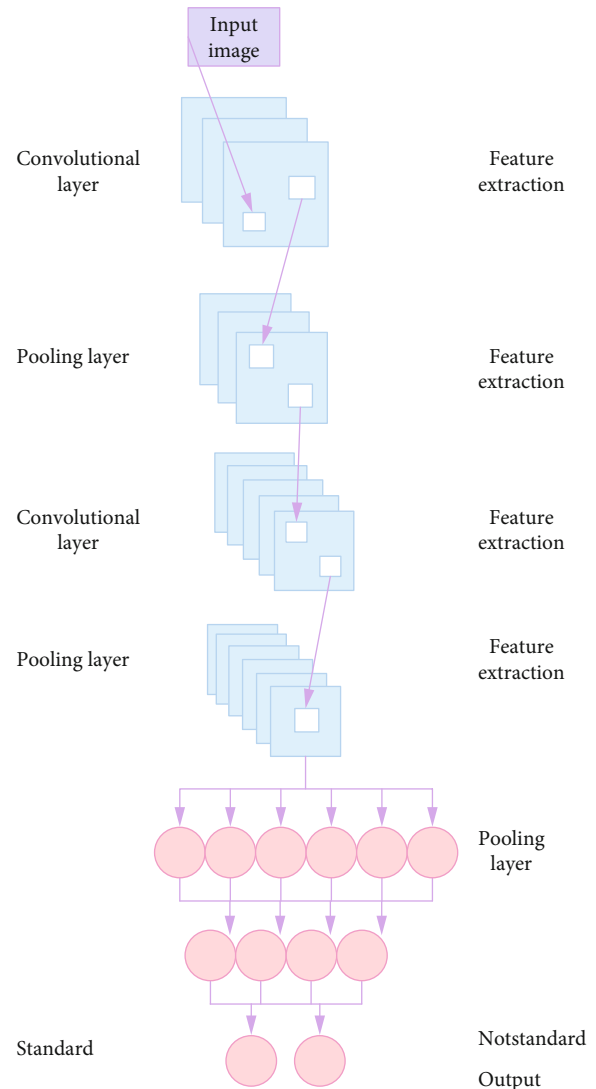
Before introducing Softmax regression, it is necessary to introduce logistic regression. Logistic regression is a simple binary classification algorithm that achieves classification by fitting the classification boundaries of the data and uses optimization methods such as gradient descent to determine


Figure 3: Convolutional network structure diagram.

the best regression coefficients [13]. One of the more important formulas in logistic regression is the step function:

$$Q(X) = \frac{1}{1 + E^{-\theta^Z X}}. \tag{1}$$

Its waveform is as follows; the value range is between [0,1]; Figure 4 is the logistic regression step function formula.

Its corresponding negative log-likelihood loss function is defined as

$$Q(\theta) = -\frac{1}{u} \left[\sum_{i=1}^{v} Y^i \log f_\theta(X^i) + (1 - Y^i) \log (1 - f_\theta(X^i)) \right]. \tag{2}$$

Based on linear regression, logistic regression applies a logistic function, but because of this logistic function, logistic regression has a favorable place in the field of machine learning [14].
FIGURE 4: The logistic regression step function formula.

The assumption of the logistic regression model is as follows:

$$h_\varphi(t) = g(\varphi^Z t). \tag{3}$$

A commonly used logic function (and also the function mainly used in this paper) is the sigmoid function, and its expression is shown in formula (4):

$$g(x) = \frac{1}{1 + e^{-x}}. \tag{4}$$

The graph of this function is shown in Figure 5.

Therefore, the assumptions of the logistic regression model are as follows (5):

$$h_\varphi(t) = \frac{1}{1 + e^{-\varphi^Z x}}. \tag{5}$$

For the LR model, the classification is based on the following: for a given input variable t, calculate the probability that the output variable is 1 according to the selected parameters, that is,

$$h_\varphi(t) = P\left(\frac{y=1}{t;\varphi}\right). \tag{6}$$

The ReLu (rectified linear units) function is a popular activation function that has gradually replaced the sigmoid function. The function graph of ReLu is shown in Figure 6; it does not tend to saturate with the gradual increase of the input x.

Details of the Softmax classifier are as follows:

$$x(i|j) = \frac{\exp(V_i \cdot j)}{\sum_{w=1}^{W} \exp(V_w \cdot j)}. \tag{7}$$

Splitting the prediction function into two steps, taking the 1st row of V and multiplying that row with j,

$$V_{i \cdot j} = \sum_{a=1}^{d} Q_{iaxa} = f_j. \tag{8}$$

Calculating all f_w, $w = 1, \cdots, W$. Applying the Softmax function to obtain normalized probabilities,

$$x(i|j) = \frac{\exp(f_j)}{\sum_{w=1}^{W} \exp(f_w)} = soft\max(f)_j. \tag{9}$$

Softmax regression is an extension of logistic regression for solving multiple classification problems. Softmax regression is a supervised learning algorithm that can be combined with deep learning methods or unsupervised learning methods [15]. In logistic regression, the training sample set consists of samples labeled $\{(m^{(1)}, n^{(1)}), (m^{(2)}, n^{(2)}), \cdots, (m^{(x)}, n^{(x)})\}$ with the input feature $m^a \in \varphi^{y+1}$. The dimension of the feature vector m is $y + 1$, $m_0 = 1$. Supposing that the function is as follows,

$$h_\alpha(m) = \frac{1}{1 + \exp(-\alpha^T m)}. \tag{10}$$
FIGURE 5: Sigmoid function diagram.
FIGURE 6: ReLu function diagram.

The model parameter α will be trained to minimize the cost function:

$$
S(\alpha) = -\frac{1}{x}\left[\sum_{i=1}^{x} n^{(a)} \log h_\alpha\left(m^{(a)}\right) \right.
$$
$$
\left. + \left(1 - n^{(a)}\right) \log\left(1 - h_\alpha\left(m^{(a)}\right)\right)\right]. \tag{11}
$$

In convolutional networks, the process of convolution includes two parameters: the first parameter is the input and the second parameter is the kernel function (i.e., the convolution kernel) [16]. The unit output by the convolution operation is called a feature map. Taking a two-dimensional image Q as input and the two-dimensional convolution kernel being P, the convolution of q and P is as follows:

$$
S(a, b) = (Q * P)(a, b) = \sum_{a}\sum_{b} Q(i, j) P(a - i, b - j). \tag{12}
$$

Mathematically, convolution is interactive because the convolution kernel is flipped relative to the input. However, most of the existing neural network libraries are based on a crosscorrelation function that does not flip the kernel and both methods are called convolution [17]. In this paper, the convolution is represented in this way. The convolution operations mentioned below are all convolution operations without flipping the convolution kernel. The crosscorrelation function is expressed as follows:

$$
S = (a, b) = (Q * P)(a, b) = \sum_{i}\sum_{j} Q(a + i, b + j) P(i, j). \tag{13}
$$

The convolutional neural network (CNN) is one of the structures of the deep learning network, which is characterized by a large number of convolution operations in the network structure. In addition, the activation function and pooling layer are also its basic structures. These three basic structures make it have better local perception characteristics and feature abstraction ability than multilayer perceptron (MLP) [18]. At present, the CNN has been widely used in many subfields of image processing and computer vision, such as image classification, image semantic segmentation, and visual object detection.

3.1.1. Calculation Output. For the l layer of the fully connected layer, the output result is as follows:

$$
A^x = g(C^x),
$$
$$
C^x = V^x A^{x-1} + Q, \tag{14}
$$
$$
E^z = \frac{1}{2}\sum_{k=1}^{l}(P_k^z - B_k^z)^2 = \frac{1}{2}\|P^z - B^z\|_2^2.
$$

In the formula, P^z is the expected output value of the zth sample and B^z represents the actual output value of the zth sample after the network operation.

3.1.2. Backpropagation. The data is calculated layer by layer through the network, and the error between the actual output and the expected output is obtained, which can be regarded as the sensitivity of the neuron base. The formula is as follows:

$$
\frac{\partial E}{\partial Q} = \frac{\partial E}{\partial C}\frac{\partial C}{\partial Q}. \tag{15}
$$

The formula for the sensitivity of layer x in the backpropagation stage is as follows:

$$
\delta^P = \left(V^{x+1}\right)^P \delta^{x+1} \bullet g'(C^p). \tag{16}
$$

The sensitivity of the output layer node is as follows:

$$
\delta = g'(C^x) \bullet (B^z - P^z). \tag{17}
$$

3.1.3. Weight Update. The derivation of the error for the x layer weight of the fully connected layer is the crossproduct of the x layer input and its sensitivity. The weight update formula is as follows:

$$
\frac{\partial E}{\partial V} = A^{x-1}(\delta^x)^P,
$$
$$
\Delta V^x = -\eta \frac{\partial E}{\partial V^x}. \tag{18}
$$

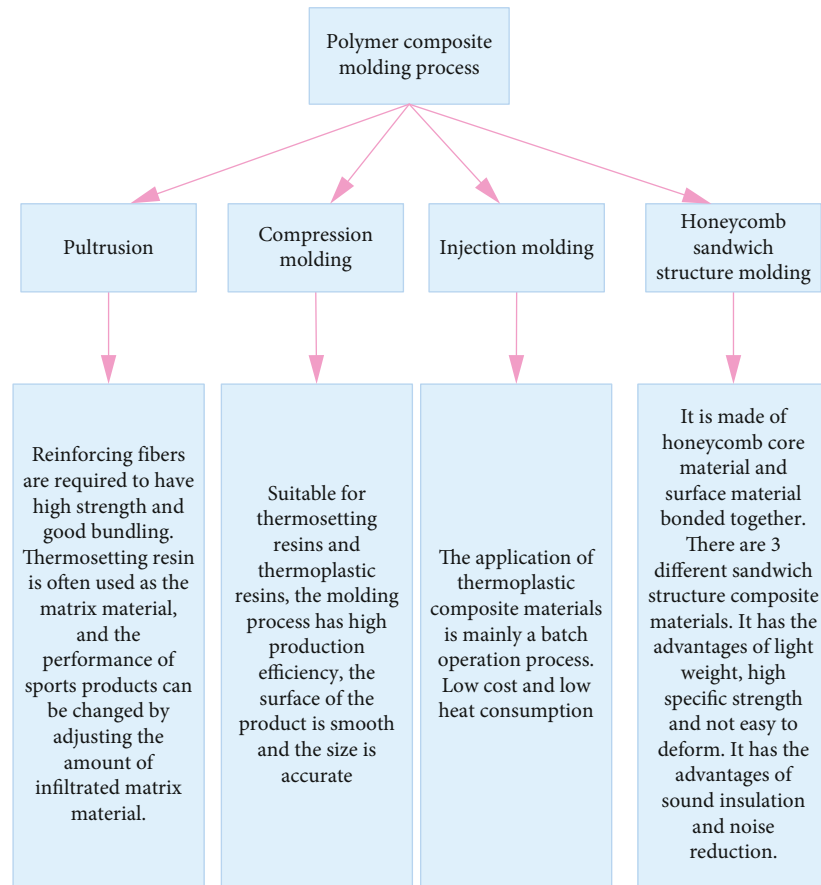
3.2. Polymer Composites. The biggest advantage of polymer composite materials is the advantages of various materials, such as high strength, light weight, temperature resistance, corrosion resistance, heat insulation, insulation, and other properties. According to the application purpose, select


FIGURE 7: Polymer composite-type process.

polymer materials and other materials with special properties to make composite materials that meet the needs.

Polymer composite materials synthesized according to structural requirements are called polymer structural composite materials, and polymer structural composite materials synthesized according to different functional requirements are called polymer functional composite materials. Polymer functional composites are usually composed of the reinforcement phase and matrix phase. Generally, the commonly used reinforcing phases are fibrous materials, such as boron fibers, glass fibers, and carbon fibers. Dispersing them in a matrix phase enhances the overall strength, elasticity and impact resistance of the material. The function of the matrix phase is mainly to bond the dispersed material fibers into a group. The matrix phase materials generally have high special size and special strength, such as plastic epoxy resin, polypropylene, and polyimide. Due to its superior properties, it is used in the cutting-edge technology as well as defense and security. Due to the needs of sports, some sports equipment must have specific functions. Therefore, resin matrix materials are combined with materials with special functions, such as luminescence, antistatic, and magnetic properties, to form polymer functional composites [19, 20].

The molding process of polymer composite materials includes pultrusion molding, compression molding, injection molding, honeycomb structure molding, and other molding processes. The characteristics of some molding processes are shown in Figure 7.

4. Experiment and Analysis of the Comfort of Polymer Composites in Sports Facilities

4.1. Questionnaire Survey. A sample of 362 people was selected through the sampling survey, including 218 males and 144 females. It can be seen from the numbers that boys exercise more frequently than girls. The survey on the quality satisfaction of sports facilities is shown in Figure 8. The respondents showed a "∩" situation in the middle and two lows in terms of their recognition of the quality of sports equipment and their own proprioception during physical exercise. It can be seen in Figure 8(a) that among the quality recognition of sports equipment, 38 people chose to be more satisfied, accounting for 10.50%, 88 people chose to be more satisfied, accounting for 24.31%, the number of people who chose ordinary is 126, accounting for 34.81%, 78 people chose not satisfied, accounting for 21.55%, and 32 people chose very dissatisfied, accounting for 8.84%. As can be seen in Figure 8(b), among the feeling of sports equipment when exercising, 30 people choose very satisfied, accounting for 8.29%, 122 people choose relatively satisfied, accounting for 33.70%, 104 people choose in general, accounting for 28.73%, 74 people who are not satisfied, accounting for 20.44%, and 32 people who choose very dissatisfied,
FIGURE 8: Respondents' satisfaction with the quality of sports equipment.

accounting for 8.84%. It shows that the respondents' recognition of the quality of sports facilities and equipment is generally at a medium level.

Figure 9(a) shows that sports facilities are occasionally damaged. As a sports facility, due to frequent use by people, 79.56% of occasional damage is normal. For this kind of normal damage, how the relevant departments should deal with it is a problem. The survey in Figure 9(b) shows that 80.66% of the respondents believe that these sports facilities have not been repaired and dealt with in time after the damage.

In addition, the survey on the maintenance and maintenance of sports facilities showed that 80% of the respondents believed that the relevant departments did not regularly maintain the sports facilities in a timely manner. More than 70% of the respondents believed that the relevant departments did not replace the damaged and irreparable equipment and facilities in time. Thirty percent of the respondents have a potential danger when engaging in physical exercise and feel that they may have potential safety hazards during the exercise process, and nearly 70% of the respondents will choose another kind of equipment for exercise.

To sum up, due to the needs of sports, some sports equipment must have specific functions. Resin-based matrix materials are combined with materials with special functions, such as glowing, antistatic, and magnetic, to form polymer functional composite materials. The following will analyze the experimental performance of polymer composite materials for sports equipment.

4.2. The Use of Common Polymer Composite Materials for Sports Equipment. Polymer engineering materials are used in the design and production of certain sports facilities and sports equipment to meet different sports needs, such as an equipment compact structure, heat resistance, corrosion resistance, and long service life. The available properties of some selected sports equipment materials are shown in Table 1.

Natural rubber and synthetic rubber are two types of rubber. In some sports, athletes will be subjected to a strong impact force and the rubber material can effectively reduce the impact force, thereby protecting the personal safety of the athletes, and can also effectively absorb shock and slip. Therefore, some rubber composite materials are often used in the design and production of sports equipment, such as high-elastic sports shoes for cushioning landing impact and protective equipment for cushioning impact. When the elastic material is subjected to external pressure, it does not break but causes reversible deformation; when the external force is removed, the rubber returns to its original shape. The main application aspects and properties of rubber materials in the sports field are shown in Table 2.

In the production and manufacture of sports facilities and equipment, rubber is one of the most widely used polymer materials, with excellent elastic properties, improving sports safety for athletes and providing athletes with a comfortable experience. Its rubber and composite materials are also widely used in ball equipment such as volleyball, basketball, and football, as well as dumbbells, shuttlecocks, racket outer layers, and racket handles. So, its rubber and composites are used for PVC. Its wide application can slow down the various impact forces received by the human body during use to exercise the body and significantly improve the safety and comfort of sports.

The sports industry is inseparable from the application of fiber polymer materials. Table 3 shows some related sports goods and materials, as well as some corresponding properties.

4.3. Impact of Polymer Composites on Comfort in Facilities. In the design and production of sports equipment, health and comfort should be the primary requirements for material selection. Coolmax fiber fabrics, cool plus fiber fabrics, or cotton fabrics are materials that perform well on this demand and can be used in the design and production of

(a) Respondents' perception of damage to sports facilities

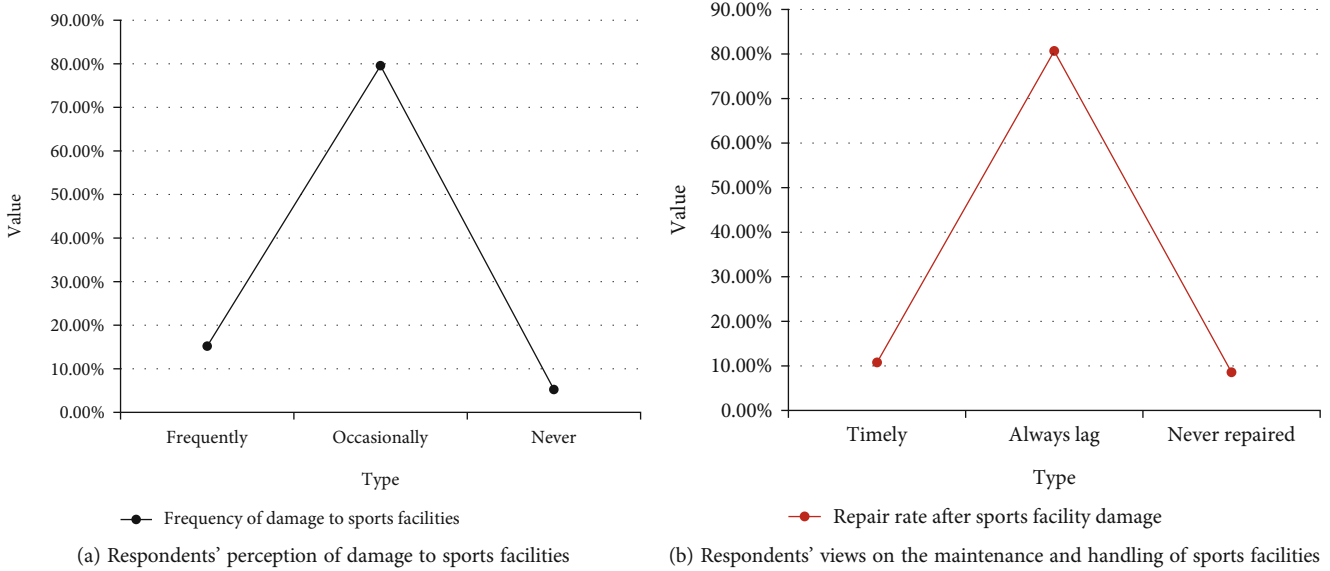
(b) Respondents' views on the maintenance and handling of sports facilities


FIGURE 9: Respondents' survey on postmaintenance of sports equipment.

TABLE 1: Performance of polymer materials commonly used in sports equipment.

Sporting goods	Material	Effect
Sports bike	Polyetheretherketone, polycarbonate	Strong, heat resistance, impact resistance
Rubber track	Polyurethane rubber	Friction resistance, solvent resistance, oil resistance, aging resistance, high strength
Basketball	PVC	Antiaging and corrosion resistance
Table tennis	Polyester	High toughness and friction resistance

TABLE 2: Performance of polymer materials commonly used in sports equipment.

Sporting goods	Material	Chemical nature	Nature
Racing	Natural rubber cavity (NR)	Polyisoprene	For racing tires, with high elasticity
Sports shoes	Styrene butadiene rubber (SBR)	Polystyrene-butadiene	For shoe soles, antiwet and low rolling resistance
Protective equipment	Nitrile rubber (NBR)	Acrylonitrile-butadiene copolymerization	Strong oil resistance, aging resistance, friction resistance

sportswear. Swimsuits and wetsuits for water sports must be highly elastic, soft, and waterproof. Therefore, polyurethane can be treated by the combination of primer and final coating to reduce the resistance of water sports, can improve the comfort and freedom of athletes during water sports, and can effectively help athletes achieve better competition performance [21].

Today, most of the running tracks are built with plastic tracks, replacing the previous tracks with cement; the floors of sports fields and gyms also use plastic floors, which are very important to improve the comfort of athletes. Plastic runway and plastic floor have excellent recovery, sound absorption, shock absorption, abrasion resistance, and slip resistance. Compared with the traditional material track, the plastic track has significant elastic kinetic energy, strong force rotation, and vibration reduction ability, which can effectively reduce the impact force of the foot. The risk of injury to the athlete is reduced, and the athlete is more comfortable during training or competition without leg pain associated with prolonged exercise. The plastic track has a

certain breathability. At high temperatures, athletes are less likely to emit unpleasant odors. The composition of the plastic track is shown in Figure 10. The construction of the lower layer should ensure the stability of the foundation. The construction of the abovementioned fourth, fifth, and sixth layers is made of plastic materials. The outer layer of the main material is polyacrylic acid, which is closely related to the direct contact with athletes and has strong elasticity and comfort.

Materials commonly used in water sports facilities, such as rowing boats, jet skis, surfboards, and windsurfing boards, are both plastics and composites. These facilities must withstand the mass of athletes and resist the impact of water. Therefore, it must have strong hardness and rigidity. Therefore, composite fiber materials are usually added to plastic materials to improve the durability of the device and meet the needs of athletes. Most of these factories are made of thermoplastic and thermoset materials, which not only are lightweight but also allow athletes to control speed and direction, and have a good feel, thus improving the comfort

TABLE 3: Applications of fibrous polymer materials.

Sporting goods	Material	Nature
Sports clothing	Nylon, acrylic, polyester	Soft, antiwrinkle, comfortable, easy to wash, and quick dry
Rackets, pitch bars, bicycles, surfboards	Composite fiber material	High strength and elasticity
Golf clubs	Carbon fiber composite material	Increase the mass of the club head, provide greater power, and improve the initial speed and stability of the ball when flying
Ski board	Composite use of carbon fiber-reinforced plastics and other materials	Enhanced bearing capacity and increased stability
Sport bike	Carbon fiber-reinforced plastic	Reduce mass, improve rigidity, and increase driving comfort
Mountaineering equipment	Carbon fiber-reinforced plastic	Improve the strength of the climbing rope, enhance wear resistance, and ensure safety
FIGURE 10: Plastic runway structure.

of sports. In addition to fiber-reinforced plastics, the outer layers of wakeboards, surfboards, and other aquatic facilities often use polyurethane foam composites with thermal insulation, which can reduce the energy consumption of athletes in the water to a certain extent [22]. Other functional materials are made with the motorboat saddle, which can significantly improve the comfort of use.

5. Discussion

First of all, through the study of relevant knowledge points of literature works, this paper initially masters the relevant basic knowledge and analyzes how to study the influence of polymer composite materials on the adaptability and comfort of sports and fitness facilities. The concept and deep learning algorithm of polymer composite materials are expounded, and the applicability of polymer composite materials in sports equipment is tested through experiments.

Comfort is the state of mind that a person is in a carefree, relaxed environment in an environment. It is the subjective feeling of people, including physical, psychological, environmental, and other aspects. There are clear physical and psychological differences between different age groups. So, comfort requires facilities in the public space environ-

ment to meet the needs of most people, while installing universal design facilities. For larger sports facilities, simple and varied designs can be installed to meet the needs of different age groups. When designing fitness facilities, factors such as different sizes and heights can be considered to meet the comfort of different groups of people [23]. The choice of material is very important, especially the parts that are in direct contact with people, which directly determines the comfort level of people.

Through the experimental analysis in this paper, it can be seen that polymer composite materials are widely used in the production and manufacture of sports equipment and facilities due to their wide range of sources. The casting process is simple and the cost is low. The use of composite materials has greatly improved the comfort and safety of sports equipment and facilities. With the continuous progress of science and technology, the production of sports facilities must go hand in hand with the development of science and technology in order to promote the development of national sports [24].

6. Conclusions

Since the reform and opening up, with the improvement of the quality of life, people have more free time and begin to gradually enjoy life and pursue health. This study mainly analyzes and discusses the factors that affect the comfort of sports facilities; the research focuses on the analysis of the design and construction of sports facilities and examines the comfort provided to residents during physical exercise. In the category of psychology, influencing factors vary by personal values, but also by personal emotions at different times. This is a relatively complex system. This study explores the factors that affect the comfort of sports facilities. This paper discusses the factors affecting the comfort of sports facilities and is aimed at further constructing the evaluation scale for the comfort of sports facilities, and establish a scientific, reasonable and flexible evaluation index system for the comfort of public sports facilities, and then continue to find and solve problems. For public sports facilities in the design, this scale can be used as a basis. Along with the overall planning of Khao Chung, the focus was on improving the comfort of public sports facilities. Therefore, this study will

conduct in-depth research on this issue in the future, construct a sports facility comfort assessment scale, and conduct a scientific assessment of the comfort of sports facilities.

Corynebacterium glutamicum is an authenticated microorganism that supports amino acid production consistent with dietary importance. Fermentation parameters like temperature, agitation speed, and carbon source concentration were optimized using response surface methodology. Surface response model suggested that optimal fermentation parameters including 30°C, 50 g/L glucose concentration, and shaking speed of 120 rpm furnished 14.2 g/L of glutamic acid and 5.1 g/L lysine, comparable with the predicted values. After optimizing fermentation parameters in shake flasks, the fermentation kinetics was studied in a stirred fermenter. The kinetic study revealed that the substrate consumption rate achieved a maximum level of 3.36 g/L/hour between 12 and 18 hours; afterwards, it decreased and fell to 1.9 g/L/hour. Average biomass yield over a period of 48 hours was 0.337 g/L; however, maximum biomass yield of 0.51 g/L was noted between 10 and 20 hours. Overall molar yield coefficient of CO_2 ($Y^C_{CO2/S}$) was found to be 0.234. The molar yield coefficient of biomass ($Y^C_{X/S}$) was 0.6 in exponential phase which decreased afterwards. This study indicates that the average biomass yield over a time of 48 hours was 0.337 g/L, with a maximum yield within 10 to 20 hours obtained under optimized conditions. The molar yield coefficient of CO_2 ($Y^C_{CO2/S}$) was found to be 0.234. The molar yield coefficient of biomass ($Y^C_{X/S}$) was 0.6 in exponential phase which decreased and fell to near zero at 48 hrs.

1. Introduction

Amino acids are the basic functional and structural units of proteins and play a major role in the regulation of vital metabolic pathways for the sustainable cultivation of microorganisms [1]. Amino acids are very helpful in promoting growth through several actions including efficient regulation of muscle protein, controlling growth and immunity of organisms, and optimizing the efficiency of food metabolism [2–4]. Since 1907, the production of monosodium glutamate

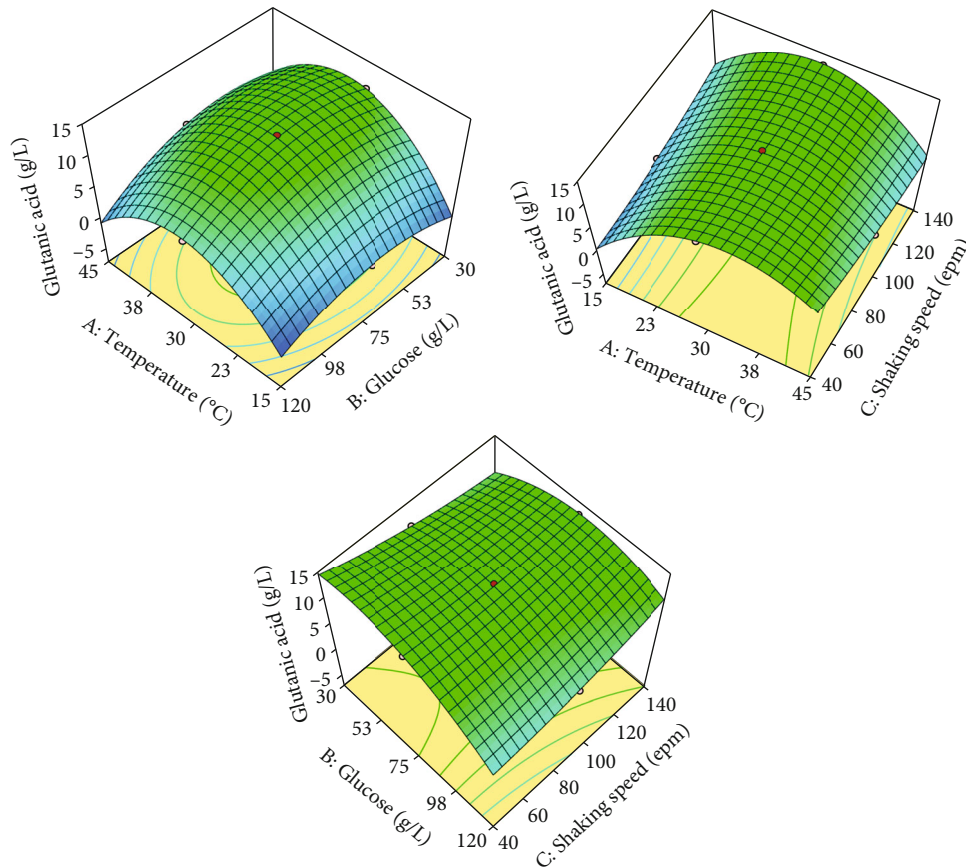
[5] has raised its demand in international market and gave a boost to amino acid production. A wide range of biochemical products have also multiplied as a result of their applications in industries particularly in the area of livestock as feed additive, as healthy ingredient in pharmaceuticals and cosmetics, and as seasoning in human nutrition [6]. Production of amino acids has been tremendously increased as these biomolecules have vast applications that include animal feed supplements, cosmetics, additives in food, chemicals in agriculture, and polymer materials.


Figure 1: Synergism between parameters affecting glutamic acid production.

Fermentation is well thought-out as the most efficient, cost-effective, and beneficial technique in terms of amino acid synthesis. During fermentation, microorganisms use cheap raw materials as fermentation substrates. The process of fermentation is an advanced industrial method that uses several microorganisms to transform sugar substrates into a wide range of amino acids, both aerobically and anaerobically. A number of reasons contribute to the efficacy of amino acid synthesis by fermentation. First, as a result of fermentation, only the L-form stereoisomer of amino acids is produced which help escape any additional purification steps. Second, fermentation procedure is carried out at mild conditions which prevent any product degradation. Third, the maintenance costs are significantly less in comparison to the extraction processes [6, 7].

In recent years, varieties of technologies have been developed due to increased interest in amino acid production. Bacteria like *E. coli* and *C. glutamicum* are both useful for amino acid production through fermentation [7]. A variety of genetically engineered species have been applied under optimized conditions as amino acid producers. Lysine and glutamic acid are produced by genetically modified C. glutamicum with high yields up to 50% (*w/w*) [8, 9]. There are many strains of microorganisms that have been modified genetically and are used for amino acid production. *Corynebacterium glutamicum* is primarily aerobic, nonpathogenic, rod-shaped, Gram-positive bacterium, commonly recog-

nized as a safe (GRAS) creature for manufacturing bioelements like amino acids and nucleotides [10–12]. *C. glutamicum* was recognized in the biotechnology industry for amino acid production on a business scale containing L-lysine and L-glutamate as flavor enhancers since 1960 [13–15]. Since half a century after its discovery, this microorganism has participated in the amino acid production by fermentation and has an extensive and effective record in the biotechnological formation of L-lysine and L-glutamic acid [16, 17]. *C. glutamicum* is genetically modified for the production of glutamic acid with maximal yield (50% ww^{-1}), while aromatic amino acids are produced by genetically modified *Escherichia coli* [18].

2. Results and Discussion

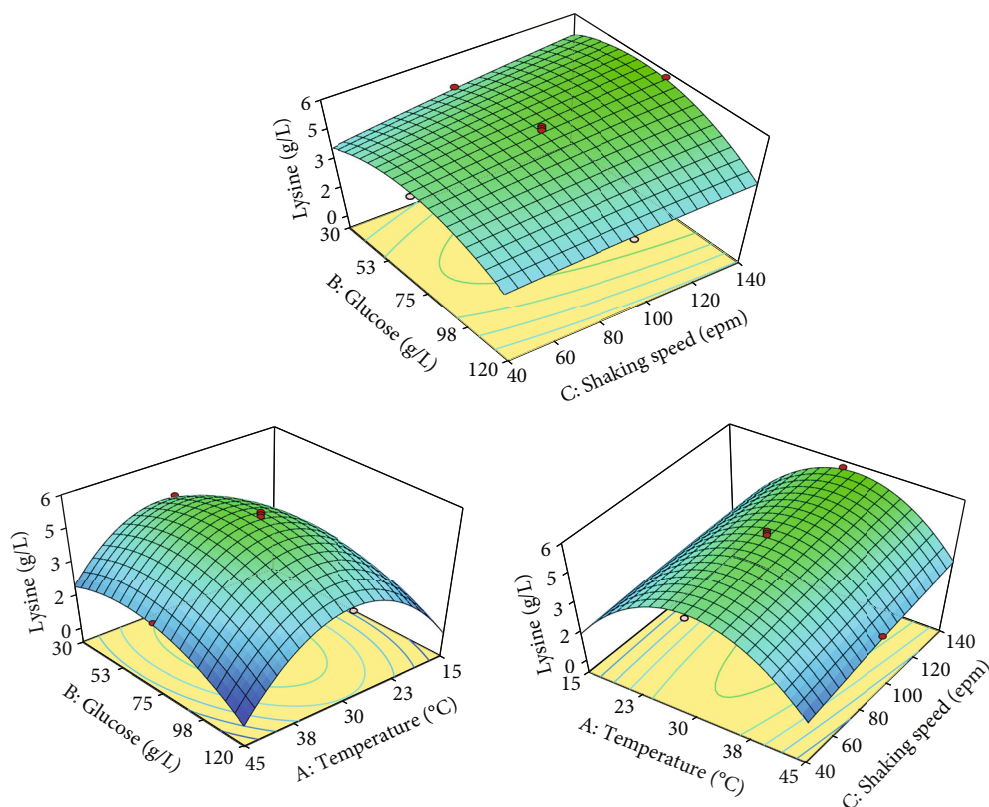
2.1. RSM-Based Simultaneous Optimization of Temperature, Shaking Speed, and Carbon Source Concentration. Response surface methodology was followed for optimizing fermentation parameter including temperature, amount of glucose syrup (with 60% solids) in the fermentation medium, and rotational speed of an orbital shaking incubator. Many experiments were performed, and reaction conditions were carefully investigated to determine the optimum parameters for the production of glutamic acid (Figure 1) and lysine (Figure 2).


FIGURE 2: Synergism between parameters affecting lysine production.

The analysis of variance data indicated that the applied model has good fit over the selected range of fermentation conditions. Similarly, coefficient of variation range established that results produced are quite reliable and the experimental model can be effectively used to predict the responses. The high R^2 values of models for the optimization of glutamic acid and lysine production also affirm the validity of experimental models.

The analysis of variance data predicted that the temperature and glucose concentration significantly influence the production of glutamic acid as well as lysine while the effect of shaking speed was found to be nonsignificant for the production of amino acids with p values > 0.5.

Figures 1 shows that increasing the concentration of glucose up to 50 g/L, improved the production of glutamic acid up till it reached 65 g/L. Likewise, increasing the concentration of glucose up to 55 g/L improved the production of lysine to a level of 5.1 g/L and further increase in glucose concentration resulted in reduction in lysine yield.

Finally, validation experiments conducted under most desirable conditions revealed that the fermentation conditions embracing 30°C temperature, 50 g/L glucose concentration, and 120 rpm shaking speed furnished 14.2 g/L of glutamic acid and 5.1 g/L of lysine.

3. Fermentation Kinetics

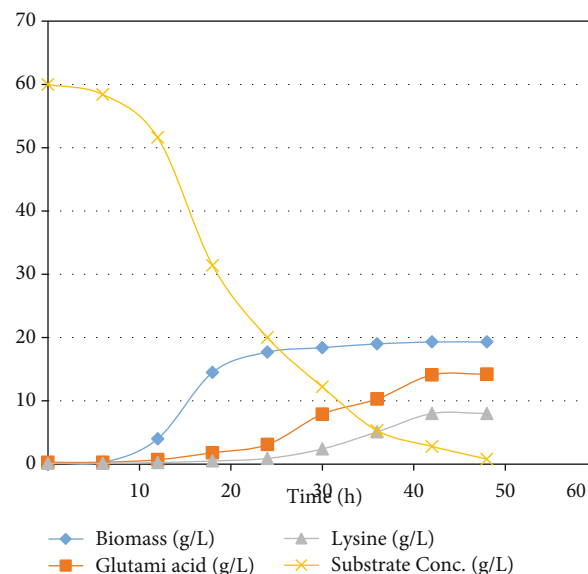
3.1. Fermentation Pattern in a Stirred Fermenter. Figure 3 shows the conversion of the feather hydrolysate into micro-


FIGURE 3: Fermentation profile of amino acid production in a stirred fermenter.

bial cell mass and amino acids as the function of fermentation period in the fermenter. The figure indicates that the rate of substrate consumption and biomass production was high for the first 30 hours of fermentation process. But amino acids were progressively released into the fermentation medium at
Figure 4: Growth curve showing specific growth rate.
Figure 5: Concentration time graphs for substrate consumption rates.

an admirable level till 48 hours of submerged fermentation and beyond this, decline phase started.

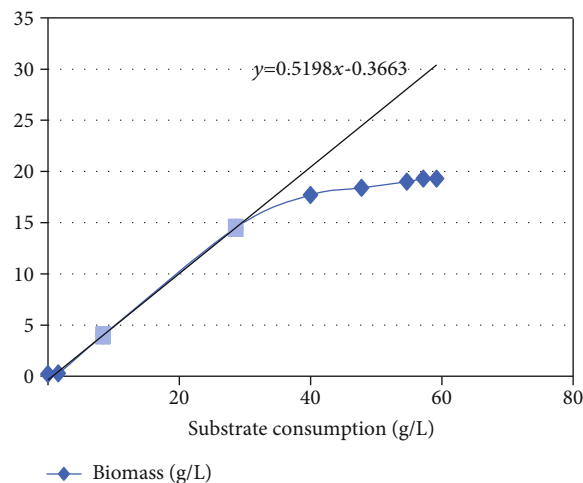
3.1.1. Specific Growth Rates.
A graph (Figure 4) between natural log of biomass and fermentation time during the amino acid production revealed that there was a six-hour lag in growth in the stirred fermenter. Lag phase was followed by a brief logarithmic phase In the log phase, the specific growth rate was $0.43 \, h^{-1}$ which was gradually decreased. After 12-hour fermentation, the specific growth started to slow down, indicating the termination of true exponential phase. The generation time and the number of generations during the exponential growth phase were 1.6 h and 3.73, respectively.


Figure 6: Biomass growth yield.
Figure 7: Molar yield coefficient of CO_2.

3.1.2. Substrate Consumption Rate and Specific Substrate Uptake Rate.
Concentration-time graph (Figure 5) for the substrate consumption shows substrate consumption rate at different levels. It is evident that initially, the rate of substrate consumption was very low and then, it increased with biomass as a function of time and achieved a maximum level of 3.36 g/L/hour between 12 and 18 hours; afterwards, it decreased and fell to 1.9 g/L/hour. This may be related to reduction in growth activity which in turn dropped the consumption rate. This may also be related to high value of Monod constant which does not allow complete utilization of the substrate. Average biomass yield over a period of 48 hours was 0.337 g/g; however, maximum biomass yield of 0.51 was noted between 10 and 20 hours as shown in Figure 6.

3.1.3. Growth Yield ($Y_{X/S}$) and Product Yield ($Y_{P/S}$).
It is pronounced from Figure 7 that biomass yield ($Y_{X/S}$) remained 0.52 during the log phase along with economic coefficient: 1.96 g substrate/g biomass. During the logarithmic phase, nearly 59.8% carbon of the consumed substrate was converted
FIGURE 8: Molar biomass yield.

into biomass. However, after 24 hours, the metabolic activities slowed down and the substrate used participated mainly in providing the maintenance energy through oxidation resulting in a molar yield coefficient of CO_2 ($Y^C_{CO2/S}$) equal to 0.234.

Figure 8 shows that molar yield coefficient of biomass ($Y^C_{X/S}$) was 0.6 in the exponential phase which decreased afterwards. At the end of 48 hours, instantaneous conversion of substrate to microbial biomass fell to near zero.

4. Materials and Methods

4.1. Microorganism. *Corynebacterium* glutamicum was obtained from Biotechnology and Food Research Centre, PCSIR Lahore, and was maintained on preprepared nutrient agar slants. The cultured slants were refrigerated at 4°C.

4.2. Fermentation. The fermentation parameters were optimized in shake flasks using a shaking incubator (New Brunswick, USA) set at 120 rpm, whereas the fermentation kinetics was studied in a bioreactor of 7.5 L capacity (New Brunswick). Half liter of 18 h old vegetative inoculum was shifted to the bioreactor containing 4.5 L sterile fermentation medium. The medium already optimized in shake flasks consisted of (g/L), glucose syrup (60DS): 100; feather hydrolysate: 20; CaCl$_2$:2.0; NaCl:2.0; MgSO$_4$.7H$_2$O:0.5; yeast extract: 5.0; KH$_2$PO$_4$:v0.5; ammonium sulphate: 20; and K$_2$HPO$_4$: 1.0. The pH was set at 7.0 ± 0.2 which was maintained using 1 N phosphoric acid and 12.5% aqueous ammonia along with this temperature which was set at 30°C. During the period of fermentation, the rate of aeration was kept constant at 0.55/L/min and by controlling the speed of stirrer from 100 to 130 rpm, the dissolved oxygen (DO) was maintained at 20%.

4.3. Optimization of Fermentation Process. Response surface methodology was carried out for the optimization of fermentation process. The parameter selected for this purpose were as follows: temperature in the range of 15-45°C, amount of glucose syrup (with 60% solids) in the fermentation medium within the range of 30-120 g/L, and the rotational speed of the orbital shaking incubator between 40 and 140 rpm. Various experiments were carried out, and reaction conditions were cautiously monitored to find out the optimum conditions for the production of glutamic acid and lysine. The experimental data was checked against different statistical models, i.e., linear quadratic and factorial, and the model which best fitted on data was chosen for further optimization studies; the selection was made on the bases of different statistical parameters (i.e., sequential p value, lack of fit p value, R^2 value, and the normality as well as predicted vs. actual plots). The parameters and their interaction terms which could significantly affect the amino acid yield were determined by the help of ANOVA and response surface plots.

4.4. Biomass Estimation. Two methods were used to determine the microbial biomass that includes total dry cell mass and optical density measurements. Using a spectrophotometer, the optical density was set at 600 nm which helped in the determination of total cell concentration [19]. Culture tubes of 1 mL capacity were taken to measure dry cell weight in triplets. Tubes were centrifuged at room temperature for about 15 minutes with a speed of 13,000 rpm (ScanSpeed Mini, Denmark), and sterilized containers were used to collect the supernatant. Supernatant was built up for further analysis. 50 mM PB of pH 7.2 was taken in where stored pallets were resuspended and centrifuged in preweighed culture tubes and finally dried at 80°C until constant weight.

4.5. Amino Acid Analysis. The concentration of amino acids in the fermentation media was determined by the method of [20] using HPLC system with C-18 column and a photodiode array detector at 338 nm. Samples were eluted with a linear gradient of solvent A (40 mmol/L Na$_2$HPO$_4$, pH 6.8) and solvent b (10% H$_2$O, 45% methanol, 45% acetonitrile) at the flow rate of 2 mL/min.

4.6. Estimation of Protein Content. Total protein content was estimated according to the Lowry protocol. Bovine serum albumin was used as a standard in this method [21].

4.7. Estimation of Glucose Content. The glucose content was estimated by Miller reagent, which was based on the reduction of 3,5-dinitro-2-hydroxybenzoic acid to an orange-red complex, under alkaline conditions. The absorbance was taken at 540 nm.

4.8. Determination of CO_2. Evolution of carbon dioxide gas from the fermenter was determined by absorbing the gas in a known volume of 1.0 molar KOH solution [22]. The unused KOH was titrated against 0.1 M HCl. In this way, moles of carbon dioxide produced during a definite period of time were calculated. The rate of CO_2 evolution was determined as

$$\text{Rate of CO}_2 \text{ evolution} = \frac{\text{moles of CO}_2 \times 44}{\text{period of evolution(hours)}}. \quad (1)$$

Data Availability

The data used to support the findings of this study are included within the article.

With the fast growth of nanotechnology, the usage of nuclear materials is becoming increasingly widespread, and the exposure of people, plants, and fauna to nanomaterials has become unavoidable. As scaffolds of biomaterials, nanomaterials are widely used in tissue engineering because of their good biocompatibility, noncytotoxicity, and noninflammatory reaction. In this paper, the tissue engineering properties of nanomaterials and their performance evaluation for repairing sports ligament injuries in dance sports were investigated. Sports ligament injury is a common sports disease, and ligament injury has a very serious impact on sports performance and sports life of athletes. In this paper, we takes football as an example, establishes a human body model of tendon-bone repair after anterior cruciate ligament reconstruction, evaluated the effect of injectable rhBMP-2 nanocontrolled release capsule on ligament bone tunnel interface repair, and evaluated from the scientific and biomechanical point of view. In addition, human ligament research and rabbit ligament supplementary experiment were carried out. In the study of human ligament, we selected 30 patients with unilateral polyarticular ligament injury caused by sports dance as the research subjects and randomly divided them into control group, experimental group, and blank group. The experimental group underwent the repair and reconstruction of rhBMP-2 nanocontrolled release capsule ligament. The results of human ligament study showed that the injectable rhBMP-2 nanocontrolled release capsules showed positive staining and uniform staining for ligament repair. The stiffness of the tender bony temple junction was 11.73%, 15.65%, and 50.59% greater in the test group than in the control group at 2, 4, and 8 weeks postoperatively, respectively.

1. Introduction

Ligaments connect bone to bone and are distinct fibrous tissues that either attach to the skin of the bone or fuse to the external shell of the articular bag to enhance the stabilization of the joint and prevent damage. Injury occurs when a ligament is stretched beyond its tolerance due to violence and nonphysiological activity. A partial injury to the ligament without causing a tendency to dislocate the joint is called a bruise. The ligament itself is completely ruptured, and the bone at its attachment site can also be avulsed, resulting in potential joint dislocation, subluxation, or even complete dislocation. Failure to treat ligament damage can lead to osteoarthritis. Therefore, its surgical repair and functional reconstruction are one of the most important research topics in the field of joint surgery. Although the development of modern surgery makes it possible for humans to replace damaged ligaments, there are still many problems. With the emergence of tissue engineering, a small number of tissue cells are used for in vitro culture and growth, adsorbed by highly biocompatible biological materials, degraded and absorbed in the body, and then inoculated into the body to form new vitality and related functions. Tissues are expected to achieve artificially activated toughness. The biological

characteristics of seed cells, scaffolds, and biologically active factors are the three main themes of tissue engineering.

In the research of tissue engineering ligament, suitable seed cells must be selected. The seed cells must have the ability to form new tissues. These cells can be exogenous, or they can be recruited from the local environment of the transplant recipient. The exogenous cells should be easy to obtain and have little damage to the donor site. The ability of proliferation and differentiation is strong when cultured in vitro, and it can be effectively repaired in the recipient area [1, 2]. At present, it is believed that fibroblasts are a kind of "pluripotent cells," which have different migration rates, adhesion, proliferation, and collagen synthesis capabilities in different tissues, but whether they can effectively repair in the environment of joint fluid is still controversial. Since the autologous patellar tendon graft still undergoes a process of necrosis and strength weakening after transplantation, let alone fibroblasts, therefore, it is not suitable as a seed cell [3, 4]. The purpose of this paper is to evaluate the tissue engineering properties of nanomaterials and their performance in the repair of ligament injury in sports dance sports, in order to make a certain contribution to the repair of ligament injury.

The innovations of this paper are as follows: (1) the tissue engineering properties of nanomaterials and the basic knowledge of repairing sports ligament injuries are introduced. (2) Follow up 30 patients to understand the basic situation, infection situation, and calculate the morbidity rate. In order to improve the research results, a supplementary experiment was also performed on 26 rabbits to verify the performance difference between the reconstructed ligament and the native ligament. (3) Through the local application of nanocontrolled release capsules, BMP-2 can reconstruct the tendon-bone tunnel interface of the anterior cruciate ligament, form a tendon-like structure at the bone anchor point, and reconstruct the intramedullary canal.

2. Related Work and This Paper's Work

With the development of science and technology, materials science and biomedicine are more and more closely integrated, and nanomaterials have made great achievements in biological applications. This paper focuses on the research status of nanomaterials in tissue-engineered ligament research and evaluates the performance of nanomaterials in repairing ligament injury. In order to improve the strength, flexibility, and biomechanical properties of the tested female basketball players, Kahn and Xu prepared a training plan for sports injury prevention and conducted a control experiment. Compared with the anterior and posterior training ligaments in the control group, Kahn' and Xu's damage reduction plan can dramatically alter the mobility, power, and biomechanical characteristics associated with ACL damage and reduce an athlete's exposure to damage. However, in the research process, Kahn and Xu did not consider the difference of individual factors; so, the experimental results are not very reliable [5]. In order to further understand the mechanism of ACL injury, Bertona et al. investigated the occurrence of ACL injury in a large number

of samples over the past 20 years and proved the relationship between the occurrence of ACL injury and dynamic knee alignment at the time of injury. Bertona' et al.'s research has not fundamentally solved the problem, and there is no data to show that the reliability is not high [6]. Malvasi et al. developed an online activity survey, which used a prospective method to record monthly participation in all major exercises related to the patient group. He conducted a reliability study by continuously enrolling 145 patients with ACL injury and retested the online activity survey two days after recording test answers. Malvasi et al.'s research methods are relatively new but lack of interpretable statistical analysis [7]. In order to explore the relationship between ACL-SRI score and strength and strength score after ACLR, Ithurburn et al. recruited 452 male athletes who underwent primary ACLR and conducted ACL-SRI questionnaire, isokinetic muscle strength test, and jumping test about 9 months after operation. In the research of Ithurburn et al., there is no objective view on the relationship between body strength and strength measurement; so, it needs further improvement [8].

3. Nanomaterials and Sports Ligament Injury

3.1. Nanomaterial Application. Nanomaterials include nanobiomaterials, which have the potential to become the core materials of biomaterials in the 21st century, which is due to the large number of fine nanostructures in their bodies. Nanomaterials can be divided into two levels: nano-ultrafine particle materials and nanosolid materials [9]. Nano-ultrafine particles refer to ultrafine particles with a particle size of 1-100 nm, and nanosolids refer to solid materials made of nano-ultrafine particles. And people are accustomed to control the composition or grain structure below 100 nanometers in length dimension called nanomaterials. In addition, nanobiomedical materials solve the urgent needs of high-performance tissue repair, organ replacement, disease diagnosis, and treatment [10, 11]. Nanostructure is a new system constructed or constructed according to certain rules on the basis of nanoscale material units [12]. It includes nanoarray system, mesoporous assembly system, and thin-film mosaic system.

Nanotechnology refers to the arrangement of atoms/molecules on the surface of nanoparticles through specific technical design to produce a special structure. And in the performance of specific technical properties or functions, such nanomaterials can be called nanotechnology [13]. Using nanotechnology to transform traditional tissue engineering materials, nanotissue engineering materials have unique biological characteristics, and the application research in the field of tissue engineering has attracted people's attention [14]. For example, nanoceramics, carbon nanowires, and nanometal materials are used for bone and cartilage tissue engineering; titanium nanomaterials, polylactic acid lactic acid nanomaterials, and nanofiber materials are used for artery tissue engineering; and peptide nanoskeleton and nanofiber are used for scaffold [15, 16]. At the same time, with the continuous advancement of science and technology, especially in the sunrise industry of the electronics industry,

nanotechnology has been greatly developed. It mainly focuses on electronic composite films, using ultrafine particles to improve the electrical, magnetic, and magneto-optical properties of the film, as well as magnetic recording, nanosensitive materials, etc.

3.2. Application of Nanomaterials in the Bone and Cartilage Tissue Engineering.

In nanophase ceramics, nanohydroxyapatite is a natural bone component; so, it can be used as a substitute for bone to achieve bone transplantation. They can promote the formation of mineralization. The composite material composed of hydroxyapatite nanocrystals and collagen is the tissue engineering material closest to the natural bone structure. The nanohydroxyapatite material is mixed with collagen at the ratio of $93:7$, $83:17$, and $81:19$ to form a composite material with a density of $2.8 \, g/cm^3$ [17, 18]. Through high-power electron microscopy, it can be observed that all composite materials and collagen structure are parallel, and their diameter and length are the same, 50-100 nm and $20 \, \mu m$, respectively [19, 20]. In addition, zinc oxide can react with titanium and aluminum, promote the formation of collagen and precipitation of calcification, and finally strengthen the activity of alkaline phosphatase.

Cartilage is composed of cartilage tissue and its surrounding perichondrium, and cartilage tissue is composed of chondrocytes, matrix, and fibers. According to the different fibrous components contained in cartilage tissue, cartilage can be divided into three types: hyaline cartilage, elastic cartilage, and fibrocartilage. Among them, hyaline cartilage has a wider distribution and a more typical structure. By studying the formation and development of human bones, we can discover how the human body regulates and assembles collagen and can also figure out the growth mechanism of calcium phosphate crystals and the human body's healing mechanism. On this basis, following the idea of bionics, a nanocrystalline calcium phosphate collagen bone repair material was invented to simulate the process of biomineralization and self-assembly. The porosity of the material is about 80%, and the void size is mainly distributed between 100 and $400 \, \mu m$ [21]. The hydroxyapatite crystals of the material have a particle size of about 30 nm and grow in the gaps between the collagen fibers. It can be found that they are axisymmetric with the collagen fiber structure, and they have an asynchronous structure before, which is similar to natural bone and nanosynthetic bones. The bone cells obtained through this harvesting technology are very similar to normal human bone cells, and they have excellent ductility and softness, as well as excellent plasticity [22, 23].

3.3. Repair of Sports Ligament Injury.

Ligaments connect bone to bone and are obvious fibrous tissues, either attached to the surface of the bone or fused with the outer layer of the joint capsule to strengthen the stability of the joint to avoid injury. Injury occurs when a ligament is stretched beyond its tolerance due to violence, resulting in nonphysiological activity. In the field of sports medicine, there is the most difficult problem; that is, in the network of relational ligaments, there are multiple ligaments injured, each ligament receives different degrees of damage, and the injury of multiple key ligaments destroys the stability of the knee [24]. When there is a nonphysiological movement in a certain direction, the ligaments that limit the movement of the knee joint to this direction must bear the brunt. The medial capsular ligament and medial collateral ligament are mainly damaged when the knee joint is externally rotated and abducted in the flexion position and is subjected to external violence. Severe cases can involve the anterior cruciate ligament and medial meniscus, which are the most common types of injury. Patients with multiple ligament injuries are very likely to suffer from medial and lateral meniscus injuries. Among them, the largest injury probability is the displacement of lateral and intra-articular ligaments, which will lead to dislocation and fracture of the joint. After ligament injury, there are usually small blood vessels rupture and hemorrhage, local pain, swelling, intraorganism hemorrhage, hematoma, joint swelling, movement disorder, and tenderness. On physical examination, the traction ligaments were found to be significantly painful, and if completely ruptured, the stability of the joint was reduced. Therefore, our goal in the future is to repair and reconstruct the ligament, which can fully help the establishment of bone and joint.

The knee joint is very unstable and usually has important nerve tissue (such as common peroneal nerve) and important blood vessels. One of the biggest difficulties is that it involves a variety of orthopedic disciplines, and a single doctor cannot effectively deal with orthopedic injuries in various disciplines, resulting in patients cannot achieve effective and timely treatment, which seriously hinders the athletes' sports career and subsequent normal life. At present, with the improvement of living standards, more and more young people like highly confrontational sports, such as football and basketball, which also increases the risk of joint ligament injury.

For the ligament damage that has occurred, if you do not intervene in time, it may lead to serious consequences. For example, it will cause knee instability. Secondly, it may accelerate the degradation of the patient's knee cartilage and eventually lead to the early appearance of osteoarthritis symptoms and will affect the quality of life of patients. Ligament injury should be treated early and fully repaired. If it is not treated in time, the joint will be repeatedly sprained, which will inevitably cause damage to articular cartilage, meniscus, and other important structures, resulting in premature aging of the joint and severe secondary traumatic arthritis. The key to its treatment lies in the repair of damaged ligaments. Partial tears can be directly sutured and repaired, while complete ruptures require surgery to transfer and reconstruct adjacent tendons, fascia, and other tissues. With the latest development of arthroscopic technology and the improvement of tissue library, arthroscopy is usually the next step in the reconstruction and repair of multiple knee ligament injuries. Excellent results have been achieved, and there is also a report of bilateral knee joint multiligament injury. One year after ligament reconstruction, the patient can return to leisure sports, but at the same time, there are still many issues that have not yet reached a consensus.

Due to the complex anatomical structure of the knee joint, it is usually difficult to reconstruct and repair multiple

ligament injuries, and these ligaments also have strict requirements for the repair sequence. If the reconstruction sequence is not correct, the repair effect is great, which meets the requirements, but the reliability and plasticity of transplantation can be ensured after the correct sequence and steps. In order to meet the requirements of reconstruction procedures, surgeons provide a series of suggestions: first, repair KD-I ligament injury and rupture and tendon reconstruction and repair, then KD-II: ACL + PCL injury, then KD-III type: ACL + PCL + MCL or (PMC/PLC) damage, and finally, repair type KD-IV ACL + PCL + MCL + (PLC)/ LCL) is damaged.

The ideal knee reconstruction implant should have the advantages of high toughness, high strength, convenient operation and microfixation, easy access to materials, and minimal postoperative complications. In the existing materials, there is still a lack of materials to meet these requirements, which can only be met by allogeneic transplantation and tendon transfer. Autogenous tendon transplantation is transplanted through the existing tendon and ligament in the body, usually taking PA bone or rope tendon two parts. Allogeneic transplantation is to rely on the implantation of artificial ligaments to meet the requirements. For multiple ligament injuries of the joint, it is generally necessary to reconstruct and repair multiple ligaments; so, it is not possible to use self-transplantation, but only rely on the means of allogeneic transplantation.

4. Experimental Materials and Methods

4.1. Experimental Materials and Experimental Methods and Equipment-Related Drugs.
In this experimental equipment, we used the following: antibacterial micro Qiao suture, electric drill, automatic dehydrator, basic surgical instruments, denture base tree, penicillin, pentobarbital sodium powder, and finally, denture base polymer and normal saline for injection.

4.2. Collection and Production of Patient Experimental Specimens.
A total of 30 patients with unilateral knee multi-ligament injury caused by sports dance were included in this study, including 6 cases of ACL, PCL, and MCL injury, 4 cases of ACL, PCL, and PLC injury, 8 cases of ACL and PCL injury, 6 cases of ACL and MCL injury, and 6 cases of PCL and MCL injury. These patients were all of grade III injury. There were 12 cases of left knee injury, 18 cases of right knee injury, 20 cases of male, and 10 cases of female. The average age of patients was 35.35 ± 2.31 years (18-55 years). There were 17 cases of traffic accident injury, 4 cases of falling injury, and 9 cases of acute sports injury. The main clinical manifestations were severe pain, swelling, and instability of knee joint. The time from injury to operation was 7.0-14.0 days, with an average of 10.12 ± 1.35 days.

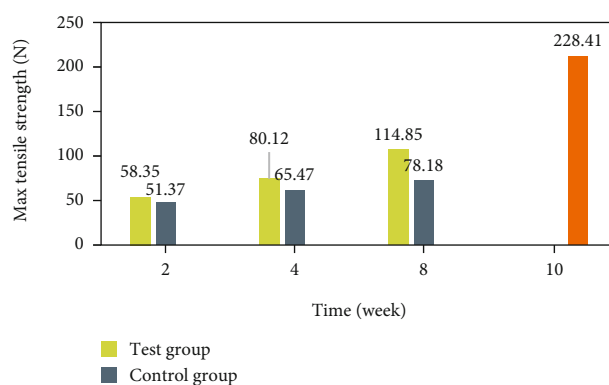
This experiment is divided into three groups: the experimental group, the control group, and the blank group. The experimental group uses rhBMP-2 nanocontrolled release capsules to repair and reconstruct the ligaments, and the control group uses the current mainstream biological equipment to repair and reconstruct the ligaments. Repair and


FIGURE 1: Maximum tensile strength histogram.

reconstruction were performed, and the ligament in the blank group was not damaged.

4.3. Collection and Production of Animal Experimental Specimens.
In this study, we also selected 24 adult rabbits with knee joint disease and 2 adult rabbits without joint disease to conduct supplementary experiment. These rabbits all met the requirements of cleanliness level, weighing 3.29 ± 0.26 kg, which could adapt to reproduction and environment. One week before the experiment, they were put into a new feeding environment for normal feeding activities. After that, the animals were treated according to the "guidelines for the treatment of experimental animals." Methods were as follows: 24 rabbits (48 knees in total) were operated on with the common specimen of bilateral knee tendon bone tunnel interface, and the experimental animals were divided into groups.

The experimental group used rhBMP-2 nanocontrolled release capsule to repair and reconstruct the ligament, the control group used the mainstream biological equipment to repair and reconstruct the ligament, and the blank group was that the ligament was not damaged.

According to the normal management, it was stored in the refrigerator at -80°C. The normal fixation, demineralization, slicing, and dyeing preparations were used as the normal indexes of the control. At the second, fourth, and eighth postoperative weeks, experimental animals in the test and control groups were executed under overanesthesia, and the knee joints were similarly extracted.

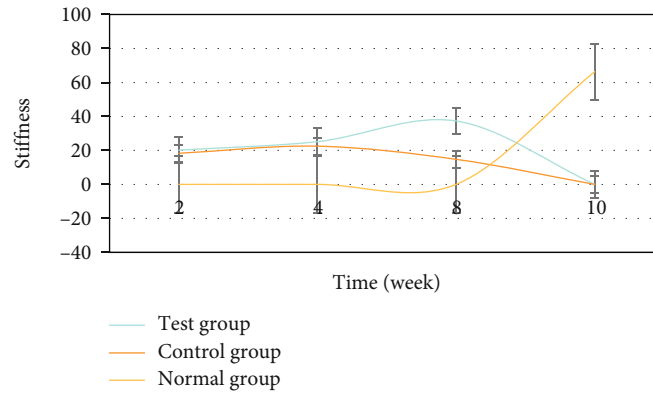
Before the test, thaw at room temperature and immerse the sample in saline, the resin is hardened to remove the bone, and the tendon thread is used as the braided part of the tendon. The sample is fixed on the Instron 8874 mechanical tester. First, the pretreatment is completed; that is, a tensile force of 5 N is applied to the test piece for 30 seconds, and then a tensile test is performed until the ligament yields and breaks. Set the traction speed to 3 mm/min, calculate the stiffness, and record the displacement distance and load strength. The stiffness value of the tendon-tunnel channel interface refers to the ability of the tendon-tunnel channel interface of the knee joint to resist elastic deformation under force, and its elastic deformation the degree is this value. Generally, the slope of the linear section is calculated from the linear section of the load-displacement curve.


FIGURE 2: Stiffness histogram.

TABLE 1: Yamakado split type ($n = 8$, n).

Time		Tendon bone separation	Loose connective tissue link	Sharpey structure link	Direct link
	4 W	2	6	0	0
Test group	8 W	0	7	1	0
	16 W	0	1	7	0
	4 W	4	4	0	0
Control group	8 W	1	7	0	0
	16 W	0	2	6	0
	4 W	1	7	0	0
Blank group	8 W	0	4	4	0
	16 W	0	2	6	0

Tensile strength (N) is as follows: in a biomechanical tensile test, the maximum tensile strength at the tendon-bone tunnel interface of the knee joint sample can be a bearable value.

4.4. Experimental Analysis Method. Use IBM SPSS23.0 statistical software for statistical analysis. If the continuous variable presents a normal distribution, use the paired sample X^2 test.

$$X^2 = \sum \left(\frac{2(f0 - fc)}{fc} \right). \tag{1}$$

Among them, sending f_0 represents the actual number of times obtained, and f_c represents the theoretical number of times determined by the hypothesis.

If it does not conform to the normal distribution, please use the nonparametric test, the result is expressed as the median (interquartile range), and the difference is statistically significant, $P < 0.05$. Categorical variables are expressed in frequency (percentage) and tested using Fisher's exact probability method.

$$P = \frac{O_{1\bullet}!O_{2\bullet}!O_{\bullet 1}!O_{\bullet 2}!}{O_{11}!O_{12}!O_{21}!O_{22}!}, (N! = 1 \times 2 \times \cdots \times N). \tag{2}$$

The result shows that the variable matches the normal distribution, $P > 0.05$. Box plots are used to find outliers,
FIGURE 3: Lysholm score and range of motion of the knee joint before and after the last follow-up.

the categorical variable is Fisher's test, and $P < 0.05$ is considered statistically significant.

5. Experimental Results and Analysis

5.1. The Test Results of rhBMP-2 Nanocontrolled Release Capsule for Repairing Ligaments. The maximum tensile strength of tendon and bone tunnel interface in each group was as shown in Figure 1. The experimental group was repaired by rhBMP-2 nanocontrolled release capsule, the

TABLE 2: The results of the stability examination of the knee joint before and after the last follow-up.

Stability examination	Preoperative physical examination		Physical examination at the last follow-up		
	III degree positive	Negative	I degree positive	II degree positive	Negative
Front drawer test case (%)	24	0	3	3	18
Back drawer test case (%)	24	0	3	1	20
Lachman test case (%)	24	0	3	3	18
Flexion 30° eversion stress test example (%)	18	0	1	2	15
Flexion 30° varus stress test example (%)	4	0	1	0	3

control group was repaired according to the current main-stream surgical method, and the blank group was normal ligament without disease. The results showed that there was a significant difference between the experimental group and the control group at three time points after operation ($P < 0.005$).

As shown in Figure 1, the maximum tensile strength of the rhBMP-2 nanocontrolled release capsule for ligament repair is higher than that of the control group. Two weeks after the operation, there was no significant difference in the maximum tensile strength of the tendon-bone tunnel interface between the experimental group and the control group ($P > 0.005$). Eight weeks after surgery, there were significant differences in the maximum tensile strength of the tendon-bone tunnel interface among the three groups ($F = 219.32$, $P < 0.005$). The results show that the experimental group is better than the control group in terms of tensile strength, each group has been greatly improved, and the test values are very different.

The results of the postoperative study on the tendon tunnel interface stiffness are shown in Figure 2.

5.2. Composite Ligament Reconstruction ACL. According to Yamakado classification, the morphology was divided into tendon bone separation, loose connective tissue connection, Sharpey fiber structure connection, and direct connection. According to the Yamakado classification method, the morphological and histological observation was carried out at 4 W, 8 W, and 16 W. The results are shown in Table 1.

As can be seen from Table 1, in the use of rhBMP-2 nanocontrolled release capsules to reconstruct the joint ligaments (experimental group), after incising the skin, the implant was completely covered by the synovium, with bright luster, compact structure, superficial capillary growth, and joints light yellow glaze in the cavity. The interface between the ligament and the bone is wrapped in the new bone and becomes unified, and when the compression nail is removed, the ligament and the bone are firmly connected. In the current best-performing joint ligament reconstruction (control group), the surface of the implant is completely covered by synovium, the structure is compact, there are no blood vessels, and there are soft tissues around it. After removing the pin, the implant can be pulled out forcefully. In the unaffected normal joint ligaments (blank group), the surface is as smooth as normal tendons, and the ends are tightly connected to the bone tunnel.

All patients were followed up for 12-24 months (average 15.60 ± 2.65 months). All patients recovered well after operation. No knee instability and stiffness occurred. The postoperative follow-up results are shown in Figure 3.

It can be seen from Figure 3 that the active range of motion of the knee joint of 30 patients recovered significantly compared with that before the operation. At the last follow-up, the range of active motion of the knee joint increased to 121.83. Compared with 47.23 before operation, the difference was statistically significant ($P < 0.05$).

At the last follow-up, the positive rate of knee joint stability physical examination decreased significantly, and the difference was statistically significant ($P < 0.05$). The negative rate of anterior drawer test was 75%, and the positive rate was 25%. The positive rate of knee joint stability physical examination was shown in Table 2.

It can be seen from Table 2 that there are 3 cases of degree I positive and degree II positive; the negative rate of the back drawer test is 83.3%, and the positive rate is 16.7%, of which 3 cases are positive for degree I and 1 case is positive for degree II; the negative rate of Lachman test is 75%. The positive rate was 25%, of which 3 cases were positive for degree I and positive for degree II; 15 cases had no relaxation in the 30° flexion stress test, 2 cases of degree I relaxation, and 1 case of degree II relaxation, while the 30° buckling stress test was 0 cases. There were 3 cases of relaxation and 1 case of degree I relaxation. At the last follow-up, the Lysholm score of the knee joint reached 85.00 points, which was statistically different from 30.93 points before surgery ($P < 0.05$). IKDC rating at the last follow-up was as follows: 20 cases were normal (grade A), 8 cases were close to normal (grade B), and 2 cases were abnormal (grade C). The X-ray film and CT in the outpatient department after operation showed that the internal fixation and the bone canal were in good position, and the bone canal was not enlarged.

5.3. ACL Reconstruction in Animal Ligaments. Randomly select 3 groups (4 W, 8 W, 16 W) and divide them into the experimental group treated with rhBMP-2 nanocontrolled release capsules, the control group using the current mainstream surgery, and the normal diseased blank group, each with 4 mice The rabbit undergoes a CT examination. X-ray cross-sectional imaging of the rabbit femoral tunnel passes through the vertical axis. Each rabbit randomly selected 10 images and measured the CT value of the 1 mm² interface
FIGURE 4: Detect CT value in different time periods.

between the screw and the bone. Measure the CT value of the $1\,mm^2$ area between the screw and the bone interface, use x and S to represent all the CT values measured in each group, and analyze the connection structure between the ligaments and the time of the bone in the day; after modification, the relative position of screw channel is shown in Figure 4.

It can be seen from Figure 4 that, similar to normal ACL, after the cruciate ligament is reconstructed, the nutrition needed by the implant is mainly provided by blood in the superficial synovial membrane, except for a small amount of synovial fluid in the joint cavity. Theoretically, this not only preserves the ligament stump and promotes the fusion of soft tissues and grafts but also an adequate blood supply also increases the nutrient supply of the graft, thereby allowing new synovial vascularization on the surface of the graft. Indicating that the reconstruction can be preserved, the survival rate of the ligament should be significantly higher than the unreserved stump group.

At the same time, the application of nanomaterials in tissue engineering is still in the early stage. Especially in biomedicine, most of the research is still in the stage of animal experiments, a large number of clinical trials are needed to confirm, and the biosafety of nanomaterials needs to be further improved. There are still many problems to be solved for clinical application: how to construct an ideal cell-nanomaterial interface, how to protect allogeneic biological tissues and cells cultured on nanoscaffold materials from being recognized and rejected by the recipient immune system, how to maintain the viability of cultured cells and maintain their function for a long time, and how to further improve the biocompatibility of nanomaterials.

6. Conclusions

The ligament is a bridge that maintains the close connection between bones. It is rich in elasticity and rich in collagen tissue. However, after the ligament is injured, it cannot be cured, and it is difficult to reach a healthy level. This also causes the joints to become extremely unhealthy: stable, but from causing serious damage to the relationship, the most causing deterioration and pain, the most typical cases of which are arthritis and meniscus injury. It is precisely because of this that we must reconstruct it, these reconstruction methods are mainly carried out through surgery, and most of them are through and means.

The experimental design of the ligament reconstruction model and the nanocontrolled release capsule manufacturing model is effective for basic research related to BMP-2 repairing the tendon-bone tunnel interface and can be used as a reference for experimental research models. In the early stage after injury and anterior cruciate ligament reconstruction, BMP-2 promotes the formation of a similar direct stagnant structure at the tendon-bone tunnel interface. Experiments show that rhBMP-2 can effectively promote and enhance the repair of the tendon and bone tunnel interface.

In this study, when the anterior cruciate ligament was reconstructed after knee injury, the injectable BMP-2 controlled release capsule was chosen when reconstructing the tendon-bone tunnel interface. The results showed that BMP-2 was performed after the reconstruction of the anterior cruciate ligament of the knee joint. After the reconstruction of the anterior cruciate ligament, the tendon tunnel interface helps to form a direct stop point, thereby improving the maximum tensile strength and stiffness of the tendon tunnel interface. This leads to improved pathophysiological properties and mechanical strength of the reconstructed ligament structure. In the next few years, nanoceramics in biomaterials will play a leading role in artificial bones, and inorganic and organic composite nanomaterials with various properties will also play a great role in interventional repair of ligament injuries. We will also conduct further in-depth research on this.

Retracted: Application Value Analysis of Nanooptical Materials in Martial Art Single-Kick Protective Equipment

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/ participant consent to participate, and/or agreement to publish patient/ participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

If there is no protective equipment in martial art single practice, it is very easy to be injured, so protective equipment in martial arts has been paid more and more attention. The protective effect of Wushu Sanda protective gear is related to the safety of every Wushu Sanda practitioner. The purpose of this paper is to study crystalline nanooptical materials and Wushu Sanda protective gear and propose the idea of using more crystalline nanooptical materials in the manufacture and use of Wushu Sanda protective gear. This paper mainly introduces the related content of crystalline nanooptical materials, martial art single-leg kick, and martial art single-leg protective gear and conducts experiments on crystalline nanooptical materials and martial art single-leg protective gear based on crystalline nanooptical materials. The experimental results show that the protective effect of protective equipment based on crystalline nanooptical materials can play a greater role than traditional protective equipment. In the experiments in this paper, the martial art single-leg kicking protective gear based on crystalline nanooptical materials has at least a 10% improvement in protective effect.

1. Introduction

With the improvement of people's living standards, more and more people who are interested in study and work will take time to participate in some activities, such as Wushu Sanda when they are in Wushu singles. However, there are often some factors that affect their own safety. Therefore, Wushu single protective equipment plays a pivotal role in the safety of martial art singles. Therefore, Wushu single-kick protective equipment plays an important role in protecting the safety of Wushu single kick. Due to its special microstructure, nanocrystalline materials have a series of excellent mechanical properties such as higher yield strength, hardness, and good wear resistance that conventional coarse-grained materials do not have and have attracted extensive attention from sports people.

In recent years, the safety of martial art single kick has become the focus of society and schools. How to effectively prevent and properly handle the safety accident of single kicking in martial arts is an important problem that all sectors of society need to think about and solve. The development of a reasonable use of martial art equipment is one of the ways to reduce safety accidents in martial arts. When practicing martial art movements, wearing martial art equipment reasonably can reduce self-injury caused by uncontrolled movements during practice.

With the development of society, nanocrystalline materials have attracted more and more attention. In one study, Shaat and Abdelkefi investigated the modeling and performance of mechanical resonators for biological cell mass detection, nanocrystalline material characterization, and human immunoviral disease diagnosis [1]. In their research, Ovid'ko and Sheinerman described the effect of free surfaces on grain boundary dislocation-mediated rotational deformation in nanocrystalline materials [2]. Likewise, other researchers have conducted extensive experimental studies on nanomaterials. Fang et al. experiments show that stress-driven grain growth will strongly affect the motion and distribution of dislocations in nanocrystalline materials. At the same time, their research also shows that nanotwins often originate from the generation and slip of partial dislocations, which are also affected by grain growth [3]. Tserpes et al. use finite element models to test and simulate tungsten-copper alloys with coarse and nanocrystalline microstructures. The effect of the sharpness of the

Berkovich indenter was also investigated. Experimental results show the superiority of nanocrystalline materials, with better convergence for the rounded tip of the indenter [4]. In terms of sports safety research, Hong et al. expand safe and healthy life sports activities in Korea by carrying out education, management, and best practices related to life sports safety in Germany and establish an accident prevention system in Korea [5]. At the same time, in order to examine the consistency of sports safety with school administration quality standards and teacher compliance practices, Jani et al. conducted an experiment using a questionnaire. The experimental results show that all schools have good quality standards for sports safety administration. There is a very close and important relationship between the quality standards of administration and the compliance of teachers' sports safety practices [6]. In the research of sports safety protective equipment, Park and Ko developed safety clothing, which is a must for young people to protect their bodies from accidental injuries and pursue activities and individuality [7]. These methods provide some references for our research, which have not been recognized by the public due to the short time and large scope of the relevant research. These researchers have outstanding performance in their respective research fields, but their research scope is often very large, which is not conducive to further in-depth experimental research.

The innovation of this paper lies in the research on crystalline nanooptical materials. Through the understanding of the properties of nanomaterials, especially the research on crystalline nanooptical materials, after fully understanding their unique mechanical properties, they are applied to the manufacture and use of martial art single-kick protective equipment. Through the use of crystalline nanooptical materials, not only can the role of nanomaterials be fully utilized but also the safety and reliability of martial art single-kick protective equipment can be improved. Nanomaterials and nanotechnology have provided new ideas and approaches for the research of modern equipment protection technology and laid the foundation for the breakthrough improvement of its performance.

2. Crystalline Nanooptical Materials and Motion

2.1. Crystalline Nanooptical Materials. Crystalline materials with a particle size of 1 to 250 nm are called nanocrystalline materials. Nanopowders can be used in thick-film technology to fabricate elongated conductive tunnels. The porous nanomaterial sintered body has strong activity and is suitable for catalysts and high-power capacitors. If the particle size of nanocrystalline material becomes smaller, its volume fraction will increase [8]. Generally speaking, the internal structure of nanocrystals consists of two different types of atoms. Atoms in a crystal are arranged in adjacent lattices, and there are different atomic spacings between grain boundary atoms. The proportion of atoms in the interface of nanocrystalline material is related to the tightness of the interface of nanocrystalline material. The following is a brief discussion on the related content of nanocrystalline materials [9].

2.1.1. Mechanical Properties of Nanocrystalline Materials

(1) Yield Strength. Yield strength is the stress that resists slight plastic deformation under external load, that is, the yield limit of metallic materials [10]. When the stress reaches a certain value and enters the yield stage, the deformation increases rapidly. At this stage, elastic deformation and local plastic deformation occur simultaneously. With increasing stress, the plastic strain changes greatly, but the stress and strain hardly change. This phenomenon is called yielding [11]. The maximum stress at this stage is called the upper yield point, and the minimum stress is called the lower yield point. Here, a relatively stable low yield point value is used as an indicator of material resistance, namely, yield strength or yield point [12]. The grain size has a great influence on the yield strength of the material. The most important factor affecting the yield strength is the size of the crystal force. Taking tensile strength as an example, under the same strain condition, for a sample with a small grain size, the smaller the uniformly distributed strain inside the grain, the smaller the dislocation density. Therefore, the yield strength is greater. The relationship between yield stress and grain size is based on the relationship between traditional coarse-grained materials, and its correlation formula conforms to the Hall-Petch relationship:

$$\partial_i = \partial_o + md^{1/2}. \tag{1}$$

(2) Scalability. Ductility refers to the property of a material stretching without breaking under an external load, and ductility refers to the property of a material rolling into a thin sheet without breaking under an external load. It is a mechanical property of a substance that expresses the ability of a material to deform plastically before fracture under force [13]. Under the action of shock and vibration loads, the material of the structure is required to be able to absorb a large amount of energy, and at the same time, it can produce a certain deformation without damage; that is, the structure or component is required to have good ductility. In conventional crystalline materials, the grain size decreases and the ductility of the material increases. The ductility of nanocrystalline materials is also affected by these deformation mechanisms. Zhang changed the grain size of the nanocrystalline material Zn by changing the processing times. The researchers found that the nanocrystalline material Zn can exhibit good strength and ductility at the same time after a period of treatment [14]. The processed material contains 30% larger grains. This optimal microstructure exhibits more strain hardening than other machined materials studied. It can be said that reasonable grain size distribution and strain hardening help to improve the ductility of the material [15].

(3) Anti-Hall-Petch Relationship. The general law of the Petch relationship is that the grain size decreases and the yield stress of the material increases. Figure 1 shows the HP relationship of the nanocrystalline material Cu.

From Figure 1, we can clearly find that as the particle size decreases below 25 nm, the HP relationship of
FIGURE 1: Variation of yield stress of Cu material with grain size from coarse to nanocrystalline.

nanocrystalline materials is not visible. The slope of the HP relationship for nanocrystalline materials decreases with decreasing grain size [16].

2.1.2. Fatigue Damage of Nanocrystalline Materials. Crack growth can be divided into two forms: unstable growth and subcritical crack growth. Unstable growth is a rapid crack growth process. An important condition for its occurrence is that the stress expansion coefficient of the crack tip inside the material reaches or exceeds the fracture toughness of the material [17]. Subcritical crack growth is a slow-growing process where microcracks develop inside the material before reaching critically fast and unstable growth conditions. For traditional fatigue testing, we get a very classic *SN* curve, the fracture curve between the cycles of the metal being fractured and the cyclic stress or alternating stress, where *S* and *N* represent the magnitude of the cyclic stress and fracture, respectively; pressure, respectively; and hours of the week [18]. The *SN* curve of the material can be divided into three parts: static strength stage, low cycle fatigue stage, and high cycle fatigue stage. Figure 2 shows the fatigue curve of the material.

The place where fatigue cracks are most likely to initiate is the place where it is most likely to slip, and the place that is most likely to slip is also the place where the local plastic deformation is the largest. Fatigue crack initiation, propagation, and fatigue strength are all affected by slip [19]. Grain refinement increases the barrier of grain boundaries, thereby slowing the initiation and propagation of fatigue cracks. The crack growth rate is a method for predicting crack growth rate and crack growth life of a mechanical structure, which belongs to the calculation method of the fatigue crack growth rate and crack growth length of mechanical structure. The main expression for the crack growth rate is

$$\frac{Da}{DW} = c(\Delta n)^t. \tag{2}$$
FIGURE 2: Fatigue curve of material.
FIGURE 3: Three different forms of cracks.

With regard to cracks, cracks are mainly classified into Type I cracks, Type II cracks, and Type III cracks. As shown in Figure 3, there are three different forms of cracks.

(1) Mechanical Model. For the establishment of the mechanical model, the first consideration is the critical condition of crack initiation at the twin boundary. Numerous studies have found that cracks in nanotwinned materials usually originate from three places: grain boundaries, twin boundaries, and slip zones. In the fatigue cracking study of nanotwinned materials, it is found that under high-cycle fatigue loads, cracks generally originate from twin boundaries, and the initiation mechanism is due to the stress concentration generated by elastic anisotropy on both sides, dual interface [20]. Under low-cycle fatigue loads, the location of fatigue cracks becomes very complex.

(i) *Schmid Factor.* Zhang expresses the relationship between the shear stress α at the twin boundary and the resulting dislocation density β:

$$\alpha = \alpha_0 + MNc\sqrt{\beta}, \tag{3}$$

where M is a constant, N is the shear modulus, and c is the Burgers vector. Since the orientation of the twin boundary has an influence on the critical

condition of the twin boundary fracture, it can be known from Schmid's law that

$$\alpha = \varepsilon\lambda, \tag{4}$$

where ε represents the flow stress and λ represents the orientation factor. And due to the cumulative value of dislocations per unit length,

$$j = \sqrt{\beta}. \tag{5}$$

Derive from the above formula:

$$j = \sqrt{\beta} = \frac{m(\varepsilon - \varepsilon_0)}{MNc}. \tag{6}$$

If the average thickness of the twin boundary is set as E, the dislocation accumulation amount caused by different orientations is expressed as

$$j_m = \sqrt{\beta} = \frac{m(\varepsilon - \varepsilon_0)}{MNc}E. \tag{7}$$

(ii) *The Influence of Stacking Fault Energy.* The critical condition for considering the fracture of twin boundaries is only affected by the stacking fault energy. In face-centered cubic metals, in order to reduce the energy, a complete dislocation is decomposed into two incomplete dislocations, and the two incomplete dislocations are connected by a stacking fault band, that is, an extended dislocation [21]. When the extended dislocations are in equilibrium, the gravitational force θ per unit length produced by stacking faults and the repulsive force T produced by partial dislocations are balanced:

$$U = \frac{T}{\theta}, \tag{8}$$

where U represents the width of the stacking fault and is a constant. But when the dislocation moves and approaches the twin boundary, it will be repulsed by the twin boundary P. The equilibrium equation at this time is

$$P + \theta = \frac{T}{U}. \tag{9}$$

It can be seen from Wei Yujie's research that the expression of critical shear stress α during twinning deformation is

$$\alpha = \alpha_1 + \varepsilon\frac{8}{\pi}\frac{2 - w}{1 - w}\frac{E}{c}\delta k^i - \frac{2\theta_{th}}{Ek^i}. \tag{10}$$

As the shear rate α increases, the appearance of the extrudate shows unstable flow phenomena such as surface roughness, undulation, helical twist, and even melt fracture. Therefore, the shear stress during molding must be lower than α.

FIGURE 4: Martial art single kick.

2.2. Martial Art Singles and Their Protective Equipment. In a broad sense, martial art singles are also called sports. It refers to the basic means of consciously organizing social activities, improving people's physical strength, promoting all-round development, enriching social and cultural life, and promoting spiritual civilization [22]. Figure 4 shows martial art singles.

2.2.1. The Role of Single Kick in Martial Arts. Exercise promotes the growth of human bones and muscles, improves cardiopulmonary function, and improves the functional status of the blood circulatory system, respiratory system, and digestive system. In particular, it has a very important impact on the quality of people's mental health [23].

Mental health qualifications are formed by a combination of genetics and environment. They are intrinsic, basic, and relatively stable psychological qualities and characteristics. These psychological attributes and physiological characteristics determine whether to affect the individual's psychological, physiological, and social functions and then affect the individual's mental health [24]. Therefore, the quality of mental health is an important aspect of mental health that affects a person's level of mental health. Mental health quality and mental health are important signs of individual psychological phenomena. In a word, the quality of mental health is a stable psychological characteristic, and mental health is a state of psychological safety and happiness. The level of mental health quality is directly related to the level of mental health. Quality indicators of mental health often include many indicators of mental health.

(1) Evaluation Standard of Mental Health Quality. Scholars at home and abroad have a good understanding of the benchmark of mental health from different perspectives and social backgrounds. According to the college education and training goals and social development requirements of college students, the mental health standards of college students are determined by the following aspects: (1) normal cognitive ability [25], including sharp thinking, good memory, rich imagination, perception, and learning ability; (2)

Figure 5: Common sports protective gear.

healthy and stable interpersonal relationships: emotions, emotional stability, quick response, satisfaction, happiness and other positive emotions, as well as optimistic thoughts dominate, and can reasonably vent, adjust, and control negative emotions; (3) perfect personality, coordinated actions, excellent self-awareness, able to maintain the integrity and coordination of personality, and effectively control their own psychology and actions and keep the internal reflection of the action consistent with the external performance; and (4) harmonious interpersonal relationships: in study, life, and work, being good at communication and being able to objectively evaluate others, handle emergencies reasonably, accept the shortcomings of others, adapt to the environment, and establish harmonious interpersonal relationships.

(2) Mental Health Quality Measurement Tools. Mental health measurement tools are developed according to the development needs of various research fields, combined with definitions and evaluation criteria. At present, the commonly used mental health assessment tools mainly include the symptom self-rating scale and the Japanese revised personality question questionnaire. In addition, there are emotional state scales, depression self-assessment scales, mental health diagnostic tests, motor perception scales, existential personality scales, life events scales, and state characteristic anxiety scales. At the same time, the use of physiological indicators is mainly EMG, reaction time, heart rate and blood pressure, brain waves, and other evaluation methods.

2.2.2. Martial Art Single-Kick Protector. When people engage in martial art single kick, martial art single-kick protective equipment is essential. On the one hand, the protective equipment for martial art single-leg kicks needs to ensure that the personnel being used can be protected. On the other hand, the material of the protective equipment itself should not be harmful to the human body but provide high-quality protection for human activities. Due to the particularity of the composition and structure of nanocrystalline materials, its performance has been significantly improved compared with traditional materials, especially the particularity of super hardness, super modulus effect, etc., so it has become an important material for martial art single-kick protective equipment.

Table 1: Parameter comparison table.

Scope	Symbol	Value
Burgers vector size	C	0.266 nm
Taylor constant	Alpha	0.6
Lattice constant	Large	0.4 nm

Knee pads	72%	86%

Safety protective equipment is a necessary preventive device to protect the safety and health of athletes during sports. Use specific shields, pendants, or floats to protect athletes through barriers, absorption, dispersion, and containment and protect part or the entire body of an athlete from external attack. The use of personal protective equipment is an important means to prevent or mitigate sports safety accidents. There are many classification methods for safety protection equipment, which can be classified according to the use, the protection part, and the nature of the raw materials used. According to different uses, it can be divided into cold-proof products, shock-proof products, antidrop products, mechanical trauma products, antifouling products, waterproof products, and life-saving products. According to the protective gear, there are 8 kinds of protective gears for the head, face, eyes, airway, ears, hands, feet, and body. The protective effect of various protective tools is limited. In order to prevent accidents, it is necessary to use protective tools correctly and choose protective equipment reasonably
FIGURE 6: Relationship between crystal nanometer thickness and crack.

according to the type of exercise. Figure 5 is a common sports protective gear.

3. Experiments on Crystalline Nanooptical Materials and Martial Art Single-Kick Protective Equipment

3.1. Mechanical Experiments of Crystalline Nanooptical Materials. This experiment is based on the theoretical model of mechanics, taking crystalline nanooptical materials as the research object, to study the mechanical properties of crystalline nanooptical materials. In this experiment, pure copper samples with nanobimorph layers of different thicknesses were prepared, and tensile-tensile fatigue experiments under constant stress amplitude were carried out on these products. Pure copper has good electrical conductivity and is widely used in the manufacture of wires, cables, brushes, etc.; it has good thermal conductivity and is often used to manufacture magnetic instruments and meters that

must be protected from magnetic interference; it has excellent plasticity and is easy to be processed by hot pressing and cold pressing. Table 1 is a reference table of the parameters required in the calculation process of the mechanical model.

3.2. Wushu Single-Kick Research Experiment. This experiment investigates the form of physical exercise and the quality of mental health of students in a university. Good psychological quality is the foundation of a healthy life for college students, and having a healthy body and mind is an important guarantee for their adulthood, talent, and success. Tables 2 and 3 show the mental health quality scores of regular and infrequent physical exercisers, the mental health status of different age groups, respectively, and quality comparison.

As can be seen from Tables 2 and 3, students who actively participated in sports had higher mental health scores in every aspect than students who participated in

sports occasionally, indicating that students actively participated in sports.

3.3. Experimental Design of the Effect of Sports Protective Equipment Based on Crystalline Nanooptical Materials. For experiments on sports protective gear of nanooptical materials, first, an initial solution is provided; secondly, a metal compound is added to the initial solution and mixed under alkaline conditions to obtain an intermediate solution; finally, a quantum dot precursor is added to the intermediate solution to obtain nanomaterials, and then, the nanomaterials are added to the sports protective gear. During the experiment, a control experiment was also conducted on ordinary sports protective gear. In this experiment, data on the protective effects of different protective gears were collected. Table 4 is a statistical table of the protective effects of various protective gears in this experiment.

It can be seen from Table 4 that the performance of the protective gear with nanomaterial protective equipment is much higher than that of ordinary protective gear. It shows that nanomaterial protective equipment is better than ordinary protective equipment.

4. Experimental Analysis of Crystal-Based Nanooptical Materials and Sports Protective Equipment

4.1. Mechanical Experimental Results of Crystalline Nanooptical Materials. In this experiment, the mechanical properties of crystalline nanooptical materials were fully studied. During the experiment, the effect of the thickness of the crystalline nanomaterial bimorph on the crack suppression of the material was investigated. Combined with the experiments in this paper, a schematic diagram of the effect of the thickness of the crystalline nanooptical material wafer on the inhibition of crystal cracks is obtained, as shown in Figure 6:

It can be seen from Figure 6 that under the condition of constant applied load, when the thickness of the double crystal layer is $E = 10$ nm, the condition for the initiation of double grain boundary cracks is that the grain size $dG > 190$ nm; when the thickness of the double crystal layer $E = 30$ nm, the condition for the initiation of grain boundary cracks is that the grain size $dG > 420$ nm. From the data summarized in Figure 6, it can be seen that when the grain size cannot be refined, increasing the thickness of the twin layer can inhibit the initiation of twin boundary cracks, thereby improving the strength and hardness of the material.

4.2. Experimental Results of the Effect of Sports Protective Equipment Based on Crystalline Nanooptical Materials. According to Table 4, a comparison chart of the effects of sports protective equipment of different materials is obtained, as shown in Figure 7.

According to Figure 7, it can be concluded that it is a great improvement compared to conventional protection. It can be clearly seen from Figure 7 that the protective effect of sports protective equipment based on crystalline nanooptical materials has increased by an average of 12%.
Figure 7: Comparison of different materials for sports protective equipment.

5. Conclusions

Nanooptical materials have high yield strength, hardness, and good wear resistance, making sports protective equipment based on crystalline nanooptical materials safe and reliable. Sex life is greatly improved. From the experiments in this paper, it can be concluded that the protective effect of sports protective gear based on crystalline nanooptical materials has been qualitatively improved, with a maximum increase of 21%.

At present, algorithm technology has achieved very rapid development, and it is more and more widely penetrated and applied in people's production and life. Among them, product design based on intelligent algorithm has also been widely used. This technology plays an important role in promoting product innovation and design and contributes to the improvement and optimization of technology, showing very significant application benefits in the product design and development process of major enterprises. The application of intelligent algorithms in product design can not only make products more in line with customers' usage habits, but also products blessed with intelligent algorithms often have more commercial value. Therefore, in order to enhance the added value of commodities, innovative design of products has become a must. Nanomaterials must have unique properties that are unmatched by general building materials, such as high surface activity, strong oxidation, and superparamagnetic. This article mainly studies design strategies from two aspects, namely the innovation of material properties and application methods, and introduces the properties of nanomaterials, their application status, and the existing problems. And it starts from the application of intelligent technology in nanomaterial products, innovative design, and development prospects, combined with actual cases, to find a feasible way for the development of innovative design and research of nanomaterial products. On this basis, it is proposed that the idea of expanding the design should reunderstand and reposition the product design of nanomaterials and make the design more acceptable to more consumers. New design ideas and methods such as adjusting material properties through intelligent algorithms provide certain assistance and support for the application of intelligent algorithms in product design innovation practice. Some completed application practices are also presented to illustrate the rationality of the application of intelligent algorithms in nanomaterial products. The results show that the crowd search algorithm has the highest optimization degree and has good stability and optimization effect, and its standard deviation is the lowest close to 0.

1. Introduction

Materials are the material basis for human survival and development. In the 1980s, people regarded new materials, information technology, and biotechnology as important symbols of the new technology revolution, and it was considered to be one of the pillars of modern science and technology in the twenty-first century. As an indispensable element in product design, material innovation has formed a preliminary structure and system during the Bauhaus period in Germany. Common materials have many quality

defects, which lead to serious constraints in product design. And nanomaterials are completely different. With its excellent material quality, it can play an important and unique role in fields that ordinary materials cannot. Nanomaterials are one of the most important directions for the development of new materials in the twenty-first century. With the development of nanotechnology, the innovation of material properties can not only maintain the basic properties of nanomaterials, but also make up for the deficiencies and shortcomings of their properties to a large extent. In the process of product innovation and design, the initial stage
Figure 1: Artificial intelligence optimization algorithm diagram.

focused on divergent thinking and continued to expand outward with the design point as the center, seeking various possible design solutions.

Intelligent algorithm is based on intelligence and performs relatively fast global optimization, which can better simulate the initial design thinking in product innovation design. In the detailed design stage, the main focus is on convergent thinking, fully absorbing the design points of the excellent scheme and thinking in one direction. For the research and development and production of nanomaterial products, the innovation of product design and concept in the product development stage needs to meet people's objective requirements in a true sense, and at the same time, it must be implemented in the production process, so that it can be effectively realized. In this context, it is necessary to keep pace with the times and deeply study the design methods of nanomaterials. This paper makes full use of intelligent algorithm technology to lay a solid foundation for the research and development and innovation of new products, explore its new path for innovative practice, and effectively solve technical problems related to product design.

Based on the intelligent algorithm, the relationship between nanomaterial products and artistic design is discussed, the procedures and ways of applying intelligent algorithm to product innovation design are studied, and several algorithmic product innovation design models are proposed, and the development of an innovative design example system is one of the innovations of this paper.

2. Related Work

For the topic of "intelligent algorithm + nanomaterial products," some scholars have carried out research on it.

Yin got a highly ordered alumina obtained under ultrahigh vacuum (UHV) by NiAl(110) surface oxidation. He

physical vapor deposition at room temperature and annealed at temperatures up to 500°C. It was verified by the nearly constant I–V characteristics of the PureB diodes and the microscopic examination of the deposited layers [2].

Agenor examined the interaction between access to finance, product innovation, and labor supply in a two-stage overlapping generational model of endogenous skill distribution and financial market imperfection. An ambitious policy aimed at alleviating the constraints on innovators' access to funding may allow a country to escape this trap by promoting idea generation and improving incentives for investment in skills [3].

Engelman aims to study the impact of intellectual capital on firm absorptive capacity and the impact of intellectual capital on product innovation. He believes that companies mobilize intellectual capital and other intangible assets through dynamic capabilities such as ACAP. He conducted a quantitative study, structural equation modeling, to verify the validity of structural and theoretical models. He found that intellectual capital does affect ACAP. His findings also show that ACAP affects product innovation, but each of its dimensions exhibits different effects [4].

Wang believes that product innovation not only enables organizations to introduce new products to the market, but also challenges organizations to update their technical capabilities. Through a longitudinal study of product introductions in the workstation industry, he found that capability extension reduces the chances of new product survival. In addition, he found that organizational boundaries moderate the negative relationship between capability extension and product survival. He derives the implications of the link between product innovation and capability development [5].

Hui studied the common domain name format of http://www.zol/, processed the data of consumer online reviews of three Huawei Mate phones, explored the correlation between online reviews and phone improvements, and made suggestions for future product improvements. This empirical study showed that changes in mobile phone functional satisfaction are strongly correlated with improvements in mobile phone performance. This research helps companies grasp market demand, understand consumer behavior, and improve the quality and efficiency of product innovation [6].

Bos examines the impact of access to imported intermediate inputs on firm-level product innovation in five developing countries, combining trade data with innovation survey data and developing a method to determine whether new inputs are critical for product innovation. He found evidence that the number of new imported varieties has a significant impact on product innovation that depends on new inputs and provides instructive evidence that this impact comes from access to better quality imported products [7].

3. Intelligent Algorithms, Nanomaterial Products, and Innovative Art Design

3.1. Intelligent Algorithm. Intelligent algorithms are new algorithms based on artificial intelligence. Like most computing, intelligent computing is a kind of natural computing inspired by nature. It first comes from biology; people imitate the evolution process of creatures in nature, thus abstracting such an algorithm [8]. In the process of continuous development, intelligent algorithms are slowly being applied to scientific problems, but these problems are also encountered by people in real life. Over time, people have summarized and summed up a special algorithm and named it intelligent algorithm. Figure 1 shows the AI optimization algorithm diagram.

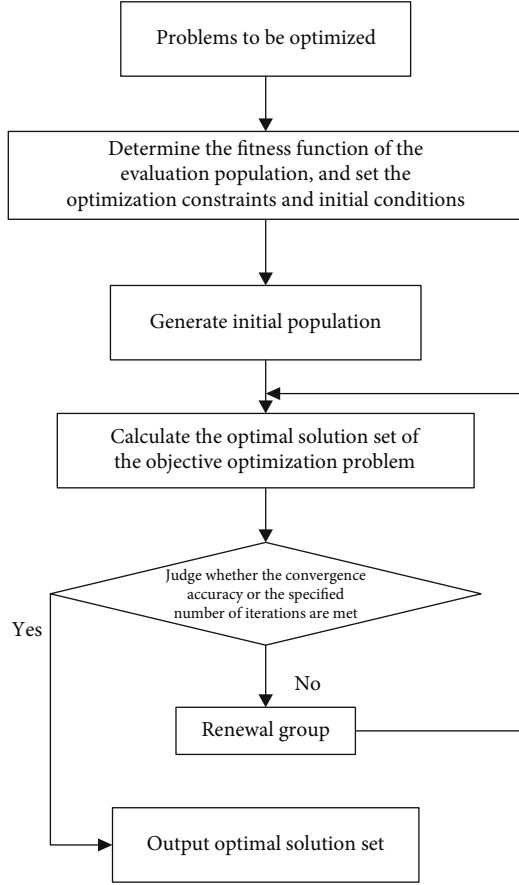
In fact, the development of intelligent algorithms is far beyond imagination. With the development of time, new ideas of intelligent algorithms have sprung up, and various theories about intelligent algorithms have been proposed, and they have also been improved and updated. But despite this, the basic process of intelligent algorithm has not changed, and its basic process is generally shown in Figure 2. From the frame diagram of the algorithm, it was found that at the beginning of the algorithm operation, it must initialize


Figure 4: Multivariate optimization flow chart based on genetic algorithm.

Table 2: Convergence performance.

Algorithm	Evolutionary algebra reaching convergence	Number of times to reach convergence
PSO algorithm	68	912
GA algorithm	42	937
SOA algorithm	19	993

all the relevant parameters of the algorithm and then randomly generate a position, that is, the most initial solution [9]. Then, the solution space will generate a different solution according to certain rules; that is, a global search for the solution will be performed until a better solution is judged. According to the different conditions of the solution, the corresponding algorithm will be used to perform a local search near the more optimal solution, so as to further find the optimal solution, until the optimal solution satisfies the termination condition, and the output ends. Otherwise, the algorithm automatically loops and starts to research for the optimal solution [10].

3.1.1. Crowd Search Algorithm. Crowd search algorithm is a heuristic random search algorithm, which draws on human social experience, simulates human search behavior, and regards human self-interest behavior, altruistic behavior,

self-organization aggregation behavior, preaction behavior and uncertainty reasoning behavior as advanced intelligence. The body is analyzed and its model is established to calculate the search direction and step size. The crowd search algorithm is a relatively effective search method, and its main working principle is to use the local optimal method. In the search process, the algorithm first finds a continuous spatial position and then judges whether there is an optimal solution based on this position. If the optimal solution is not found at this position, the algorithm will redetermine a continuous space until the optimal solution is finally found. However, the optimal solution generated by the crowd search algorithm is often a local optimal solution, which is far from replacing the global optimal solution [11]. The operation flow of the SOA algorithm is shown in Figure 3.

In the process of searching the space, because the position and the search area are uncertain, the first thing that needs to be done is to determine the relative position of the search target and determine the area according to this position. Its specific function is described as follows:

$$y_i = y_{\max} - \frac{d - U_i}{d - U}(y_{\max} - y_{\min}), i = 1, 2, \cdots, d, \quad (1)$$

$$y_{ij} = \text{rand}(y_i, 1), j = 1, 2, \cdots, D. \quad (2)$$

In the above formula, y_i is a position parameter of the objective function value i; y_{ij} is the relative position of the objective function value i of the parameter j; U_i is the specific number of $x_i(t)$ after arranging the overall position in a certain order; D is the actual size of the search space.

According to some conditions about the position in formulas (1) and (2), we can now get the position parameter y_{ij}. According to the above two formulas, the step size formula can be obtained as

$$\beta_{ij} = \chi_{ij} - \sqrt{-\ln\left(y_{ij}\right)}. \quad (3)$$

Among them β_{ij} is a position space constant in j-dimensional space; χ_{ij} is a parameter of the basis function, and the formula for its value is

$$\chi_{ij} = \omega \cdot sab(x_{\min} - x_{\max}), \quad (4)$$

$$\omega = \frac{(R_{\max} - r)}{R_{\max}}. \quad (5)$$

In formula (5), $x_{\max}$ and $x_{\min}$ are the values of the relative position in the process of finding the optimal solution; ω is the weight transformation of the position; r and $R_{\max}$ are, respectively, the number of iterations the algorithm performs in the process of finding the optimal solution.

After the relative position information is obtained, the model is analyzed by estimating the target. In this process, the expected action direction $d_{i,\text{ego}}$, the actual movement direction $d_{i,\text{alt}}$, and the preparation action direction $d_{i,\text{pro}}$ of any i search targets can be obtained. Finally, through the

(a)

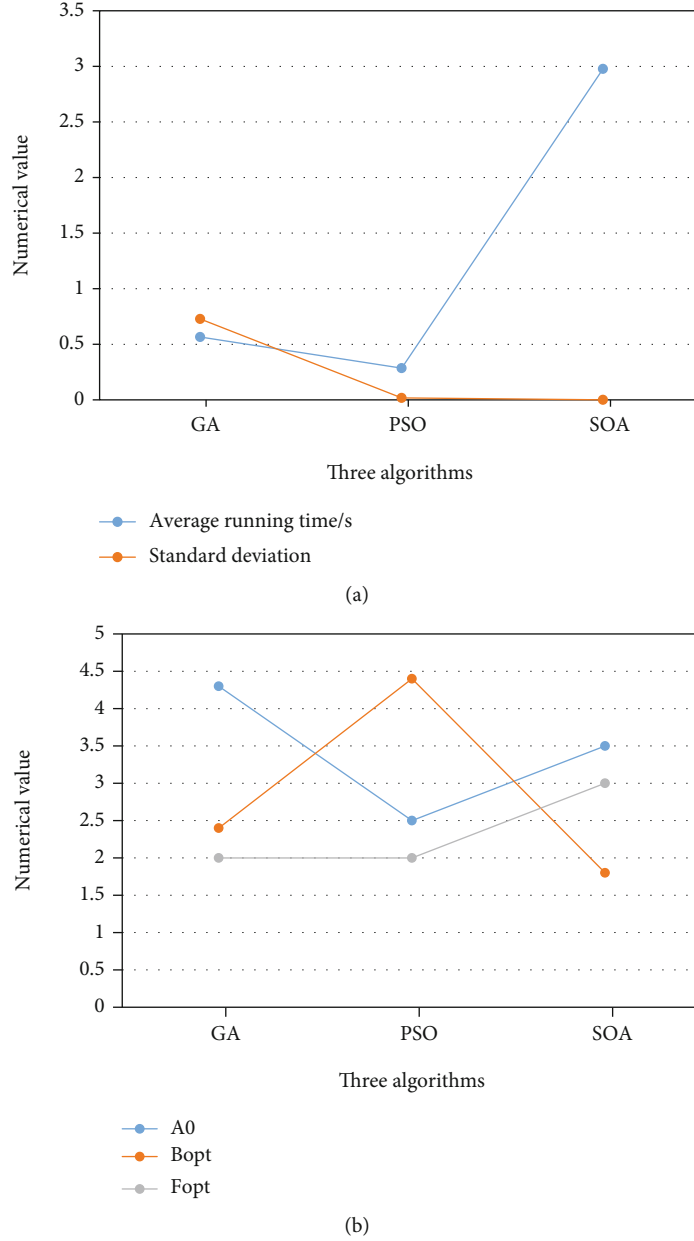
(b)


FIGURE 5: Statistical data and optimization results of three algorithms.

calculation of these three, we can get the final search direction.

$$d_{i,\text{ego}}(t) = p_{i,\text{best}} - y_i(t), \qquad (6)$$

$$d_{i,\text{alt}}(t) = g_{i,\text{best}} - y_i(t), \qquad (7)$$

$$d_{i,\text{pro}}(t) = y_i(t_1) - y_i(t_2), \qquad (8)$$

$$d_i(t) = \text{sign}\left(\chi_1 d_{i,\text{ego}} + \chi_2 d_{i,\text{alt}} + \omega d_{i,\text{pro}}\right). \qquad (9)$$

In the formula, $t_1, t_2 \in \{t, t-1, t-2\}$; $y_i(t_1)$; $y_i(t_2)$ are the initial positions of $\{y_i(t-2), y_i(t-1), y_i(t)\}$; $g_{i,\text{best}}$ is the relative optimal position in the space where the ith search target is located; $p_{i,\text{best}}$ is the possible target position

found by the ith search target; χ_1 and χ_2 are a real number randomly selected in the known interval $[0, 1]$.

The position transformation formula of the target to be searched is

$$\Delta y_{ij}(t+1) = \beta_{ij}(t)d_{ij}(t), \qquad (10)$$

$$y_{ij}(t+1) = y_{ij}(t) + \Delta y_{ij}(t+1). \qquad (11)$$

3.1.2. Genetic Algorithm. Genetic algorithm is a kind of random search algorithm that is widely used at present. Compared with other algorithms, it can operate directly on configuration parameters, so its operation is particularly simple. The algorithm is based on the typical principles of survival of the fittest. After the parameter configuration of

FIGURE 6: Nanoproducts.

the first-generation algorithm is generated, it can iterate and evolve continuously and finally produce more and more optimal approximate solutions [12]. The operations of crossover, mutation, and selection of genetic algorithm are carried out in a probabilistic way. The factors of the genetic algorithm are calculated by crossbreeding and mutation in biotechnology.

It is worth mentioning that the genetic algorithm can also realize the direct calculation of the product. In this process, the algorithm continuously evolves through the acquisition of product information. Genetic algorithms can also provide us with an analysis of different parts of the product when we need to do a corresponding analysis of that product. In the iterative process, the genetic algorithm has good convergence and high efficiency. By using the algorithm to simulate the components of the nanomaterial product, we can finally get the shape of the product [13].

But the genetic algorithm cannot solve the problems in dynamic simulation. In order to better demonstrate the dynamic process of product innovation, artistic design, and modeling, particle swarms were introduced to optimize the algorithm to a certain extent. The results show that the performance of the genetic algorithm optimized by particle swarm optimization is significantly better than that of the traditional genetic algorithm.

The reason why the genetic algorithm has such efficient performance is mainly because it uses an iterative calculation method in the process of numerical calculation. Compared with traditional algorithms, traditional iterative processes tend to fall into the loop of local optimization. The genetic-based iteration abandons the drawbacks of the traditional model, so that only the individual with the highest fitness in the global scope is kept as the optimal solution [14]. The relevant parameters of the genetic algorithm are set as shown in Table 1.

The optimization goal of this paper is to find the global optimal solution, so it is necessary for us to make certain improvements to the above algorithm to meet our design

of the innovative art of nanomaterial products. The optimization function is as follows:

$$g(x) = \min (T_E, H_e). \tag{12}$$

Similar to the objective function in most intelligent algorithms, we also introduce an objective function here called the fitness function. After considering the actual value of the fitness function, the fitness function is also adjusted as follows:

$$fit(f(x)) = \frac{1}{g(x)}. \tag{13}$$

The optimization model based on genetic algorithm is shown in Figure 4. Evolutionary rules are the main components of genetic algorithms, which can simulate natural phenomena such as birth, aging, illness, and death and determine the dynamic function of the state at the next moment according to the current state and its neighbors. At the same time, the central states will influence each other and promote the interaction between local populations. Its basic model is

$$If S^t = 1, S^{t+1} = \begin{cases} 1, A_i \le n \le B_i, \\ 0, n < A_j, n > B_j. \end{cases} \tag{14}$$

3.1.3. Particle Swarm Optimization Algorithm. Particle swarm optimization (PSO) is an emerging stochastic optimization algorithm that simulates the foraging behavior of birds, which can effectively optimize various functions. This algorithm relies on random processes and uses the concept of fitness value. On the basis of the previous intelligent algorithm, we introduce a new intelligent algorithm, namely particle swarm optimization algorithm. In an era of increasingly abundant data and information, particle swarm optimization algorithms are known for their multidata parallelism and simplicity. The algorithm has few control parameters, and the concept is particularly easy to understand. In actual operation, all particles are governed by two parameters, one determines the position of the particle, and the other determines the initial velocity of the particle. In terms of finding the optimal solution, the algorithm firstly seeks the individual optimal solution and then seeks the global optimal solution on this basis [15]. In the process of finding the solution, the particle needs to continuously change its position and velocity. The formula for its velocity and position is

$$b_{ij}(t+1) = q b_{ij}(t) + c_1 r_1 \left[p_{ij} - x_{ij}(t) \right] + c_2 r_2 \left[p_{jg} - x_{ij}(t) \right], \tag{15}$$

$$x_{ij}(t+1) = x_{ij}(t) + b_{ij}(t+1), (j = 1, 2, \cdots, n). \tag{16}$$

In the formula, q is the inertia weight, and its value is 1.49; c_1 and c_2 are positive learning factors, and its value is 0.5; r_1 and r_2 are random numbers, which are uniformly distributed between 0 and 1.

The design objective function is

$$A_0 = \min \left\{ \max A(\beta_2, f) \right\}. \tag{17}$$

In addition, the speed update formula is

$$w_{id}^{k+1} + r_1 c_1 \left(p_{id} - z_{id}^{k} \right) = c_2 r_2 \left(p_{dg} - z_{id}^{k} \right) + v w_{id}^{k}. \tag{18}$$

Next, in order to test the stability and adaptability of the performance simulation algorithm, we selected three algorithms, respectively, and let them complete 1000 optimal solution searches alone to test their convergence. The final simulation statistical results are shown in Table 2.

Table 2 shows that in the process of finding the optimal solution for the three algorithms, the final test accuracy of each algorithm is above 90%, which shows that the three algorithms have relatively high efficiency in finding the optimal solution. In terms of convergence, the SOA algorithm has the lowest convergence, less than 2%, which fully demonstrates the superiority of the algorithm.

After calculating the standard deviation and search time of the above results, 15 optimized results were added, and all data were screened as a whole. Figure 5 is the final statistical result. The data analysis shows that the crowd search algorithm is the most optimized among the three algorithms, and the standard deviation is close to 0, which is 0.7 percentage points lower than the GA algorithm. Based on this, we

can draw relevant conclusions, that is, the innovative artistic design of nanomaterial products based on this algorithm has good stability and optimization effect.

3.2. Nanomaterial Products. Nanomaterials are ultrafine natural or man-made materials, mainly in the form of agglomerates or powders, and their grain size is nanometer. Its particle size is larger than atomic clusters but smaller than ordinary particles. The size is generally 100~102 nm, and the total number of elementary particles exceeds half. The surface activity of nanomaterials is relatively active, which makes nanomaterials have special electrical, mechanical, optical, magnetic, thermal, and other chemical properties. Nanomaterials mainly include nanoparticles, nanotubes, nanoblocks, nanofilms, and nanocomposites. Nanotechnology is a multidisciplinary science and technology that studies the properties and interactions of matter (including atoms and molecules) at the nanoscale (1~100 nm) and utilizes these properties. Nanotechnology is based on modern science and technology in many fields such as molecular biology, microelectronics, quantum mechanics, computer technology, and mesoscopic physics. It has been more than 20 years since the advent of nanomaterials and the technologies developed with them. The stage of material innovation and performance development has been roughly completed, and now it has entered the stage of technological improvement and comprehensive application [16].

3.2.1. Application of Nanomaterials and Key Products. As a new type of material, nanomaterials have been widely used in product design and have received extensive attention from the government and scientific researchers since its inception. The rapid development of nanotechnology is bound to trigger a new design revolution. In the 1980s, nanocalcium carbonate was developed. It is a new type of

ultrafine inorganic material with a particle size of usually 20~100 nm, but its technical content is relatively low. Due to its low price and high quality, it is widely used as an improved filling material. The data shows that nanocalcium carbonate materials have dominated the entire nanomarket and accounted for 29% of the overall size of the nano new material market. In addition to nanometer calcium carbonate, there are typical nanomaterials such as titanium dioxide and zinc oxide [17]. Figure 6 shows some common nanoproducts.

There are several nanomaterial technologies, devices, and products with excellent performance in the market, such as single electronic device, nanoblood glucose detector, immunochromatographic monitoring technology of nano-crystal bioprobe, nonpolluting nanowater-based paint, nanomodified high-power lithium ion battery, nanomodified solar cell, nano-self-cleaning cashmere sweater, nano-modified pigments, and nano-self-cleaning glass. Some typical application products of nanomaterials include nano-ceramic knife, nanozinc oxide coated refrigerator, and nano-titanium dioxide car paint [18].

3.2.2. User Needs of Nanomaterial Products

(1) Users pay attention to the functional satisfaction of products and hope that nanoproducts have many functions and can get feedback more quickly

For example, nanotoothpaste should not only clean teeth like normal toothpaste, but also diagnose oral diseases and reduce inflammation and pain. More importantly, the free nanohydroxyapatite component contained in the nano-toothpaste has the effect of protecting and repairing the gums. The most basic function of ordinary refrigerators is the function of refrigeration and preservation, but this is
(a)
(b)

Figure 10: Continued.
(c)

Figure 10: Inspiral workflow completion time optimization results.

not enough. People require that refrigerators coated with nanozinc dioxide can effectively help people to sterilize and inhibit bacteria, thereby reducing or even avoiding the unpleasant smell of food stored in the refrigerator due to spoilage or peculiar smell from food. Compared with ordinary skin care products, the cosmetic effect of nanoskin care products is faster and more efficient. In addition, people also require that nanoskin care products can quickly form resistance to the dermis of the skin so as to play a repair function on damaged cells and then instantly achieve the surprising effect of antiaging. The role of nanosilver clothing is radiation protection and can effectively treat skin diseases. People's demand for its physical therapy and as a health care product far exceeds the demand for its beauty, cold resistance, and frost resistance [19]. The car paint added with nanotitanium dioxide can increase the hardness and strength of the car surface and increase the wear resistance and impact resistance of the paint. Moreover, nanotitanium dioxide can change the angle of its visible light with the change of sunlight, thereby reducing light pollution and meeting people's requirements for environmental protection. Nanoceramic knives have greater hardness than diamond and can always maintain people's functional requirements for "sharpness" without grinding. Nanozirconia ceramics have strong chemical stability, acid and alkali resistance, and antifouling characteristics, so they are more clean and hygienic.

(2) The user attaches great importance to the reliability of nanoproducts and requires nanoproducts to be durable, safe, and reliable

As small as nanotoothpaste, skin care products, underwear, sunscreen in daily life, and as large as nanodrug deliv-

ery vehicles, these products are in direct contact with the internal cells of the human body or the external epidermis of the body. While they were astounding, people also demanded that they not be toxic, damage, or have other undesirable side effects to the cells inside the body. Another example is the products that are in direct contact with food, such as nanoknives, plastic wrap, and refrigerators that are common in the kitchen. It is required that it should not have a certain chemical effect with food, which will lead to food spoilage or residual or harmful substances on the surface of food [20].

(3) Nanoproducts meet the interactive needs of users, which is mainly reflected in the portability of nano products

Because of their small size, light weight, and strong plasticity, nanoproducts are loved by the public because of their portability. The thickness of nanosolar cells is only 2 nm~6 nm, which is very thin and small, so it is easy to carry. The nanoelectronic display has good flexibility, bending resistance, and light weight, which can be easily carried by users. It opens the door to the design of wearable electronic products, which can make the distance between electronic products and people even smaller.

3.3. Innovative Art Design. The poor definition of the initial state has become one of the main characteristics of product innovation design, which is a very creative problem-solving process. More specifically, at the beginning of the design, the designer has only an incomplete and vague mental representation of the upcoming design. This requires designers to understand how to implement the next steps in the

product innovation design process. Various loops in the process of innovative design have been studied and analyzed by a large number of scholars, such as iterative loops in problem space and pattern space, loops in problem definition, and loops in evaluation and generation stages [21]. IRTZ theory is a systematic, knowledge-based innovation method system, as shown in Table 3. It includes innovative thinking, analytical tools, and problem-solving tools, making it more operable and practical in application.

IRTZ is a problem-solving theory of invention, and the flow chart of IRTZ (shown in Figure 7) can be used as a description of IRTZ tools and methods.

The first step is to study and analyze the problems encountered. If contradictions and conflicts are found, the problems can be solved according to the principles. If the problem encountered is very clear but do not know how to solve it, then it needs to be used with some kind of effect to run a whole set of technological system evolution process that predicts innovation and then evaluate this process to achieve the final step. If a new problem is found during the implementation, the above process is repeated again until the problem is solved [22].

4. Nanomaterials and Models

4.1. Sensitivity of Nanomaterial Design Properties. In order to ensure the accuracy of the test, several nanomaterial simulation analysis methods are placed in the same test environment to test the accuracy ability. The settings of the test environment are mainly shown in Table 4.

In order to study the user's perceived intention needs, based on the online survey, the author distributed 100 questionnaires about the difference subscale of sensory vocabulary of nanomaterials. A total of 100 subjects' perception evaluations of nanomaterials were collected. According to the characteristics of materials, nine groups of perceptual adjectives, namely "clean and messy, natural and industrial, simple and gorgeous, light and heavy, safe and dangerous, modern and classical, individual and ordinary, delicate and rough, soft and hard," were selected. A 5-level lexical difference subscale was developed, as shown in Table 5. The nanomaterials involved in the questionnaire are all raw materials of the original color. According to the previous survey, the author also distributed 5 offline questionnaires with the same content as the online questionnaire. The results are shown in Figure 8. It can be seen from the survey that the respondents who filled out the offline questionnaire believed that the soft nano was the lightest and most comfortable to touch; the hard nano had the most modern features, and the wrinkled nano was softer than the hard nano. This clearly shows that there is a certain degree of deviation between the results of the online survey and the offline survey, with the maximum difference reaching 1.26. The reason why the perceptual evaluation of this material is so different is because there are also some differences in the visual and tactile effects [23].

According to Table 5, we can see that the softer nanomaterials give a more homely feel, while the harder nanomaterials give a modern freshness, and the wrinkled nanomaterials give a softer feeling. From the overall effect, good nanomaterials generally give people a simple and brisk feeling.

4.2. Montage Experimental Results. Under the Montage model, when the task volume is 25, 50, and 100, respectively, the maximum, average, and minimum values of the average completion time of each algorithm are shown in Figure 9. The formulas for calculating the mean and variance are

$$\bar{A}_i = \frac{\sum_{k=1}^{K} A_i^{\ k}}{K}, \tag{19}$$

$$\sigma = \left[\frac{\sum_{k=1}^{K} \left(\bar{A}_i - A_i^{\ k} \right)^2}{(K-1)} \right]. \tag{20}$$

σ and $\bar{A}_i$ represent the variance and mean of the ith evaluation value, where the range of i is $[1, 48]$.

According to Figure 9, the analysis is as follows: when the number of tasks is relatively small, the average completion time of algorithm ABC and algorithm ACO is lower than that of other algorithms, which are 74.13 and 76.17, respectively, while algorithm BA and algorithm GA are dwarfed. With the increase of the number of tasks, the average completion time of the algorithm ABO shows a significant upward trend, slowly surpassing all other algorithms, and also reduces its efficiency. In contrast, when the number of tasks is 25 and 50, the CRO completion time is relatively short. When the number of tasks is 100, the average completion time is the shortest among all algorithms. Compared to other algorithms, CRO is much more efficient in workflow completion time [24].

4.3. Inspiral Experiment Results. It can be analyzed from Figure 10 that when the amount of tasks is small, SFLA has the shortest average completion time, with a value of 2808.21, followed by ABC, and then GA. It is worth noting that the average completion time of algorithm MA is 0.7 times that of algorithm PSO. However, when the number of tasks is 100, among all algorithms, ABC has the longest average completion time, reaching 7287.47, followed by CS, reaching 6750.98. This comparative analysis reflects the extreme instability of the ABC algorithm in terms of average completion time. It can be concluded that as the number of tasks gradually increases, so does the time for each algorithm to run and complete. When the task volume is 100, the average completion time of CRO is the shortest, which is only three-quarters of the average completion time of CS.

5. Discussion

As a new type of material, nanomaterials have developed rapidly since entering the twenty-first century. They are receiving great attention and attention from the world, and researchers are also conducting in-depth research on them at a strategic height. The application of nanomaterials in product design is very exploratory, and this kind of exploration has special significance in the context of increasingly prominent environmental problems, so it has also attracted

great attention from relevant personnel. Nanomaterials have irreplaceable advantages in product design. Taking material properties and usage patterns as innovative strategies, they have played a positive role in people's reunderstanding and positioning of nanomaterial product design. At the same time, it also enables nanomaterial product design to play an important role in a broader commercial platform. The innovative artistic design of products based on various nanomaterials is a follow-up to the concept of environmental protection, because nanomaterials are multifunctional. At the same time, it is also suitable for various processing technologies, which makes it widely used in different product fields, so as to further explore and effectively analyze the product innovation design of nanomaterials. Crowd search algorithm is more stable than genetic algorithm and particle swarm algorithm. According to the actual problems and cases, the effectiveness of the optimization algorithm is verified, and it can be found that the designed optimization algorithm can achieve a good optimization effect in application.

6. Conclusion

Through the above research and analysis, we can clearly see that the innovative design technology assisted by intelligent algorithms has been widely used in the product design process. Better optimization results can be obtained, and the innovation and efficiency of product design can be effectively improved to a greater extent. According to different design ideas and concepts, it proposes a method of product innovation design based on genetic algorithm. The results show that this method is very practical because of its realization of innovation. In the future, in the process of product art design, the use of intelligent algorithms to assist product innovation technology will certainly achieve diversified development and make the methods and methods to effectively solve the problems in this process multidimensional. Through the use of advanced modern technical resources, designers can further improve their ability to control product design and their ability to innovate and create. Most importantly, these achievements can be given back to the society and users in a more diversified way. Combining the characteristics of product design practice, this paper promotes the construction of nanomaterial experience library, provides effective methods and approaches for design practice innovation, and gradually forms a new design mode of material perception experience, which is one of the important development directions in the future. This research lays a theoretical foundation for establishing a practical intelligent algorithm-assisted product innovation system. In the future, we will comprehensively consider adding relevant constraint mechanisms to combine them with relevant evolutionary mechanisms to establish a product innovation design system that meets the needs of different subjects.

The growing awareness of the environmental damage caused by petroleum-based fibres has led to an increase in renewable and biodegradable resources. The continually growing demand for eco-friendly and sustainable materials pushes automakers and material researchers to consider the ecological importance of their materials during fabricating, recovering, and disposal. Natural fibre-reinforced composites (NFRC) have been introduced into the automobile market substantially over the last ten years due to their renewability, eco-friendliness, recyclability, biodegradability, light weight, better specific strength, good resistance to impact and corrosion, abundantly available, ease of processing, and cost-effectiveness. Due to cost-effectiveness and weight reduction, NFRC is becoming a better replacement for petroleum/synthetic fibres like aramid, kevlar, carbon, and glass fibre-reinforced composites, and the transportation sector has instigated the use of these materials in many applications like car interiors and exteriors, dash boards, bumpers, spoilers, seat covers, and mirror casings. NFRC with nanofillers is gaining more attention in the field of engineering, particularly for automotive, defense, building, and construction applications due to better aspect ratio, larger surface area, and attractive properties. The mechanical, tribological, and thermal properties of plant fibre-reinforced composites can be improved through the incorporation of organic or inorganic nanofillers. The present review profoundly explores the effects of various factors influencing NFRC with nanofillers. This paper also summarises the effects of various chemical reagents, fabrication techniques, and industrial applications of NFRC.

1. Introduction

Increasing ecological threats and the diminution of petroleum-based products are dynamic forces that cause chemical industries to shift from petrochemicals to eco-friendly resources [1]. Material selection is crucial in the design and manufacture of a sustainable product [2]. Materials are investigated for their mechanical and thermal properties to improve the product efficiency and increase customer satisfaction [3]. Cellulosic fibres derived

from plants will play a vital role in this evolution as a significant renewable resource. NFRCs are one such material that offers flexibility during fabrication, desirable properties, and lower cost [4, 5]. Natural fibres act as reinforcing elements (discontinuous phase) in the composites used for various purposes. As a result, they have a more significant impact on a country's socioeconomic progress. Therefore, the exploitation of natural fibres to make sustainable and renewable products has engendered considerable attention. For example, NFRC has become increasingly important in the transportation segment where better strength characteristics and nondimensional change have to be combined amid less weight [6–8]. Biofibres are often derived from three sources: plants, animals, and minerals. Mineral-based fibres are underutilised in fibre-reinforced composite (FRC) research because they include asbestos, which is harmful to human health [9, 10]. On the other hand, plant-based fibres are endowed with hopeful distinctiveness, for example, cost effectiveness, biodegradability, ease of use, and excellent strength properties [11–15]. Figure 1 shows the classifications of natural fibres based on various categories. The performance of natural fibre is influenced by numerous factors such as plant seed quality, soil performance, fertiliser used, fibre maturity duration and age, fibre retting techniques, cultivation timing, retting degree, climatic change, fibre microfibrillar angle, fibre structure, fibre layer cell dimensions, fibre storage place, and fibre testing procedures [16–24]. Constituents such as cellulose, lignin, hemicellulose, pectin, waxes, oils, and moisture content make up natural fibres. The physical, mechanical, and thermal performance of NFRC can be influenced by many factors, including the selection of reinforcement and matrix, form of reinforcement, manufacturing methods adopted, volume/weight fraction of the reinforcement or matrix, the fibre aspect ratio, fibre matrix interaction, chemical reagents adopted for fibre treatment, stacking sequence, and orientation of the fibres, laminate curing temperature, and time [25–32]. Natural fibres are constructed as chemical constituents like cellulose, hemicellulose, lignin, wax, moisture, and ash content. The chemical constituents considerably vary between fibres to fibres and also affect the overall mechanical properties of the natural fibres. The diameters of the fibres varied considerably from the length of the individual filaments. The disadvantage of cellulosic fibres as reinforcement is that their hydrophilic nature makes them incompatible with thermoset or thermoplastic polymers, resulting in weak adhesion between the matrix and reinforcement because the polymer matrix is hydrophobic in nature [33–35]. However, adhesion between fibre and petroleum-based polymer should be enhanced with appropriate chemical treatment [36–38]. It is critical to building a better interphase for better composites in terms of performance; the external stress should be passed to fibres from polymeric resin. Chemical treatment is one method for natural fibres to maximise the adhesion at the interface. Since it minimises the amount of OH placed over the surface of the fibre and reduces the aspect ratio of the fibre, which improves the adhesion at the interface zone due to supe-

rior effective fibre surface area and aspect ratio. The outcome of fibre surface treatment depends on treatment time, type of reagent and its concentration, and temperature [39–44]. Different chemical reagents for various natural fibres include alkaline, benzoylation, acrylation, peroxide, silane, potassium permanganate, dewaxing, maleated coupling agent, stearic acid, graft copolymerization, acetylation, and isocyanate treatment [45–51].

Appropriate manufacturing techniques should be adopted to convert the raw materials into the final product without causing any defects. For the selection of proper manufacturing techniques to develop fibre reinforced composites, design and manufacturing experts would primarily consider a few factors. Such factors are size and shape of the end product, properties of reinforcement and matrix, processing characteristics of raw materials like processing temperature, pressure, curing time and curing temperature, production time, and manufacturing cost [52–57]. Conventionally, fibre-reinforced composites have been fabricated through various methods like autoclave, vacuum bag molding, compression molding, resin transfer molding, injection molding, filament winding, spray-up, and pultrusion [58–66]. The fibre/nanofiller-reinforced polymer composites are used in automobiles, aerospace, construction materials, packaging applications, and medical applications. Nanofillers could belong to organic and inorganic groups in nature. The particles like nanographeme, nanoclay, silica (SiO_2), nanomontmorillonite (MMT), titanium dioxide (TiO_2), carbon nanotube (CNT), calcium carbonate ($CaCO_3$), and n-SiC are inorganic fillers. However, the fillers, such as rice husk, coconut shell nanofiller, pinecone char, wood shaving char, and cellulosic nanofillers, are extracted from renewable sources and represent organic nanofillers [67–71]. For the nanocomposite preparation, nanofillers are mostly added using a weight fraction method in order to analyse the effect of filler loadings. Wagner et al. [72] revealed that the addition of just below 6 vol.% of polymer nanoparticles as reinforcements to make composite materials improved a wide array of properties like reduction in weight, dimensional stability, heat conductivity, and electrical conductivity. Saba et al. [73] in their research article showed that kenaf and jute fibres have a low density of 1.3 g/cm3 and bond well with thermosets (epoxy) and thermoplastic polymers. They also claimed that nanosized reinforcements develop better properties in the composite materials compared to their microsized counterparts. The review aims to summarise the effects of various factors influencing natural fibre-reinforced composites with nanofillers and various chemical reagents on different natural fibres. Furthermore, it summarises the effects of various manufacturing methods and industrial applications of NFRCs.

2. Effect of Various Factors on NFRC with Nanofillers

The influence of fibre length and weight fraction on the mechanical characteristics of agave/polypropylene composites was studied by Jayaraman [74]. He concluded that

FIGURE 1: Classification of plant fibres.

composite materials with a fibre length of more than 10 mm and a fibre weight fraction of between 15% and 35% revealed excellent mechanical performance. Stalin et al. [75] studied the mechanical properties of vetiver/banana/vinyl ester composites by varying the weight fraction of fibres. The mechanical properties of composites were improved by the hybridization of vetiver and banana fibre. Vinayaga-moorthy and Rajeswari [76] examined the mechanical properties of Vetiveria zizanioides/jute/glass composites by varying the weight fraction of fibres. Flexural, impact, compression, and hardness of hybrid composites were increased by 26.8%, 30.44%, 59.1%, and 28.65%, respectively. Sathishkumar et al. [77] analysed the mechanical characteristics of randomly oriented snake grass/banana/coir fibre hybrid composites. They revealed that the snake grass/banana and snake grass/coir fibre composites had better mechanical properties than banana/coir composites. Sanjay and Yogesha [78] studied the physical and mechanical properties of jute/kenaf/E-glass/epoxy hybrid composites. The mechanical properties of the laminates are influenced by the fibre arrangements and adhesion levels of the fabrics and the sequencing of high-strength fibre plies in the laminates. [79] examined the density and thermal stability of Furcraea foetida (FF) fibre-reinforced composites. The density of the Furcraea foetida fibre

(778 kg/m3) was relatively reduced in comparison with synthetic fibres, which are useful for making less dense products. FF fibres have a thermal stability of 320.5°C, which is much greater than thermoplastic polymerization temperatures. The effect of the volume fraction of snake grass fibre on tensile and flexural strength was analysed by Sathishkumar et al. [80]. They noticed that an increase in snake grass fibre of up to 25% exhibited the highest properties. Arpitha et al. [81] fabricated five different hybrid composites by using conventional manufacturing methods and varying fibre stacking sequences and studied the water absorption and tensile strength of sisal/glass/epoxy/filler composite laminates. They discovered that adding E-glass and SiC filler to composites can reduce voids and water absorption intake. Also, they revealed that the tensile strength of sisal/glass/epoxy/filler composites increased with an increase in glass fibre volume fraction. Sanjay and Yogesha [82] examined the effect of the fibre stacking sequence of jute, kenaf, and E-glass woven fabric composites on water absorption properties. The water absorption tests were performed on specimens immersed in three different water conditions: normal, distilled, and salt water. They observed that the hybridization of E-glass with jute and kenaf fibres decreases the maximum water absorption. Sanjay et al. [83] investigated the

TABLE 1: Effect of various factors on NFRC.

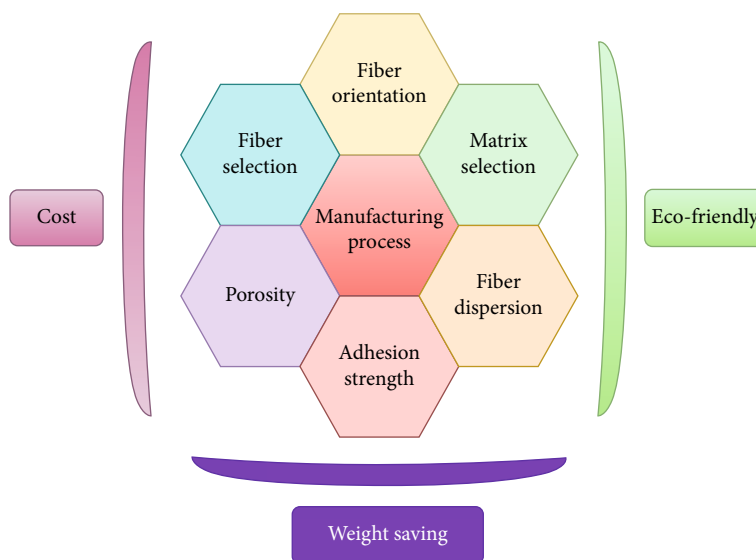
S. no	Fibres used	Factors influenced	Effects	Reference
1	Pineapple leaf	Fibre content	Tensile and flexural properties increase with fibre content.	[96]
2	Bamboo	Moisture absorption	An increase in moisture resulted in decreased interfacial shear strength.	[97]
3	Palmyra	Length and weight fraction	Better mechanical properties were obtained with a length of 55 mm and a weight of 55%.	[98]
4	Jute	Water absorption	An increase in water absorption resulted in poor flexural and compressive properties.	[99]
5	Banana/sisal	Length and weight	Up to 50% by weight, mechanical properties increased and water absorption decreased.	[100]
6	Banana/sisal	Weight fraction	The highest mechanical properties were obtained at 0.4%.	[101]
7	Chopped snake grass	Volume fraction	Improved mechanical properties when the volume fraction increases.	[80]
8	Abaca	Fibre loading	The mechanical properties showed an increasing tendency up to 40 wt.% of fibre loading.	[102]
9	Banana/sisal	Microfibrillar angle (MFA)	High tensile characteristics are seen in fibres with high cellulose content and a low MFA content.	[103]
10	Kenaf	Fibre content	Improved mechanical properties at 25% and 30% fibre content.	[104]
11	Luffa	Volume fraction of fibres	The mechanical characteristics of treated fibre composites were found to be optimal at 40% fibre volume fraction.	[105]
12	Snake grass	Volume fraction and fibre length	Improved mechanical properties of the short fibre isophthalic polyester composite were achieved at 25% V_f for the 30 mm fibre length.	[106]
13	Luffa cylindrica	Fibre content	Improved mechanical properties at 40% fibre content.	[107]
14	Oil palm	Aging and wear behavior	The wear test was carried out in dry conditions, and it was discovered that the composites immersed in engine oil and diesel performed better than the others.	[108]
15	Lantana camara	Load and fibre content	(1) The proportional wear loss increased in direct proportion to the increase in normal load (2) The optimum wear resistance property was obtained at a fibre content of 40%	[109]
16	Agave	Fibre length (3, 5, and 7 mm)	3 mm agave fibre reinforcement that has been alkali-treated had better mechanical properties.	[110]
17	Sansevieria cylindrica	Fibre length and weight	The mechanical characteristics of composites were optimal at 30 mm fibre length and then deteriorated beyond that.	[111]
18	Vakka	Volume fraction	Tensile characteristics improved as the percentage of vakka fibre in the composite increased.	[86]
19	Coir/silk	Fibre length	The mechanical characteristics of composites with 2 cm fibre length were the best.	[112]
20	Palm/coir fibre	Fibre weight fraction	The mechanical characteristics of composites with 30% fibre reinforcement were the best.	[113]
21	Sisal/nanoclay/polyester	Fibre and filler weight fraction	Improvement in tensile strength and water absorption when 25% sisal and 3% nanoclay.	[114]
22	Bagasse/nano-SiO$_2$/HDPE	Filler loading (2% to 5%)	Improvement in tensile strength by 71.46%.	[115]
23	Bagasse/nano-TiO$_2$/vinyl acetate	Filler loading (2%)	10% improvement in tensile strength.	[116]
24	Ramie/CNT/epoxy	Filler loading (0 to 0.6%)	Flexural strength and modulus were increased by 34% and 37%, respectively.	[117]
25	Bagasse/nanographene/PP	Filler loading	Improvement in mechanical properties such as tensile, flexural, and impact strength.	[118]
26	Jute/nanographeme/epoxy	Filler loading	Improvement in mechanical properties such as tensile, flexural, and impact strength.	[119]


FIGURE 2: Various factors affecting NFRC.

hybridization effect of jute, kenaf, and E-glass fibres-reinforced hybrid composites on mechanical properties as a function of varying fibre layer sequences. They observed that incorporating glass fibre with jute and kenaf fibres enhanced the impact and interlaminar shear strength over pure NFRC. Compared to other laminates, the hybrid laminate with glass and kenaf fibre plies on the outside and jute fibre plies on the inside has improved characteristics. Vijay et al. [84] investigated the tensile strength, thermal stability, and surface properties of untreated and NaOH-treated Tridax procumbens fibres. They found that there was an increase in cellulose level after NaOH treatment and a decrease in hemicellulose, pectin, and wax, which improved thermal stability, tensile strength, and surface roughness. Sanjay et al. [85] assessed the tensile, flexural, and impact characteristics of hemp/glass fibre-reinforced hybrid composites as a function of fibre-layering sequences. They revealed that the incorporation of synthetic fibre with natural fibre decreased the water absorption and increased the mechanical properties of the composites. Murali Mohan Rao et al. [86] studied the tensile and flexural strength of composites made by strengthening vakka fibre into a polyester polymer as a function of the volume fraction of fibre. They revealed that vakka fibre composites had better tensile and flexural properties than banana and sisal fibre composites and were similar to bamboo-composite at the maximum volume fraction of fibre. Okubo et al. [87] analysed the flexural properties of bamboo/polypropylene composites. Due to enhanced bonding at the interface and fewer voids, the composite's flexural strength and flexural modulus increase by roughly 22% and 40%, respectively. Shanmugam and Thiruchitrambalam [88] studied the dynamic mechanical analysis of palmyra palm/jute/polyester hybrid composites. They observed that combining jute fibres with palmyra palm increased the impact and ILSS by 18% and 25%, respectively. Raghul et al. [89] present a detailed survey on the mechanical behavior of glass fibre reinforced epoxy composites with nanofillers. This composite is manufactured by the compression modelling method in the form of laminates. The weight fraction of the nanofiller in the matrix ranges from 1%wt to 7%wt. This nanocomposite consists of improved mechanical properties suitable for industrial manufacturing. Biswas [90] prepared an effect of silicon carbide (SiC) in bamboo/epoxy composites as a function of weight percentage of filler loadings. The optimum tensile and flexural strengths were observed at 10 wt.% SiC and 5 wt.% SiC, respectively. The highest hardness was found at 15 wt.% SiC. From the SEM analysis, it was concluded that poor adhesion is responsible for low mechanical strengths. Nguong et al. [91] studied the effect of n-SiC on polymer matrix composites with different weight loadings of fillers. They observed that the mechanical properties were increased when 1 wt.% of n-SiC was reinforced into the epoxy matrix. The tensile strength, flexural strength, and fracture toughness of the composites were significantly increased when fillers were added to the composites. The effect of the addition of silicon carbide to jute fibre-reinforced epoxy hybrid composite was studied by Ramadan et al. [92]. Jute fabric-reinforced epoxy composites with silicon carbide ranging from 2 to 8% were fabricated by the vacuum assisted resin infusion method. The jute fibre-reinforced composites with 4 vol.% SiC exhibited excellent tensile and flexural strength. The mechanical properties of the composite were decreased when the SiC content was exceeded by 4 vol.%. Finally, they observed that the addition of SiC to jute fibre reinforced epoxy composites significantly increased their tensile, flexural, and impact strength. Ali and Ahmad [93] have investigated the compressive strength, thermal stability, and morphology of the empty fruit bunch and nanoclay-reinforced hybrid polyurethane foam composites. The result reveals that the hybridization of empty fruit bunch and nanoclay enhances the mechanical and thermal

Stage	Factors effecting fiber quality

Plant growth
- Species of plant
- Crop cultivation
- Crop location
- Fiber location
- Local climate

Harvesting stage
- Cell wall thickness, coarseness of fiber
- Size and shape of lumen, porosity, microfibril angle
- Adherence between fibers and surrounding structure

Fiber extraction stage
- Decortication process
- Type of retting method

Degree of ripeness
- Hollow fiber
- Optimum strength
- Lignification

Supply stage
- Storage conditions
- Transportation conditions
- Age of fiber

Fiber processing
- Dry/mechanical
- Wet/steam explosion and ultrasound

Measurement conditions
- Tensile speed, gauge length
- Moisture temperature
- Different cross section of fibers at different points

Figure 3: Various factors affecting quality of natural fibres.

stabilities of the composites more than the empty fruit bunch alone filled composites. Olumuyiwa et al. [94] have studied the tensile, hardness, and impact strength of the coconut shell powder-reinforced polyethylene composite for different nanofiller loadings (5–25 wt.%). The hardness is found to be increased when the coconut shell filler loadings increase and the tensile strength, modulus of elasticity, impact energy, and ductility of the composite decrease with the increasing coconut shell filler loadings. They have also suggested that coconut shell powder-reinforced polyethylene composites are suitable for interior parts of automobiles. The thermal stability, electrical conductivity, water sorption, and mechanical properties of three different nanofillers (plastic waste char (PWC), wood shavings char (WSC), and pinecone char (PCC)) reinforced epoxy composites are analysed by Ahmetli et al. [95]. The result has revealed that the incorporation of nanochar particles enhances the mechanical and ther-

mal stability of the composites. Among three nanochar-filled composites, plastic waste char-filled composites have produced more thermal stability and decreased the moisture diffusivity of neat epoxy. Table 1 presents the effects of various factors influencing NFRC. Figure 2 shows various factors influencing NFRC. Figure 3 shows various factors influencing the quality of the natural fibre.

3. Effect of Chemical Treatments on NFRC with Nanofillers

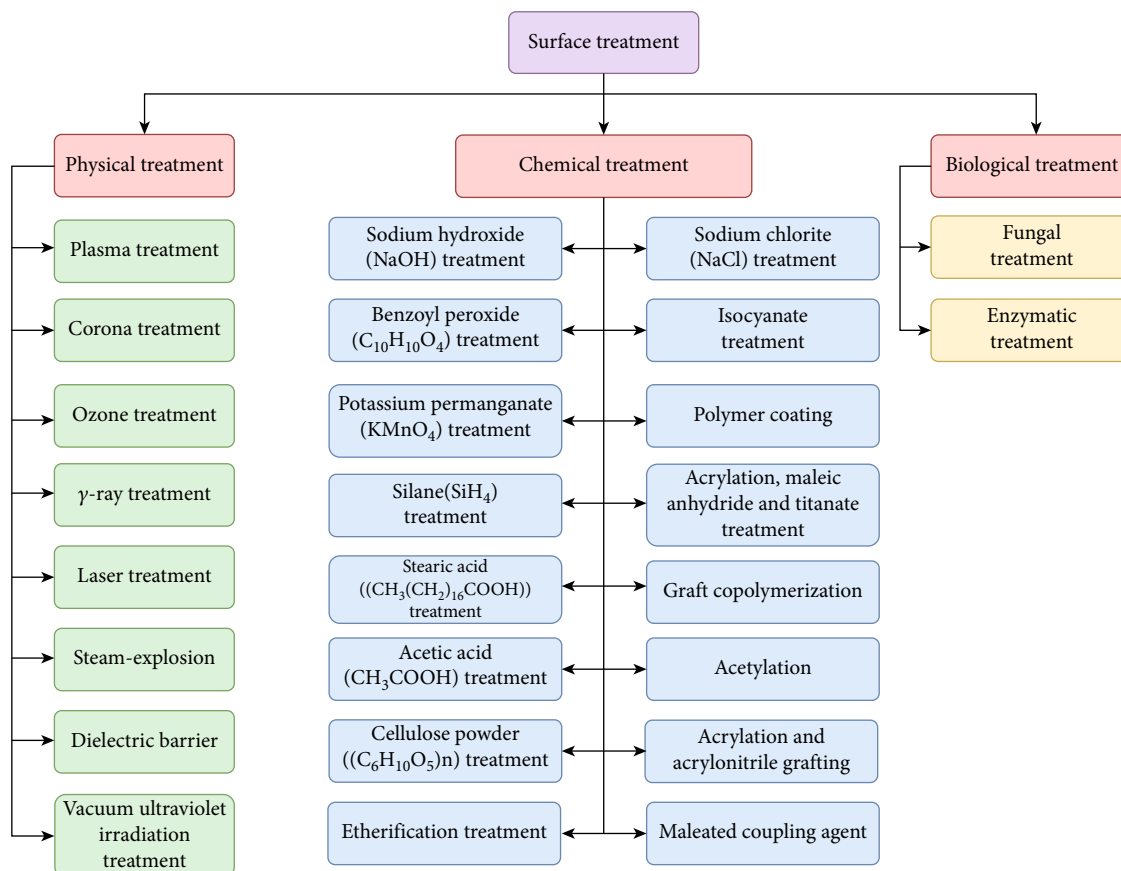
Plant fibres generally consist of cellulose, hemicellulose, lignin, pectin, water-soluble, and waxy elements [120]. From the chemical point of view, the primary constituents of plant fibres are cellulose, in which Dglucopyranose units are linked together by b-(1-4)-glucosidic bonds; hemicelluloses consist mainly of D-pentose sugar units strongly bonded with cellulose fibrils through hydrogen


FIGURE 4: Types of chemical treatments.

bonding; and lignin, consisting of aromatic alcohol units such as coniferyl alcohol, sinapyl alcohol, and coumaryl alcohol [121, 122]. Pectin acts as an adhesive to hold fibres together in bundles and bundles to nonfibrous tissues. Hemicellulose, pectin, and lignin act like a matrix, whereas cellulose acts as reinforcement to the matrix, contributing to the strength of the fibre. Plant fibres are amenable to modifications as they bear hydroxyl groups (OH) from cellulose and lignin. The hydroxyl groups may be involved in hydrogen bonding within the cellulose molecules, thus reducing the matrix activity. Surface modifications can either stimulate OH groups or create new moieties that can interconnect with the polymer effectively [123]. Fibre surface characteristics such as adhesion, porosity, surface tension, and wetting can be enhanced upon chemical treatment. Surface modification of natural fibres can result in significant physical changes such as the removal of an oil or waxy layer, changes in fibre structure, density changes, and surface roughness changes [124, 125]. The interfacial adhesion of the composites can be enhanced by altering the fibre surface, altering the matrix, or altering both. Chemical treatment is necessary to improve the adhesion and wettability at the interface [126]. Figure 4 shows the types of various chemical treatments of natural fibres. Mwaikambo and Ansell [127] reported that alkalization improved the characteristics of kapok, sisal, jute, and hemp fibres, resulting in increased fibre–resin adhe-

sion and more incredible interfacial energy. Teli and Jadhav [128] studied the influence of NaOH reagent on the mechanical properties of Agave augustifolia fibres with changing reagent concentrations (i.e., 2, 5, 10, 15, and 20%) for 1 h and found the most extraordinary mechanical properties at 15%. Sawpan et al. [35] showed that the flexural properties of hemp fibre were enhanced by mercerization treatment with a NaOH concentration of 5%.

Dhanalakshmi et al. [129] assessed the alkali treatment effect on the flexural strength of areca fibre-reinforced epoxy composites and observed that flexural strength improved after treatment due to eliminating the hemicellulose, lignin, pectin, and waxes. After mercerization treatment, the characteristics of henequen fibres/high-density polyethylene composites improved owing to the elimination of a few lignin and hemicelluloses from the fibre surface, resulting in a larger contact surface area at the interface zone [130]. The 5% NaOH treatment increased the mechanical characteristics of Borassus fruit fibres by increasing their surface area and improving their interfacial properties [131]. Paul et al. [132] subjected banana fibre to permanganate treatment and investigated the influence of permanganate treatment on the tensile and flexural properties of banana-polypropylene composites. They found that the tensile and flexural properties increased by 5% and 10%, respectively. Lopez Manchado et al. [133] subjected flax fibre to acetylation treatment and analysed the influence of acetylation

TABLE 2: Effect of various chemical treatments on NFRC.

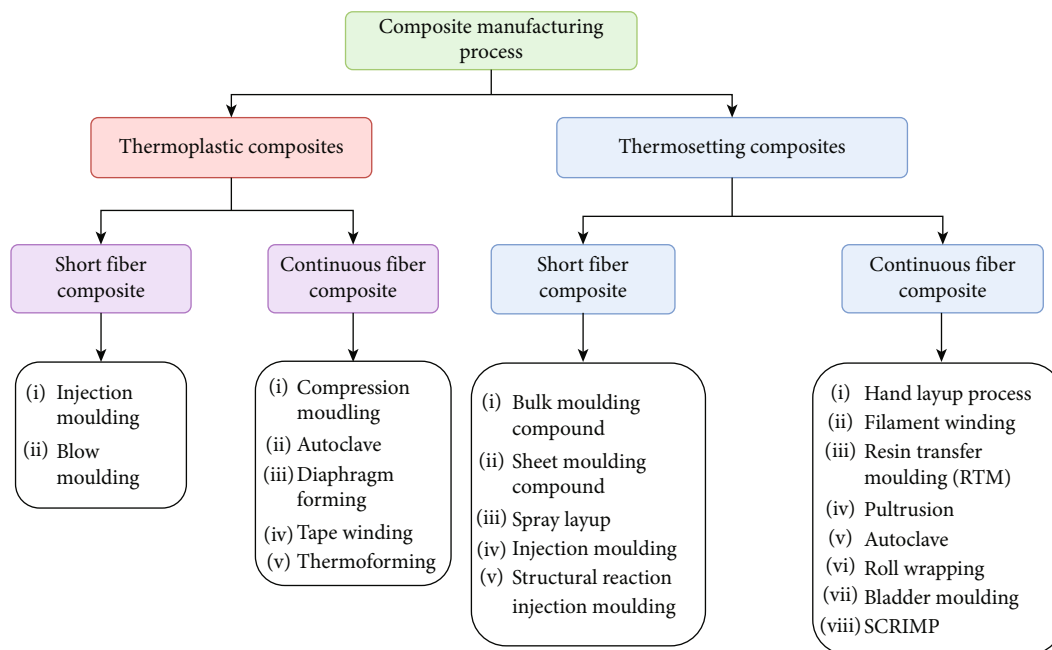
S. no	Fibres used	Type of chemical treatment	Effects	Reference
1	Sisal and roselle	Alkaline	Increased mechanical properties.	[141]
2	Alfa	Acetylation	Improved resistance to moisture absorption	[142]
3	Continuous henequen fibres	Silane (0.015 wt. %)	Improved mechanical properties.	[143]
4	Borassus fruit fibres	Alkaline	Thermal stability and tensile properties have been slightly improved.	[144]
5	Agave fourcroydes	Alkaline	Improved fibre matrix adhesion	[145]
6	Bagasse	Mercerization and acrylic acid	Superior tensile and flexural properties and reduced moisture absorption.	[145]
7	Unidirectional Roystonea regia	Alkaline	Improved tensile and flexural properties.	[146]
8	Sisal	Alkaline	Intracrystalline lignin and waxy, and resulted in improved mechanical interlocking.	[147]
9	Oil palm	Alkaline, acrylonitrile grafting, silane, acrylation, permanganate, acetylation, peroxide treatment	(1) Silane treatment-tensile strength reduced (2) Acrylation-enhanced tensile strength (3) Alkali and permanganate-tensile modulus increased (4) Silane and acrylate treatments showed optimum mechanical properties	[148]
10	Coir fibre	Alkaline	Interfacial adhesion between coir fibre and natural rubber was improved.	[149]
11	Sisal	Alkaline	The internal structure that resulted in a specific stiffness that was approximately the same as steel.	[150]
12	Kenaf	Alkaline	Improved mechanical properties	[151]
13	Ramie	Alkaline	Tensile strength of the ramie fibre improved from 4 to 18% compared to untreated fibre while Young's modulus decreased. Tensile strength increases as a result of a change in microfibrillar angle.	[152]
14	Bagasse	Alkaline	Improvement in tensile, flexural, and impact strength by 13%, 14%, and 16% compared to untreated fibres.	[153]
15	Sisal	Alkaline and benzoyl chloride treatment	Higher thermal stability.	[154]
16	Flax	Benzoyl chloride	Moisture absorption is reduced, and tensile properties are improved.	[155]
17	Jute	Alkaline	Improved dynamic mechanical properties.	[156]
18	Alfa	Styrene, acrylic acid, and maleic anhydride	These treatments resulted in reduced water uptake.	[157]
19	Kenaf	Alkaline	3% NaOH treatment led to ineffective removal of impurities. 9% NaOH cleaned the fibre surface.	[158]
20	Coir	Alkali and UV radiation	Higher shrinkage of the polymer grafted with fibre resulted in physicomechanical properties.	[159]
21	Sisal/5% nanomontmorillonite (MMT)/PP	Maleic anhydride grafted polypropylene	Improvement in tensile strength	[160]


FIGURE 5: Classifications of manufacturing methods.

treatment on the thermal and mechanical properties of flax fibre-reinforced polypropylene composites. They found that the thermal and mechanical properties were enhanced by 50% and 25%, respectively. Singh et al. [134] discovered that an alkali-treated agave reinforced epoxy composite has better fracture strain and interfacial adhesion between fibre and matrix than an untreated fibre. Shanmugam and Thiruchitrambalam [88] revealed that the maleated anhydride-treated jute fibre-reinforced high-density polyethylene composite exhibits improved adhesion between fibre and matrix, which enhances the dynamic and static properties such as tensile, flexural, and impact strength. Singh et al. [134] investigated whether an alkali-treated agave-reinforced epoxy composite exhibits greater fracture strain and interfacial adhesion between the hydrophilic fibre and the hydrophobic matrix than an untreated fibre. Arbelaiz et al. [135] studied that 20 wt% of NaOH-treated flax fibre-reinforced polypropylene (PP) composites exhibited greater maximum interfacial shear strength (ILSS) than untreated flax fibre-reinforced composites. De Rosa et al. [136] observed that the composite containing 10% acetic acid-treated okra fibre has less tensile strength and Young's modulus than those containing untreated okra fibre-reinforced composites. Mwaikambo et al. [137] investigated the effect of alkaline treatment on the tensile and impact strength of hemp/euphorbia composites and reported that the tensile and impact strength increased by 30% each compared to untreated composites. Lopez Manchado et al. [133] examined the influence of alkaline treatment on the tensile and flexural properties of bamboo/polyester composites and found that the tensile and flexural strength increased by 10% and 2%, respectively, over untreated composites. [138] reported the result of alkali treatments on the mechanical properties of a jute/polyester composite. They observed

that 10% NaOH-treated fibre composites for 3 h provided an improvement in tensile strength, flexural strength, and impact strength. Shanmugam and Thiruchitrambalam [88] attempted to increase the mechanical properties of palmyra palm/jute/polyester hybrid composites by alkaline treatment with 5% NaOH for a duration of 30 min. They found that the mechanical properties such as tensile, flexural, and impact strength increased by 40%, 55%, and 4%, respectively. The new cane fibres were alkali treated for 24 hours at different concentrations of 2, 4, 6, and 8%, with the highest tensile and flexural strength being revealed at 6% [139]. The effect of mercerization on the flexural and impact strength of coir fibre-reinforced polyester composites was investigated by Prasad et al. [140]. The treated fibre composites outperformed the untreated ones due to stronger interfacial bonding between fibre and matrix after 72 hours of treatment with a 5% NaOH solution. Ragunathan et al. have fabricated rice husk powder-reinforced polypropylene/recycled acrylonitrile butadiene rubber composites by a melt mixing technique. The rice husk-filled composite is fabricated with silane and anhydride. The composites are characterised by mechanical, FTIR, and morphological properties. The composites influenced by anhydride exhibit better mechanical strength than the composites treated with silane. The coupling agent increases the bond between the rice husk filler and the matrix. Table 2 presents the effects of various chemical treatments on NFRC.

4. Effect of Various Manufacturing Methods on NFRC with Nanofillers

Shibata et al. [161] investigated the influence of the volume fraction of kenaf and bagasse fibres on reinforced corn starch composites manufactured by compression molding

TABLE 3: Effect of various manufacturing methods on NFRC.

S. no	Fibre/matrix	Manufacturing method used	Effects	Reference
1	Long discontinuous kenaf and jute-reinforced polypropylene	Hot-press	Maximum tensile strength and modulus were obtained at 40% fibre weight fraction.	[179]
2	Short bamboo fibre	Injection molding	Improved mechanical properties.	[180]
3	Chicken feather fibre/PLA	Injection molding	The SEM image indicated that an even distribution of CFF in the PLA matrix existed.	[181]
4	Sisal, banana, jute, and flax/propylene	Extrusion and compression molding	Enhanced the mechanical properties.	[182]
5	Silk/gelation	Compression molding	Mechanical properties were increased.	[183]
6	Agave/epoxy	Hand layup	Wear properties were improved.	[184]
7	Luffa/coir/PP	Injection molding	Mechanical properties were improved.	[185]
8	Luffa/thermoplastic starch	Compression molding	Mechanical properties were improved.	[107]
9	Luffa and groundnut/epoxy	Hand layup	Mechanical properties were improved.	[105]
10	Alfa/polyester	Hand layup	Mechanical properties increased up to 5% NaOH treatment.	[186]
11	Snake grass/polyester	Hand layup	Mechanical properties were improved.	[187]
12	Tea/epoxy	Compression molding	Mechanical properties were improved.	[188]
13	Cissus quadrangularis stem fibre/unsaturated polyester	Compression molding	Mechanical properties were improved.	[189]
14	Short Sansevieria cylindrica/polyester	Compression molding	Mechanical properties were improved.	[111]
15	Tapsi fibre	Hand layup	Mechanical properties were improved.	[190]
16	Prosopis juliflora/epoxy	Hand layup	Mechanical properties were improved.	[14]
17	Tea leaf fibre	Compression molding	Mechanical properties were improved.	[191]
18	Flax	Compression molding	Mechanical properties were improved.	[192]
19	Long jute fibre yarn	Injection molding	Mechanical properties were improved.	[173]
20	Short date palm leaves	Injection molding	Mechanical properties were improved.	[193]
21	Wood flour/6% MMT/PP	Injection molding	Tensile and flexural strength were improved by 20% and 13%, respectively.	[194]
22	Sisal/2-5% MMT/epoxy	Compression molding	Tensile strength and tensile modulus were improved by 27% and 47%, respectively.	[195]
23	Sisal/5% nanoclay/epoxy	Compression molding	Water absorption was reduced by 1/3 times.	[195]
24	Hemp/nanoclay/polyester	Compression molding	Water absorption and tensile strength were reduced by 8% and 20%, respectively.	[196]
25	Bamboo/MMT/HDPE	Melt compounding	Mechanical properties were decreased.	[197]
26	Bamboo/CNT/epoxy	Hand layup	Tensile strength and flexural strength were increased by 6.67% and 5.8%, respectively.	[198]

techniques and found that an increase in the volume fraction of kenaf and bagasse fibres led to an increase in the flexural modulus of composites by 60% and 66%, respectively. Barone [162] studied the influence of fibre length on the tensile, impact, and flexural strength of abaca fibre-reinforced phenolic composites manufactured by the compression molding technique and found that the fibre length of 30 mm was optimum for obtaining higher mechanical properties such as tensile, impact, and flexural strength. Kafi et al. [163] assessed the effect of styrene chemical treatment on the crack propagation of jute fibre-reinforced polyester composites manufactured by compression molding technique and reported that the resistance to crack propagation was enhanced when jute fibre was treated with styrene. Sharma and Kumar [164] investigated the effect of the weight frac-

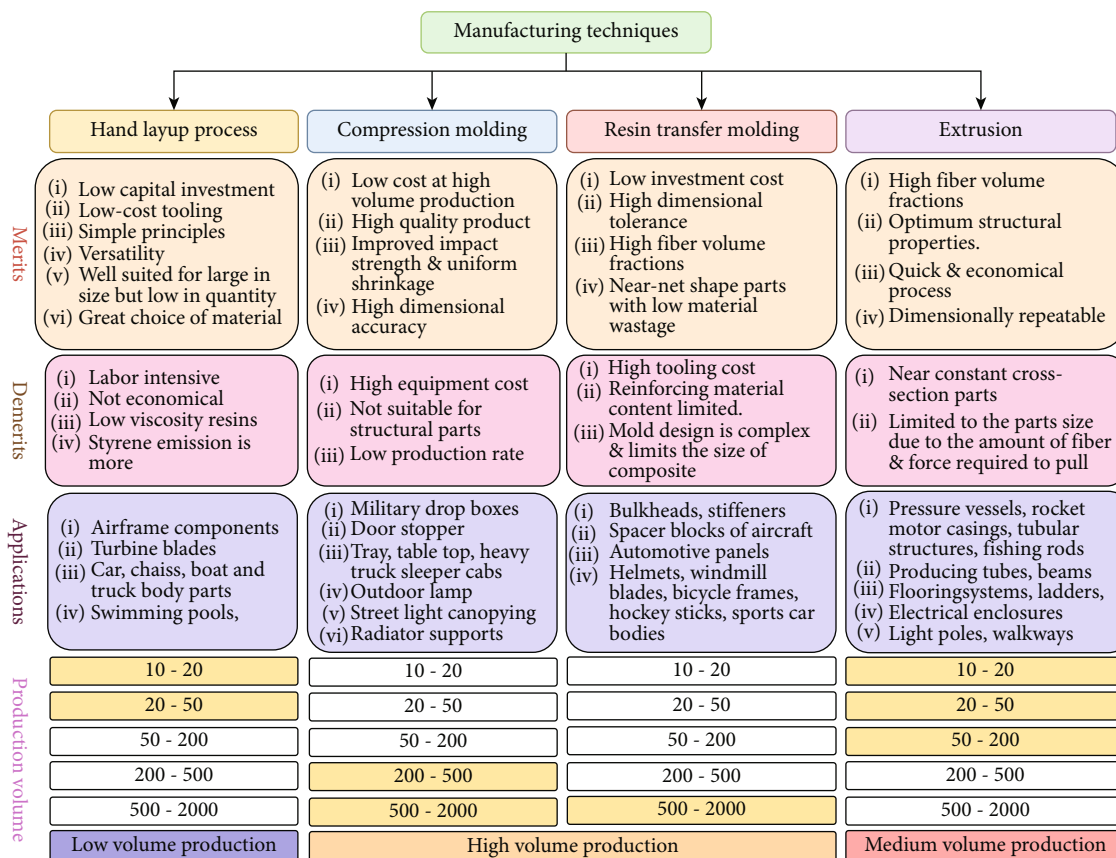
tion of fibre on the flexural strength of banana fibre-reinforced polyurethane composites manufactured by a compression molding technique. They found that a fibre content of 15% by weight was optimum for achieving better flexural strength. Alamri and Low [165] reported that recycled cellulose fibre-reinforced epoxy composites manufactured by compression molding techniques with the weight content of fibre up to 46% had higher fracture toughness. Cao et al. [153] discovered that bagasse fibre-reinforced polyester composites manufactured by compression molding with 65% fibre content by weight had a 30% higher impact strength than other weight fractions of fibre. Jandas et al. [166] studied the effect of the volume fraction of banana fibres on the polylactic acid composite manufactured by the compression molding technique with 25% fibre


FIGURE 6: Merits, demerits, and applications of NFRC.

content by volume, resulting in higher impact strength compared to other volume fractions of fibres. Bledzki et al. [167] studied the influence of volume fraction on the impact strength of jute and flax fibre-reinforced epoxy hybrid composites manufactured by compression molding. They found that the impact strength of the hybrid composite was improved when there was an increase in the fibre content by volume and also reported that flax fibre-reinforced composites had greater maximum impact strength than jute reinforced composites. Yousif and El-Tayeb [168] studied the effect of fibre length and fibre diameter on the wear rate of oil palm fibre-reinforced polyester composites manufactured by hand layup technique and found that the fibre length of 1–1.5 mm and fibre diameter of 350 micro m ^{2}notably reduced the wear rate by about three to four times compared to pure polyester resin. El-Tayeb [169] investigated the influence of fibre length on the wear resistance of sugarcane fibre-reinforced polyester composites manufactured by hand layup technique and found that the composite with a fibre length greater than 5 mm has increased wear resistance due to less fibre pullout present at that length. Assarar et al. [170] studied the flax fibre-reinforced epoxy composite manufactured by hand layup technique and reported that water aging significantly increased the strain rate by 61% and decreased the Young's modulus by 40% of the composite compared to the manmade glass fibre. Venkateshwaran et al. [171] analysed the influence of NaOH

reagent on the mechanical properties of banana/epoxy composite manufactured by hand layup technique. They concluded that 1% alkaline-treated fibre increased the mechanical properties of untreated fibre composites. Ray et al. [172] analysed the influence of NaOH reagent on the ILSS of a jute/vinyl ester composite manufactured by hand layup technique and concluded that the fibre treated with 5% NaOH for 4 hrs gave 20% progress in the ILSS. Prasad et al. [140] studied the influence of NaOH reagent on the impact and flexural strength of coir/polyester composites manufactured by hand layup technique and noticed that the coir fibre bleached with 5% NaOH for 3 days gave a 40% enhancement in the impact and flexural strength. Gao and Mader [173] fabricated a jute fibre reinforced polypropylene composite using injection molding techniques and noticed that the fibre length was significantly influencing the tensile properties of the composite. Karmaker and Schneider [174] fabricated jute and kenaf fibre-reinforced polypropylene hybrid composites using injection molding techniques and reported that the hybrid composite had higher mechanical properties with maximum jute fibre than kenaf fibre. Bledzki et al. [175] analysed the influence of acetylation treatment on the mechanical characteristics of a flax fibre-reinforced polypropylene composite fabricated by injection molding technique. They concluded that the mechanical characteristics of the treated fibre composite increased by up to 35% compared to untreated fibre. Yang

Manufacturer	Model	Applications
Rover	2000 and others	Rear storage shelf/panel and insulations
Opel	Vectra, Astra, Zafira	Door panels, pillar cover panel and instrumental panel
Volkswagen	Passat, Golf, A4, Bora	Seat back, boot-lid finish panel and boot-liner
Audi	A2, A4, A6, A8, Roadstar, Coupe	Back door panel, spare tire lining, seat back and boot-liner
Daimle chrysler	A, C., E and S class, Evobus	Car dashboard/windshield, door panels and pillar cover panel
BMW	3,5,7 series and other pilot	Headliner panel, door panels noise insulations panels, seat back and moulded foot well things
Peugeot	406	Parcel shelf, seat backs and rear/front door panels
Fiat	Marea, punto, brava, alfa romeo 146, 156, 15	Door panel
General motors	Cadillac De Ville, Chevrolet Trail blazer	Corgo area floor mat and seat backs
Toyota	ES3	Interior parts and pillar garnish
Saturn	L300	Door panel and package trays
Volvo	V70, C70	Natural foams, seat padding and cargo floor tray
Ford	Mondeo CD 162, Focus	Door panels, boot-liner, B pillar, door inserts and food trays
Saab	9S	Door panels, roof cover, trunk panel
Renault	Clio, Twingo	Rear parcel shelf
Toyota	Brevis, Harrier, Celsior	Seat backs, floor mats, door panels and spare tire cover
Mitsubishi	-	Instrumental panel, door panels and cargo area floor
Mercedes benz	A, C., E and S classes	Glove box, door panels, Instrumental panel support insulation, Moulding rod/apertures, seat backrest panel, trunk panel, seat surface/backrest, internal engine cover, engine insulation, sun visor, bumper, interior insulation, wheel box and roof cover.

FIGURE 7: Automobile applications of NFRC [213–217].

et al. [176] investigated the influence of maleated anhydride treatment on the tensile strength of a rice husk fibre-reinforced polypropylene composite fabricated by injection molding technique and noticed that the tensile strength of the treated fibre composite was improved due to enhanced adhesion between the hydrophilic fibre and the hydrophobic matrix. Pickering et al. [177] analysed the influence of fungal and NaOH reagents on the mechanical characteristics of a hemp/polypropylene composite fabricated by injection molding technique. They noticed that the mechanical characteristics of fungal-treated and combined fungal/alkaline-treated composites were increased by 22% and 32%, respectively. Wielage et al. [178] fabricated flax and hemp fibre-reinforced polypropylene composites using injection molding techniques and noticed that maleated anhydride-grafted treatment significantly enhanced the dynamic
FIGURE 8: Industrial applications of NFRC [218–220].

mechanical properties of the composites compared to untreated fibre composites. Figure 5 shows the classifications of manufacturing methods for the NFRC. Table 3 presents the effect of various manufacturing methods on NFRC. Figure 6 presents the merits, demerits, and applications of NFRC.

5. Industrial Applications of NFRC

Composites reinforced with natural fibres are gaining more attention in the market right now, as demand for high strength-to-weight ratios for industrial applications grows. The NFRC material has a high strength-to-weight ratio,

TABLE 4: Applications of NFRC in various fields.

S. no	Fibre	Components	Reference
1	Flax/sisal	Door trim panels and cable linings	[221]
2	Kenaf	Automobile dashboards, carpet padding, and products as rope, twine, bagging, and rugs	[222]
3	Jute	Brake pad and car insulation	[223]
4	Sisal	Ropes, mats, carpets, and fancy articles	[15]
5	Soybean oil	High-quality paint enamel	[224]
6	Coconut	Interior trim and seat cushioning	[225]
7	Banana	Household telephone stand	[226]
8	Soy oil	Structural panels	[227]
9	Kenaf/glass	Car bumper	[228]
10	Coir	Liquid storage tanks	[229]
11	Sugar palm fibre	Brushes, ropes	[230]
12	Mature coconut	Textiles (mats and carpets), building (thermal insulation), and automobile (cushion and seat covers)	[231]
13	Ichu fibre	Construction material	[232]
14	Tapsi/karaya gum	Food and pharmaceutical industries	[233]
15	Date palm	Insulation material in buildings	[234]
16	Azadirachta indica	Car roofing, interior and exterior panels, home appliances, container boxes, particle boards, and parcel shelves.	[235]
17	Tridax procumbens	Ayurvedic medicines to treat liver disorders	[84]

moderate stiffness, impact resistance, durability, improved corrosion resistance, and excellent fatigue strength. Because of these numerous benefits, NFRC has found applications in construction, aircraft, defense, hockey sticks, homes, surgical equipment, leisure, ship hulls, and automobile parts [199–203]. Snake grass, bamboo, kenaf, flax, vetiver, areca, and ramie fibres are used in various applications like office furniture, textile products, ropes, home appliances, fishing nets, the paper industry, packing materials, and building materials [204]. Textiles, households, oil pipes, packing products, and structural panels were all made with hemp/epoxy composites. The roof cover, electronic panels, trunk panels, seatback covers, packing items, and support insulation are all made from kenaf. Fibre-reinforced composites in the bast and seed category were used in the glove box, back rest panels, filter cloths, wheel boxes, and household furnishings [205]. The pineapple and sisal fibre-reinforced hybrid composites were used in underfloor-body panels, partition panels, door cladding, parcel shelves, two-wheeler bumpers, crates, drainage pipe, table mats, fishing boats, and automobile body building [206]. The coir/epoxy composites were used in the seat cushions, mirror casings, storage tanks, postboxes, helmet casings, brushes, ropes, bags, brooms, door shutters, and building panels [207].

Daimler Chrysler used flax, cotton, sisal, and banana fibres for floor panels, dashboards, seat back rests, door panels, and pillar cover panels of A, C, and E class models. Lotus Peugeot used hemp and sisal fibre reinforced composites for packaging trays, door panels, interior mats, seat backs, and body panels of the eco-elsie 406 [208]. The coir/natural latex rubber-reinforced hybrid composites were used in seat belt lining, soundproofing

panels, particle boards, and parcel shelves. Flax, sisal, and coir fibres with thermoplastic matrix such as PP, PE, PS, and PVC were used in automobile components, containers for logistics, interior parts, and household products. Nippon Electric Company (NEC) used kenaf fibres to reinforce PLA biocomposite for mobile phone casings. Museeuw Bikes used flax and hemp fibres reinforced with epoxy composites for racing bicycle frames and casings for musical instruments [209]. Flax/sisal/epoxy composites were used in parcel shelves, curtains, seat backs, back cushions, floor mats, and interior panels for top-class vehicles [210]. Door bolsters, centre consoles, carriers for covered door panels, seat back panels, covered components for instrument panels, rear deck trays, pillars, covered inserts, seat backs, carriers for hard and soft armrests, door panels, headliners, side and backwalls, load floors, and trunk trim were all made from bast fibre-reinforced PP/polyester composites [211].The sisal/glass/filler/epoxy-reinforced composites were used in the frames, toys, and electronic panels [81]. The flax/epoxy composites were used in the aerospace-military aviation fuselage, rudder, slats, and wings [212]. Figure 7 presents various automobile applications of NFRC. Figure 8 shows industrial applications of NFRC. Table 4 presents applications of NFRC in various fields.

6. Conclusions

The exploitation of natural fibre-reinforced composites by using an emerging technology transforms the future of the coming days. The hydrophilic nature of natural fibres affects bonding to a hydrophobic polymer, which results in poor

mechanical properties. To overcome this issue, the natural fibre surface must be modified to promote better interaction between fibre and matrix. The innovative and commercial applications of natural fibre-reinforced composites can help develop new revolts to maintain our natural properties. Natural fibres such as flax, snake grass, ramie, vetiver, areca, kenaf, hemp, kenaf, pineapple, and bamboo are gifted to the transportation industry because of their renewability, sustainability, eco-friendliness, and biodegradability. Composites reinforced with natural fibres are gaining traction in the market as the market's demand for high strength-to-weight ratio for industrial applications grows. This extensive range of different benefits has led fibre-reinforced composites to find more applications in the automobile, aerospace, marine, biomedical, construction, household, and sports industries. Incorporating nanofillers to plant fibre-reinforced composites introduces a positive effect on physical and mechanical properties. Many investigations are revealed, reviewed, and presented in this article concerning the effects of various factors influencing different types of chemical treatment and manufacturing methods and industrial applications of natural fibres and reinforced composites.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that there is no conflict of interest regarding the publication of this article.

The river sand is a primary parameter in the concrete structure. This work replaces accessible locally accessible substitution materials like red soil and manufactured sand (M-Sand). In this paper, the mechanical properties and durability of concrete containing red soil and M-Sand have been studied. In this investigation, M30 grade concrete was used, and tests were conducted for two sets of combinations; i.e., red soil as a partial replacement for river sand seems to be 20%, 30%, 40%, 50%, and 60%, and red soil as a partial replacement for manufactured sand (M-Sand) seems to be 60%, 50%, 40%, 30%, and 20%. The compressive strength (7 days, 28 days, 90 days), split tensile strength (28 days), and flexural strength (28 days) have been determined. The combination S4-50% river sand + 50% red soil and S9-70% M-Sand + 30% red soil gives more compressive strength than other combinations. Similarly, the combination S3-60% river sand + 40% red soil and S6-40% M-Sand + 60% red soil gives more flexural and split tensile strength than other combinations. The scanning electron microscope (SEM) analysis, EDAX analysis, and durability tests like alkalinity, sulfate attack, and chloride attack have also been studied.

1. Introduction

Sand near the water's edge has long been prized for its suitability as a building material. The use of natural river sand is being expanded to increase its use. River sand may not be of adequate quality to be used for construction in any case. River sand (M-Sand) can be substituted for M-Sand to support solid growth. Smashing hard rock yields manufactured sand. Washing and inspecting the smashed sand are done to use it for development purposes. M-Sand has a diameter of less than 4.75 mm. The demand for waterway sand for construction has led to an increase in the use of M-Sand. The total development cost can be reduced by using M-Sand as an optional fine entire material. There are no natural and dissolvable compounds in cement and pollutions, such as residue, dirt, or dust, that can affect its quality. To achieve cubical M-Sand, new technology is used. Machines currently in use are being used to get the fundamental evaluation zone.

Indian states like Tamil Nadu, Kerala, and Karnataka, located in the southern part of the country, have some of

the best red soil. When compared to the other soil, the red one has more waste properties. Mud and limestone have molded it into its current form. When the limestone is raised, the earth on the land's periphery is mixed together and turned into red soil. Iron oxide builds up and turns the dirt red during this process, which generates heat and causes it to interact with one another. Because of the sun's heat, the color of the dirt is turning red in areas with little rainfall. Indian red soil contains less phosphorus, nitrogen, and lime than other soils in the world. Despite this, certain grains like wheat, rice, cotton, sugarcane, and heartbeats can grow on red soil if the manures are appropriate.

The concrete's compressive strength for 7 days, 14 days, and 28 days increases at a rate of up to 30% M-Sand, then decreases as the M-Sand rate increases. It was found that 30% M-Sand was the ideal percentage for compressive strength considerations. The concrete's split tensile and flexural quality decrease as the percentage of M-Sand increases for the first seven and 28 days, respectively. It was found that 30% M-Sand was the ideal percentage for compressive strength considerations. As a result, the compressive, tensile, and flexural strengths increased by up to 30 percent. M-Sand was the most crucial factor in each case [1].

Red mud can be used up to 15% of the weight of cement in concrete, based on the results of a study on concrete subjected to different rates of reddish mud. There was an increase in workability with an increase in the amount of red soil in concrete, while there was a decrease in workability with an increase in the red mud percentage. We can conclude that the increase in compressive quality is a result of the lengthy contemplation. At the same time, the rate of red mud has increased by up to 15%. After that, the percentage of ruddy mud in concrete as a cement replacement decreased significantly. The flexural strength of concrete increased up to 15% of the red mud substance, but its restraint also reduced as the red mud substance increased in concrete. The part's pliable strength increased as the red mud's extents grew to a specific limit. The ideal amount of red earth to substitute for cement was 15%. Quality deteriorated after that. The need for water maintenance decreased as the amount of red mud in concrete increased. It implies that red mud has pushed concrete's toughness to new heights. Elasticity decreased as red mud content in concrete increased [2].

The quality and invulnerability of red soil blended cement surpass those of plain cement. When it comes to porosity, red soil blended solid has a higher porosity than bare concrete. Penetrability is nonexistent in red soil that has been separated from a plain concrete. Small pores in fine soil allow it to hold water more firmly, making it more porous. It is a waste of liquid. On the off chance that you utilize this solid as part of RCC, there will be no steel utilization. It is possible to use red soil as a component of RCC and prestressed concrete. Inquire about shell structures, prestressed, and RCC, to confirm that red soil can be used as a parcel of multistory building after development is finished [3].

The earth soil is not a standalone aggregate material appropriate for construction work most particularly concrete generation. The production of the concrete requires the good amount of the M-Sand for better performance [4].

Appropriate measurement of self-curing gels will increment the quality and serviceability of concrete. M40 grade concrete is compared with the conventional concrete with the various proportions such as 0.1%, 0.2%, and 0.3% [5].

Replace natural coarse aggregates with E-plastic waste within the run of 0–16.5% and full substitution of fine aggregates with M-Sand for M30 mix. The flexural strength and tensile strength increased by 11% and 6%, respectively, due to the addition of the E-waste [6].

The red clay-concrete interface shows softening behavior beneath distinctive ordinary stress levels. The mobilized shear stress decreases decently with the number of cycles and, in this way, remains consistent after 500 cycles of loading. The reaction of interface subjected to cyclic loading appears clear aeolotropy due to shear directions in each cycle. Interface shear stiffness and damping ratio decrease with expanding cycle numbers. The red clay-concrete interface speaks to a generally contraction behavior in cyclic and postcyclic direct shear tests. The cyclic loading does not lead to degradation for postcyclic shear strength [7].

The expansion of red mud improved 7 days toughness due to the quickened hydration prepare, whereas decreased the workability and the mechanical properties of UHPC. The debased workability may influence the application within the building with complex shapes, but it can still be connected in common development. An ultrahigh strength of UHPC counting 40% red mud can be produced after high-temperature curing, in spite of the fact that the addition of red mud decreases the compressive strength [8].

The comprehensive utilization of red mud is primarily found in three areas: the development and chemical industry, the natural assurance and horticulture industry, and the profitable component extraction industry. A brief report is additionally made on the related research of ruddy mud within the areas of cement, concrete, glass, ceramics, adsorbents, geopolymers, catalysts, composite materials, sewage treatment, squander gas treatment, soil advancement, and profitable component recuperation [9].

The axial compressive behaviour of concrete column is improved significantly, by partial substitution of sand with 60% M-Sand for M30 grade concrete [10].

The exploratory work carried out by preparing five concrete mixtures changing 10% of M-Sand extending 60–100 percent by weight of fine aggregate, 15% by weight of cement, and 1% by volume of steel fiber; the fraction kept consistent based on past considers. Different extents of M30 grade concrete were inspected by conducting mechanical and flexural conduct tests. The results obtained are palatable for 80% of the M-Sand substitution. Extra M-Sand substitution tends to decrease concrete strength [11].

Manufactured fine total (M-Sand) was partly replaced by E-waste (E-sand) in several rates (0%, 10%, 20%, 30%, and 40%), with 0.45 water cement (W.C) proportion. With

reference of Indian standard (IS) 10262:2019 rules, M30 grade concrete was arranged. The flexural, compressive, split tensile strength, and chloride permeability tests were performed on concrete with different mix extents, and test results were related with the result of reference concrete. Partly replacing of 20% factory-made sand (M-Sand) by E-waste (E-sand) yields greatest strength and superior chloride permeability with progressed smaller scale structure than ordinary concrete [12].

The main objective is to move forward strength of concrete by utilizing pozzolanic materials such as silica rage, metakaolin, GGBS as partial substitution to weight of cement by changing percentages (5, 10, and 15), and M-Sand as complete substitution to river sand. In this article, the test work is primarily concentrated on analyzing the mechanical strength, split tensile strength conjointly nondestructive tests like rebound hammer, and ultrasonic pulse velocity tests was performed at an age of 7 days and 28 days [13].

The behavior of concrete utilizes M-Sand at M30 and M65 grades for which test work is carried out to know the compressive strength, flexural strength, and split tensile strength of concrete. The examples were tried at the ages of 7, 28, 56, and 91 days of curing. The test results have appeared that the need of water required to fulfill the workability condition and subsequently quality of cement is additionally marginally expanded. The results appear way better execution to replace with natural sand [14].

The GGBS is replaced for the manufactured sand by 30%, 35%, 40%, and 45%. At that point, the strength is gotten by carrying out compression, split tensile, and the flexural tests. At that point, the optimization value of the GGBS is found as 30%, and the impact of measure of coarse aggregate is found out with the optimized value of GGBS. Then, the durability tests are carried out for the corrosive activity due to sulfate, chloride, etc. At last, the results are examined, and the conclusions are obtained [15].

Slump decreases as GGBS content increases. When fine aggregate is replaced by 30% GGBS, the compressive strength increases by 8%. When 30% GGBS with fine aggregate is substituted for the fine total, the ductile strength increases by 17%. When 30% GGBS with fine aggregate is substituted for the fine total, the flexural strength increases by 44%. 30% GGBS for M-Sand is the ideal replacement for fine aggregate, as the quality improves when the fine aggregate is replaced with 30% GGBS. Compressive strength increases with the addition of each additional 20 mm of aggregate. The strength of an aggregate decreases as the size of the aggregate decreases.

There were issues related to the extended W/B proportion and decreased mechanical properties because the cement substance decreased and the water substance expanded compared to the planned blend. Because of this, compared to the substitution method, the expansion strategy utilizing liquefied red mud is recommended. Liquefied red mud was used to replace some cement because of concerns about changes in smoothness and mechanical properties of the concrete. The mechanical properties of the liquid red soil-included concrete were affected by the high alkaline environment created by the development of red mud on the hydration things of cement. Testing shows that slag

cement contains 20% LRM in addition to liquefied red mud (LRM) in the concrete mixture [16].

A superplasticizer can improve the workability of manufactured sand concrete, which is lower than regular concrete. Compressive strength, split tensile strength, and flexural strength of M-Sand have all increased in comparison to standard concrete as a result of its expansion. All grades of manufactured sand concrete have low water absorption and low penetration. Conventional concrete, on the other hand, appears to have lower corrosion and sulfate- and carbonation-resistance in all grades of concrete. In the interfacial move zone (ITZ), the unpleasant and prolonged structure of M-Sand helped reduce microcracks and, as a result, a strong bond between the cement network and the M-Sand at ITZ [17].

Using neutralized red mud as a partial replacement for cement, it can be said that 15% neutralized red mud is the perfect amount to use in blended cement tests (0% to 20% substitution of cement by neutralized red mud). When it comes to compressive strength, M 30 grade neutralized red mud concrete (i.e., 15% substitution) expands 21.712% within 28 days [18].

Compared to sweater curing in the development of fly ash class-C (20%), concrete's compressive strength decreases in the M20 and M30 grades when used in ordinary water curing. For seawater curing, compressive strength is 35.13 N/sq. mm, and for seawater curing without fly ash on the 84th day, compressive strength is 15.57 N/sq. mm. Due to a lack of consideration for seawater curing in red soil, the ultrasonic beat speed appears to have been created. In comparison to conventional water curing, the concrete's rebound pound resistance value is increased by 20% with fly ash class C to 38 in the 84th day using seawater mending for M30 concrete in red soil [19].

In the three-day and seven-day tests, the quality of the sand substituted for river sand was superior to that of regular concrete. When compared to regular concrete, the three-day strength of the 100 percent smash sand blend is about a seven-day improvement. There were no noticeable differences in the results when 30% fly ash was substituted for cement, and 0.3 M NaOH was used. The blend with stream sand replaced by 100% pulverised is stronger after 28 days than the regular mix [20].

When it comes to fine aggregate, manufactured sand could be a viable alternative. The close proximity of nanosilica makes significant progress in the strength of concrete with counterfeit sand at a much earlier age than in standard concrete. Nondestructive tests like rebound pound yielded values of compressive strength that met the requirements of IS codes for both mixes without and with 2% nanosilica development. The ultrasonic pulse velocity (UPV) test results show that both concrete blends for the M20 survey are excellent and palatable. Increasing the rate of substitution of characteristic sand with made sand increases the modulus of flexibility [21].

The main difference between stream sand and fabricated sand was the shape and conduct of the sand when it was incorporated into a concrete mixture. Aside from its roundness, the material's length-to-width ratio (L/W) was significantly larger than that of waterway sand, which had a lower L/W ratio than the manufactured sand. Concrete

conduct is less dependent on the sand's molecule size, shape, and surface. Making sand management solid requires a higher water-decreasing operator in order to achieve the comparative usefulness of stream sand containing concrete. High-quality concrete can be produced by using sand that has a higher roundness and length-to-width ratio.

The expansion of red soil as a stream sand alternative shows excellent results in terms of quality and impenetrability. When red soil was added to cement as a substitute, the material's mechanical properties were significantly improved. The quality and obscurity of the solid are greatly improved when red soil is used in place of stream sand. Contrasting stream sand and red soil, the effect quality property of red soil is usually quite good [22]. In place of stream sand, it is possible to use the powdered waste generated during the cleaning of fired tiles.

As solid properties improve in solidarity, engineered sand becomes a more important component in the production of superior cement. It is possible to reduce the environmental impact of solid concrete projects by using ultra-high-quality cement and fabricated sand instead of readily available waterway sand. When compared to regular, customary cement, the ultra-high quality cement made with made sand offers superior performance. The manufactured sand can be used in concrete as a partial or complete replacement for stream sand. When compared to typical regular cement, produced sand exhibits superior compressive quality when used in its place 100% [23].

Fractional substitution of metakaolin for cement and M-Sand for fine aggregate can significantly improve the compressive and flexural strength of concrete, allowing for new designs. M-Sand can be used as a limited substitute for conventional sand in specific applications. Using M-Sand in place of regular sand has a perfect substitution rate of 100%. Strength also rises as the rate at which metakaolin and M-Sand are produced and consumed increases [24].

Three grinding stages are recognized and shown for the red clay-concrete interface shear practices, to be specific coordinate adaptable stages, plastic softening stages, and remaining contact stages. Clay matrix furrowing developments on the interface are at the heart of each one of these examples. When the clay and concrete surfaces are in close contact, the shear quality on the interface is primarily influenced by an increased cohesion and grinding strength. The measured peak and remaining shear strength values in the smooth interface tests are remarkably close to each other with no shear development observed in the tests. It is clear that the shear failure plane lies on the clay–concrete smooth interface because the red clay's strength parameters are higher than those of the smooth interface [25].

Expansion of nanosilica leads to a noteworthiness increase within the characteristic strength and durability of concrete. Substitution of cement with 0.5% of nanosilica gives more strength than the M-Sand mix conjointly; the durability has been extended compared to the M-Sand mix. The self-weight of the nanoblend is lighter than the M-Sand and the conventional blend. The workability decreases with the addition of nanosilica compared to the routine blend and the M-Sand mix. The infiltration level of chlorides and acids is less in nanoconcrete compared to that of conventional and M-Sand blend [26]. Increment in

TABLE 1: Properties of fine aggregates.

Particular	River sand	M-Sand	Red soil
Specific gravity	2.633	2.623	2.537
Water absorption	1% by wt	2% by wt	4% by wt

red mud substance diminishes the compressive strength as well as tensile strength of concrete. Ideal rate of the substitution of cement by weight is found to be 25%. Concrete organized by utilizing red mud is sensible in enhancing works and gives beautifully brilliant appearance. Workability of concrete may get affected with increase of red mud but it can be made strides by counting superplastcizers. We utilize mix of red mud and cement for nonfundamental work [27].

The compressive strength and flexure strength of concrete can be moved forward by halfway substitution of silica fume for cement and M-Sand for fine aggregate. M-Sand can be utilized as halfway substitution for the normal sand, and the compressive and flexure strengths are expanded as the rate of M-Sand is extended up to perfect level. The ideal rate of substitution of normal sand by M-Sand is 50% [28, 29]. In this work, an endeavour is made to replace normally accessible waterway sand with locally accessible substitution materials. In this examination, the result of red soil as a replacement for sand and M-Sand for mechanical properties and durability of concrete has been researched. The mechanical properties for concrete specimens have been done for samples containing red soil and fabricated sand (M-Sand). In this examination, two arrangements of various mixes were considered.

2. Experimental Procedures

2.1. Materials Used. All blends use Ordinary Portland cement (OPC-53 grade). Cement has a specific gravity of 3.15. The river sand used in concrete has a specific gravity of 2.63. The specific gravity of M-Sand used in concrete is 2.623, which is an essential source of fine aggregate replacement.

Red soil has a specific gravity of 2.546, which is closer to that of river sand and M-Sand than other types of sand. To make up for the lack of stream and M-Sand, it is now used as a partial replacement in concrete. As a fine aggregate material in the concrete mix, red soil is sieved through a 420 micron strainer. Both strong and union fewer particles are present in it. A 20 mm sifter and a 12.5 mm filter are used to sieve the coarse total. All blends have a specific gravity of 2.78, which is the same for all.

2.2. Chemical Composition of Red Soil. The chemical composition of red soil are nonsoluble material (90.45%), iron (3.60%), aluminium (2.90%), organic matter (1%), magnesium (0.70%), lime (0.55%), carbon dioxide (0.30%), potash (0.23%), soda (0.10%), phosphorus (0.09%), and nitrogen (0.08%).

2.3. Material Testing

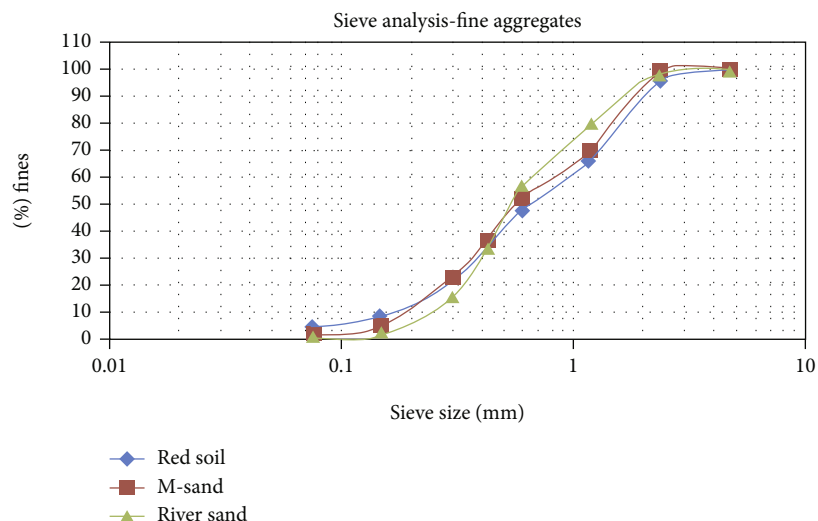
2.3.1. Fineness Modulus of Fine Aggregate. In order to control fine totals, sieve analysis is employed. They used


FIGURE 1: Sieve analysis graph for fine aggregates. Note: reviewing fine total materials was affirmed to zone II of table-9 of IS: 383-2016.

4.75 mm, 2.36 mm, and 1.18 m and 600 microns, 300 microns, and 150 microns and a container as filters for the study. Sifters were used to sieve the fine totals for a period of 10 minutes. The weight of the example was measured on each filter, and the total weight of the example was calculated. According to IS 383-2016, the strainer examination result for fine total materials and their prescribed range are shown in Table 1. In order to control fine totals, sieve analysis is employed. They used 4.75 mm, 2.36 mm, and 1.18 m and 600 microns, 300 microns, and 150 microns and a container as filters for the study. Sifters were used to sieve the fine totals for a period of 10 minutes. The weight of the example was measured on each filter, and the total weight of the example was calculated. The graphical portrayal of the sieve analysis result for fine total materials and their prescribed range as per IS 383-2016 is shown in Figure 1.

2.4. Properties of Fine Aggregate and Coarse Aggregate.
The properties of the fine total exposed to explicit gravity and water ingestion test as indicated by IS 2386 (part III) are shown in Table 1.

The properties of the coarse total exposed to explicit gravity, water ingestion, and fineness modulus test as indicated by IS 2386 (part III) are shown in Table 2.

2.5. Quality of Water.
As per IS456:2000, the water quality must be fulfilled. The accompanying boundaries are shown in Table 3.

The test results of the sample water are shown in Table 4.

2.6. Mix Proportions.
During this study, eleven different blends were analyzed in total. Fine natural river sand was used as the main ingredient in the control mix. Red soil is a partial replacement for a fine aggregate in the S1, S2, S3, S4, and S5 mixes, each of which has 20%, 30%, 40%, and 60%, respectively. S5, S6, S7, S8, and S10 are the mix of M-Sand and red soil that are traded for ordinary river sand.

tested. There were 150 mm × 150 mm × 150 mm cube specimens and 150 mm diameter × 300 mm height cylindrical specimens used for the compressive strength and split tensile strength, respectively. Prisms of 100 mm × 100 mm × 500 mm have passed the flexural strength.

2.9. Durability Test. Red soil was used as a fractional substitute for river sand and M-Sand in concrete specimens that were tested for their strength. The cube specimens have been subjected to a durability test. Water curing has been applied

to the cast specimens. For a period of 28 days, the models were subjected to three different types of durability tests to determine the durability of concrete samples containing red soil and M-Sand. These tests examined the resistance to alkalinity, sulfate attack, and chloride attack.

2.9.1. Alkalinity Test. Alkaline attack on different concrete blends has been tested in accordance with IS 456 : 2000. Five percent sodium hydroxide (NaOH) water was used to immerse the concrete cubes. For this, three concrete

specimens were tested, one with red soil as a partial substitute for river sand and another with red soil as a partial substitute for M-Sand, immersed in a tub of soluble water containing 5% sodium hydroxide arrangement for aged 28 days. The results of tests conducted before and after treatment have been compared in terms of their weight. All examples show that the weight loss rate is the same. Percentage misfortune of significance of show and compressive strength was used to determine concrete's alkaline resistance [30–35].

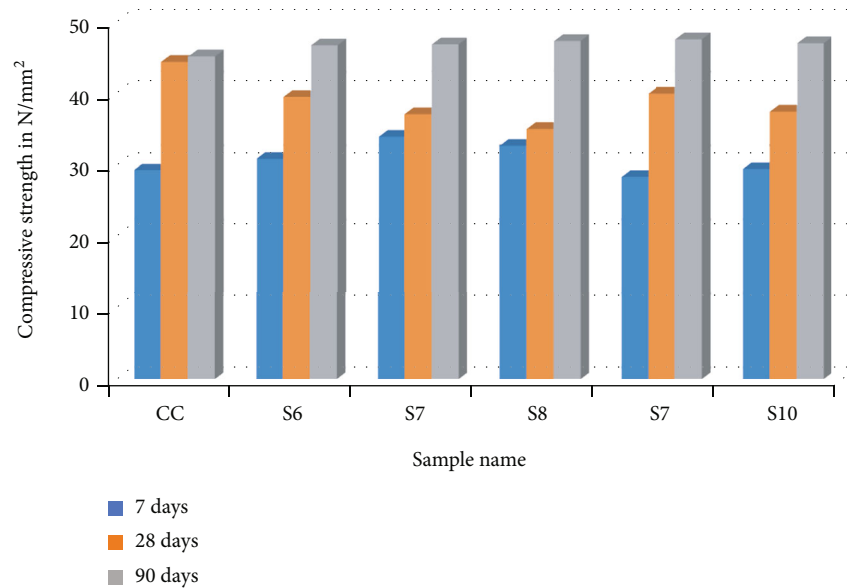
2.9.2. Sulfate Attack Test. According to ASTM C1012:2004, the resistance of concrete to sulfate attacks has been considered. The concrete cubes were submerged in sulfate water, having 5% of sodium sulfate (Na_2SO_4) and 5% magnesium sulfate ($MgSO_4$) by volume of water. For these two arrangements of concrete specimens that were taken, one set of concrete models was made with red soil as a fractional swap for river sand and another set containing red soil as a partial substitution for M-Sand, for aged 28 days and permitted to dry for one day. At that point, specimens were dunked


Figure 4: Compressive strength for M-Sand and red soil combination.

totally in a tub containing sulfate water having 5% of sodium sulfate (Na_2SO_4) and 5% magnesium sulfate ($MgSO_4$) for 28 days [36–40]. Following a time of 28 days, the specimens were taken and dried out. The weight of the models before treatment and after treatment is being looked at. The regular rate decrease in weight is found out for all the specimens as shown in Figure 2.

2.9.3. Chloride Attack Test. Two sets of concrete specimens were taken, one containing three concrete samples made with red soil as a partial substitution for sand and the other containing red soil as a partial substitution for M-Sand, for aged 28 days and allowed to dry for a day, according to BS 1881 standards. By completely immersing the models in a tub containing concentrated hydrochloric acid (HCL) with a normality of 1 N, the chloride attack test was carried out on concrete samples. It is necessary to add a certain volume of water to the water for 28 days [41–45]. These concrete samples were removed from the acid bath and dried out after a period of 28 days. There is a comparison of the specimens' weight before and after treatment. All samples' weight loss is averaged out to arrive at an overall weight loss percentage.

3. Results and Discussion

3.1. Compressive Strength. The compressive strength for concrete specimens containing red soil as a substitution of sand is shown in Table 7.

According to the above findings, the strength of the red soil and river sand-concrete samples was inferior to that of the standard mix after 28 days. However, after 28 days, the red soil in concrete begins to react with the cementitious materials in the concrete, resulting in a strong and durable product. In comparison to a standard mix, the strength of the concrete was increased by 1.5% [46–50]. The strength

Table 9: Split tensile strength for red soil and river sand combination.

Sample name	28-day strength (MPa)
CC	3.11
S1	2.46
S2	2.53
S3	2.56
S4	2.84
S5	2.85

for concrete samples containing red soil as partial substitution of sand is shown in Figure 3.

The compressive strength for concrete samples that have red soil as a replacement for M-Sand is shown in Table 8.

The compressive strength for concrete samples containing red soil as partial substitution of M-Sand is shown in Figure 4.

The results suggested that up to 70% of red soil as replacement material by weight of cement with M-Sand shows good compressive strength compared to conventional mix, but further addition of red soil results in the decrease of power. Similar to the previous results, the addition of red soil shows good strength in the later stage of concrete.

3.2. Split Tensile Strength. The tensile strength for samples containing red soil as a substitution for sand is shown in Table 9.

The split tensile strength for concrete samples containing red soil as a substitution for sand is shown in Figure 5.

The results suggest that up to 28 days, tensile strength for concrete samples containing both red soil and river sand was low compared to that of the standard mix. But after 28 days, the red soil present in concrete may react

28 days split tensile strength in N/mm^2
FIGURE 5: 28-day split tensile strength for red soil and river sand combination.

with the cementitious materials in concrete and show good tensile strength [50–54]. Tensile strength for concrete samples containing red soil as a replacement for M-Sand is shown in Table 10.

The split tensile strength for concrete samples containing red soil as substitution of M-Sand is shown in Figure 6.

The results suggested that up to 60% substitution for red soil by weight of cement with M-Sand shows good split tensile strength compared to conventional mix, but on further addition of red soil results in a decrease in strength. Similar to previous results, the addition of red soil shows good stability in the later concrete stage as shown in Figure 7.

3.3. Flexural Strength.

The flexural strength of samples containing red soil as a replacement for normal river sand is shown in Table 11. The flexural test specimen is presented in Figure 8.

The flexural strength for concrete samples containing red soil as substitution of sand is shown in Figure 9.

The flexural strength of the concrete samples containing red soil shows less power than that of the standard mix. The addition of red soil affects the flexural behaviour of the concrete to some extent. The flexural strength of the concrete samples containing red soil as a limited substitution for M-Sand is shown in Table 12.

The flexural strength for concrete samples containing red soil as a partial replacement for river sand is shown in Figure 10.

The flexural strength of the concrete samples containing 60% of red soil as a replacement along with M-Sand shows the same strength as that of the conventional mix, so this type of concrete can be used as a replacement in terms of flexural strength over the traditional concrete.

3.4. Durability Test.

The compressive strength for concrete samples containing red soil as a substitution for sand after the durability test is shown in Table 13.

For testing the durability of concrete samples, three different tests (i.e., alkalinity, sulfate, and chloride attack test) were conducted for concrete. In this investigation, the durability tests were conducted for 28 days. The 28-day durability test results for the concrete samples are shown in Table 14. The results indicate a slight reduction in the strength of concrete in the range of 4 to 7% as shown in Figure 11.

TABLE 10: Split tensile strength for M-Sand and red soil combination.

The percentage reduction in weight of the concrete samples containing red soil as substitution of sand after the durability test is shown in Table 15.

The compressive test results of samples having red soil as a replacement for M-Sand after durability test are shown in Table 14.

The percentage reduction in weight of the concrete samples containing red soil as a sand replacement after durability test is shown in Table 16.

Similar to the river sand and red soil combinations, durability is also being conducted for samples containing M-Sand and red soil. But compared to the previous results, the reduction in strength was quite lofty in contrast to earlier combinations. So, these river and red soil combinations are light ahead in preference in terms of durability as shown in Figure 12.

When combining the test results of all the experiments, it can conclude that the S9 combination shows promising result in terms of both strength and durability perspectives. Moreover, for detailed understanding regarding the compositions and microstructure of red soil in both the combinations, the scanning electron microscope analysis was conducted for both the variety samples.

3.5. Scanning Electron Microscope (SEM) Analysis Test.

The microstructure of the concrete mixes was examined utilizing scanning electron microscope (SEM) which for all intents and purposes makes a difference to imagine the microstructure of the hydrated cement paste. The SEM analysis of S9 combinations is illustrated in Figure 13. The figure shows that the soil particles in the concrete samples show a sponge-like structure and have a wide variation of diameter in size. Due to the existence of minerals, CSH gel formation

is more for S9 combination (70% M-Sand +30% red soil) that leads to give better compressive strength.

3.6. EDAX Analysis. To determine the purity of the red soil particles, EDAX analysis was conducted on the concrete samples. The samples were placed on the copper grid coated with carbon, and the whole setup was placed inside an air evacuated chamber.

The EDAX results for S9 combination (70% M-Sand +30% red soil) show that the silica level has tremendously increased to 77.48% atom as shown in Figure 14.

4. Conclusion

In this paper, we have tried out two sets of combinations, one set of manufactured sand with red soil and another set of river sand with the red soil of 10 proportions, based on the following results.

4.1. The Combination of River Sand and Red Soil

(i) The sample name S4 (50% of red soil and 50% of river sand) gives the better compressive strength when compared to all other proportions of river sand with red soil

(ii) Likewise, sample name S5 (60% of river sand and 40% of red soil) gives better flexural strength and split tensile strength compared to all other proportions of river sand with red soil

4.2. The Combinations of Manufactured Sand (M-Sand) and Red Soil

(i) The sample name S9 (30% of red soil and 70% of manufactured sand) gives high compressive strength compared to all other proportions

(ii) Likewise, the sample name S6 (60% of red soil and 40% of manufactured sand) gives better flexural strength and tensile strength in contrast against various proportions

4.3. Durability Tests

(i) For the durability test, the S4 and S9 combination samples have been taken, which shows high 28-day compressive strength

4.4. Justification

(i) Red soil has high porosity and less permeability, and it can absorb a considerable quantity of water compared to ordinary river sand due to its minor pores. The concrete surface is low in permeability, increasing the durability of concrete where the steel corrosion can be prohibited. Compared to 100% river sand as a fine aggregate in concrete, the complete substitution of M-Sand and red soil concrete has shown better performance. Still, in the future, these are potential materials for replacing river sand

(ii) The manufactured sand has many fine particles, which is more than that of natural aggregate, so it may give a large contact area, which is the ultimate reason behind the increased strength of samples. But there will be a decrease in the workability of samples due to the fine particles present, which absorbs the large quantity of water. Thus, to keep the surface of the concrete in wet conditions, a large amount of mater has to be added. Therefore, strength is significantly high for the samples containing manufactured sand as sand replacement

(iii) Red soil is used as a best replacement material for sand to reduce the demand that developed on river sand. The concrete samples containing red soil and river sand show higher compressive strength than the mix containing M-Sand and red soil

Data Availability

The data used to support the findings of this study are included in the article.

The material technology industrialization model is in promoting the adjustment of the financial market industrial economic structure. The experiment realized the adjustment of industrial economic structure by the adsorption of nano materials. TiO2-rGO was prepared firstly, and then Mn dioxide nanoparticles (HM NPs) were synthesized. The specific surface area and pore volume were determined by N2 adsorption BET method. The infrared spectrum was obtained by infrared spectrometer (MA). The sample was heated to 900°C at 10°C to determine TGA. In order to explore the surface composition and chemical element state of the material, X-ray photoelectron spectroscopy (XPS) was used with monochromatic al Ka ray. The structure and composition of the substance can be deduced by characterization. The Zr metal organic framework was applied to the adsorption of 2,4,6-trichlorophenol (2,4,6-TCP) in water. he experimental data show that the degradation efficiency of metronidazole is the best in the presence of visible light and hydrogen peroxide, which can reach about 80% in 60 minutes. The results show that nano materials and nanotechnology can promote the adjustment of economic structure of financial market industry, and have a great impetus to the entire financial industry.

1. Introduction

Nanotechnology, as one of the high-tech, has high value-added in the process of its development and application. It can not only bring great economic benefits, but also improve labor productivity and achieve better social effects. Science and technology is a double-edged sword. Nanotechnology brings great benefits and also has high risk characteristics. Nanotechnology is in the forefront of science and technology, and it is a new and high-level technology, with obvious characteristics of advanced research and many unpredictable factors. Therefore, to avoid harm and benefit, to reduce the negative effects of nanotechnology, we need the high guidance of philosophy. Among them, photothermal nanomaterials can convert the absorbed light energy into heat to increase the temperature of the surrounding environment, and have shown great application potential in tumor multi-mode imaging and optical therapy [1].

The development of financial technology will improve the efficiency of financial operations and bring a new environment for private enterprise financing and financial risk prevention, but it also brings new challenges to financial supervision [2]. According to the recent intensive signals released by the regulatory authorities, fintech will receive greater policy support, and fintech supervision will also be tightened simultaneously.

The application of nanomaterials is innovative for the development of financial industry. Song X uses fractal theory and thermal conduction theory to analyze the sensitivity of energetic materials, the correlation between thermal conduction and fractal dimension, and at the same time, he established a fractal heat conduction model for micron and nanometer energetic materials to verify the correctness of the model, Calculated the fractal dimension and surface fractal dimension of two nitramine explosives with different particle sizes. Although his research method is more detailed, but the consideration is not precise enough [3].

In this paper, nanomaterials are used as adsorbents to degrade organic matter in water, thereby greatly improving its photocatalytic efficiency. The adsorption efficiency of nano-adsorbents for heavy metal ions in water is better than other current adsorbents, and can be regenerated and reused. In the research of nanotechnology industrialization operation mechanism, transformation mechanism plays a connecting role. Universities and enterprises play an important role in the process of transformation. The State formulates relevant policies to encourage the transformation of nanotechnology achievements in universities and actively transform traditional industries. Health financial plays a role as a lubricant in the system of coordinated development of man and land, and the implementation of health financial plays an extremely important role in promoting the sustainable development of tourism [4, 5].

2. Financial Market and Nanomaterials

2.1. Financial Industry. Health financial industry should be based on people's needs for physical and mental health, with health as the goal, health therapy as the means, and recreation as the process to provide financial related services around the theme of health. The products provided by the health financial industry are the same as the general financial products, which are the specific products in the non physical form, but the production and operation modes are different. There are many production and service fields involved, and the industry boundary is fuzzy, so it has the characteristics of multi management; the differences of people's health and financial demand create the diversity of health financial products; only by optimizing the industrial structure, integrating management, management, technology and other means, and better coordinating the government and social resource elements, can we promote the scientific and healthy development of health financial industry [6, 7].

The most important thing of sustainable financial is to pay attention to the protection of ecological environment in the process of financial development, so as to avoid irreversible damage of financial resources in the process of development due to excessive development of natural resources and ecological environment damage [8]. Specifically speaking, sustainable financial means that in the process of developing tourism, we should also pay attention to the sustainability of development, and emphasize that the development of financial should be harmonious with local economy, society, culture and ecological environment. On the one hand, it means that the development of financial industry can not break through the local environmental carrying capacity; on the other hand, it means that the development of financial industry also needs to constantly innovate financial products and services according to the changes of economic and social forms, so as to continuously meet the market demand under different economic and social backgrounds [9, 10].

2.2. Nanomaterials Technology Industrialization Model. The dependence of nanotechnology industry on the development of nanomaterials technology can also be seen from the

dynamic development of high-tech industry. Without quantum theory, there will be no development of integrated circuits and computers; without the discovery of relativity and nuclear fission theory, there will be no widely used nuclear technology. Without the new achievements of molecular biology and genetics, there would be no biotechnology industry benefiting human beings [11]. This is mainly because the development of biotechnology is inseparable from the emergence of new research results. In the process of exploring this field, the theories and concepts formed will be widely used in our production and life. Human beings will establish new ideas which are quite different from the material world that can be observed by our naked eyes. It will greatly enrich our cognitive world and bring conceptual changes to human society. From the perspective of human development, nanotechnology promotes the miniaturization, high performance and environment friendliness of products, which will greatly save resources and energy, reduce excessive dependence on it, and promote the improvement of ecological environment [12]. In the input continuous image sequence, the gray value change of each independent pixel is subject to a single Gaussian probability function, then the Gaussian model of the nanoparticle is:

$$\mu_0(x, y) = \frac{1}{T} \sum_{i=0}^{T-1} f_i(x, y) \tag{1}$$

$$\sigma_0^2(x, y) = \frac{1}{T} \sum_{i=0}^{T-1} [f_i(x, y) - \mu_0(x, y)]^2 \tag{2}$$

In the formula, $f_i(x, y)$ represents the gray value of the i-th particle in the image.

As enterprises increase the demand for nanotechnology achievements, they are largely affected by the supply of nanotechnology achievements. Obviously, the more nanotechnology achievements enterprises have, the better position they can occupy in the competition. Different from traditional technological achievements, nanotechnology achievements are not completed by traditional experience or skills, but by the use of modern science and technology with high-tech content [13]. The research process is also a complex process, which requires a lot of human, material and financial resources. Therefore, there are two ways for enterprises to obtain nanotechnology achievements: one is to improve their independent research and development ability, improve their innovation ability, introduce talents to overcome difficulties, and obtain self-sufficiency of nanotechnology achievements. The second is to buy from scientific research institutes and universities for digestion and absorption. This scheme is more suitable for the development of enterprises, which not only saves the time of research and development, but also reduces the risk. At the same time, due to the competition of supply, the price drops, and reduces the purchase cost of enterprises [14, 15].

2.3. Industrial Economic Structure Adjustment. With the development of the economy and the improvement of production factors, industries are constantly growing and

changing, and adjustments and conversions between different industries often occur, thereby forming an industrial structure. Along with economic growth, the industrial structure is also undergoing transformation. Industrial structure adjustment refers to the mutual change and adjustment of production factors among various departments and regions. It includes two aspects: rationalization and advancedization of industrial institutions. The rationalization of industrial structure refers to the coordination of the quantity ratio of production factors between industries, the economic and technological linkage, in order to adapt to market demand and achieve the optimal industrial structure, the process of coordination and balance of all aspects of the industry and finally obtain the best benefits. The theory of sustainable development is closely related to the development of healthy tourism, and it is of great significance for the research and guidance of the development of healthy financial market [16, 17]. Only sustainable development can bring a healthy circular development result to finance.

Based on the perspective of spillover effects, the high-tech content of Internet products enables relevant practitioners to have higher quality and knowledge reserves. The flow of these high-quality employees promotes the overflow of manpower and can promote the improvement of the employment structure of the financial industry. It is of great significance for the financial industry that is positioned as a labor-intensive industry. On the other hand, Internet technology is applied to traditional industries to form a demonstration effect, through information sharing, knowledge and technology introduction, promote innovation, improve the production efficiency of financial industry and product added value, thereby improving the quality of financial industry development [18, 19]. Demonstration effect refers to the impact of changes in the consumption expenditure and income of some consumers or households on the consumption expenditure of other consumers and households, that is, consumers compare each other in space when they consume, and try to compare the consumption level. Above others or at least not below others of the same class. Therefore, consumers' consumption expenditure is not only affected by their own income, but also by other people's consumption expenditure and income.

3. Nanomaterials Adsorption Experiment on Scenic Wastewater

3.1. Experimental Equipment and Materials.
The main instruments used in the experiment are as follows: high performance liquid chromatography, ordinary optical microscope, laser confocal microscope, flow cytometer, enzyme-linked immunosorbent assay, laser, CO_2 constant temperature incubator, etc [20].

The main reagents used in the experiment are as follows: potassium permanganate, oleic acid, absolute ethanol, adriamycin hydrochloride, IR-780 iodide, sodium dihydrogen phosphate, disodium hydrogen phosphate, polyethylene glycol (PEG), dimethyl sulfoxide (DMSO), potassium bromide, MNP, etc [21].

3.2. Preparation of TiO2-rGO.
Firstly, 1.925 mg GO was dissolved in the mixed solution of 10 ml ethanol and 20 ml distilled water, and then 1.7 ml tetrabutyl titanate was slowly added into 10 ml ethanol to prepare mixed solution B. the mixed solution B was added dropwise into the high-speed stirring mixed solution A, and then transferred to a 50 ml reactor for 3 h and reacted at 200°C for 12 h. The product was centrifugally washed to neutral. The TiO2-rGO composite powder (rGO mass ratio of 0.5%) was obtained by washing once with alcohol and drying at 40°C for 24 h. Similarly, TiO2-rGO composite powders with 0-3% rGO mass ratio were obtained in a similar process [22, 23].

3.3. Synthesis of Manganese Dioxide Nanoparticles (HM NPs).
First use an electronic analytical balance to weigh 0.1 g of KMnO4 in a 100 ml flask, and then add 50 ml of ultrapure water. Stir the above solution on a magnetic stirrer at room temperature for 30 minutes, and the magnetic stirring speed is 600 r/min. After potassium permanganate is completely dispersed in ultrapure water, use a 2 mL syringe to take 1 ml of oleic acid (OA) and add it dropwise to the potassium permanganate solution at a very slow rate, and continue the reaction for 24 hours at room temperature. After the reaction, the original solution changed from purple-red to dark brown turbid liquid state. The post-processing is centrifugal treatment, the centrifugal speed is 10000 r/min, the centrifugation is three times, the centrifugation time is 8 min once, and the washing liquid is ethanol [24, 25].

3.4. Characterization of TiO2-rGO.
X-ray powder diffraction with cuka ray is used for the crystalline phase of the material. The scanning angle is 5° to 90° and the resolution is 0.02°. The specific surface area and pore volume were determined by N2 adsorption BET method. The infrared spectrum was obtained by NEXUS670 infrared spectrometer (MA) and KBr tablet pressing method [26]. The TGA (Q5000V3.15) was determined by heating the sample at 10°C to 900°C. In order to explore the surface composition and chemical element state of the material, X-ray photoelectron spectroscopy (XPS) was used with monochromatic Al Ka ray [27].

3.5. PTT Performance Evaluation.
Firstly, 0.3 mg/ml PDA-CE6 solution was prepared, and the heating conditions of laser wavelength of 808 nm and different energy powers of 2.0, 2.5, 3.0 and 3.5 W/cm2 were investigated; then 0.1, 0.2, 0.4 and 0.5 mg/ml PDA-CE6 solutions were diluted, respectively, as the experimental group, deionized water was used as the blank control group, and the laser irradiation power was 3 W/cm2 at the same wavelength. The temperature curves of different concentrations of pda-ce6 nanoparticles with different illumination time were plotted to evaluate the photothermal conversion ability of PDA-CE6 [28].

3.6. Adsorption Experiment.
Batch experiments were carried out in a 10 ml simulated wastewater system. In the experimental process, the concentration of adsorbent is controlled to 0.02 g/l, the pH of solution is adjusted by hydrochloric acid or sodium hydroxide, the ionic strength is mainly controlled by 1 m sodium chloride, and the pH affects the adsorption effect of TCP. We mainly control the pH range

from 3 to 10, and the kinetic experiment is carried out at the temperature of 30°C, and the concentration of TCP is 20 mg/L. In order to explore the thermodynamic characteristics of adsorption, the adsorption process was carried out in 10 ml of solution containing $0.5 \sim 20$ mg/L TCP at various temperatures of 303 K, 313 K and 323 K. Three parallel experiments were conducted in all experiments, and the average value of the three groups of experiments was taken as the experimental results.

4. Nano Materials in the Financial Market

4.1. Nanoparticles on Water Sources in Scenic Spots. Although the ecological benefits of financial industry cannot be accounted and counted independently, its characteristics and scale have been formed. At this stage, the state attaches importance to the ecological development of tourist attractions and financial products, and guides the financial industry to take the ecological road in policy. With the implementation of sustainable development strategy, the concept of ecological oriented financial industry is gradually introduced into China. Both the government and tourists have a profound understanding of the environmental impact of financial industry. The understanding of eco-financial and green financial is more and more in-depth. The ecological oriented financial mode is also getting more and more support from all walks of life. At this stage, although the financial industry is still mainly economic oriented, ecological orientation has begun to penetrate into all aspects of the development of financial industry. The degradation effect of nanoparticles on wastewater is shown in Table 1 and Figure 1. It can be found from the figure that the degradation efficiency of metronidazole by iron doped titanium dioxide in the presence of visible light and hydrogen peroxide is the best, which can reach about 80% in 60 minutes. Accordingly, the manganese doped titanium dioxide with the smallest band gap has poor degradation activity for metronidazole solution. This is because the structure of metronidazole is relatively stable and difficult to decompose, and the redox ability of holes or electrons generated by photocatalysts with too small band gap is also relatively weak. These two reasons lead to the poor degradation activity of manganese doped titanium dioxide. Therefore, iron doped titanium dioxide catalyst is the most suitable.

4.2. Nanomaterials on Tourism. The financial industry has entered the national strategic level. As a comprehensive strategic pillar industry, the development concept of ecological civilization of respecting nature, conforming to nature and protecting nature has been established. The financial industry has entered a new era of multi-dimensional, multi-dimensional and multi-dimensional development of economy, ecology and society. Under the guidance of the development concept of "innovation, coordination, green, openness and sharing" and the basic national policy of saving resources and protecting the environment, the financial industry has changed its concept and pursued more and more green development to promote the unity of environment and economy. Mesoporous silica is a new material developed in recent years. It has large specific surface area, regular pore structure, good thermal and chemical stability, so it has a wide application prospect in adsorption and separation, macromolecular catalysis and other fields. Silica is non-toxic, easy to obtain, exists in the form of aggregates, has good catalytic adsorption performance, and can provide enough pores and three-dimensional space for magnetic nanoparticles to be evenly dispersed in the interior. It can be used as a carrier to slow down the agglomeration of iron nanoparticles, and can be used to immobilize nanoparticles. The adsorption efficiency of silica for water sources of tourist attractions is shown in Table 2 and Figure 2. It can be seen from the figure that with the continuous reaction, the concentration of nitrate nitrogen continues to decrease. The removal rate reaches 98.3% in 30 min and almost 100% in 120 min. During the reaction process, 15.2% of nitrate nitrogen was reduced to nitrite nitrogen and remained in the solution in the form of intermediate by-products. With the reaction going on, it could be further converted into ammonia nitrogen, and 4.3% nitrite nitrogen remained in the final solution. The concentration of ammonia nitrogen has been increasing, and 79.4% of the final product is ammonia nitrogen. The total nitrogen decreased at first and then increased. Finally, the total nitrogen decreased by 15.5%.

Nanomaterials enterprises must rely on their own feasible business plans, excellent product functions and market prospects to attract venture capital, and obtain much-needed financial support and guidance in operation and management. This stage is also the key period for venture capital to consider entering and obtain certain equity, so as to lay the foundation for high return on investment in the future. In order to become a strategic partner or strategic shareholder of the enterprise. After the intervention of venture capital, due to the enhancement of financial strength and risk-taking ability of enterprises, some commercial banks familiar with the operation of two nano materials enterprises will moderately intervene and provide a certain degree of loan support. In addition, the entrepreneurial fund set up by the government to support high-tech enterprises also has a significant role in supporting enterprises at this stage. The main reason is that many companies today are the product of self-employment, and capital has become the most critical factor for these companies.

In the case of nano material adsorbent, the change of the number of tourists in recent five years is shown in Figure 3. As can be seen from the figure, the application of nano materials has greatly improved the health of tourist attractions. Especially in 2016, the number of tourists reached the peak in nearly five years, with 7.01 million. The change of the flow of people naturally affects the whole financial industry. Financial industry is a comprehensive industry, which is determined by the consumption characteristics of tourists. On the one hand, the consumption process of financial almost includes all the contents of life, that is, the multiple needs of food, housing, tourism, transportation, shopping, entertainment and so on during the period from leaving home to returning to the settlement. In order to meet the multiple needs of tourists, there must be a variety of different types of enterprises to provide tourists with goods and

services. On the other hand, financial consumption is diversified and tends to be personalized. Therefore, meeting the needs of financial consumers is not only reflected in the material aspects of tourist attractions, hotel facilities, transportation tools, but also in the cultural and spiritual aspects. This requires a higher level of cultural content and the quality of service personnel in tourist destinations. Therefore, as far as enterprises in different industries are concerned, the link of meeting the needs of consumers connects them together and makes them become a collection. The complexity and diversity of financial business constitute the comprehensive characteristics of tourism.

4.3. Changes in the Economic Structure of the Financial Market. To perfect the policy and regulation system of financial and cultural industry, we need to start from many aspects. First, break the status quo of coexistence of segmentation and industry barriers. Break through one of the management systems among industries such as the development and operation of financial and cultural attractions, financial accommodation and catering, financial and transportation, financial and entertainment, financial and commerce, and festivals and exhibitions, and establish and encourage various industries to compete with each other. A long-term policy and regulation system with multi-regulation and integration of cooperation and mutual promotion. Secondly, a sound and feasible safety policy and regulation system

should be improved. Formulate strict tourist attractions development and operation safety regulations, financial accommodation and catering safety standards, financial traffic safety laws and regulations, financial and entertainment business service quality standards, festivals and exhibitions safety guarantees and emergency response measures, and other financial and cultural industry guarantee policies and regulations system. Finally, improve the internal rules and regulations of various industries. Standardize the market order of various industries in the financial and cultural industry, and protect the rights and interests between the operators and consumers of the financial and cultural industry.

In the past, the environmental governance of financial industry is to control the end environmental pollution without changing the development mode, rather than the control of material flow and energy flow based on the source and the whole production cycle. In the past, the environmental governance was limited to the departments of resource management and environmental protection, rather than the cooperation of multiple departments and the joint governance of the whole society. In particular, with the implementation of the green awareness of financial industry by financial enterprises, the competition mode of financial enterprises has changed from the market competition mode to the dual competition mode of market competition and ecological competition. More and more financial enterprises adhere to the guidance of tourist satisfaction and gradually
Figure 2: The adsorption efficiency of silica for water sources in tourist attractions.
Figure 3: Changes in the number of tourists.
Figure 4: The proportion of China's financial industry's overall contribution to GDP.

improve the competitiveness of financial enterprises by providing more and more high-quality financial products and green financial products. And further strengthen the confidence of green development of financial enterprises. At the same time, with the improvement of tourists' education level and income level, the awareness of environmental protection and sustainable development of tourists is becoming stronger and stronger. The non environmental protection behaviors in financial cause less and less damage to the ecological environment of scenic spots, and the concept of green consumption is becoming more and more popular. The proportion of China's financial industry's comprehensive contribution to GDP is shown in Figure 4. In terms of economic benefits, the three major markets of domestic tourism, inbound financial and outbound financial in China's financial industry are booming in an all-round way. China has become the world's largest domestic financial market, the world's first largest international financial consumer, and the world's fourth largest financial destination country. China's financial industry has made more outstanding contributions to China's and the world's economic and social development, and has become an important member of the world's financial industry. Financial industry has become a new driving force to promote China's economic development. From the proportion index of financial industry's comprehensive contribution to GDP, we can see that the proportion of financial industry's comprehensive contribution to GDP showed an overall upward trend from 2009 to 2017. By 2017, the comprehensive contribution value of financial industry in China's GDP was as high as 913 billion yuan, accounting for 11.04% of the total, becoming an important industry in the tertiary industry.

5. Conclusions

At present, nanotechnology research in China has made some achievements, but the application of nanotechnology achievements is still in the primary stage, and the industrialization effect is not very ideal. Although nanotechnology has unique functions, it is not extravagant and needs practical implementation. Nanotechnology as the mainstream of high-tech industrialization, its progress is inseparable from the common development of computer technology, information technology and other fields. Only products and technologies recognized by the public can have a good market prospect. Nanotechnology, as a new technology, has a general cognition among researchers, but the general public's cognitive knowledge of nanotechnology remains on the surface, and some people are even misled by the words of some scheming people. They only see the negative side of nanotechnology and refuse or even reject nanotechnology and nanotechnology products. To a certain extent, it hinders the development of technology and social progress.

This paper defines the concepts related to the structure of financial culture industry, uses the Marxist theoretical basis related to the industrial structure of financial culture, and studies the innovation and development of the industrial structure of financial culture by using the methods of theoretical analysis, case comparison, literature research

and interdisciplinary research. The development of financial industry has been integrated into the global value chain and the world financial map; driven by innovation, China's financial industry has achieved remarkable improvement in quality and efficiency; the green development of financial industry has made considerable progress; the benign development of financial enterprises has become a strong support for the sustainable development of the industry. Of course, from these typical characteristics, we can find the problems of China's financial industry at present: the imbalance of supply and demand of financial industry, the difficulty of green transformation and upgrading; the lack of leading enterprises in the global value chain of financial enterprises, and the low competitiveness; the low value-added financial products have reduced the support for the sustainable growth of China's financial economy. The restriction of ecological environment on China's financial industry is increasingly apparent.

In this paper, a new type of photocatalyst TiO2-rGO was synthesized by the simultaneous high-temperature reduction of GO and high-temperature hydrolysis of titanium ester, which showed excellent photocatalytic activity under visible light. In this paper, the catalyst was characterized by XRD, DRS, TEM and other means, and its catalytic ability was tested by catalytic degradation of rhodamine B. The degradation results showed that TiO2-rGO under visible light showed excellent catalytic activity that TiO2 did not have in the past. In addition, through repeated degradation of Rhodamine B, TiO2-rGO showed excellent stability and reproducibility. Utilizing the advantages of nanomaterials can greatly reduce the degree of pollution of water bodies, ensure the cleanliness of water sources in scenic spots, and promote the economic development of tourism. The research is only for the financial industry, and the next research direction can be developed in other industries.

Architecture is the precipitation of history, not only the embodiment of technical level but also the inheritance of history and culture. Excellent architecture contains high historical value and emotional factors, and it continues to deepen over time. Nanotechnology is a new technology that was born in the late 1980s and is emerging. It mainly refers to the study of the laws of motion and interactions of electrons, atoms, and molecules in the composition system of matter in the range of 0.1 to 100 nm. Nanomaterials have special properties and structures, and the composite materials made of them have the effect of strengthening and toughening the polymer by virtue of their high-quality strength and toughness. Therefore, the aim of this text is to explore the application of nanocomposite building materials in modern architectural design and analyze the advantages and development trends of new building materials. The method in this paper is to use the method of experimental comparison to analyze the performance improvement effect of nanocomposite building materials on the current main building materials of concrete. By establishing a model to study the impact on the shrinkage and mechanical properties of cement-based materials, it can also improve the environmental performance and comprehensive evaluation of building materials. Corresponding conclusions are drawn through data comparison. When the amount of nanocomposite building materials is 1.5%, the chemical shrinkage value of the cement paste will increase by 58.2%, and the shrinkage strain will increase by 15.3%. When the fly ash content is 20%, the chemical shrinkage value of cement paste is reduced by 30.5%, and the shrinkage strain of concrete is reduced by 8.8%. Therefore, adding nanocomposite building materials to cement-based materials can promote cement hydration, optimize pore structure, and to a certain extent can make up for the shortcomings of mineral admixtures and achieve better improvement effects.

1. Introduction

Nanotechnology is a new technology emerging in the late 1980s. The emerging nanomaterial technology has been applied in many fields, especially in new building materials. Materials are the basic elements of architecture. As an important material carrier for the inheritance and development of modern civilization and cultural spirit, architecture carries decisive significance. Therefore, it is very important to construct elegant, beautiful, and practical buildings. The performance of materials is to integrate all buildings. Nanocomposite building materials have brought an unprecedented revolution to modern architectural design with

their unique properties and unique characteristics of light, electricity, heat, and magnetism. Making an appropriate material design strategy has become an important part of modern architectural design.

The traditional building materials are mainly cement concrete, and the current consumption is about 2 billion cubic meters, which is an indispensable building material at present [1]. However, as people's requirements for building design become higher and higher, some problems in concrete itself have gradually expanded. After years of exposure to the air, cracks and damage will inevitably occur, and the rigidity of ordinary cement concrete is too high, and the flexibility is insufficient. The environmental protection is

poor in the production process, which restricts the development of concrete in the future architectural design [2, 3]. As an indispensable part of building materials, the amount is considerable, and the requirements for stability and durability are very strict. The future development trend of modern architectural design is bound to be in line with the development of nanomaterials. Development is linked together [4]. Many scholars have done a lot of research on nanocomposites, and they all believe that nanomaterials are very important in new building materials, and they can get better development space in future special constructions [5]. In the research of foreign scholars, nano-conforming building materials are regarded as an unprecedented revolution. Combined with nanotechnology, many new materials can be developed, which are in line with today's architectural design concepts. The use of nanomaterials to shield ultraviolet rays can improve the antiaging yellowing performance of the wall, greatly improve the strength of plastic pipes, and increase the service life [6, 7]. Domestic research has also begun to explore the development and application of nanomaterials and nanotechnology in building materials and found that nano-conforming building materials also have a good self-cleaning function, which is useful for antibacterial and antimildew coatings in buildings and some conductive materials. Functionally developed conductive coatings have a positive guiding role [8]. Therefore, nano-building materials have great economic and social benefits in the field of building materials.

This article starts with the meaning and relationship between nanocomposite building materials and modern architectural design and explores the influence of different building materials on modern buildings. Through the experiment of improving the performance of concrete with nanomaterials, future solutions are proposed, so as to more accurately grasp the direction of modern architectural design and propose more optimized treatment plans. This will help promote the innovation and development of building materials. By comparing and analyzing specific experimental results, we can find out the balance between quality assurance and environmental friendliness and organically combine the two. Provide technical experience with reference value for future architectural design, obtain the similarities and differences of research directions through comparative advantage analysis, learn advanced experience, make suggestions for improvement in the selection of future building materials and in-depth understanding of more properties of nanocomposite building materials, strengthen the specialization and accuracy of architectural design, and provide theoretical basis for the field of materials science.

2. Theoretical Basis and Method

2.1. Core Concepts

2.1.1. Nanocomposite Materials. Nanocomposites are based on resins, rubbers, ceramics, and metals as the continuous phase and nanosized metals, semiconductors, rigid particles and other inorganic particles, fibers, carbon nanotubes, and other modifiers as the dispersed phase. The method uniformly disperses the modifier in the matrix material to form a composite system containing nanometer-sized materials in one phase, and the system material is called nanocomposite material. Since its inception, nanotechnology has gained the attention of the world. After more than 20 years of theoretical research, it has become one of the most promising technology industries [9, 10]. The use of nanotechnology can be applied to many industries, can greatly promote the development of productivity, and has achieved good results in medical, construction, military, and other aspects [11]. In the field of architecture, nanocomposite coating is the nanopowder used in the coating to get a kind of aging resistance, radiation resistance, high peel strength, or some special functions of the coating, in building materials which has been applied and has shown its unique charm. The same nanoparticle in different sizes will have different effects; different kinds of nanoparticles can also play the same role in the coating [12, 13]. Through this unique structure and excellent performance, it will be used in a wider range of fields, such as aerospace, transportation, culture, and sports. The development of new materials can determine the level of a country's industry, and all countries in the world have put nanocomposite materials in a priority development position and can be in a leading position in future international competition. There are many kinds of nanocomposites, including nanopolymer matrix composites, carbon nanotube functional composites, and nano-tungsten-copper composites [14].

2.1.2. Architectural Design. The so-called architectural design is the application of "virtual reality" technology in urban planning, architectural design, and other fields. Architectural design refers to a series of ideas and ideas about the building proposed by the designer according to the construction task before the building is built and then displayed through drawings or documents [15]. Excellent architectural design will consider various problems that occur during the entire building construction process and propose preparatory plans and emergency measures. Therefore, building construction is more of a holistic project. Architectural design must not only consider the construction requirements but also calculate the material preparation, construction organization work, and the conditions that various types of work rely on in production and construction [16, 17]. Only in this way can we coordinate and cooperate with each other, so that the entire project can be successfully completed within the predetermined investment limit and in accordance with the predetermined plan carefully considered. Architectural design in a narrow sense refers to the use of technology to turn virtual reality into reality, and design tools are becoming more and more advanced. It bids farewell to traditional drawing operations and uses human-computer interaction, real architectural space, and large-area 3D terrain simulation technology to make it more realistic. Accurately express the architectural design concept [18, 19]. Use dynamic interaction to meet the various requirements and uses expected by users and society, and conduct comprehensive and multiangle judgments and inspections of future buildings. At the same time, it can also achieve real-time switching and comparison of multiple environmental effects.

Observe the scene from any angle, distance, and degree of precision; accept customer experience feedback; and make timely adjustments, saving unnecessary cost and waste. With the development of society and the advancement of science and technology, the content of architecture and the problems to be solved are becoming more and more complex, and more and more related disciplines are involved.

2.2. Application of Nanomaterials in Building Materials

2.2.1. Application of Nanomaterials in Concrete Materials. Cement concrete is a general term for engineering composite materials that are mixed with water such as cement, sand, and stone to form a whole. Cement concrete has always played a pivotal role in the construction industry. As a traditional building material, it has made important contributions to the social industrialization and infrastructure construction of various countries. Its output and consumption are constantly increasing, but at the same time, the loss has always been high. [20]. Therefore, the use of nanomaterials to develop cement-based composite materials has become the focus of the material field. Under the new architectural design requirements, people's expectations for building materials are getting higher and higher, such as sound absorption, antifreeze, high strength, and high toughness. Nanomaterials have excellent characteristics such as small size effect, quantum effect, and surface and interface effects and combined with concrete can form very effective composite materials [21]. Use nanotechnology to develop new types of concrete, and use the excellent properties of nanomaterials to improve the strength, construction performance, and durability of concrete. In construction engineering, it can not only fill cement voids and increase concrete fluidity, but it can also improve the interface structure between cement stone and aggregate in concrete, improving the strength, impermeability, and durability of the concrete.

2.2.2. Application of Nanomaterials in Architectural Coatings. The core of the building is reinforced concrete, and the coating as the exterior of the building cannot be separated from the addition of nanomaterials. Traditional coatings always have various problems, such as poor scrub resistance, poor finish, and aging resistance. Nanocomposite coatings can be divided into nanomodified coatings and nanostructured coatings. Using some functions of nanoparticles to modify existing coatings to improve the performance of coatings, such coatings are called nanomodified coatings; for coatings prepared by some special processes, in which the fineness of a special component is in the nanometer range grade, such coatings are called nanostructured coatings [22]. The use of nanocomposite coatings can effectively improve the performance of concrete. When used in coatings, it will have antiaging, antiradiation, high peel strength, or some special functions, which greatly improves the use effect of coatings. Due to the particularity of its surface and structure, nanomaterials have excellent properties that are difficult to obtain with general materials. By combining with reinforced concrete materials, there is a great opportunity to obtain composite materials with excellent performance, so that the traditional coating function is modified, and macromaterials have many special and unprecedented excellent properties. Nanocomposite building materials can be used as composite materials for exterior decoration through nanocoating materials composed of nanoparticles, and traditional coatings can be modified by adding nanoparticles. The advantage of this method is that the cost is less and the preparation process is relatively simple. The actual use process is feasible and does not require a complete application of nanomaterials, which can improve the comprehensive performance of concrete. This is also the method of most current building material selection, and due to technical and cost issues, it is also in modern architectural design, one aspect to focus on.

2.2.3. The Application of Nanotechnology in Ceramic Materials. Due to the mechanical properties of the second phase, oxide nanomaterials have an artistic process that is different from ordinary ceramics. Relatively, the cost and consumption are naturally rising. Cermets containing 20% nano-cobalt powder are high-temperature-resistant materials for rocket jet nozzles. In this respect, they are superior to homogeneous traditional ceramic materials. In the field of building materials, ceramics have always been loved by people, so ceramic materials are added Nanomaterials are the development direction in modern architectural design. In recent years, the development and application of nanocomposite ceramics have been relatively mature. The introduction of nanodispersed phases into the micron-level matrix for compounding can greatly increase the fracture strength and fracture toughness of the material by 2 to 4 times and increase the maximum use temperature by 400°C~600°C; it can also improve the hardness, elastic modulus, creep resistance, and fatigue damage resistance of the material. Nanotechnology's porous ceramic (ceramic microporous material) material may filter and separate industrial waste gas. Porous ceramics provide strong heat resistance and chemical corrosion resistance, as well as being long lasting and low maintenance.

3. Experiment on the Influence of Nanomaterials on Concrete Materials

3.1. Experimental Materials. The main raw materials used in this article are cement, mineral admixtures, and nanocomposite silica. Cement is an ordinary Portland cement used in construction and meets the national safety and health standards. Since its inception, cement concrete has been the most important structural material in construction engineering and has been widely used. For cement-based materials, in order to better compare the effects, mineral powder and fly ash are also used to restrict the concrete by using its compressive strength and elastic modulus. Table 1 shows the performance of the cement used this time.

The performance data of the experimental materials are shown in Table 2. Among them, the average particle size of fly ash is 4.10 μm, the median diameter is 3.08 μm, and its specific surface area is 600 square meters per kilogram;

TABLE 1: Properties of cement.

Setting time		Stability	Compressive strength (MPa)		Flexural strength (MPa)	
Initial setting	Final coagulation	Qualified	3 d	28 d	3 d	28 d
2 h 30 min	3 h 42 min		22.3	50.1	5.4	8.9

TABLE 2: Physical properties of mineral blends.

Nature	Fine aggregate	Coarse aggregate
Specific weight (t/m^2)	2.62	2.6
Bulk density (t/m^2)	1.50	1.58
Void ratio (%)	42	38
Water absorption (%)	2.2	0.6
Crushing value (%)	1.2	0.35
Silt content (%)	2.9	1.1
Fineness modulus	2.5	1.3

FIGURE 1: Chemical shrinkage of cement paste with different silica content at various ages.

the average particle size of mineral powder is 12.34 μm, the median diameter is 9.89 μm, and the specific surface area is 360 square meters per kilogram. At the same time, the nanocomposite building material silica was used as the experimental material, and the fumed nanosilica hydrophilic-300 (hydrophilic type) produced by Shanghai Aladdin Biochemical Technology Company was selected. The purity is about 99%. The specific surface area is 300 square meters per gram, and the particle size is in the range of 7-40 nm. Nano-silicon dioxide (English name nano-silicon dioxide) is an inorganic chemical material, commonly known as silica. Because it is ultrafine and nano-scale, with a size range of 1~100 nm, it has many unique properties, such as optical properties against ultraviolet rays, which can improve the aging resistance, strength, and chemical resistance of other materials. Finally, in order to ensure a scientific experimental environment, the admixtures that are often used in the preparation of cement-based materials, including water-reducing agents and expansion agents, are also added. The water-reducing agent used in this test is Wanshan brand naphthalene water-reducing agent, which has a relatively stable chemical structure, with a solid content of 92% or more and a water-reducing rate of 18%-28%. The expansion agent used in this test is UEA-type expansion agent produced by Shandong Yantai Hongxiang Building Materials, with an alkali content of 0.3%, and the recommended dosage is 0.3%-0.5%.

3.2. Experimental Process. First, the density test and the specific surface area test are carried out. The density of mineral blends is measured by liquid displacement method. After high-temperature drying, it is cooled in a dry environment and then wiped clean with filter paper, and 80 g sample is taken out. Put it in a pycnometer, use ultrasonic vibration to completely eliminate air bubbles, and use formula to calculate density. After calculating the mass of the material in
the same way, put it into the FBT-9 full-automatic specific surface area tester for repeated calculations.

$$\rho = \frac{p}{v_2 - v_1},$$
$$W = \rho V (1 - \varepsilon). \tag{1}$$

Subsequently, add nanocomposite materials and concrete for mixing; first, add water and disperse in ultrasonic for 6 minutes; then, add cement, mineral admixtures, and additives; stir for 2 minutes at different mixing speeds; and place them in the curing room for curing after vibrating. You can get the bulk density and porosity of the sand. As we all know, the comprehensive performance of concrete can be reflected by slump, so the test of concrete slump is also essential. According to the "Standard for Test Methods of Mechanical Properties of Ordinary Concrete" (GB/T50081-2002), the pressure resistance test is carried out. The sample is placed directly under the testing machine until the sample structure is broken, and the average value is obtained after repeated testing. In the process of testing the chemical shrinkage test of cement, test pieces are made with the help of molds. After the test pieces are formed, they are cured in a standard curing room and then, the molds are removed. The shrinkage test pieces are placed in a constant temperature and humidity room for curing, and then put the test piece into it. Read the dial indicator value after the specimen rack.

Finally, the results can be obtained by analyzing various data. The added nanocomposite silica itself also has stronger pozzolanic properties. During the production process, it speeds up the setting time of concrete and increases the

toughness of the surface. The induction period of cement hydration exotherm can also be shortened by using nanosilica. In contrast, other mineral blends have not achieved this effect. Although the shrinkage time is accelerated to a certain extent, the compactness and uniformity need to be improved.

3.3. Experimental Significance. Through the above experiments, it can be known that the use of nanocomposite building materials can promote the process of cement hydration, increase the shrinkage of cement-based materials, and promote the hydration reaction of cement at the same time. Cement-based composite materials refer to Portland cement as the matrix and alkali-resistant glass fibers, general-purpose synthetic fibers, various ceramic fibers, high-performance fibers such as carbon and aramid, metal wires, and natural plant fibers and mineral fibers as reinforcements, a composite material formed by adding fillers, chemical additives, and water through a composite process [23, 24]. This shows that the current concrete-based architectural design ideas can be improved, and environmentally friendly, novel solutions can be added to match the nanocomposite materials that meet the quality requirements. As a basic issue of architecture, materials have always been the core of architectural design research. The selection of building materials is not only the use of different construction requirements and material characteristics but also the embodiment of architectural design and cultural skills. The architectural design displayed by different building materials is also very different. Therefore, in modern architectural design, the natural properties of the material and the emotional cognition of the material itself are equally important. Only in this way can we be comfortable in architectural design. Only when the professional skill attributes of architectural design and emotional belonging are integrated it is possible to make progress in the inheritance of traditional culture, science and technology, and concepts in architectural manufacturing. Therefore, the use of new materials, including nanocomposite building materials, is an innovation in life concepts and design concepts, which is particularly important for designers to grasp the relationship between architecture, space, and materials. At the cultural level, the continuous adjustment of architectural design is the development of design ideas and the enrichment of the practical process. The perfect combination of material materials and structural construction, as well as the natural environment, achieves practical, cognitive, and aesthetic social functions.

4. Data Analysis

As shown in Figure 1, the degree of shrinkage of cement is different according to different degrees of nanocomposite materials. With the increase of time, the change gradually increases. The chemical shrinkage without addition is a normal change, and the degrees of shrinkage are, respectively, 0 ml/g, 1.5 ml/g, 2 ml/g, 2.3 ml/g, 2.5 ml/g, and 2.6 ml/g. When the blending amount is 0.3%, the degree of shrinkage is 0.1 ml/g, 1.75 ml/g, 2.2 ml/g, 2.5 ml/g, 2.7 ml/g, and 3.2 ml/g, respectively. It can be seen that with
FIGURE 2: Filtration efficiency of different material fiber membranes for PM2.5.
FIGURE 3: Nanocomposite fiber membrane under an electron microscope.

the increase of time, the small amount of addition does not change much at the beginning, but after 50 hours, the gap begins to widen. When the blending amount is 0.6%, the degree of shrinkage is 0.15 ml/g, 1.9 ml/g, 2.5 ml/g, 2.8 ml/g, 3.5 ml/g, and 4.0 ml/g, respectively. When the blending amount is 0.9%, the degree of shrinkage is 0.3 ml/g, 2 ml/g, 2.6 ml/g, 3.2 ml/g, 3.9 ml/g, and 4.2 ml/g, respectively. These two compare at 40 hours. There have been different changes in growth rate. When the blending amount is 1.2%, the degree of shrinkage is 0.45 ml/g, 3 ml/g, 3.8 ml/g, 4.3 ml/g, 4.6 ml/g, and 5.1 ml/g, respectively.

The use of nanocomposite building materials can prepare excellent fiber membranes, which can effectively purify indoor air while adsorbing harmful components. As shown in Figure 2, the fiber membrane made of metal honeycomb mesh has a filtration efficiency of only 72% for PM2.5. The polypropylene nonwoven fabric made of nanoparticles can intercept 99.7% of particulate matter when filtering PM2.5 and more embodies the environmental protection characteristics of architectural design. The fiber membrane made of polyester fiber material can achieve 86.7% of filtration effect, which is far inferior to nanomaterials. In addition, the use of glass fiber materials can intercept 84.5% of particulate matter, while polystyrene can achieve a filtering effect of 69.8%. The comparison shows that in the future, under the
FIGURE 4: Thermogravimetric analysis diagram of nano-carbonic acid and phenolic resin after fusion and curing.

environmental protection and green architectural design concept, nanocomposite building materials will definitely access to a broad market.

As shown in Figure 3, the observation and research using an electron microscope can find that when the sampling speed is controlled to 1.0 ml/h, the particulate filtering polylactic acid material has extremely strong stability. Due to the low boiling point of chloroform, it is volatile and therefore, it will cause holes on the fiber surface. This creates a resultant force with balance properties during use. Under the same conditions of temperature, humidity, and spinning speed, the increase in voltage has a small effect on the diameter, but it will affect the depth of the hole. With the increase in voltage, the more obvious the hole formation, the deeper the hole depth and the hole and the clearer the interface. Under the same temperature, humidity, and voltage conditions, the injection speed has a small effect on the hole size and depth but has a greater effect on the fiber diameter. The fiber diameter increases as the injection speed increases. The high-quality properties of nanocomposite materials can resolve external influences and ensure the stability of the overall structure.

As shown in Figure 4 (figure from http://www.baidu.com/), by exploring the thermogravimetric analysis after the fusion and curing of nano-carbonic acid and phenolic resin, it can be seen that the thermal stability of nanocomposite materials is enhanced when making building materials, and the heat loss is low. On the whole, in the experimental environment, the three curves are in a state of weight loss as the temperature increases. At the starting temperature, the initial weight loss temperature is not much different, all of which are 100%. The first curve changes. It is 98%, 90%, 65%, 46%, and 44%. The second curve has a heat loss mass percentage of 49% at 800 degrees, and the third curve has a heat loss mass percentage of 44% at 800 degrees. In comparison, the slope of the first curve is small, indicating that the thermal reaction rate of the modified sol system becomes smaller, so that it is sufficient to obtain the thermal stability of the nano-carbonate and acid resin system after the modifier is added. There is increased performance and less heat loss.

5. Conclusion

With the continuous growth of the economic level and the improvement of the construction level, people's requirements for buildings are also constantly updated, which affects the development of architectural concepts, architectural design, building materials, and construction. Infrastructure construction is also an important industry for the development of a country's national economy, so the demand is very broad. In the current construction industry in most countries, the consumption of building materials accounts for more than half of the total consumption. 52% of the huge demand and consumption is concentrated in steel and cement. Therefore, the improvement of building materials will not only change the style of building design; it will promote the safety, applicability, and durability of engineering buildings. As an important branch of ecological environmental materials, according to its meaning, ecological building materials should refer to the coordination with the ecological environment in the process of material production, use, disposal, and recycling, to meet the minimum resource and energy consumption, minimum or no environmental pollution, and the best use performance; the highest recycling rate requires the design and production of building materials [25, 26].

Inferred from the current development speed, the problem of building energy consumption has gradually become an urgent problem that needs to be solved. It will not only cause a certain degree of waste but also cause considerable pollution to the environment. Therefore, under the influence of various conditions, new building materials occupy an increasingly important position. Many countries in the world have listed nanotechnology as an important national basic project. Although nanotechnology has not yet been widely applied to the market, a large amount of basic research has been completed at the technical and theoretical level, and some cutting-edge technologies have gradually been applied to cutting-edge fields. However, there are still some technical problems that have not been well perfected, such as how to control the structure and performance of nanomaterials. The cost of nanocomposite

building materials in modified concrete and architectural coatings is very high, and it will take time to fully apply. As a new discipline, nanotechnology will inevitably affect all areas of society, and it will inevitably have an inestimable effect on the performance improvement and use of traditional building materials. Nanocomposite building materials conform to the development trend of economy, environmental protection, green, and energy saving and have become the top priority of current architectural design considerations in the future and represent the future development prospects of the construction industry. At present, the nanocomposite building material system that has been timed is complete and diverse, and its share in the market continues to expand. With the promotion of China's sustainable development strategy and the development of the construction field, new building materials will surely have their unique advantages in the construction industry, shine brilliantly, and promote human development and progress.

Architecture, as a special expression of culture and history, integrates the national and ethnic styles and the customs of various regions in the early design stage. In the architectural design process, we must fully consider the cultural connotation and the future direction of architectural manufacturing. The performance of architecture should reflect the humanistic spirit of different times. Material is the material carrier of the building and through it reflects the spiritual temperament that the building should have. With the development and development of new technologies, architectural design has made great breakthroughs in the way of expression, giving designers more imagination. On this basis, the current materials should be used optimally, their shortcomings should be reasonably compensated, strengths should be used to avoid weaknesses, and the synchronization of the times should be emphasized.

With the development of society, people's purchasing power is gradually increasing, and more and more people choose to buy handicrafts. The popularity of handicrafts has also promoted the development of production technology and production materials, and high-quality handicrafts are most favored by consumers. As an enduring material, ceramics are also under continuous development. This article is aimed at studying nanoceramic materials and gaining a detailed understanding of the classification, structure, and manufacturing process of nanoceramic materials. In the experimental stage of this article, through the analysis of whether nanoceramic materials and technology are used in modern crafts, it is verified whether nanoceramic materials contribute to the advancement of modern craft design and the growth of product sales. This article shows through experimental research that the application of nanoceramic materials to handicrafts can not only increase its sales by more than 30% but also increase its sales unit price by 36%.

1. Introduction

People need materials in order to make products. In product design, material is the most basic thing to ensure the function and shape of the product. Regarding the definition of matter, it generally refers to the raw materials used by human beings as objects, which are the basis for the existence of all natural and artificial objects. Since the beginning of the Neolithic age, humans made stone tools consciously, so the design and materials were closely integrated. Design is an engraving activity with dual functions of material and spirit, physiology, and psychology. Material is the basic condition for realizing design. More than a century later, the development classics of product design reflect strong nationalization and various languages and cultural contents, with rich spiritual and cultural connotations. There are many types and quantities of materials suitable for modern product design. People have used ceramics as raw materials for a long time. Silicon has long been one of the most basic raw materials for making ceramic materials. With the continuous innovation of society, most of the new ceramic materials and ceramic products are mainly composed of pure oxides, carbides, and nitrides. In the era of modern industrial production, ceramics still bear an important role and mission in modern product design by virtue of its unique color, texture, and inherent quality. Handicraft refers to the art of handicraft with a unique style. It is different from the arts and crafts that mass produce standardized daily use handicrafts by means of large-scale industrial mechanization. Handicrafts refer to products made purely by hand or with the help of tools.

Decorative art is a bridge connecting human spiritual civilization and material civilization. Ceramic art is a formal feature. It not only embodies the value of beauty in appearance but also embodies the craftsmanship and production technology of people to create beauty. At the same time, the combination of craftsmanship and decoration needs to be manipulated through artistic techniques to get its exquisite artistic effect. More and more people are pursuing ceramic art. Our ideal lies in its changes. We use the beauty created by ceramic art to embellish people's daily life environment, improve people's lives, and further

enhance people's artistic vision. Ceramic art is designed to meet the material and spiritual requirements of the people in their work and life. Indeed, as a product of traditional Chinese culture, ceramics have undergone continuous development, change, and innovation of decorative patterns in the early lacquered pottery era. The materials and technology of ceramics and the continuous update and progress of craftsmen reflect the diligence and wisdom of the Chinese people. It has become China's far-reaching cultural heritage. Of course, we should look at the mainstream of Chinese traditional culture and the fundamental source of national culture. The continuation of this traditional culture and the continuity of the evolution of totems depend on the study of decorative images that are close to the reliability of human life and art. All in all, the application of ceramics in the design of modern industrial products shows its unparalleled charm and appeal. Modern ceramic decoration design is inseparable from the trend of the times, modern craft materials, technology, and aesthetic preferences. We must keep pace with the times, grasp the requirements of the times, grasp the market and technical information of modern ceramic art and crafts, and strive to create more and more updated ceramic products. The design of modern art and crafts needs to combine the completion of ceramic art with art and then make new features of pottery.

With the continuous development of society, ceramic materials and their production technology are also constantly evolving. Simonenko et al. stated that nanocrystalline (19 nm) silicon carbide powder is made by combining the sol-gel treatment of the finely dispersed and chemically reactive SiO_2-C system with the carbothermic synthesis under vacuum medium temperature (1400°C). Porous ceramic materials can be produced by hot pressing methods [1]. In addition to porous ceramic materials, Scribot et al. have shown through experiments that using red mud and broken glass soda as raw materials, heat treatment at 600-800°C for 1 hour can also successfully synthesize new foamed geopolymer materials [2]. In the research on the production of ceramic materials, Kairakbaev et al. used the Mossbauer effect to establish the distribution of iron ions during the firing of acid-resistant ceramic materials using production waste as raw materials. Studies have shown that by calculating the area of the double peaks of the spectrum, the iron compounds on the surface of the studied sample are mainly represented by hematite. In this case, the acid resistance of the sample is reduced [3]. At the same time, in the further development of ceramic materials, Baranova and Valiakhmetov have shown through continuous practice results that through the minimum preparation of raw materials used, a corundum material with high thermal stability can be obtained. The corundum material can be used to produce the parts of the molybdenum heater insulator in the voltage stabilizer furnace for the stabilizer casting blade made of high-temperature alloy [4]. Through the continuous advancement of ceramic manufacturing technology, the development of nanoceramic materials is getting faster and faster. Yin et al. prepared Al_2O_3-based micro-nano-composite ceramic tool materials by hot pressing. The tribological behavior and wear mechanism on metals (stainless steel, chromium

steel) and cemented carbide (Si3N4) were studied. Yin et al.'s research shows that when it rubs with stainless steel, the friction coefficient is the smallest and the wear rate is the largest [5]. With the continuous development of nanoceramic production technology, the use of nanoceramics in various fields is also becoming wider and wider. In medicine, Liu et al. said that the nanoceramic coating on the surface of titanium-based metal implants is a potential clinical choice in orthopedic surgery. Stem cells have been found to have osteogenic ability, and it is necessary to study the effect of functionalized nanoceramic coatings on stem cell differentiation and proliferation in vivo [6]. In the application and research of ceramic crafts, Ivkovi et al. studied Belgrade ceramic craftsmanship and craftsman's archaeology through ceramic petrography and chemical analysis, as well as the production technology of these porcelains, including ceramic bodies, slips, and glazes. And use the chaîne opératoire conceptual framework to explain the results [7]. Although ceramic manufacturing technology and manufacturing processes are beginning to be used in more and more fields, the cost of production and use of ceramic materials is much higher than that of other materials, and ceramic materials require high technical levels of production, especially nanoceramics. It needs to use the latest production equipment for production, the production cycle is long, and the cost is high.

The innovation of this article is to incorporate modern nanoparticle ceramic technology into the design of modern handicrafts and to apply advanced nanoceramics to the design of contemporary handicrafts, so that contemporary handicrafts can fully demonstrate the beauty of the fusion of modern technology and modern design. I mainly researched the characteristics and production technology of nanoparticle ceramics to find the most suitable ceramic materials for contemporary handicraft design, so as to better promote the design and promotion of modern industrial products. Because of its high strength, high hardness, corrosion resistance, high temperature resistance, and other characteristics, ceramic materials have become the development center of new materials and received extensive attention, and the application field is also expanding.

2. The Application of Nanoparticle Ceramic Materials in the Design of Modern Handicrafts

2.1. Ceramic Materials. Ceramic materials are one of the most common materials in daily life and play an important role that most materials cannot replace in people's daily work and life. Because of its fragile surface, the ceramics that people produce early have the shortcomings of fragility and low flexibility. With the large-scale application of nanoceramic technology in ceramic production, we hope to produce ceramic materials with higher strength, better flexibility, and wider applicability, such as ceramics that can be used for metal preparation [8, 9]. Nanoceramics are a new type of ceramic material that appeared around 1970. The development of nanotechnology means that the microstructure, grain boundaries, and particles of ceramic materials have

changed. All of these are to improve the compression resistance, foldability, and plasticity of the material. Ceramic engineering has overcome many shortcomings, which have important effects on electrical, thermal, magnetic, optical, and other mechanical properties. Nanoceramic materials have gradually become engineering materials that can replace traditional industries [10].

2.1.1. Preparation of Nanoceramics.

Different from traditional ceramic sintering, in the process of nanoceramic sintering, cutting countermeasures must be studied in order to control particles [11]. The special sintering method of nanoceramics can control the size of nanoceramic particles, so as not to have a serious impact on the inherent characteristics of nanoceramics after growth [12]. As shown in Figure 1, there are mainly four methods.

2.1.2. The Structural Foundation and Basic Performance of Ceramics

(1) Ceramic Material Bonding Bond. Chemical bonding is divided into strong bonding and weak bonding. Among them, strong bond refers to metal bond, covalent bond, and ionic bond, and weak bond generally refers to hydrogen bond and van der Waals bond [13]. Most people think that covalent bonds and ionic bonds are the most important structural combination of ceramic materials. However, after detailed investigation and research, they will find that the bonding properties of ceramic materials vary widely, and there are usually many intermediate types of ceramics. Usually people can judge the degree of ion binding by using electronegativity [14]. The ratio of ion bonding in the ceramic structure composed of two elements a and b can be calculated from the formula given in

$$M = 1 - \exp\left[-\frac{(X_a - X_b)}{4}\right].$$ (1)

In the formula, M is the ratio of ion binding components and X_a and X_b are the electronegativity of element a and element b, respectively. In the formula, if the difference between X_a and X_b is greater, M is greater. That is, the ratio of ion binding becomes larger. Conversely, the smaller the difference between X_a and X_b, the smaller M is. In other words, the proportion of covalent bonds becomes larger [15]. When $X_a = X_b$, the measured ceramic materials are all covalent bonds, and there are no ionic bonds. In general, the ion bonding ratio of oxides is higher than the ion bonding ratio of carbides, and the ion bonding ratio of nitrides is higher.

(2) Pauling's Rule. The most basic characteristic of Pauling's rule is to use positive ion coordination polyhedrons as the basic structural unit instead of the common lattice structure as the basic structural unit. Therefore, when studying its complex structure, the unit presented by it has its own uniqueness [16]. This rule plays a very important role in understanding the structure of ionic crystals, and it also plays a great reference for crystals with covalent bonds and ions. However, this rule is not suitable for crystals with a single structure [17]. There are 5 rules in total, which are imported as described in Figure 2.

The first rule: the positive ion is in the center, surrounded by many negative ions to form a polyhedron. The algebra of the radius of the positive and negative ions determines the distance between the positive and negative ions. In actual practice, most of the time ions are described as spheres with a fixed volume. A^+ and A^- represent the radius of positive and negative ions, respectively, and the coordination number of positive ions can be represented by the value of A^+/A^-. Put positive ions into a gap smaller than its volume to form a stable structure. In particular when the size of the positive ion is consistent with the size of the gap, the formed structure is very stable. Conversely, if the size of the gap is larger than the size of the cation, the structure formed will become unstable [18]. Table 1 shows the relationship between A^+/A^- and the coordination number.

The second rule: electricity tariff rules. This rule firstly plays a decisive role in the distribution of the number of vertices and polyhedrons and secondly determines whether the result of studying a certain crystal is stable. This rule shows that there is also a certain algebraic relationship in the crystal structure; specifically, there is a certain relationship between the values of positive and negative ions [19]. In other words, the algebraic sum of the electrostatic bonding strength of the positive ions in the vicinity of the negative ions to the negative ions is equal to the value of the negative ions, and the deviation is less than 1/4. The formula for electricity tariff rules is as follows:

$$E^- = \sum_n S_n = \sum_n \frac{E^+}{W}.$$ (2)

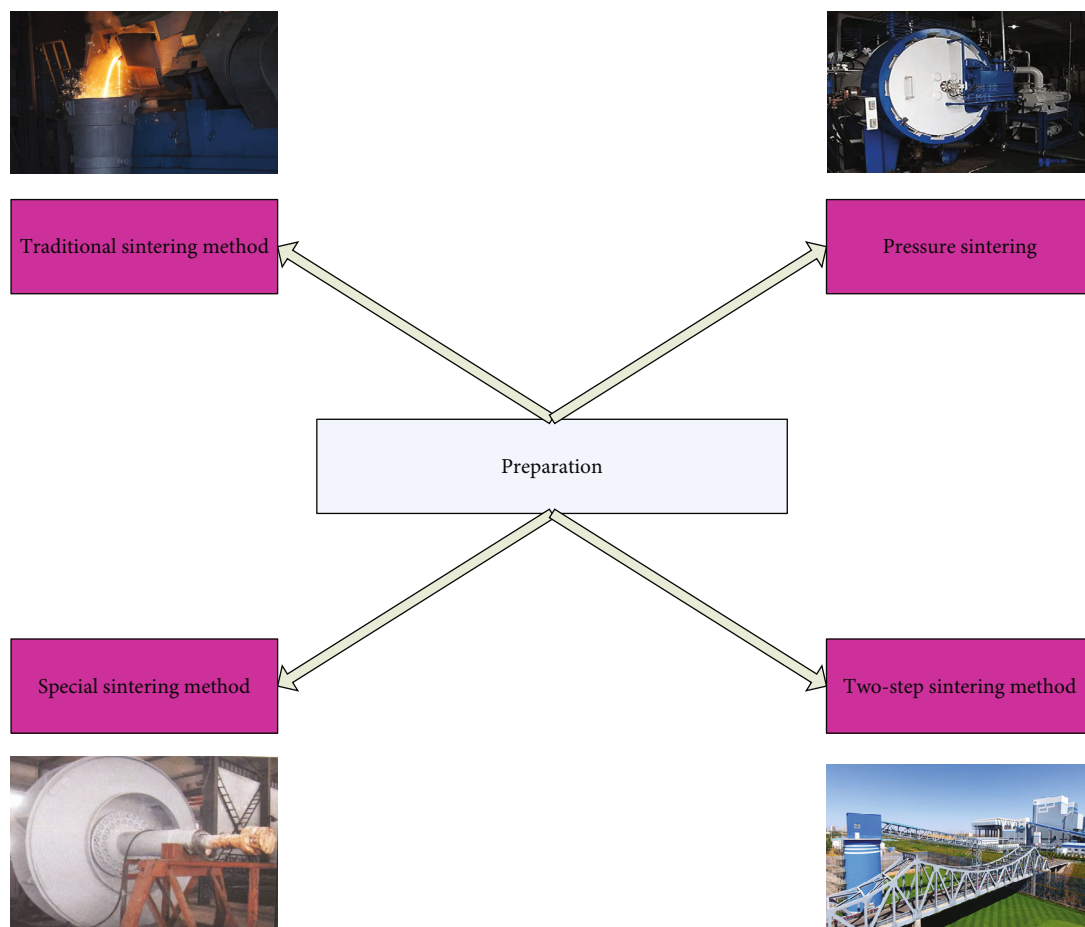
The third rule: the rule of cotop, face, and edge of polyhedron. The rule is to measure the structural stability of the crystal from the connection mode of the polyhedron. Pauling's law proposes that whether the ionic crystal structure is stable is subject to the collection of polyhedrons. In other words, the structural stability of coplanar crystals is weaker than that of different polyhedral crystals connected at the edge of a common edge [20]. This is due to the presence of high valence positive ions in gaps with low coordination numbers. The intensity of electrostatic coupling can be allocated to adjacent coordinated negative ions, but it cannot completely shield the electric field emitted by positive ions. If the number of common edges between anion polyhedrons increases, the distance between cations becomes shorter. At this time, the repulsive force that is not completely shielded between the cations becomes larger [21]. In particular, when a plurality of such polyhedrons is coplanarly connected, the stability of the crystal structure may decrease. Therefore, the polyhedrons of a crystal with a stable structure are not the same edge or the same plane but are formed at the same angle.


FIGURE 1: Four manufacturing methods of nanoparticle ceramic materials.
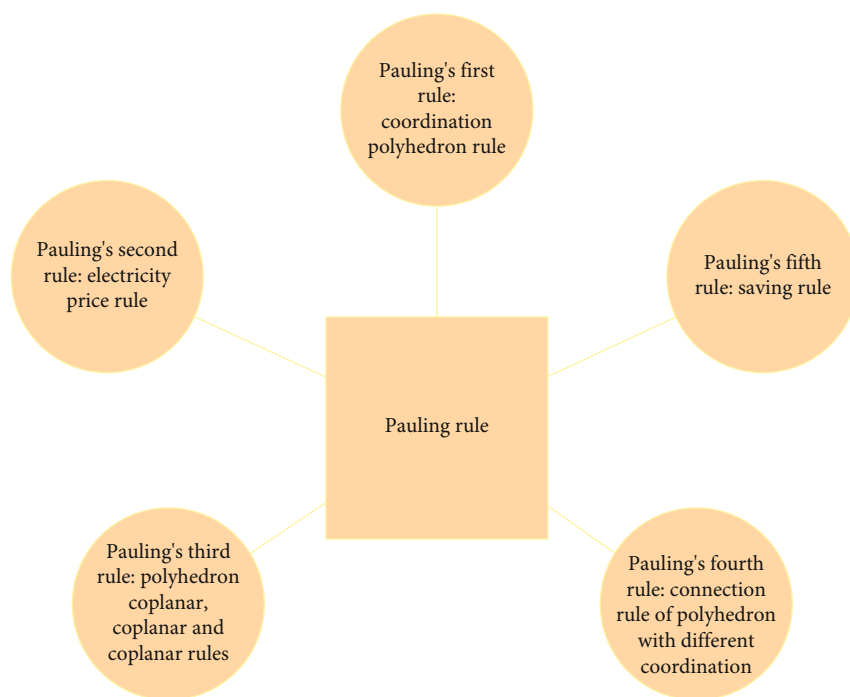

FIGURE 2: Pauling rule.

TABLE 1: Relationship between A^+/A^- and the coordination number.

A^+ to A^- radius ratio	Coordination number	Coordination polyhedron
0.000~0.155	2	Dumbbell shape
0.155~0.255	3	Plane triangle
0.255~0.414	4	Tetrahedron
0.414~0.732	6	Octahedron
0.732~1.000	8	Cube
1.000	12	Tetrahedron

The fourth rule: this rule shows that if there are multiple different cations in the same ionic crystal structure, polyhedrons with high atomic valence and low coordination are likely to fail to connect to each other [22]. For example, in $BaTiO_3$, the titanium oxide octahedrons are not connected on the same plane or common edge but connected only at the upper corners. Fortsulight is divided into tetrahedron (SiO_4) and octahedron (MgO6) two coordination polyhedrons, but the Si^{4+} coordination number is low and the electricity cost is high, so it is connected by tetrahedron (SiO_4) and separated by octahedron (MgO_6) [23].

The fifth rule: saving rules. This rule shows that in the same ionic crystal, there is a tendency to minimize the number of different structural units. In other words, cations of the same type must be in the same coordination environment [24]. The basis of this rule is the symmetry and periodicity of the crystal structure. The basic units that make up the crystal are of different types and large numbers, and when each basic unit forms its own regularity and periodicity, they will interfere. As a result, a stable crystal structure cannot be formed.

(3) Typical Crystal Structure. Ceramic structures are generally more complex, but generally speaking, the following typical structures are inseparable. This can be considered the most densely filled voids in which positive ions are filled into negative ions [25–27]. The following briefly introduces several typical ceramic structures. The first introduction is the perovskite-type structure, and its structure is shown in Figure 3.

The perovskite-type composite compound has the general formula WTY3, and the coordination number is $W : T : Y = 12 : 6 : 6$. The radii Q_W, Q_T, and Q_Y of W, T, and Y ions have the following relationship:

$$Q_W + Q_Y = \sqrt{2}(Q_Y + Q_T). \tag{3}$$

The above equation is the condition for the spheres of radii Q_W, Q_T, and Q_Y to contact. But in fact, there is a certain radius difference between the W-site ions and the oxygen ions, and the T-site ions may not contact the oxygen ions constituting the octahedron [28]. Therefore, the
FIGURE 3: Perovskite crystal structure.

tolerance of the radius can be expressed by the tolerance coefficient e, which can be expressed by the following relational formula:

$$Q_W + Q_Y = \sqrt{2}e(Q_T + Q_Y). \tag{4}$$

The value of e ranges from 0.77 to 1.10. In the case of $e = 0.77$ to 1.10, the structure of the WTY3 compound is a perovskite type. When the value of e is not within this range, it will change to another crystal structure. In the case of $e < 0.77$, it is a ferro-titanium-type structure. In the case of $e > 1.10$, there is a calcite or calcite structure.

(4) Basic Properties of Ceramic Materials. Dielectric constant is the main parameter reflecting the dielectric properties or polarization properties of piezoelectric smart materials under the action of electrostatic field ε. Piezoelectric components for different purposes have different requirements for the dielectric constant of piezoelectric smart materials. When the shape and size of piezoelectric smart materials are certain, the dielectric constant ε is determined by measuring the inherent capacitance (CP) of piezoelectric smart materials. In many materials, the specific permittivity is an indispensable characteristic parameter, reflecting the ability of the charge storage material. This is closely related to the

polarization of the material. The relationship between the polarization parameter and the specific permittivity R can be obtained from cloud computing and Mossotti's equation:

$$\frac{R_I - 1}{R_I + 1} = \frac{1}{3R_0} \sum j N_j \propto_j. \tag{5}$$

The above formula reflects the relationship between the polarizability and the specific permittivity, combining the macroscopic quantity and the microscopic quantity.

The quality factor is a parameter for measuring the electric field, especially the internal dielectric loss of the medium in the AC electric field. The quality coefficient Qu is generally expressed as follows:

$$\frac{1}{\tan \delta} = Qu = \frac{\omega_r^2}{2\pi FY}. \tag{6}$$

It can be concluded from formula (6) that the Qu $*$ F value is a physical quantity reflecting material loss and an important parameter to explain the quality of ceramic microwave dielectric properties. The Qu $*$ F value of ceramic materials can be increased by selecting suitable raw materials and improving the preparation and sintering process. Only an excellent preparation method can ensure that the dielectric loss of the ceramic is small.

(5) Performance Requirements of Ceramic Packaging Materials. This package mainly plays the role of transporting and supporting chips and electronic components, connecting electronic circuits, sending signals, and protecting heat dissipation. Therefore, as shown in Table 2, ceramic packaging materials mainly have electrical and mechanical requirements.

For packaging materials, the most important requirements for electrical properties are dielectric loss and insulation resistance. The dielectric loss can be expressed by the tangent value of the phase angle of the polarization current of the delayed material voltage, which is the following relational formula:

$$\tan A = Wcr. \tag{7}$$

In the formula, A is the loss angle, W is the signal frequency, and c and r are the circuit distribution parameters. Over time, the signal sent to the material will disappear in the form of heat, so especially in high-frequency applications, it is necessary to reduce the dielectric loss. The signal transmission speed v can be expressed by equation (8):

$$v = \frac{s}{\sqrt{\varepsilon e}}. \tag{8}$$

2.2. Alumina Composite Ceramic Materials

2.2.1. The Structure, Performance, and Application of Al_2O_3 Ceramics. At present, Al_2O_3 ceramics are one of the largest

TABLE 2: Properties of ceramic packaging materials.

Nature	Specific requirements
Electrical properties	Low dielectric loss High insulation voltage
Mechanical properties	High mechanical strength Easy to achieve multiple layers Flat and smooth surface
Other properties	Easy to metallize Resistant to oil and chemical corrosion

production and widely used ceramic materials in the world. Not only is it widely used in the most cutting-edge technical fields such as national defense and aerospace but also due to its heat resistance, corrosion resistance, wear resistance, and other characteristics, part of the material made of it can completely replace part of the metal material. Through effective dispersion and recombination, nanoceramic composites make heterogeneous nanoparticles uniformly dispersed and retained in the ceramic matrix structure, which greatly improves the toughness and wear resistance and high-temperature mechanical properties. Nanoceramic materials can not only bend freely without cracks like metal materials at low temperature but also carry out mechanical cutting like metal materials and even make ceramic springs. These excellent mechanical properties of nanoceramic materials make them widely used in cutting tools, bearings, automobile engine parts, and so on. Figure 4 shows the schematic diagram of the microstructure of the Al_2O_3 ceramic-sintered body.

Al_2O_3 ceramic materials have excellent physical properties and chemical stability (high mechanical strength, wear resistance, high temperature resistance, corrosion resistance, high hardness, excellent insulation properties, low dielectric loss, etc.). At the same time, Al_2O_3 ceramics are widely used in machinery, aerospace, electronic instruments, electric power, and chemical industries.

2.3. Nanoceramic Materials. At present, the preparation of nanoceramics is still relatively small, but through the efforts of a large number of researchers, a variety of oxide nanoceramics have been successfully prepared, and a perfect sintering theory has been formed, which provides theoretical and experimental support for the preparation of $BiFeO_3$ nanoceramics. Compared with the traditional solid-phase reaction method and rapid liquid-phase sintering method, it has the advantages of high product particle purity, convenient operation, simple synthesis conditions, and easy control. The sintering theory and research progress of nanoceramics are introduced as follows.

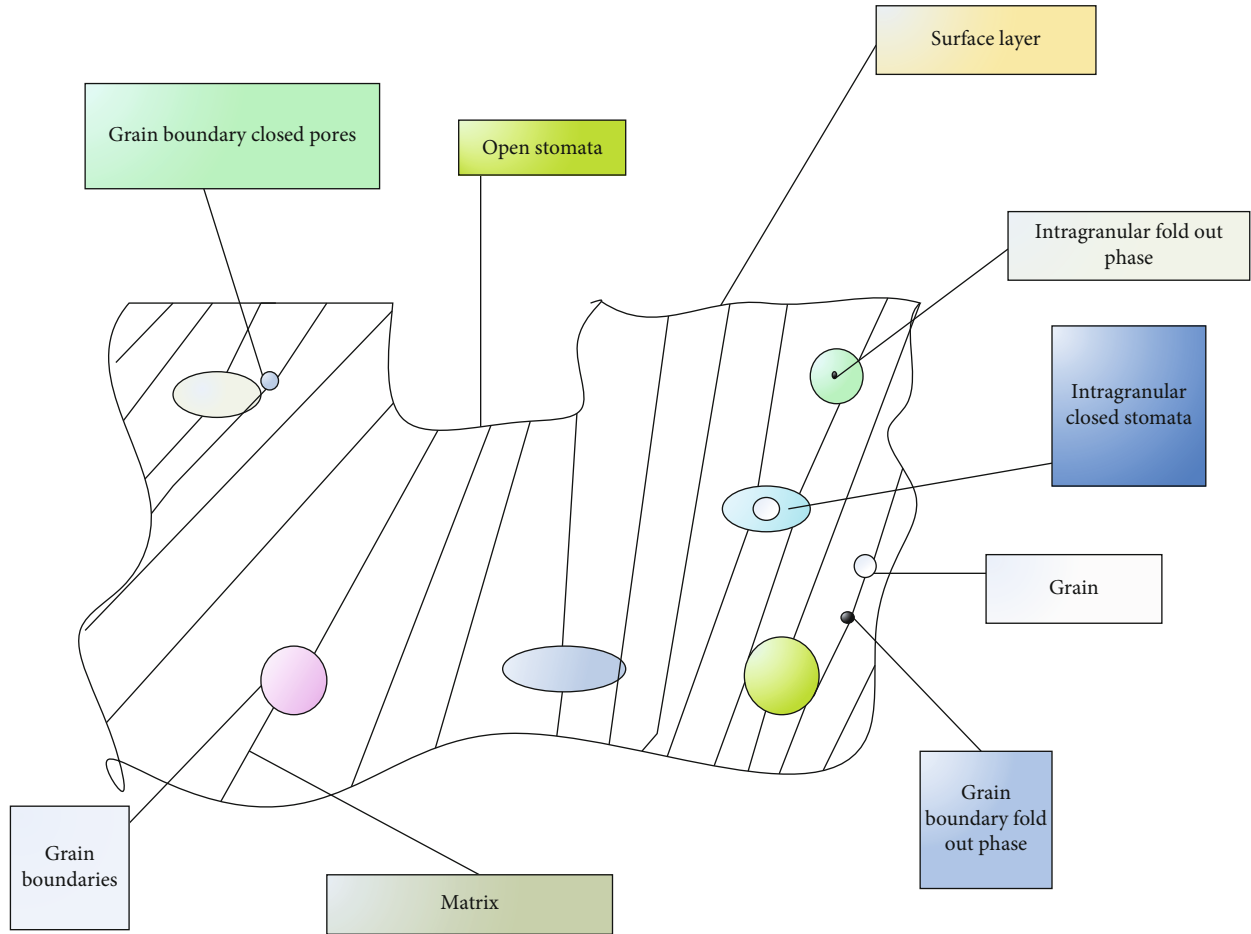
2.3.1. Introduction to the Sintering Theory of Nanoceramics. At the microstructure level, sintering refers to the process of powder solid phase material transfer, accompanied by particle growth and densification. Sintering generally includes volatilization-condensation, surface diffusion, grain boundary diffusion, bulk diffusion, plastic deformation, and


FIGURE 4: Schematic diagram of the microstructure of the Al_2O_3 ceramic-sintered body.

other processes. In the process of densification, only particle diffusion, volume diffusion, and plastic deformation play a role. In the process of sintering without external stress and in the densification of ceramics, only particle diffusion and volume diffusion play a role. Taking the effect of particle diffusion as an example, the rate of change of all particle diffusion can be expressed as follows:

$$\frac{Ac}{Ax}\bigg| WQ = B_{WQ} \frac{\alpha_{WQ}}{(2\pi m * r * t)^{1/2}} * \frac{\Omega N_{\text{flat}} E_{WQ}}{KY} * \sum B. \quad (9)$$

Among them, m is the gas constant, t is the absolute temperature, and Ω is the volume of the unit powder. The absolute shrinkage is expressed as the sum of grain boundary diffusion and bulk diffusion, which can be expressed as

$$\frac{DV}{VDt}\bigg| D = B \frac{DV}{VDt}\bigg| WQ + \frac{DV}{VDt} V = M * R * \sum b. \quad (10)$$

In the formula, C is a constant related to temperature and A is the area of grain boundaries. The change of grain

TABLE 3: The main raw materials used in the experiment.

Drug name	Chemical formula	Molecular weight	Specification
Ferric nitrate	$Fe(NO_3)_3$	404	500 g
Bismuth nitrate	$Bi(NO_3)_3$	485.07	500 g

Ethylene glycol	$(CH^2OH)_2$	123.22	100 g
Absolute ethanol	C_2H_6O	46.07	500 ml
Nitric acid	HNO_3	60.05	500 ml

size in the process of grain growth can be expressed by the following formula:

$$\frac{E_R}{E_T} = \left(L_{B-A} * I_{B-A} + L_W * I_W + L_Q * I_Q \right) B. \quad (11)$$

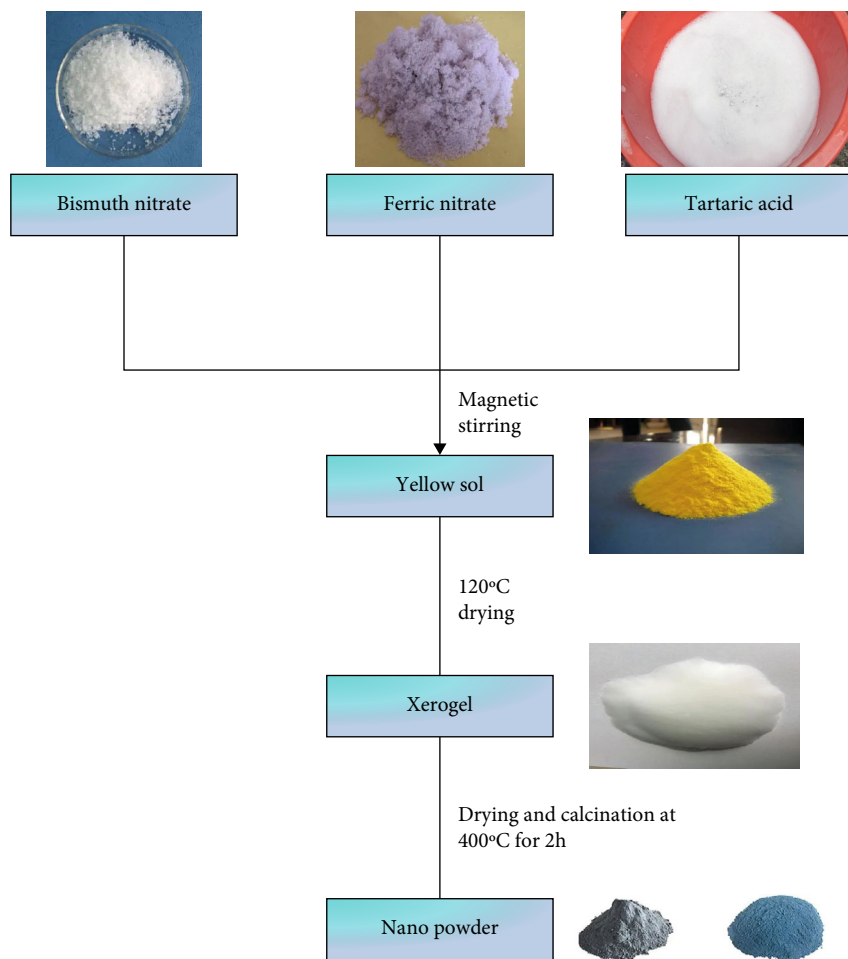
2.3.2. Preparation Principle of BiFeO$_3$-Based Nanoceramics


Figure 5: Preparation flowchart of BiFeO$_3$ nanopowder.
Figure 6: XRD pattern of BiFeO$_3$ nanopowder.

(1) Experimental materials and experimental equipment, as shown in Table 3

(2) Performance characterization

First, the resistance analysis of the ceramics is carried out, and the surface of the ceramic samples is ground and polished and electrodes are covered. Among them, the relationship between the imaginary part of the impedance and the corresponding frequency is

$$X'' = r \left[\frac{\omega rc}{1 + (\omega rc)^2} \right]. \tag{12}$$

The relationship between the imaginary part of the electric modulus and the frequency is

$$T'' = \frac{\varepsilon_0}{c} \left[\frac{\omega rc}{1 + (\omega rc)^2} \right]. \tag{13}$$

Among them, ω is the angular frequency $= 2\pi F$ and $\varepsilon_o = 8.854 * 10^{-14}\,\text{F}\cdot\text{cm}^{-1}$ is the dielectric constant in vacuum. The maximum value of the semicircle is the peak value of the Debye peak, and the frequency corresponding to the peak value is

$$\omega_{\text{MAX}} = 2\pi F = (rc)^{-1}. \tag{14}$$

The maximum resistance value r and the minimum capacitance value c are extracted by the relaxation peaks of $X'' - F$ and $T'' - F$. From formula (12), the following can be obtained:

$$X'^{'}{}_{\text{MAX}} = \frac{r}{2},$$
$$T'^{'}{}_{\text{MAX}} = \frac{\varepsilon_0}{2c}. \tag{15}$$

When extracting the contribution of defects to Debye relaxation, the extracted system grain boundary and grain conductance can be fitted by fitting, and the relationship between conductance and temperature obeys the Arrhenius formula:

$$\alpha = \alpha_0 \exp\left(-\frac{\text{Wa}}{Ki}\right), \tag{16}$$

where α is the conductivity, K is the Boltzmann constant, i is the absolute temperature, and Wa is the activation energy.

$$\text{In}(\alpha) = \text{In}(\alpha) - \frac{\text{Wa}}{Ki}. \tag{17}$$

The activation energy obtained by fitting can distinguish the dominant defect types of the system. When

extracting the contribution of the defect type to the dielectric relaxation, by fitting the relationship between the relaxation time T and the reciprocal of the absolute temperature:

$$T = T_0 \exp\left(-\frac{\text{We}}{Ki}\right), \tag{18}$$

the relaxation time can be calculated from the frequency corresponding to the peak in the $X'' - F$ spectrum:

$$T = \frac{1}{2\pi F_{\text{max}}}. \tag{19}$$

(3) Ceramic preparation process

$BiFeO_3$ and a series of materials derived from it belong to single-phase perovskite oxide-type multiferroic materials, with ferroelectric, piezoelectric, dielectric, electrooptical, ferromagnetic, photovoltaic, and magnetoelectric coupling, photocatalysis, etc. at the same time above room temperature effect. It has important application prospects in many new smart devices. The mixed nitrate solution is prepared according to the stoichiometric ratio of 1 : 1 of $Fe(NO_3)$ 3.9h2o and Bi (NO3) 3.5h2o or Fe_2O_3 and Bi_2O_3. Glycine is added as fuel, 5~10 ml of oxalic acid is added for dehydration, and the resulting solution is put into a microwave oven and heated with 800 W power. After evaporating the water, it is heated for 10~20 seconds. The mixture undergoes a rapid combustion reaction to obtain loose nanoparticle powder products. The obtained granular

powder is pressed into small pieces by a tablet press to obtain a block sample. Then, the bulk sample was sintered in a microwave oven and quenched to room temperature to obtain the product with uniform-size $BiFeO_3$ prepared by this method having high purity, uniform particle size, and adjustable particle size. $BiFeO_3$ adopts a sol-gel method to prepare nanopowder, and the preparation process is shown in Figure 5.

After the dry gel is ground and sieved, it is placed in a muffle furnace and calcined at 400°C for 2 hours to completely drain the organic matter and nitrate in the dry gel and at the same time obtain pure $BiFeO_3$ nanopowder. The XRD of the nanopowder is shown in Figure 6.

The preparation process of nanoceramics mainly includes the preparation, molding, and sintering of nanopowder. The methods are as follows: (1) settlement method, (2) in situ solidification method, and (3) sintering or hot pressing method.

It can be seen from Figure 6 that there is no obvious second phase in the nanopowder. According to the Scherer formula,

$$Q = \frac{wy}{E \cos \vartheta}, \tag{20}$$

where Q is the grain size, w is the Scherrer constant with a value of 0.89, E is the half-height width of the diffraction peak of the measured sample, θ is the diffraction angle, y is the X-ray wavelength, and its value is 0.154056 nm for the known nanopowder. The grain size is 15.95 nm.

3. Experimental Design and Result Analysis

3.1. Preparation of Nanoceramics in the Application of Handicrafts. The preparation methods of nanomaterials can be divided into physical method, chemical method,

(a) Sintering temperature

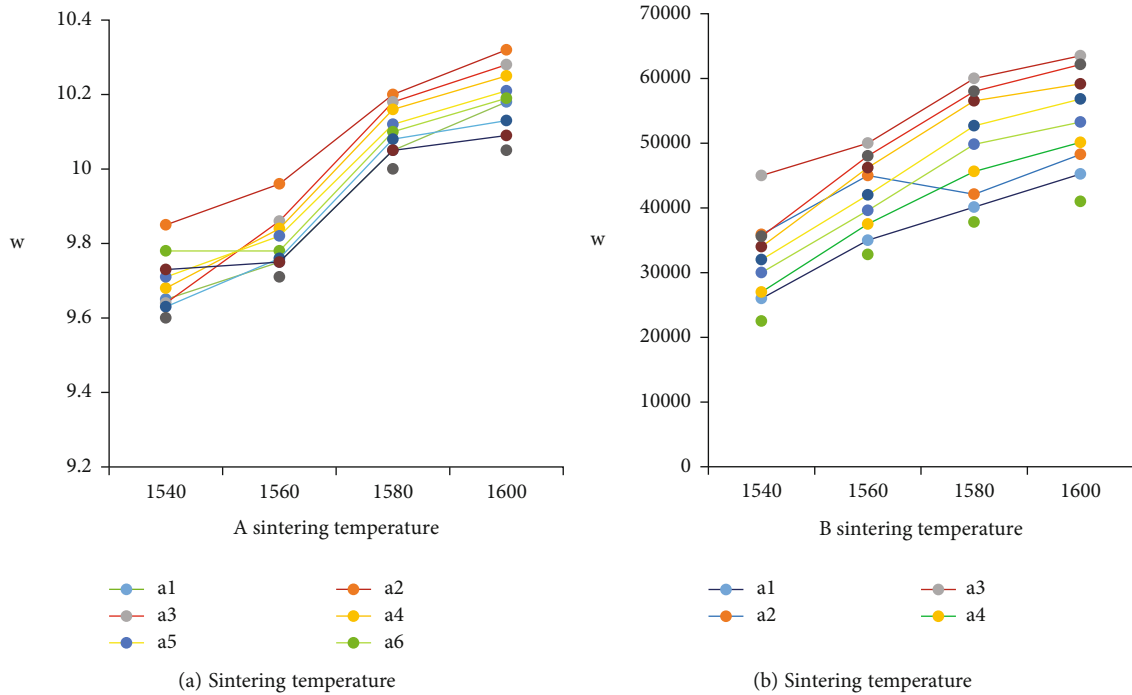
(b) Sintering temperature


FIGURE 8: Al_2O_3 ceramic dielectric performance test results.

(a) Sintering temperature

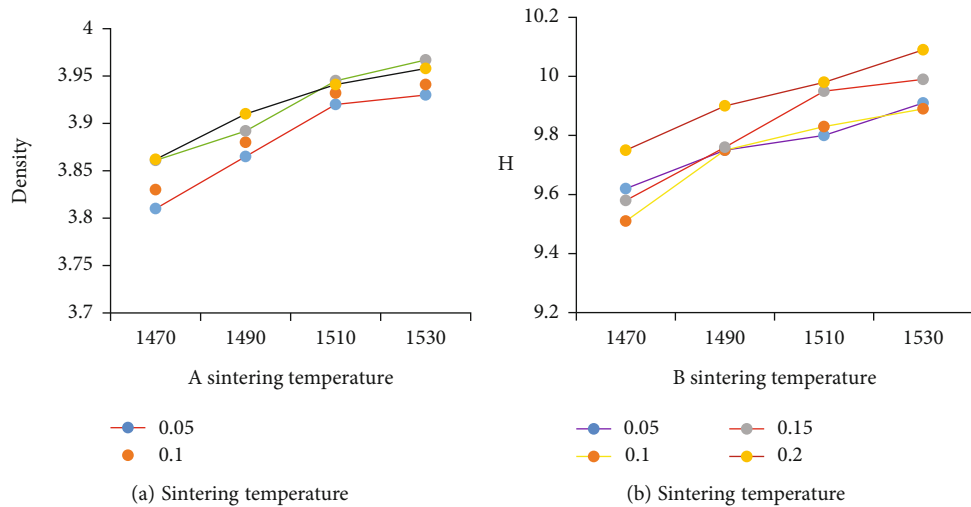
(b) Sintering temperature


FIGURE 9: The density and dielectric constant of Al_2O_3 ceramics change with the sintering temperature.

and other methods. Physical methods include crushing method, deposition method, sputtering method, etc. Chemical methods include sol-gel method, precipitation method, evaporation solvent pyrolysis method, oxidation-reduction method, solvothermal method, etc.

LAO$_3$ and Y_2O_3 have better performance on the absorption and emission peaks of transparent ceramics, while $BiFeO_3$ is not suitable for application in this field. The main raw materials used in this experiment are high-purity Al_2O_3, La_2O_3, and Y_2O_3 with different particle sizes from different manufacturers. The name, molecular formula, manufacturer, and purity are shown in Table 4.

After calculating and weighing the raw materials, use the solid-phase sintering method to prepare Al_2O_3 ceramics, test the sintered samples, and perform performance analysis. Table 5 shows the main equipment and test equipment used in the entire preparation and testing process.

This article uses the most commonly used solid-phase sintering method in industrial production to prepare 99 alumina ceramics. The ceramic preparation process is shown in Figure 7.

The advantages of the solid-phase reaction sintering method for preparing ceramic samples are as follows: the experimental conditions are easy to control, the preparation process is relatively simple, the cost is relatively low, and the
FIGURE 10: Variation curve of the ceramic $O * F$ constant value with sintering temperature.
FIGURE 11: Sales volume and sales comparison chart of handicrafts with different materials.

chemical composition of the raw materials of this method is uniform, easy to popularize, and suitable for large-scale industrial production; the disadvantage is that the calcination temperature is high and energy consumption is high. It is easy to introduce impurities during the grinding process, and the process parameters are more complicated.

3.2. Preparation Results of Nanoceramics in the Application of Handicrafts. In this section, the solid-phase reaction sintering method commonly used in industrial production is used to prepare pure Al_2O_3 ceramics. The raw materials involved are nine kinds of high-purity Al_2O_3 powders with different particle sizes from different manufacturers, num-

bered a1~a9. Using a vector network analyzer, the microwave dielectric properties of the sintered ceramic samples were tested. The test result is shown in Figure 8.

It can be seen from Figure 8 that as the sintering temperature increases, the relative permittivity and $Q \times f$ value of Al_2O_3 ceramics numbered a1 to a9 increase. This shows that as the sintering temperature increases, the pores in the ceramic are gradually discharged, the grain size becomes larger, the ceramic compactness becomes better, and the relative permittivity and $Q \times f$ value are closely related to the density and grain size of the ceramic material. It can be seen from Figure 8(b) that the $Q \times f$ value of a3 Al_2O_3 ceramics is much higher than that of the other 8 Al_2O_3

ceramics. Compared with other Al_2O_3 ceramics, it exhibits extremely excellent microwave dielectric properties.

The density test was performed on the ceramic samples after sintering. Figure 9 shows a graph of the density and dielectric constant of Al_2O_3 ceramics as the sintering temperature changes.

As shown in Figure 9, it can be seen that the ceramic becomes dense with the increase in the sintering temperature, and its density increases with the increase in temperature. At the same time, with the increase in MgO doping amount, the density of ceramic samples increased first and then decreased. At 1530°C, when doped with 0.15% MgO, the density of Al_2O_3 ceramics reached the maximum 3.961 g/cm^3.

Then, use the vector network analyzer to test the microwave performance of the sintered ceramic samples. As shown in Figure 10, the ceramic $O * F$ constant value changes with the sintering temperature:

It can be seen from Figure 10 that as the sintering temperature increases, the ceramic density gradually increases, the relative dielectric constant also increases, and the $Q \times f$ value of MgO-doped Al_2O_3 ceramics increases. Since the relative permittivity of MgO is 9.7, the relative permittivity of pure Al_2O_3 ceramics is relatively close, and the amount of MgO doped is small, it has little effect on the relative permittivity of MgO-doped Al_2O_3 ceramics.

3.3. The Application of Nanoparticle Ceramic Materials in the Design of Modern Handicrafts.

3.3. The Application of Nanoparticle Ceramic Materials in the Design of Modern Handicrafts. Through the investigation and analysis of the sales volume of some modern handicrafts made with nanoceramic materials and the sales volume of traditional handicrafts, Figure 11 is obtained.

From the data in Figure 11, it can be concluded that not only has the sales volume of handicrafts using nanoceramic materials increased greatly but also the average sales volume is more than 35% higher than that of handicrafts made of ordinary materials, and the selling price is due to the use of new materials. The new production process has also increased the price of a single product. According to a comprehensive analysis, the average selling price of crafts using nanoceramic materials is at least 40% higher than that of traditional crafts.

4. Discussion

This article is devoted to the research of nanoceramic materials and applies them to modern handicrafts. This article discusses the production process, manufacturing technique, and manufacturing materials of nanoceramic materials. While discussing, we will also apply it to our modern handicrafts in the experimental stage and then conduct research and analysis on the sales volume and sales of modern handicrafts, so as to better explore the use of nanoparticle ceramics in modern handicrafts. In addition, this article mainly conducts sufficient research on the different forging methods of nanoceramics and conducts experiments on nanoceramics in terms of dielectric loss and temperature resistance. The experimental results in this article also show that nanoceramic materials have a wear resistance, high temperature resistance, corrosion resistance, hardness, insula-

tion performance, dielectric loss rate, and other aspects superior to ordinary ceramic materials.

The analysis of the experimental cases in this article shows that the performance of nanoceramic materials is much better than that of other materials, and its use in modern handicrafts has also been favored by most consumers. Modern handicraft design and production manufacturers can make full use of the existing nanoceramic technology and integrate it into the design of handicrafts. Of course, enterprises can also choose good production materials and production techniques according to their own conditions to help them develop better.

In this paper, the production of nanoceramics is firstly studied, and the raw materials that are more suitable for the production of nanoceramics are obtained through experiments, and then, the nanoceramic materials after the improvement of production are studied, and the nanoceramic materials that are more suitable for use in daily life are selected. Finally, through the research on the sales and price of handicrafts using nanoceramic materials in daily life, the survey results show that not only can modern handicrafts using nanoceramic materials occupy a 30% advantage in sales but also it is better than traditional crafts.

5. Conclusions

Through the analysis of this case, the following conclusions can be drawn: modern handicrafts designed and manufactured using nanoceramic materials can not only increase the sales and selling prices of modern handicrafts by more than 30% but also increase the use value and ornamental value of the products. There has also been a qualitative leap in collection value. As one of the three main materials, ceramic materials are world-renowned as unique craft buildings. Modern handicraft design is an important carrier reflecting its culture. Excellent handicraft design should not only reflect the uniqueness and superiority of product information but also use cultural connotation to highlight the taste, grade, and value of the design. While modern handicraft design reflects contemporary culture, it is also the demand for modern design innovation in terms of the expression strategy of design creativity, the shaping of the brand image, and the ecological design concept of materials. For example, in this case, the merchants who use nanoceramic materials to design and produce modern handicrafts, because of the use of nanoceramic technology, make their product sales, and sales prices have a great leap. It can be seen that the average selling price of handicrafts using nanoceramic materials is at least 40% higher than that of traditional handicrafts.

If the load exercise exceeds a certain degree, it will lead to sports injury. The main reason for this phenomenon is that the human body produces a lot of free radicals after sports training. Free radicals can attack human cells and cause lipid peroxidation to damage cell membrane. The human body can improve the antioxidant capacity of the body by supplementing some trace elements. Selenium, iodine, zinc, iron, and calcium are all trace elements that contribute to antioxidants in the body. Nanoselenium is of great interest among many immune modulators because of its high antioxidant properties and remarkable immune protective function. In this paper, grey rabbits were used as the research object to carry out aerobic endurance training. Nanoselenium and placebo were supplemented in each group. The evaluation model of nanoselenium on aerobic endurance exercise was established by system control method, exhaustion compensation method, and analytic hierarchy process. The adaptive changes of nanoselenium on aerobic endurance exercise of grey rabbits were studied in detail, and the effects of exercise and antioxidant on the body were observed. Compared with the previous research methods, the difference is that the decentralized control theory is introduced as the guiding ideology of the research. According to the experimental results, the accuracy of the overall experimental results is improved by about 20%, and the accuracy is higher, which has certain practical value.

1. Introduction

Selenium is one of the essential trace elements for human body, which is crucial for human survival and development. As an emerging bionanotechnology, research on the preparation of selenium nanoparticles is gaining more and more attention and has a broad application prospect. After exercise training, the human body will produce a lot of free radicals, such as oxygen free radicals and hydroxyl radicals, which have high oxidation activity. They are very unstable and highly active. They attack cell membrane and mitochondrial membrane and react with unsaturated fatty acids in membrane, resulting in enhanced lipid peroxidation and changes in membrane fluidity and permeability. This destroys the integrity of cell membrane structure. Lipid peroxidation injury of cell membrane is an important mechanism of exercise-induced fatigue and injury. In order to eliminate sports fatigue and quickly reduce sports injury and improve the body's sports ability, we must try to reduce

the production of excessive free radicals in the body or increase the body's ability to remove free radicals.

The production of reactive oxygen species (ROS) can cause serious oxidative damage to proteins, lipids, and genomic structures. Shirvani et al.'s study showed that the production of reactive oxygen species increased during high-intensity exercise training. The purpose of Shirvani et al.'s study was to investigate the effects of high-intensity intermittent training on the levels of 8-oxoguanidine DNA glycosidase (OGG1) and 8-hydroxy-2'-deoxyguanosine (8-OHdG) in brain and liver tissues [1]. In Shubhangi et al.'s study, Shubhangi et al. reported (a) the biosynthesis of selenium nanoparticles (SE NPs) and (b) the protective effect of selenium nanoparticles on broilers [2]. An effective bacterial strain isolated from farmland soil has been identified as pantoea aggregate (GenBank: KU500622). It can tolerate high concentration of selenium dioxide (9 mm) and produce selenium nanoparticles under aerobic conditions. The results show that the selenium nanoparticles are amorphous and

spherical, and the particle size is less than 100 nm. Shubhangi et al. studied that selenium NP supplementation could significantly restore these values in the control group, even higher than that in the control group. Efruxifermin (EFX) is an Fc-FGF21 fusion protein. The adverse effects of EFX were prevented by simultaneous exposure to selenium nanoparticles (0.6 mg per kg feed) in poultry feed. Maynar et al. studied the changes of serum copper, chromium, manganese, nickel, and selenium contents of high-level athletes [3]. Before the training, 80 professional athletes with different metabolic patterns were recruited. The control group consisted of 31 sedentary participants from the same geographical area. Copper, chromium, manganese, nickel, and selenium were analyzed by inductively coupled plasma mass spectrometry (ICP-MS). Selenium ecotoxicology is one of the most famous examples of the effects of biotransformation and food chain transfer of toxic elements on the environment. However, it has been gradually recognized that biotransformation of selenium by microorganisms and plants may also be the key to in situ bioremediation of selenium pollution in large-scale situations (such as agricultural drainage systems). A kind of euryhaline algae (Chlorella vulgaris) was isolated from the wastewater containing selenium. The aerobic biotransformation activity of Chlorella vulgaris to seleno anion was studied by GCMS and multinuclear magnetic resonance (NMR). Fan et al. found that the algae were active in the volatilization of alkyl selenides, the production of hypothetical selenide precursors of alkyl selenides, and the precipitation of selenium, while exhibiting a very low accumulation of toxic selenomethionine in free form. Therefore, this kind of microalgae is of great significance for in situ bioremediation and biogeochemical cycle of selenium in contaminated saline alkali soil [4].

So far, different bacteria have linked selenite resistance with the production of metal selenium nanoparticles (senps). Although senps have many biotechnological applications in different fields, the molecular mechanism of their microbial genesis has not been fully understood. Alpaca is a physiologically multifunctional β-protein associated bacterial group [5]. Here, Tan et al. reveal another physiological characteristic of CIB strain, which is related to its resistance to seleno anion and the formation of senps. Selenium oxygen anion reduction is an effective detoxification or assimilation process in organisms, but its mechanism is poorly understood [6]. Se (VI)/SE (IV) was reduced to selenium nanoparticles (senps) with less toxicity. For se (VI) reduction, sulfate reduction and Se (VI) reduction showed a competitive relationship. When the required sulfate-reducing genes were destroyed, Se (VI) did not reduce to red senps. Therefore, the reduction of Se (VI) is catalyzed by enzymes in the sulfate reduction pathway. In the aspect of Se (IV) reduction, SERT, a potential molybdenum oxidoreductase, was screened and further applied to the analysis of Se (IV) reduction. Selenite is the main form of selenium in aerobic soil, but different from selenite, the mechanism of plant absorbing selenite is not clear. Ming et al. studied the effects of different concentrations of selenite and selenite on the absorption, transport, and selenium forms of wheat through hydroponic experiment. Nanoselenium (100-500 nm) has

high bioavailability and relatively low toxicity [7]. Gulyás et al. studied the effects of selenium-free control diet and nanoselenium diet supplemented with 4.25 mg/kg DM on liver proteome of broilers. Two-dimensional gel electrophoresis (2D-PAGE) and trypsin digestion (LC-MS) were used for differential proteomic analysis. A total of 788 protein spots were detected in the two groups, and the intensity of 18 protein spots was significantly different ($P < 0.05$). Compared with the control group, the expression of 8 kinds of proteins was increased, and the expression of 5 kinds of proteins was decreased. The function of the differentially expressed proteins indicated that dietary stress was caused by high-dose selenium supplementation. Selenium supplementation can affect the metabolism and antioxidant system of fatty acids and carbohydrates and increase the content of actin in cytoskeleton and the expression of actin regulatory protein [8]. Nanoselenium avoids the side effects of selenium, but little research has been done on the adaptation of aerobic endurance exercise.

In this paper, the effects of different selenium sources and selenium supplement time on growth performance, plasma antioxidant capacity, and tissue selenium deposition of gray rabbits were studied.

2. Research Methods

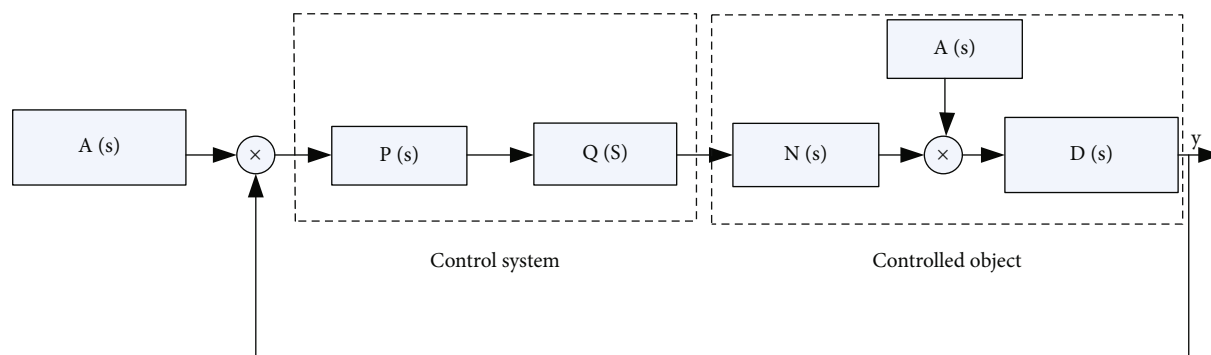
2.1. Decentralized System Control Method. In this paper, in the evaluation model of the effect of nanoselenium on aerobic endurance exercise, the transfer function of the controlled object is $g(s) = y(s) - U(s) = n(s) - D(s)$, and the control system is $K(s) = P(s) - Q(s)$. Where $n(s)$ and $D(s)$ are the zero polynomials and pole polynomials of $G(s)$, and the degree of $D(s)$ is not less than the degree of $n(s)$, where $p(s)$ and $Q(s)$ are the zero and pole polynomials of $K(s)$, and the degree of $Q(s)$ is not less than that of $P(s)$. The expression is as follows:

$$y_{re\int}^{-1} = \frac{1}{A_{re\int}(s)} y_{re\int}(0), \omega(s) = \frac{1}{A_\omega(s)} \omega(0). \tag{1}$$

Let the zeros of $A(s)$ and $A(J)$ lie in the right semiclosed plane of the complex plane. The least common multiple of these two polynomials is $A(s)$, as shown in Figure 1.

The connections in Figure 1 are as follows:

$$
\begin{aligned}
e &= \frac{D(s)Q(s)}{N(s)P(s) + D(s)Q(s)} y_{re\int} - \frac{Q(s)}{N(s)P(s) + D(s)Q(s)} \omega \\
&= \frac{D(s)Q(s)}{N(s)P(s) + D(s)Q(s)} \cdot \frac{1}{A_{re\int}(s)} y_{re\int}(0) \\
&\quad - \frac{Q(s)}{N(s)P(s) = D(s)Q(s)} \cdot \frac{1}{A_\omega(s)} \omega(0).
\end{aligned}
\tag{2}
$$

In the evaluation model of the effect of nanoselenium on aerobic endurance exercise, the objective is to make the system composed of data of each group form a closed loop, and the internal stability makes the steady value of output value y


F<small>IGURE</small> 1: Relationship diagram of experimental coefficients.

independent of the interference factor ω, and track the reference output value y, which is expressed as follows:

$$\lim e(t) = \lim s \cdot e = 0, \forall \overline{y_{re}}\int(0), \bar{\omega}(0). \tag{3}$$

The condition for the establishment of formula (3) is that $Q(s)$ is divided by both sums. This means that the control system contains a model of external instability. This calculation method can make the experimental data more accurate [9, 10].

2.2. Preparation Method of Nanoselenium.

Nanoselenium has higher biological activity than selenium and is the safest of known selenium products.

Selenium is an essential trace element with a small gap between effective and toxic doses. Red monomeric selenium has the same antioxidant, immunomodulatory, and antiaging functions of selenium, but its toxicity is lower than that of general inorganic and organic selenium. In order to ensure the stability and reliability of the prepared cross immunochromatographic strip, the qualified nanomarker must be stable, economical, and sensitive.

The preparation of nanoselenium requires the purity and grade of water and reagents. In the process of experiment, it was found that the size of nanoselenium particles prepared by ordinary deionized water was not uniform, and the suspension stability was poor. Only by using ultrapure water of $18.2 \, m\Omega$ can the selenium nanoparticles with uniform size and dispersion be prepared. In addition, the beaker and centrifuge tube used in the experiment must be clean and free of strong ions. Otherwise, the prepared nanoselenium solution will become turbid and cannot be used in subsequent experiments. In addition, all reagents must be analytically pure, and the purity must be greater than 99.7%. The results show that the nanoselenium prepared by low-grade chemical reagent has irregular morphology and uneven size, the color development effect of the test paper is poor, and the sensitivity is low [11].

Nanoselenium has many stabilizers. In this study, BSA, glucose, gelatin, gum Arabic powder, SDS, PEG, and PVP were used as stabilizers to prepare nanoselenium. Only glucose, Arabian gum powder, SDS, and SDS + peg can be used as markers for cross immunochromatography. However, the performance of the test strips prepared from glucose and SDS was not stable, and the difference between batches was large. The preparation of LFICS with Arabic gum powder as stabilizer requires high protein labeling concentration and high preparation cost of test paper. When SDS and peg are used as templates, they are considered to be the chemical reagents commonly used in the preparation of LFICS. SDS is an anionic surfactant, which can reduce the background interference of LFICS and reduce the false-positive results. Nail is a kind of polymer compound, which can increase the stability of sol [12, 13].

2.3. Exhaustion Compensation Method.

In order to evaluate the relative biological efficiency of nutrients, depletion compensation method is usually used. The model of nutrient deficiency was established. Usually, animals are fed on a nutrient-deficient diet for a period of time and then supplemented with different forms of nutrition. According to the influence of nutrients on the relevant indicators of animals, determine whether the nutrients are deficient and the effects of supplements on experimental animals [2, 14].

At present, there are several methods to study the biological potency of selenium: (1) isotope tracer method is used to evaluate the absorption, retention, and excretion of selenium, but the test cycle is relatively short, but the cost is high. (2) Slope ratio method is a commonly used method to evaluate the relative biological potency of nutrients, that is, to select a nutrient form, define its biological potency as 100% and establish a regression curve with nutrients as reference. According to the reference index, the slope of nutrient of $20000 \, m^3$ was calculated, and the relative bioavailability of nutrient to be tested was obtained. At present, the slope ratio method is the main method to evaluate the relative biological potency of selenium, that is, taking sodium selenite as the standard reference material, the biological potency of sodium selenite is defined as 100%. The loss compensation method is used to feed animals with selenium deficiency diet to achieve the effect of selenium deficiency and then add different selenium sources at different levels or at the same time and at different times Source. By comparing the relative indexes of selenium, such as the deposition of selenium in tissues and the activity of GPX in tissues and plasma, the regression equations of these indexes with selenium level or selenium supplement time

were established, and then the slope of sodium selenite and selenium source was compared to determine the relative value [15, 16]. In this study, we established a model of selenium deficiency in grey rabbits and then added three selenium sources: sodium selenite, yeast selenium, and biological nanoelement selenium. The effects of three selenium sources on growth performance, antioxidant capacity, and tissue selenium deposition of grey rabbits were analyzed to evaluate the relative biological efficacy of biological nanoelement selenium.

2.4. Analytic Hierarchy Process. Analytic hierarchy process (AHP) is a multicriteria decision-making method. This method can combine qualitative analysis with quantitative analysis. Its basic idea is to decompose complex decision-making problems in order to obtain an ordered hierarchical structure. Then, the relative importance of each index is compared in the hierarchical model, and several judgment matrices are constructed. Then, the relative importance weight of each level element is calculated; finally, according to the total ranking of each level, the relative weight of all indicators in the whole hierarchical model is calculated, and the research problems are comprehensively evaluated. In China, AHP has been successfully used to solve many problems. To study the data asset evaluation model, AHP method can be used to determine the index weight and calculate the complete evaluation model. The local variables of a function are independent and do not affect each other, and recursion must be approximated to the condition of exit from recursion, otherwise, it is infinite recursion. On the basis of strict mathematical theory, AHP can not only carry out qualitative analysis but also ensure the effectiveness of quantitative analysis, so the evaluation results are more convincing [17]. Hierarchical analysis is not only suitable for situations where there is uncertainty and subjective information but also allows the use of experience, insight, and intuition in a logical manner.

According to the related theory of AHP, the basic idea of AHP depends on the nature of the problem and the overall objective to be achieved, to decompose complex decision-making problems and get several lower-level indicators. Then, the hierarchical structure model is established, and then, the judgment matrix is constructed according to the structure model. Finally, the weight coefficient of each index is calculated to sort the total hierarchy.

(1) *Establish Hierarchical Model.* In the process of analyzing the hierarchical structure, the most important step is to establish the hierarchical structure model of indicators and construct the judgment matrix according to the structure model. Only after the judgment matrix has passed the consistency test can it be analyzed and calculated. The structural model can be divided into three levels. The highest level is the target level, which is the purpose and problem of decision-making. The middle layer is the factor to be considered in decision-making, which is the standard of decision-making, and the lowest level is the alternative scheme of decision-making. In this paper, the hierarchical model refers

to the hierarchical model constructed by the factors that affect the value of data assets. In the construction process, we need to consider the value factors. Experts, references, and other methods can be consulted to consider [18]. Hierarchical model is the basis of data asset evaluation model

(2) *Establish Judgment Matrix.* After the construction of the hierarchy model, the judgment matrix is established according to the indicators in the hierarchy model. The judgment matrix represents the relative importance of all factors in this layer to a certain factor in the upper layer [19]. Judgment matrix has an important impact on the follow-up results and is also the embodiment of the quantitative nature of AHP. The construction of judgment matrix can refer to the opinions of experts, and the elements of judgment matrix can be assigned by relevant professionals. When assigning values to the elements of the judgment matrix, the nine level scaling method can be used (i.e., the relative importance between indicators is represented by the number 1 to 9 and its reciprocal), which is also the most commonly used method in AHP. The specific scaling method is shown in the table

Hierarchical analysis treats the research object as a system and makes decisions according to the way of thinking of decomposition, comparative judgment, and synthesis, which has become an important tool of system analysis developed after mechanistic analysis and statistical analysis. Based on the number of specific experimental data, the accuracy of the data was qualitatively analyzed to verify the validity of the analysis model. The specific analysis model is shown in Figure 2.

3. Experimental Design

There were 80 adult male grey rabbits, all of them were in normal condition. According to the different sampling time, they were divided into a nonexercise selenium supplement group, B exercise supplement selenium group, C exercise group, and D no exercise no selenium supplement group. According to the time, the test cycle of each exercise group was controlled. Each exercise group was divided into control group and Nan Kuang se group, as shown in Table 1.

After adaptive training, the training lasted for 30 minutes, and the running speed was 25 meters per minute. Exercise six days a week. The temperature is controlled at 20-25 °C. The humidity is 60-80%.

In addition to normal feeding, the rats in the supplement group were given intragastric administration of 200 UG/kg body weight from 6:00 to 8:00 every night. The control group was given placebo at the same time and dose.

According to different sampling requirements, the specific sampling procedures are as follows: after the grey rabbits were killed, the stomach of quadriceps femoris was taken, the liver was washed with normal saline ~ dried and weighed with filter paper, homogenized with 0.2 mol/

absorbance at 562 nm; according to the absorbance value of the sample, calculate the selenium content in the sample through the standard curve

4. The Effect of Nanoselenium on Aerobic Endurance Exercise of Grey Rabbits

As shown in Table 2, SOD of quadriceps femoris in group C was higher at rest before exercise, decreased immediately after exercise, and slightly increased at 2 hours after exercise, while GSH PX decreased immediately after exercise and significantly decreased at 2 hours after exercise, with significant difference compared with that before exercise; MDA increased immediately after exercise. 2 hours after exercise, the value decreased slightly, but still higher than that at rest.

After a week of training, the sod value of preexercise group was significantly higher than that of quiet group ($P < 0.05$), and there were significant differences between the two groups immediately after exercise and 3 hours after exercise ($P < 0.05$); the value of GSH-Px decreased immediately after exercise, but did not recover 3 hours after exercise, which was still lower than that before exercise; MDA value before exercise was higher than that before quiet, immediately after exercise was higher than that before exercise, and decreased at 2 hours after exercise.

As shown in Table 3, the content of selenium in liver of grey rabbits after selenium supplement was higher than that in normal control group ($1.32 \pm 0.065 \, \mu g/g$) ($P < 0.05$). The content of selenium in liver of group C ($1.8 \pm 16.251 \, \mu g/g$) and group D ($1.6 \pm 16.752 \, \mu g/g$) was significantly higher than that in group A ($1.67 \pm 0.31 \, \mu g/g$) ($P < 0.05$).

After a week of training, the sod value of preexercise group was significantly higher than that of quiet group ($P < 0.05$), and there were significant differences between the two groups immediately after exercise and 3 hours after exercise ($P < 0.05$); the value of GSH-Px decreased immediately after exercise, but did not recover 3 hours after exercise, which was still lower than that before exercise; MDA value before exercise was higher than that before quiet, immedi-

ately after exercise was higher than that before exercise, and decreased at 2 hours after exercise.

As shown in Figure 3, the content of selenium in liver of grey rabbits after selenium supplement was higher than that in normal control group ($1.32 \pm 0.065 \, \mu g/g$) ($P < 0.05$). The content of selenium in liver of group C ($1.8 \pm 16.251 \, \mu g/g$) and group D ($1.6 \pm 16.752 \, \mu g/g$) was significantly higher than that in group A ($1.67 \pm 0.31 \, \mu g/g$) ($P < 0.05$).

Selenium content in liver cells of grey rabbits was detected in vitro. 926 cells were treated with H2O2 as an inducer of oxidative stress. The effects of low concentration (0.5 and $1 \, \mu m$) of nanoselenium on endothelial cell oxidative damage were studied by detecting the related markers of cell viability and oxidative stress. The results of MTT assay and LDH activity assay showed that H2O2 induced vascular endothelial cell viability decreased and LDH leakage increased, while nanoselenium pretreatment for 24 hours could significantly inhibit H2O2 induced vascular endothelial cell injury. It was found that hydrogen peroxide could increase the content of malondialdehyde, decrease the activities of SOD and GPX, and decrease the content of glutathione, which indicated that hydrogen peroxide-induced oxidative stress, and nanoselenium pretreatment could significantly reduce the oxidative stress induced by hydrogen peroxide. These results indicate that low concentration of nanoselenium can protect vascular endothelial cells from H2O2-induced injury through antioxidant effect.

As shown in Figures 4 and 5, before exercise, SOD index decreased (1 week), increased (2-4 weeks), and exceeded. The results show that the GSH PX index is relatively unstable, with an increase in volatility (1.3 weeks) and a decrease in volatility (2.4 weeks), but there is no significant difference between them. MDA increased (1 week) and decreased (2-4 weeks), close to the level of 0 weeks, and decreased with continuous exercise.

At 3 hours after liver exercise, SOD index increased with continuous exercise, and there was significant difference between 2-4 weeks and 0 weeks. On the one hand, free radicals have a great influence on the activity of SOD in the liver during 0-week transportation; on the other hand, it also
FIGURE 3: Selenium concentration in animal liver cells.
FIGURE 4: Sod index chart.

FIGURE 5: GSH PX index chart.

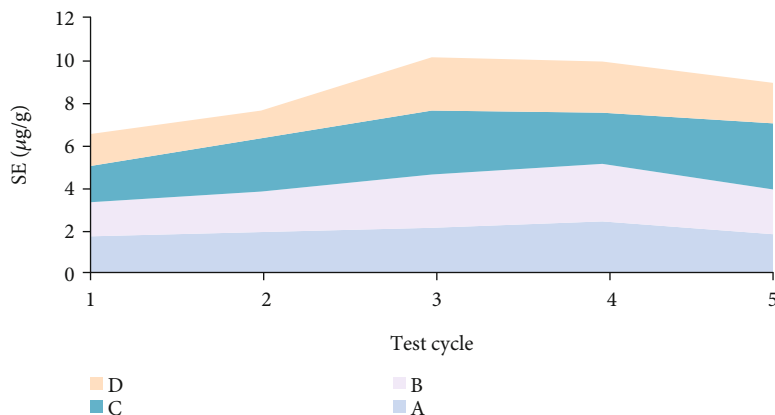
reflects the strong adaptability and recovery ability of visceral organ liver to exercise. As the exercise continued, GSH PX index also showed an overall upward trend, and there were significant differences between the values at week 1 and week 4 and those at week 0. Combined with the activity levels of GSH PX in the second and third weeks of exercise and before exercise, the difference may be due to the lower operating value in the first week, rather than caused by exercise factors; MDA first increased and then decreased in the first week, and the value of the third and fourth week was close to the level of 0 week. The preexercise value is the recovery value 24 hours after the last training of each week. The results showed that the activities of SOD and GSH PX did not fully recover after 0 week of training, but the values of 3 hours in the first week after exercise were very close to those before exercise, while the results of 2-4 weeks showed that the recovery of antioxidant enzyme activity was basically completed 3 hours after exercise. Compared with the


FIGURE 6: Selenium content cycle chart.

changes of antioxidant enzymes in quadriceps femoris, it was found that the recovery efficiency of liver was higher 3 hours after the first week of exercise, and the enzyme activity was close to the level before exercise.

There was no significant difference in SOD and GSH PX at 4 weeks after liver exercise, but increased continuously from 0 to 4 weeks. MDA first increased (week 1), then decreased (week 2-4), close to the level of week 0. The mobile trend is downward. The increase of antioxidant enzyme activity indicated that the stress ability of liver to stimulation was enhanced on the basis of adaptive exercise.

As shown in Figure 6, after a week of intensive training, the accumulation of free radicals in quadriceps femoris increased, and the consumption of SOD and GSH PX increased, resulting in the decrease of SOD and GSH PX activity after exercise, and the change of SOD was significant, which still affected the recovery period. 3 hours after exercise, the changes of antioxidant enzymes in liver were different from those in quadriceps femoris. The recovery rate of SOD was higher than that of resting state. The level of GSH PX also changed significantly. Although nanoselenium products were supplemented at the same time, the emergency capacity of antioxidant enzymes was still very poor in the first week. However, the changes of liver and quadriceps femoris were different 3 hours after exercise. We think it may be related to liver function. However, due to the lack of comparison between the selenium supplement group and the control group, the effect of nanoselenium in the first week needs further analysis. After the second week of exercise, the activities of SOD and GSH PX increased immediately, and the body under the pressure of exercise increased.

GSH PX is an important enzyme that catalyzes the decomposition of hydrogen peroxide. Its active center is selenocysteine, and selenium is an important component of GSH px. After two weeks of supplementation of nanoselenium, we believe that the activity of GSH PX is increased, the ability of scavenging tian0 is enhanced, and the stress capacity is increased due to the increase of selenium content in vivo. However, H0 is not only an inhibitor of SOD but also an inhibitor of superoxide anion.

The activity of SOD will also destroy the structure of SOD and make it lose its activity irreversibly. After adding nanoselenium, the ability of GSH PX and the activity of SOD were improved. Based on hydroxyl radical quenching, rhodamine B fluorescence method can be used to detect the free radical scavenging effect and antioxidant effect of antioxidants. The free radical scavenging effects of selenium nanoparticles (senp), ascorbic acid (VC), and sodium selenite (Na2SeO3) were determined by fluorescence method. With the increase of antioxidant concentration, their ability to scavenge hydroxyl radicals also increased. When the concentration reached a certain level, the scavenging rate decreased. Within a certain concentration range, there was a linear relationship between antioxidant concentration and elimination rate.

These results indicate that selenium nanoparticles are not only stronger than ascorbic acid but also stronger than inorganic salts of selenium, especially in the dose. It is an antioxidant with strong antioxidant activity, which may be the reason why the biological activity of selenium nanoparticles is higher than that of traditional inorganic salts.

5. Discussion

In order to eliminate sports fatigue and reduce sports injury, it is necessary to reduce excessive free radicals in the body. The body relies on certain enzymes and antioxidants to remove free radicals. Proper selenium supplementation can improve the activity of glutathione peroxidase (GSH PX) and enhance the antioxidant capacity of human body. In this study, selenium nanoparticles were prepared, and their scavenging effects on free radicals were studied.

In this paper, through the establishment of nanoselenium on aerobic endurance exercise evaluation model, the effect of nanoselenium on biological aerobic exercise was studied by detecting the related markers of cell viability and oxidative stress. The results of MTT assay and LDH activity assay showed that H2O2 induced vascular endothelial cell viability decreased and LDH leakage increased, while nanoselenium pretreatment for 24 hours could significantly inhibit H2O2 induced vascular endothelial cell injury. It was found that hydrogen peroxide could increase the content of malondialdehyde, decrease the activities of SOD and GPX, and decrease the content of glutathione, which

indicated that hydrogen peroxide-induced oxidative stress, and nanoselenium pretreatment could significantly reduce the oxidative stress induced by hydrogen peroxide. These results indicate that low concentration of nanoselenium can protect vascular endothelial cells from H2O2-induced injury through antioxidant effect.

Due to the limited experience of the author, the research scope is small, but nanoselenium has many functions, such as antibacterial, anticancer, anti-inflammatory, and antioxidant. However, there are still many problems when nanoselenium is used as a disease treatment drug, antibacterial material, or nutritional supplement. Therefore, it is necessary to develop some analytical and detection methods, especially fluorescent labeling technology, to trace nanoselenium in vivo. In order to further expand the application and product development of nanoselenium in biomedical field, it is necessary to continue to explore and research.

Ligament injury is a ligament injury caused by excessive or improper exercise. The purpose of this paper is to analyze the optimal recovery time of patients after anterior cruciate ligament reconstruction and to provide some reference guidance for clinical rehabilitation after ACL reconstruction. Ligament injury not only directly affects the stability of joints but also causes motor dysfunction, thus directly affecting the normal life of patients. A ligament injury occurs when the ligament site is cut or subjected to violent or prolonged stress, and the ligament is stretched beyond its capacity. At present, the treatment cycle of motor ligament injury is relatively long, and the treatment effect needs to be further improved. Rehabilitation training is a kind of functional exercise, also known as functional exercise. For the damaged ankle joint, progressive functional rehabilitation training is one of the irreplaceable treatment and rehabilitation methods in the rehabilitation process, which can effectively improve the sports performance of athletes. Therefore, it is of great significance to explore scientific and efficient treatment methods for motor ligament injury. The purpose of this study is to explore the application value of nanoligaments combined with rehabilitation training of athletes in the treatment of patients with ligament injuries. In this paper, 82 patients with motor ligament injuries treated in our hospital from January 2019 to January 2020 were selected as the final study subjects and randomly divided into control group and observation group, with 41 patients in each group. The control group received a single treatment with nanoligament implantation, while the observation group received a comprehensive treatment with nanoligament implantation combined with rehabilitation training of athletes. Changes in HSS, Lysholm, Lkss, daily life ability, and complications of the two groups of patients before and after treatment were compared. It was found that HSS (The HSS knee scoring criteria involves pain, function, range of motion, muscle strength, flexion deformity, stability, and deduction items.), Lysholm, Lkss, and daily life ability scores of patients in the two groups were increased after treatment compared with before treatment, but the increase was larger in the observation group. All experiments and subjects in the article were conducted under the condition of knowing and signing the agreement. In addition, the probability of complications and ligament injury recurrence in the observation group was 3.12% and 0.97%, respectively, far lower than that in the control group. In order to make the patient recover as soon as possible and return to work as soon as possible, it is necessary to carry out rehabilitation treatment as soon as possible after the operation of the patient, instead of continuously delaying the timing of rehabilitation treatment. *Conclusion.* Nanoligaments combined with rehabilitation training of athletes can improve the therapeutic effect of sports ligament injuries and effectively improve the knee joint function and daily life ability of patients. The timing of rehabilitation intervention is not the sooner the better. Within one to two weeks, such rehabilitation intervention will produce better therapeutic effects.

1. Introduction

Ligament injuries are ligament injuries caused by excessive or improper exercise. Ligament injuries not only directly affect the stability of joints but also cause motor dysfunction, thus directly affecting the normal life of patients [1]. At present, anterior cruciate ligament reconstruction is very effective in the treatment of ligament injury, so it is fully

applied in the treatment of ACL injury. After ligament damage, its recovery ability is low, which is widely used in clinical autograft, allograft, and artificial ligament grafts in the way of treatment, but in the overall exercise ligament damage with a long cycle of treatment, treatment effect also needs to be further promoted; exploring scientific and efficient way of treating sports ligament injury is of great significance [2, 3]. The ankle lateral ligament injury is the most common ankle injury. Whether it is the general population or high-level athletes in the process of work, life, and sports, they are prone to ankle injury due to the influence of the external environment or their own factors. The most common and most frequent joint injury is the lateral ankle ligament injury. However, the final curative effect of anterior ligament reconstruction does not only depend on precise and successful surgery. The complete cure of the patient cannot be guaranteed after surgery. Reasonable postoperative rehabilitation training is also a link that cannot be ignored in rehabilitation treatment.

For the evaluation of knee joint function, proprioceptive indicators are often selected, such as joint position sense, kinematic sense, vibration sense, and balance function, among which the measurement of joint position sense is the most used. There is a problem in competitive sports that we cannot avoid and urgently need to solve, that is, sports injuries that are hard to avoid in training and competition [4]. Because sports injury is an objective phenomenon, no matter what kind of competitive events, only in accordance with the scientific law of gradual training, can methodically improve the level of sports and competition results. On the contrary, not following the scientific law of the growth of motor skills and the scientific law of athletes' physical and mental development will easily lead to the occurrence of injury. For athletes, the occurrence of sports injury is inevitable, but it is necessary to understand the relevant knowledge of injury, which can take effective rehabilitation training after injury, to minimize or avoid the occurrence of injury to athletes training and competitive level caused by the adverse impact. The application of artificial ligaments in the treatment of ligament damage has a history of over 100 years. As early as 1903, foreign scholars proposed the use of silk thread substitutes for ligament repair and carried out relevant case studies, which finally proved that silk ligament implantation could stabilize the joint structure to some extent [5]. The scholar believed that although the growth process of connective tissue was hindered to some extent under silk fibers, once the silk connective tissue was finally formed, the tissue would have good function and emergency [6]. In 1906, other scholars confirmed the conclusion that silk thread was a good material for artificial ligament through experimental progress. In the 1970s and 1980s, artificial ligaments began to be used in the clinical treatment of ligament injuries [7]. In 1973, the FDA approved the treatment of inhibition of artificial ligaments. Jenkins demonstrated in 1978 that carbon fiber could be used in the manufacture of artificial ligaments and that carbon fiber only stayed in human tissues for a short time. The main purpose of the existence of carbon fiber artificial ligaments is to promote the formation of new tissue fibers [8, 9]. In view of

this argument, many scholars have put forward different views. In 1980, Kennedy et al. used synthetic fibrous ligaments in clinical treatment. Such ligaments are less active in the human body and have good biocompatibility, which can share the weight of ligaments sutured and avoid premature absorption of ligaments for transplantation. Some scholars have used cruciate ligaments in postpartum reconstruction of acl and achieved good short-term therapeutic effects [10]. However, a large amount of clinical time indicates that there is a great friction between the artificial ligament of the above materials and the bone, which has a great impact on the service life of the artificial ligament. The emergence of nanomaterials solves this problem well. Currently, nanomaterials are widely used in biomedicine [11, 12]. The role of the knee joint should not be underestimated, but it is prone to injury during the process of functioning. The degree of injury and the treatment effect and rehabilitation effect after the injury all need to adopt certain evaluation standards.

The specific method for measuring the range of motion of the knee joint is as follows: the center of the angle ruler is placed on the lateral epicondyle of the femur, the fixation arm is placed at the midline of the femur, aligned with the greater trochanter, and the moving arm is placed on the midline of the fibula, aligned with the direction of the midline of the lateral malleolus, and placed well. After positioning, fix the knee angle ruler on the affected limb, and let the patient do the maximum flexion and extension of the knee joint without weight-bearing. Rehabilitation training is a related physical activity to promote the improvement and recovery of the function of the injured part as soon as possible [13]. With the continuous updating of medical concepts, people pay more and more attention to postoperative rehabilitation training [14]. Rehabilitation training makes up for the deficiency of traditional treatment, can realize the rapid healing of injury, and plays an important role in the recovery of the function of the injured part. At present, the application of rehabilitation training in clinical follow-up treatment is more and more extensive, and it also plays an important role in clinical treatment. In this paper, a comprehensive treatment method of nanoligaments combined with rehabilitation training of athletes was proposed, and the changes of HSS, Lysholm, Lkss, daily life ability, and complications of the two groups of patients before and after treatment were compared by means of clinical analysis of cases. The effectiveness of this treatment method has been proved, indicating that this method is worthy of extensive promotion in clinical treatment. The study in this paper not only promoted the renewal of the treatment mode and the improvement of the treatment effect of the injury of the motor ligament but also laid a theoretical foundation for the later development of related studies.

2. Theoretical Elaboration

2.1. Ligament Injury.
Ligaments are connections between bones and are relatively obvious microscopic structures. Some ligaments are attached to the surface of bones, while others are fused to the outer layer of the joint capsule.

Ligaments can improve joint stability and reduce and avoid joint injury. Under the condition of external violence, the body will form nonphysiological activities, which will cause excessive stretching of the ligaments, so that its ability to withstand the stretching is far beyond the tolerance of the ligaments, and the ligaments will suffer permanent injuries. The local injury to the ligament that does not involve the joint is called a transitional injury. Complete ligament fracture and avulsion of the bone at the ligamentum attachment site may lead to potential joint dislocation, supracrustal dislocation, or even complete dislocation. The main causes of ligament injury are external factors, such as impingement. Injuries of ligaments caused by sports are called sports ligament injuries. Ligament injuries are usually accompanied by bleeding caused by rupture of small blood vessels, pain and swelling in local areas, and a series of pain and swelling in the ligament tissues, as well as movement disorders in joint parts. Moreover, once the ligament is pulled, there will be significant pain. If the ligament is completely broken, the stability of the human joint will be greatly reduced. The examination to determine ligament injury mainly includes X-ray examination, magnetic resonance examination, arthroscopy, and other special examinations [15]. When ligament damage occurs, first aid treatment must be given to reduce the deep injury caused by ligament damage. First aid treatment for ligament damage includes elevation of the affected limb, cold compress, and compression. After the ligament is injured, it must be treated and comprehensively repaired quickly. If the ligament injury is not treated in time, the joint will be repeatedly injured, and a series of important structures such as the meniscus and articular cartilage will be damaged over time, resulting in joint lordosis, and even further development of secondary traumatic arthritis in severe cases. Repair of damaged ligaments is the focus and core of the treatment of ligament injuries. Partial rupture of ligaments can be repaired by direct suture, and complete ligament exercise can be reconstructed by artificial ligaments and tissue metastasis.

2.2. *Rehabilitation Training.* After the injury occurs, the related physical activities to promote the functional improvement and recovery of the injured part as soon as possible are called rehabilitation training. In addition to some serious injuries that require bed rest, some general injuries may require appropriate exercise. Scientific and reasonable physical activity training can realize the rapid healing of injury and play an important role in the recovery of the function of the injured part. The purpose of rehabilitation training mainly includes four aspects: first, keep good physical condition. The use of rehabilitation training can effectively avoid the occurrence of muscular atrophy, so that the limb can maintain normal motor ability and cardiopulmonary function. Second is to prevent the occurrence of comprehensive symptoms of suspension. The human body will establish various types of conditioned reflex in the long time of activities. If the body activity and movement stop suddenly, the movement balance of the body will be destroyed, and in severe cases, the functional disorder of the severity of the nerd will occur. Thirdly, scientific rehabil-

itation training after physical injury can improve joint stability and promote metabolism of injury location and speed of injury recovery. Fourthly, the use of rehabilitation training can gradually balance the normal metabolism of the body, avoid weight gain caused by rest, and improve the recovery time of injury. The principles of rehabilitation training include the following aspects: first, diagnostic correctness. Correct and comprehensive diagnosis is an important basis for the development of scientific rehabilitation training plan. Second is the principle of individual treatment. The development of rehabilitation training plan should be individualized, and relevant strategies should be developed according to the actual situation of patients such as age and function, so as to promote the continuous improvement of patients' muscle strength and joint activity. Thirdly, the premise of rehabilitation training is not to aggravate the injury and affect the recovery of the injured part. Therefore, the local and systemic movements of patients should not be stopped immediately, and the muscle training should be carried out as soon as possible. Fourthly, the rehabilitation training plan should be comprehensive, insist on gradual progress, and attach importance to the appropriateness of the amount of exercise. In rehabilitation training, it cannot be accomplished overnight. The scope, time, and frequency of training activities should be improved from small to large and slowly. Be guided by the principle of moderation. Too much rapid training can aggravate the injury.

2.3. *Nanotechnology and Nanoligaments.* At present, nanotechnology is widely used in the medical field, which is mainly reflected in stomatology, drug delivery, gene therapy, cardiovascular disease treatment, and orthopedic medicine. First is the application in the oral cavity. In recent years, nanotechnology has been widely used in dental composites and tooth reconstruction. The two most common nanomaterials are filler materials and nanohybrids. Second is nanotechnology load drug function. With the continuous maturity of nanotechnology, the concept of "magic bullet" gradually appeared in the medical field and gradually developed into a systematic nanoloaded drug and delivery system. The formation of this system marks that the research on pharmaceutical preparations has gradually stepped to a higher stage. Third is nanotechnology and gene therapy. At present, low delivery efficiency and unknown direction are the difficulties of gene therapy, but there are great risks in using viral vectors for gene therapy. In order to realize the scientific design of targeted vector, some scholars have tried to introduce nanotechnology into gene therapy. At present, the use of nonviral nanoparticles has been able to successfully realize the transmission of DNA, and the application prospect of gene therapy has been further expanded. Fourth, nanotechnology treats cardiovascular disease. Fifthly, the application of nanotechnology in orthopedics is mainly used as the construction of new bone components. The nanometer size, the number of interfaces and the number of free surfaces, and the interaction between nanometer units are the three common characteristics of nanomaterials. The most commonly used nanomaterials in clinical practice in the new stage include inorganic, organic, and loaded nanomaterials.

Different nanomaterials have different application scope in the medical field, and the use of each nanomaterial should be considered according to its characteristics.

Nanometer ligaments are artificial ligaments mainly composed of nanomaterials. These artificial ligaments overcome the deficiencies of traditional artificial ligaments, have good biological characterization, have the advantages of nontoxicity and low infectivity, and do not hinder the normal growth of tissues around the human body. The most important thing is that the friction between the artificial ligament and the bone is relatively small, so the life of the artificial ligament is relatively long, and it has a long-term effect on ligament injury. Generally speaking, nanoligaments, as artificial ligaments, are suitable for wide application in the field of medicine due to their unique advantages. After the implantation of nanoligaments into human body, as a scaffold material, human microcells can be successfully implanted and attached on the nanoligaments and have a good growth state. This indicates that the three-dimensional structure and biocompatible characteristics of the nanoligament should be good, and it is a brand new scaffold material capable of effectively repairing ligament damage, which can be further studied and used. At present, the key to the preparation of nanoligaments is to produce intelligent nanobiomimetic materials with special functions to effectively regulate the specific properties of cells, so as to further improve the biological activity and compatibility of nanoligaments. For a long time to come, the preparation of nanoligaments still has great room for improvement.

3. Case Analysis Experiment

3.1. Experimental Subjects.
In this study, 82 patients with motor ligament injuries treated in our hospital from January 2019 to January 2020 were selected as the final research subjects. The inclusion criteria of the experimental subjects were as follows: first, after imaging detection, it was determined to be motor ligament injury; second, the subjects were all over 18 years old. Thirdly, sports ligament surgery and related treatment were selected. The time period from ligament injury to operation was 3 weeks to 17 months. Fourthly, the patient has relatively clear consciousness and understanding ability and can independently complete the questionnaire survey and relevant scoring test. Fifthly, the patients and their families all volunteered to participate in this experiment and signed a consent form. The exclusion criteria for subjects were as follows: first, patients with an abnormal mental state or some degree of drug dependence; second, patients with other types of severe disease; and third, patients with low compliance and compliance. The 82 patients were randomly divided into two groups (41 patients in each group), the control group and the observation group. The control group included 14 female patients and 27 male patients, with an average age of 29.6 years. The observation group included 13 female patients and 28 male patients, with an average age of 29.4 years old. There was no significant statistical difference in the basic data of the two groups of patients, which could be used for the experimental comparison in this paper.

3.2. Experimental Methods.
Patients in the control group were implanted with nanoligaments during the surgical treatment. During the implantation of nanoligaments, attention was paid to the rejection response of the body to avoid infection. After the operation, only the traditional way of rehabilitation was used, mainly repose. Observation group of patients with intraoperative implantation of nanoligament, postoperative use of athlete way of rehabilitation training for recovery, and specific rehabilitation training method is as follows: after the surgery using pressurized elastic band to bind up the limb, external use fixed support, to practice straight a ligament out slowly, the side of the operation in training of muscle and ligament surrounding tissues; one day after the surgery, quadriceps femoris muscles were trained for contraction, and the joints were autonomously pressed or lifted, 15 times in a group, 10 times a day. 2 d after the operation, the range of motion of the ligaments on the surgical side was trained. The ligaments on the surgical side were elevated with a pillow in the sitting position, and the ligaments were relaxed after stretching for 10 s. The training duration was 5 min each time, 3 times a day. After the operation, the ligament function was trained in 3D. The ligament flexion and extension angle was between 0° and 30°. The ligament was trained once every half an hour and twice a day. Then, according to the doctor's advice, walk with the help of tools and try to carry out weight training. The weight of the weight-bearing object should increase gradually. 2 to 4 weeks after the operation, proprioception was reconstructed, and balance strength was trained, activity strength of one side of the injured ligament was further improved, and rehabilitation training time was reasonably prolonged. From April to June after the surgery, the ligament resistance training should be carried out, and some training such as swimming should be arranged reasonably to help the further recovery of ligament function.

3.3. Evaluation Index.
With reference to the existing research materials, the writer will determine the final evaluation index for the following several aspects: first, the ligament function evaluation, before and after treatment for 6 months, is ligament score (HSS), and by using the Lysholm ligament function (LKSS) to assess the patient ligament function, HSS score includes pain, activity level, function, muscle strength, acute and buckling stability a few main dimension, such as the final income comes higher scores on behalf of the ligament functional recovery, the better. LKSS scores mainly include swelling, pain, squatting, and other aspects. 100 is normal, more than 80 is excellent, 70 to 79 is good, 60 to 69 is qualified, and less than 60 is poor. Second is self-efficacy evaluation. The GSES table was used to evaluate patients' self-efficacy before and after treatment, including their ability to solve and deal with things. The higher the final score, the higher the patient's sense of self-efficacy. Third is daily life evaluation. The BI table was used to evaluate the patient's daily life ability. The evaluation content included multiple aspects of the patient's daily life, and the final score was in direct proportion to the patient's daily life ability. Fourth is statistical observation of complications

TABLE 1: HSS score data table.

Group	Time	Pain	Function	Activity	Muscle strength	Flexion deformity	Stability
Observation group	Before treatment	15.26	12.65	11.76	6.21	5.63	6.22
	After treatment	25.56	18.41	16.23	9.05	9.24	9.32
Control group	Before treatment	15.31	12.68	11.83	6.32	5.64	6.23
	After treatment	21.16	15.61	14.02	7.86	7.96	7.98

*Data came from the experimental analysis.
FIGURE 1: LKSS score data of the observation group before and after treatment.
FIGURE 2: LKSS score data of the control group before and after treatment.

and recurrence rate. Postoperative complications and recurrence were counted in the two groups.

3.4. Experimental Data Statistics. SPSS statistical software was used to conduct statistical collation of experimental data. After the completion of data statistics, computer graphics software was used to draw data charts and draw relevant experimental conclusions based on the analysis of data charts. In the process of data recording, the accuracy and comprehensiveness of experimental data must be guaranteed to avoid conclusion errors due to experimental data errors.

4. Experimental Results and Discussion

4.1. Experimental Results

4.1.1. HSS Data Comparison. Table 1 is the HSS score data table. It can be seen from the data in the table that after treatment, the HSS score of patients in the control group

GSES table data comparison
Figure 3: Comparison of GSES table data.

and the observation group increased as well as before treatment. However, compared with the control group, patients in the observation group were significantly higher in pain, muscle strength, activity, function, and stability after the treatment with the nanotube combined with athlete rehabilitation training.

4.1.2. Comparison of LKSS Scores. Figures 1 and 2, respectively, show the LKSS scores of patients with motor ligament injury in the observation group and the control group before and after treatment. As can be seen from the data in the figure, the LKSS scores of patients in both groups before and after treatment presented an increasing trend. But on the whole, the scores of exercise patients in the observation group improved more in all dimensions before and after treatment. Therefore, the combination of nanoligaments and rehabilitation training for athletes can effectively improve the function of ligaments in patients.

4.1.3. Comparison between CSES Table and BI Index Score. Figures 3 and 4, respectively, show the GSES table data in contrast with BI index score data, the data we can see from the picture; after treatment, the observation group and control group in the GSES table and BI experienced score rise, but the whole observation group of patients with GSES table and BI index score was significantly higher than the control group patients. This indicates that the use of nanoligaments combined with rehabilitation training for athletes can promote the continuous improvement of patients' self-efficacy and daily life ability.

4.1.4. Comparison of Complications and Recurrence Rates. Table 2 shows the data of complications and recurrence after treatment in the two groups. It can be seen from the data in the table that the probability of complications and recurrence of ligament injury in the control group is 17.21% and 16.54%, respectively, while the probability of complications and recurrence of ligament injury in the observation group is 3.12% and 0.97%, respectively. This indicates that the combined treatment of nanoligaments combined with rehabilitation training for athletes has a stronger safety compared with the single treatment, which can greatly reduce the

possibility of recurrence of ligament injuries, and has a good therapeutic effect.

4.2. Discussion of Experimental Results. Ligament injury is a condition of ligament injury caused by sports. Ligament injury will have a direct impact on the overall stability of human joints, promote the continuous acceleration of joint degradation, and thus have a very adverse impact on ligament, joint function, and the quality of life of patients. At present, the treatment of ligament injury is still dominated by arthroscopic revascularization. However, due to the complex overall structure of ligaments and joints, the recovery of fitness, function and exercise ability is also relatively complex. If the patient performs joint immobilization unscientifically or rests in bed for a long time after surgery, it will directly affect the dynamic balance of the joints and ligaments, and even lead to muscle atrophy, which is not conducive to the recovery of the patient's motor function. Therefore, attention must be paid to rehabilitation training after treatment, which can not only promote the improvement of nursing efficiency but also greatly improve the final treatment effect.

At present, studies of nanometer materials applied in tissue engineering is still at the primary stage, especially in the biomedical field; a lot of research is still in the stage of animal experiments, according to a lot of clinical experiments which verified the conclusion; in addition, the application of nanometer materials in the process of biological safety needs further improvement. Due to the continuous steps of nanotechnology, subdisciplines related to nanotechnology have been established and improved, such as nanoelectronics, biology, medicine, and materials science. The fusion between nanomaterials and the above disciplines is getting closer and closer. Some experts predict that nanoceramics will play an important role in the manufacture of artificial bones for a long period of time in the future, and organic and inorganic composite nanomaterials with various properties will certainly play an important role in the interventional repair of ligament injuries. Existing research data show that human ligaments are composed of many fibers, and these fibers have a stopping point at both the tibia and femur. When the knee joint is at different positions, some of the fibers are tensioned and play a role in stabilizing the knee joint. Therefore, when the motor ligament is completely broken, it is extremely important to use the nanoligament to reconstruct the human ligament. For the patients with partial injury of the motor ligament, they can make corresponding choices according to their specific conditions. Animal experiments confirmed that the toughness and elasticity of the healed ligaments were almost the same as that of the injured anterior ligaments. The experiment in this paper confirmed that the overall function and stability of ligamentum knee joints of patients with ligament injuries were significantly improved after rehabilitation training of athletes. The muscles near the knee joint can compensate for the instability of the knee joint under slow motion. If the muscles around the joint are weak, effective control of the joint cannot be achieved. Whether ligaments can realize the effective play of motor function is also closely related
BI index score data

FIGURE 4: BI index scoring data.

TABLE 2: Data of complications and recurrence in the two groups.

Group	Complications	Recurrence rate
Control group	17.21%	16.54%
Observation group	3.12%	0.97%

*Data came from the experimental analysis.

to the recovery of proprioception of human body. Therefore, after the completion of the corresponding surgical treatment, patients with sports injuries should also strengthen the muscle strength and proprioceptive training in the early stage to avoid muscular atrophy and other conditions, so as to effectively prevent secondary knee injuries caused by sports ligament injuries.

In this study, the control group was treated only by nanoligament implantation, while the observation group was given rehabilitation training for athletes after the completion of nanoligament implantation, so as to highlight the patients' initiative in rehabilitation training and develop reasonable rehabilitation training strategies according to their own deficiencies. On the basis of stabilizing the injury condition, the recovery of life ability and overall motor function of the patients was promoted. The results showed that the HSS and LKSS functional scores of the patients in the observation group were significantly higher than those in the control group after 6 months of treatment, and the improvement of daily life ability of the patients in the observation group was much better than that of the control group. In addition, the author has also made after treatment for patients with complications and recurrence monitoring; monitoring results show that the observation group of patients with postoperative complications and recurrence of ligament damage probability is significantly lower than the control group, two groups of results and no statistical difference; however, this may be caused by experimental sample number less, which later still needs thorough expansion of research samples.

To sum up, the use of nano-combined athlete rehabilitation therapy can promote the overall treatment effect of patients with ligament injury, and promote the effective improvement of joint ligament function in patients, and is also beneficial to patients' self-efficacy and further improvement of daily living ability. It has good clinical application value and is worthy of further promotion in clinical experiments.

5. Conclusion

Sports injury and rehabilitation training are closely linked and affect each other. It is very necessary to carry out active and effective rehabilitation training after the occurrence of injury, which can promote the rapid recovery of the injured part of the athletes. There are many types of sports injuries, and rehabilitation training programs for different injuries are different. It is necessary to study targeted rehabilitation training for the common injury parts in sports, such as knee joint and ankle joint. In this paper, a comprehensive treatment method of nanoligaments combined with rehabilitation training of athletes was proposed, and the changes of HSS, Lysholm, Lkss, daily life ability, and complications of the two groups of patients before and after treatment were compared by means of clinical analysis of cases. To sum up, the rehabilitation treatment of articular ligament in athletes can promote the overall treatment effect of patients with ligament injury, and promote the effective improvement of ligament function of patients, and is also beneficial to the patient's self-efficacy and further improving the ability of daily life. It has a good curative effect and is worthy of further promotion in clinical trials. However, the exact clinical application of this treatment method needs further research and exploration.

Data Availability

No data were used to support this study.

In the fast-paced development of life in today's society, the use of ECG signals is not only used in the medical direction to scan patients; portable ECG signal acquisition tools can collect and analyze the corresponding ECG signals in time and respond to the wearer in time, so that the user can make timely adjustments or seek medical treatment in time to avoid a malignant situation that occurs. For people in sports, the collection of ECG signals is more helpful to the arrangement and estimation of training conditions. Based on nonvolatile memory technology, data will not be lost when the computer is turned off or suddenly or unexpectedly shut down. This research puts forward the design of an antiexercise ECG monitoring system that collects ECG signals for a group that is in the process of exercise. Use mathematical calculation system to classify, and conduct in-depth analysis of the reasons for poor anti-interference ability, and use the original denoising algorithm calculation as the basis to adapt to the dynamic situation in the opposite situation to the normal ECG signal acquisition in the static state. The collection is modified from the original basis. This research proposes an improved scheme for multichannel acquisition. Chips of semiconductor memory devices based on nonvolatile memory are embedded in mobile devices for use. The experimental results in this paper show that the comparison experiment ratio of collecting ECG signals from the sixth, third, fourth, and fifth directions can effectively reduce the mean square error (MSE), and the error of channel 6 is directly from 0.1598. It is down to 0.00143. Several other items showed a significant decrease. It shows that the anti-interference ability of the ECG monitoring system can be further enhanced by increasing the number of collection terminals.

1. Introduction

1.1. Background. In today's society where speed is the main development, the fast-paced life and work have produced huge pressures, and people's physical conditions are basically in a subhealthy physiological state, which is one of the cases where there are no serious illnesses and many minor problems. Today's smart Internet is undergoing rapid development. With the widespread popularity of its applications, research in the direction of the medical industry has also begun to reform itself. This should be due to the pressure brought by digital networking. The worries about medical resources have now initially become an important influence plaguing its development. The masses now have the burden of "difficult and expensive" medical treatment for the medical industry. In addition, society has entered a

serious aging trend. The continued development of the medical industry is the focus of global attention. For patients with heart disease, there is a medical gap that is difficult to bridge. According to medical statistics, more than 71% of heart disease cases occur outside the hospital, and three-fifths of them immediately die at home. Therefore, the existence of an ECG signal collector that can detect the time of a heart attack by a system with monitoring performance has an inevitable effect. When a disease occurs, it can feedback information in time, and the wearer who receives the prompt information in time can respond to it in the first time and make corresponding treatment in time. Therefore, the best treatment time will not be missed. So most patients can get timely diagnosis and treatment when they are sick and can be treated with the help of medical advice and can avoid death. Therefore, if they can wear portable health

appliances to monitor heart function and real-time monitoring and diagnosis, it will play an important role in alleviating diseases and implementing aid. For athletes, the ECG monitoring system can allow trainers to better understand the physical information of the athlete and avoid physical injury; it can also enable the athlete to maintain the exercise intensity and make the exercise effect better.

1.2. Significance. As far as the ECG signal acquisition and monitoring system is concerned, most of the current ECG monitors on the market require a static environment to collect ECG information, and the overall appearance is not too small. Even if there are portable ECG monitors on the market today, most of them are inefficient and relatively expensive. The test results are somewhat unreliable. Therefore, further research on the portable ECG monitoring system is also the focus of the development of the medical industry. The portable ECG signal monitoring system is in urgent need of further research and is also an important measure in the medical industry.

1.3. Related Work. Based on the current social population's emphasis on health, the ECG signal that can monitor the physical condition to a certain extent has been deeply researched. In the current research on the collection and storage of ECG signals, Son et al. first reported on their observations of these writing characteristics in the article: (1) log writing dominates storage writing. (2) Overwriting is frequently in mobile storage. And most importantly, (3) these overlays only change a small part of the data. Based on these observations, they recommend using a nonvolatile write buffer backed by small capacitors and using it to store small writes persistently without logging. This allows them to completely avoid those lowercase log writes, which helps to significantly reduce log-induced writes while still providing the same level of data consistency and durability [1]. The traditional PoP structure using FC-BGA (Flip Chip-BGA) has some problems in package warpage and thickness. To solve these problems, Tanaka et al. developed an embedded device package called MCeP (Molded Core Embedded Package) for the bottom package of the PoP structure. MCeP consists of a top substrate, a bottom substrate, and an embedded layer, and the IC device is encapsulated in the embedded layer by molding resin. This kind of package has the beneficial characteristics of reducing package warpage. The package warpage can be controlled by optimizing the thickness and material of each layer (top substrate, bottom substrate, and embedded layer) [2]. Lai and Shynk propose a two-stage continuous cancellation (SC) algorithm that sequentially separates the fetal and maternal heartbeats from the intrauterine electrocardiogram (IuECG) signal containing the fetal and maternal QRS complex. The ECG signal is modeled as a series of fetal, maternal, and noise events. Peak detection is first used to locate potential fetal and maternal QRS complexes, called candidate events. Each stage automatically generates source templates from candidate events in the initialization stage and then classifies the remaining candidate events according to template matching technology. Before the weaker signals are initialized and

classified, the detected stronger signal events are subtracted from the composite ECG signal. Once the fetal and maternal complex is successfully detected and separated, the counting mechanism will be used to derive the corresponding heart rate [3]. Prove the capacitive effect and nonvolatile storage capability. A low-power passive filter is designed, which can be used in the design of reprogrammable analog circuits, paving the way for future multifunctional nanodevices [4]. As an active material for supercapacitor electrodes, biomass-derived carbon has attracted much attention due to its environmental friendliness, richness, and porosity. In this case, in Keppetipola et al., activated carbon prepared from coconut shell through a simple activation process (water or steam as the activator) is used as the active material in the electrode of the environmentally friendly supercapacitor. Studies have shown that the activated carbon produced by this method exhibits a graphite phase, high surface area, and large pore volume [5]. Xu et al. proposed a method for denoising and baseline drift correction of electrocardiogram (ECG) signals based on a complete set of adaptive noise into empirical mode decomposition (CEEM-DAN) and wavelet threshold. Although CEEMDAN is based on empirical mode decomposition (EMD), it represents a significant improvement over the original EMD by overcoming the problem of mode mixing [6]. Abdullah et al. proposed a robust method for extracting fetal maternal heart rate from noninvasive composite abdominal electrocardiogram (aECG) signals. The proposed method is based on the fully integrated empirical mode decomposition (CEEM-DAN) method with adaptive noise, in which the composite aECG signal is decomposed into its constituent frequency components, called intrinsic mode function (IMF) or simply "mode." The separated IMF is then manually selected according to the possible maternal-fetal heart rate information and further processed to quantify maternal-fetal heart rate and variability analysis [7]. The research expertise of the above scholars is extremely high and requires a deeper understanding of it and experience. During the verification process, the experimental samples are difficult to collect, and the operation technology requirements are high, and it is difficult to operate.

1.4. Innovation. Most ECG signal monitoring systems on the market today have a common defect; that is, only when the test subject with testing needs is in a certain static situation, a qualified ECG signal sample can be extracted. That is to say, the ECG signal receiving system of the existing portable ECG monitoring system on the market has poor antiexercise interference ability [8], because the human body will have a larger breathing pattern after exercise, which is more intense. The respiration of the ECG signal will cause the collected ECG signal to be mixed with larger amplitude noise, which will distort the sample recorded in the ECG signal, and excessive noise will cause the waveform of the ECG signal to be distorted. Therefore, in this case, it is very necessary to study and explore the experimental design of antiexercise portable ECG monitor to improve the performance of ECG anti-interference.

2. Collect Nonvolatile Memory Based on ECG Signal

2.1. The Basic Principle of Nonvolatile Storage Based on ECG Signal Acquisition. Nonvolatile memory is a computer memory whose stored data does not disappear when the current is turned off. The main classification of current nonvolatile memory is shown in Figure 1. The storage is divided according to the different ways of data processing, and the nonvolatile semiconductor memory is divided into two types [9]. Random access memory allows reading and writing of stored data, but when the power is turned off and power is lost, it will cause the stored data source to lose its storage content [10]; read-only memory operates normally without external interference. In the case that only the data content in the storage unit is allowed to be read, the stored data content cannot be modified [11]. Its advantage lies in the stored data even when the power is lost. The samples can also be kept intact [12].

The modern system chip design of the IP core based on the nonvolatile storage circuit allows system designers to explore different system architectures. The application of the IP core makes the system architecture unnecessary to study each module in-depth [13]. This method effectively reduces the complexity of the problems encountered in the design process [14]. This can shorten the design cycle and speed up the product speed. You can use existing process solutions more effectively and reduce costs [15]. Embedded nonvolatile memory is used as part of many current system solutions. Not only can it provide the ability to change the execution data on each software production line or on-site software. Communication applications include mobile phones, mobile phone communication devices and smart cards, and in-vehicle electronic devices. This design can extend the life of the entire system, reduce the chip area [16], and save costs.

2.2. Nonvolatile Memory Programming Mechanism Based on ECG Signal. Nonvolatile storage [17] can be freely written and modified by the user, such as programmable, erasable programmable, electrically erasable, flash memory, and storage. Among them, the programmable ROM is manufactured with fuses, and the interconnection between memory cells is realized by blowing the fuses [18]. ROM is an abbreviation for read-only memory that can only read and cannot write information. Erasable programmable ROM uses ultraviolet rays to inject and remove hot electrons from the floating gate of the memory cell to achieve memory programming and erasing operations [19]. Both electrically erasable PROM and flash memory belong to electrically erasable nonvolatile memory; PROM is short for programmable read-only memory. Their working mechanism is to inject electrons into floating gate devices through electrical means [20]. Below, we mainly discuss the two types of programming and erasing. The main methods are FN tunnel effect and channel hot electron injection.

The threshold voltage VT of the floating gate transistor can be changed by programming. A high voltage is connected to the source grounding gate terminal and the drain

terminal. The high potential difference will generate a strong electric field, and then, the strong electric field will cause electron avalanche injection. When the electrons get enough energy, they will pass through the first insulating oxide layer and be trapped by the floating gate. Therefore, floating gate transistors are also called floating gate avalanche injection.

(1) FN tunneling effect: for nonvolatile memory, the tunneling effect is an important injection method [21]. Macroscopic quantum tunneling is one of the fundamental quantum phenomena; that is, when the total energy of a microscopic particle is less than the height of the potential barrier, the particle can still pass through the potential barrier [22]. Electrically programmable read-only memory (EPROM) uses channel hot electron injection for programming, but hot electron injection cannot be used for erasing. EPROM erasing is achieved by irradiating ultraviolet rays (UV) onto the unit through a closed transparent window. When EPROM is programmed and read, it is addressed in the unit of byte, and each byte can be addressed separately [23]. However, when erasing with ultraviolet light, the entire memory area will be affected. At the same time, UV erasing has problems such as time-consuming, poor durability, and low reliability. EPROM uses UV erasing, so a quartz window needs to be provided in the package, which leads to higher costs for EPROM packaging. On the other hand, EPROM has a simple structure and high density, so it can produce large-capacity memory at a lower cost, so there is still a certain market in some applications that do not require frequent erasure and reprogramming [24]. But due to price and reliability reasons, EPROM was replaced by flash memory. The electron passes through the tunnel, and its current density is expressed as

$$G = \delta V_{\text{ing}}^2 \exp\left\{-\frac{\beta}{V\text{ing}}\right\}, \tag{1}$$

$$\delta = \frac{Q^3}{8\pi H \Phi r} \frac{n}{n^*}, \tag{2}$$

$$\beta = 4\sqrt{2n^*} \frac{\varphi_n^{3/2}}{3HQ}. \tag{3}$$

In the equation, H represents the Planck constant, Φr is the barrier height when injected at the interface, Q represents the charge of a single electron, and n represents the free electron. Among them, $H = h/2\pi$

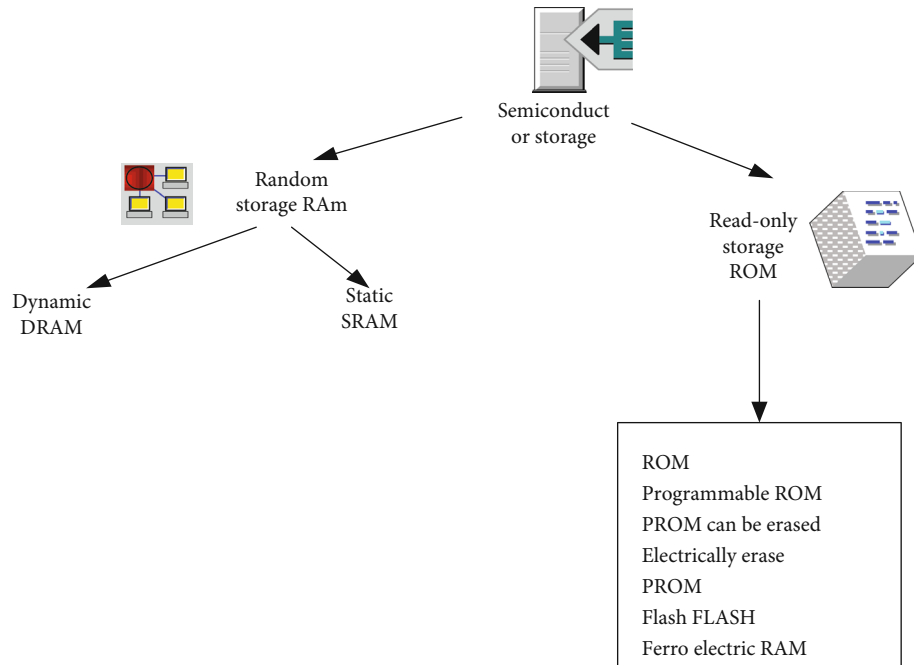
(2) Thermal injection of carriers: the process of electron injection is to inject electrons into the floating gate through the discharge of the memory cell area [25]. The electric field receives the electric field from it. If there is a positive voltage and when the electrons pass through the substrate and the gate, the barrier


Figure 1: Storage classification.

between the oxides rises 3.3 eV with the negative voltage of VDS. The control gate VCG absorbs electric heat to the floating gate. Since the floating gate is surrounded by silicon dioxide and has no contact with other things, and silicon dioxide is an excellent insulator, the negative charges captured by the floating gate are not easily lost and can stay in the floating gate for a long time. For a long time, even if there is no power supply voltage, it will not be affected at all. This is the reason why the memory with floating gate transistor as the core component is called nonvolatile memory [26]

In fact, almost all current nonvolatile memories are based on floating gate transistors [27], and the different types of nonvolatile memories are mainly due to their different erasing mechanisms. This EPROM cell structure is shown in Figure 2. Figure 2(a) is a diagram of the corresponding basic structure of the storage unit; Figure 2(b) is a cross-sectional view from the perspective of the installation direction of the structural diagram on the left, and Figure 2(c) shows the schematic diagram of the circuit structure of its operation. But the improvement of EEPROM function comes at the expense of area. Because EEPROM performs various operations in bytes, its memory cell is composed of two transistors, one is a memory transistor [28], and the other is a selection transistor. Compared with a tube of EPROM, EEPROM has two transistors.

Table 1 shows the voltage value of each port of the EEPROM cell under different operating conditions.

Flash memory (FLASH) is combined with electronic processing and removal to realize your EPROM tube. It can be deleted completely, or the function can be deleted in one operation.

Currently, there are two types of flash memory systems: NOR-based flash memory (FLASH) memory used for program and data storage and NAND-based flash memory (FLASH) storage tools required for large-capacity data storage, such as memory cards and state disk devices. Flash, Flash EEPROM, was proposed in 1984 and soon developed into the most widely used nonvolatile memory structure. Flash memory is equivalent to a technical combination of EPROM and EEPROM. It is based on a floating gate structure and uses avalanche hot electron injection programming and electrical signal erasing. However, unlike EEPROM, the erasing of Flash is not done in bytes. Block erase is performed on a subpart of the memory. Although it is not as flexible as EEPROM in this respect, its advantages are also obvious. The cell structure eliminates the access transistor, so that the cell area is significantly reduced, the density is higher, the integration level is improved, and the production cost is reduced.

2.3. ECG Signal Noise. The ECG signal not only contains a variety of noise interference, but its own waveform also has unpredictable volatility, which is an unstable nonlinear signal. When analyzing and detecting ECG signals, it is often necessary to decompose and analyze the local information. Therefore, the classic Fourier transform technology obviously cannot be satisfied. The short-time Fourier transform developed on the basis of the Fourier transform to some extent made up for the shortcomings of the former localization analysis. The phase of the Fourier transform is very sensitive to noise. Even if a small segment of the data is wrong, the phase obtained by the Fourier transform will be much different from the real phase [29]. But because it still uses a continuous periodic sine function as the transform base function, it leads to its time domain. Analyzing ability and
FIGURE 2: Schematic diagram of structure, storage unit, and cross-section.

VS	GND	FLOAT	GND
VB	GND	GND	GND

frequency domain analysis ability often constrain each other and cannot adapt to signals with changeable time-frequency characteristics at the same time. In recent years, wavelet transform has developed rapidly, and the technical level has become more mature. Because of its excellent time-frequency analysis and localized analysis characteristics, wavelet transform has been applied to many fields such as earthquake prediction, petroleum exploration, image processing, and speech recognition.

The ECG signal is the physiological signal of the human body, and it is a weak signal. In the process of collection and transmission, it will be interfered with by the electrical characteristics, the environment, and the activities of the human body itself, and it will be doped with many noises and interferences.

(1) Power frequency noise: power frequency interference comes from the electromagnetic field emitted by the power frequency power supply and the transmission line near the equipment. Line frequency noise is generally related to the measurement and use environment. However, the source of interference in the environment still exists, so further processing is still needed in the monitoring center

(2) Baseline drift noise: the basic noise comes from the human body. The body and tissues in the thoracic cavity will change to different degrees when a person breathes. The small change in the electrode's skin interface impedance becomes the influence of the amplitude. In addition, the amplitude of the ECG waveform is recorded on the body surface, affecting the image. This type of noise rarely has signal interference, and the frequency is usually less than 1 Hz. When such a curve is superimposed on the ECG waveform, the waveform changes, making it difficult to analyze and analyze the ECG waveform, especially the segments that affect the ECG waveform

(3) EMG noise: EMG noise interference is a very large interference, which can change up to 30 mV inside and outside the human epidermis. The ECG signal is input through the electrodes on the body surface, causing noise interference

(4) Motion artifact noise: since the ECG monitoring terminal is movable, the movement of the user in daily life will inevitably cause slight movement or jitter in the contact part of the electrode, which will cause the difference between the electrode and the skin. The impedance changes, causing contact noise. This interference generally lasts for a long time, and the amplitude can exceed the amplitude of the ECG signal and even lead to the full output of the amplifier, resulting in jump interference

3. System Design of Multichannel ECG Monitoring against Exercise Interference

The frequency response curve of the filter is not a perfect step curve, but a straight line with a slope. Therefore, even after the filter is used to denoise, the noise near the ECG signal frequency still exists. Noise seems to affect the ECG signal, so improve the signal to get a good ECG signal.

3.1. ECG Signal Measurement Based on Exercise Monitoring. The electrocardiogram is an important indicator to measure the bioelectricity produced by the human body. The reason for the electrocardiogram is that the energy cycle of the heart involves changes in its volume. Since the human body can be regarded as a very valuable conductor, the exchange capacity of the heart can be quickly transferred to the surface of the human body. Therefore, by attaching electrodes to the surface of the body, the capacitance during the heartbeat can

TABLE 2: Main noise of ECG signal.

Noise	Power frequency interference	EMG interference	Baseline drift
Frequency	50 Hz and high frequency harmonics	0-1000 Hz	0.05-2 Hz
Amplitude	Less than 50% of the ECG signal wave value	5 mV	ECG signal peak 15%
Manifestations	There are regular small ripples	Irregular small ripples	Up and down shift of heart waves

be separated, and the heartbeat can completely collect electrical signals to obtain the corresponding electrocardiogram [30].

First, determine the item of the original item listed. Key indicators include ECG signal and noise. These usually include the influence of power frequency, route drift, and EMG interference, as shown in Table 2. Power frequency interference is generally 50 Hz power line interference and a small amount of interference resolution. Due to the distribution of the human body surface, the human body has an antenna effect. In addition, under normal circumstances, whenever the ECG receives a signal, a long time reading occurs, which affects the frequency response. The skin volume of the outer and inner layers of the human body is 30 millivolts. If the skin stretches slightly, it will drop to 25 mV. Therefore, a skin capacitance of up to 5 mV should be superimposed on the ECG signal. This is the noise that people see due to myoelectric contraction. When users are stressed and affected by certain diseases, EMG frequencies may occur. Briefly summarize the main noises into a table:

3.2. Improvement Direction of Acquisition Circuit Based on Motion Monitoring. Simply put, the amplifier circuit is to amplify the weak signal provided by the signal source to drive the load to work normally. The failure of the amplifier operating circuit is random, and this random error causes the initial phase of the multisignal receiving system to be different, and the phase difference is not constant. In this experiment, the six purchased terminals passed a signal processing circuit. Each signal processing circuit has two operational amplifiers on the chip, but each amplifier in the amplifying circuit and filter circuit corresponds to the operational amplifier chip. In fact, only one of them is used, and the other op amps in the chip are in idle state. The advantage of this design is that it is easy to debug the circuit at each stage. There are two disadvantages. One is the high cost, and the other is the increase in errors caused by subtle differences in the circuit. Between each amplifier is not neutral. Therefore, if allowed, high-performance machines should be purchased. The difference between twins is not limited to cousins, because the difference between two amplifiers packaged on the same chip is much smaller than the difference in appearance and appearance of the amplifiers packaged on two chips. Therefore, you can choose a chip with greater internal noise to reduce errors. The best scenario for this test is to buy a chip with internal noise and send the signal to the amplifier on the chip. Reduce the random error reported by the amplifier circuit parameters. The loop created in this experiment has no obvious effect on efficiency, so you do not have to spend time rebuilding the loop based on the above improvements, but as the number of

receiving channels increases, the error will be random. There is no doubt that the circuit will affect the experiment, so if you encounter this problem in future experiments, please install electrical equipment according to the above procedures.

3.3. Hybrid Algorithm Design. Based on the sum of wavelet coefficients of wavelet transform, the collected ECG signals are classified. The analysis method of wavelet transform inherits and develops the idea of localization of short-time Fourier transform and at the same time overcomes the shortcomings of window size that does not change with frequency. It is an ideal tool for signal time-frequency analysis and processing. After classifying the interference factors, analyze them one by one and divide them into 6 branches.

As shown in Figure 3, even if the original signal is processed by the filter circuit, there is still residual noise, resulting in distortion of the ECG signal.

4. Hybrid Algorithm Denoising Algorithm and Experimental Results

4.1. Wavelet and Independent Component Analysis. The ECG signal is located in the low frequency region of 0.03-45 Hz, which is relatively stable, and the noise signal usually appears as a high signal. Therefore, as shown in Figure 4, it is best to use the wavelet transform method to decompose the noisy original signal. Noise is usually in high-frequency wavelet coefficients, which is characterized by large amplitude and small size in the ECG signal. When the wavelet coefficient is similar to the noise, it is characterized by small amplitude and large value. Based on the above characteristics, an initialization method can be used to process the wavelet coefficients. The algorithm block diagram is shown as in Figure 5.

As shown in Figure 6, it can be seen that the baseline drift of the six ECG signals caused by respiration has been basically eliminated, and other interference components have also been greatly weakened.

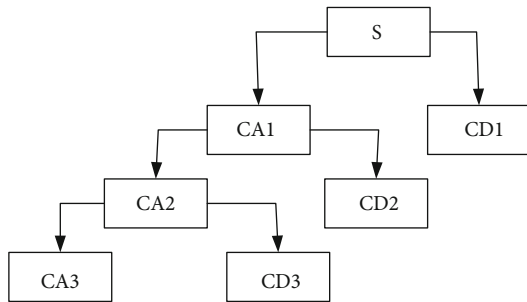
However, the ECG signal in Figure 6 still contains residual power frequency interference and other intermediate frequency noise components. The reason for this is that the frequency of the noise is similar or even the same as the frequency of the ECG signal. Therefore, the threshold method cannot separate the ECG signal and noise. In order to finely filter the noise, independent component analysis methods must be used. The independent component analysis method is based on the mutual statistical independence between the sources. Compared with traditional filtering methods and accumulative averaging methods, independent component analysis does not destroy the details of other signals while
FIGURE 3: Timing diagram of the original electrical signal.


FIGURE 4: Schematic diagram of the decomposition process.

eliminating noise, and the denoising performance is often much better than traditional filtering methods. This experiment has 6 signal acquisition channels, which are sufficient to estimate the residual power frequency interference and EMG interference. The six signal channels are analyzed independently to obtain separated ECG signal and noise, as shown in Figure 7.

It can be seen that the residual noise of the ECG signal is suppressed, and the waveform is closer to the standard ECG signal.

If you compare the advantages and disadvantages of the four methods, it is far from enough to make qualitative statements based on observation methods. However, when conditions permit, mathematical evaluation indicators should be used to make quantitative statements. For quantitative analysis, two indicators, signal-to-noise ratio (SNr) and root mean square error (MSe), are used. The signal-to-noise ratio refers to the ratio of the power of the propagated signal to

the power of the noise involved in the process of signal propagation. That is to say, the larger the signal-to-noise ratio, the stronger the noise suppression capability. Root mean square error (MSe) is the arithmetic square root of variance, which is used to measure the degree of dispersion of a set of numbers itself, which can better reflect the actual situation of the predicted value error, as shown in Equations (4) and (5). Among them, Y_i represents the amplitude corresponding to time i, while X_i represents the estimated amplitude after processing.

$$\text{SNr} = 10 \times \log 10 \left[\sum_{I=1}^{t} \frac{X_i^2}{\left(X_i^2 - Y_i^2\right)} \right], \quad (4)$$

$$\text{MSe} = \frac{1}{t} \sum_{I=1}^{t} (Yi - Xi)^2. \quad (5)$$

The experimental results are shown in Figure 8. It can be seen that when compared with each other, the line graph does not show monotonous characteristics, and it seems that the results are contrary to expectations.

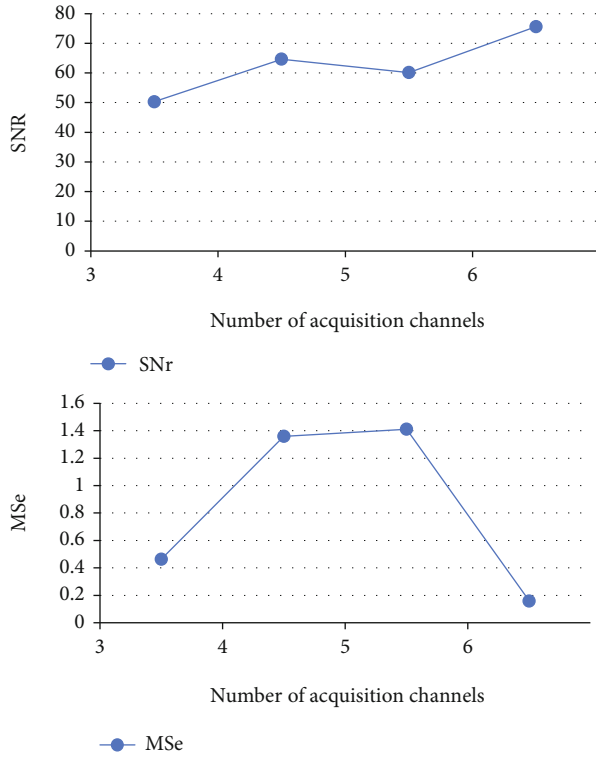
4.2. Problems Encountered Based on Motion Signal Acquisition. The results of this experiment do show that the quality of the six-channel acquisition and the five-, four-, and three-channel acquisition signal quality is not regular at all. If you do not carefully analyze it, it is too sloppy to conclude from the results. This section will focus on the analysis process and point out the difference between the actual
FIGURE 5: Schematic diagram of denoising process.
FIGURE 6: ECG with baseline drift removed.
FIGURE 7: Acquisition signal after unmixing.


FIGURE 8: Line chart after comparison experiment.

situation and the ideal situation described in theory. Review the expression of independent component analysis again:

$$\begin{bmatrix} x1 \\ x2 \\ \vdots \\ xn \end{bmatrix} = \begin{bmatrix} a11, a12 \cdots a1n \\ a12, a22 \cdots a2m \\ \vdots \\ an1, an2 \cdots anm \end{bmatrix} \begin{bmatrix} s1 \\ s2 \\ \vdots \\ sm \end{bmatrix}, \quad (6)$$

which is

$$X = Bh. \quad (7)$$

Using evaluation indicators, three, four, five, and six of the six acquisition signals are registered, and then, independent component analysis is performed in turn to investigate whether the acquisition signal registration will affect the quality of the estimated source signal, and it is also semiqualitative. Analyze the influence of signal synchronization on the quality of the estimated source signal. The comparison between the evaluation SNr and MSe after registration and the comparison before registration is shown in Figure 9:

It can be seen that the synchronization of the signal has a great influence on the results of the independent component analysis.

4.3. Improvement of ECG Signal Registration Method Based on Exercise Monitoring. The meaning of the convex peak of the function $M(x)$ is as follows:

$$\begin{cases} M'(x) = 0, \\ M''(x) < 0. \end{cases} \quad (8)$$

Or

$$\begin{cases} M'(x + \Delta x) < 0, \\ M'(x - \Delta x) > 0, \\ M'(x) = 0. \end{cases} \quad (9)$$

Based on the second derivative of the signal, Equation (8) and Equation (9) are two ways of expressing the logical relationship.

Since the ECG signal needs to be converted by A/D, the ECG signal changes from a continuous signal to a discrete signal, and a differential operation is required:

$$\mathrm{diff}\, M(xn) = \frac{M(xn) - M(xn - 1)}{n - (n - 1)} = M(xn + 1) - M(xn). \quad (10)$$

Among them, $M(xn)$ represents the standard amplitude change time n, and $M(xn)$ represents the previous standard value. The advantage of determining the ECG signal is that you can see the highest point xn of the value point, which shows the uniqueness of this point:

$$\begin{cases} M(xn) - M(xn - 1) > 0, \\ M(xn + 1) - M(xn) < 0. \end{cases} \quad (11)$$

Based on improving the efficiency of the code, the symbolic function is used in combination with the maximum value. The meaning of the symbolic function is

$$\mathrm{sign}\,(x) = \begin{cases} 1, x \le 0, \\ -1, x > 0. \end{cases} \quad (12)$$

Therefore, the maximum candidate points satisfy

$$\mathrm{diff}\,\{\mathrm{sign}\,[\mathrm{diff}\, M(xn)]\} = -2. \quad (13)$$

By extracting the sample points that meet the conditions in the ECG signal, the maximum preselection $x1 \cdots xn$ can be obtained:

Since there are many sample points in the ECG signal that meet the conditions of maximum value discrimination, it is necessary to judge by the amplitude relationship of the maximum value belonging to the wave crest. Therefore, the conditions that need to be filtered by the threshold are

$$M(xn) \ge \mathrm{thresh}. \quad (14)$$

Filter the remaining extreme points based on nonpeak
FIGURE 9: Polyline comparison after matching.

extreme points. Use time relationship to separate major and minor peaks. The selection conditions based on the ECG cycle are

$$Mn + 1\text{-}M \leq \frac{t}{2}. \tag{15}$$

Among them, T is the period of an ECG waveform, and the main peak and the secondary peak belonging to an ECG cycle can be separated by this filtering condition.

$$\bar{x} = \sum_{I=1}^{6} xi. \tag{16}$$

Then, pass the time compensation amount of the signal:

$$\Delta xi = xi - \bar{x}. \tag{17}$$

Generally, the advantage of using the average value as the registration position instead of taking a signal as the reference is that it reduces the influence of circuit delay on the signal and can compensate for the delay caused by each processing circuit. The principle is similar to that of multiple experiments. The average value improves the accuracy of the collected signal in terms of time.

5. Conclusions

In this article, we use wavelet transform to decompose the original signal in multiple layers, and each layer will get an approximate signal. The more decomposed layers, the stronger the integrity of the approximated signal, but it will also increase the amount of calculation. We use wavelet transform and independent component analysis algorithms to process the collected ECG signals and analyze the unrecorded signal processing results in detail. It can be seen that the transient ICA model and the signal quality evaluation parameters are sensitive to the signal. Synchronize this feature to make the results meet expectations. In addition, by comparing the 6-channel acquisition method after signal registration with 5-channel, 4-channel, and 3-channel, it is proved for the first time that the quality of the ECG signal collected by the system can be improved by increasing the number. When the experiment is running stably, the ECG monitoring system increases the number of collection terminals by collecting ECG signals in 6 directions, 5 directions, 4 directions, and 3 directions. In addition, this paper refines the registration method, so that the registration algorithm has the effect of suppressing spikes. In terms of time accuracy, the average registration method is used to create the reconstructed ECG signal after registration, which makes it better than the original signal.

The present research work reports the facile and green synthesis of TiO$_2$ nanoparticles from *Phyllanthus niruri* leaf extract using the coprecipitation method. The plant biomolecules were responsible for the nanoproduction and exhibited reduction and stabilization activity. The green synthesized TiO$_2$ nanoparticles were analyzed in various characterization methods. The crystalline size (23 nm) and anatase phase of TiO$_2$ nanoparticles were analyzed from X-ray diffraction study. The reduction and stabilization response functional group of TiO$_2$ nanoparticles was studied from FTIR analysis. The optical properties of TiO$_2$ nanoparticles were constructed from the UV-DRS technique, and their calculated bandgap is 3.16 eV. The spherical morphology and their existing materials were identified using FESEM with EDX. The catalytic activity of TiO$_2$ nanoparticles was examined against methylene blue dye under ultraviolet and visible light irradiation. It was detected that ultraviolet irradiation showed higher photocatalytic activity than visible light irradiation. In addition, visible light irradiation provides the above 90 percentage degradation of methylene blue dye. Hence, TiO$_2$ nanoparticles were proposed as a potential catalyst of photocatalytic dye degradation application and water remediation activities.

1. Introduction

Nanoscience is one of the most widely used and effective fields of research in scientific discovery. Nanotechnology has recently become a highly advanced technology with intra- and interstudy spanning chemistry, physics, biology, material science, and medicine. The production of nanometer-sized materials of various morphologies and sizes, as well as monodispersion, is an important field of research in nanoscience [1, 2]. Nanoparticles of varying sizes, shapes, and controlled disparity are synthesized by many researchers. Catalysis, optical, electric, and magnetic aspects; diagnostics; biological probes; and display devices are among the applications for metal nanoparticles [3].

The synthesis of metal and metal oxide nanoparticles is an existing field of material chemistry that has piqued interest due to applications in a wide range of fields, including air and water purification, medicine, antimicrobials, information technology, photocatalytic, antimicrobial, energy reservoirs, and biosensors [4]. Nanomaterial synthesis methods are divided into physical and chemical processes due to their enormous surface area. These procedures, however, are not ideal for medical and biological applications due to their environmental hazards. As a consequence, researchers are opting for a green synthesis method to synthesize nanomaterials although it is efficient, environmentally friendly, and cost effective [5, 6]. Green synthesis is an exciting material science approach [7–9]. Plants provide a better platform

for nanoparticle manufacturing since they do not contain hazardous compounds and provide natural capping agents [10]. Numerous organic substances are widespread in nature extracts including amino acids, proteins, polysaccharides, alkaloids, flavonoids, and phenolic compounds [11–13]. TiO$_2$ has become extremely prevalent in a broad spectrum of applications [14–24]. TiO$_2$ is an excellent material for photocatalysis and biomaterial creation [25]. Titania's biocompatibility makes it suitable for use in bone tissue engineering for bone regeneration and healing [26]. TiO$_2$ is a powerful catalyst that may be used to remove a variety of contaminants from the environment and has been shown to clean water and surfaces [26–34]. The Phyllanthus genus is one of the most prominent groupings of plants traded in India as a raw herbal medication [35]. The Phyllanthus genus, which belongs to the *Euphorbiaceae* family, contains over 1000 species that are found on tropical and subtropical continents like America, Africa, Australia, and Asia. The Phyllanthus genus is widely applicable in the human medical system [35–39]. *Phyllanthus niruri* has been used in traditional medicine to treat lung and skin-related diseases. The presence of various biologically active substances serves an impeccable role in the reduction, capping, and stabilization processes. These plant compounds reduced the toxicity level during the production of nanophase materials. Moreover, the plant derivatives obtained various bioactive elements that can be used in antibacterial, antifungal, and diabetic-related applications [39–47]. The bioreduction compounds of lignin, saponins, and flavonoids give the chemical-free zero-valent atom and provoke the stabilization process. In addition, these biocompounds increased microbial resistivity and are highly appreciable in liver-related diseases. The present work investigates the nanoproduction of TiO$_2$ nanoparticles using *Phyllanthus niruri* leaf extract. The structural, optical, and morphological entities of the synthesized nanoparticles were investigated. In addition, the photocatalytic activity of the synthesized nanoparticles was observed from ultraviolet and visible light irradiation.

2. Experimental

2.1. Materials. The titanium tetra isopropoxide (TTIP) (Sigma-Aldrich, AR grade, purity > 99 percent) was used to synthesize the TiO$_2$ nanoparticles. Fresh leaves of *Phyllanthus niruri* were collected from Tirunelveli, and their extract was used as a bioreductant. The methylene blue dye was purchased from HiMedia. There are no extra chemicals were used for the purification and synthesis process.

2.2. Green Synthesis of TiO$_2$ NPs. The *Phyllanthus niruri* leaf extract and 0.1 M TTIP solutions were used in the green synthesis of TiO$_2$ nanoparticles. 0.1 M TTIP solution was poured into 90 mL leaf extract under magnetic stirring. The stirring and biomolecules of the leaf extract have modified the color into white and produced precipitation. The white precipitation was centrifuged for 12000 rpm for 15 minutes two times. The obtained pellets were filtered with Whatman no. 1 filter paper and kept in an oven for 200°C at 3 hrs. Finally, the white TiO$_2$ nanoparticles are character-

ized by various analyses. The formation of TiO$_2$ is depicted in Scheme 1.

2.3. Characterization. The synthesized TiO$_2$ nanoparticles were evaluated by structural, optical, and morphological analyses. The crystalline property of TiO$_2$ nanoparticles was observed from the X-ray diffractometer (XRD) (PANalytical X-ray diffractometer, Cu-Kα radiation = 0.154 nm, angle 10°–80° and 40 kV/15 mA). The optical property of TiO$_2$ nanoparticles was captured from the UV Shimadzu 2700 UV-DRS spectrophotometer. The functional group and formed TiO$_2$ nanoparticles were recorded from the FT-IR (PerkinElmer, 400–4000 cm^{-1}, USA). The morphological entity was observed from scanning electron microscopy (HRSEM-SEM, Carl Zeiss, Germany) coupled with material identification energy-dispersive X-ray spectroscopy (EDX).

2.4. Photocatalytic Activity. The photocatalyst of TiO$_2$ nanoparticles was performed against visible and UV light irradiation to determine the photocatalytic MB dye degradation. The light source is an important key factor to modify the rate of degradation to degrade the organic pollutants. The 10 ppm MB (100 mL) dye solution was inoculated with a 10 mg photocatalyst. After that, the combined solution was kept in dark condition to attain the adsorption-desorption equilibrium level. Finally, the mixed solution was placed in UV and visible light circumstances. The irradiated samples were withdrawn (5 mL) in a regular interval (30 minutes) to measure the degradation efficacy of TiO$_2$ nanoparticles. The photocatalytic dye degradation efficacy was observed from the following equation: dye degradation efficiency $= C - C_1/C$, where C is the initial dye absorbance at time $= 0$, C_1 is the dye absorbance with light at time $= 30$ min, and t is the time.

3. Results and Discussion

3.1. X-Ray Diffraction (XRD). The X-ray diffraction pattern of the green synthesized TiO$_2$ nanoparticles is shown in Figure 1. The structural, crystallite size and material phases were identified from X-ray diffraction. The obtained peaks are 25.27° (1 0 1), 37.86° (0 0 4), 48.23° (2 0 0), 54.31° (1 0 5), 55.09° (2 1 1), 62.62° (1 1 8), and 75.21° (2 1 5) compared with those of the standard JCPDS card no. 78-2486 [48, 49]. The anatase phase of TiO$_2$ nanoparticles exhibits enhanced catalytic activity than the rutile and brookite phases. The photocatalyst TiO$_2$ nanoparticle crystallite size was calculated from the Debye Scherrer formula, and their calculated value is 23 nm in (1 0 1) plane at a high-intensity peak. The lowest crystallite size demonstrates the large surface area and outstanding photocatalytic activity of the synthesized materials.

3.2. FTIR Analysis. The plant active functional groups of the TiO$_2$ nanoparticles were analyzed by FTIR spectrum and displayed in Figure 2. The broad peak at 4000–3500 cm^{-1} specifically at 3420 cm^{-1} belongs to hydroxyl groups of O–H stretching vibration [50]. The band at 2923 cm^{-1} is attributed to C-H vibrations. The C-H vibrations are restricting
SCHEME 1: Synthesis formation of TiO$_2$ nanoparticles.
FIGURE 1: XRD diffraction pattern of green synthesized TiO$_2$ NPs.

the phase changes and promote the organic precipitation in synthesis time. Another prominent peak of TiO$_2$ nanoparticles is located at 1627 cm^{-1}, which can be ascribed to C=C which came from plant carbon molecules. The carbon molecules are associated with hydrogen and oxygen from the source materials. The carbon association produces the −C-O stretching and −C-H bending to the source precursors [50–53]. These compounds come from the plant extract biomolecules which can control the growth of the particles and reduction/stabilization activity. The peak at 720 cm^{-1} is attributed to the Ti-O stretching bands. The stretching modes of Ti-O-Ti all are observed at 500–700 cm^{-1} [54]. The plant bioderivatives produce the nonvalent atoms through the flavonoids, saponins, and lignin. These plant derivatives are responsible for metal and oxygen bond for-

mation. The formed metal and oxygen elements were stabilized from plant derivatives.

3.3. UV-DRS Analysis.

The optical properties of the TiO$_2$ nanoparticles were performed from the UV-DRS technique. The DRS spectrum is shown in Figure 3(a) which can indicate the optical reliability of the TiO$_2$ nanoparticles in the UV region at 390 nm. The optical transformations and their defects were determined the bandgap of the materials. There is no adsorption edge involved in the visible region which can denote the highest photonic energy. The optical bandgap values are calculated from Tauc eqn. The calculated bandgap value shows the relationship between the incident photon energy of semiconductors and absorption coefficient: $\alpha h\upsilon = A(h\upsilon - \text{Eg})^n$, where α is the absorption coefficient, υ is
FIGURE 2: FTIR spectrum of green synthesized TiO_2 NPs.

the frequency, Eg is the Bandgap, and n is the 1/2 direct bandgap semiconductor. The obtained band gap is 3.16 eV. The wide bandgap of TiO_2 nanoparticles exhibited the charge carrier formation and liberation in the photocatalytic activity [55, 56].

3.4. FESEM with EDX. Figure 4 shows the surface morphological and elemental analysis of green synthesized TiO_2 nanoparticles. FESEM images represent the spherical morphology with even distribution on the surface. The formed spherical shape and their smaller size particles accelerate the free radical formation. The existing plant biomolecules occupied the surface which gives the agglomerations and large grain size particles. The existing plant molecules derived the irregular distribution of the TiO_2 nanoparticles. The spherical shape is a more benefit able shape in catalytic activity than other shapes due to their large surface area [57–60]. The EDX spectrum displays the Ti and O element existence over the surface. The remaining small peaks exhibit the plant molecules which was well explained in FTIR analysis. The elemental percentages were displayed in Figure 4(d). The Ti elements occupied the major places in synthesized TiO_2 nanoparticles. The FE-SEM morphology images showed the spherical and semispherical shapes of the TiO_2 nanoparticles. The spherical shape occupied the major area of the TiO_2 nanoparticles which are attached to

it shown as larger grain size particles due to their plant derivatives. The excessive plant compounds construct the layer over the TiO$_2$ surface and merged the two particles. Therefore, it shows semispherical and spherical shapes. The distribution of the TiO$_2$ nanoparticles was calculated from ImageJ software, and their values are displayed in Figure 5.

3.5. Photocatalytic Activity. The green synthesized TiO$_2$ nanoparticles against methylene blue dye under different light sources are shown in Figures 6(a) and 6(b). The visible light irradiation slowly increased the degradation rate due to the reactive sites of the catalyst. Above 60 minutes of visible light irradiation exhibits the higher degradation because of their OH radicals which provokes the oxidation of the dye molecules [61, 62]. The plant biomolecules sustained the electron-hole pair recombination which derived strong oxi-

dation and reduction of dye molecules over the catalyst. This process takes 60 minutes to 90 minutes with the migration of electrons and holes of the concern bands. The ultraviolet irradiation exhibits the vigorous degradation than visible light irradiation due to their OH radicals [16–23]. The ultraviolet light provokes the electron mobilization and evoked the electron-hole pair which promotes better degradation efficiency. The 30-minute ultraviolet light irradiation of TiO$_2$ nanoparticles exhibited above 80% degradation. The ultraviolet irradiation (98.2%) of TiO$_2$ nanoparticles showed enhanced degradation efficiency than visible light irradiation (94.42%) (Figure 7(a)). The photocatalyst efficiency was calculated from the C/C_0 spectrum (Figure 7(b)) The degradation efficiency is dependent on a light source, catalyst dosage, pH, and dye concentration [63]. TiO$_2$ nanoparticles are extensively used in photocatalytic activity due to their wide bandgap and e-h pair restriction property. The anatase

FIGURE 8: Photocatalytic degradation mechanism of green synthesized TiO_2 nanoparticles.

TiO_2 nanoparticles exhibited a wide bandgap (3.16 eV) and lower crystallite size and large surface area which was ensured by DRS, XRD, and FESEM analyses, respectively. The degradation rate of the catalyst was constructed from pseudo-first-order kinetics (Figure 7(c)). The kinetic equation is as follows: $-\ln(C_t/C_0) = -Kt$, where C_t is the light irradiated dye absorbance at time t, C_0 is the initial dye absorbance at time $t = 0$, and t is the activity time of degradation. The obtained pseudo-first-order kinetics delivered the ultraviolet irradiation potential which is more effective than visible light irradiation. The present work is compared with earlier published work of TiO_2 nanoparticles. The comparison of TiO_2 nanoparticle photocatalytic activity is tabulated in Table 1. The pure and doped TiO_2 photocatalytic degradation work is reported. The degradation is based on the light source, size, dopants, and surface area. The table denotes the catalytic activity of TiO_2 nanoparticles in various doping, light sources, and time. The visible light irradiation degradation is low compared to ultraviolet irradiation but the addition of metal compounds increased the catalytic efficiency. Free radicals production increased the oxidation ability of dye molecules. The radical formations are evoked in visible light irradiation [64–67]. The present visible light irradiation catalytic activity produced the superoxides and radicals which exhibited a better photocatalytic dye degrada-

tion activity than previously reported works. Therefore, the present work focused on visible and ultraviolet light irradiation and demonstrates that biogenic TiO_2 nanoparticles prove heightened degradation ability against the MB dye.

The photocatalyst mechanism of the TiO_2 nanoparticles is shown in Figure 8. The mechanism of TiO_2 nanoparticle-excited electrons traveled from the valence band to the conduction band during the illumination. The modified electrons and holes get a reduction and oxidation property. The generated charge carriers produce free radicals and superoxides. These compounds dissociated the dye molecules to noxious compounds [61, 62, 68, 69]. The UV light irradiation inhibits the e-h pair very strappingly and produces an enormous amount of free radicals than visible light irradiation. The detailed mechanism is as follows:

$$
\begin{aligned}
TiO_2 + h\nu &\longrightarrow e^-(C.B) + h^+(V.B)., \\
(H_2O \longrightarrow H^+ + OH^-) + h^+(V.B) &\longrightarrow H^+ + \cdot OH, \\
O_2 + e^-(C.B) \longrightarrow O_2^- + H^+ + OH^- &\longrightarrow HO_2^\cdot + {}^-OH, \\
HO_2^\cdot + {}^-OH + h^+(V.B) &\longrightarrow \cdot OH.
\end{aligned}
$$
(1)
Based on the results, specify that the green synthesized TiO_2 nanoparticles have upgraded catalytic activity and enhanced dye adsorption behavior in ultraviolet light irradiation. Hence, the green synthesized TiO_2 nanoparticles detached the dye molecules from the aquatic surface and more powerful degradation in the ultraviolet region.

4. Conclusion

The current work reported the green production of nanoparticles from *Phyllanthus niruri* leaf extract. The plant extract using nanoparticles is an eco-friendly and noxious-free reduction to synthesize the nanophase materials. The photocatalyst of the TiO_2 structural tetragonal pattern was confirmed by XRD, and their size 23 nm was calculated using the Debye Scherrer equation. The plant derivatives and their reduction/stabilization involved biomolecules, and their functional groups were identified from FTIR spectroscopy.

The optical measurement and their wide bandgap values were evident by DRS analysis. The spherical surface and elemental investigation were obtained from FESEM with EDX. The photocatalyst of TiO_2 nanoparticles was performed in ultraviolet and visible light irradiation against MB dye. The results exposed that ultraviolet irradiation of TiO_2 nanoparticles exhibited better catalytic activity than visible light photocatalytic activity. Therefore, constructed on the results of the current study, we recommended that the green synthesized TiO_2 nanoparticles are a more active and high possible catalyst in wastewater removal treatment.

Data Availability

All research data used to assist the findings of this work are included within the manuscript.

Retracted: Application and Optimization of Wing Structure Design of DF-2 Light Sports Aircraft Based on Composite Material Characteristics

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Compared with ordinary metal structures, advanced composite materials have the characteristics of high strength, high rigidity, and light weight. The use of composite materials in aircraft structures is currently a hot research topic. This research mainly discusses the optimization design of the composite wing structure of the DF-2 light sports aircraft. This article takes the DF-2 light sports aircraft planned to be produced by the company as the source. Based on its overall design basis, aerodynamic requirements, and the original wing structure design, according to the composite material aircraft structure design theory and method, the aircraft wing structure is carried out. Composite materials are materials with new properties that are composed of two or more materials with different properties at the macroscale by physical and chemical methods. Composite materials can be divided into functional composite materials and structural composite materials according to the nature of the application. Functional composites are materials with special functions, such as conductive composites, ablative materials, and frictional composites. At present, the main research is on structural composite materials, which are composed of two components: matrix material and reinforcing material. The new structural scheme design and structural strength analysis are designed to meet the structural strength requirements of the wing and the lightest weight. In this paper, according to the force transmission characteristics of different structural types of the wing, the characteristics of the load transmission are analyzed, and the shape parameters and load parameters of the wing structure design are used as initial conditions, and the quantitative analysis model of the wing structure is constructed according to the requirements of strength, stiffness, and stability. Through rapid mathematical modeling and analysis of the wing structure, the weight and efficiency of different configurations can be evaluated. Through the quantitative analysis model of the wing, the wing structure type can be quickly determined according to the wing parameters in the preliminary design, which makes the basis for the selection of the wing structure type. After optimization, the weight of the wing structure decreased from 0.966 kg to 0.803 kg, a decrease of 16.87%. The designability of composite materials is one of its major characteristics. By optimizing the layup angle, layup sequence, and dropout area, the performance indicators of the structure are finally improved. This research will promote the further development of the aerospace field.

1. Introduction

Compared with the conventional mechanical structure design, aviation structural design requires very strict control of its structural weight. Because composite materials have superior performance in this respect, they are favored by aviation

manufacturers and are more and more widely used in the design of aircraft structures.

Excessive cost is still the main obstacle restricting the large-scale application of composite materials in aircraft structures. If manufacturing and assembly problems are considered at the design stage, the aircraft can have an

adjustable lift-to-drag ratio, shorter take-off and landing distance, less fuel consumption, wider range, higher ceiling, and higher mobility and stealth performance. And stealth performance is another important trend in the development of composite materials.

Composite structures have different structural properties due to the different percentage and sequence of layering at different angles. Yuan et al.'s loading of Au nanoparticles (AuNPs) onto environmentally sensitive polymer microgels is increasingly used to regulate their optical properties and catalytic activity. Here, they synthesized a composite polymer microgel composed of poly (n-isopropylacrylamide-co-3-methylpropyltrimethoxysilane)/poly (acrylic acid) with a core-shell structure and used nanoparticles to load AuNPs onto the network chain of the polymer microgel in a controlled manner. The prepared AuNP composite has good pH sensitivity. Therefore, the electromagnetic coupling between AuNPs can be regulated by the swelling/deswelling of polymer microgels under various acidic/alkaline conditions. More importantly, the coordination interaction between carboxyl groups and Cu ions in the PAA chain is altered by changing the content of Cu ions at different pH conditions, thus modulating the local surface plasmon resonance of AuNPs. These structural characteristics of the prepared composite microgel can adjust the optical properties of AuNPs in the following ways [1]. Chesterman et al. believe that resin-based composites (RBC) are increasingly used in posterior tooth restoration. The growing demand for aesthetically pleasing, tooth color restorations, coupled with patient concerns about using mercury-containing restorations, has driven the explosion in RBC material use. With the minamata convention of 2013 calling for the phasing out of dental amalgam and dental schools increasingly teaching RBC repair techniques for posterior teeth, the dental industry's reliance on RBC repair for posterior teeth is likely only to grow. To simplify and speed the placement of large rear RBCs, manufacturers produce a range of materials that can be placed in single or deeper increments, called bulk RBCs. In a relatively short period of time, many bulk RBCs have become available, with incremental depths of between 4 and 10 mm. The placement of these large incremental RBCs may reduce the time required to repair after placement, thus reducing technical sensitivity [2]. Palumbo et al. believe that thermoelastic signal phases associated with inherent dissipation processes occurring in materials have been used to locate and assess damage areas in a quantitative manner. In addition, thermoelastic phase analysis leads to the evaluation of the durability limits of composites. In fact, by comparing the results with those provided by standard test methods, the potential of the proposed procedure is shown first as a nondestructive technique for continuous monitoring of damage to composite structures subjected to fatigue loads and secondly as a fatigue limit index [3]. Boumhaout et al.'s work deals with the thermomechanical properties of composites made from mortar and date fiber mesh (DPF). The objective is to evaluate the thermal and mechanical properties of this material for building insulation. The volume percentage of date FibreNet in tested samples ranged from 0% to 51%. The thermal characteristics of the sample are experimentally determined in terms of conductivity, diffusivity,

Table 1: Main performance parameters of composite materials used in wing structure.

Material	T700/epoxy	Fabric_T700	NOMEX
Axial modulus (GPa)	120	56	0.3
Transverse modulus (GPa)	9	56	0.3
Z-direction modulus (GPa)	9	8	91
Shear modulus (XY/GPa)	4.8	4.6	0.06
Shear modulus (YZ/GPa)	4.8	4.6	20
Shear modulus (XZ/GPa)	4.8	4.6	30
Poisson's ratio (XY)	0.3	0.15	0.33
Poisson's ratio (YZ)	0.3	0.15	0.01
Poisson's ratio (XZ)	0.3	0.15	0.01

capacity, and flow rate. In addition, the bending and compression strengths of the samples were systematically evaluated. DPF grid has a positive effect on the thermomechanical properties of composites. In fact, it significantly improves the insulation ability of mortar, increases the thermal diffusion damping rate, and makes mortar lighter. DPF mesh also improves the ductility of mortar and meets the mechanical requirements of building materials [4]. Based on plant waste corn cob and nitrogen source melamine, Li et al. adopted an innovative method to controllable synthesis of multistage nanotube @ mesoporous carbon composites through heat treatment. Corn cobs provide a carbon source and a small amount of Fe as a catalyst, while melamine provides a nitrogen source. The corn cob is pretreated with concentrated sulfuric acid and then mixed with melamine. After calcination at 800°C for 2 hours, a large number of thin walled nitrogen-doped carbon nanotubes (MWNTS) grew vertically on mesoporous carbon skeleton with unique structure. The diameter of the nanotubes is about 50 nm, and their length varies between 0.1 and 20 μm, which can be controlled by adjusting the ratio of the pretreated corn cob to melamine. At the same time, the composite material has stable interconnect pores and channels with a surface area up to 1100 m^2/g, which significantly accelerates the ion and electron transport rates [5]. In the assembly of composite components, the fastener holes need to be processed not only in large quantity and high quality requirements but also difficult, which is one of the most difficult processing procedures in composite processing. It is easy to produce delamination, tearing, splitting, and other phenomena when making holes in composite materials, so the hole making connection is an important link that affects the assembly quality of composite components. Composite layup optimization is to optimize the design in the combination of these types of layup angles, while considering the laying position of each layer of composite materials, so as to maximize the excellent properties of composite materials [6].

The honeycomb sandwich structure has been widely used in aircraft structural parts due to its excellent bending stiffness characteristics. The full-height sandwich structure is used on the control surface, which achieves a significant weight

reduction effect on the premise of ensuring strength and rigidity [7]. Combining the design theories and methods of composite laminates and sandwich panels, as well as the introduction of bioengineering structural design concepts and topological structure design concepts, this article will maximize the use of composite materials to design the wing in detail. According to the requirements of the initial design, after designing and analyzing the initial structure, tests were carried out to prove the feasibility of the design. From the test, it can be seen that the initial design is relatively conservative, and the strength of the material and the rigidity of the structure are still too high. Based on this situation, a lightweight design of the wing was implemented. Regarding the feasibility and operability of the molding scheme of various structural components, the explanation is based on the analysis of factors such as the existing technical level and manufacturing cost, manufacturing cycle, and technical level of personnel.

2. Optimized Plan for Composite Wing

2.1. Optimizing the Thickness of Composite Material Structure Ply

2.1.1. Establishment of Optimization Model. The honeycomb structure has high deformation and supporting force and is suitable as a candidate for a deformed structure. However, the general honeycomb cannot be actively deformed, and the active deformation honeycomb based on shape memory materials has a slow deformation speed and cannot meet the requirements of an adaptive structure [8].

If the material structure and shape of the honeycomb core layer are determined, the core layer structure can be treated as a laminate when designing the honeycomb core layer composite structure. The core layer is just another layer, and the thickness is the same as the height of the core layer. The core material of the skin's honeycomb is NOMEX honeycomb [9]. The closed wing box structure is composed of the skin and the beams and ribs of the wing. The skin of the wing box is mainly used for torsion, improving the torsional rigidity of the skin and making the skin with high damage and peeling resistance. It is covered by carbon fiber cloth. Fabric is the outermost layer of the T700 wing, and the carbon fiber cloth is composed of longitudinal fibers and transverse fibers. The main performance parameters of the composite materials used in the wing structure are shown in Table 1.

2.1.2. Stiffness Performance of Composite Laminates. The physical equations of laminates can be derived from the classical laminate theory of composite materials [10, 11]:

$$\begin{pmatrix} V \\ M \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{Bmatrix} \chi \\ \gamma \end{Bmatrix}. \tag{1}$$

N is the resultant force array in the middle of the laminate; M is the resultant moment array in the middle of the laminate [12].

Since the lower wing panel mainly bears the tensile load, the tensile load-bearing capacity of the initial model of the

TABLE 2: Test protocol and results.

Test number	$W1$ /mm	$W2$ /mm	Wing tip deformation/mm	Maximum stress/MPa
1	320	190	19.551	184.11
2	280	190	11.836	126.1
3	360	190	11.92	122.07
4	320	223	23.011	173.84
5	280	223	15.327	121.21
6	360	223	16.614	101.76
7	320	256	22.55	183.54
8	280	256	13.633	76.959
9	360	256	15.613	91.109

open area can be calculated first. In order to explore other properties of the open-ended laminate, the stability load-bearing capacity and postbuckling load-bearing capacity of the structure are also calculated. Analyze the calculation result and use it as the design basis for the reinforcement scheme of the opening area. Tensile stiffness array of laminate A is as follows[13]:

$$A = \sum_{k=1}^{n} Q(Z_K - Z_{K-1}) = \sum_{k=1}^{n} Qh_K. \tag{2}$$

Laminated plate tension and bending coupling stiffness matrix B are as follows [14]:

$$B = \frac{1}{2} \sum_{K=1} Q\left(Z_K^2 - Z_{K-1}^2\right) = \sum_{K=1} QZHK + 1. \tag{3}$$

Among them, Z represents the distance between the middle surface and the middle surface of the k-th layer [15, 16].

The plies involved in this article are symmetrical and balanced pavement designs, and a reasonable pavement structure design that meets the requirements of structural rigidity, strength, and stability has been found.

2.2. Kriging Model.
In this paper, the response surface method of Kriging model is applied to the optimization of the wing spar position, thereby improving the prediction accuracy of its response surface. In the Kriging model, the original unknown function can be expressed as follows [17]:

$$y(x) = f(x) + Z(x), \tag{4}$$

where $f(x)$ is an unknown function of x.

The predicted estimated value $y(x)$ of the response value $y(x)$ at the unknown vector x is given by the following formula [18, 19]:

$$\widehat{y}(x) = \widehat{\beta} + r^T(x)R^{-1}\left(y(x) - f\widehat{\beta}\right). \tag{5}$$
FIGURE 1: The integration process of genetic evolution.
FIGURE 2: Strain of each test point.

Among them, $r^T(x)$ is the correlation vector between the unknown vector x of length n and the sample data [20].

$$r^T(x) = [R(x, x_1), R(x, x_2), R(x, x_3), \cdots, R(x, x_n)]^T. \quad (6)$$

From the narrative about the Kriging model, we can know that having a certain amount of sample data is the premise of establishing the Kriging model. When selecting samples in the entire design space, a limited number of samples should be used. It is possible to fully reflect the characteristics of the design space, which requires experimental design. There are many methods of experimental design, such as full factorial design and central composite design. This paper uses the central composite design method to arrange the response surface test, which is designed on three levels, and a total of 9 sets of parameter variables $W1$ and $W2$ are designed. The test plan and results are shown in Table 2.

2.3. Optimal Mathematical Model. Since changing the position of the spar has little effect on the quality of the wing, it is not considered here. Under the condition of meeting the strength requirements, the stiffness of the structure is selected as the objective function, which is measured by the deformation of the wing tip [21].

According to the constraints of the wing geometry size, the variation ranges of the parameter variables $W1$ and $W2$ are, respectively, taken as $280\,\text{mm} \leq W1 \leq 360\,\text{mm}$ and $190\,\text{mm} \leq W2 \leq 256\,\text{mm}$, and the optimized mathematical model can be described as follows [22, 23]:

$$\begin{cases} \min S(X) \\ |F|_{\max}(x) - 1 < 0 \\ X_i \leq X_n \leq X_k. \end{cases} \quad (7)$$
Figure 3: Left and right wing stiffness test.

Among them, S is the stiffness index. This paper selects the maximum deformation of the wing tip to characterize it; X_n is the position parameter of the spar; F is the failure factor of the wing structure [24].

2.4. Optimized Structure. ISIGHT can integrate various types of simulation software into a unified framework. The setting of input files and output files; the writing of the call commands of the process simulation software; the drawing, reading, and writing of parameters; the selection of design variables; and other comprehensive optimization algorithms create the entire design process to achieve generalization, automation, parameterization, and visualization, eliminating the limitations of conventional settings in the accounting process. ISIGHT has powerful postprocessing functions. Users can draw optimization process curves, output data tables, and generate analysis reports.

The ISIGHT software has the data interface of many mainstream engineering software, so it can fully realize the data transmission between various software. Using the ISIGHT software to integrate MATLAB and ABAQUS, a multi-island genetic algorithm for optimizing stack thickness is realized. First, use MATLAB to generate the layup information of the front and rear wing beams, and send the layup information. The results were imported into the ABAQUS software, and a finite element model was established for the calculation. The calculated structural quality, TSui-Wu damage coefficient, and maximum deformation displacement information are introduced by MATLAB, and selection and transfer operations are performed to generate the next generation of hierarchical information and then generate the next generation of genetic evolution. The integration process is shown in Figure 1.

2.5. Load Test. The design load test is a test to evaluate the ability of the test piece to bear the design load. In all major design cases, the load usually must be 100% of the design load. However, in the main structure, under the premise of ensuring the structural strength, a certain proportion of the initial design load can be load tested on a part of the design case. For each main design case, when the test load exceeds the use load test, the load needs to be adjusted in stages according to an increment of less than 5% of the design load at each stage, as well as strain, displacement, and damage. The test parts must be measured and recorded periodically. The test piece can bear 100% of the design load, and the structure will not be damaged for at least 3 seconds under 100% of the design load.

3. Optimization Results of Composite Wing Structure of DF-2 Light Sports Aircraft

It can be seen from the curve shape of Figure 2 that when the titanium alloy joint is subjected to the maximum load, the strain at each test point will not change, but will change linearly. After the load is completely removed, the strain will all return to zero. Observe all the distortion curves and obtain the maximum distortion curve of the curve corresponding to each 10 channels; the maximum value is 1019 $\mu\varepsilon$. The position of the tenth strain gauge is the connection structure between the wing and the fuselage at the wing beam. According to calculations, the stress value at this point is 1088 MPa. Therefore, the maximum stress is all less than 42.73 MPa. Because the tensile strength of the titanium alloy is 900 MPa, it can be seen that all the measurement points meet the strength requirements of the titanium alloy. Moreover, the finite element simulation data, the contrast test data, and the finite element simulation of the stress value of 10~131 MPa are much larger than the actual test data. This is the result of finite element simulation analysis and contact. The use of components to establish bolted connections has stress concentration, and the finite element simulation error is very large. Therefore, in the connection of the titanium alloy, the maximum stress value of the composite material and the titanium alloy that reaches 1079 MPa is a big error. Combined with the previous engineering design experience, the structural design here will
Figure 4: Evolutionary process.
Figure 5: The evolution process of laminate ply angle optimization.

not fail but can meet the strength requirements. The strain of each test point is shown in Figure 2.

It can be seen from Figure 3 that the deformation curves of the left and right wing ends are quite different. When the test load is applied in stages, the left and right wing ends often have a deviation of about 20 mm. This is mainly due to the error of the measurement position selected by the test operator during the measurement process and the unstable initial configuration. The maximum deformation of the blade

obtained by finite element simulation is 96.519 mm. The maximum deformation error and simulation data of the left and right wings are 16.81% and 8.39%, respectively. Since the test data and simulation data are both above 180 mm, the rigidity of the wing structure is very high, which meets the conditions. The left and right wing stiffness test is shown in Figure 3.

After 10 generations of genetic evolution, the 753th evolutionary individual in the eighth generation was found

Table 3: Hierarchical optimization results of wing structure.

	Parameters before optimization	Parameters after optimization
Beam ratio 1	0.3	0.32
Beam ratio 2	0.75	0.78
Beam ratio 3	0.3	0.27
Beam ratio 4	0.75	0.86
Beam 1 width (mm)	15	15.21
Beam 2 width (mm)	15	14.23
Rib 1 (mm)	300	267.21
Rib 2 (mm)	600	576.34

Table 4: The height record of the root and tip of the wing at both ends of the wing during the test.

Load	Left wing tip height	Left root height	Left wing difference	Right wing tip height
10% load	253.98	214.46	39.52	241.8
20% load	267.9	216.88	51.02	245.28
30% load	273.6	218.54	55.06	254.22
40% load	275.5	211.56	63.94	256.2
50% load	284.68	212.8	71.88	258.42
60% load	291.62	214.58	77.04	265.00
70% load	294.00	208.46	85.54	268.38
80% load	299.02	208.28	90.74	272.82

to meet the design requirements and the lowest quality individual. The layer thickness information expressed is as follows: the variable cross-section area of the front beam 1-7 is 6/4/2/2/2/2/2, and the variable cross-section area of the rear beam 1-7 is 8/4/4/2. The weight of the wing structure decreased from 0.966 kg to 0.803 kg, a decrease of 16.87%. The evolution process is shown in Figure 4.

The angle optimization of the laminate ply adopts the same method as the thickness optimization, and the evolution process is shown in Figure 5.

Through the first-level optimization of the beam and rib layout and the second-level optimization of the composite material ply, the structural mass is reduced from 1.173 kg to 0.803 kg, and the mass is reduced by 31.54%. The maximum deformation displacement of the structure changed from 34.49 mm to 40.95 mm, an increase of 18.7%. The failure factor of Tsai-Wu changed from 0.512 to 0.472, a decrease of 7.8%. Through the grading optimization study of the wing structure, a good weight reduction effect has been achieved under the premise of meeting various design indicators. The hierarchical optimization results of the wing structure are shown in Table 3. The Tsai-Wu criterion will be applied to determine the safety factor for composite orthotropic shells. This criterion considers the total strain energy (including distortion energy and expansion energy) for predicting failure.

During the test, the record of the height of the wing root and wing tip at both ends of the wing during the test is shown in Table 4. The data in the table is plotted against the aforementioned analysis data. Since this test is a load test, the design load (150% use load), 87.2 mm of the analysis result is converted into the use load result, and the resulting deformation is 58.1 mm. Therefore, the error of the test and analysis results is 3%, which is considered acceptable within the scope of the project, and neither of them exceeds the overall required value.

Quantitative analysis method is a method for analyzing the quantitative characteristics, quantitative relationships, and quantitative changes of social phenomena. The quantitative analysis model method is used to model and analyze the two structural types of beam configuration and monolithic configuration. With the shape parameters as the initial conditions, the mathematical analysis model is constructed, and the weight of the wing structure under different loads is obtained by changing the value of the load. The relationship curve with load is shown in Figure 6. The load density at the root of the wing is 1357 N/mm. It can be seen from Figure 6 that the monolithic configuration is selected at this load level, and the weight of the wing structure is lighter.

4. Discussion

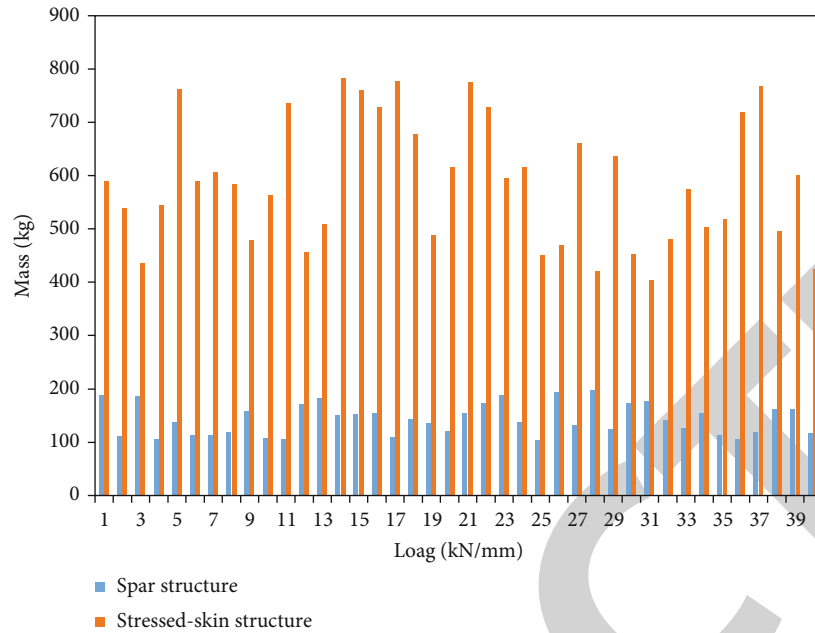
After the outer panel and the number of positions of the composite wing are fixed, the components need to be assembled. However, most of the initial researches on the manufacturing process of composite wings mainly focus on the design, molding, and performance testing of composite parts. There is almost no research on the assembly process of composite parts, especially the assembly of composite parts. The structural optimization technology of composite materials refers to engineering application technologies that improve the rigidity, strength, and stability of fiber-reinforced resin matrix composites by optimizing layer shape, ply angle, and other layer information. As the proportion of aircraft structural composite materials increases, the assembly of aircraft composite structures will account for an increasing proportion of aircraft assembly. New assembly tools must fully consider the structural characteristics of composite materials, combined with new technologies such as flexibility and reconstruction, and improve the quality and efficiency of assembly during the design process. Different load-bearing levels will affect the choice of wing structure and the internal configuration of the wing structure. Before explaining the influence of different load levels on the wing structure layout, the single wing load level range must be defined. The typical stress modes of various wing structures are beam type, monolithic type, and multiwall type. Based on the above analysis, the choice of wing structure mainly affects the rigidity and stability


Figure 6: The relationship between the weight of the wing structure and the load under different loads.

of the wing structure. In the assembly process, it is necessary to repeatedly optimize the assembly sequence to find a suitable assembly process to ensure the adjusted assembly of the chassis. In addition, due to the limitations of natural material forming processes and methods, compared with metal components, the manufacturing geometric accuracy of composite components is not easy to control and can be assembled due to large rigidity, brittle matrix, and weak interlayer strength. The deformation is very small, and it is generally not allowed to drop, and it is difficult to correct the assembly gap. These all show the high components of composite components [25, 26].

The connection design and strength analysis of composite structures are different from those of metal structures. The influencing factors of composite material structure are much more complicated than the influencing factors of metal structure, and the damage mechanism is essentially different from the influencing factors of metal structure. Regarding the metal connection, according to the plasticity of the metal material, the load can be redistributed to the multinail connection, and the force of each nail element becomes uniform. After confirming the connection strength of the nail elements, each nail element is loaded. However, composite materials are brittle materials with small plastic deformation, multiple nail connections, and large difference in load distribution of nail elements. In addition, the nail holes in the connecting parts of the composite material cut off the reinforcing fibers, resulting in a complicated stress distribution and a more serious stress concentration problem at the end of the hole. There are various types of combinations of wing separation surfaces. Therefore, it is necessary to comprehensively consider the overall structural characteristics and determine the appropriate power transmission path according to the link components such as the beam edge between the wing segments and the long truss configuration. There is a unified design of the connection

method of the wing separation surface, which largely depends on the designer's design experience [27].

Composite materials are widely used in aerospace and completely replaced metals in some fields such as wind power blades. Carbon fiber reinforced composite material (CFRP) has the advantages of high specific strength, high specific rigidity, and high heat resistance, so it is widely used in ultra-high-speed aircraft. Due to corrosion resistance, fatigue resistance, and design, composite materials can be used in complex environments such as plains, plateaus, and the sea. The working hours and maintenance intervals become longer, and they can play an irreplaceable role in some areas such as forwards. Compared with the traditional optimization method, the optimization method adopted in this paper has a series of optimization characteristics, including generalization, automation, parameterization, and visualization. For complex design variables such as panel and number of bits, the platform can be optimized at the same time. The optimization results show that the structural quality is reduced, the strength and rigidity are improved, and the optimization efficiency of the composite material is improved. This research includes finite element theoretical research on laminated plate structure and honeycomb sandwich structure. The typical structure of the composite wing, such as the main beam, will be analyzed and optimized according to the general requirements of the engineering field [28, 29].

The extensive use of composite materials in the aviation field actually brings many possibilities to the structural design of aircraft. This is because, compared with metal materials, composite materials have higher strength and higher designability. The wing layer has orthotropic anisotropy, and the structural characteristics are determined by the angle and order of the layers. In the past, the aircraft manufacturing and assembly process, the number of tools,

the size, and the diversity all have the disadvantages of high cost and a lot of labor costs for disassembly and assembly. To cooperate with automated robotic mining systems, reconfigurable, low-cost design, and manufacturing technologies are required. The positioning configuration adopts a modular design, which can complete the positioning of the dynamic module and modify the mode of the dynamic module by moving various dynamic modules. This technology is very important for reducing costs and achieving flexible assembly.

According to the anisotropy and unevenness of the lamination of the composite material, the longitudinal and transverse characteristics are completely different, and the tensile characteristics and compression characteristics are also different. According to the anisotropy, the direction of each layer of the composite material can be adjusted at will, personalized design according to various structures and uses, and the elastic properties and strength properties of the material can be adjusted according to various needs to obtain the best structural effect. The deformable aircraft can change its shape according to different flight conditions, so it can obtain the best performance in the entire flight process. The outer panel of a deformable aircraft can not only deform with the structure but also needs to withstand the air load. Foaming material is a new type of composite material using fuel gas filler. There are many types of foam materials, but they generally have the following characteristics: light weight, material saving, low thermal conductivity, excellent heat insulation performance, excellent sound insulation effect, impact load absorption, excellent cushioning performance, and high strength.

With the intensification of market competition, the aviation industry has undergone fundamental changes in the performance and cost of aircraft design concepts. Aircraft designers and manufacturers have begun to focus on ways to reduce aircraft costs to obtain higher performance, and as a result, they have carried out aircraft design. In addition to considering the aerodynamic shape and structural weight, manufacturing possibilities, manufacturing costs, and other factors must also be considered. The final decision of the design plan not only considers the mechanical point of view (aerodynamic characteristics and structural characteristics) but also considers whether the structure is easy to manufacture and whether it can accept manufacturing costs and other factors. According to the final design plan, factors such as aerodynamics, structure, manufacturing possibilities, and manufacturing costs are comprehensively balanced. The use of smart materials and structures can realize the configuration and reorganization of the aircraft during flight and obtain the best air performance. In the future, airplanes can fly like birds, and intelligently deformed airplanes are an important direction for future development of airplanes. The deformable aircraft can be adapted to various flight conditions by changing its configuration to achieve the best overall performance. Deformable technology, high energy density drive technology, and adaptive construction technology are still the main technologies for realizing deformable aircraft [30].

5. Conclusion

This article first introduces the main types of wing structures and the design characteristics of composite materials and then summarizes the main methods of modern wing structure selection and design and proposes a quantitative analysis model method that combines force transmission analysis with finite element. According to the force transmission characteristics of different components, a specific construction method that is different from the construction standard of the quantitative analysis model is provided. Next, a quantitative analysis model of the beam configuration and the monolithic configuration is constructed, and the load-weight characteristic curve of the structure is displayed. The box section simulation process restores the actual stress distribution of the wing structure through multiple modeling analyses. The calculation formula for important elements of the stability of the box segment has been optimized to ensure the accuracy of the calculation results. On this basis, through the strength analysis of the wing structure, the classification method, the optimized size layout of the wing structure, and the optimization process analysis and comparison of the structural efficiency of the design schemes, the best design of the wing can be completed quickly and accurately structure. This article did not study the ply sequence and ply optimization of composite laminate structure or sandwich structure. In the future, it should be combined with related theories and algorithms to make the structure design more perfect.

Retracted: Realization of a Noncontact IC Chip with Embedded Ferroelectric Memory in an Auxiliary Timing Device for Sports Games

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

The research direction of the new generation of embedded memory can be summarized into two types of embedded nonvolatile memory and embedded volatile memory; the research on online testing of embedded memory started in the past ten years, and there are few research results. This article analyzes the feasibility of the noncontact IC chip in the embedded ferroelectric memory of the sports game auxiliary timing device and is aimed at obtaining an optimized embedded ferroelectric memory by analyzing the relevant data to achieve the update and update of the sports game timing device system. Early sports event timing methods generally use manual timing (stopwatch) or camera shooting timing; this method is inefficient, poor real-time, huge workload, and prone to errors. This research mainly focuses on the analysis and discussion of the material structure and performance of the embedded ferroelectric memory and the process of noncontact IC chip. This article uses custom welding circuit technology to prepare the best ferroelectric filter in the test part and verifies the influence of temperature on the material; in order to understand the properties of ferroelectric materials at the electronic and atomic level, a first-order statistical method is obtained. The numerical calculation results of the experiment verify that the evaluation value of the serial port synchronization module as a whole exceeds the pulse synchronization; the network synchronization as a whole exceeds the code synchronization, and the result of the network time service module is the opposite, but as a whole, each module of the noncontact IC chip has strong performance adaptability; in the application of auxiliary timing, the maintainability of noncontact IC chip is quite outstanding, and the maximum value is 7.97; a large number of complex simulation system tasks can be completed by simple and direct tasks.

1. Introduction

Competitive sports highlights a new development culture, and promoting sports development has become one of the important strategies for the development of sports in many countries [1]. The continuous improvement of athletes' competitive sports level will make the education system gradually become another important foundation for the cultivation of competitive sports reserve talents after the competitive sports system [2]. The development of competitive sports is not only an expectation to cultivate high-level athletes with all-round development of morality, intelligence, and physical fitness but also a useful supplement to the competitive sports system and a useful reference to foreign competitive sports [3]. This is the fundamental reason why competitive sports has attracted the attention of the Chinese people, continues to develop, and has a bright future. The development of competitive sports urgently needs to strengthen the research of competitive sports events, but most of the existing researches are partial and unilateral status quo investigations or macrotheoretical analysis on the organization, management, construction, and training guarantee of competitive sports teams [4].

With the rapid development of VLSI technology and the rapid promotion of the concept of Internet of Things, the importance of information storage has become more and more obvious [5]. Embedded memory originally refers to the memory integrated on the embedded microprocessor chip, used for code or other long-term data storage. Now

in a broad sense, the storage circuit uses the same process as other working circuits and is integrated into a chip to work. The main purpose of this is to greatly reduce the delay of the data interface and to greatly accelerate the speed of the memory and reduce the application [6]. The research direction of the new generation of embedded memory can be summarized into two types of embedded nonvolatile memory and embedded volatile memory. Embedded non-volatile memory is divided into high-speed and low-power applications. These types of memories are aimed at different applications, and all have strong application prospects [7].

New embedded nonvolatile memory (eNVM) for large-scale technology nodes such as ferroelectric field effect transistors (FeFET) has been studied in depth and is very promising. Sasaki et al. describe a magnetic resonance wireless power transmission system with auxiliary coils. The system was proposed to supply power from the bed to an "implantable cardioverter defibrillator" (ICD) device. ICDs are the most effective treatment for preventing sudden cardiac death (SCD), with supportive pacing and antitachycardia pacing, low-energy cardioversion, and high-energy defibrillation [8]. In this study, a 1/2 scale model was used to study the power efficiency of a magnetic resonance wireless power transmission system with auxiliary coils. When the transmission distance is 100 mm and the main resistance is $20\,\Omega$, the maximum transmission efficiency of using the auxiliary coil is about 70% higher than that when the auxiliary coil is not used [9]. For the first time, Popov et al. observed direct bonding on Si or C-sapphire substrates and hydrogen transfer from the silicon layer in the silicon on sapphire (SOS) structure through HREM for the first time. The conclusion is that the OII phase is mainly stabilized by high compressive stress [10]. Kobayashi et al. designed and manufactured a nonvolatile SRAM by integrating with ferroelectric HfO_2 capacitors and proved its storage/recall operation before/after power failure through experiments. The sub-10 nm thick ferroelectric HfO_2 capacitor has obtained excellent ferroelectricity and memory characteristics. NVSRAM with ferroelectric HfO_2 capacitors can be a candidate for cost-effective, normally off, and ultralow power embedded memory solutions for IoT power management [11]. Inference and on-chip learning can be facilitated by further eNVM technology options, such as multibit operations and linear switching. Lederer et al. introduced the advantages of FeFETs based on hafnium oxide for such applications because they have a basic three-terminal structure that can selectively activate or deactivate selected devices and adjust linearity and dynamic range for certain applications. In addition, the effects of the material properties of the ferroelectric layer, the thickness of the interface layer, and the scaling on the device performance are discussed [12]. Chien et al. recommend embedding 256 kb resistive random access (ReRAM) in the microcontroller unit as a data buffer for communication with independent flash memory. It is manufactured using a combination of TSMC0.18 μm process and Industrial Technology Research Institute ReRAM back-end process. Simulations show that compared with other nonvolatile memory (such as ferroelectric RAM), ReRAM buffers run at least 51% faster [13]. Khan et al. studied the potential of ferroelectric field effect transistor technology in current embedded nonvolatile mem-

ory applications and future memory, bionic, and alternative computing models. The material and device-level challenges involved in high-volume manufacturing of advanced technology nodes ($\leq$10 nm) are emphasized, which is reminiscent of the challenges encountered in the early development of high-K metal gate transistors [14]. Ferroelectric field effect transistors (FeFETs) based on ferroelectric hafnium oxide (HfO_2) films show great potential for future embedded nonvolatile memory applications. Yurchuk et al. verified the possibility of charge trapping in HfO_2-based FeFET memory during standard operation. The single-pulse ID-VG technique (MOS tube Id-Vg curve data) was used to analyze in detail the kinetics of charge trapping and its interaction with ferroelectric polarization switching. In addition, the impact of charge trapping on important storage characteristics (such as retention and durability) has also been studied [15]. These studies have carried out detailed research through experiments. They have carried out data acquisition on related objects such as embedded memories of ferroelectric materials. However, it can be found that their research angles are relatively single and belong to the study of physical properties. The demonstration of the practical application of the experimental results is still lacking.

Ferroelectric film is the basis of ferroelectric memory. According to the requirements of embedded ferroelectric memory for ferroelectric materials, the microstructure and electrical properties of different parts of thin ferroelectric film are discussed, and a good integrated capacitor is provided through customized integration technology. The analysis of the etch degradation process of ferroelectric films during aggregation shows that the magnitude of the reheat treatment does not completely correct the cause of etch degradation. In the high-speed memory, we used a conventional bandgap reference voltage-controlled oscillator charge pump scheme [16]. As for the design of low power consumption, we implement the reference current reference and reference voltage reference with circuits, respectively. The program makes full use of the high-speed and precise calculations in data processing to design some of the best automated business automation and continuous and efficient operation of the business. On the basis of in-depth research on data mining technology, we eliminate general data miningalgorithms and develop intermediate class libraries as technical tools and process analysis for sports events. For the specific development process of a noncontact IC card chip, methods such as gated clocks and optimized layout structures are used to reduce chip area and reduce chip power consumption.

2. Embodiment of the Auxiliary Function of Ferroelectric Memory

2.1. The Combination of Sports Events and Computer Technology. People have gradually realized the original concentrated advantage. After all, the high-intensity stand-alone training program is a highly developed model based on high investment, high elimination rate, and low throughput. It is a systematic cultural study at the expense of young people's cost of improving the level of competition [17]. With the rapid development of computer technology and network technology, people have ushered in a new era of network

characterized by information and knowledge. The information that people are exposed to, especially digital information, is increasing exponentially. As the most powerful tool for modern human development, computer technology will inevitably play an inescapable responsibility in the development of sports competition. Through information management, the problems of large number of participants in previous competitions and sports competitions, complex project settings, tight timeliness, and difficulty in scheduling have been solved [18]. Computer technology uses relevant information to automatically generate graphics, tables, etc. to provide users with high-level information services to meet the requirements of statistical analysis and decision support proposed by users. The information can also provide relevant information to coaches and athletes participating in the competition in a timely and accurate manner. With the rapid development of science and technology, the use of high-tech technology to assist referees in judgment has become a reality, the accuracy of judgments has also been improved, and the pressure on referees has also been reduced. The use of high technology plays an important role in the accuracy and speed of task execution. And it has been widely used in the judicial procedures of many sports events. In order to improve the level of sports competition, more and more countries continue to apply new technologies to sports competitions [19]. The clear 3D animation display, the rapid response within a few seconds, and the pressure line or out-of-bounds gap accurate to the millimeter are all showing the world the convenience and precision that high-tech brings us.

Data mining is the process of searching for information hidden in a large amount of data through algorithms. Data mining brings data technology to the next level. It not only needs and transfers past data but also discovers multiple connections between data, thereby promoting the generation of useful information [20]. The system can not only express the business logic flow in reality but also store and process the business in reality and persist the corresponding data according to the data model. When there is an error in the data that needs to be modified, in the face of a less rigorous system, you only need to provide a corresponding means to repair the error, not the information that cannot be modified [21]. The communication and low coupling between the modules are fully considered, and more user loads can be quickly met, and it can be expanded downward when the system utilization is not high, saving costs.

2.2. Embedded Ferroelectric Memory and Noncontact IC Chip. Driven by fast-paced memory products, a number of successful memory technologies have emerged in the memory field in the past ten years, eliminating traditional technologies in the industry and expanding the application space of memory technologies [22]. As the concept of the Internet of Things and consumer applications have grown substantially, embedded storage applications have begun to flourish. Embedded memory has also encountered bottlenecks in its further development. At present, the process and manufacturing of memory cells are also at a relatively advanced level in the world, but at the same time, it also

encounters general problems in new memory research, such as process volatility and instability. It poses challenges to process research and circuit design. More and more new memory technologies pursuing different product segments are introduced one by one [23]. For the new generation of nonvolatile embedded memory, low power consumption, low cost, high speed, and other characteristics are required. The market for modern processors and embedded applications is extremely competitive, and only those competitors with high production characteristics and performance can win. Due to the importance of standard transmission interfaces and standard procedures for interoperability, middleware has become an integral part of many measurement tasks. For application software development, middleware is more important than system and network services [24].

With the substantial increase in chip integration, circuit design and application pose new challenges to discrete memories. Limited by the frequency of incoming and outgoing signals, the high-speed clock cannot be transmitted to the chip, providing a clock signal for the overall operation of the chip [25]. If the peak value is too high, the power supply voltage will drop too much, which may cause the chip to reset or fail to work normally, showing that the working distance of the card becomes shorter. The charge pump used in a good memory needs to meet the driving voltage and driving current and has the smallest possible area and power consumption. The specific design depends on different types of memory [26]. New devices combining ferroelectric materials and semiconductor devices have gradually been applied. Ferroelectric memory is a nonvolatile memory produced by a combination of thin ferroelectric film and CMOS technology. Bonded film is a key component of embedded ferroelectric memory; it is the specific application of spontaneous polarization of integrated ferroelectric film and its inversion retention characteristics under the action of electric field [27]. The field of embedded ferroelectric storage devices is a major breakthrough in microelectronics technology and information storage and manufacturing technology. It has opened up many new ways for the fame and development of microelectronics technology, information storage, and manufacturing technology and greatly stimulated the research and development of various universities. In order to understand the properties of ferroelectric materials at the electronic and atomic level, humans have developed a first-order calculation method, in which electrons are the main calculation object for the interaction of intermediate ions [28, 29]. The relationship between the strength of the ferroelectric capacitor and the electric field is

$$
\bar{R}_a = \bar{R}_i - \left(\bar{R}_o + \bar{R}_{\sin}\right)\left\{\frac{1}{\pi} \sin\left[a\chi_a\left(\bar{R}_i + \bar{R}\right)\right] + \frac{1}{2}\right\},
$$
$$
O = i \bullet \frac{l\bar{R}}{L} = i * \frac{l}{L\bar{R}}\left(\delta_i \frac{\bar{L}}{m} + p\right). \tag{1}
$$

Among them, $\bar{L}$ is the voltage, m is the thickness, and i is the area. Calculating the polarization intensity of the capacitor. It is different during the voltage rise $\bar{R}$ and fall

phases. The corresponding expression is automatically selected according to the change of the input voltage during the simulation, that is

$$\chi = f_i - \frac{\left(\|f_i + f_{i-1}\|\right) \otimes 1}{\left(1 + \alpha^{(f+f_i)}\right) + m},$$

$$i : f_i = L\alpha^{-\chi(a+a_i)^2} + l(l-1), \tag{2}$$

$$\alpha : \delta = O\left[\cos l\sqrt{\phi(i + i_{m-1})}\right] \otimes l(f_i).$$

In the design and simulation of large-scale integrated circuits, it will take more time and reduce the simulation efficiency f_i. δ is the residual polarization in the positive and negative directions, and the maximum value that can be reached in the other direction is calculated by the formula:

$$i = \int_{\forall i \in \delta} (m-1)\left(\bar{R}(i-1)\right) l\bar{R}\left(\bar{R} + \chi_{i-1}\right),$$

$$f' = \sqrt{\delta_{i-1}}\left(\cos^2(\alpha_{i=1}l) - \delta_{i-1} \bullet \frac{\alpha}{\alpha_{-1}}\right). \tag{3}$$

The phase f' of the detection signal represents the sign of the charge, and the amplitude δ_{i-1} of the electrostatic force signal reflects the density of the polarized charge or the magnitude of the electric potential.

3. Ferroelectric Memory and Noncontact IC Chip Auxiliary Timing Experiment

3.1. Properties of the Embedded Ferroelectric Memory. In the mid-1990s, ferroelectric memory products were already on the market. Ferroelectric memory has become one of the most promising new members in the memory family. Since the ferroelectric device does not require an external or current power supply to maintain the two states, it can be used to make a storage device to store digital data, and the storage device can maintain its internal storage information without a power supply. The composite film storage unit has an excellent editing function, which can temporarily maintain its intelligent state. Ferroelectric random access memory is a nuclear mode of operation. After this kind of destructive reading, the data needs to be rewritten, so a large number of erasing and rewriting tasks will be accompanied in the information reading process. The concept of memory is very wide and has multiple levels and types, but in the process of information storage, data must be converted into binary data. With a large number of reads and writes, reliability problems such as fatigue failure will occur. In the case that the continuous reduction of the size of the memory cell will cause various problems, many researchers have realized that breaking the limitations of binary storage will greatly increase the storage density of the memory. When the memory cell is read, the state of the memory cell will change due to the read operation. After each read, the original position is damaged, and a voltage must be applied to restore the original polarization. The schematic diagram of the structure of the ferroelectric memory storage unit is shown in Figure 1.

The development of material science research, material preparation technology, and microelectronic integration technology has made great progress in the application of ferroelectric thin films in nonvolatile memory. Initially, researchers focused on the use of ferroelectric thin film polarization. Ferroelectric memory inserts can be written at bus speed; there is no write delay during data transmission, there are no restrictions on the amount of data transmission and write delay, and the system can complete the writing of the entire chip. Compared with other memories, the writing speed of ferroelectric memories is more than 10,000 times faster. The reading speed is also very fast, and there is no obvious speed difference from the writing process. The performance comparison of embedded ferroelectric memory, EEPROM, and FLASH is shown in Table 1.

Studying the morphology and microstructure of ferroelectric thin films is very important for analyzing the performance of ferroelectric thin films and mechanical devices. The electrical properties and customization content of thin ferroelectric thin films are the same as those of general ferroelectric materials, but there are special considerations in the application of thin film materials, and the research methods and technologies are different. Ferroelectric thin film is a key component of ferroelectric memory. High-quality thin ferroelectric thin film is the foundation and stability of ferroelectric memory, and the quality of ferroelectric thin film is reflected by specific performance parameters. The memory-related parameters of different storage unit power consumption are shown in Table 2.

Embedded ferroelectric memory is essentially a combination of the functions of a semiconducting CMOS circuit and an integrated ferroelectric capacitor. Therefore, from a process point of view, the two can form different device structures during the process of mutual integration. Although many experiments have been done to improve the retention of ferroelectric storage and improve it, the visual problem between ferroelectrics and semiconductors has not been well resolved. The analysis of the crystalline and electrical properties of ferroelectric films with different structures shows that the electrical properties of ferroelectric films are closely related to the crystalline properties of the films. The experimental setup is shown in Figure 2.

The grain boundaries between the surface grains and the internal grain boundaries will not affect the overall electrical environment of the film. Ferroelectric memory uses the different orientations of polarized electric domains and the reversal movement of electric domains to store and read information. The preparation and processing of the ferroelectric film will affect the performance of the coupling circuit. At the same time, the processing of the thin ferroelectric film and the back-end coupling circuit will also cause certain damage to the thin ferroelectric film, resulting in the degradation of the ferroelectric capacitor.

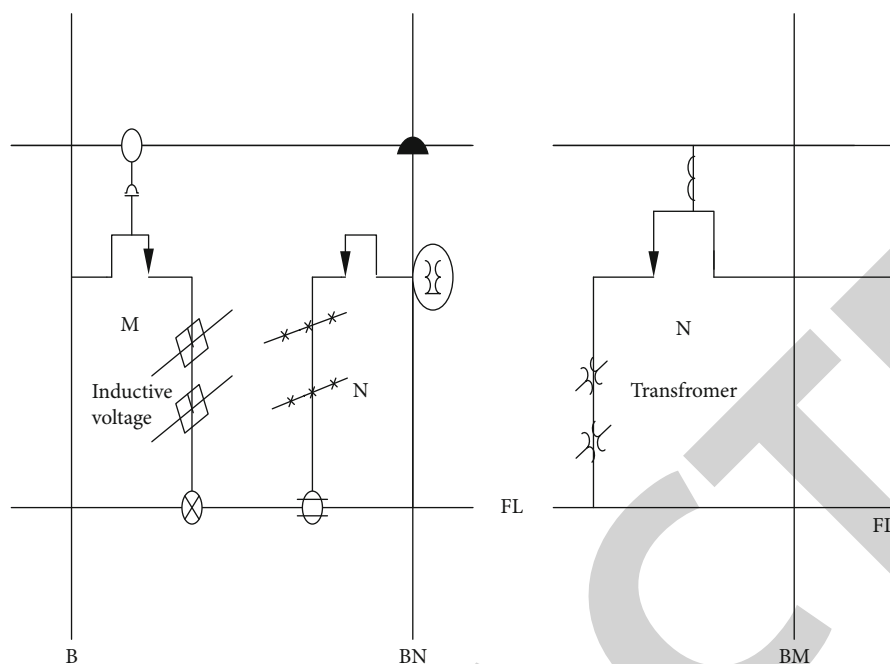
The development of microelectronics, optoelectronics, sensors, and other related technologies has also put forward further demands for the miniaturization, thin-film, and high-density applications of ferroelectrics. From the perspective of the device structure, the integrated ferroelectric capacitor is mainly used to replace the ordinary dielectric


FIGURE 1: Storage unit structure.

capacitor in the semiconductor memory. There are many types of ferroelectric memory storage cells. After the amplifier outputs the signal, the ferroelectric capacitor should be rewritten to restore the destroyed polarization state. After the amplifier generates a signal, the ferroelectric capacitor

should be rebuilt to restore the damaged polarization state. In terms of electrodes, the existing ferroelectric materials do not have the negative crystalline properties of traditional Pt electrodes, which affect the performance of the materials. Although pulsed laser technology can effectively control the composition of the film, the problem of small particles on the surface of the film and the preparation of large-area film coatings is a problem that needs to be solved. The content of molecules at different temperatures is shown in Figure 3.

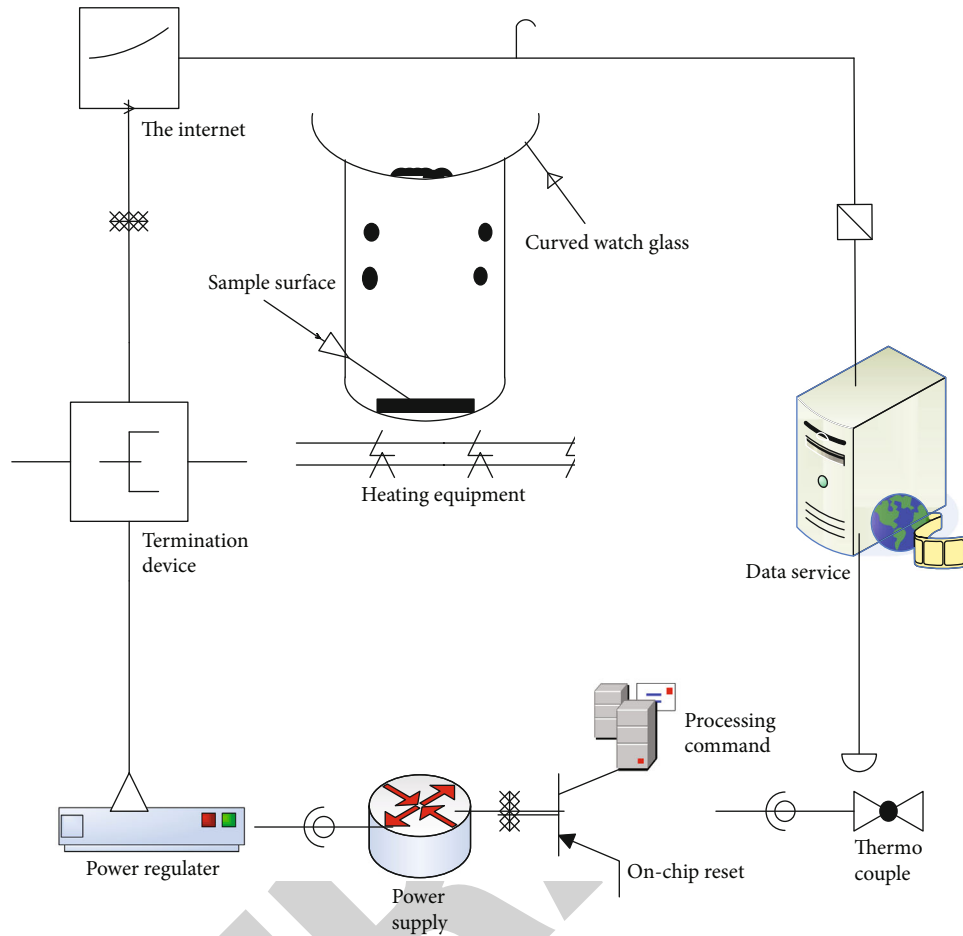
It can be seen that the ferroelectric properties of the samples with different holding time are different. This is mainly due to the influence of the holding time on the grain size and film structure, resulting in different ferroelectric properties. The lower electrode material controls the structure and electrical properties of the ferroelectric thin film, and the interaction between the electrode material and the substrate directly determines the function and life of the ferroelectric memory. The development of the information age requires large-capacity and small-sized memory, which means that


FIGURE 2: Experimental setup test.

the density of the storage unit needs to be increased, and the volume of the storage unit needs to be reduced. The size of the ferroelectric film as a storage medium is also reduced. The residual polarization capacity of the material should be as large as possible, so that the small ferroelectric capacitor area can accept a large polarization current change, which is beneficial to reduce the cell area of the ferroelectric memory. The dielectric frequency should be small because high-frequency dielectric materials will produce a large linear conversion rate, which obscures the availability of the polarization conversion curve. Under the action of an external electric field, the ferroelectric observes the turning polarization through the destruction and development process of the data and the movement of the surrounding particles. The corresponding relationship between the drive capability of the ferroelectric memory and the area, capacitance, and power consumption is shown in Table 3.

3.2. Application of Noncontact IC Chip in Time Monitoring. Even for two-state storage based on epitaxial ultrathin film, the writing of the storage state is very unstable. By applying a current-limited writing method, the storage device can realize multilogic state storage. Ferroelectric reversible diodes cannot maintain a high switching ratio storage state

after power failure. In order to promote the application of such electronic storage devices, the problem of maintaining high switching ratio storage after power failure must be solved. Because the interface barrier is affected by the internal defects of the electrode and the ferroelectric material, although the ferroelectric memory based on the ferroelectric capacitor is a relatively new operating system, its characteristics and mechanical properties are still unclear and require in-depth study. With the development and progress of society, smart cards have been widely used in many fields, especially noncontact IC cards, work permits, and identity certificates. The characteristic coefficient of noncontact IC chip is shown in Figure 4.

In fact, although the same preparation parameters are used when different substrates are used, the quality of the prepared films is not the same. Therefore, the design of low-power circuits has developed innovative and scientific methods. With the gradual improvement of integrated circuit design technology, there will be fewer and fewer ways to reduce chip power consumption, and the share of power consumption will also become smaller and smaller. Reducing the area of the chip can avoid large parasitic resistance and capacitance and can reduce the power consumption of the chip. Use it to establish a connection with the internal
Figure 3: Temperature affects volatilization parameters.

Table 3: Related correspondence index.

Drive capability	Area	Capacitance	Power consumption
CL	4.98*1.89	0.0078	0.0021

C4	4.98*7.82	0.219	0.0569

circuit. It can not only make test points but also can be used for imaging and repairing. Analyzing the application of IC chip is shown in Figure 5.

The biggest feature of the noncontact IC card system is the use of RFID technology for noncontact identification. The antenna of the IC card contact is not integrated on the chip. On the one hand, this increases the cost of card manufacturing, and on the other hand, it also limits the flexibility of applications, thereby limiting the application range of noncontact IC cards. The chip card IC is mounted on the label using flip chip technology. This type of label is usually attached to the horizontal surface of the paper and covered with adhesive on the back. In this way, the antenna has a winding on the back of the ferrite core, and a film mark is made as a sticker mark, and a round shape is provided. Digital correction uses a group of different living body signal worlds to reflect the distributed digital information and only needs to locate and judge the change of the living body signal during the demodulation process. In order to maximize the antinoise capability of the system, channel coding technology is needed to manage possible or existing errors.

Channel coding is to change the original digital signal with no equivalent or equivalent to a digital signal with normal or equivalent enhancement. Data intrusion is achieved by controlling the access status of storage areas and redundant storage. Controlling the access status of the storage area can prevent the destruction of the stored data when an error occurs. Simulating different synchronized data for evaluation in different modules is shown in Figure 6.

Obviously, the evaluation value of the serial port synchronization module as a whole exceeds the pulse synchronization; the network synchronization as a whole exceeds the code synchronization, and the result is the opposite in the network time service module, but the overall performance of each module of the noncontact IC chip is adaptable. If the external time reference source is a wired source, the program is also used for correction to obtain a more accurate second pulse. The time synchronization device sends out a pulse signal at regular intervals. After receiving this pulse, the timing equipment uses the rising or falling edge of the pulse to calibrate the local clock. Comparison of function consumption before and after optimization is shown in Figure 7.

When performing functional simulation of the chip, record the real-time flip information of each device of the chip, combine the parasitic parameter information of the power supply network and the signal network, and analyze the power consumption, IRDrop, and electromigration problems caused by all the flips in the chip at the same time. The first clock of the first standby synchronization system receives the wireless time service, and the time service is sent by the other party. We can set the view to receive the time
FIGURE 4: Noncontact IC chip.

service sent by the top-level synchronization. Analyze the feasibility of simulating auxiliary timing for this operating design, and the result is shown in Figure 8.

Judging from the 9 test results of noncontact IC chips, the feature of maintainability is quite prominent in the application of auxiliary timing, with a maximum value of 7.97. According to the requirements of traditional gymnasium design and sports competition rules, it provides a fair competition environment for athletes, the gymnasium prohibits the use of natural lighting during the game, and artificial lighting is used without skylights. The consequence of this design is that the use of the stadium requires the help of artificial equipment. The introduction of skylight lighting has greatly reduced the energy consumption of gymnasiums, and the enthusiasm of university gymnasiums to open to the outside world is also increasing day by day. The noncontact IC of embedded ferroelectric material can realize a large number of complex simulation system tasks through simple and easy operations in time, which greatly reduces the labor of competitors, improves performance, and ensures the accuracy and reliability of data, the probability of technology and economy, and the feasibility of management.

4. Discussion

As the parts in the form of circular circuits become smaller and smaller, the coupling degree is higher and higher, and

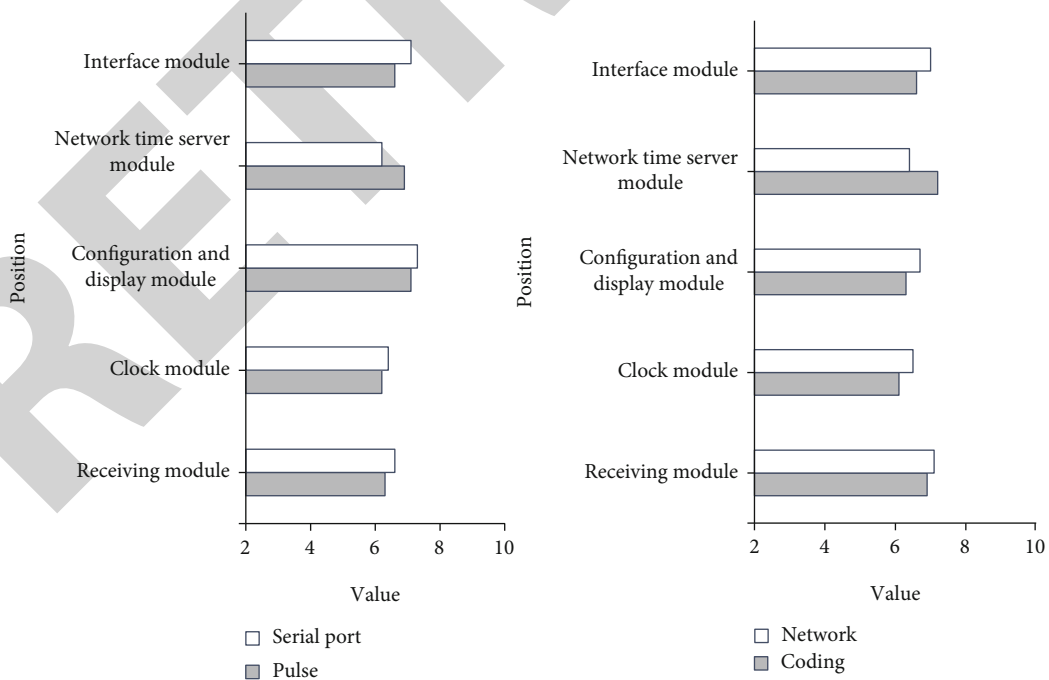
the speed is getting faster and faster; people in the manufacturing chain have found many problems that cause it and gradually focus their work on the design and research of energy efficiency optimization. The process size of the coupling circuit is getting smaller and smaller, the number of transistors that can be accommodated in a single area increases, and the area of the cut leads to an increasing power density, which is prone to overheating. Adjust the loading process and design constraints according to the characteristics of the chip module, and plan the additional loading plan of the chip according to the average flip position of the display during normal operation; complete all stored back-end programs, save time, usage, and other parameters according to the previous storage characteristics to ensure the continuity of the design. Then, complete various verifications of the chip to ensure the correctness of the chip design. The weak ferroelectricity of ultrathin films needs to be detected by special instruments. Piezoelectric atomic force microscope is a commonly used tool for detecting ferroelectric properties. Although it has been very advanced, it still needs development in the detection of weak ferroelectricity. With the continuous progress of integrated circuit design and manufacturing technology, the proportion of embedded memory in the chip is getting higher and higher. Due to the increase of transistor density in embedded memory, it is easy to find internal defects, and people have conducted in-depth research on the test of embedded
Figure 5: Application of noncontact IC chip.


Figure 6: Synchronized formal parameters under different module positions.
Figure 7: Comparison before and after function consumption optimization.
FIGURE 8: Auxiliary timing test results.

memory. With the further improvement of film preparation technology, the preparation technology of epitaxial film has been mastered by many scientific workers.

5. Conclusion

At present, the system only recognizes the functions of game score statistics, and there are many shortcomings in providing humanized services and drills throughout the game. In terms of practice, it analyzes and sorts out general college gymnasiums, college gymnasiums that take into account urban competitions, and urban gymnasium space design data models and provides suggestions for optimization of the space design of the competition hall and activates the space design thinking of the competition hall, gets rid of some misunderstandings in the current design, and broaden the vision of the current space design. Out of the consideration of both urban events and the use of competitive sports, the choice of technology should be based on the needs of both aspects, respect the principle of rationality of technology, and must not blindly use it to cause unnecessary waste. The key to solving this problem lies in two aspects. On the one hand, it is necessary to further study the process of resistive random access memory to reduce the current of the write operation as much as possible. On the other hand, it is to optimize the high-voltage module plan and try to use a smaller capacitor to achieve the appropriate operating current, which is also the next step in the work of resistive random access memory. Since many future research and development environments are currently undergoing research and development, ferroelectric memory has unique advantages compared to other types of memory; ferroelectric memory is very likely to become a new product that replaces existing traditional memory and flash memory. In recent years, noncontact IC cards have integrated data protection and cryptography, electronic computing technology, manufacturing technology, and many other professional application technologies, forming an independent technical field. The combination of the two overcomes the main technical obstacles to the integration of ferroelectrics and semiconductor devices, making it possible to integrate ferroelectric devices compatible with semiconductor technology, and has greatly promoted the development of ferroelectric thin film preparation and material research.

Because of its large specific surface area, small particle size, high surface energy, and unique nanoeffect, the morphological characteristics of nanoparticles are the key factors affecting the properties of materials. How to detect and evaluate the morphological characteristics of nanoparticles is the first problem to be solved in the preparation and application of nanomaterials. The main purpose of this paper is to use TEM to recognize the image features of nanoparticles and introduce the transmission electron microscope and image edge segmentation method and random forest algorithm. A method integrating the in situ characterization of modern electron microscopy and the measurement of the electrical properties of nanomonomers was developed. In this paper, a multielectrode TEM in situ electrical measurement platform is prepared, which improves the contact during the integration of nanomaterials and improves the electrical measurement accuracy of the TEM in situ electrical method. In this paper, based on the random forest algorithm, a multirandom forest algorithm is proposed. Due to the different gray levels of images referenced by the multirandom forest algorithm, the segmentation results are processed by FCM clustering algorithm. Experimental results show that in terms of image segmentation accuracy, the minimum Jaccard coefficient obtained by multiple random forest algorithm is 89% and 95%, respectively, which is obviously better than watershed segmentation method and maximum entropy threshold segmentation. In the aspect of automatic image segmentation of nanoparticles, the image segmentation accuracy is the highest when the sample block size and the number of sample blocks selected in the multiple random forest algorithm are $5 * 5$, 7500, and 35, respectively. Therefore, the multirandom forest algorithm has achieved high accuracy in image segmentation of nanoparticles, which provides valuable information for the preparation and application of nanomaterials. A new type of TEM dark-field imaging diaphragm was prepared, which greatly improved the imaging quality of weak-phase bulk materials represented by graphene and nonspiral biological samples represented by intracellular polyvesicles.

1. Introduction

At present, the traditional CMOS process is close to the limit of development, and the traditional means of improving the performance of nanoelectronic devices by reducing the device size will become less and less feasible in the foreseeable future. Application requirements such as high-performance computing and big data have put forward higher requirements

on the computing speed and reliability of electronic devices. In recent years, with the continuous research of image processing technology in the field of computer, the emergence of electron microscope provides the possibility for people to explore the mystery of the micro world. After years of development, it has become an indispensable tool in modern science and technology. For nanomaterials, the size and distribution of nanoparticles determine the physical and chemical properties of

nanomaterials. Therefore, the measurement and characterization of nanoparticle size are an important aspect of nanomaterial structure research, especially the measurement of nanoparticle distribution has important practical significance. Nanoparticle recognition refers to the extraction and analysis of particle features in nanoparticle images. Transmission electron microscopy (TEM) is an important tool for characterizing nanomaterials [1]. It can observe the submicroscopic or ultramicrostructure which cannot be seen under the optical microscope below 0.2 μm.

Strzeciwilk et al. describe the results of TEM training at TiC Crystal and Co. Teak crystals are prepared using high temperature superconductivity (HTS) technology using cobalt as high temperature oil. The physical structure of the crystal is investigated by natural metal. X-ray phase analysis of the samples was performed. Li et al. focused on the study of twins in bulk metals FCC and BCC and their effects on the mechanical properties of all metals. It is possible that these unique defects are directly related to the properties of the macro machine that uses the flexible mounting tool to simultaneously degrade the nanomachine and the nanoimage [2, 3]. Mayer et al. combine double-angle shear geometry and flat-bore compression at nanointerter to determine the mechanical properties of these films under shear stress. In order to further explain the voltage attenuation failure device, TEM-mounted tests were performed on TEM sheets with dual markers. Aluminum layer thicknesses of 50 nm and 100 nm were used to indicate the effect of the restriction on deformation. Compared to the 100 nm sample (423 ± 28.7 MPa), the tensile strength of the 50 nm sample is higher (690 ± 54 MPa) [4]. Shen and Sun introduce external fields such as electronics, thermal energy, light field, and electricity to TEM, which can create a nanolaboratory at TEM and compare real-world environments. Therefore, in addition to static structural design, the indoor TEM can also recognize the capabilities of the two-dimensional material structure and the evolution of performance. This extension is expected to handle and create two-dimensional materials in individual size, providing the necessary features and properties for future applications [5].

Lyon et al. reduced Au to water-soluble gold-plated iron magnetic oxide nanoparticles with a diameter of 60 nm on the surface 2-Fe2O3 or Fe3O4 oxidized particles partially from recycled hydroxylamine. The morphology and optical properties of the core/shell particles depend on the amount of gold deposited, while the magnetic properties are very independent of the amount of gold added [6]. Wei et al. solve this problem by synchronizing 30 nm nanoprecipitation via Ostwald maturation. When the prefrontal cortex has a large swelling of the membrane, 2 hours of boiling or 10 days of ambient aging allow the gelatinous material to grow into a nonuniform nanoparticle [7]. Nayral et al. prepared core-core nanocomposites consisting of a sn0 core and a thin-layer tin oxide with thermal decomposition of [{Sn (Nm2) 2} 2] containing a small amount of water control in anisole. The particles are exposed by electron microscopy (TEM, HRTEM, and SEM), X-ray diffraction (XRD), photoelectron spectroscopy (XPS), and Mossbauer (Mssbauer) spectroscopy. TEM micrographs show the magnitude of a

particle's rotation, and their distribution depends on the initial test conditions, such as temperature, time, water concentration, and pretin concentration [8]. Copolymers of ε-caprolactone and L-lactide (pCLLA) with different monomer fractions were synthesized at the rate of GEH polymerization and the drug accumulated in large amounts of PCL, PLLA, and their copolymers were prepared by precipitation. Large particles are indicated by XRD, TEM, and attenuation luminescence. The size of LiYF4 molecules can be adjusted by converting the F ratio to lanthanide ions. After passivation with oleic acid ligands, LiYF4 nanoparticles can be readily dispersed in various nonpolar liquids, such as hexane, cyclohexane, dichloromethane, and toluene [9, 10].

This paper mainly introduces the transmission electron microscope, image edge segmentation method, and random forest algorithm. In this paper, based on the random forest algorithm, a multirandom forest algorithm is proposed. Due to the different gray levels of images referenced by the multirandom forest algorithm, the segmentation results are processed by FCM clustering algorithm. The experimental results show that the multirandom forest algorithm achieves high accuracy in the segmentation of nanoparticles. The electrodes prepared by this technique can be easily improved into excellent ohmic contacts when integrated with nanomaterials, which can reduce the influence of contact resistance on the measurement of electrical properties. In addition, the technology realizes the adjustable number, size, and spacing of electrodes, and it is easy to obtain contact resistance information by multiterminal electrical measurement, so as to obtain more reliable electrical properties.

2. TEM and Nanoparticles

2.1. Transmission Electron Microscope. Since the advent of the world's first transistor in 1947, integrated circuits based on microelectronics technology have greatly changed human production and lifestyle. During this period, the development of integrated circuits has always followed Moore's law, that is, the number of integrated transistors per unit area doubles every 18 months, and the critical size of transistors shrinks by a factor of 0.7 every 18 months. By 2009, the feature size of the marketed microprocessors in integrated circuits has reached 45 nm, the 32 nm size is brewing into mass production, and the industry and academia have aimed at 22 nm.

Transmission electron microscope (TEM) is one of the important tools to detect the micromorphology, crystal structure, and chemical composition of materials. It uses a short wavelength high-energy electron beam as the incident light source [11]. Under a certain accelerating voltage, the electron beam converges through the electromagnetic lens and passes through the sample, thus obtaining the subangstrom spatial resolution.

TEM is generally composed of three parts: electronic optical part (lighting system, imaging system, observation, and recording system), vacuum part (vacuum system and vacuum display instrument), and electronic part (various power supply, safety system, and control system). Electron optics is the core part of electron microscope. According to

the different types of electron gun in lighting system, TEM can be divided into thermal emission transmission electron microscope and field emission transmission electron microscope. In TEM, an incident electron beam is generated by heating the filament with lanthanum hexaborate (LaB6). Tungsten wire is used as electron emission source of field emission TEM. Under the strong electric field, the internal electrons will be emitted from the filament surface above the barrier due to the tunneling effect. Compared with thermal emission, field emission can produce electron beam with higher brightness, better coherence, and single wavelength. Combined with the TEM-SPM technique, the structure-dependent in situ electrical measurement experiments were carried out on a variety of nanomaterials. First press the gold tip of the STM with the gold electrode inside the sample holder. It was then slowly separated under TEM observation until atomically sized gold nanowires were obtained. Since the entire stretching process can be imaged in TEM, the width of the nanowires is controlled to be only a single atom wide.

(1) Lighting system

The electrical system is essentially an electrical circuit breaker, a condenser, an electronic pistol, and a printer. Your job is to provide a light source with high brightness, low beam angle, good contrast, and stable beam. In order to meet the requirements of the dark field image, the light beam can be adjusted to 2-3 degrees.

(1) Electron gun

The electron gun is the light source that emits electrons. It is actually an electrostatic lens composed of cathode, grid, and anode. The cathode is the source of free electrons. There are usually direct heating and close contact heating as well as cathode separation, each of which remains independent. In electron microscopy, the cathode is usually made of heated filament and tungsten metal, which has the characteristics of low cost, low brightness, and short life. The cathode is the source of free electrons. Once the cathode is heated, it can produce free electrons, anode, and cathode electric field. The anode can attract the cathode that emits free electrons and change its motion state from chaos to orderly orientation. After the cathode grid is biased, it can produce the convergence effect of the electron beam, that is, to gather to the central axis, so that the electron beam is in the center of the axis the movement can be carried out through anode and injection gun to form the required light source to irradiate the sample.

Within a certain limit, the amount of free electrons emitted by the filament is proportional to the heating current intensity, but after this limit is exceeded, the current continues to increase, which can only reduce the service life of the filament, but cannot increase the amount of free electrons emitted. We call this critical point the filament saturation point, which means that the emission of free electrons has reached "full capacity" and can no longer be added. In normal use, the heating current of the filament is often adjusted and set at a position close to saturation, which is called "undersaturation point." In this way, the service life of the filament can be extended to the maximum extent under the condition that a large amount of free electron emission can be obtained.

The grid is located between the cathode and anode, near the end of the filament. It is a cap-shaped metal object with a small hole in the center for the electron beam to pass through. Apply a negative voltage of 0-1000 v (cathode) to the grid. This negative voltage is called gate bias, its height is different, and users can adjust it according to their needs. The grid bias voltage can make the electron beam converge to the central axis and control and restrain the electron emission on the filament to a certain extent.

The working principle of the electron gun: under the action of the filament power supply, the current flows through the cathode of the filament and heats it to above 2500°C. Free electrons are generated and escape from the surface of the filament. When the power is turned on, an accelerating voltage is generated. The positive charge generated on the anode surface forms a positive electric field, and the free electrons on the cathode surface escape after being affected by the electric field and are emitted by the electron gun to form a power supply. In the process of electron microscope, the filament can be adjusted to the low saturation point, and the beam current can be controlled by adjusting the gate bias voltage.

In the electron microscope, the acceleration voltage is also adjustable, so as long as the acceleration voltage is increased, the penetration can be enhanced, because the acceleration of voltage will reduce the wavelength, and the smaller the wavelength, the stronger the penetration. Although this can improve the resolution, but also brings the corresponding disadvantages, that is, the reduction of imaging contrast. Therefore, when the application of high-resolution observation is not pursued, a lower acceleration voltage can be selected to obtain a larger imaging contrast, especially for biological samples with low contrast, it is sometimes advantageous to choose a lower acceleration voltage.

(2) Condenser

The capacitor is under the gun. The condenser is composed of a first condenser and a second condenser. The purpose of setting a condenser in the electron microscope is to gather the electron beam emitted by the electron gun into a spot with uniform brightness and adjustable irradiation range and project it on the sample below. After the electron beam passes through the capacitor, a uniform spot with adjustable irradiation range is formed and projected onto the sample. The first condenser is a strong magnetic field lens, and the second one is a weak magnetic field lens. All levels of capacitors are used together to adjust the diameter of the light beam spot, so as to change the intensity of illumination brightness. The corresponding adjustment knob is generally set on the control panel of the electron microscope. The first concentrator and the second concentrator have different magnetic pole shape and working current, so the first concentrator has stronger magnetic field strength, while the

second concentrator has lower magnetic field strength. The method of changing the brightness by adjusting the capacitance current is actually an indirect method. The maximum brightness is limited by the electron beam. In order to change the brightness of the light to a greater extent, the size of the electron beam can be fundamentally changed by adjusting the gate bias voltage in the electron gun mentioned above. The main requirements for magnifying imaging lenses such as intermediate mirrors and projection mirrors are to obtain the highest magnification required for high resolution and the lowest magnification required to find a suitable field of view under the condition of shortening the height of the lens barrel as much as possible. It is also hoped that their aberrations, distortions, and axial astigmatism are as small as possible when conducting electron diffraction image analysis, doing special observations such as selected-area diffraction and small-angle diffraction.

The condenser is located below the electron gun and is generally composed of one stage, which are called the first and second condensers in order from top to bottom. The purpose of setting the condenser in the electron microscope is to condense the electron beam emitted by the electron gun into a light spot with uniform brightness and adjustable illumination range and project it on the sample below. The structures of the first condenser and the second condenser are similar, but the shape of the pole piece and the working current are different, so the strength and use of the magnetic field formed are also different. The first condenser is a strong magnetic field lens, and the second condenser is a weak magnetic field lens. The condensers of all levels are used together to adjust the diameter of the illumination beam spot, thereby changing the intensity of the illumination brightness. Generally, it is set on the electron microscope control panel. There are corresponding adjustment knobs.

(2) Imaging system

(1) Sample room

The sample chamber is under the condenser, and there is a sample stage for loading the sample. The sample stage must be able to move on the horizontal plane and direction to select and move the observation field. Correspondingly, it is equipped with a joystick or a rotating handwheel, which is a precise adjustment mechanism to move left and right in a certain direction. Modern high-end electron microscopes can be equipped with a computer-controlled motor-driven sample stage, which strives to be accurate when moving, stable when fixed, and can make label-type positioning marks on the sample by the computer, so that users can rely on it when they need to do retrospective comparison. Computer positioning search is difficult to achieve in manual selection operations.

Because of the short electron wavelength and weak penetration, it is necessary to make very thin samples. At this time, ultrathin slicing machine is needed for cutting. In order to achieve better cutting effect, diamond cutter or special glass cutter is required for ultrathin slicer. The sample is first installed on the copper wire and then fixed on the sample table. The sample table and the sample holding rod are integrated, which is a very fine part. There is an O-shaped rubber sealing ring in the middle of the sample bar, and the surface of the sealing ring is coated with vacuum grease to isolate the vacuum between the sample chamber and the outside of the mirror body.

(2) Objective

The objective lens is the most important part of electron microscope. Its function is to keep the phase of the elastic scattering beam converging on the focusing plane from the difference direction of the sample. A scattering pattern containing the sample structure or diffraction pattern will converge the elastic scattering beam of the same sample point on the image plane to form the sample group corresponding to the microscopic image. The quality of TEM depends on the quality of objective lens to a great extent.

The objective lens is a strong magnetic lens with a very short focal length, which requires extremely high working conditions such as material purity, processing accuracy, and pollution conditions during use. The core problem of improving the resolution index of an electron microscope is the comprehensive assessment of the performance design and process manufacturing of the objective lens. The focal length is as short as possible, the aberration is small, and the space is expected to be large, which is convenient for sample manipulation, but there are many contradictory links in the middle.

The function of the objective lens is to enlarge the main image, change the working current of the objective lens, and adjust the focal length. An electron microscope is used to change the operating current of the objective. After passing through the sample, the electron beam is projected onto the objective lens to form the first image, which usually determines the imaging accuracy. If there is an error in this kind of imaging, even if the error is very small, it will be displayed at a higher magnification once it is amplified.

(3) Intermediate mirror and projection mirror

An intermediate mirror, a first projection mirror, and a second projection mirror are arranged below the objective to complete the further magnification of the objective lens imaging. The total magnification of electron microscope is the product of objective lens, intermediate lens, and projection lens. The intermediate lens is mainly used for secondary magnification or reduction of objective lens imaging. By changing the position of the intermediate lens, the imaging operation or electron diffraction operation is controlled. The imaging operation is to enlarge the image of the objective lens and display it on the fluorescent screen. In order to obtain the imaging operation, the objective plane of the central lens and the image plane of the objective lens should overlap. The operation of electron diffraction is to reduce the object image and display it on the fluorescent screen. Through the imaging operation mode, we can obtain the morphology, structure, and other information of the sample, while the phase analysis of the sample requires the diffraction operation mode.

In the TEM-SPM method, the Schottky contact between the sample and the electrode is easy to form, which affects the measurement of the electrical properties of nanomaterials. Currently, TEM-SPM optimizes the contact between nanomaterials and electrodes by applying Joule heat generated by a suitable current. The contact Schottky resistance obtained in this way is large, the resistance difference between different contacts is obvious, and the TEM-SPM method is difficult to improve to the ohmic contact.

2.2. Medical Ultrasound Imaging Based on Edge Segmentation Method.

Edge is the important visual information contained in the image, and it contains most of the information of the image [12]. Edge detection is a key step in image processing and machine vision. The effect of edge detection is very important for image analysis and understanding. Images contain a lot of information, but not all of it [13–15]. By edge detection, not only the structural attributes of the image are preserved but also the information irrelevant to the image processing target is eliminated, greatly reducing the amount of data contained in the image, and finally, the edge information we need is obtained [16–18]. The edge-based segmentation method is used to detect the gray change of the discontinuous position image in terms of texture, gray level, and color and reflect the gray level gradient, represented by $\nabla f(a, b) = \partial f / \partial f i + \partial f / \partial f j$ [19]. The edge detection operator $e(a, b) = \sqrt{f_a^2(a, b) + f_b^2(a, b)}$ is defined, which is the amplitude of $\nabla f(a, b)$. To simplify the calculation, it can also be defined as the sum of the absolute values of the partial derivatives f_a, f_b:

$$e(a, b) = |f_a(a + b)| + |f_b(a + b)|. \tag{1}$$

(1) Sobel operator

Sobel operator image a point is as the center, in the neighborhood of $3 * 3$D direction and the partial derivative of the direction [20, 21]. The formula of Sobel operator is as follows:

In the vertical direction:

$$\begin{aligned} S_1(x, y) = |&f(x - 1, y - 1) + 2f(x, y - 1) + f(x + 1, y - 1) \\ &- (f(x - 1, y + 1) + 2f(x, y + 1) + f(x + 1, y + 1))|. \end{aligned} \tag{2}$$

In the horizontal direction:

$$\begin{aligned} S_2(x, y) = |&f(x - 1, y - 1) + 2f(x - 1, y) + f(x - 1, y + 1) \\ &- (f(x + 1, y - 1) + 2f(x + 1, y) + f(x + 1, y + 1))|. \end{aligned} \tag{3}$$

Select a threshold T, if $S_1(x, y) > T$, it means there is edge passing in the vertical direction of (x, y), and (x, y) is edge point. In the same way, if $S(x, y) > T$, also means edge point in (x, y) [22].

(2) Roberts operator

The gradient in the Roberts algorithm can be seen as the difference between two pixels in any vertical direction. The Roberts operator, on the other hand, takes the difference between two adjacent pixels in the diagonal direction:

$$\Delta_i f = f(x, y) - f(x + 1, y + 1), \tag{4}$$

$$\Delta_j f = f(x, y + 1) - f(x + 1, y). \tag{5}$$

Its gradient amplitude value is

$$R(x, y) = |\Delta_i f| + |\Delta_j f|, \tag{6}$$

or

$$R(x, y) = \sqrt{\Delta_i^2 f + \Delta_j^2 f}. \tag{7}$$

The convolution operator is expressed as

$$\Delta_i f = \begin{vmatrix} 1 & 0 \\ 0 & -1 \end{vmatrix}, \Delta_j f = \begin{vmatrix} 0 & 1 \\ -1 & 0 \end{vmatrix}. \tag{8}$$

Select the close value T appropriately, if $R(x, y) > T$, then, (x, y) is the edge point.

(3) Laplace operator

Laplace operator is a second derivative operator, whose center of function is zero in the frequency domain is symmetric, so it has rotation invariance. This graph is processed by Laplace operator, and the pixel has the feature of zero gray mean. The Laplace transform of a two-dimensional graph function is the isotropic second derivative. The formula is as follows:

$$\nabla^2 f(a, b) = \frac{\partial^2 f(a, b)}{\partial a^2} + \frac{\partial^2 f(a, b)}{\partial b^2}. \tag{9}$$

Let us write it as a difference:

$$\begin{aligned} \nabla^2 f(x, y) = &f(x - 1, y) + f(x, y + 1) + f(x + 1, y) \\ &+ f(x, y - 1) - 4f(x, y). \end{aligned} \tag{10}$$

2.3. Random Forest Algorithm

2.3.1. Bagging Algorithm.
The principle of bagging algorithm is to determine the training set, get the number of training samples, and determine the number of weak classifiers. Then, the samples are randomly put back from the training set until the samples are equal to the training samples. If the number of existing weak classifiers reaches the standard, stop sampling and construct a strong classifier by voting strategy as the final classification result. If the number of weak classifiers is not enough, the samples are randomly put back from the training set.

2.3.2. Random Forest Algorithm. The principle of a random forest algorithm is the development of many independent decision trees, and each decision tree can be trained independently with training samples [23]. Each decision tree is according to the training plan. In order to create decision trees, it is necessary to create a corresponding number of training programs. Creation of N training units is from an original training base with a statistical modeling process. The test samples are categorized according to randomly assigned subtrees, and the results of each background are summarized. As a powerful classifier, the random forest algorithm has a strong power.

Random forest algorithm has many excellent characteristics. Random forest algorithm can be applied in many fields and has achieved excellent performance. It has the following advantages: (1) the algorithm is simple and easy to understand and easy to implement; (2) it can detect the interaction between features in the training process; (3) it has good antinoise ability and good ability to deal with a certain amount of data loss; (4) it can be processed in parallel.

3. Experimental Design

3.1. Experimental Design. These data include 800 transmission electron microscope (TEM) images of nanoparticles with an acceleration voltage of 70 kV and a magnification of 6000.

When the nearest neighbor field is initialized, a 5×5 window is used to sample the reference image set a uniformly and independently, and a set of 8000 effective blocks is obtained.

In the process of image block matching, the matching block of the block to be searched is searched step by step. Table 1 shows the experimental results of one query block under three different search steps and calculates the best five matching blocks. Di represents the distance between the query block and the 6-neighborhood block.

The weights of the corresponding tag matching blocks are extracted and optimized. Six query blocks are selected, and the similarity weights between the optimal matching of each query and the five blocks are calculated according to the formula.

From Tables 1 and 2, we can get the d_i and w_i values of each query block, search out the optimal image matching block of the query block, and finally extract the optimal matching block for weighting to reconstruct the initial segmentation results of nanoparticles.

3.2. Experimental Steps. In this experiment, n reference images with different gray levels are extracted from database X and y for decision tree algorithm processing: (1) generate n-ary tree through training set; (2) analyze the path generation rules of n-tree generated; (3) predict or classify new data according to the generated rule set. After processing, n decision trees are generated, and a single random forest is collected to form multiple random forests. Input the image a to be segmented and output the segmentation result of image a of each random forest classifier. In the experiment, n different random forest classifiers are used to get the segmentation results of N graphs a. After getting n different

TABLE 1: Experimental results of three different search steps.

Search step size	The distance value Di between query block and 6 domain block					
	D1	D2	D3	D4	D5	D6
4	38	65	295	85	125	315
2	59	315	65	326	106	178
1	79	48	71	35	105	299

TABLE 2: Similarity weight between query block and optimal block.

Image block number	Similarity weight W1 between the query block and the best matching block				
	W1	W2	W3	W4	W5
1	0.2235	0.2156	0.2030	0.1985	0.1923
2	0.2185	0.2015	0.1985	0.1867	0.1815
3	0.2376	0.2278	0.2056	0.1975	0.1862
4	0.2163	0.2085	0.1989	0.1875	0.1832
5	0.2623	0.2073	0.1975	0.1865	0.1812
6	0.2185	0.2015	0.1956	0.1929	0.1918

segmentation results, FCM clustering algorithm is used for processing. The steps of FCM clustering algorithm are as follows:

(1) The gray values of N pixels with the same coordinates in the segmentation results are extracted, and the $X * y$ samples with sample size n are finally obtained

(2) According to the obtained $x * y$ samples of N, the probability of the points expressed as nanoparticles in each sample s is calculated. Let $n(a, b)$ be the number of points labeled as nanoparticles in row a and column B of N segmentation results, and $P(a, b)$ is the probability of points labeled as nanoparticles in column A and column B in n segmentation results

(3) By calculating the probability p of nanoparticles for all the sample data, we can construct the probability map of the base film obtained by N results

(4) FCM clustering is performed on the calculated probability graph

(5) Through the above four steps, after completing the classification of $X * y$ samples, the postprocessing of N segmentation results is completed. After constructing the probability map of nanoparticles, the structure of nanoparticles was extracted by FCM clustering, and the segmentation results with high accuracy were obtained after optimization

4. Analysis of Experimental Results

4.1. Evaluation of Image Segmentation Accuracy. In this paper, the segmentation results are compared with the

TABLE 3: Jaccard similarity coefficient of three different methods.

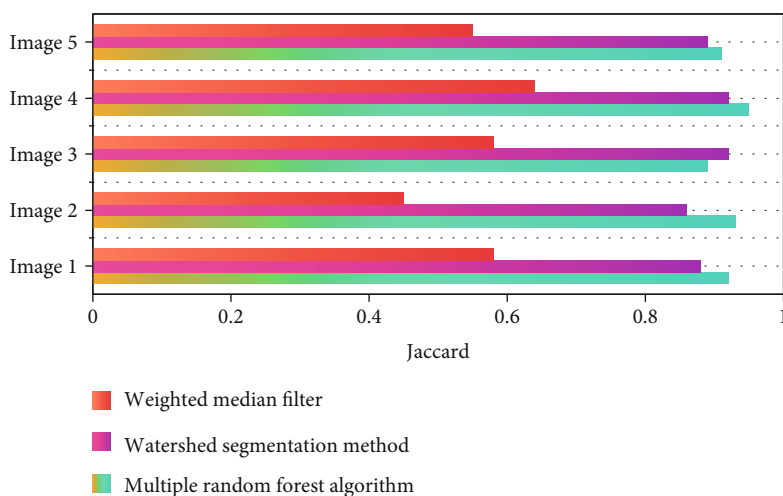
Method	Image 1	Image 2	Image 3	Image 4	Image 5
Multiple random forest algorithm	0.92	0.93	0.89	0.95	0.91
Watershed segmentation method	0.88	0.86	0.92	0.92	0.89
Weighted median filter	0.58	0.45	0.58	0.64	0.55


FIGURE 1: Jaccard similarity coefficient of three different methods.
FIGURE 2: Effect of sample size on segmentation accuracy.
FIGURE 3: The influence of sample number on segmentation results.

manual segmentation golden standard image, and the Jaccard index is used to evaluate the segmentation results. Jaccard index is a geometric similarity measure function. The larger the Jaccard value, the better the segmentation performance. The formula is as follows:

$$\text{Jaccard}(X, Y) = |X \cap Y| / |X \cup Y|. \tag{11}$$

In the formula, a and B are the results of manual segmentation and automatic segmentation, respectively, and the overlap rate of nanoparticle regions between the two results is calculated. The similarity coefficient is between [0,1]. The Jaccard value is 1 when the manually segmented nanoparticle region completely overlaps with the auto segmented basement

membrane region, and 0 when there is no overlap term. The closer to 1, the higher the similarity, the better the segmentation effect.

In this paper, we use multiple random forest algorithm, watershed segmentation method, and maximum entropy threshold segmentation to detect TEM images of 800 groups of nanoparticles. Jaccard similarity coefficient of three different methods is shown in Table 3.

As can be seen from Figure 1, the minimum Jaccard coefficient obtained by the multiple random forest algorithm is 89%, and the highest is 95%. The lowest and highest Jaccard coefficients are 86% and 92%, respectively. The lowest and highest Jaccard coefficients are 45% and 58%, respectively. For the same group of images, from left to right is
FIGURE 4: The influence of the number of random forests on segmentation results.

corresponding to the multirandom forest algorithm, watershed segmentation method, and maximum entropy threshold segmentation Jaccard coefficient.

4.2. The Size of Sample Block Affects the Segmentation Result.
In the initialization process, the size of sample block directly affects the accuracy of segmentation results. In this experiment, eight groups of images are selected to calculate the influence of sample block size on the segmentation results of each group, as shown in Figure 2.

As can be seen from Figure 2, when the size of the sample block is less than $5 * 5$, the segmentation accuracy does not change much; when the size of the sample block is greater than $5 * 5$, the segmentation accuracy begins to decline. Considering the segmentation results and computational complexity, the computational complexity of $5 * 5$ size is less than $3 * 3$ size in the case of low image accuracy. Therefore, the size of the sample block is suggested to be $5 * 5$.

4.3. The Influence of the Number of Evenly Distributed Samples on Segmentation Results.
In the process of image block matching, the number of evenly distributed samples directly affects the result of image segmentation. In this experiment, we selected 8 groups of images to calculate the effect of sample size on the segmentation effect of each group of images, as shown in Figure 3.

The smaller the number of samples, the worse the segmentation effect. This is mainly because the sample block contains too little information, resulting in poor matching effect and resulting in poor segmentation effect. When the number of samples is more than 7500, the accuracy of segmentation has little change. Considering the segmentation results and computational complexity, this paper suggests that 7500 is the most suitable sample size.

4.4. The Influence of the Number of Random Forests on Segmentation Results.
In the process of multirandom forest algorithm segmentation, the number of constructed forests has a direct impact on the image segmentation results. In

this experiment, eight groups of images are selected, and the influence of the number of forests on the segmentation effect is calculated.

It can be seen from Figure 4 that the segmentation effect is gradually enhanced with the increase of the number of selected forests ($n \leq 35$). This is mainly because the information of gray distribution is too little, which will lead to poor matching effect and poor segmentation effect. When the number of random forests is 15, the segmentation accuracy of 8 groups of images is very different. The main reason is that when building multiple random forests, some images will choose the training images with similar gray levels, so the segmentation accuracy is higher than other images. With the increase of the number of random forests, the segmentation accuracy of 8 groups of images is gradually improved. When the number of trees is more than 35, the segmentation accuracy changes little. Considering the segmentation results and computational complexity, the number of forests should be set to 35.

The experimental results show that in terms of image segmentation accuracy, the Jaccard coefficient obtained by the multiple random forest algorithm is significantly better than watershed segmentation method and maximum entropy threshold segmentation and is more suitable for the segmentation of nanoparticles. Multiforest algorithm uses multiple random forest classification. When the number of forests is large enough, there will always be one or more training images whose gray value is close to the gray value of the segmented image. It overcomes the problem of low image accuracy caused by gray difference between different images and improves the segmentation accuracy of nanoparticles. When the size of the sample block is less than $5 * 5$, the segmentation accuracy does not change much when the size of the sample block is less than $5 * 5$; when the size of the sample block is greater than $5 * 5$, the segmentation accuracy begins to decline. It is suggested that the size of the sample block should be $5 * 5$. When the number of samples is more than 7500, the accuracy of segmentation does not change much. With the increase of the number of selected forests ($n \leq 35$), the segmentation effect is

gradually enhanced. When the number of trees is more than 35, the segmentation accuracy changes little. When the multiple random forest algorithm is used, the best result is when the number of forests is set to 35.

5. Conclusion

With the development of materials science, nanoparticles have large specific surface area, small particle size, high surface energy, and unique nanoeffect. The morphology of nanoparticles is a key factor affecting the properties of materials.

In this paper, we mainly study the image recognition of TEM nanoparticles. We mainly introduce transmission electron microscopy, image edge segmentation, and random forest algorithm. In this paper, based on the random forest algorithm, a multirandom forest algorithm is proposed. Due to the different gray levels of images referenced by the multirandom forest algorithm, the segmentation results are processed by FCM clustering algorithm. This paper improves the imaging quality of TEM for weak phase bulk materials and biological samples, builds a multielectrode TEM in situ electrical platform based on microchips, realizes pollution-free etching with atomic precision, prepares nanodots, and observes coulombs. The blocking phenomenon was observed, the nanowire-induced fracture process was observed, and the nanowire fracture mechanism was studied. The minimum and maximum Jaccard coefficients obtained by multiple random forest algorithm are 89% and 95%, respectively. The lowest and highest Jaccard coefficients are 86% and 92%, respectively. The lowest and highest Jaccard coefficients are 45% and 58%, respectively. The Jaccard coefficient of the proposed algorithm is higher than that of watershed segmentation and maximum entropy threshold segmentation. In the aspect of automatic image segmentation of nanoparticles, the image segmentation accuracy is the highest when the sample block size and the number of sample blocks selected in the multiple random forest algorithm are $5 * 5$, 7500, and 35, respectively. As the feature size of CMOS shrinks to the nanometer scale, the electromigration of metal interconnects seriously affects the reliability of microelectronic devices. After the metal nanowires are prepared on the microchip, the microscopic dynamic changes in the metal electromigration can be directly observed by using the TEM in situ electrical technology, and the metal electromigration mechanism can be further studied, thereby providing a guarantee for increasing the reliability of electronic devices. Using TEM in situ electrical technology to study the working mechanism of new memory devices, new memory devices such as resistive memory and phase change memory have attracted much attention because of their fast speed and high storage density. Uniformity is an urgent problem to be solved in the large-scale application of these new memory devices. After the new memory device is fabricated on the microchip, the working process of the device is directly observed by TEM in situ electrical technology, and the working mechanism of the device is analyzed, thereby reducing the uniformity problem of the new memory device.

In this paper, the multirandom forest algorithm is proposed because of the randomness of the automatic segmentation method of nanoparticle image. The next step is how to improve the speed of automatic segmentation of nanoparticle image and ensure the accuracy of image segmentation.

This article mainly studies the effect of nanoligament combined with tennis on the rehabilitation of ligament injury patients. This article first uses nanoligaments made by ACL reconstruction technology to give targeted rehabilitation treatment to patients with ligament injuries, analyzes the internal structure of the knee joint cavity ligaments, and clarifies the rehabilitation of ACL injuries and other combined injuries. The construction method of nanoligament composite fiber composite ligament is mainly introduced. Secondly, the nanoligament damage mechanism can be used to prevent excessive knee deformation and internal rotation. Finally, the nanoligament is combined with the fiber composite ligament, and the silk fibroin filament yarn is used as the axis to form a composite structure on the fiber composite ligament structure to strengthen the rehabilitation effect for patients with ligament injury. In this study, combined with the data analysis of patients with nanoligament injury, it was found that after 50 patients have undergone corresponding tennis training and knee flexion angle observation, the recovery speed is 5 times faster than that of ordinary patients. The experimental results show that the combination of nanoligaments and tennis has a positive effect on rehabilitation training for patients with ligament injury.

1. Introduction

1.1. Background and Significance. Anterior cruciate ligament (ACL) injury is a common serious sports injury. The anterior cruciate ligament has the important function of restricting the excessive advancement of the hard bone and controlling the rotation. Knee joint instability occurs after the anterior cruciate ligament is damaged. Since then, meniscus cartilage injury, articular cartilage injury, and knee arthritis symptoms are treated. Treatment is a hot spot in the field of sports medicine. About 3.5 million anterior cruciate ligaments are damaged in the United States each year, and the annual medical cost is $6.5 billion. With the development of China's national strength and sports competition, the incidence of anterior cruciate ligament injury has increased significantly, but there are also studies showing that the incidence of anterior cruciate ligament injury in Chinese athletes is 0.39%. The main cause of anterior cruciate ligament rupture is sports injuries, accounting for more

than 70%, and the most affected people are basketball and football. For the treatment of patients with ligament injuries, people have developed nanoartificial ligaments to reconstruct anterior cruciate ligaments and use the exercise effect of tennis to strengthen the repair of sports injuries.

The material of the nanoartificial ligament is polyethylene terephthalate (PET), which is the same as the material of surgical sutures and artificial blood vessels and has good biocompatibility. It can effectively share the gravity and be absorbed by the human body. It is safe to use and will not cause rejection. The nanoartificial ligament adopts the bionic structure design, and the two end structures are densely woven in the middle; there is loose free fiber in the middle, and the mechanical properties are good. In addition, the tennis exercise accelerates the repair of the patient's physical function, and the effect is more excellent [1, 2]. The safety and functional evaluation of the knee joint is an important part of the evaluation of the efficacy after ACL reconstruction. Currently, Lachman is used to evaluate the

front and back stability of the knee joint, and the axial movement test is used to evaluate the rotation stability of the knee joint. Flexible stability is required in activities [3]. Modern three-dimensional walking analysis technology provides a new method for objectively, accurately, and quantitatively evaluating the stability and function of sports knee joints and is widely used to evaluate the efficacy after ACL reconstruction [4, 5].

1.2. Related Work. Seijas mentioned in his paper that an anterior cruciate ligament (ACL) injury is a highly injured accident in the working area of young athletes. The use of bone grafts, despite being a treatment option, can still cause postoperative problems, such as pain in the anterior knee, which limits its use and leads people to prefer alternative grafts. Their purpose was to evaluate whether the application of PRGF can reduce the pain of the anterior knee at the donor site reconstructed by BTB-ACL. The materials and methods they used are as follows: 55 patients participated in double-blind and randomized clinical trials, compared two groups of patients who used ACL transplantation for ACL reconstruction, and whether they used PRGF at the donor site after harvesting the graft. Knee pain results compared with the control group: the pain in the donor site of the PRGF group was reduced, and there was a significant difference in the first two months of follow-up [6]. Kim's research believes that various knee joint injuries caused by anterior cruciate ligament have been identified as important risk factors for the development of knee osteoarthritis (OA). However, no studies have been conducted using large sample studies to examine the relationship between ACL and OA. His research goal was to use the National Health Insurance Service Cohort data to study the impact of ACL injuries and other related knee joint structures on the development of OA. It also designed a retrospective cohort study of epidemiology and set up a database of epidemiological research service groups from the active adult population of the National Health Insurance [7]. Gomes' study believes that knee osteoarthritis (KOA) lacks sufficient treatment response outcome indicators. The role of ultrasound in the treatment of inflammatory joints and periarticular diseases has been well established, but its application in OA is less. The purpose is to develop a new high-resolution US protocol to assess the structure and inflammation of primary knee osteoarthritis. The scanning protocol was jointly developed by three high-level rheumatologists with similar experience in the United States. The proposed scheme has been shown to be reliable for patients with KOA and is therefore a promising tool that can be used for clinical practice and research purposes [8].

1.3. Innovation in This Article. The main innovative work of this paper includes the following aspects: (1) use modern three-dimensional gait analysis technology to evaluate the dynamic knee rotation stability and lower extremity function after ACL reconstruction with nanoartificial ligament and compare it with patients after autologous tendon transplantation. (2) The expression of PDGF and BMP-2 in the tendon-bone interface was measured by immunohistochem-

istry, which laid a certain foundation for further clarification of the vascularization of the tendon-bone interface and the specific bone formation mechanism. The research in this paper can provide a perfect and improved development suggestion for the rehabilitation training of patients with ligament injury and can also provide new ideas for the research in the field of medical rehabilitation.

2. Nanoligament Combined with Tennis Training Method for Rehabilitation Training

2.1. Nanoligament Based on ACL Reconstruction Technology. ACL reconstruction was performed in a supine position. Bone and joint endoscopy was performed after bleeding, and the knee joint cavity was regularly checked to confirm ACL injuries and other beds. At this time, first consider using nanoligaments to help patients deal with ligament injuries; first deal with combined injuries: the extent of half-moon cartilage injury, shaping, subtotal resection, total resection, or suture [9, 10]. According to the principles of isometric reconstruction surgery described in the literature, reassemble the ACL and regularly maintain the ACL gap. First, use special locators to create tunnels for the hard bones and thigh bones. The external connector of the cervical bone is approached through the inside of the front, the center of the opening of the Qinggu tunnel joint is 7 mm in front of the PCL, and the blind needle forms a cervical bone tunnel with a diameter of 6.5 mm through the ACL stump [11, 12]. Then, arrange the thigh bone external device through the hard bone tunnel. The center of the inner mouth of the thigh bone tunnel is located in the hepatology of the right knee. The liver and the lower edge of the posterior wall fall 6 mm. The position of the femur is generally determined by medical instruments. Drill the guide pin through the femur in reverse, penetrate the skin in front of and on the side of the thigh, make a 4 cm skin incision at the point of the femoral needle, use a series of cannulas to protect the soft tissue of the thigh, and drill from the lateral femur with a guide needle Through the femoral tunnel reaching the knee joint, the specific scheme is shown in Figure 1 [13, 14].

Once the bone tunnel is established, the nanoligaments will be installed and fixed. Select 150 bundles of fibrous LARS artificial nanoligaments (AC 120 2B) from the left or right knee [15]. Electric wires are introduced from the external opening of the thigh tunnel through the knee joint and connected through the hard bone tunnel. Place the LARS artificial ligament on the steel wire, and after the external port of the bony tunnel passes through the knee joint, the LARS artificial nanoligament will pass the ACL stump from bottom to top. The free fiber enters the thigh tunnel 1 mm, and the external ligament rotates slightly outward. Along the external opening of the thigh tunnel, connect the 8 mm diameter interface to squeeze the screw to fix the ligament. Attach a loop of artificial nanoligament at the end of the bone, bend or unfold the knee joint 30 times, adjust the ligament tension, confirm the knee joint mobility, spine angle projection, and confirm whether the LARS artificial nanoligament will affect the impact between the head and the posterior cruciate ligament (PCL) [16, 17]. In a 30- to 40-degree
Figure 1: ACL reconstruction technique treatment plan.

bend of the knee, push the hard bone backwards and use three 15 mm diameter interfaces to braid the screw to fix the hard bone end of the ligament. Cut the extra ligament outside the femoral tunnel and the hard bone tunnel, and suture the incision [18, 19].

Use the same rehabilitation program in the four centers. No bracing is required after surgery. From the first day after the operation, the quadriceps muscle function training was started. Subsequent training programs and training volumes are determined according to the degree of recovery. The next day, the ground was partially weight-bearing. The knee ROM reached 0°-90° 1 week after the operation. Partial weight-bearing of abduction was 1-2 weeks after operation, and it gradually transitioned to complete weight-bearing at 4 weeks after operation. Daily activities resumed 6 weeks to 3 months after surgery, started jogging 4 months after surgery, and gradually resumed unrestricted exercise 3 to 6 months after surgery [20, 21].

After the operation, apply pressure to all patients, wrap the bandage in a correct position and fix it, raise the affected arms and legs, apply a local cold compress to the knee joints, relieve pain, and implement anti-inflammatory treatment. On the first day after surgery, it is best for patients to straighten the affected limbs and take active measures such as the sand head muscles [22, 23]. The cotton legs were removed the next day after rehabilitation removal surgery.

The knee joints were fixed with external support frames. The external fixed struts had a range of motion of 0°-90° (0° full expansion). They adjusted the position and encouraged patients to go out [24]. Within the setting range of the fixed bracket, nonsupporting bearings activate bending and extend knee joints and continuous manual mechanical movement. Partial weight support can be used for squat exercise after one week of surgery. At this time, the patient's physical function has gradually recovered. Continue to observe for another week. At this time, the patient's physical function has gradually recovered. Continue to observe for another week, and the external fixed bracket is removed two weeks after surgery. Knee joint active flexion and renal motion indicate the supporting part of weight walking [25].

2.2. Structure of Knee Ligaments and Damage Mechanism. The medial structure of the knee ligament is divided into three layers from the surface layer to the myocardium. The medial ligament (MCL) and the medial joint capsule and their thick parts have the function of preventing excessive dryness of the knee joint. The lateral structure is divided into 3 layers, the first layer is the urethral tube branch and the posterior expansion of the arm, and the second layer is the anterior knee muscle membrane and the posterior part of the quadriceps and the two knee bands. The third layer is the half-moon ligament, lateral half-moon ligament, arcuate

ligament, and joint capsule. The posterior structure is reinforced by the posterior structure formed by the wrist tendon and the forearm thigh and its accessory structure. It is separated from the joint capsule by the synovial capsule; the posterior part is healed with the joint capsule and the medial meniscus. The side structure mainly prevents excessive knee reversal, and the second role is to prevent excessive knee deformation and internal rotation. The anterior cruciate ligament and posterior cruciate ligament of the joint. The anterior cruciate ligament can be divided into the anterior medial, posterior and external junctions, and the anterior internal junction. In knee extension, the long axis of the attachment surface is nearly vertical. The cross section of the attachment end of the tibia is approximately triangular, with the base facing forward and the tip facing backward. The important function of this angle is to prevent forelimb bones, medial rotation, knees, and hyperextension. The posterior cruciate ligament can be divided into anterior posterior and posterior and posterior interior. The anterior and external are tense, the posterior and internal are slack, the posterior and internal are stretched when the knee is stretched, and the anterior and external are slack.

The most common electromechanical damage to the medial ligament is the direct violence on the side of the knee joint, which leads to knee trauma and damage to the medial ligament. Because the lower dead point of the medial ligament is wider, it is generally stopped at the thigh or joint space where the injury occurs near the ligament. If the violence is severe or the knee joint rotates and hurts in parallel, ligament rupture and joint dislocation may occur simultaneously. Lateral ligament injuries are mostly caused by direct violence against the medial knee, and the incidence is significantly lower than that of the medial ligament ligaments, and the posterior tendon is damaged by the hard bone mutation and lateral ligament injury. There are damaged ligaments and arcuate ligaments in the lateral structure. If the violence is large, the posterior structure of the knee joint will be damaged, and the cruciate ligaments can be merged. When walking or exercising, it will cause pain above the fibular head on the posterolateral side of the knee. In addition, the patient will also cause pain on the outside of the knee joint when the patient bends his legs or crosses his legs. The damaged mechanism of the anterior cruciate ligament often bends, and the lateral turn is injured, causing the medial ligament to be injured. There are also few trauma injuries, partial or complete fracture of the anterior cruciate ligament. Damage to the posterior cruciate ligament often occurs when the forearm is hardened; that is, the posterior cruciate ligament ruptures in front of the muscle bone. The posterior cruciate ligament is affected by femoral osteoporosis and the posterior cervical bone platform. The ligament may be injured when bending occurs. Excessive knee injury may cause posterior cruciate ligament injury.

2.3. Construction Method of Nanoligament Combined Fiber Composite Ligament.
Since the mechanical properties of ligament materials made of regenerated silk fibroin materials cannot meet the requirements, the dense structure of liga-

FIGURE 2: Schematic diagram of nanoligament fabric formation.

ment materials composed of natural silk fibroin fibers affects the adhesion and growth of cells. The above silk fibroin materials have their own performance defects, and we combine three methods to form artificial nanoligaments to form a regenerated silk fibroin nanoligament composed of silk fibroin fibers, silk fibrils, and natural silk fibrils. The main structural design of the regenerated silk fibroin fiber composite nanoligament still uses YTS2-24 vertical rotary polishing machine and core brake. It can demonstrate well the original basic structure of the regenerated silk fibroin nanoligament. The schematic diagram of fabric formation is shown in Figure 2 (picture from http://www.pixabay.com). During the construction process, silk fibers were first woven with cashmere, which greatly improved the shortcomings of the easily deformable tubular fabric. Second, the outer gauze is used to dye the fabric layer between natural silk fibrin fibers and cotton, and the outer gauze is used to make the fabric layer. After being controlled with an angle of $45 + 2°$, the outer layer of the electrospun nanofiber membrane with a thickness of 3 mm is packaged. This fibrous membrane is one of the main ways to prepare nanofibrous materials, which can be effectively applied to the immobilization of enzyme catalysts. As a result, the broad fabric layer is woven with natural silk fibroin fibers from the packaging raw yarn. Finally, the composite structure of regenerated silk fibroin fiber composite nanoligaments is composed of electrospun nanofiber membranes and natural silk fibrous fiber fabrics.

According to the conclusion of the mechanical properties of the ligament material formed by different layers of natural silk fibroin fibers, if weaving 8 layers, the mechanical properties of the material are close to the human ACL, so during the formation of composite nanoligaments, the individual layer fiber weaving method is matched with two different silk fibroin fiber materials. In the hybrid project, the ratio of electrospun nanofiber membranes to natural silk fibroin is 1 : 1; that is, the number of fabric layers formed by natural silk fibroin fibers is 8 layers, while the electrospun nanofiber membranes have 7 layers. The silk fibroin filaments are woven into the middle of the nanoligament material as a shaft yarn. This ratio is mainly to unify the applicability and functionality of the nanoligaments.

3. Nanoligament Rehabilitation Training Experiment

3.1. Experimental Sample. The subjects of this experiment were 100 patients with different degrees of ligament injury. According to their prevalence, 50 patients underwent corresponding nanoligament surgery. In the subsequent rehabilitation training, data collection was carried out. First, tennis was added to 100 rehabilitation patients to assist in knee flexion. The experiment recorded the knee flexion test results of 50 nanoligament treatment and nontreatment patients. Later, different tennis techniques were used to record the recovery of patients with nanoligaments. Finally, do another set of comparative tests. Patients treated with nanoligaments were divided into three groups to test the knee flexion angle. The LARS group, the HT group, and the control group were 2.7 ± 1.3 degrees, 2.8 ± 2.5 degrees, and 2.1 ± 2.7 degrees, respectively. These different knee flexion angles represent different degrees of injury in rehabilitation patients, which are used as experimental variable data in this paper.

3.2. Experimental Environment Classification Setting. The degree of knee nanoligament damage can be divided into 3 degrees: first degree: ligament fiber rupture, local pain, no change in joint stability; second degree: most ligament fiber rupture, severe local reaction, function is obviously limited, but almost does not affect the stability of the joint; third degree: the ligament is completely damaged. According to the pressure test after ligament injury, the degree of the edge of the joint surface can be divided into mild (6 mm), intermediate (6-15 mm), and severe (greater than 15 mm). The treatment of first-degree and second-degree injuries requires conservative treatment. Patients with mildly injured ligament rupture and minor restlessness can also be treated conservatively. Conservative treatment is largely aimed at the patient population without severe impairment of joint stability. Four to 7 weeks of fixed plaster to strengthen the quadriceps movement can obtain satisfactory results. If the lateral ligament and surrounding tissue are severely damaged, unstable, or the cruciate ligament or meniscus is damaged, it should be repaired in time.

3.3. Experimental Procedure

(1) Experimental preparation: exclude patients with carotid artery injury and related fractures. The patient was placed in a supine position and underwent spinal canal anesthesia. In many cases of ligament injury, epidural block anesthesia is used. The inflatable tourniquet near the thigh was pressurized. Reconfirm the stability of the front, back, inside, outside, and rotation of the knee

(2) Experimental examination: arthroscopy device (arthroscopy equipment belongs to medical imaging equipment, mainly including American Stryker brand monitors, cold light sources, cameras, and image systems) and knee arthroscopy, standard surgical method for knee arthroscopy, anterior cruciate ligament reconstruction device. After stopping the blood, pressurize the tourniquet and check the blood in the joints. First, check the joint cavity, repair the damaged meniscus, perform suture, formation or resection, check the end and continuity of ACL and PCL, regularly clean, and explore under the microscope to maintain the stability of ACL and PCL. This is for the late replacement of blood circulation and blood circulation reconstruction of ligaments and the rapid recovery of inherent tolerance. Observe the medial and lateral articular walls of the hematoma under a microscope, observe the structural damage signals of the medial and lateral sides, and perform knee cartilage injury and classification

(3) Reconstruction of the posterior cruciate ligament: insert the PCL tibial catheter into the posterior tibia from the anterior medial aspect. In addition, it can also be placed under the observation of the posterior medial approach, and its front end is embedded in the exit of the tibial tunnel. Select the guide pin through the anterior cortex of the tibia (45- to 50-degree direction), select the appropriate diameter of the drill according to the size of the graft, to avoid nerve and blood vessel damage at the roost, and please pay attention to the tibia. The bones and soft tissues remaining in the tunnel are cleaned to avoid sharp parts. Similarly, a rocket tunnel of the same diameter was excavated using a femoral locator. After the tunnel is completed, the needle is inserted into the tibial tunnel from front to back, and the front end of the needle is slightly curved to facilitate the clamping of the intercondylar notch. Similarly, the femoral wire or microbridge stays ahead and follows the tibial tunnel to a single figure. The traction line of the head button is close to the traction line of the femur to connect the femur. The lead is pulled to rotate the built-in button, and the graft is retracted by 6 mm. The button is pressed parallel to the cortex of the femur at the external opening of the bone tract, and the tibial end of the graft is tightened, and the distal bone tract is fixed with absorbable nails larger than the same diameter

(4) Anterior cruciate ligament reconstruction: connect the tibial tunnel guide, position the top of the guide at the midpoint of the line between the anterior angle of the lateral meniscus and the medial condyle (a more accurate positioning method), and follow the locator drill into the guide pin and observe whether the position of the needle point is accurate under the microscope. Then, use the tibial drill bit to drill the tibial tunnel of the same diameter along the guide pin to clean the excess tissue of the tunnel. Then, use the femoral end guide to locate the ACL. At the top dead center, after the positioning is accurate, drill the guide pin along the positioner, use a 4.5 mm diameter hollow drill and the same implant diameter drill bit to drill the rocket-shaped tunnel, and the guide pin is pulled to place the pull wire.

Connect the graft traction line with the indwelling traction line in the knee flexion position, pull it out along the tibial tunnel, joint cavity, and femoral tunnel, flip the button so that the button is parallel to the femoral cortex embedded in the external opening of the bone tract, and tighten the end of the tibia. Fix the distal bone tract with absorbable nails larger than the same diameter. After the reconstruction is completed, the position relationship of the reconstructed ligament can be checked under the microscope again, and there is no intercondylar impact when the joint is moving

4. Analysis of Postoperative Rehabilitation of Patients Treated with Nanoligaments

4.1. Effect of Different Tennis Stretching Exercises on Patients after Nanoligament Surgery. In tennis, the functional traction of the body's flexibility mainly reflects the lateral flexion and expansion of the entire spine, so the lateral flexion and expansion of the body are indicators of testing the body's flexibility. Ligaments are distributed throughout the body, preventing bones from bending and expanding. The entire range of motion of the ligaments is very large and can be used for bending and elongation movements around the front axis. Nanoligaments treat patients with lateral flexion motions around the rotation axis and orbital motions and circular motions around the vertical axis. Generally, ligament activity is large, and rib activity is low. Ligaments are the key to maintaining joint movements of the body. The trunk is the core that connects the limbs and the head. The brain communicates commands to all parts of the body and controls the core connection of body movement. According to the biomechanics principles of tennis technical action, the center of gravity of the body should be kept stable during the strike, the body should not be shaken during the strike, and the quality of the strike should not be affected. The range of motion of the ligament should be maintained on a relatively fixed vertical axis.

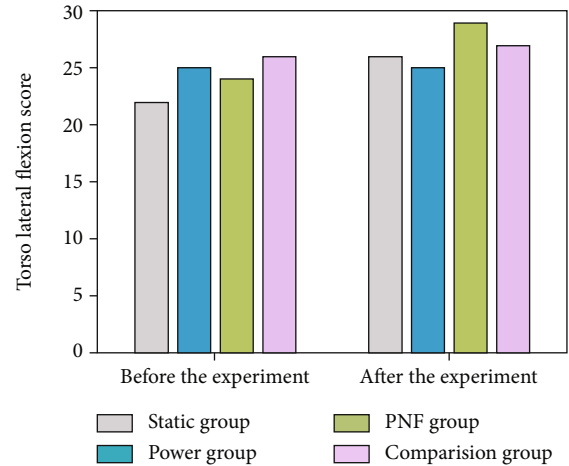
As can be seen from Figure 3, after 8 weeks of training, the performance of each experimental group has been improved in the bending test of the side of the body of patients treated with nanoligaments, which is accelerated by nearly 5 times faster than that of general treated patients through static stretching exercises The sport effect is the most ideal. The static stretching exercise is to continuously and stably stimulate the stability of the ligament of the subject, thereby improving the structural function of skeletal muscles. With the deepening of the training phase, the static stretching exercise is more beneficial to the training effect of nanotreatment patients. Subjects can improve the level of flexible quality training in system management and increase the degree of lateral ligament curvature. In the process of stretching, the human lumbar spine does not have many muscle protection functions. It is necessary to pay attention to the muscles of the spine muscles in the lumbar spine, square muscles in the lumbar spine, and part of the erector spinae. The main function of the human waist and abdomen is not to simply improve the mobility of the joints, but to


FIGURE 3: Comparison of the results of each group's lateral flexion test.
FIGURE 4: Table of the types of technical actions that affect the occurrence of knee ligament injury.

TABLE 1: Technical action factors affecting the occurrence of knee injury.

Serial number	Relevant factors	Load factor
1	Unfamiliar technical action	0.75
2	Technical moves are difficult	0.73
3	Technical action is very standard	0.24
4	Wrong technical action	0.78

emphasize painless activities within the normal range of human motion, so pay attention not to damage the lumbar spine during the stretching exercise. No matter what kind of stretching method is used, you must avoid sneak attacks and oppressions. Pay attention to it in sections, increase

TABLE 2: Knee flexion and extension and rotation angle.

Knee flexion and extension angle during standing	LARS group	HT group	Compare group	p value group
Heel	2.7 ± 1.3	2.8 ± 2.5	2.1 ± 2.7	0.457
Knee bending angle	31.2 ± 8.6	6.9 ± 3.5	31.5 ± 8.8	0.354
Knee flexion angle	7.1 ± 3.5	30.8 ± 4.7	6.8 ± 3.2	0.452
Maximum internal rotation	5.3 ± 1.4	5.2 ± 1.0	4.8 ± 1.5	0.321
Minimum internal rotation	7.2 ± 0.9	7.8 ± 1.3	5.2 ± 1.6	<0.002

the range of ligament movement in a slow and powerful way, and improve the body's ability to stretch the body of the tennis ligament patient while ensuring safety. And the breathing adjustment mentioned in the previous specific experimental program can make the stretching exercise get better results.

4.2. Analysis of Tennis Movement Technical Movements on Patients after Nanoligament Operation.

As the key reason that affects whether a person's ligament is vulnerable to damage, technical action should be divided into various factors for analysis and research. Patients with different ages of nanoligament treatment should show their own type of technical action. The difference is very limited, and the analysis and research on the types and factors of technical actions should not be divided into different age groups.

The data in Figure 4 shows that the technical actions that caused the injury of the nanoligaments to treat patients were ranked as follows: 14% serve, 10% backhand ball, 18% forehand ball, 100% backhand ball fifteenth, 10% for emergency stop change, 8% for high pressure ball, 13% for forehand, and 12% for interception. For tennis players, every incorrect technical action may lead to damage to the knee ligaments. Among them, serving, backhand drawing, forehand drawing, and backhand cutting cause a high probability of knee injury. But at the same time, every standard action can avoid a knee injury. Therefore, the treatment of patients with nanoligaments can use standardized actions to accelerate the speed of recovery.

According to the sociological statistical methods and statistical principles, using SPSS 15.0 data analysis software, the load factor range of 16 causative factors is $0 < K < 1$; that is, the larger the K value, the more likely to have knee ligament injury, and the more Xiaoyue is conducive to the protection of the knee joint. Because the influence of each factor on the knee ligament injury is not absolute, it is impossible to have $K = 0$ or $K = 1$. The specific load factor is shown in Table 1.

Analysis of the data in Table 1 shows that the technical action factors greatly affect whether the rehabilitation of patients with ligament injury can be accelerated. This requires that the technical movements mastered by the patients in training must conform to the characteristics of tennis and at the same time meet the requirements of physiological anatomy or try to comply with the principles of biomechanics. Effective and correct technical actions are conducive to the full play of athletes' physiology and psychology and help nanoligament treatment patients to achieve good rehabilitation results.
FIGURE 5: Knee flexion and extension angle when walking.

4.3. Analysis of Knee Flexion Angle after Nanoligament Treatment.

Using one-way analysis of variance (ANONA), the time-distance parameters, knee internal rotation, external rotation angle, knee flexion, knee extension angle, and sagittal plane vertical reaction of the LARS group and the HT group affected lower limbs and normal control force comparison. SPSS 12.0 software was used for all statistical analysis. The significance level is $a < 0.04$. Sagittal knee angle during stance: the knee flexion angle when the heel is on the ground is 2.7 ± 1.3 degrees, 2.8 ± 2.5 degrees, and 2.1 ± 2.7 degrees in the LARS group, the HT group, and the control group, respectively. There was no difference between the three groups (statistical significance $p > 0.04$). The maximum knee flexion angle and the minimum knee flexion angle in the standing period are 31.2 ± 8.6 degrees and 6.9 ± 3.5 degrees, 31.5 ± 8.8 degrees and 7.1 ± 3.5 degrees, and 30.8 ± 4.7 degrees and 6.8 ± 3.2 degrees in the LARS group, the HT group, and the control group, respectively. Compared with the three groups, the difference was not statistically significant ($p > 0.05$), as shown in Table 2 and Figure 5.

The knee rotation angle of patients with nanoligaments during walking is shown in Table 2 and Figure 6. The maximum internal rotation angle was 5.3 ± 1.4 degrees, 5.2 ± 1.0 degrees, and 4.8 ± 1.5 in the LARS group, the HT group, and
FIGURE 6: Knee rotation angle when walking.

the control group, respectively. There was no statistically significant difference between the three groups ($p > 0.04$). The maximum external rotation angle of the knee joint was 7.8 ± 1.1 degrees, 8.2 ± 1.4 degrees, and 5.6 ± 1.9 degrees in the LARS group, the HT group, and the control group, respectively. The HT group and the LARS group were significantly larger than the control group ($p < 0.002$). There was no significant difference between the HT group and the LARS group ($p > 0.04$). Based on the above data and image analysis, nanoligament injury patients undergo tennis training and technical movement analysis after surgery, and a certain knee bending angle will also affect the rehabilitation effect of nanoligament treatment patients. Within a reasonable range, the corresponding rehabilitation training will speed up.

5. Conclusions

This research is aimed at the current clinical application of nanoligaments and the research of tennis sports on rehabilitation patients with sports injuries and the surface modification of nanoligament materials to improve their biocompatibility. And because of their small size, nanomaterials are very different from traditional materials in terms of optical properties, electrical properties, and chemical activity. The special properties of nanomaterials make it have full play in ECL sensing; in particular, some emerging nanomaterials are paid attention by researchers due to their superior performance and are widely used in ECL. Some inspirations can be obtained from this, which helps to clarify the future research direction of artificial ligaments.

This study further confirmed that from the biomechanical point of view, the combination of nanoligaments and

tennis can promote the healing of the tendon and bone boundary surface after surgery. In order to avoid reconstruction failure caused by ACL slack, theoretical support is provided. The results of this experiment also show that the synthesized nanomaterials can act as a scaffold in the body, allowing PRP to slowly and fully release growth factors, gradually absorbed by new bone growth, and finally replaced by new bone, which is a more suitable scaffold.

In this study, at the early stage after surgery, the interface with a strength similar to the rest point is directly reduced. For the buffering of the stop stress, the mechanical characteristics of this rest point structure are better than the indirect rest point, and the bonding force of the tendon-bone interface is improved. This provides us with a new way of thinking, that is, after ACL transplantation, early recovery of work and exercise ability, to avoid failure of reconstruction caused by ACL relaxation and to promote functional rehabilitation in clinical practice. This experiment has only been studied in morphology, and the more direct evidence is that it needs the support of biomechanical experiments. Although this paper has carried out a profound study on the rehabilitation training of patients with ligament injury by using nanoligament combined with tennis exercise therapy, there are still many deficiencies. We will study appropriate treatment methods and means from more perspectives based on the existing technology and level and continuously improve the quality of rehabilitation treatment.

In today's environment where the society attaches great importance to environmental pollution, there has been a certain amount of research at home and abroad to explore the solutions to pollution of the large amount of polluting and persistent harmful substances that remain in nature. And most people think that it is necessary to solve the problem of pollution in two ways. (1) Energy: without discussing other energy sources, we will only discuss the main oil of today's energy. The treatment and use of this energy will cause pollution to a certain degree, and it has been overexploited. The exploration of new energy sources and increasing the use of natural energy such as wind and solar energy are the main research directions today. (2) Degradation of existing pollutants: nowadays, due to the rapid development of various industries, attention to environmental pollution has reached a point that cannot be ignored. As a kind of brominated flame retardant, polybrominated diphenyl ethers are widely used because of their low price and stable chemical properties, mostly in electronic appliances, building materials, textiles, furniture, and other products. But the substance is extremely harmful. This article focuses on the degradation treatment of tetrabromodiphenyl ether, which is one of the polybrominated diphenyl ethers that are long-lasting and difficult to be degraded in the environment. It has become an emerging persistent organic pollutant due to its toxicity, persistence, and bioaccumulation. Based on the reduction and debromination of zero-valent iron, the effect of debromination of tetrabromodiphenyl ether is explored under the coupling effect of the nanosized iron powder with the smaller particles of zero-valent iron and vitamin B_{12}. The experimental results in this paper show that when the dosage of nanoiron powder is between $0.0\,g/L$ and $0.15\,g/L$, according to the degradation diagram, the reaction rate is continuously strengthened with the increase of nanoiron powder. When the dosage of nanoiron powder is $0.15\,g/L$-$1.0\,g/L$, the effect will be weakened with the increase of the concentration. Therefore, an increase in the concentration of nanoiron powder will promote the progress of the debromination reaction. But when it reaches a certain level, the reaction rate will gradually decrease until it stops.

1. Introduction

The current state of environmental pollution cannot be underestimated. Through the diffusion of the food chain in nature, the atmosphere, and the air, pollutants are permeated around people, which have affected people's daily life, and even the weather has undergone abnormal changes due to its influence. The intensification of the greenhouse effect will have serious consequences. Now, the era is devel-

oping rapidly. With the advancement of related scientific research results of computer network portable technology, the process of electrical appliance industrialization has accelerated and expanded. Nowadays, a large number of electronic devices are updated every year, resulting in a large amount of electronic waste. Polybrominated diphenyl ethers (PBDEs) are widely used as flame retardants in industrial production and they are widely used in plastic flame-retardant parts in electronic appliances. By analyzing the

physical and chemical properties, exposure pathways, and pollution levels of PBDEs, this article summarizes the main pathways of photodegradation and aerobic and anaerobic microbial degradation. This article makes a corresponding risk assessment for its carcinogenic properties and compares the risk of impact in various environments. Through the risk comparison between adults and children, this article explores the catalytic debromination effect of metal oxides under sunlight. Metals and vitamin B_{12} have catalytic reduction effects and are highly efficient in the field of degrading organic matter. Therefore, this article proposes the debromination reaction of tetrabromodiphenyl by metal combined with vitamin B_{12} and conducts corresponding experiments on the effects of various metals.

Polybrominated diphenyl ethers are a type of global organic pollutants that are widespread in the environment. Because of its good flame retardancy, it is often used as an additive flame retardant and widely used in various products. In the process of production and use, it can be released from the product and enter the ecosystem through various channels. But it has high bioaccumulation effect and high carcinogenicity. It has a great impact on the environment, and children are more affected by its toxicity than adults. It can be seen that the research on the degradation direction of polybrominated diphenyl ethers is of inevitable significance. Now, a large amount of electronic waste is generated every year. The flame-retardant plastics of electronic waste release highly toxic by-products during their disposal, and related research has attracted the attention of many scholars. The original treatment of e-waste may release a large amount of organic pollutants into the environment, but its scale and mechanism still need to be fully resolved. Li et al. have carried out heat treatment and open burning of typical electronic waste, namely, plastics and printed circuit boards. The emission factor of the sum of 39 polybrominated diphenyl ethers ($\sum_{-}(39)$PBDE) in the heat treatment is $817 - 1.60 \times 10 \sim (5)$ng g $\sim (-1)$ and undetected $-9.14 \times 10 \sim (4)$ ng g $\sim (-1)$. In open burning, airborne particulate matter (87%) is the main carrier of PBDEs, followed by residual ash (13%) and gaseous components (0.3%). In the open fire heat treatment, they were 30%, 43%, and 27%, respectively. Evaporation and reabsorption may be the main emission mechanism of slightly brominated BDE, but severely brominated BDE is often related to particles produced by heating or combustion. The different size distributions of PBDEs in the emission source and nearby air indicate a remarkable reprocessing process in the atmospheric diffusion process [1]. The triglyceride of ricinoleic acid and the acid residue contain both hydroxyl and double bonds, which can be easily functionalized. Hydroxyl groups can be converted into phosphorous esters of different structures, and unsaturated groups can easily be added to bromine. Using spectroscopy and thermal methods, Howell and Ostrander fully characterize castor oil derivatives that contain phosphorus, bromine, or phosphorus and bromine. The thermal stability and degradation modes of these compounds have been evaluated by thermogravimetric analysis and infrared spectroscopy [2]. In terms of phosphorus-based flame retardants, Daniel and Howell use four phosphorus esters derived from industrially

obtained glucose derivative isosorbide as starting materials. After thermal degradation, the four esters showed different degradation curves. Phosphate esters provide better coke yields than phosphonates and phosphinates, the latter being more thermally stable. Fourier transform infrared spectroscopy and thermogravimetric analysis were used to monitor the thermal stability of the compound under constant temperature and variable time. Studies have shown that degradation is accompanied by the release of corresponding phosphoric acid [3]. By rationally manufacturing metal nanostructures to excite plasmon resonance, the efficiency of hot carrier excitation can be significantly improved. Ishii et al. have conducted in-depth research on these plasma-enhanced photoelectric and photothermal conversion from a basic and application-oriented perspective. Among them, it exclusively uses gold and silver. In contrast, this progress report covers nonmetallic materials that can be used for plasma-enhanced photoelectric and photothermal conversion [4]. After exploring and researching many modified anodic oxides, Chen et al. tried to summarize the latest developments in the rational design and modification of these oxides before, during, and after anodization. Each part completely solves the reasonable design strategy, aiming to improve the overall PEC performance [5]. Park et al. proposed and researched a transparent light-emitting diode (LED) panel with a 16×16 multicolor LED array for signage applications. As a transparent electrode, it can use established simulation models to manufacture and characterize three layers of oxide/metal/oxide (OMO) with various Al interlayer thicknesses. Using commercial ray tracing optics and SPICE simulation tools, Park et al. designed the LED panel and studied its optical and electrical characteristics. In addition, in order to solve the waveguide effect and voltage drop problems of the entire panel, they integrated additional optical structures and various OMO widths in the design. The results show that the OMO electrode interconnection and the proposed design consider the key aspects of implementing transparent LED digital signage applications [6]. Guo et al.'s research results show that low temperature is an important way to improve the stability of high-concentration precursor solutions in the sol-gel process. In addition, a stable precursor solution is used, followed by spin coating and sequential layer annealing. Then, a thick BLFO film is prepared on an indium tin oxide/glass substrate, which has a perovskite structure without impurity phases. In particular, it can obtain a high remanent polarization (P r) of 42.85 $\mu C/cm^2$. This may be related to lanthanum doping, preferred (110) orientation and relatively dense microstructure [7]. The scholars' research discussed above has certain auxiliary guidance for the research of this paper, but most of the abovementioned research processes require special professional techniques and a deep understanding of experimental supplies in order to further avoid the process harm. Its content is too complicated, and the experiment process is accompanied by certain dangers and the harmfulness of gases, so more attention should be paid to the experiment.

The innovations of this article are as follows: (1) It is proposed to use nanoscale iron powder for debromination
FIGURE 1: The basic principle of photocatalysis of metal oxide materials.

reaction; (2) after coupling vitamin B$_{12}$ and iron powder, the tetrabromodiphenyl ether is debrominated, and the Good results; and (3) the degradation ability of various metals such as Al, Zn, Fe, and Sn on the reduction and debromination of tetrabromodiphenyl ether was discussed. And this article analyzes the effect of debromination with the addition of vitamin B$_{12}$.

2. Polybrominated Diphenyl Ethers Based on Metal Oxides

2.1. Application of Metal Oxides in the Catalytic Degradation of Pollutants Under Sunlight. Now, the world is facing the same dilemma, that is, the shortage of available energy and the increasingly serious environmental pollution. It has caused extreme weather in the global climate [8]. And the emission of greenhouse gases has caused global warming. People attach great importance to sustainable and pollution-free new energy sources in nature [9]. The first thing that comes to our mind is solar energy. As a daily visible and very important existence in nature, solar energy has naturally attracted people's attention. Solar cells, photocatalytic hydrogen production, and photocatalytic degradation of organic pollutants are all intuitive manifestations of people's utilization of solar energy [10]. Metal oxide semiconductor materials are used for photovoltaic power generation, hydrogen production, and catalytic decomposition [11]. Due to the different properties of metal elements, the oxides formed by them exhibit different properties and application characteristics, such as in a wide range of environmental pollution control, metal oxide materials can be used as catalysts and adsorbents to treat industrial toxic waste gas and environmental organic pollutants [12]. In semiconductor materials, when the energy is greater than the band gap, the surface can be irradiated with light energy to absorb the light energy. Electrons are excited from the valence band to the conduction band and become holes. Figure 1 shows its catalytic texture, which can improve catalytic efficiency.

For the research of metal semioxide semiconductor materials, there have been research directions for related content as early as before. It was discovered that titanium dioxide can catalyze the start of hydrogen production under the action of sunlight [13]. The photocatalysis of metal oxide semiconductor materials has been rapidly developed. Through the study of the photocatalytic reaction of a variety of metal oxide materials, it is found that the hyperactive metal oxides have a certain degree of restrictive conditions in the reaction effect of photocatalytic hydrogen production. From all researches on catalytic hydrogen production, it is found that not all metal oxide semiconductor materials can be used for catalytic hydrogen production. However, the application of this material in environmental protection has only begun to develop and prevail in the past ten years. Studies have found that titanium dioxide can catalyze the degradation of organic pollutants polychlorinated biphenols under ultraviolet light in the sun [14]. In the research of metal oxide materials in the past few years, it can be said that this material has become an important research object in the chemical field for the treatment of pollutants due to its high efficiency, less secondary pollution, low cost, and easy preparation [15].

2.2. Polybrominated Diphenyl Ethers Based on Metal Oxides. Polybrominated diphenyl ethers are abbreviated as PBDEs, which are brominated flame retardants [16]. PBDEs are aromatic compounds based on bromine-substituted hydrogen atoms in biphenyls. According to the position and number of bromine substitutions, there are 209 kinds of homologues. It has good flame retardant properties and stable performance. It is also widely used in electronics, electrical appliances, fabrics, building materials, petroleum, and other industries because of its low price and low impact on materials [17]. PBDEs have the characteristics of low vapor pressure and strong lipophilicity at room temperature, high boiling point, and low solubility in water. It has a fairly stable chemical structure [18], and its chemical structure is shown in Figure 2. It is difficult to degrade through physical, chemical, or biological means.

The flame retardant properties of PBDEs are gas phase flame retardant, and the specific mechanism is as follows. PBDEs are decomposed by heat to generate HBr, which can capture active free radicals that transfer combustion chain reactions [19]. It can produce bromine free radicals with lower activity, which can slow down or stop the combustion reaction. In addition, HBr is a high-density, low-flammability gas [20]. It can not only dilute the oxygen in the air but also cover the surface of the material. It can be isolated from the air to slow down combustion and spontaneous combustion [21]. However, if it is in a high temperature environment, it can release bromine atoms and burn it under certain conditions, which will generate more toxic PBDD/DFs.

Studies have shown that PBDEs are a variety of pollutants found in the environment and have been detected in a variety of environmental media such as water, air, soil, organisms, and humans [22]. Highly brominated diphenyl ether is soluble in water or volatilized in the air and

Oxygen atom

Br, m

Br, n

M + n = 1 – 10
FIGURE 2: The chemical structure of polybrominated diphenyl ethers.

deposited on organisms. It is debrominated in the natural environment, decomposed into low-brominated diphenyl ether, and then passed through water, air, bioaccumulation, etc. The path propagates in the environment and finally constitutes the path [23]. The environmental behavior of PBDEs mainly includes the movement between pollution sources, environmental media, and the transformation and final fate during the movement [24]. Its impact on the environment is shown in Figure 3.

Because PBDEs are persistent in the environment, their increasing exposure routes bring great risks to human health [25].

3. Health Risks of Polybrominated Diphenyl Ether PBDEs Based on Optoelectronic Materials

Nowadays, people have a certain degree of awareness about the pollution of polybrominated diphenyl ethers, and the amount of exposure in the environment is increasing day by day, and the substance has a certain degree of carcinogenic risk. This ingredient is a serious hazard to human health, especially for children who are underdeveloped. This chapter evaluates the health risks posed by polybrominated diphenyl ethers and discusses the carcinogenic risks posed by them. Exposure refers to the exposure of the human body to one or more physical, chemical, or biological factors in time and space. There are two ways to expose. External exposure refers to the level of external environmental pollutants that the human body directly contacts; internal exposure refers to the actual exposure level of these pollutants in the body after being absorbed by the human body through various interfaces and other biological material samples to obtain the concentration of pollutants [26, 27].

3.1. Evaluation of PBDEs Exposure in Smoke. Respiratory inhalation is an important way to be affected by smoke pollution. Compared with other methods, breathing and inhalation of PBDEs is the main way of human exposure [28]. For the inhalation method, the risk assessment method affected by pollutants is adopted this time. The evaluation method calculates the concentration of pollutants contained in the flue gas in a specific scenario, and the calculation equation is as follows:

$$HRsingle = \frac{Rair \times inhC \times HEInh \times HF \times HD}{QHF \times BL}, \quad (1)$$

$$HRtotal = HRsingle \sum_{1-i}^{i=10} BDEs. \quad (2)$$

Among them, InhC represents the volume of air breathed by adults every day, and the related parameter value is $1.6E + 0.1$. HEInh represents the absorption conversion factor of the lungs, and the value of this parameter is $7.5E + 0.5$. HF represents the frequency of exposure, and the value is $2.5E + 0.2$. HD represents the exposure period of an adult, and the parameter is $2.5E + 0.1$. The value of the life cycle BL is $2.6E + 0.4$. The concentration factor QHF of PM10 is $1.4E + 1.2$. These values are combined with Equations (1) and (2), plus the required measurement values in the area, namely, the particle concentration Rair in the flue gas, the average monomer exposure concentration Rair, and the total concentration HRtotal of lifetime exposure. The calculation results are shown in Table 1.

It can be seen from Table 1 that under different regeneration temperatures, the lifetime exposure concentration of PBDEs in the flue gas to adults is different [29, 30]. The general trend is that as the temperature increases, the exposure concentration continues to increase.

3.2. Risk Assessment Method. Health risk assessment includes noncarcinogenic risk assessment and carcinogenic risk assessment. The classification is based on whether the pollutants have carcinogenic properties. The formula for calculating the carcinogenic risk (CHF) of toxic compounds is

$$CHF = HC \times RUN. \quad (3)$$

In Equation (3), CHF represents the carcinogenic risk index of respiratory inhalation, and HC is the concentration of compound exposure and the carcinogenic risk RUN per unit of respiratory inhalation [31]. After referring to the toxicity of PCBs and the intake factors, the RUN value is calculated, and the following is calculated:

The carcinogenic risk of smoke also increases with the increase in temperature, which is consistent with the exposure level. The higher the level of exposure, the higher the risk of cancer. In the temperature range of 180-210°C, compared with the US EPA health risk standards, the carcinogenic risk of tribromo and nonabromodiphenyl ether is between 1.0E-03 and 1.0E-01. Its carcinogenic risk level is in a high position, and the carcinogenic risk values of other homologues are all higher than 1.0E-01, and its carcinogenic risk level is very high [32].
FIGURE 3: Environmental behavior characteristics of polybrominated diphenyl ethers.

TABLE 1: Respiratory exposure of PBDEs in flue gas at different temperatures.

Exposure level of each series	180-190°C	190-200°C	200-210°C
Tri	0.26	0.12	0.13
Tetra	0.26	0.18	0.2
Penta	0.34	0.32	0.25
Hexa	0.77	1.46	1.2
Hepta	1.65	2.17	3.16
Oeta	0.1	0.28	0.33
Nona	0.06	0.18	0.18
Deca	8.17	11.12	12.06
PBDEs	11.7	15.9	17.5

3.3. Exposure Risk Assessment Model. Exposure mainly refers to the process by which the human body is exposed to chemicals through different environments. It is closely related to the exposure time, way, and intensity. The selection of parameters is the basis for risk evaluation [33]. With reference to relevant literature, this section selects three models of breathing inhalation, skin contact, and hand-oral ingestion to analyze PBDE exposure. Among them, the hand-oral intake route is unique to children, and the details are as follows:

Model of breathing and inhalation method:

$$\text{Hinh} = \frac{R \times \text{IC} \times L}{\text{BW}}, \quad (4)$$

$$R = \frac{\text{MC} \times \text{BS}}{U \times Q}. \quad (5)$$

In Equations (4) and (5), Hinh represents the way of breathing and inhalation, R represents the release of PBDEs in the air, IC represents the inhalation rate, L represents the daily exposure time, and BW represents the quality of the inhaled population. The indoor volume U and the ventilation rate Q are related to each other. BS is the contact area. MC represents the daily release of indoor PBDEs.

Exposure model by skin contact:

$$\text{Hderm} = \frac{\text{MC}' \times \text{RA} \times L}{\text{BW}}. \quad (6)$$

Hderm is the amount of exposure by skin contact, and B is the probability of PBDEs migrating to the hands. RA represents the contact area of the skin.

Hand-oral intake model:

$$\text{Horal} = \frac{M \times \text{LH} \times \text{BS} \times \text{HF}}{\text{BW}}. \quad (7)$$

TABLE 2: Experimental reagents and material list.

Reagent materials	Chemical formula	Purity
Vitamin B_{12}	$C_{63}H_{88}O_{14}N_{14}PCO$	98%
Tetrabromodiphenyl ether	$C_{12}H_6C_{12}H_6Br_4O$	95%
Nano iron powder	Fe	99%
Methanol	CH_3OH	Chromatogram pure
Tetrahydrofuran	C_4H_8O	Analytically pure
Hydrochloric acid	HCl	Analytically pure
Sodium hydroxide	NaOH	Analytically pure
FIGURE 4: Scanning electron microscope image of reduced iron powder and nanoiron powder.
FIGURE 5: Degradation effects of different metals.

Horal represents the exposure by hand-oral ingestion, and LH is the transfer probability of PBDEs per exposure. HF represents the probability of contact.

As polybrominated diphenyl ethers are widely used as flame retardants in a variety of consumer products, the per capita annual exposure continues to rise. Moreover, bioaccumulation and environmental persistence may increase the risk of human carcinogenesis. Therefore, the following models can be used to assess its potential nonchemical carcinogenic risk:

$$EP = \frac{Hinh + Hderm + Horal}{CfD}. \tag{8}$$

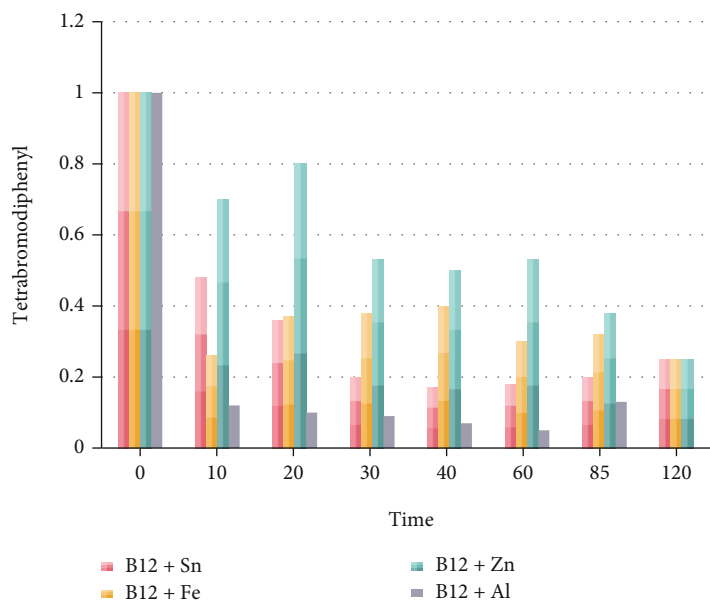
Among them, the risk of nonchemical carcinogenesis is represented by EP, and the noncarcinogenic reference dose of pollutants is CfD.


Figure 6: Different metals coordinate the debromination effect of B_{12}.
Figure 7: The effect of increasing nanometer iron powder on debromination.

3.4. Degradation of PBDEs.

Biodegradation: it refers to the reduction of harmful substances by microorganisms in the natural environment [34]. Microbial degradation can be divided into two types: (1) aerobic degradation, which is mainly through the isolation and cultivation of a certain strain that has high degradability for PBDEs, and (2) anaerobic degradation, which refers to the use of the extracted anaerobic bacterial populations to debromine and degrade PBDEs through the cultivated bacterial species, because PBDEs will undergo debromination and degradation reactions to varying degrees in an anaerobic environment.

Photodegradation Method: it refers to the photolysis reaction of most harmful substances in the natural environment under the action of absorbed sunlight [35]. As an important way to transform PBDEs, PBDEs are degraded by absorbing the ultraviolet band in sunlight.

Zero-valent Iron Degradation: it is a relatively popular degradation method in recent years. It is mainly a degradation method of debromination of PBDEs through zero-valent metals [36].

Hydrothermal Reaction Treatment: it is a common treatment method in daily life. For example, tetrabromobisphenol
FIGURE 8: The effect of increasing B_{12} on debromination under the same quality of iron powder.
FIGURE 9: The effect of pretreatment on debromination.

reacts in high temperature subcritical water for a period of time, and the debromination reaction occurs [37] .

Composite Degradation Technology: based on the stable and long-lasting characteristics of PBDEs, a single degradation method cannot completely produce a good degradation effect on PBDEs. Therefore, the fusion application of multiple degradation methods can achieve a relatively good effect on its degradation [38].

3.5. Metal-Based Oxide Debromination Experiment. This experiment uses vitamins and zero-valent metal particles to decompose low-concentration halogenated organic matter in the soil and other systems to achieve actual therapeutic effects. The zero-valent iron reduction/debromination method has been developed in recent years. Because iron is a very active metal, and its chemical properties are also

very active, it is more and more popular. Facts have proved that it has greater electronegativity and redox characteristics. It can reduce a variety of pollutants. There are several other advantages of zero-valent iron in the treatment of pollutants. Due to its electrochemical properties, it has a certain role, such as in microelectrolysis. In addition, due to its porous material properties, it has the effect of adsorbing organic pollutants in a specific pH range. Compared with zero-valent iron powder, nanoiron powder has finer particles. This experiment uses metal materials, which decompose tetrabromodiphenyl ether under the combined action of vitamin B_{12}. Then, by observing the effect of each addition of zero-valent iron on the experimental effect, the experiment discussed the decomposition effect of various metals and the possibility of decomposition in the scene of fusion with vitamin B_{12}.
FIGURE 10: The effect of initial concentration on the debromination effect of tetrabromodiphenyl ether.

3.6. Reagents Needed for Experiment.
The main experimental materials are shown in Table 2.

3.7. Sample Analysis Method for Degradation Experiment.
The total amount of the reaction solution for the decomposition and debromination experiment is 30 mL. The experiment was carried out in a 50 mL three-necked flask, adding 500 mg/L of tetrabromodiphenyl ether stock solution and an initial concentration of 10 mg/L of tetrabromodiphenyl ether. Brominated diphenyl ether reaction liquid is a mixed solution of methanol and water. It is added with different amounts of vitamin B_{12} and nanoiron powder. It uses sodium hydroxide or hydrochloric acid to adjust the pH. The rotation speed is controlled to 220 rpm under protective gas and light-proof conditions. All reactions are completed under normal temperature and pressure.

3.8. Scanning Electron Microscopy (Sem) Analysis of Nanometer Iron Powder.
The scanning electron micrographs of iron powder and nanoiron powder are shown in Figure 4, respectively.

As shown in Figure 4(a), the particles of reduced iron powder are relatively coarse. The scanning electron micrograph of the nanoiron powder is shown in Figure 4(b). In contrast, the nanoiron powder has a much smaller particle size and the diameter is in the nanometer range. The study found that nanoiron powder is more reactive than ordinary iron powder and iron filings, and it has a larger specific surface area due to the nanosize effect. With strong reactivity and excellent adsorption performance, it has been widely studied and applied.

4. Result Analysis

4.1. The Influence of Different Metals on the Debromination Effect of Tetrabromodiphenyl Ether.
The results of degradation effect of different metals Al, Zn, Fe, and Sn are shown in Figure 5.

The decomposition rates of metals Al, Zn, Fe, and Sn are 16.64%, 24.20%, 29.04%, and 27.44%, respectively. Its low decomposition efficiency is mainly due to the high reduction of active metals, which can reduce many pollutants. It also has specific electrochemical and adsorption characteristics, electrolysis, and adsorption of pollutants. Therefore, the main catalytic reaction without a catalyst leads to less decomposition of pollutants. Secondly, in the larger metal particles and partial oxidation of their surface, etc., tetrabromodiphenyl ether is likely to deteriorate. The results show that the decomposition effect is Fe>Sn>Zn>Al. This may be related to the nature of the metal itself. The slow decomposition rate of aluminum is mainly due to the formation of a dense oxide film in the environment, which hinders the reaction.

4.2. The Effect of Different Metals and Vitamin B_{12} on the Debromination Effect of Tetrabromodiphenyl Ether.
Coupling Al, Zn, Fe, and Sn with B_{12} to degrade, the experiment takes a certain quality of metal B_{12}. The experimental results are shown in Figure 6.

As shown in Figure 6, the decomposition rates of metals and vitamins after coupling are 84.57%, 82.41%, 82.81%, and 98.89%. From the point of view of the increase of time, the decomposition rate shows an obvious decreasing trend with the passage of time, but the decomposition rate of several metals maintains a stable state at the end, respectively. The results show that the coupling of the ball-milled aluminum powder with B_{12} can efficiently and quickly decompose tetrabromodiphenyl ether. The reason for the impact may be that the ball mill restored the aluminum reduction ability. It destroys the oxide layer on the surface and makes the reaction more thorough.

4.3. 4.2 The Influence of the Dosage of Main Reactants on Debromination.
The dosage of nanometer iron powder affects the debromination effect. For the reaction system, when the dosage of B_{12} is 0.1 mM, the degradation diagram
FIGURE 11: The effect of pH on the debromination effect.
FIGURE 12: pH changes during the process.

of the dosage of nanometer iron powder on the debromination effect is shown in Figure 7.

As shown in Figure 7, the amount of nanoiron powder ranges from 0.0 g/L to 0.15 g/L. With the increase in the amount of nanoiron powder, the decomposition rate of tetrabromodiphenyl ether has a slope change. When the dosage of nanoiron powder is from 0.15 g/L to 1.0 g/L, the effect decreases as the concentration increases. This may be due to the increase in the concentration of nanoiron powder that can provide more reaction sites. If the concentration is too high, the hydrogen concentration generated by iron corrosion that covers the iron surface and interferes with the reaction will be too high. Therefore, increasing the concentration of nanoiron powder will accelerate the dehydrogenation reaction, but when it reaches a certain level, the reaction rate gradually decreases and stops.

The influence of the dosage of B_{12} on the debromination effect of tetrabromodiphenyl ether is shown in Figure 8. Under the dosage of 0.15 g/L nanoiron powder, this article

discusses the effect of vitamin B_{12} dosage on the degradation of tetrabromodiphenyl ether. In the range of 0.0 mM-0.1 mM, increasing the dose of vitamin B_{12} will accelerate the degradation efficiency. At concentrations between 0.1 and 2.0 mM, the degradation rate decreases as the concentration increases. When the amount of vitamin B_{12} is gradually increased to a certain amount, tetrabromodiphenyl ether is rapidly degraded within 120 minutes. This shows that increasing the vitamin B_{12} level within a certain range will significantly increase the rate of reaction degradation. Too high levels of vitamin B_{12} can interfere with electron transfer.

4.4. The Influence of Pretreatment Process on the Debromination Effect of Tetrabromodiphenyl Ether. When the reduced iron powder is subjected to various pretreatments and combined with B_{12}, the decomposition effect of the nanoiron powder is significantly higher than that of acid washing, alkaline washing, and methanol washing, as shown

in Figure 9. Alkaline washing refers to a high-strength lye solution prepared with sodium hydroxide and sodium carbonate or trisodium phosphate to soften, loosen, emulsify, and disperse deposits; pickling refers to the use of acid solution to remove oxide scale and rust on the surface of steel method. According to the degradation rate, the pretreatment methods are sorted into acid washing, alkaline washing, nanoiron powder, and methanol treatment processes. This is due to the large specific surface area and fine particles of the nanoiron powder, which can provide more reaction sites, which in turn can better provide electrons for the reaction. The results show that the effect of pickling is better than alkaline washing and methanol washing. Acid can remove the oxide film on the metal surface, clean the surface, and improve the debromination effect.

The initial concentration range of tetrabromodiphenyl ether is 10-100 mg/L. After 120 minutes of reaction, the result of measuring the effect on the dehydrogenation effect is shown in Figure 10. The degradation efficiency of tetrabromodiphenyl ether continued to decrease as the initial concentration increased. The removal rates after the reaction were 91.62%, 82.44%, 13.63%, and 5.39%, respectively. This is mainly because when the reaction concentration of tetrabromodiphenyl ether is low, nanoiron can provide a large effective surface area. So increasing the contact area ratio of the reaction will result in more active sites. So its dismantling is relatively complete. Therefore, if the pollutant concentration increases before the reaction, the tetrabromodiphenyl ether will eventually contact the nanoiron surface only after fierce competition. It can cover the surface when it is fully occupied, and only when it comes into contact with other molecules can it cause interference. Therefore, its debromination effect has been reduced.

4.5. The Influence of pH on the Debromination Effect of Tetrabromodiphenyl Ether. The initial pH of the system is 4.0 to 10.0, and the reaction is carried out under alkaline conditions. Figure 11 shows the effect of the initial pH of the system on the removal rate of tetrabromodiphenyl ether. The weakly acidic system environment is conducive to the dehydrogenation reaction. If the pH value changes during the reaction, the initial pH value of the system will become acidic, and the concentration of tetrabromodiphenyl ether will drop rapidly. The results show that the reaction is easier to proceed under acidic conditions, while the reaction is slower under alkaline conditions. The main reason is that the high hydrogen ion concentration enhances the cleaning ability of the metal, increases the corrosion rate, and at the same time promotes the production of reducing substances, thereby promoting the reaction, and vice versa. As the H+ concentration in the system increases, iron corrosion occurs rapidly, and its surface is blocked. This is not conducive to the progress of the reaction.

The change in pH value in Figure 12 shows a trend of small fluctuations during the reaction time, which is basically stable thereafter. With the initial increase of pH, the final degradation of tetrabromodiphenyl ether was 5.36, 7.08, 7.25, and 9.45. Under acidic conditions, the increase in pH may be due to the consumption of H+ or the production of OH-. As the pH increases, the slowing down of degradation may be due to the fact that the reaction is basically stable. Iron dissolves in the aqueous medium and emits electrons to produce H2. These reactions increase the pH. Under acidic and neutral conditions, as an electron acceptor, H+ can compete with tetrabromodiphenyl ether for electrons.

5. Conclusions

This paper discusses that the environmental behavior of PBDEs is the basis for their pollution prevention and control, due to their far-reaching impact on social and economic development and human health. Therefore, it is urgent to develop a fast, efficient, and thorough polybrominated diphenyl ether degradation technology. In the experiment, we studied the catalytic reduction effect of tetrabromodiphenyl ether and influencing factors with nanoiron powder and vitamin B_{12}. The experiment investigated the effects of vitamin B_{12} dosage, iron dosage, pH value, pretreatment conditions, reaction concentration, pH change value, etc. on the decomposition rate of tetrabromodiphenyl ether. The optimal reaction conditions for the catalytic reduction of tetrabromodiphenyl ether with nanoiron powder and vitamin B_{12} are as follows: the amount of nanoiron powder is 0.15 g/L, the amount of vitamin B_{12} is 0.1 mM, and the initial pH value is 6.0 under pickling. It is the best reaction condition under all the listed conditions. The removal rate of 10 mg/L tetrabromodiphenyl ether after 120 minutes of reaction is as high as 91.62%. Compared with traditional zero-valent iron powder, nanoiron powder has stronger reducing power and higher surface activity. This means that it can provide more active centers for the reaction.

At present, with the acceleration of rural urbanization, people's market demand for new building materials is also increasing, and the research and development of new PVC/fine sand imitation stone composite materials are also in continuous progress and development. The purpose of this article is to analyze the feasibility of developing new PVC/fine sand imitation stone composite materials to promote rural urbanization and propose the application of more new PVC/fine sand imitation stone composite materials to our urbanization construction. In, we first conducted research on the new PVC/fine sand imitation stone composite material and rural urbanization, and then, we conducted research on the various properties of the new PVC/fine sand imitation stone composite material and the development of rural urbanization. The research results show that the new PVC/fine sand imitation stone composite material has at least 400% improvement in compressive performance compared with the traditional PVC material, and it is also better than the traditional PVC material in terms of the material expansion and contraction performance, which is more conducive to the application our rural urbanization is under construction.

1. Introduction

Urbanization is a natural historical process in which nonagricultural industries agglomerate in cities and towns and rural populations are concentrated in cities and towns along with the development of industrialization. It is an objective trend in the development of human society. Traditional urbanization has led to a series of problems in my country, such as uneven regional development, low resource carrying capacity, excessive reliance on land support, and environmental pollution. Therefore, a new type of urbanization has emerged. Polyvinyl chloride, as one of the world's earliest industrialized plastics, is one of the five general purpose resins. It has been widely used in national life and social economy because of its excellent performance and economic price. Polyvinyl chloride has excellent physical properties and has outstanding performance in corrosion resistance, chemical stability, and flame resistance. Compared with other materials, it has the advantage of low price. Therefore, PVC is widely used, and its use is in thermoplastic resin. It is second only to polyethylene, accounting for one-third of the total global synthetic resin

consumption. In the social environment with the rapid development of science and technology and the gradual expansion of the application scope of polymer materials, the requirements for various materials in urbanization construction are getting higher and higher, and plastic products are required to meet the more and more precise division of labor, and the needs of the industry are increasing.

Architecture is a symbol of human civilization, and the regional and nationality of architecture are expressed by building materials. Although many people have conducted research on PVC composite materials, the research focuses on the application of PVC composite materials in traditional buildings, and there is no systematic detailed classification of contemporary applications of PVC composite materials. In the construction of a new type of urbanization, in today's urgent need for regional feelings, we take the application of PVC composite materials as the core part of in-depth research, apply its divergent thinking to all aspects of urbanization, and actively explore the use of bamboo and wood. The ideological expression, aesthetic expression, and technical expression of the local materials

represented by brick and stone in the new urbanization construction have summarized a set of guiding principles, which will be implemented in the future new urbanization construction and promote regional culture. With the rapid development of contemporary construction technology and new materials, the expression methods of PVC composite materials are no longer limited to traditional techniques. Under the guidance of new concepts and new processes, many innovative expression methods have been formed. The artistic appeal and spiritual symbolism of bamboo, wood, brick, and stone improve the aesthetic quality and cultural connotation of the building and give people the enjoyment of beauty [1]. The buildings in the new urbanization construction should strive to achieve equal emphasis on traditional PVC composite materials and modern technology and try to find a new way of innovation in the continuation. This is not only a respect for the local natural environment and national culture, but also a warning for modern people to lose themselves and blindly seek development.

With the continuous progress of society, the process of rural urbanization is also accelerating. Goodall SK based the research on the migration of nomads from rural to urban areas in the western Ladakh Himalayas and stated that the case study is consistent with the rapid urbanization currently underway in Leh related to [2]. Arouri M's survey on rural urbanization found that urbanization has stimulated the transition from agricultural activities to nonagricultural activities in rural areas. Rural households have experienced a decrease in agricultural income and an increase in wages and nonagricultural income. And urbanization helps rural families reduce the poverty rate of expenditure [3]. The development of the government governance system is also a major factor in promoting rural urbanization. In a study, Oke D analyzed some related factors of Lagos urbanization caused by rural to urban migration. The research results show that the education and modern transportation provided by the Lagos government are crucial to the country's urbanization drive [4]. In the process of rural urbanization, some problems inevitably arise. Guo Y's in-depth case study of the South China Sea in the Pearl River Delta revealed the unexpected seriousness between local villagers and migrant workers in villages undergoing effective urbanization, social inequality, and isolation [5]. Although some problems will inevitably arise in the process of rural urbanization, they cannot stop the development of urbanization. As a commonly used PVC composite material in rural construction, it is also undergoing continuous innovation and development. Dan-Asabe B pointed out that Dum Palm particle-reinforced polyvinyl chloride (PVC) composites were developed with relatively low-cost materials, providing overall light weight and good mechanical properties, which can be used as potential applications for pipeline materials [6]. Sacramento AS described a new method of producing antibody-like bionic materials in the study of composite materials. It includes the preparation of composite imprinting materials that have never appeared before, with highly conductive supporting nanostructures, and the assembly of highly conductive polymer layers at low temperatures [7].

In the research on the production of composite materials, people are also making continuous progress. In a research conducted by Lyubimova ON, a mathematical model and simulation method for calculating the temperature field and material property distribution in the production process of composite materials were provided to better study composite materials [8]. Although the continuous development of PVC composite materials has improved its own usability, PVC composite materials have also made some people not consider using them as building materials for houses and their decorations due to their low heat resistance [9].

The innovation of this article lies in the full research and analysis of new PVC composite materials and rural urbanization. The new PVC/fine sand imitation stone composite materials are used in rural urbanization construction, and new composite materials with more wear resistance, corrosion resistance, high flame resistance, and lower prices are introduced into rural urbanization construction. This is to help rural people build their homes by using more cost-effective materials.

2. Development of New PVC/Fine Sand Imitation Stone Composite Materials and Methods to Promote Rural Urbanization

2.1. PVC Material. Polyvinyl chloride, called PVC, is a white powder with an amorphous structure. In 1835, the Von Liebig Institute in Houston, Germany, synthesized vinyl chloride, and in 1872, Barman synthesized polyvinyl chloride [10, 11]. However, actual PVC products were not produced in the USA until the 1920s, and a large-scale production in Europe will begin in the next 20 years. Because of its abundant raw materials, the manufacturing process is very mature, the price is very low, and the uses are very wide. It is still second only to polyethylene resin in the world [12]. The two main general purpose resins account for 29% of the world's total synthetic resin production. There are many processing methods for PVC processing, such as molding, lamination, injection molding, extrusion molding, calendar ring, and brooch molding. PVC can manufacture software products and hardware products. Among them, software products mainly include artificial leather, films, steel wire sheaths, and soft boards, and hardware products mainly include boards, doors, windows, pipes, valves and other configuration materials [13]. Chlorinated polyethylene has excellent flame retardancy and high chemical resistance [14].

Polyvinyl chloride is a noncrystalline polymer, and its main feature is that it is amorphous, nonbranched, and regularly arranged with lock-like links. The polymerization degree n of polyvinyl chloride is generally 500~2000. This material is a material with high mechanical strength, and its chemical properties are very stable [15]. Due to the large amount of chlorine molecules in the molecular structure, it has high polarity and excellent flame retardancy. Plastic products made of polyvinyl chloride have excellent advantages such as abrasion resistance, acid resistance, alkali resistance, and insulation [16]. However, the optical

and thermal stability of the device is relatively low, and if no thermal stabilizer is added, it starts to decompose at 100 degrees Celsius. Experiments show that the higher the temperature, the faster the decomposition [17]. At present, the PVC industry is developing rapidly all over the world and has broad prospects. All countries are optimistic about the possibilities of PVC and the benefits of the ecological environment. With its outstanding and unique performance, PVC has proved its role to the world. Yes, social development needs it, and environmental protection needs it. This is an inevitable trend of the progress of our human social civilization [18].

2.1.1. Preparation of PVC Composite Materials. According to the formula, the uniformly mixed materials are supplied to the extruder barrel through the hopper. Under the action of the rotating movement of the screw, the material mixture moves along the rotation until it is pressed in front of the barrel, and then is cooled and formed, and the pushed product is completed. Figure 1 shows part of the production machine required for the preparation of PVC composite materials [19]. These machines have their own preparation process, in different forms.

Figure 2 shows the production flow chart of the new PVC/fine sand imitation stone composite material.

A composite material is a combination of one material as the matrix and another as the reinforcement [20]. Various materials complement each other in terms of performance, resulting in a synergistic effect, so that the comprehensive performance of the composite material is better than that of the original material to meet various requirements. With PVC as the matrix, it is divided according to different types of reinforcements. There are currently 4 categories. PVC composite materials: one is fiber, the other is powder, and the third is granular, such as PVDC and polyurethane.

After the preparation of the PVC composite material, the thermal conductivity and flame retardant performance should be tested separately. In the production process, since PVC is a heat-sensitive material, even adding a heat stabilizer can only increase the decomposition temperature and prolong the stabilization time without decomposition [21]. This requires that the molding processing temperature of PVC should be strictly controlled. In particular, rigid PVC, because its processing temperature is very close to the decomposition temperature, often decomposes due to improper temperature control. The quality of extrusion granulation is closely related to the characteristics of the extruder, the structure of the head, the temperature, the feeding speed, the rotation speed of the main engine, the traction speed, and other factors. In the thermal conductivity test, the composite material sample is made into a circular sample with a diameter of 6 mm, and the upper temperature of the instrument is set to 36°C, and the lower temperature is set to 15°C, when the indicator does not change more than 0.1 within one minute. Put the sample on the thermal conductivity tester at °C, start the test after the thermal conductivity is stable, test once a minute, start counting, and measure three times within the range of the value difference

not exceeding 5% [22]. The calculation formula of thermal conductivity:

$$\frac{\Delta W}{\Delta T} = \lambda * Q \frac{\theta_1 - \theta_2}{H}. \tag{1}$$

When testing the flame retardancy of PVC composite materials, the sample size is as follows: length × width × height = $(100 \, \text{mm}) \times (6.5 \pm 0.5 \, \text{mm}) \times (3 \pm 0.5 \, \text{mm})$. During the test, first consult the literature to estimate the range of the oxygen index of the sample, adjust the oxygen and nitrogen proportionally to this value, clamp the sample vertically on the iron clamp, and then use an igniter to ignite [23]. Adjust the ratio of oxygen and nitrogen, and observe the burning distance of the sample after 3 minutes until the burning of the sample starts timing. If it exceeds 60 mm, it means that the oxygen concentration is high and adjusts it downward; if it is less than 60 mm, it means that the oxygen concentration is low and adjusts it upward. When it reaches 60 mm in 3 minutes, the oxygen content is the oxygen index of the composite material. The calculation formula of oxygen index is as follows:

$$\text{OT} = \frac{\text{WO}_2}{\text{WO}_2 + \text{WM}_2} * 100\%, \tag{2}$$

where OT represents the oxygen index, WO_2 represents the oxygen flow rate, and WM_2 represents the nitrogen flow rate.

2.1.2. Composite Material Processing Performance Test. The polymer melt can exhibit viscous flow and elastic deformation under the influence of external force, so the processing and molding of PVC are manifested in viscous flow [24]. The most basic manifestation of its processing performance is its rheological properties, and rheological properties refer to the viscous flow of materials. For a long time, scholars have established the relationship between the speed and torque in the torque rheometer for the first time, to the research on the theoretical model of the processing conditions, rheological parameters and geometric dimensions of the torque rheometer, and then to Bousmina. Based on the power law fluid equation, a series of theoretical derivations are carried out, and the following relational expressions are obtained. When the fluid flows in the pipeline, the distance it flows in a certain period of time is the flow velocity. The flow velocity generally refers to the average flow velocity of the fluid, and the unit is m/s.

$$\Gamma = 2^{2N+1} \pi^{N+1} \text{WLR}^2{}_B M^N \frac{1 + q^{N+1}}{\left[N \left(\beta^{2/N} - 1 \right) \right]^N}, \tag{3}$$

$$R_n = 2^{n+1} \pi^{n+1} \text{LR}_B^2 \frac{1 + q^{n+1}}{\left[n \left(\beta^{2/n} - 1 \right) \right]^n}, \tag{4}$$

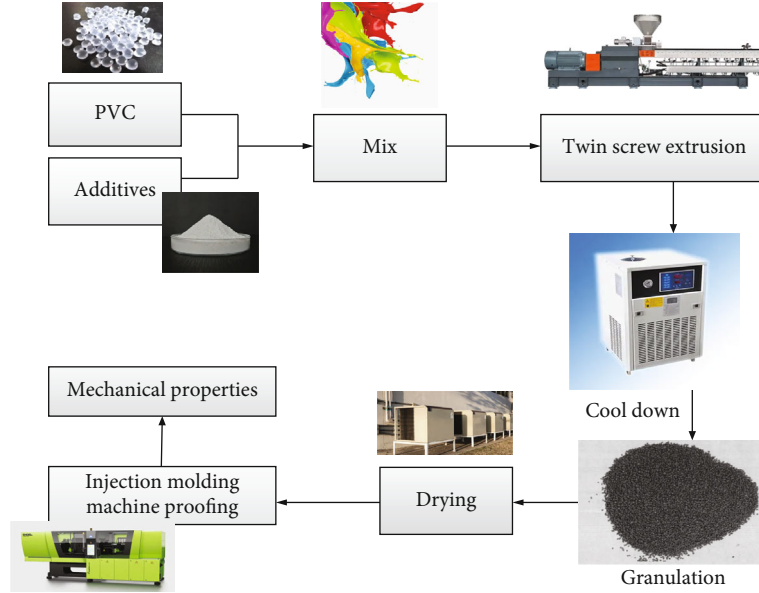
$$\beta = \frac{R_B}{R_I}, \tag{5}$$
FIGURE 1: Part of the machine diagram for preparing PVC composite materials.


FIGURE 2: The production flowchart of the new PVC/fine sand imitation stone composite material.

where R_B is the equivalent radius; R_I is the radius of the mixer; L is the length of the rotor; q is the speed ratio of the two rotors; Γ is the balance torque, $N \cdot m$; W is the consistency coefficient; n is the power law index; and WL is the indicator. The above formula can be transformed to obtain the rotor equivalent radius R_I formula, as shown in

$$R_I = \frac{R_B}{\left[1 + (4\pi N/n)(2\pi WLR_B^c(1 + q^{N+1}/\Gamma))^{1/n}\right]^{n/2}}. \quad (6)$$

Bousmina also gave the calculation formula of the shear rate and shear viscosity of the polymer melt in the torque rheometer, as shown in

$$\chi = \chi_{1/2} = \frac{2^{2(1+(1/N))}\pi n}{N} \frac{\beta^{2/N}}{(1 + \beta)^{2/N}\left(\beta^{2/N} - 1\right)}, \quad (7)$$

$$\eta(\chi) = \frac{\Gamma}{\pi L(R_B + R_I)(1 + q^{N+1})\chi}. \quad (8)$$

However, when Bousmina calculates the melt viscosity and equivalent radius, it is calculated according to the set temperature of torque rheology. It does not take into account the actual temperature of the material in the cavity, so some scholars have carried out temperature correction.

The relationship between viscosity and temperature is as follows:

$$\eta = A \exp(\Delta Q/RE). \quad (9)$$

From the above formula:

$$\frac{\eta(E)}{\eta(E)'} = \frac{\Gamma(E)}{\Gamma(E)'} = \exp\left[\frac{\Delta Q}{R}\left(\frac{1}{E} - \frac{1}{E'}\right)\right]. \quad (10)$$

2.2. Rural Urbanization. "Urbanization" has a very rich connotation. It was in the twentieth century that urbanization gradually became popular and accepted by the masses. With the development of society and economy, the concept and connotation of urbanization are constantly enriched and improved [25]. Scholars in various fields have given meaning to urbanization from various angles. Sociologists believe that urbanization is a process by which rural residents enjoy the material and spiritual enrichment brought about by urban development and urban production and lifestyle changes. Many scholars have studied this transformation through the illiteracy rate, mass communication penetration rate, and language uniformity rate. Demographers believe that urbanization is a process in which local populations continue to gather in cities and cities. This process will inevitably lead to an increase in the number of cities and cities. The essence of urbanization is the

urbanization of the population. Many scholars' research on the level of urbanization is also based on the ratio of urban permanent residents to the total population [26].

2.2.1. Development History of Urbanization.

The urbanization process since the founding of New China is roughly divided into three stages. The first stage: 1949~1957. Soon after the founding of the People's Republic of China, it entered a period of large-scale industrialization and urban construction under the "First Five-Year Plan." The second stage: from 1958 to 1978. The urban population accounts for 30%~70% of the total population. Urbanization has entered a period of rapid development, and the urban population can exceed 50% in a relatively short period of time and then rise to about 70%. The third stage: Since 1978, since the reform and opening up, China has entered a stage of steadily advancing urbanization. The implementation of a series of reform and opening policies has greatly promoted the development of urbanization. In the 42 years from 1978 to 2020, the level of urbanization in China has increased from 17.9% to 63.89%. Figure 3 shows the development map of China's urbanization process.

2.2.2. Measurement of Urbanization Level.

The level of urbanization is an important indicator of the social and economic development of countries and regions. It has always been the focus of scholars to determine the level of urbanization in line with reality through scientific and objective methods [27]. There are many methods to measure the level of urbanization, which can generally be divided into four categories: entropy method, population index method, other main index method, and compound index method.

The first introduction is the entropy method. "Entropy" is the measure of uncertainty. Experiments show that the more elements, the more comprehensive the index, the smaller the uncertainty, and the smaller the entropy. Experiments show that the fewer the elements, the higher the unilateralist of the index, and the greater the uncertainty [28]. Therefore, the degree of dispersion of the index can be judged from the result of the entropy value. Experiments show that the smaller the entropy value, the greater the weight and the greater the degree of dispersion. Experiments show the greater impact of indicators on the results and vice versa. The calculation steps of the entropy method are as follows:

(1) Matrix construction and standardization: Assuming a comprehensive evaluation of the y indicators of w objects, a matrix of 18 $w \times y$ can be established, where Amn represents the value of the nth indicator in the m area, $m = 1, 2, \cdots, W, n = 1, 2, \cdots, y$; w is the number of regions, and y is the number of indicators

(2) Data standardization: The unit, positive and negative directions, and the size of various indicators are different, and the original data must be standardized. The formula for calculating the positive index is as follows:

$$A'_{mn} = (A_{mn} - \min \{A_n\})/(\max \{A_n\} - \min \{A_n\}). \quad (11)$$

The calculation formula of the negative index is

$$A'_{mn} = (\max \{A_n\} - A_{mn})/(\max \{A_n\} - \min \{A_n\}). \quad (12)$$

(3) Calculate the proportion of the j-th index value in the i-th year:

$$T_{mn} = \frac{A'_{mn}}{\sum_{m=1}^{w} A'_{mn}}. \quad (13)$$

(4) Calculation of index entropy:

$$O_n = -K \sum_{m=1}^{w} (T_{mn} * \ln T_{mn}). \quad (14)$$

(5) Calculation of entropy redundancy:

$$D_m = 1 - O_n. \quad (15)$$

(6) The weight of the indicator:

$$q_m = \frac{D_m}{\sum_{n=1}^{w} D_m}. \quad (16)$$

(7) Evaluation scores for individual indicators:

$$E_{mn} = q_m * A'_{mn}. \quad (17)$$

(8) Comprehensive level score of the i-th year:

$$E_m = \sum_{n=1}^{y} E_{mn}. \quad (18)$$

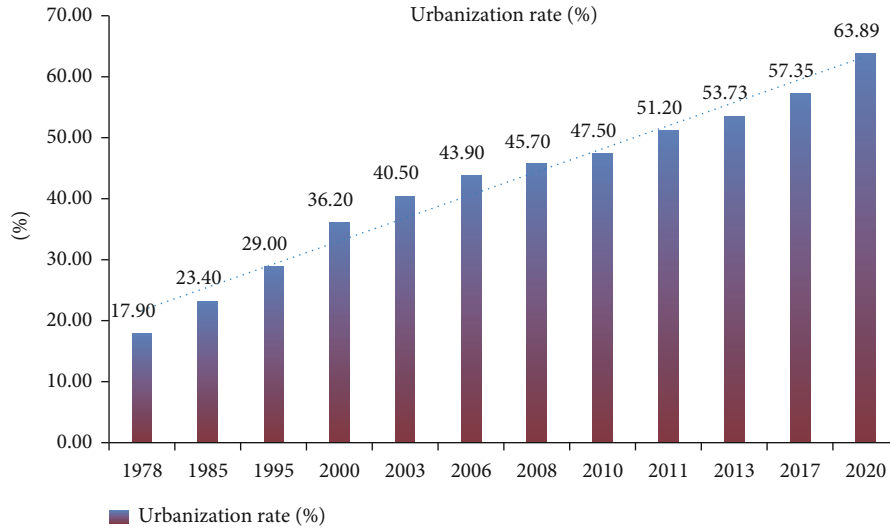
The second introduction is the population index method, which indicates that the level of urbanization is


Figure 3: Development of China's urbanization process.

the ratio of the urban population (or urban nonagricultural population) to the total population. The formula is as follows:

$$CU = \frac{U}{C} * 100\%, \tag{19}$$

where CU represents the level of urbanization, C represents the total population, and U represents the urban population. Towns and villages are the two basic forms of human settlements, and their essence is the agglomeration of population in space. From the perspective of population aggregation, the difference between towns and villages lies in the fact that towns have large populations, large scales, and high densities, and the opposite is true in rural areas [29]. Population urbanization is the process of population transfer and agglomeration from rural to urban areas. It is the result of the combined effect of the "pull force" of cities and towns and the "push force" of rural areas. It is the essence of urbanization.

Finally, the compound index method is introduced, which refers to selecting several or more indicators that reflect the various characteristics of urbanization, and by calculating the weights of each indicator and summing them, the total score representing the comprehensive level of urbanization in a country or region is obtained. The mathematical expression of this method is as follows:

$$P = \sum F_i G_i, \tag{20}$$

where P refers to the comprehensive level of urbanization, F_i refers to the value of various indicators in urbanization, and G_i refers to the weight corresponding to each indicator. The compound index method is to overcome the shortcomings and limitations of the single index method, trying to measure the comprehensive level of urbanization from multiple perspectives of the connotation of urbanization [30]. Although the compound index method can fully reflect the

connotation of urbanization, its biggest disadvantage lies in its strong pertinence and weak versatility.

2.2.3. The Development and Content of New Rural Urbanization. With the continuous development of society, the process of urbanization in rural areas has been accelerating. With the continuous development of urbanization, rural infrastructure has been improved, basic housing conditions have been improved, and the presence of large industrial and commercial enterprises has provided a large number of employment opportunities for people in rural areas. However, with the development of urbanization, farmland resources in rural areas are continuously lost, environmental pollution has increased, and large numbers of rural people have migrated to cities. Figure 4 shows the problems caused by the process of rural urbanization in some areas.

In the process of rural urbanization development, five requirements must be followed, namely, integrating urban civilization on the basis of protecting rural culture, integrating urban-rural integration with local characteristics, new-type urbanization must focus on environmental protection, and new-type urbanization. When the "elements" are pushed forward neatly, the reform of the land management system must be followed up. Figure 5 is a schematic diagram of the five requirements for the development of rural urbanization.

2.2.4. Characteristics of Urbanization. First, people are the core of development. The core of the scientific concept of development is people-oriented. The new type of towns urges cities to provide complete basic public services; solve the problems of difficult medical treatment, expensive medical treatment, and difficulty in schooling; and realize the equalization of rural residents in pension insurance, medical treatment, salary level, children's education, housing, and comprehensive coverage. The permanent population of the city enables the vast number of migrant workers entering the city to also enjoy the public services that urban

residents should have and then live and work in peace and contentment.

The second point is the intensification of development models. Intensive development refers to improving labor productivity by improving technology and improving man-agement methods, continuously reducing energy consumption and production costs, and improving the quality and efficiency of production factors to achieve economic growth.

The third point is to coordinate urban and rural development. Traditional urbanization refers to the transfer of rural

population to cities, and the indicator to measure the level of urbanization is also the proportion of urban permanent residents to the total population of the city. The urbanization model that sends samples can be said to be a "population transfer" urbanization path. However, urbanization is also a comprehensive indicator that reflects the level of economic development of a region. The new urbanization believes that as the speed of urbanization continues to accelerate, the urban industrial structure is continuously adjusted and further optimized, and the economic links between cities and regions become closer. The flow of resources between urban and rural areas is more convenient and effective, the income gap between urban residents and rural residents will continue to shrink, basic social welfare will be equalized, development barriers between urban and rural areas will be eliminated, and the integrated development of urban and rural areas will be truly realized. The coordinated development of urban and rural areas is to maintain equal emphasis on urban and rural areas and narrow the gap. The two forms of social and economic spatial organization of urban and rural areas cannot be homogenized. The construction of new rural areas must maintain the local characteristics and original features of rural areas. Persisting in the coordinated development of urban and rural areas and urban radiation and driving rural development and rural promotion and support for the rise of cities are an effective way to enhance the overall economic and social development of a country and region, and it is also the only way to long-term development.

The fourth point is the sustainability of development. The new urbanization adheres to the premise of "ecological protection" and achieves simultaneous urbanization in the four aspects of population, society, economy, and land. With the advancement of new urbanization, the protection and construction of urban ecology should be equally emphasized, industrial upgrading should be accelerated, the development of modern service industries and modern agriculture should be accelerated, the gap between urban and rural areas should be continuously narrowed, and the

fruits of social development can be shared by all, and the rational development and utilization of energy should be achieved by controlling the rate of economic growth. Coordinating the relationship between man and nature with resources effectively curbs the "urban diseases" caused by traditional urbanization, such as traffic congestion, environmental degradation, and polarization between the rich and the poor, so as to achieve an orderly, healthy, and sustainable development of towns.

2.3. New PVC/Fine Sand Imitation Stone Composite Material. The new PVC/fine sand imitation stone composite material is a new composite material made by combining PVC material and fine sand. This material is superior to traditional composite materials in terms of heat resistance, scalability, and impact resistance. This article mainly introduces the production of the composite material.

2.3.1. Preliminary Treatment of Fine Sand. The fine sand we see is basically free of impurities, and the sand grains are relatively regular, but it cannot be denied that some sand grains are attached to the surface of yellow-brown. In the pretreatment of fine sand, it is first necessary to rinse with water to remove the mud and attachments on the surface of the fine sand and to increase the twisting force between the surface of the fine sand and the PVC molecular chain before use. In order to make the surface of the fine sand look rough and concave, alkali immersion cleaning is performed. After these cleaning steps are completed, polar chemical bonds will be formed on the surface of the fine sand. Figure 6 is a comparison diagram of fine sand before and after cleaning:

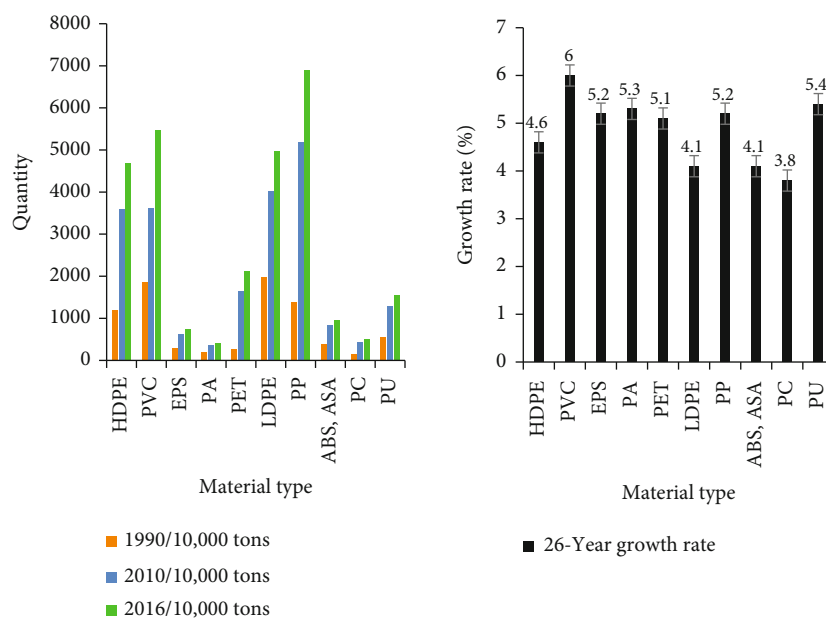
2.3.2. Pretreatment of PVC/Fine Sand Imitation Stone Composite Material. The first step is to modify the surface of the fine sand and use a coupling to correct the surface of the pretreated fine sand. Increase the friction force indicated by the fine sand, make the reinforced material (fine sand) compatible with the matrix (PVC), and improve the performance effect of promoting various characteristics of the composite material after forming. Secondly, the required components of the composite material are proportioned, and the dyeing treatment is carried out. According to the performance requirements of composite materials, the matrix can be divided into one or more types using polymer compounds. As a reinforcing material, the fine sand and the addition amount can also be adjusted in a wider range according to different usage requirements. The general purpose is to add to the quality of PVC and fine sand at a ratio of 1 : 3 and use other additives such as composite heat stabilizers. A variety of color series using organic pigments is to dye the modified sand and the dyeing of the mixture of PVC and sand (or pure PVC) to have a better effect and also make the color of the composite material uniform and bright. The third step is to use an internal mixer to mix the modified and dyed sand and PVC and add plasticizers for mixing and preplasticization and thermal stability to compress them. It can also be molded by extrusion molding, injection molding, and other methods. Finally, there is the surface treatment part. The surface treatment uses


FIGURE 7: Changes in world demand for several common plastics.

PVC/fine sand composite material to evenly disperse the fine sand particles on the substrate. The color of the fine sand particles and the accumulation state of the particles will be changed by the corresponding process. The surface of the composite material can show the texture of various sandstones. Its appearance can be made into a smooth surface with limited molding once, or it can be formed only once.

3. Experimental Design and Result Analysis of New PVC/Fine Sand Imitation Stone Composite Materials and Promotion of Rural Urbanization Construction

3.1. Investigation and Result Analysis of Changes in the Consumption Demand of PVC Materials. The demand for plastics is increasing worldwide. According to the relevant data of the world plastics industry, from 1990 to 2016, all kinds of plastics in the world have been growing steadily. Table 1 shows the global demand for some commonly used plastics.

According to the latest data report from an agency in the USA, the global demand for plastic pipes has steadily increased at an annual rate of 8.5% from 2013 to 2017. Among them, chlorinated polyethylene is a resin suitable for manufacturing pipes. PVC is an organic polymer compound polymerized by vinyl chloride under the condition of a starting agent. It is one of the world's five main general purpose plastics and is supported in all fields. It is now a plastic variety second only to polyvinyl chloride and polypropylene.

According to Table 1, we can get the world demand change diagram of several commonly used plastics around the world, as shown in Figure 7.

TABLE 2: Vicat softening temperature table of common plastics.

	Minimum softening temperature	Maximum softening temperature
Polyvinyl acetate	35	85
Polyoxymeth	165	185
Polystyrene	70	115
Polypropylene	160	170
Polyvinyl chloride	60	85
Nylon12	170	180
Compound PVC	90	110

From Figure 7, we can see that the main market shares are polyethylene plastic (PE), polypropylene plastic (PP), polyvinyl chloride plastic (PVC), and polystyrene plastic (PS), and the future of plastics in the market Demand will also continue to expand. Among them, PVC has the fastest growth rate, reaching a growth rate of 7%.

3.2. Test and Analysis of the Heat Resistance Performance of the New PVC/Fine Sand Imitation Stone Composite Material. Vicat softening temperature is an important index for evaluating the heat resistance of materials and reflecting the physical and mechanical properties of products under heating conditions. The higher the Vicat softening temperature of the material, the higher the dimensional stability of the material when heated, the lower the possibility of thermal deformation, and the higher the heat resistance of the material. Table 2 is the Vicat softening temperature table of some common plastics.
FIGURE 8: Comparison of Vicat softening temperature of some materials.

According to Table 2 and related literature data, we can get the Vicat softening temperature comparison chart of some plastics, as shown in Figure 8:

According to Figure 8, we can conclude that the Vicat softening temperature of some materials such as polyoxymethylene, polypropylene, and nylon 12 exceeds 160°C, while the Vicat softening temperature of ordinary PVC materials is 63°C. The average Vicat softening point of the sand imitation stone composite material is 103°C. Although materials such as polyoxymethylene and polypropylene have higher heat resistance than PVC materials, these materials are not suitable for ordinary construction. Although the heat resistance of traditional PVC materials is not high, it also meets the requirements of modern and ordinary construction. With the development of new PVC composite materials, its heat resistance is higher than that of ordinary PVC materials, so it has a wider range of applications and is more popular than traditional PVC materials. Due to its high chemical stability, it can be used to make anticorrosion pipelines, pipe fittings, oil pipelines, centrifugal pumps, and blowers. The rigid board of PVC is widely used in the chemical industry to make the lining of various storage tanks, corrugated boards of buildings, door and window structures, wall decorations, and other building materials. Due to its excellent electrical insulation properties, it can be used in the manufacture of plugs, sockets, switches, and cables in the electrical and electronic industries.

3.3. Comprehensive Performance Test and Result Analysis of the New PVC/Fine Sand Imitation Stone Composite Material.

In order to better test the various properties of the new PVC/fine sand imitation stone composite material, we conducted related experiments on the composite mate-

TABLE 3: Compressive strength performance test table.

	Test result 1	Test result 2	Average value
1	9.2	9.6	9.4
2	8.6	9.0	8.8
3	10.8	10.4	10.6
4	16.4	15.2	15.8
5	18.6	19.6	19.1
6	12.9	13.1	13.0

TABLE 4: Scale performance test table.

	Test result 1	Test result 2	Average value
1	98	112	105
2	152	156	154
3	182	184	183
4	194	206	200

rial's compression resistance, abrasion resistance, and scalability. Table 3 and Table 4 are the compressive strength performance test table and the expansion performance test table of the new PVC/fine sand imitation stone composite material, respectively.

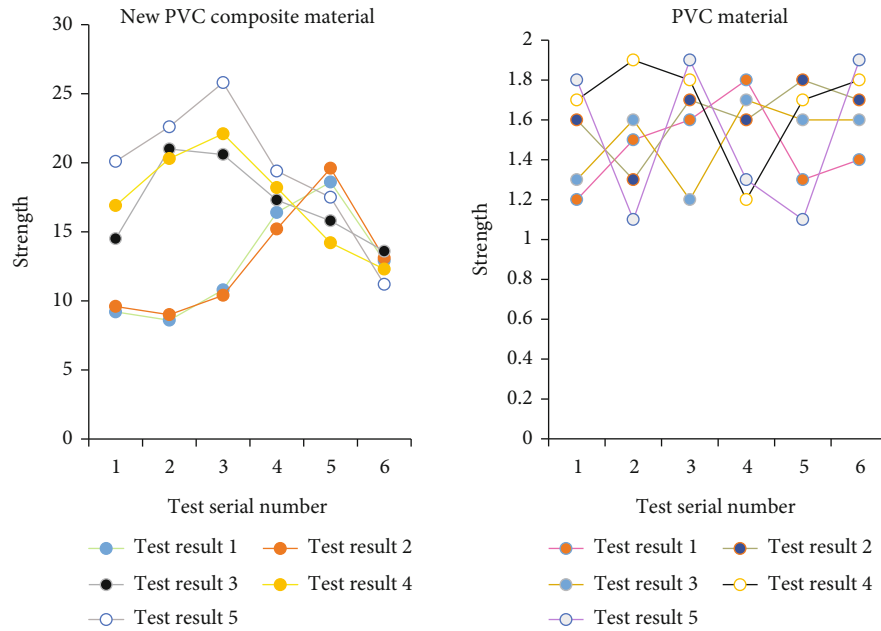
According to the experimental results in Table 3 and Table 4, it can be concluded that the average compressive strength of the new PVC composite material is higher than $9KJ/m^2$, and the average value of its expansion performance is greater than 100 MPa. The reason for the large difference


FIGURE 9: Comparison of the compressive strength of the new and old PVC materials.

between the experimental data of the same material is that the given pressure is quite different. According to some other experimental data, we get a comparison chart of the compressive strength of the new PVC composite material and the compressive strength of ordinary PVC, as shown in Figure 9:

According to Figure 9, we can find that the compressive strength of the new PVC composite material is more than 400% higher than that of the ordinary PVC material. Therefore, the application range of the new PVC fine sand imitation stone composite material in the construction of rural urbanization will be much larger than that of ordinary PVC materials. The two properties of pressure resistance and elasticity can be regarded as outstanding features of the new PVC/fine sand imitation stone composites.

3.4. Rural Urbanization Survey and Result Analysis. This survey is aimed at a certain province in central China. We have investigated the changes in population and urban size in the development of rural urbanization in this province. We analyze from three perspectives: population, number of towns, and number of companies. The specific survey results are shown in Table 5:

According to Table 5, we can see that with the development of rural urbanization in this province, the number of rural urban population has increased, and the number of industrial enterprises in rural urban areas is also increasing. According to some data we have, we have obtained the changes in China's urban population over a period of time, as shown in Figure 10:

According to Figure 10, we can see that between 2008 and 2015, the proportion of urban population has increased by 10%, and the number of people absorbed by the eastern region far exceeds that of other regions, accounting for more than 70% of the total population. With the acceleration of

TABLE 5: Changes in various factors in rural urbanization.

	Population	Number of towns	Number of companies
2014	2501000	3	15
2015	2543000	4	21
2016	3620100	5	29
2017	3692001	7	35
2018	3764100	9	41
2019	3859000	12	48
2020	3964001	15	55
2021	4042100	17	64

the urbanization process, the vigorous construction of various infrastructures, the development of houses, and the development of industry, people's demand for new PVC materials will gradually increase.

4. Discussion

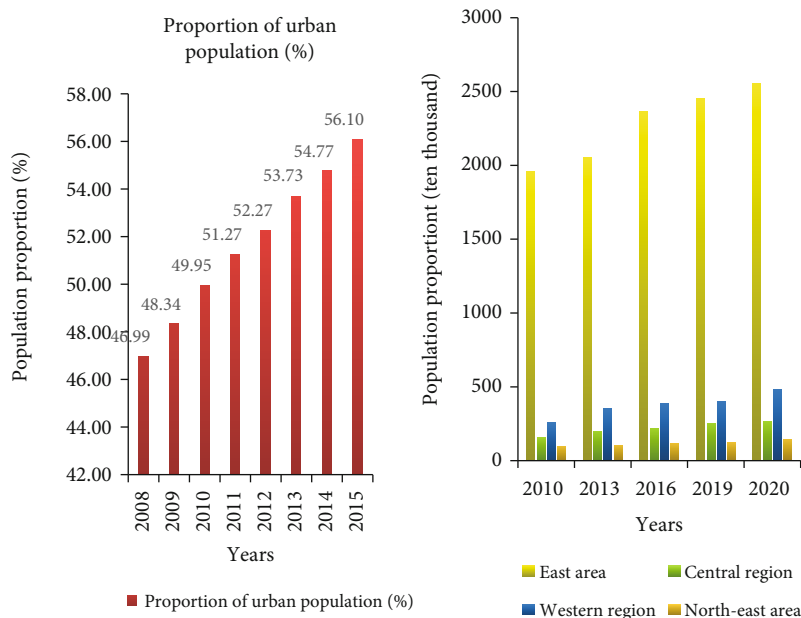
This article is devoted to the research of the new PVC/fine sand imitation stone composite material, and the development of the new PVC/fine sand imitation stone composite material is applied to the feasibility study of our rural urbanization. We not only discussed the new PVC/fine sand imitation stone composite material, but also studied the preparation material and preparation process of the new PVC/fine sand imitation stone composite material. At the same time, we also conducted research and analysis on our urbanization development process and other aspects. In this article, we have analyzed the demand for PVC materials. Through the study of the new and old PVC materials, the results show that the new PVC/fine sand imitation stone


Figure 10: Urban population change map.

composite material is more in line with the product's compressive strength and expansion performance.

Through the analysis of the case in this article, we can conclude that the development and application of the new PVC/fine sand imitation stone composite material are more conducive to rural urbanization. In the process of urban construction, people can apply the new PVC/fine sand imitation stone composite material to our house construction, house decoration, parks, bridges, and guardrails. By using the new PVC/fine sand imitation stone composite material, not only can it improve its compression resistance, abrasion resistance, and heat resistance, but the appearance of the new PVC/fine sand imitation stone composite material is more tactile and cost-effective. It is cheaper than other materials.

This article starts with the global demand for PVC materials. Through the changes in demand for PVC, the performance test, and analysis of the new PVC/fine sand imitation stone composite material, the advantages of the new PVC/fine sand imitation stone composite material in the rural urbanization construction are studied. Research and analysis show that the new PVC/fine sand imitation stone composite material has more advantages in terms of comprehensive performance, use, cost, and appearance and has more application markets in rural urbanization.

5. Conclusions

Through the research and analysis of the results of the experiments and cases in this article, we have come to an important conclusion: With the continuous development of society, the process of rural urbanization is also developing rapidly, and China's urbanization rate increased during 2008-2015 alone, by 10%. The development of urbanization is indispensable to the construction of various infrastruc-

tures in cities and towns, and the new PVC/fine sand imitation stone composite materials have also played an indispensable role in these constructions. Our research shows that the compressive performance of the new PVC/fine sand imitation stone composite material is 400% higher than that of the traditional PVC material, and there has been a lot of improvement in the elasticity of the material. In the construction of urbanization, more use of new PVC/fine sand imitation stone composite materials can not only improve the reliability of the building, but also reduce the construction cost of the building. While the above conclusions are obtained in this paper, due to the limitation of time, energy, and processing conditions, there are still some imperfections in the experiment, which need to be further improved.

Sports events are an indispensable part of popularization and strong entertainment and can promote the physical and mental health of the people and the construction of cultural and spiritual civilization. Therefore, it is necessary to use a timer to record and analyze data during the game. In the traditional sense, the game timer is a fixed system. And now we can design sports event timer operations through mobile phones, computers, and other equipment to assist in the calculation of game time and competition. Ferroelectric memory is a kind of random access memory, which combines the fast read and write access of dynamic random access memory with the ability to retain data. Based on this, the ferroelectric memory timer proposed in this paper is intended to improve the accuracy and fairness of sports events. Therefore, this article has tested the function of the timer designed in this article by studying the ferroelectric memory and experimental construction and testing methods and finally concluded that the design is reasonable, but there is still a problem of data susceptibility. The experimental results show that there is a certain gap between the time interval measurement level of the timer and SR, the difference is 47 ps, the pulse width difference is controlled at 0.004, and the measurement uncertainty of timer interval is better than 60 ps. This shows that the timer can be applied, but it needs further improvement.

1. Introduction

Ferroelectric memory has the characteristics of small size and low power consumption. It has a wide frequency range used in sports competitions, mainly used for timing sports events, and can also be used as other equipment such as stylus pens and other physical sports counting tools. Its internal structure is relatively simple, the volume is relatively small, the performance is stable, and the anti-interference ability is very good. Large storage space, small size, and light weight are one of the main characteristics of ferromagnetic materials. This feature is also closely related to the application value: when used in sports timers, it can not only realize the data storage function but also effectively improve the efficiency of the game.

The sports event timer is a device that can record the time of the event. It consists of a display screen, buttons, and a timer. Count according to the time of the sporting event and display it on the display screen, so that you can visually see all the data recorded on the display. This not only improves work efficiency but also avoids erroneous actions. Specifically, it releases the clock information in real-time and accurately through the front-end multiseed clock equipment, so that the time of each intelligent system is centralized and synchronized. After the game is over, the statistics and analysis of the data in the game timer are also a technical method [1]. In order to achieve the structural optimization design of the sports game timer, it is necessary to implement its technical indicators on the software.

When the traditional timer is used for sports competitions, the data to be displayed is usually first input to the display and then displayed on the display. Although this has the advantages of intuitiveness and convenient operation. But to a certain extent, it will give people a feeling of cumbersome, inconvenient, and error-prone. So there are many researches on sports timers and ferroelectric memory. Memory allows

designers to write data to nonvolatile memory faster and more frequently at a lower price [2]. Among them, Li et al. took the FM28V100 ferroelectric memory model as the research object, conducted electron radiation experiments, and studied the damage law of the total radiation dose of the ferroelectric memory under different working methods and different radiation sources [3]. An'an et al. conducted an experimental study on the single-event effects of medium and high energy protons on two commercial ferroelectric memories and found that one of the devices exhibited single-event reversal and functional interruption under proton irradiation [4]. Feizhuan et al.'s traditional basketball game uses manual scoring or flops and uses a timer to complete the game timing. This timing and scoring involve many human factors, which affect the fairness of the game and the fairness of performance to a certain extent [5]. Pengcheng combined the NBA game rules and put forward a 24-second countdown overall plan for basketball games based on the AHDL language [6]. In order to overcome the shortcomings of existing microcontroller timer applications that cannot be paused or restarted, Kang describes a timer that uses external interrupts to pause or restart [7]. Xiaocheng et al. proposed the design requirements of basketball timers according to FIBA's requirements for the DE10_Lite timer and functions of Uniview Technology [8]. In sports events, the accuracy of the timer is a symbol of fairness in the arena. The ferroelectric memory has the characteristics of less interference, so it is a way of choice to apply it to the timer.

The innovation of this paper is to compare the advantages between them by studying the types of ferroelectric memory, ferroelectric film capacitors, ferroelectric storage technology, and structure and functional principles, then propose a sports timer based on ferroelectric memory, and carry out this system structure design and analysis. Through analysis and design and further experimental verification, the designed timers are compared in terms of pulse width and time accuracy. Thereby, the experimental data results and conclusions can be drawn.

2. The Structure Timer of Sports Event Timer Based on Ferroelectric Memory

2.1. Ferroelectric Memory

2.1.1. Classification of Ferroelectrics. Ferroelectric crystals include gallium arsenide, lamination, multijunction, and perovskite. Among all ferroelectric crystals, the perovskite structure is the most typical and common structure. Although it was later discovered that CaTiO3 is actually a twisted perovskite structure, the name still exists [9, 10].

2.1.2. Ferroelectric Film Capacitor. Ferroelectric film capacitors are a type of flat capacitors. Using the knowledge of dielectric physics, we know that the charge H stored in a capacitor can be expressed as

$$H = S \cdot C. \tag{1}$$

Among them, S is the area of the capacitor plate, and C is

the electric displacement vector in the ferroelectric film. The definition of electric displacement vector is

$$C = M(F) + \theta_0 F, \tag{2}$$

where F is the electric field strength (physical quantity indicating the strength and direction of electric field), and the θ_0 is dielectric constant. M is the polarization intensity, which is a nonlinear function of F. The electric field strength F can be expressed as

$$F = \frac{v}{t}, \tag{3}$$

where v is the voltage and t is the thickness of the ferroelectric film. The polarization intensity M can be expressed as

$$M(F) = \theta_0 \left(\theta_q(F) - 1 \right) \cdot F. \tag{4}$$

θ_q is the relative permittivity, which is also a function of the electric field F. Substituting formula (1) into formula (2) and taking into account that the relative permittivity of ferroelectrics is usually much greater than that, we can get

$$C(F) = \theta_0 \cdot \theta_q(F) \cdot F \approx \theta_0 \cdot \left(\theta_q(F) - 1 \right) \cdot F = M. \tag{5}$$

Substituting this approximate expression into equation (1), we can get

$$P = G_{\text{dip}} + G_F + G_g. \tag{6}$$

Formula (6) relates the microscopic physical quantity in the ferroelectric film to the macroscopic measurable charge quantity. Iron sheet structure film is composed of several grains with different sizes. The total free energy P of the polycrystalline film is composed of three parts. The surface depolarization field does work G_F, the domain wall pinning field does work G_g, and the dipole flips work G_{dip}, namely,

$$P = G_{\text{dip}} + G_F + G_g. \tag{7}$$

If the film is very thin and can only accommodate one layer of electrical domains, the polarization direction of the ferroelectric domains is perpendicular to the electrode and the orientation is the same, then:

$$F = -\frac{1}{\theta_0} M. \tag{8}$$

If the situation is a little more complicated, the polarization direction of the domains perpendicular to the interface will periodically change, and this distribution makes G_{dip} reach the minimum value. At this time, there are

$$G_F = \frac{\theta^* \cdot k \cdot M_0 \cdot v}{t}. \tag{9}$$

Among them, t is the thickness of the film, k is the width of the electric domain, M_0 is the polarization intensity in each electric domain, v is the volume of the entire film, and θ^* is a factor related to the dielectric constant. If the rolling work μ_{wall} is determined per unit area of the domain wall, the total work G_g done by the domain wall is

$$G_g = \frac{\mu_{wall}}{k} \cdot v. \qquad (10)$$

Combining formulas (9) and (10), there are

$$G_F + G_g = \frac{\theta^* \cdot k \cdot M_0 \cdot v}{t} + \frac{\mu_{wall}}{k} \cdot v. \qquad (11)$$

When formula (11) takes the minimum value, there are

$$k = \sqrt{\frac{\mu_{wall} \cdot t}{\theta^* \cdot M_0^2}}. \qquad (12)$$

From formula (12), the following conclusion can be drawn: as long as the polarization of the ferroelectric thin film is not zero, the ferroelectric domain width is a finite domain wall. Neither work nor domain width k will be 0 [11, 12].

2.1.3. The Structure and Function Principle of Ferroelectric Memory.
The function of storing data in ferroelectric memory is mainly completed by ferroelectric capacitors with thin-film ferroelectric materials as the carrier [13]. Generally speaking, ferroelectric materials do not contain "iron," but refer to ferroelectric crystals. Compared with traditional nonvolatile memory such as EEPROM and FLASH, ferroelectric memory has lower leakage current, because the data storage of ferroelectric memory is not carried out by free electrons, but by atomic polarization [14, 15]. When an electric field is applied to a ferroelectric crystal, the central atom inside the ferroelectric crystal will move and change with the distribution of the electric field. When the atom gains a certain amount of energy, the violent movement of free carriers in the crystal expands rapidly, causing the charge to collapse [16]. In this case, the polarization of the ferroelectric material is a certain function of the applied electric field. When the applied electric field disappears, the polarization of the ferroelectric material becomes stable, and the corresponding data information is stored in the ferroelectric crystal [17, 18].

Figure 1 shows the hysteresis loop block diagram of the ferroelectric capacitor and the block diagram of the ferroelectric memory. In (1), the abscissa represents the applied electric field, and the ordinate represents the polarization intensity. Figure (a) is a schematic diagram of 1T1C ferroelectric memory. Among them, the word line is connected to the gate of the transistor to control the turn-on and turn-off of the transistor. The bit line is connected to the source of the transistor. Figure (b) is a block diagram of 1T2C ferroelectric memory, the structure is similar to 1T1C ferroelectric memory [19, 20].

The manufacturing technology of ferroelectric memory integrates ferroelectric thin film process and traditional CMOS process. Ferroelectric memory not only includes a ferroelectric memory array that stores data but also includes CMOS peripheral circuits that amplify and read signals, control timing signals, and data latch functions [21, 22].

FRAM has many advantages and is suitable for embedded systems. It is a new type of memory with relatively mature industrialization technology. It can work in extreme environments and may replace Si-based devices that currently require heat preservation devices to be used in spacecraft or aerospace probes. In order to reduce launch costs or increase satellite functions, it is considered to have great potential for space applications. Compared with SRAM, although ferroelectric memory is not advantageous in terms of speed and price, from the perspective of the overall design, ferroelectric memory still has certain advantages. Ferroelectric memory is very resistant to electromagnetic radiation, elementary particle radiation, and nuclear radiation. They generally will not interfere with the stored information due to the radiation of a single charged particle, and they can withstand high dose rates of X-rays and neutrons and large total doses of radiation [23].

2.2. Sports Event Timer Based on Ferroelectric Memory.
The sports event timer based on ferroelectric memory is mainly composed of two parts: hardware circuit and software program. A simple circuit diagram is designed in the hardware part. First use a multimeter to measure whether the connection between each device and the microcontroller is correct. Then through the analysis of the data, the corresponding parameter values are obtained and displayed. At the same time, these variables can be converted into voltage signals and input to the PC terminal.

The sports event timer based on ferroelectric memory uses the digital pulse waveform to convert the data into the required signal through the analog circuit and then process it by the single-chip microcomputer. The output of the analog circuit is a sine wave, variance, time interval, and other parameter information; and in actual use, due to some uncertain factors that affect the final result, it will lead to large errors or inaccurate realization of moving objects within the measurement value range. And so on, digital integrated circuits can be used to complete data acquisition and control.

The working principle of ferroelectric memory is first, in the display, there is a sliding rheostat and two data drive boards. When a certain number appears on the display screen (red LED red light). Then connect the data line to the intermediate relay control module for data recording and storage; finally, the corresponding time, location, and other information will be displayed on the display screen for people's reference (including the time unit of sports events). The structure design of the ferroelectric memory mainly utilizes a sliding rheostat and two light-emitting diodes. The specific design is shown in Figure 2.

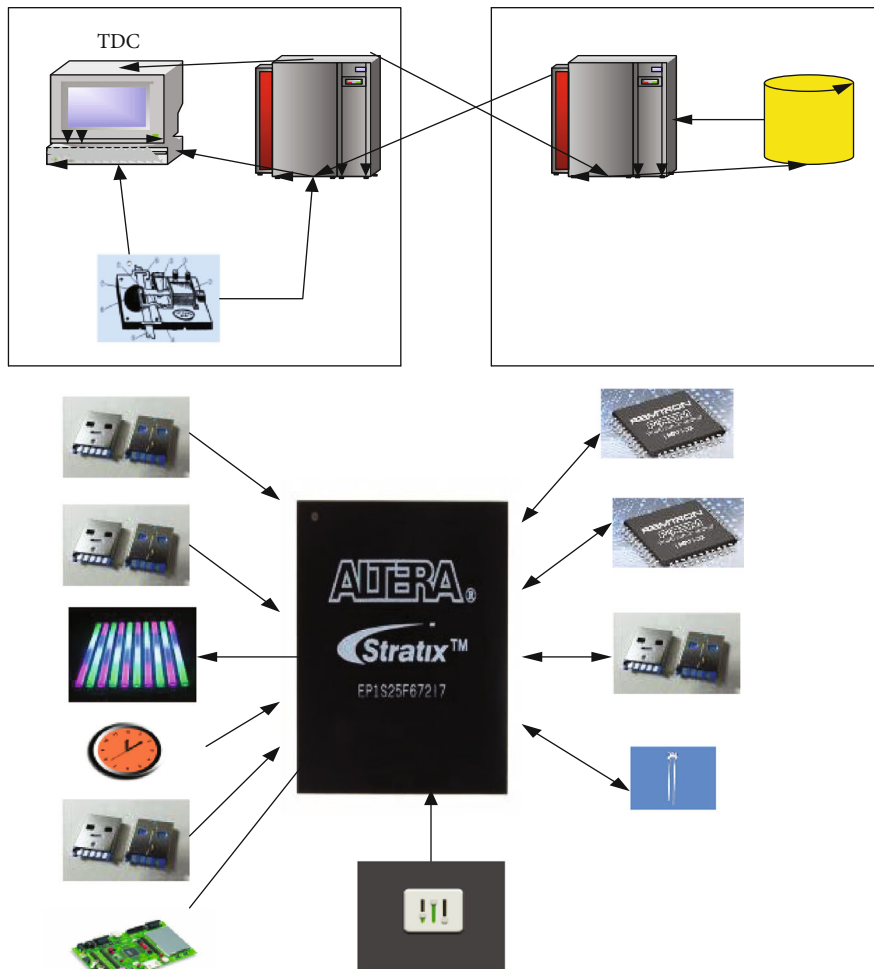
The game timer based on ferroelectric memory does not need to be modified in the program. First, it is simulated by software, and then, its function and implementation method
FIGURE 1: Electric circuit of ferrocapacitance and ferroelectric memory circuit structure.


FIGURE 2: Functional block diagram of Stratix FPGA development board.

are improved. When used, the display was found to be the same as the previous design. However, because there are many interference factors in the hardware circuit that affect the display effect of the display screen and cannot save the

data content information well; second, the software part does not add the corresponding module so that it can better utilize the functions of the PC to complete the accuracy index required by timer (for example: time and speed).

2.3. *Design of Two-Step Timer.* The two-step TDC is actually not a fixed circuit structure, but a TDC design idea that combines two TDC basic structures. Usually, two structures with complementary advantages are selected for design in the basic implementation structure of TDC. In order to take into account the time resolution accuracy and dynamic range of this subject, while completing the layout design in the smallest possible area, a combination of pulse counting TDC and delay line-based TDC was selected. The two-step TDC combines the advantages of the basic clock cycle counting method and the delay line-based TDC two timing methods and can achieve both dynamic range and time resolution accuracy. The "two-step" of two-step TDC has a dual meaning. The first meaning is expressed in the structure of the TDC. The start signal and the stop signal, respectively, represent the timing start signal and timing end signal of the TDC. The two-step TDC has a two-stage structure, namely, the fine interpolator and the coarse timer. These two modules are also the two most critical modules of the two-step TDC. They have their own division of labor when measuring the time interval to be measured.

Choosing a suitable delay unit is very critical for realizing the ideal time resolution accuracy of TDC. The structures of delay units that are often used include inverters, buffers, differential inverters, and switching inverters. The inverter has the greatest advantages in terms of structure, time resolution accuracy, and area. Regarding the delay line structure, the design challenge is to ensure the linearity of the circuit. The inverter structure is single-ended input and single-ended output, which is more sensitive to noise. Using an inverter as a delay unit is bound to introduce fine interpolator greater nonideal factors. Therefore, considering the structure, time resolution accuracy, area, and antinoise ability, a differential inverter is used as the delay unit.

Based on the Cadence platform, the simulation of the fine timer is carried out. A rising edge signal is input to the fine timer during simulation, and the rising edge signal passes through the delay unit on the delay line. The position of the rising edge will lag equidistantly on the time axis, and the simulation results are consistent with the theoretical analysis. At the same time, it can be seen that after the input rising edge signal passes through the delay line, there is a delay, and the delay of each delay unit is about 186 ps. Therefore, the designed two-step TDC fine interpolator has a time resolution accuracy of 186 ps and a dynamic range of 2 ns.

The coarse adjustment timer is a circuit that can record the number of clock cycles of the reference clock, that is, the pulse timer. A binary timer can be used in the specific circuit design. The basic unit of a binary timer is an edge-type flip-flop. Among them, if you want to realize the function of clearing the output state of the coarse adjustment timer, the trigger needs to be improved.

The two-step TDC uses a coarse adjustment timer to process the time to be measured that is an integer multiple of the reference clock period, while the residual time uses a 16-bit fine interpolator for processing. Its timing error sources are the timer and the interpolator.

The work of the two key circuit modules of the two-step TDC-the fine interpolator and the coarse timer is controlled by the edge signal. The signal propagates in the circuit and will inevitably be interfered by noise, parasitics, and other factors, which will cause the signal to be distorted. One of the most straightforward ways to optimize single-shot accuracy is to increase the frequency of the reference clock. Another way to improve the single input accuracy of TDC is to interpolate the residual time, where the residual time refers to the time less than one reference clock cycle, that is, the part of the time processed by the fine interpolator in the two-step TDC.

The overall block diagram and workflow of the hardware design are shown in Figure 3. The hardware of this system includes single-chip microcomputer MSP430F149 and its peripheral circuit parts (reset circuit and clock crystal oscillator), relay part, independent button part, display part, and drive circuit part. The whole circuit is controlled by the single-chip MSP430F149; the key control mode, time, and step are driven by ULN2803; and the corresponding data is displayed on the LCD12864 display.

Driven by the clock circuit, the single-chip microcomputer can run normally and stably, mainly because of the operation of the clock circuit, which helps each component of the single-chip microcomputer to perform its own work well. This kind of operation among them is automatic. The clock circuit uses pulse signals to satisfy the operation of the hardware part. In order to proceed with the work progress of the circuit from the initial state, it is necessary to make the core parts of the system in the initial state.

For the clock circuit, from the point of view of the microcontroller, the significance of the clock circuit is to provide a signal that the circuit system can perform stably, and this signal is timed. In order to achieve such a state, two parts are required, one part is that the other part of the crystal oscillator is a matching peripheral circuit, and the so-called timing time is the timing clock of the system. Time is the timing clock of the system. The clock circuit is an oscillator, which provides a beat to the single-chip microcomputer. The single-chip microcomputer must perform various operations under the control of this beat. Therefore, the single-chip microcomputer will not work normally without a clock circuit. The clock circuit itself does not control anything. The clock circuit helps the microcontroller to work in a stable state. The subsystem clock, auxiliary clock signal, and main clock signal provide signals for the MSP430F149 microcontroller. The subsystem clock provides services for some peripheral high-speed operating circuit modules, the auxiliary clock signal provides services for some peripheral low-speed operating circuits, and the main clock signal is a normal circuit module operating in a stable state.

3. System Testing and Analysis

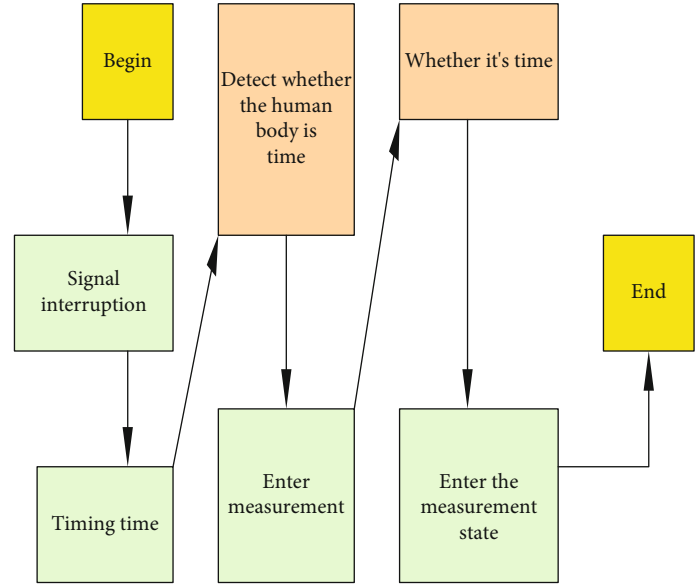
After the system design is completed, it is necessary to build an experimental platform to evaluate the performance of the system. First, it introduces the experimental testing methods and evaluation indicators used in this article. Then select the


Figure 3: Overall block diagram and workflow of hardware design.

Table 1: Timer comparison with SR540 data results.

Time	Calculagraph	SR540	Time interval	Standard deviations
0	506.67	506.42	57.6/10.2	0.0562
1800	506.73	506.43	57.5/9.9	0.0573
3600	506.75	506.45	57.3/10.3	0.0596
5400	506.81	506.46	56.6/9.8	0.0654
7200	506.79	506.44	57.2/9.4	0.0725
9000	506.75	506.43	56.6/9.3	0.0849

signal source to test the accuracy of the timer's measurement. Finally, test the timer's time interval and pulse width measurement functions separately, use the test data to evaluate the performance indicators of the timer, and analyze the problems in the timer.

3.1. Test Method. The test platform with design specifications can make the test results more credible and provide a better reference for practical applications. In the field of time interval measurement, comparison method and fixed time interval measurement method are two commonly used test methods.

The comparison method is to use different measuring instruments to test the same signal source at the same time under the same external environment. The signal to be measured and the reference time are both generated by the same clock source and then transmitted to the measuring instrument through the same path, and the measurement is performed at the same time. This series of operations emphasizes the "same source." Then compare the measured results. In order to measure the performance of the developed measuring instrument, another instrument with very excellent performance is usually required. In this test platform, the measurement result of the SR540 time interval

timer with the best performance in the field of time measurement is selected as a reference for comparison.

The fixed time interval test method is to use the time interval measurement timer to measure the signal source to produce a fixed time interval without considering the cable and device delay. This method is simple to operate, and the result is more intuitive, but the signal quality of the signal source is very high. However, the accuracy of the time-to-digital conversion circuit is getting higher and higher, and the requirements for the signal source are getting higher and higher. At present, it is difficult to find a suitable signal source for testing in many cases. For this reason, this test platform does not design the realization of the fixed time interval test method separately but adopts the combination of the above two methods.

This platform uses the SR540-Timer universal time interval measurement device to compare with a channel of the timer, uses the 10 MHz signal generated by the National Time Service Center Clock Tower as the reference signal of the timer and the time base SR540, and then compares the time base of the 1 pps signal. The pulse distribution amplifier generates two signals to be measured, and each signal is sent through three channels and then sent from the other output terminal of the SR540 and the timer; the timer is connected to send the measurement results to the upper computer for processing. Different cable lengths can set different time intervals.

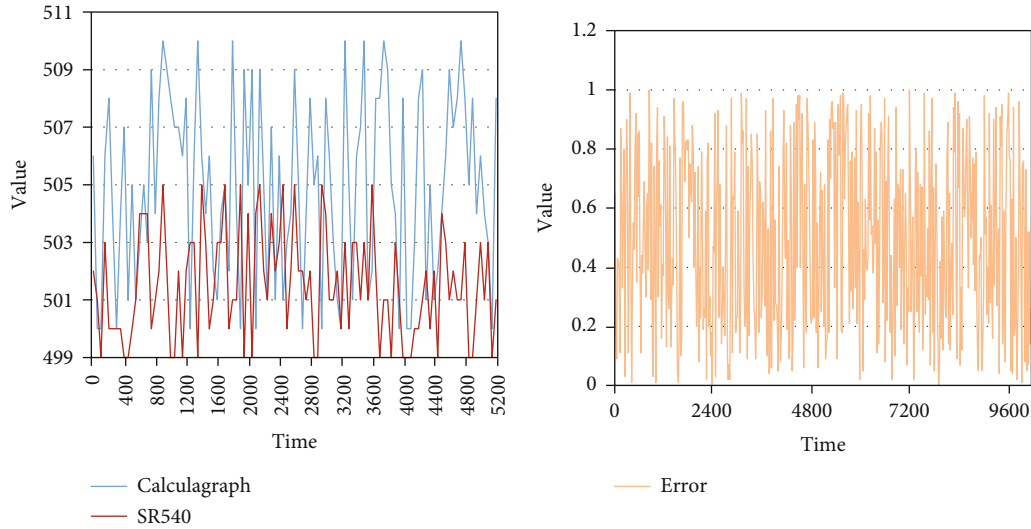
3.2. Evaluation Index. To design a measurement system, it is usually necessary to give the actual performance of the system, and scientific evaluation indicators are needed to evaluate the performance. In the field of time-frequency measurement, it is generally necessary to give the two indicators of system measurement deviation and measurement accuracy. Measurement deviation is usually affected by the stability of the time base, internal noise, trigger noise, and


FIGURE 4: Alignment of timer and SR540 measurements and error plots.

TABLE 2: Timer and SR540 pulse width measurement contrast and error value.

Time	Calculagraph	SR540	Error
0	204.859	204.857	0.41
1000	204.857	204.856	0.45
2000	204.856	204.852	0.44
3000	204.86	204.854	0.56
4000	204.856	204.855	0.47
5000	204.854	204.853	0.45
6000	204.852	204.854	0.53
7000	204.853	204.856	0.46
8000	204.854	204.856	0.55
9000	204.855	204.857	0.5

uncertainty within the system. This concept is considered more when the "absolute" value of the measurement is more important. This paper uses the standard deviation of the experimental data to characterize the measurement accuracy of the system. This is because the designed test platform mainly uses the delay line test method, that is, two delay lines of different lengths and different delays are used to send the signal to be measured into the measurement. The channel is tested. Two different delay lines produce a fixed time interval, but the exact true value of this interval cannot be determined, so it is more appropriate to use the standard deviation as an evaluation index of measurement accuracy. The standard deviation is usually a statistic used to characterize the degree of dispersion of the system measurement value relative to the mean value.

3.3. System Test. First, analyze and evaluate the accuracy of the system measurement. Test the time interval measurement function of the timer. When measuring, the reference clock uses the 10 MHz frequency signal of the clock room of the National Time Service Center. The signal to be mea-

sured is 1 pps. The signal is delayed by a length of 100 m extension cable. The timer generally has 2-4 measurement channels, which will trigger sr540, so as to adjust the level to be consistent with the trigger level of this system.

Evaluate the accuracy of the system measurement. In the actual test, the measurement value of the SR540 can be regarded as the true value based on the test method of the comparison method, and the timer and the SR540 can be measured synchronously. Subtract the value of to get the difference between the two, which can be regarded as the accuracy of the system.

When measuring the pulse width, first, when configuring the chip, set the function to pulse width measurement, that is, configure the value of configuration register 1 to 2 f. In actual measurement, TDC-GPX2 internally connects measurement pins 1 and 3 (or 2 and 4) to an input pin (STOP1 or STOP2). The rising edge is measured by channel 1 (or 2), and the falling edge is measured by channel 3 (or 4). Then make the difference of the measurement result to get the value of pulse width.

4. Analysis of Test Results

4.1. Time Interval Measurement Performance Test. Calculate the measurement results and summarize the results with Table 1. The experimental value takes 2.5 hours of synchronized measurement results and then statistics on this measurement result. From the standard deviation statistical results, it can be seen that the timer measurement interval accuracy is 56.3 ps, and the SR540 measurement interval accuracy is 9.3 ps. It can be shown that the time interval timer can achieve a single measurement accuracy better than 60 ps, which has reached a relatively good level, but there is still a certain gap with SR540.

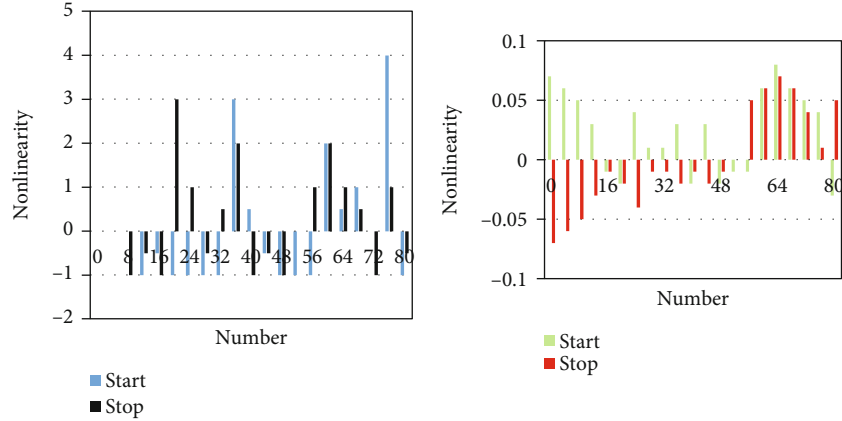
As shown in Figure 4, to evaluate the accuracy of the system measurement, in the actual test, the measurement value of the SR540 can be regarded as the true value based on the test method of the comparison method, and the value


Figure 5: Start and stop differential integral nonlinear error results comparison.

VCTRL	26°C, 3 V		-50°C, 3 V	
	F	K	F	K
1	423		409	
1.2	463		432	
1.4	694		676	
1.6	789	649	767	752
1.8	892		865	
2	1100		1005	
Figure 6: Probability distribution of measurement results.

measured by the timer and the SR540 synchronized measurement is subtracted. The difference between the two can be regarded as the accuracy of the system. It can be seen from the data that the accuracy test in two ways can ensure that the deviation of the system measurement is less than 495 ps.

4.2. Pulse Width Measurement Performance Test.
In terms of measurement accuracy, the measurement result of this function is still compared with the pulse width measurement result of SR620. The pulse width to be measured is the 1 pps signal of the clock room of the National Time Service Center, and the reference clock is the 10 MHz signal of the clock room. This paper randomly selects 10 data for analysis, as shown in Table 2.

In Table 2, the error is controlled below 0.6, and the pulse width measurement range is around 204.85. Among them, the timer is not much different from the SR540, and the performance basically meets the standard requirements.

4.3. Differential and Integral Nonlinear Error Test.
As shown in Figure 5, we can see the result of the differential nonlinearity error of a delay line (start), where the maximum value is 4 LSB and the minimum value is -1 LSB, where 1 LSB = 189.4 ps. It is the differential nonlinearity error of another delay line (stop), the maximum value is 3 LSB, the minimum value is -1 LSB, and 1 LSB = 173.6 ps. Start delay line's integral nonlinear error, the maximum value is 0.08 LSB, the minimum value is -0.03 LSB, and the average value of integral nonlinear error is 0.014 LSB, of which 1 LSB = 189.4 ps. The integral nonlinear error of the stop delay line, the maximum value is 0.07 LSB, the minimum value is -0.07 LSB, and the average value of integral nonlinear error is -0.03 LSB, where 1 LSB = 173.6 ps.

4.4. Oscillator Distribution Requirements.
Changes in temperature and process will affect the frequency range of the output clock signal of the circuit. In order to ensure that the frequency of the output clock signal of the circuit can reach the design value, it is usually desirable to have the oscillator tuning range within the system frequency requirement range. The details are shown in Table 3.

When the temperature changes from low to high, the threshold voltage becomes smaller and Kvco decreases. The output frequency of the oscillator increases with the increase of its control voltage, which meets the theoretical requirements.

4.5. System Multichannel Measurement Conformance Test.
This timer can measure multiple channels at the same time, so test the consistency of the measurement of different
Figure 7: Multichannel measurement result distribution.

channels of the system. In this test, the second, third, and fourth channels are used to test the 100 m extension cable. Channel 2 is connected to the 1 pps signal output by the pulse distribution amplifier. Analyzing the multichannel calculation data, we get Figures 6 and 7.

It can be seen from Figure 6 that in a set of data, the fine measurement value and the final measurement result are normally distributed, indicating that the source of error in this measurement is mainly random error, but the single-channel fine measurement value is not very standardized. The normal distribution indicates that the measurement results are affected by errors other than random errors. But the final measured value still shows a more standardized normal distribution.

As shown in Figure 7, it can be seen from the statistical results of the standard deviation that the 3-channel measurement accuracy is 46.7 ps, and the 4-channel measurement accuracy is 33.2 ps. The measurement consistency of each channel is better, and the measurement accuracy is better than 50 ps. The results show a normal distribution, which further shows that the main source of noise that causes system measurement errors is random noise.

5. Conclusion

The ferroelectric memory is mainly composed of a data register, two counting units, and four output modules. The core of the device is a block circuit for timing, which includes a display, buttons, buzzer alarm indicator, and other components. During sports games, ferroelectric memory chips are used as carriers to transmit the sports event time information to the processor and save it. Then according to the program control the LED light to turn on or off the required sports data register to display the current time and start date, the end of the game, the results after the game, and the summary number after the game. Determine the size of each part and the connection relationship between each component according to the parameter values such as the movement time label and time as a reference basis. This article mainly uses the time interval measurement method and the experimental comparison method to study the equipment accu-

racy of the ferroelectric memory in the system in the sports timer. Through various experimental investigation results, it is concluded that the measurement uncertainty of the timer interval designed in this paper is better than 60 ps, the measurement data is accurate and reliable, and the signal pulse width measurement performance can be consistent with the international leading measurement equipment SR540. The timer in this article has certain fluctuations in the measurement result of the frequency signal, and its performance is not ideal. It needs to be processed by a suitable filtering algorithm to improve the frequency measurement accuracy of the timer.

This paper is focused on developing composites using kenaf fibers, epoxy polymer, and incorporation of graphene fillers. The kenaf fibers are treated with 5% NaOH to remove the hydrophilic nature and reinforced it with the hydrophobic matrix. The composites are fabricated using the compression moulding technique by keeping 60 wt.% epoxy as constant, and the graphene and kenaf fiber weights are changed accordingly. The samples for tensile, flexural, impact, hardness, and water absorption tests are prepared as per the ASTM D3039, D790, D256, D2240, and D572 standards, respectively. The effect of graphene fillers in the 5% NaOH-treated kenaf fibers reinforced with the epoxy matrix is tested. Among the various samples, sample 4 which has 6% graphene addition in the epoxy matrix reinforced with 5% treated kenaf fiber displayed the highest tensile strength of 63 MPa, flexural strength of 97 MPa, impact strength of 9.56 kJ/m^2, hardness value of 97, and lower water absorption of 5.13%. This is due to the proper dispersion of graphene fillers in the matrix which caused better interfacial adhesion between the fiber and matrix. The water absorption test showed the lowest value in sample S5 as the graphene fillers obstruct water penetration in the fibers. SEM analysis is done on the prepared samples to study the surface flaws and structural changes.

1. Introduction

The usage of synthetic fibers has created many threads to the environment which prompted the researchers to search for an alternative material. Natural fibers diminish ecological risks, and they can be used as a composite by reinforcing it with the polymer matrix [1]. Researchers have worked on natural fibers to identify their expanded applications and benefits. Natural fibers can be obtained from plants, animals, and a mineral base. Plant fibers as reinforcement material play a prominent role in developing natural fiber composites [2–4]. Among the plant fibers, bast and leaf fibers provide good mechanical properties because of their stiffness and hard structure. Generally, plant fibers can be divided into the primary cell wall and secondary cell wall. The primary cell wall comprises disordered cellulose, hemicellulose, lignin, pectin, etc. The secondary cell wall has crystalline cellulose in which S2 cell is responsible for mechanical properties. Hemicellulose acts as a matrix material that surrounds the cellulose structure, and lignin provides extra strength by protecting the fiber from external damage. This makes the cellulose have strength and stiffness. As the cell divides, the

cellulose and lignin amount rise, but the polyose content remains the same throughout [5–7]. The properties of natural fibers when reinforced with polymer matrix includes fiber content, orientation, microfibrillar angle, the interfacial bond between the fiber and matrix, and high water content [8]. However, when plant fibers get reinforced with the hydrophobic matrix, it results in poor bonding leading to less mechanical properties. This is because hemicellulose absorbs more water content from the atmosphere and forms new hydrogen bonds on the surface which makes the fiber to be hydrophilic. This hydrogen bond formation can be reduced by treating the fibers chemically with different processes. In addition to this, the components such as lignin, pectin, wax, and oily substances will be removed to a better extent, and it will result in enhanced stability of the fiber [9–11]. The properties that impact the influence between the fiber and matrix are expressed as follows: (i) proper mating of two unique materials, (ii) dispersion of fiber content in the matrix, (iii) orientation of fiber, and (iv) better surface interaction. Upon treating the fibers with different treatment processes, the mechanical properties of composites get enhanced by reduced water intake and better interfacial adhesion [12–14]. Sreenivasan et al. [15] reported that potassium permanganate-treated short Sansevieria cylindrica-reinforced polyester composites showed minimum water intake when compared to other treated fibers. Mylsamy and Rajendran [16] studied the effect of alkali treatment and optimum treatment percentage on agave Americana fibers. The optimum treatment is found to be 5%, and the treated fiber reduced the noncellulosic components and thereby enhanced the tensile property of the fiber. This is in line with the author. The mechanical and tribological properties can further be enhanced by incorporating fillers with the polymer matrix [17]. Fillers are additive materials that are used to enhance wear resistance, thermal stability, and flame resistance. The property of filler depends on its size, aspect ratio, and chemical composition. Ganesan et al. [18] assessed the effect of nanoclay filler and eggshell powder on the mechanical properties of jute fiber/polyester composite. The author concluded that the incorporation of filler enhanced the mechanical properties of the composite even if it is not chemically treated. The NaOH-treated jute fiber reinforced with eggshell powder (1.5%)+nanoclay (1.5%)/polyester matrix showed the highest flexural strength of 39.52 MPa than the untreated fiber. The increment is due to filler addition which hindered the formation of crack. Venkateshwar et al. [19] investigated the effect of different fillers (Al_2O_3, $CaCO_3$, and TiO_2) on the influence of mechanical properties of Prosopis juliflora epoxy-reinforced composites. The author reported that Al_2O_3 filler mixed uniformly in the matrix which resulted in enhanced bond strength. Benin et al. [20] concluded that Prosopis juliflora/epoxy composites with 12% barium sulfate filler provided superior mechanical properties. This is because the fillers and matrix remain bonded properly. Banyan fiber reinforced with 4% graphene incorporation in the epoxy matrix showed a higher tensile strength of 40.6 MPa and flexural strength of 163.23 MPa. This increment is due to the proper dispersion of graphene fillers in the matrix [21].

Nanofillers for instance graphene and carbon nanotubes have been proven to enhance the mechanical properties and reduced the water absorption content in the composites [22, 23]. For this experimental work, kenaf fiber (*Hibiscus cannabinus*) has been preferred because of its ability to produce in various environmental circumstances [24]. A study demonstrated that kenaf fiber can be used to create panels for furniture, seats, and armrests. It was also suggested that kenaf-reinforced composite materials might be used as noise obstacles and sound dampers [25]. This experiment work highlights the significance of incorporating graphene as a filler material in 5% alkali-treated kenaf fiber-reinforced epoxy composites. The above combination has not been reported in any literature data. The major purposes of the paper are expressed in the following ways: (1) effect of 5% NaOH treatment on kenaf fibers, (2) addition of graphene fillers with various proportions (0%, 2%, 4%, 6%, and 8%) in the matrix, (3) examining the mechanical and water absorption properties in the prepared composites, and (4) analyze the surface morphology of the prepared samples using SEM.

2. Materials

Kenaf fibers were purchased from KCT, Tifac core, Coimbatore, India. Epoxy resin (LY 556) and hardener (HY 951) are chosen as matrix material, and it has been collected from Covai Seenu & Company Coimbatore, Tamil Nadu. As per the manufacturer's suggestions, it is mixed in the ratio of 10 : 1. The resin and hardener are combined to generate a chemical effect that turns the liquid stage into a solid [26, 27]. Graphene as a filler material is added to the matrix material with various proportions (0%, 2%, 4%, 6%, and 8%).

2.1. Treatment of Kenaf Fibers. Kenaf fibers are immersed in 12 litres of distilled water for 1day to eliminate the unwanted particles residing on them. Later, the fibers are left to dry in the air for 24 hours. Dried kenaf fibers are soaked in 5% NaOH to remove the hydrophilic nature to a better extent. This 5% NaOH composition is 60 ml of NaOH in 12 litres of water. Treated kenaf fibers are washed thoroughly in distilled water to remove the additional NaOH present in them. Then, the fibers are left to dry in the air for 1day.

2.2. Fabrication of Graphene-Filled Composites. The treated kenaf fibers were cut into 30 cm length with the help of a cutter based on the moulding constraints. Graphene filler and epoxy resin cannot be mixed thoroughly as the resin chosen is highly viscous. To avoid this constraint, the graphene powder was scattered into the epoxy resin and then whisked for a prolonged period of 40 min at 80°C. Then, the hardener was added to the graphene/epoxy mixture in the ratio of 10 : 1. Aluminium plates of dimension 300 ∗ 300 ∗ 5 mm are chosen for the compression moulding process (Supplier: Modern Plastics Pvt Ltd., Coimbatore, India). To obstruct heating of the plates, white grease is applied to them. For sample 1, the epoxy resin along with the hardener was poured on the surface of the aluminium plate, and then,

the 5% NaOH-treated kenaf fibers are placed above the resin mixture in a unidirectional way. Then, the epoxy resin along with the hardener was poured above the fiber. For other samples, it was prepared by the addition of graphene fillers (2%, 4%, 6%, and 8%) into the epoxy resin, and the same process is repeated as mentioned above. The prepared laminates are processed in the compression moulding machine, and they are kept at a temperature of 130°C, with a pressure of 35 bar for 45 minutes. Later, the laminates are left for the curing process for 50 minutes. With the help of a diamond cutter, the final laminate of dimensions (300 ∗ 300 ∗ 5 mm) is removed from the mould. The prepared laminated can be tested mechanically as per the ASTM standard. Table 1 shows the composition of the prepared sample.

2.3. Physical and Mechanical Tests

2.3.1. Tensile Test. It is one of the mechanical tests to determine the material behaviour under applied load. The samples are prepared as per the ASTM D3039 requirement with a dimension of 250 ∗ 25 ∗ 5 mm and a crosshead speed of 2 mm/min [28]. It was tested in a computerized universal testing machine (Supplier: Aimil Ltd., India). Before the testing process, the samples are mounted onto the machine, and utilizing a hydraulic system, they are gripped to avoid dislocation. The value of each sample tested is noted. A total of three samples were tested in each composition, and the average value is taken for the analysis.

2.3.2. Flexural Test. This test determines how much a material will bend under the applied load. The samples for this test are prepared as per the ASTM D790 requirement with a dimension of 125 ∗ 12.7 ∗ 5 mm and a crosshead speed of 2 mm/min [10]. It was tested in a computerized universal testing machine, and the values for each sample are recorded. A total of three samples were tested in each composition, and the average value is taken for the analysis.

2.3.3. Impact Test. This test determines how much a material can absorb toughness during the applied load. The samples for this test are prepared as per the ASTM D256 requirement with dimensions of 65 ∗ 12.7 ∗ 5 mm [10]. It was tested using digitalized Izod impact test, and the values for each sample are taken. A total of three samples were tested in each composition, and the average value is taken for the analysis.

2.3.4. Hardness Test. This test determines how much a material will experience localized deformation under mechanical indentation or scratching. The samples for this test are prepared as per the ASTM D2240 requirements with dimensions of 20 ∗ 20 ∗ 5 mm [10]. Shore D durometer is used to test the samples. At 6 different locations, the indentations were made, and the mean values are noted.

2.3.5. Water Absorption Test. The resistance to absorbing water is tested using this test. The samples are prepared as per the ASTM D572 requirements with dimensions 64 ∗ 12.7 ∗ 5 mm [29]. The samples are immersed in distilled water for 5 days at room temperature, and the changes are

TABLE 1: Composition of the prepared samples.

Sample number	Kenaf fiber (wt.%)	Epoxy resin (wt.%)	Graphene (wt.%)
S1	40	60	0
S2	38	60	2
S3	36	60	4
S4	34	60	6
S5	32	60	8

noted accordingly. After a certain interval of time, the samples are taken out and wiped with a cloth, and then, the weight of the sample is measured. The amount of water absorbed in a sample is determined using the below-mentioned formula, where W_b represents the final weight after immersion, W_a indicates the initial weight of a sample, and W shows the percentage of water absorbed.

$$W = \frac{W_b - W_a}{W_a} * 100. \tag{1}$$

2.4. SEM Analysis. A scanning electron microscope was used to analyze the surface flaws and structural changes of the prepared samples using SEM JEOL JSM-6510LA. For this technique, the operating voltage is 25 kV.

3. Result and Discussion

3.1. Tensile Strength. Tensile values of each composite under various loads are presented in Figure 1. 6 wt.% Gr fillers reinforced in treated kenaf/epoxy composite showed a maximum value of 63 MPa, and 0 wt.% Gr fillers showed the minimum value of 36 MPa. With the addition of Gr fillers, the tensile strength increased, and beyond a certain limit, it begins to decline. Sample S4 which have 6 wt.% Gr fillers proved to have maximum tensile strength and optimum content. This value is obtained because of the nature of graphene incorporated as a filler material. Graphene fillers obstruct the water molecules to penetrate the fiber, thereby creating proper bonding between the fiber and matrix. Graphene filler has a strong C-C bond which makes it difficult to rearrange its positions resulting in brittle nature [30]. Furthermore, the 6 wt.% Gr reinforced in treated kenaf/epoxy composite bonded properly, and graphene particles are dispersed uniformly in the matrix, thereby enhancing tensile strength than other Gr variations. 6 wt.% Gr fillers provided better interlocking with the fiber-matrix adhesion, and when stresses are applied, it is distributed evenly in the composite [31]. In sample S5, 8 wt.% Gr fillers reinforced in treated kenaf/epoxy composite showed a tensile strength of 58 MPa which is greater than 0 wt.% Gr, 2 wt.% Gr, and 4 wt.% Gr fillers samples and less than 6 wt.% Gr filler sample. With an increase in Gr fillers, the agglomeration of particles tends to take place, and crack propagation will not occur which indicated that the addition of graphene fillers makes the composite resulting in enhanced brittleness instead of higher tensile strength [21]. 8 wt.% Gr fillers will undergo a necking process within a short duration, and the
FIGURE 1: Tensile strength of graphene-filled kenaf/epoxy composites.

FIGURE 2: Flexural strength of graphene-filled kenaf/epoxy composites.

material breaks rapidly because of the brittle nature of graphene. 4 wt.% Gr fillers showed a value of 56 MPa which is greater than 0 wt.% Gr and 2 wt.% Gr and lower than 6 wt.% Gr and 8 wt.% samples. This decrement is because this concentration is not sufficient to hinder void formation in the matrix when compared to the 6 wt.% Gr filler sample [32]. 2 wt.% Gr filler sample showed a tensile strength of 41 MPa which is greater than 0 wt.% Gr and lesser than other graphene samples. This concentration reduced void content comparatively less than other Gr samples. In sample S1, the kenaf fibers are treated with 5% NaOH, and it is reinforced with epoxy resin to remove the noncellulosic contents to a good extent. The tensile strength of 32 MPa is attained due to the removal of impurities. 5% NaOH effectively removes this, but some constituents tend to degrade and created a void in it resulting in ease of water penetration also decrease in tensile strength.

3.2. Flexural Strength. The values of each sample for the flexural test are presented in Figure 2. Sample S4 displays the highest flexural strength of 97 MPa followed by sample S5 (94 MPa), sample S3 (89 MPa), sample S2 (73 MPa), and sample S1 (67 MPa). Sample S4 showed the highest flexural strength because the 6 wt.% Gr fillers with the matrix enhanced the bonding in the interface, thereby promoting better load sharing capability. Also, 6 wt.% graphene addition proved to be an optimum concentration because the fillers are dispersed uniformly in the matrix, thereby reducing holes and enhancing the flexural properties. 8 wt.% Gr fillers in sample S5 showed flexural strength of 94 MPa which is lower than sample S4 and higher than all other samples. This is due to the reason that 8 wt.% Gr fillers caused agglomeration in the matrix; also when reinforced with treated kenaf fiber, it resulted in improper interfacial bonding between the fiber/matrix. With 8 wt.% Gr addition, the flexural property of the composite starts to decline because of delamination between the layers. Also, 8 wt.% Gr fillers did not disperse throughout which caused some
debris in that region, and when the load is applied, the sample showed lower flexural properties and enhanced brittleness of the composite [21]. 4 wt.% Gr and 2 wt.% Gr fillers in samples 3 and 2 are insufficient to hinder void formation causing fiber pull-out in the surface and resulting in lower flexural strength of value 89 MPa and 73 MPa when compared to 6 wt.% Gr and 8 wt.% Gr filler samples, respectively. In sample S1, treated kenaf fibers removed the hydrophilic nature in the fiber and have been well bonded with the matrix. But the load distribution did not occur evenly in the composite because of the microgaps present in it leading to a decrease in flexural strength of a value 67 MPa when compared to other varying Gr filler samples.

3.3. Impact Strength. It determines how much a material can absorb energy under applied load. The values of each sample for this test are displayed in Figure 3. Sample S4 showed maximum impact strength of $9.56 \, \text{kJ/m}^2$ and minimum impact strength of $4.85 \, \text{kJ/m}^2$. 6 wt.% Gr fillers in sample S4 showed the highest impact strength ($9.56 \, \text{kJ/m}^2$) as 6 wt.% graphene addition absorbed more energy before the inception of brittle behaviour. This is because the optimum concentration of graphene into the matrix resulted in better interlocking between the fiber and the matrix. The increase in impact strength depends on factors like the toughness of the composite, compatibility between the fiber and matrix, and proper dispersion of filler material into the matrix [21]. 4 wt.% Gr fillers in sample S3 showed an impact strength of $7.32 \, \text{kJ/m}^2$ which is higher than 8 wt.% Gr filler samples. 4 wt.% Gr fillers absorbed more energy than 8 wt.% Gr fillers, and this is due to the fact that 4 wt.% Gr fillers did not make the composite crack easily, whereas the addition of Gr fillers beyond 6 wt.% made the composite embrittle. 8 wt.% Gr filler in sample S5 showed an impact strength of $7.18 \, \text{kJ/m}^2$ which is greater than 0 wt.% Gr and 2 wt.% Gr and less than 6 wt.% Gr and 4 wt.% Gr filler samples. This is due to the agglomeration of graphene particles in the matrix region which caused the composite to lose its
FIGURE 3: Impact strength of graphene-filled kenaf/epoxy composites.

FIGURE 4: Hardness values of graphene-filled kenaf/epoxy composites.

ductile nature and hence resulted in a reduction in impact strength. 2 wt.% Gr filler in sample S2 showed an impact strength of 6.65 kJ/m^2 which is lower than 6 wt.% Gr, 4 wt.% Gr, and 8 wt.% Gr fillers and greater than 0 wt.% Gr filler sample. This is due to the reason that 2 wt.% Gr did not hinder the void formation as compared to 6 wt.% Gr, 4 wt.% Gr, and 8 wt.% Gr filler samples. Sample S1 which has 0 wt.% Gr filler showed the lowest impact strength of 4.85 kJ/m^2 when compared to all other Gr fillers with varying samples. This is because when it is treated, the fibers are split into smaller ones making it withstand load, but the microgaps which are present in the composite led to a reduction in lower impact strength.

3.4. Hardness. It will determine how much a material can withstand penetration depth when the load is applied to it. If the material is brittle, then the hardness will be more [21]. The hardness value of each sample is displayed in Figure 4. 8 wt.% Gr filler in sample S5 showed a maximum hardness value of 97, and 0 wt.% Gr in sample S1 showed a lower hardness value of 56. 8 wt.% Gr filler in sample S5 showed a higher hardness value because the brittle nature of graphene particles also resisted penetration when the load is applied on it when compared to all other samples. 6 wt.% Gr filler in sample S4 showed a hardness value of 89, and this is greater than 0 wt.% Gr, 2 wt.% Gr, and 4 wt.% Gr fillers and also lesser than 8 wt.% Gr filler samples. 6 wt.% Gr filler showed uniformed dispersion of graphene in the matrix and enhanced the interfacial bonding between the fiber/matrix, but the addition of more graphene fillers showed resistance to penetration. 4 wt.% Gr filler in sample 3 showed a hardness value of 81 which is greater than 0 wt.% Gr and 2 wt.% Gr and lower than 8 wt.% Gr and 6 wt.% Gr filler samples. 4 wt.% Gr filler did not lock the void formation resulting in fiber pull-out from the surface which resulted in lowering of hardness value. In the sample S2, 2 wt.% Gr filler in the matrix is not sufficient to increase the hardness
FIGURE 5: Water absorption of graphene-filled kenaf/epoxy composites.

value, so this composite displayed a hardness value of 69 which is higher than 0 wt.% Gr filler but higher than other Gr filler samples. The treated kenaf fibers reinforced with epoxy matrix in sample S1 showed a hardness value of 56 which is lower than all other Gr filler samples. 5% NaOH-treated kenaf fibers provided a rough surface, so the sample resisted penetration initially, but after a certain period, it failed because of some hydrophilic nature in the fiber.

3.5. Water Absorption Tests. This test is used to determine the hydrophilic nature of the fibers. The values of water absorption tests for all samples are displayed in Figure 5. Sample S5 which have 8 wt.% Gr filler reinforced in treated kenaf/epoxy composite showed more resistance to water absorption than other samples. Graphene plays an obstacle

(a)

(b)

(c)

(d)
Figure 6: (a–d) represents SEM images for various concentration of graphene filler reinforced in treated kenaf/epoxy composite.

in transporting water to the composites [22]. With the addition of graphene fillers, the void content is minimized, thereby locking it with the matrix and leading to better interfacial adhesion between the fiber and matrix. Due to this reason, the water absorption test displayed lower valves. Sample S1 showed high water absorption of 10.56% when compared to all other Gr filler samples. The kenaf fibers are treated with 5% NaOH to remove the impurities and noncellulosic content like hemicellulose and pectin, and then, it is reinforced with epoxy resin. Even after treating the kenaf fiber, it possesses some hydrophilic nature and void content. With 2 wt.% Gr addition in sample S2, the gaps present in the matrix are removed partially, and some holes allowed the fibers to interact with water molecules, thereby absorbing water content. Sample S2 showed a water absorption value of 9.72 than sample S1 but higher than all other Gr filler samples. The addition of graphene fillers resisted water penetration by locking the void formation. In sample S4, 6 wt.% Gr addition resisted water absorption as the concentration of filler addition locks the void from interacting with the water molecules. 6 wt.% Gr filler showed a value of 5.22 which is lower than sample S5.

3.6. SEM Analysis. Figure 6(a) represents the SEM image of sample S1 which consists of 5% NaOH-treated 40 wt.% kenaf fiber reinforced with epoxy resin. This sample showed a rough surface due to the removal of noncellulosic components in it, but there are a few microholes that are present in the matrix after the treatment. These microholes may create stress concentration leading to the deterioration of mechanical properties of the composites [33]. In sample S2, the 2 wt.% Gr addition disperses well with the matrix by hindering void formation to some extent, so the water absorption is reduced, and the interfacial bond will be better than 0 wt.% Gr filler sample. This change can be seen in Figure 6(b). In sample S3, 4 wt.% Gr filler reinforced in treated kenaf/epoxy composites showed proper bonding and minimal void content in the matrix. Figure 6(c) represents the SEM image of sample S3 which showed well dispersion of graphene with the matrix, no fiber pull-out, and proper interfacial adhesion between the fiber and matrix. Above 6 wt.% Gr incorporation with the matrix leads to fiber pull-out. According to Zhang et al. [33], after 5% NaOH treatment, the interfacial adhesion between the kenaf fibers and the matrix was greatly improved with 6 wt.% Gr. Treated kenaf fibers with 6 wt.% Gr had extremely greater tensile strength than other

composition, and the fracture of treated kenaf fibers could greatly enhance the mechanical strength of composites. In Figure 6(d), the SEM image of sample S5 has 8 wt.% Gr incorporation with the matrix which displayed agglomeration in the matrix region causing weak interfacial adhesion between the fiber and matrix. The poor fiber/matrix interface could not provide sufficient stress transport; thus, the mechanical properties of the composites decreased significantly. Severe fiber/matrix debonding with nanofillers could be witnessed due to the poor interfacial adhesion between fibers and the matrix, as shown in Figure 6(d). The unnecessary voids and microholes in the composites (S1 and S2) were witnessed at lower/higher weight fraction of graphene, which may reduce the reinforcing effect of the nanofillers resulting in the reduction of mechanical properties [21].

4. Conclusion

The mechanical and water absorption test is carried out for the various concentrations of reinforcement graphene filler with kenaf. Increment in mechanical properties strongly depends on the uniform dispersion of graphene in the matrix. The major findings of incorporating graphene in the treated kenaf/epoxy composites are discussed as follows. Graphene plays a major role in obstructing water penetration in the composite, thereby minimizing void concentration in it. The investigation proved that the addition of graphene improved the performance of the composite thermal stability. With more than 6 wt.% Gr filler reinforced in treated kenaf/epoxy composites, the properties like tensile, flexural, and impact strength start to decline, but maximum hardness value of 97 is achieved at 8 wt.% Gr filler sample. Beyond 6 wt.% graphene addition, the composite becomes embrittle causing agglomeration in the matrix and reduction in mechanical properties. SEM analysis is done to study the morphological surface of various graphene concentrations reinforced in treated kenaf/epoxy composites. 6 wt.% Gr filler sample is found to optimum, and this displayed no fiber pull-out, better bonding in the SEM analysis.

Data Availability

Amorphous alloy refers to the orderly arrangement of the internal structure of various substances in nature. Amorphous solid materials include amorphous inorganic materials, amorphous polymers, and amorphous alloys. Amorphous alloys, also known as glassy alloys or metallic glasses, are atomically condensed, long-range disordered, and short-range ordered alloy materials that have the distinctive properties of both metals and glasses. Ligament injury is damage caused by different degrees of damage to the ligaments of a certain part of the body. The purpose of this paper is to investigate amorphous alloys and ferroelectric nanomaterials and the repair of athletic ligament injuries in the soccer game, using the excellent properties of amorphous alloys and ferroelectric nanomaterials to solve the problem of athletic injuries. Knee and ankle injuries and muscle strains account for a large percentage of soccer injuries. In this paper, researches and explorations have been conducted on the preparation of new composite magnetic nanomaterials, the construction of immunosensor interfaces, and the development of new signal amplification and renewable immunosensors. The rehabilitation effect of the medial collateral ligament of the athlete's knee joint is used as the research object, and various methods are used. In-depth investigation and research and statistical analysis of the data obtained one by one were carried out. The experimental results in this article show that from the age of ligament injury, the number of people between 18 and 20 is relatively small, and the number of people aged 20–40 is relatively large. The number of people who have been trained for three years and above is 5, and the proportion of ligament injuries is 0.8%; the number of training for two years is 33, and the proportion of ligament injuries is 13.7%, the number of training for one year is 98, and the proportion of ligament injuries is 40.7%, and the number of training for six months is 105, and the proportion of ligaments is 44.8%.

1. Introduction

1.1. Background. In line that scientific and artistic fields are constantly evolving, sports in China have also been flourishing. More and more sports, as well as sporting events, are getting more and more attention, especially soccer. It is a good thing for the whole society that soccer is being taken seriously, but along with the focus on performance, we should also be concerned about the physical injuries of the athletes. Soccer consists of many high-intensity and decisive action confrontations, and its fast and variable nature, high level of confrontation, and tight schedule contribute to the high incidence of sports injuries. Basically all athletes have different degrees of physical injuries, maybe a back injury or a leg injury, which are closely related to the sports injuries

we are discussing. Sports injuries are not like the bumps and bruises of our lives, especially ligament strains, which take a long time to recover from and are difficult to resist medication. Random ligament injuries have a significant impact on the life of the operator. However, until now, there has been no direct and effective way to treat sports ligament injuries and only some degree of pain relief. This type of injury is mostly characterized by localized pain in the knee joint along with swelling, flexion, and extension difficulties, and often walking difficulties, which in the long run can cause fear in daily training and affect the performance of technical movements. Currently, widely used amorphous alloy materials can be deformed according to their magnetic characteristics and are highly sensitive to external stresses. Compared with the traditional is metal magnetic material, non-alloy

material atomic arrangement disorder, high resistivity, has high permeability, low loss, can improve transformer efficiency, reduce mention, and reduce weight. In addition, nanomaterials are very small in size and can present acoustic, optical, electrical, magnetic, and thermal properties [1]. With the new characteristics, if nanomaterials can be combined with amorphous alloy materials, they may produce unexpected results when applied to the repair of ligament injuries.

1.2. Significance. The combination of nanomaterials and amorphous alloy materials in the repair of ligament injuries can fill the current lack of effective treatment of ligament injuries and promote the progress of medical care; curb the adverse effects of ligament injury on athletes, so that they can continue to struggle in their careers and improve China's sports performance; expand the use of nanomaterials and explore their functions; nanomaterials have the advantages of large specific surface area and conductivity, nanomaterials have the advantages of large specific surface area and conductivity, and their application in the construction of immunosensors can effectively improve the above shortcomings of immunosensors.

1.3. Related Work. With the development of the national economy, sports continue to receive attention, and sports performance has become the focus of national attention. But in following sporting events, it is found that the physical ailments of athletes are otherwise ignored, especially ligament injuries have caused fatal injuries to athletes. We must find an effective way to contain it. Based on basic sciences, Pearce obtained the unanimous opinion of the members of the ESSKA-AFAS Ankle Instability Team to propose a best evidence method. Before the experiment, base scientific and proclinical data on bone cell recovery after ligament rebuilding, as well as the reconstruction of sensorimotor control, were reviewed, and then members of the ESSKA-AFAS ankle instability team obtained information about the ankle based on this evidence. Rehabilitation recommendations were proposed for the early postoperative period, early recovery phase, and goal-oriented late rehabilitation and recovery exercise phases, and practical and evidence-based guidelines were adopted for the rehabilitation and recovery activities after the surgery of the lateral ankle ligament [2]. In order to obtain amorphous alloys with high plasticity, Shan SF designed a series of 100xTMx alloys to investigate the effect of Nb and Y additions on plasticity. 100xTMx alloy means $Ti_{40} Zr_{25} Cu_9 Ni_8 Be_{18}$, where $x = 0$, 1, 2, 3, and 4 and TM = Nb. The plasticity of different bulk amorphous alloys was investigated by measuring the plastic deformation energy (PDE) during loading. The obtained results indicate that the inclusion of Nb decreases the PDE level, contributes to the creation of more than one fracture zone, and obviously increases the breaking force and complexity, but the inclusion of element Y decreases the breaking force and plastic strain of the alloy [3]. Kuji systematically prepared different microstructures by annealing B-rich Fe-Si-B-Cr amorphous plates to obtain the best mechanical and processing properties of the alloy. Anneal-

ing is a metal heat treatment process that involves slowly heating the metal to a certain temperature, holding it for a sufficient amount of time, and then cooling it at a suitable rate. The purpose is to reduce hardness and improve machinability, reduce residual stress, stabilize dimensions, and reduce deformation and cracking tendencies. Thermal, structural, and mechanical analyses show that the early reaction sequence of the amorphous alloy after annealing is characterized by structural relaxation, heterogeneous nucleation of the surface α-Fe (Si) phase, and homogeneous nucleation of the metastable Fe3B nuclei, which is influenced by the α-encircled Fe shell [4]. Danylyak analyzed the thermal stability and crystallization kinetic parameters of $Fe_{82}Nb_2B_{14}REM_2$ (REM = Y, Gd, Tb, or Dy) amorphous metal alloys by differential scanning calorimetry. Iron-based alloys were crystallized in two stages; we calculated the activation energy of the two stages of crystallization of amorphous alloys according to the Kissinger, Ozawa, and Augis-Bennett models. The process of doping $Fe_{84}Nb_2B_{14}$ alloy with rare earth metals leads to an increase in temperature, crystallization activation energy, and frequency factor. The doping of rare earth metals leads to a decrease in the crystallization rate constant of alloys revealing their resistance to temperature treatment [5]. Fangping conducts the experiment by preprocessing the Zr-based amorphous alloy with ultrasonic-assisted vibration microcompression at different amplitudes and frequencies and then compresses the sample until it breaks. The process is simulated by the finite element analysis software ABAQUS. By comparing the results of simulation and experiment, the reliability of the finite element model is verified. At 0, 19, 27, 36, and 43 μm ultrasonic amplitudes and 20, 25, 30 and 35 kHz frequencies, the effect of energy flux density on the room temperature deformation behavior of Zr-based amorphous alloys was studied. The results show that as the ultrasonic amplitude and frequency increase, the elastic modulus decreases, the equivalent stress distribution becomes more uniform, and the formability improves. This is due to the increase in temperature caused by ultrasonic vibration and the increase in the free volume concentration of the compressed sample. However, studies have found that when the ultrasonic energy flow density increases, the formability of amorphous alloys decreases [6]. Ding summarizes studies that provide information on releases of ENM in occupational settings, in different industrial activities, and during the use of various nanomaterials. It also assesses background information—like the amount of material processed, protective measures, and measurement strategies—to understand which release scenarios may lead to exposure. High-energy processes, such as synthesis, spraying, and processing, are associated with the release of large numbers of primarily small-sized particles. The current analysis suggests that process-based release potential can be ranked to help prioritize release assessments, which can be useful in stratifying exposure assessment methods and guiding the implementation of workplace safety strategies [7]. Huang suggested that nanomaterials could be used in the field of sports therapy. Nanoscale materials have been widely used as reagents for therapeutic and diagnostic (i.e., therapeutic diagnostics)

purposes. He discusses some general design considerations for advanced therapeutic diagnostic materials from a diagnostic and therapeutic perspective, as well as the challenges of their use. Common classes of nanoscale biomaterials have been shown to have diagnostic and therapeutic potential, with size variations such as control and surface modifications that can modulate biocompatibility and interaction with target tissues [8]. These theories have discussed tropical damage, amorphous alloys, and ferroelectric nanomaterials to a certain extent. Because of the limitations in the research, the actual operation is not very rational and not practical.

1.4. Innovation. It is the first time that amorphous alloys and ferroelectric nanomaterials are used in the rehabilitation of ligament injuries. This is a new attempt for the entire medical field. If this method can be promoted, it will achieve a new breakthrough in sports ligament injuries. A porous nanogold film was modified on the surface of the glassy carbon electrode of the large specific surface area and strong adsorption capacity of nanogold.

2. Amorphous Alloys and Ferroelectric Nanomaterials and Repair Methods for Sports Ligament Injuries

2.1. Ferroelectric Nanomaterials. Nanomaterials are materials in which at least one dimension in three-dimensional space is at the nanometer size (1-100 nm) or consists of them as the basic unit, which is approximately equivalent to the scale of 10 to 1000 atoms closely aligned together [9, 10]. At the beginning of the twentieth century, related researchers discovered the dielectric properties of substances, combining organic matter with ferroelectric phenomena for the first time. Because of its low density, easy processing, and low price, it has been widely used. After research, it has been found that there are four kinds of crystals in ferroelectric nanomaterials, and the four kinds of substrates can be converted to each other [11]. The specific conversion is shown in Figure 1:

In the middle of the last century, the emergence of new materials is the rapid development of nanomaterials. In the subsequent gradual development, as researchers continue to explore theories, the scope of application of nanomaterials has become wider and wider. Nanoceramics have small grain size, and the grains can easily move on other grains; therefore, nanoceramic materials have very high strength and high toughness as well as good ductility; these characteristics make nanoceramic materials can be cold processed at room temperature or sub-high temperature, making them ductile and high-performance ceramics [12]. In recent years, the continuous improvement of science and technology has forced the upgrading of traditional materials. Due to the limitations of various functions, traditional scientific and technological materials can no longer meet the requirements of modern technology. New nanomaterials have a lot of room for development. From the offline situation, the entire nanomaterials are still in their infancy, and the subsequent development is still very violent. At this stage, although researchers choose different nanomaterials for experiments,
Figure 1: Four crystalline transformation relationships.
Figure 2: Magnetization of amorphous alloy materials.

but so far there have been no more satisfactory results. In short, nanomaterials are very important functional materials, and the research and application of their characteristics still need continuous research and exploration [13, 14]. The ratio of the number of surface atoms to the total number of atoms in a nanocrystal particle increases dramatically as the particle diameter becomes smaller. For example, at a particle diameter of 10 nm, the particle contains 4000 atoms, and the surface atoms account for 40%; at a particle diameter of 1 nm, the particle contains 30 atoms, and the surface atoms account for 99%.

2.2. Amorphous Alloy. Amorphous alloys refer to alloyed materials that are condensed by atoms and have an orderly structure [15]. According to the form of amorphous alloys, they can be divided into ribbons, fibers, filaments, and powders. Amorphous alloys have low elasticity, high toughness, high resistivity, high chemical activity, resistance to radiation damage, and high corrosion resistance. Amorphous alloys have their own microstructures, so it causes the lack of many functions of amorphous alloys, but amorphous alloys also have unique properties [16]. In terms of chemical functionality, compared with ordinary alloy materials, the corrosion resistance of amorphous alloys is very good. This unique advantage provides convenience for its wide application in various fields. After research by researchers, the quality of corrosion resistance is determined by the structure and composition of the substance, and the structure and formation of amorphous alloys are relatively uniform, so it has good corrosion resistance. Structural uniformity refers to a substance without structural defects such as grain boundaries and lattice defects. Composition uniformity refers to
FIGURE 3: Magnetic sensor and magnetic relationship diagram.

the absence of static inclusions and heterogeneous components in the substance. The homogeneity of the composition is due to the fact that it is a fast-hardening material and the various atoms are "localized" before they can diffuse, so there are no fluctuations in composition like segregation, inclusions, and heterogeneity in the crystalline state. Since amorphous alloy materials are satisfied, the corrosion resistance is high [17].

Amorphous alloy itself has magnetic characteristics, but because the level of development is not enough, it is difficult to directly obtain its specific quantity; usually we use the saturation magnetic induction to reflect; function expression is as follows:

$$S = \phi_0(G + K) * (G + K). \tag{1}$$

Among them, S represents the magnetic induction intensity, K represents the magnetization intensity, and ϕ_0 represents the constant.

In the technical magnetization diagram, the amorphous alloy material is basically the same as the ordinary alloy material, as shown in Figure 2:

According to Figure 2, the main influencing factor in the magnetization process is the reversible domain wall displacement or reversible domain rotation in zone a. The magnetization degree is weak in zone b, the initial magnetization rate is large in zone c, the domain rotation plays a major role in zone d, and the wall movement and domain rotation of the internal domains in zone e are all completed.

When the magnetization of amorphous alloy materials is relatively weak, the function expression is as follows:

$$Q = \alpha_1 T + \beta T^2,$$
$$W = \varphi_1 T + 4\pi\beta T^2. \tag{2}$$

Among them, Q represents the magnetization intensity, α_1 represents the magnetic susceptibility, T represents the magnetic field intensity, β represents the constant, W represents the magnetic induction intensity, and φ_1 represents the initial permeability. Figure 3 is a schematic diagram of the relationship between magnetic sensors and magnetism:

When it comes to the magnetism of amorphous alloy materials, the stretching effect is involved, which essentially refers to the energy exchange of the material. The specific function expression is as follows:

$$\begin{cases} \iota = \iota(T, \chi), \\ W = W(T, \chi), \end{cases}$$
$$\begin{cases} \chi = \chi(W, \iota), \\ T = T(W, \iota), \end{cases} \tag{3}$$

where W represents the magnetic induction intensity, T represents the magnetic field intensity, ι represents the stress, and χ represents the strain.

The electromechanical coupling coefficient has a certain relationship with the permeability and elastic modulus

FIGURE 4: Common ligament injuries.

of amorphous alloy materials, which can be expressed as follows:

$$d^2 = \frac{\lambda_a - \lambda_b}{\lambda_z} = \frac{S_Q - S_K}{S_O}, \tag{4}$$

where λ_1, λ_2 represents the reversible permeability of the amorphous alloy material under steady stress and constant strain and S_Q, S_K represents the elastic modulus of the amorphous alloy material under steady magnetic induction and steady magnetic field strength, where

$$d^2 = \omega \left(\frac{\varphi \delta}{\varphi N} \right)^2 + \frac{\lambda_1 - \lambda_2}{\lambda_Z},$$
$$S = \frac{9}{4} \frac{S\gamma_c^2}{\pi N_c^2} v_i \left(\frac{N}{N_c} \right)^2, \tag{5}$$

where ω represents the magnetic susceptibility, δ represents the expansion ratio, δ_c represents the saturation magnetostriction coefficient, N represents the magnetization, N_c represents the saturation magnetization, v_i represents the reversible permeability, and S represents the elastic modulus.

In operation, stress sensitivity can be used to evaluate the magnetostrictive effect and inverse magnetostrictive effect of amorphous alloy materials. The specific function expression is as follows:

$$T = \frac{3\gamma_c N_C}{2L_i} \sin^2 \rho_0 \cos \rho_0, \tag{6}$$

where γ_c represents the saturation magnetostriction coefficient, N_c represents the saturation magnetization, L_i represents the uniaxial magnetic anisotropy, and ρ_0 represents the angle between the magnetization vector and the magnetic field.

The electromagnetic induction effect refers to the mutual induction phenomenon of electricity and magnetism. For a

Rear	3	7	9	5

closed loop coil with a magnetic core, the function expression can be as follows:

$$L_j = -F \frac{d\mu}{di} = -FS \frac{dU}{di} = -FS \frac{d(\iota G)}{di}, \tag{7}$$

where L_j represents the induced voltage, μ represents the magnetic flux, F represents the number of coils, S represents the cross-sectional area of the magnetic core, U represents the magnetic induction intensity of the magnetic core, ι represents the magnetic permeability of the magnetic core, and G represents the magnetic field intensity.

TABLE 3: Validation of validity.

Group	Total people	Percentage (%)	Effective number of people in the structure	Percentage (%)	Number of people valid for content	Percentage (%)
Invalid	0	0	0	0	0	0
Poor results	1	9	3	27	1	9
General	0	0	2	18	0	0
Good	2	18	3	27	3	27
Excellent	5	45	4	36	1	9

If the permeability does not change with time, it means that it can be used to detect the change of the magnetic field. The specific detection is as follows:

$$L_j = -\iota F S \frac{dG}{di}. \tag{8}$$

It has been demonstrated by experimental studies that the Hall effect of ferromagnetic materials can be expressed as

$$\kappa_g = H_0 Q + \phi_0 N(H_1 - SH_0) = H_0 Q + \phi_0 H_c N, \tag{9}$$

where B represents the magnetic induction intensity of the applied magnetic field, N represents the intrinsic magnetization strength, S represents the demagnetization factor, H_0 represents the normal hall coefficient, H_1 represents the abnormal hall coefficient, and H_c represents the spontaneous hall coefficient.

In a low field, the induction intensity of amorphous alloy materials is very small, dominated by anomalous effects, which can be expressed as follows:

$$P_f = \left| \frac{\beta \mu_f}{\beta_W} \right|_{W \longrightarrow 0} = P_c,$$
$$P_{df} = \left| \frac{\beta \mu_f}{\beta_W} \right|_{W \geq N_c} = P_0. \tag{10}$$

When the external field changes the magnetic field, the amorphous alloy material will have an induced voltage phenomenon, and its function expression is as follows:

$$u_N = -\chi_a J_a \frac{dQ_a}{di} \infty - \frac{N_c{}^2 J_a}{g_a} \frac{dQ_a}{di}, \tag{11}$$

where χ_a represents the circumferential differential permeability, J_a represents the cross-sectional area of the axial magnetic circuit, Q_a represents the circumferential magnetic field strength, N_c represents the saturation magnetization, and g_a represents the circumferential magnetic anisotropy.

2.3. Sports Ligament Injury. With the continuous development of economy, people pay more and more attention to the all-round development of people [18]. The country is also advocating the all-round development of people's "ethics, intelligence, physique, beauty, and labor." Therefore, China's sports industry has also taken off. However, injury

TABLE 4: Length of ligament injury training survey.

Group	Number of people	Proportion (%)
More than three years	5	0.8
Two years	33	13.7
One year	98	40.7
Half a year	105	44.8%

in sports training is an inevitable problem. Once an injury occurs, it will not only cause great harm to the body, but also affect the performance of the game and reduce the performance of the game [19]. According to statistics, in addition to common abrasions in sports, the most common injury is ligament. Ligaments are the most critical and complex joints of the human body. Ligaments connect bone to bone and are distinct fibrous tissues that either attach to the surface of the bone or fuse with the outer layer of the joint capsule to enhance the stability of the joint and prevent injury. Injury occurs when the ligament is stretched beyond its tolerance by violence that produces nonphysiological activity. No matter what training is being performed, the flexible cooperation of ligaments is required. Because of excessive use, the probability of injury is also greatly increased. Usually we divide ligaments into medial collateral ligament, lateral collateral ligament, anterior cruciate ligament, and posterior cruciate ligament. Both sides of the medial collateral ligament, including longitudinal and oblique fibers, are used to prevent knee rotation instability. The medial side is the main structure that maintains the stability of the medial knee joint. It is related to all parts of the body. The main function is to prevent outward movement; when the knee joint is flexed, the calf is suddenly adducted and internally rotated, and the lateral collateral ligament may be injured [20, 21]. The posterior cruciate ligament starts after the spine of the embryonic bone. The posterior cruciate ligament is also an important structure to maintain the knee joint. Its injury can cause the instability of the knee joint and damage other structures in the joint. Figure 4 is a picture of common ligament injuries:

3. Amorphous Alloy and Ferroelectric Nanomaterials and the Repair Experiment of Sports Ligament Injury

3.1. Case Selection and Grouping. The experimental subjects were all patients with ligament injury, aged between 18 and
Figure 5: Schematic diagram of the forces applied.

40 years old, and were divided into 4 groups for separate experiments, and statistics were made according to the characteristics of the patients' age, symptoms, and gender [22]. The specific data is as follows:

According to the data in Table 1, in the four groups, the probability of male ligament injury is greater than that of females. Although there may be population base reasons, this situation is not obvious from the experimental data. From the perspective of the age of ligament injury, the number of people between 18 and 20 is relatively small, and the number of people with ligament injuries between 20 and 40 years old is relatively large. This reflects the flexibility of the ligament to a certain extent. Once injured, the possibility of a complete cure is very small [23].

3.2. Comparison before and after Treatment. There is no difference between the four groups of patients with ligament injury before treatment, and they are not comparable. Once different treatments are passed, we can explore the differences in treatments from the treatment results [24].

According to the data in Table 2, it can be seen that the results of treatments arranged by different groups are not the same. In the first group, the good before treatment is 0, the good after treatment is 0, the good before treatment is 0, the good after treatment is 5, the normal before treatment is 3, and the normal after treatment is 8, and the difference before treatment is 15, and the difference after treatment is 6. In the second group, the good before treatment is 0, the good after treatment is 7, the good before treatment is 0, and the good after treatment is 12. Before treatment is generally 5, after treatment is generally 13, the difference before treatment is 10, and the difference after treatment is 3; in the third group, the good before treatment is 0, and the good after

treatment is 0. It is 7 for good before treatment, 10 for good after treatment, 3 for normal before treatment, 11 for normal after treatment, 13 for poor before treatment, and 3 for poor after treatment; in the fourth group, the good is 0 before treatment, the good is 3 after the treatment, the good is 3 before the treatment, the good is 7 after the treatment, the general is 6 before the treatment, the general is 9 after the treatment, the difference before treatment was 12, and the difference after treatment was 5. According to the overall treatment effect, the treatment effect of the second group is better, and the treatment effect of the third group is relatively poor [25].

3.3. Treatment Effect Test. In order to explore the effectiveness of the treatment effect, it is not only necessary to look at the operation, but also the probability of recurrence. In order to ensure the validity of the data and scientifically and reasonably reflect the content of the research and discussion, we have analyzed the collected data in various ways. In order to increase the authority of the conclusions, we have invited relevant researchers to conduct research based on the survey questions rationality assessment. The details are as follows:

According to the data in Table 3, in the total number of questionnaires, 0% of people think it is invalid, 9% think that the effect is not good, 0% think that the average person thinks the effect is good, and 18% think that the effect is very good. In the structural effectiveness survey, 0% of people think that the effect is invalid, 27% think that the effect is not good, 18% think that the average person thinks the effect is good, 27% think that the effect is good, and the proportion thinks that the effect is very good 36%; in the content validity survey, 0% of people think it is invalid, 9% think the effect
Figure 6: Nanoferroelectric material properties.
Figure 7: Ligament rehabilitation training values.

is not good, 0% think the effect is good, 27% think the effect is very good, and 9% think the effect is very good. According to the survey results, although the overall treatment effect is not good, the data obtained is still valid. The side proves that the validity survey method is correct and can continue to be implemented.

According to the data in Table 4, it can be seen that ligament injury training is prone to occur. In the survey data, the number of people who trained for three years or more was 5, the percentage of ligament injuries was 0.8%, the number of people who trained for two years was 33, the percentage of ligament injuries was 13.7%, and the number of people who trained for one year was 98. The proportion was 40.7%, the number of training for half a year was 105, and the proportion of ligament injuries was 44.8%. According to ten sentences, ligament injuries often occur at the beginning of training, which is closely related to the training method and self-protection consciousness. The more training

time, the less chance of ligament injury, so to a certain extent the protection of ligaments. In addition to medical treatment, it is more important to increase the awareness of self-protection, find the correct training method, and reduce the probability of injury. In this way, the ligaments can be maintained in a good state without frequent injuries.

4. Amorphous Alloys and Ferroelectric Nanomaterials and the Repair Analysis of Sports Ligament Injuries

4.1. Amorphous Alloy Material Design. According to Figure 5, the distance change during the whole experiment is within 2 mm, but the voltage change is within 20 V. Although there is a linear downward trend in the performance of the entire image, the actual value is very small and difficult to measure; this phenomenon also occurs in the frequency; the distance change is only 2 mm, and the frequency is only 30 kHz floating, which will cause great difficulty to the subsequent data capture.

4.2. Ferroelectric Properties of Nanomaterials. According to the data in Figure 6, the performance of the amorphous alloy material changes greatly by changing the voltage during the experiment. When the voltage is negative, the value obtained is also negative. When the voltage is positive, the obtained value is also a positive value. When the voltage is zero, one of the obtained values is a positive value, and the other is a negative value, which indicates that the material has strong ferroelectricity. When the voltage is -10 V, the amplitude difference between the two is very small. When the voltage is -5 V, the two substances are almost the same. When the voltage is 0 V, the two substances begin to have a gap. When the voltage is 5 V, the difference between the two substances in the gap began to narrow. When the voltage was 10 V, the two substances were almost the same.

4.3. Ligament Rehabilitation Training. According to the data in Figure 7, before rehabilitation training, the gap between male and female active knee flexion angles is very small. Passive knee flexion angle is 95 degrees for boys and 115 degrees for girls. From this data, it can be shown that girls' ligaments are more flexible and injured during training. The probability is lower. After a period of training, the active knee bending angle of boys is 125 degrees, the active knee bending angle of girls is 130 degrees, and the knee bending angle of women is still greater than that of men. This proves the previous point of view. In passive knee bending training, the angle of boys after training has reached 140 degrees, and the angle of girls has reached 148 degrees. Although the overall situation has not changed, it has changed significantly from before training, indicating that this training is effective.

5. Conclusions

With the continuous advancement of science and technology, sports and sports performance have received unprecedented attention, but we must pay attention to the physical condition of the athletes while focusing on honor. The topic of this paper is the repair of amorphous alloys and ferroelectric nanomaterials and the repair of sports ligament injuries in soccer. It is expected that the excellent properties of amorphous alloys and ferroelectric nanomaterials will play a role in the treatment of ligaments. In the experiment, this paper mainly completed the following tasks: (1) Research and exploration were carried out from the preparation of new composite magnetic nanomaterials, the construction of immunosensor interface, and the development of new signal amplification and renewable immunosensors. (2) Various methods have been used to conduct in-depth investigations and studies and statistical analysis of the data obtained one by one, to formulate the corresponding rehabilitation training plan. (3) The excellent characteristics and sensitivity of amorphous alloys and ferroelectric nanomaterials are higher than those of conventional methods, with a wide linear range, and are expected to be applied in the field of clinical testing. However, there are still many shortcomings in the experimental work: (1) The experimental subjects are not large enough, and they are only searched in a limited range, which cannot represent the ligament training situation of various sports, so the data obtained is not universally representative. (2) The strength and flexibility of vulnerable parts should be strengthened during the training process. Due to the complexity of sports and different characteristics, it is impossible to provide accurate training methods.

Graphene is a two-dimensional material with excellent performance and unique structure. Since its successful manufacturing in 2004, it has quickly become a research hotspot in the fields of materials, chemistry, physics, and engineering. This article focuses on the study of exfoliated single-layer graphene based on dispersed carbon nanotubes and understands the related theories of carbon nanotubes and exfoliated single-layer graphene on the basis of literature data. The mathematical model and simulation calculation method are analyzed, and then, the effect of the single-layer graphene peeling based on the dispersed carbon nanotubes is tested, mainly to the experimental verification of the peeling process parameters and the influence of the dispersant on the peeling effect, and then, the peeled graphite quality of the graphene was tested, and the test results showed that the thickness of single-layer pure graphene is 0.6-0.9 nm, and the experimental statistics show that the graphene of single-layer and double-layer occupies 81% of the experimental sample; most of the single-layer graphene exfoliated based on dispersed carbon nanotubes in this paper is single-layer, two-layer graphene, and a relatively small amount of multilayer graphene.

1. Introduction

In recent years, due to the widespread application of computer technology and the mature development of computing technology, a new round of scientific and technological revolution has been produced for computer simulation methods [1, 2]. In addition to theoretical research and empirical analysis, computer molecular simulation has also become another important scientific investigation method for people to understand the microcosm. At the same time, it is the main tool and method for new material design research [3, 4]. The computer extracts numerical values related to atomic diffusion coefficient, electron diffusion orbital through dynamic simulation, and numerical values that cannot be reflected in theoretical research or experiments [5, 6].

As a major type of petrochemical raw material, carbon nanotubes are widely used in the separation, refining, and processing of products in the chemical industry such as petrochemical, gasoline, and natural gas [7]. The special physical properties of various aspects, such as electricity, have attracted the attention of foreign scientists [8, 9].

The natural absorption isotherms of hydrogen atoms in pore size carbon nanotubes at different working temperatures have been found that under high and low temperature conditions, a moderate increase in the diameter of the carbon tube can also help hydrogen storage [10]. Therefore, some researchers have developed almost equivalent models to analyze the mechanical properties of carbon tubes used as reinforcement materials. The research results show that when the total integral number of carbon nanotubes is fixed, the measured value of sidewall/resin carbon nanotubes

increases as the diameter of carbon nanotubes increases and continues to remain constant after exceeding the specified value. When the diameter of carbon nanotubes reaches sixty to eighty nanometers, the strength of the single-wall carbon/composite is maximized. When the volume fraction of carbon nanotubes changes, it can be found that as the volume fraction of carbon nanotubes increases, the measured value of Young's axis also increases accordingly. In other words, when the volume fraction of carbon tubes reaches 25%, the axial elastic modulus of the composite resin with the same orientation of carbon nanotubes can reach 330 GPa. At the same time, in the case of composite resins in which carbon nanotubes are randomly distributed in the range of 0 to 7%, as the volume fraction of carbon nanotubes increases, the measured value also increases [11]. Some researchers studied the exfoliated graphene and chose N,N-dimethyl-propylamine, N-(3-dimethylaminopropyl)methacrylamide, and 2-(tert-butylamino)methacetonitrile. As a solvent, it participates in the production of graphene, but because the content of the graphene diffuser produced by it varies greatly and, at the same time, due to the continuous expansion of raw materials and the continuous peeling of the precipitate, the content of graphene in the solution reaches 15 mg/mL^{-1}. This is due to the strong interaction between the substance in the solution and the graphene. Therefore, the interaction between the solvent and graphene is the key reason for determining the content of graphene in the solution, and it is also the main reason to consider when choosing the solvent [12]. Some researchers used three different molecular ratios. The preparation of graphene solution was studied through the three-proportion system method. The above three parts of the mixed solution must be mixed at a high speed of 120 revolutions per minute for ten minutes before use, and the solution and the coloring solvent must be thoroughly mixed. When the molar ratio of BA reached 1 : 3, the dispersed content of graphene was as high as 6.5 mg/mL. When the NBA molar ratio reaches 1 : 4, the graphene content is only 0.09 mg/mL, and when the molar ratio reaches 1 : 3, it is only one-72nd, and it also shows that this ratio will make the n-butanol molecule internal self-bonding generated, so that the individual DMF solution can be stripped to obtain graphene, but different mixed solutions can neither guarantee the dispersion stability of graphene nor the stability of the graphene diffusion liquid, so different mixed solutions can affect graphene. The diffusion concentration produced a great difference [13]. This type of research lacks data support, and the conclusions drawn are still open to question. In summary, the research on the preparation of graphene has attracted much attention, but the preparation process is affected by many factors, so it is necessary to investigate these factors in depth.

This paper studies the exfoliation of single-layer graphene based on dispersed carbon nanotubes and analyzes the structure of carbon nanotubes, the preparation method of exfoliated single-layer graphene, and the factors affecting the stripping effect on the basis of literature data. Research is carried out based on the mathematical model and simulation calculation method of the single-layer graphene exfoliated by dispersed carbon nanotubes, and then, the graphene exfoliated by this method is tested, and relevant conclusions are drawn from the test results.

2. Carbon Nanotubes and Exfoliated Single-Layer Graphene

2.1. The Structure of Carbon Nanotubes.
The basic structure of the carbon tube can be obtained using graphene sheet mapping [14]. The grid of the graphite sheet is represented by the vector $C = na_1 + ma2$ (n and m are integers, and a_1 and a_2 are the unit vectors of the graphite layer) [15]. The basic process of using flat grid points in the graphite layer to make carbon nanotubes is shown in the figure: starting from grid point zero, first use grid point A to establish grid vector C, and then, establish a line perpendicular to vector C, and then use points O and B to indicate. This point is a threaded grid point in the two-dimensional layer of the graphite layer, and the vector OB is a convertible vector, represented by T (see Figure 1). The straight line OD is a line parallel to the unit vector A, and the angle between the carbon-carbon bond of the hexagonal lattice perpendicular to the vector ODC and the sawtooth axis along the sawtooth axis of the hexagonal graphite lattice and the OD is θ. A line C passing through the spiral vector perpendicular to point A and a line perpendicular to point OB intersect at point B at point B'. The atomic weight contained in the rectangular OAB'B is the atomic weight contained in the single-walled carbon nanotube unit cell. On the axis OB, roll the powder sheet and align OB and A with the axis AB$'$ or align the axis OB with the axis AB$'$ to form the circumference of the main body of single-walled carbon nanotubes, and form the single-walled carbon tube of the main body at OB; the OA is formed around the single-walled carbon tube. Throughout the development process, it has been found that two parameters (n and m) can be used to describe single-walled carbon tubes. Regardless of the attribute, the structure of single-walled carbon nanotubes is completely determined by two quantities (n and m) (diameter and helix angle or both showing the graphite sheet structure index or helix vector C and translation vector T). Therefore, only selecting the spiral vector C of the graphite mesh determines the basic structure of the carbon tube and various technical parameters [16].

2.2. Preparation Method of Exfoliated Single-Layer Graphene

2.2.1. Mechanical Peeling Method.
The mechanical peeling method, as the name implies, is to use external physical and mechanical forces to resist the van der Waals force between the toner layers to peel the toner [17]. The raw material often used here is highly oriented pyrolytic graphite. The process of manufacturing graphene involves gradually grinding centimeter-sized graphite blocks into smaller graphite flakes, and then grinding them into nanoscale graphite flakes. Graphite flakes continue to decompose and become thinner and thinner.

2.2.2. Liquid Phase Exfoliation Method.
The liquid phase exfoliation method is a solution that can be produced
Figure 1: Schematic diagram of graphene sheet mapping to carbon nanotubes.

industrially, and it is also suitable for the manufacture of graphene composite materials [18]. The exfoliation method must overcome the van der Waals force between graphite layers, and the diffusion of graphite in liquid is the most direct and effective way to reduce the van der Waals force. Therefore, the liquid phase exfoliation method generally includes the following three stages: (1) the diffusion process of graphite in the solvent; (2) the auxiliary exfoliation by means of ultrasound, microwave, shear, heating, and electrochemistry; and (3) graphite obtained by centrifugation. The exfoliation preparation of graphene solution can include two types of substances: direct liquid phase exfoliation and auxiliary liquid phase exfoliation [19]. Figure 2 is a schematic diagram of the principle that the solvent disperses graphene in the solution smoothly.

2.2.3. Chemical Vapor Deposition Method. After decomposing some carbon-containing compounds, other forms of carbon can be converted to graphitic carbon. In subsequent catalysis experiments, the researchers found that the contact of hydrocarbons or carbon vapor with nickel or single crystal platinum can also form a graphite layer [20]. Subsequent studies have shown that the filled *d* orbitals of transition metals can absorb some carbon atoms. This provides a basis for the preparation of graphene by CVD [21]. When the carbon material is decomposed at a high temperature, the carbon atoms combine with the metal to form a carbon source. Due to the limited amount of molten metal carbon, sp2 hybrid carbon is deposited to form graphene. The type, concentration, and duration of the carbon source introduced during the deposition process have a significant impact on the size and number of graphene layers obtained. Figure 3 shows the preparation process of the CVD method.

2.2.4. Granulator Method. When the granulator rotates at a high speed, the water tank on the granulator rotates around the main shaft of the turntable and rotates around its own main shaft, thereby realizing planetary motion. Under the influence of high-speed centrifugal force, the crushing ball and the material in the tank rotate together at high speed, and a higher kinetic energy is formed in the relative movement between the crushing ball and the material. The shear stress and compressive stress between them cause the material to be stripped and crushed. The use of granulation in

graphene production roughly includes wet granulation and dry granulation. The main medium of granulation is organic solvent (such as DMF, NMP, and cyclobutane) [22].

2.3. Factors Affecting Peeling Effect. Because the surface energy of graphene is high, the surface energy of the solution selected in the production process must be consistent with the surface energy of graphene, and it can diffuse into the solution stably. But at the same time, solutions suitable for exfoliating graphene are usually expensive and toxic. Water is the most commonly used solution, which is relatively safe and has the highest biocompatibility. However, the surface tension of water is far from that of graphene. Regarding this issue, R&D personnel have done a lot of research and added surfactants to adjust the H tendency so that the graphene is exfoliated from the water phase [23].

2.4. Simulation Calculation Method. Molecular simulation is usually a classic engineering-based research method, including molecular engineering, Monte Carlo, and molecular dynamic simulation [24]. This method regards the molecular model or system as a classical engineering model and calculates the molecular energy by repeatedly sampling the constitutive space of the molecular system to obtain the molecular orbital and structural properties. Molecular dynamic (MD) simulation is a type of molecular simulation that not only studies the structural properties of molecular systems but also analyzes the thermodynamics, migration, and chemical properties of the system. Therefore, it is widely used in materials, biopharmaceuticals, chemistry, and other fields.

(1) The molecular dynamic simulation process is mainly composed of the following three parts. (1) Calculate the total kinetic energy of the entire system. (2) Calculate the internal force of each molecule (atom) from the relationship between kinetic energy and force. Then, according to Newton's classical mechanics, the position of the atom can be inferred. (3) Solve physical quantities such as dynamics and thermodynamic properties according to the structural properties of the system [25]

(2) Some important issues in molecular dynamic simulation

2.4.1. Potential manipulation and energy optimization. Dynamic function is a form of function that controls the interaction force between atoms, which directly determines the dynamic energy of a system composed of different atoms, and is the most important parameter to control dynamic simulation [26]. For each atom, various potential characteristics must be selected to explain the interaction between them. A typical potential function is usually formed by superimposing various forms of interaction between individuals, such as the following equation:

$$U = \sum U_{bonds} + \sum U_{angles} + \sum U_{dihedral} + \sum U_{improper} \\ + \sum U_{inverison} + \sum U_{cross} + \sum U_{\text{int } er}. \tag{1}$$
FIGURE 2: Liquid phase exfoliation (LPE) process.
FIGURE 3: Schematic illustration of the preparation of grapheme by CVD method.

In the formula, the following are shown: (1) the potential energy caused by the expansion and contraction of the bond; (2) potential energy caused by the bending of the bond angle; (3) the potential energy when the dihedral angle deviates from the equilibrium position; (4) potential energy caused by pseudo-distortion; (5) potential energy caused by face flip; (6) interaction, potential energy caused by coupling; and (7) intramolecular nonbond interaction.

2.4.2. Conditions. In order to generate relatively accurate regular statistical data and accurately predict the macroscopic properties of materials and structures, it is necessary to perform MD simulations on systems with a large number of microscopic particles. However, due to the limitations of existing calculation conditions, up to 108 particles can be simulated, which is different from the macroscopic size,

which is not enough at present. Periodic restrictions are usually introduced in the dynamic simulation to eliminate the restrictions as much as possible. In other words, the creation of a central unit gives a period limit that allows the system to recur in space and expands the system to infinity [27].

2.4.3. Overall and temperature and pressure control. MD simulates the motion of the system on the atomic scale, and the molecules perform a large amount of thermal motion. Therefore, statistics must be performed on the system containing a large number of particles to represent the statistical sample. In addition, the system for studying thermodynamics cannot be infinite, it must be finite. In quantum mechanics, the sum of the quantum states of each small particle in a thermodynamic system is its microscopic state. As a statistical engineering concept, the collection represents a collection of thermodynamic systems with the same macroscopic state but not necessarily the same microscopic state. The macroscopic state of the thermodynamic system mainly includes temperature (T), pressure (P), volume (V), and energy (E). Therefore, in the case of the same chemical composition of the system, the set can be divided into volume and energy harvesting NVE ensemble, pressure and temperature NPT set, same volume and temperature NVT set, etc.

When different holistic therapies are used in the system, the molecules in the system are in different states. Therefore, for different structures and molecules, different sets must be selected accordingly to control macroscopic conditions such as temperature and pressure.

The dynamic simulation in this paper mainly adopts the Berenson constant temperature variable method and proportional coefficient constant pressure method to control.

(1) Berenson variable scale thermal bath method. This method performs temperature control by connecting the analog system to a thermostatic bath with a temperature of

T. This means that the heat exchange rate is proportional to the temperature difference between the two.

$$\frac{dT(t)}{dt} = \frac{T_0 - T(t)}{\tau}.\tag{2}$$

1 is called the relaxation time, and the smaller the equilibrium time, the shorter (usually choose c~0. lps). As mentioned earlier, the dynamic simulation uses the difference formula to approach the differential equation step by step. Here, Taylor's expansion and Fourier's law are used to expand in 2 places to solve the problem:

$$T(t) = T_0 + (T(0) - T_0)e^{-t/\tau},\tag{3}$$

$$\frac{T(t + \Delta t/2)}{T(t - \Delta t/2)} = \lambda^2,\tag{4}$$

where 3 is the acceleration factor.

2.5. Principles of Simulation Calculation. The basic principle of molecular dynamics is to first reflect all kinds of particles to its original position and momentum and then adjust the motion rules of these particles to completely obey the Newtonian equation of motion [28]. The data can be used to solve the equations to obtain displacement, velocity, and acceleration. The principles of statistical physics calculate system mechanics, thermodynamics, kinetics, and their properties.

Imagine a system composed of N particles; the sum of the total kinetic energy and kinetic energy of the particles is the total kinetic energy of the entire system. According to Newton's second law, the acceleration of particle i is

$$a = \frac{F}{m}.\tag{5}$$

According to classical mechanics, force 1 received by each particle i is the negative gradient of the potential energy function U:

$$F_i = -\nabla_i U.\tag{6}$$

It can be seen from the above that the basic principle of molecular dynamic modeling is to first obtain the dynamic ability of the particles from the relative position of the moving particles and then calculate the force acting on the particles and the acceleration of motion by Newton's second law. After that, through the original velocity and initial displacement, the velocity and displacement after time t can be obtained, and then, through repeated cycles, the velocity and displacement of new particles can be obtained every day. The basic principle of solving the Newtonian equation of motion above is to resolve a normal quadratic differential equation step by step through the finite difference method in a very short time step. Some classic calculations are summarized below.

(1) The Verlet algorithm is usually the simplest and is loved by many researchers. Its generation is the result of Taylor's expansion of particle coordinates at time t:

$$r(t + \Delta t) = r(t) + V(t)\Delta t + \frac{1}{2!}a(t)(\Delta t)^2 + \cdots,\tag{7}$$

$$r(t + \Delta t) = r(t) - V(t)\Delta t + \frac{1}{2!}a(t)(\Delta t)^2 + ..\cdots\tag{8}$$

Add the two equations together to get

$$r(t - \Delta t) = -r(t - \Delta t) + 2r(t) + a(t)(\Delta t)^2\tag{9}$$

3. Mathematical Model and Simulation Calculation Method Based on the Exfoliation of Single-Layer Graphene from Dispersed Carbon Nanotubes

3.1. The Idea of Exfoliating Single-Layer Graphene with Dispersed Carbon Nanotubes

(1) Establish a mathematical model based on the high-speed centrifugal motion of the crushing sphere in the crushing cavity and the motion trajectories of the collision sphere and the shear sphere

(2) The centrifugal shear strength is calculated according to the model

(3) Calculate the scattering limit length of the blind zone between the spheres based on the model, that is, the boundary scattering zone

3.2. Preparation Process. Take 0.8 kg of carbon nanotube powder, 3 kg of dispersant, and 20 m of solvent, and the solvent is NMP. After the above materials are stirred and dispersed in the dispersion tank, they are continuously transported to the 30-liter crusher through a constant-speed diaphragm pump and a 30-liter crusher. The inner cavity is straight 244 mm. In the crusher, the material is continuously supplied to the crusher in a continuous crushing mode. The crusher continuously crushes and outputs the crushed materials at the same time and be crushed and dispersed at a high speed of 11 m/s for 10 hours to form a viscous dispersion of carbon nanotubes.

3.3. Establishment of Carbon Nanotube Model. The carbon tube has a hexagonal crystal structure. Each carbon atom in the carbon nanotube is connected by three other connected carbon atoms, among which the sp two-hybridization is the most important. Single-walled carbon nanotubes can also produce graphene-level mapping, so that the regular hexagonal lattice of carbon nanotubes forms a certain angle with the axis. In other words, the carbon nanotubes now appear to be spiral and have chiral characteristics.

It can be divided into three types: sawfish type, armchair type, and spiral type.

In this article, the Materials Studio modeling software is used to create carbon nanotube models and hybrid carbon nanotubes with different structural parameters. The diameter of the carbon nanotube structure is 8.14 A and the length is 120.52 A.

3.4. Centrifugal Friction Shear Strength.

The simulation calculation method provided in this article is based on the rapid centrifugal movement of the crushing balls in the crushing chamber. The balls collide with each other and shear, peel off the single-wall graphene, and disperse the carbon nanotubes. The mathematical model of collision and friction between spheres calculates the shear strength 1 between spheres as follows.

$$P_d = \frac{F_c}{(1/2)S_q} = \frac{4\rho v^2 r^2}{3R^2}, \tag{10}$$

$$n_i = \frac{V_1}{V_2} = \frac{3m}{4\rho\pi r^3}, \tag{11}$$

$$\sum P = n_i P_d = \frac{mv^2}{\pi R^2 r}, \tag{12}$$

where 1 is the linear velocity of the centrifugal movement of the sphere, R is the radius of the grinding cavity, r is the radius of the sphere, 2 is the shear friction between the two spheres, and S sphere is the surface sphere of the grinding cavity. V is the volume of a single sphere, 5 is the density of the sphere, 3 is the shear strength of the friction between the spheres, 6 is the number of spheres, m is the total mass of the sphere, and 4 is the shear force and the shear strength between the total friction.

3.5. The Dispersion Limit Length of the Dispersion Limit Zone.

Table 1 takes a 30 L grinder with a direct inner cavity of 244 mm and a linear velocity of 11 m/s as an example to calculate the selection of balls and the limit dispersion table:

From the data in Table 1, we can see that when the diameter of the sphere is less than $1.2\mu m$, the dispersion limit length of the limit dispersion zone is less than $1\mu m$. In other words, the dispersion is performed at the nanometer level. The diameter r of the sphere is less than $0.38\mu m$, and the shear strength reaches the limit value of 650.12 GPa, which is the peeling of graphite flakes. The toner flakes are peeled to form a single layer of graphene dispersed in the liquid.

3.6. Stripping Parameters.

The grinding process contains a variety of process parameters that need to be balanced and controlled, such as graphene exfoliation and carbon nanotube diffusion. Through the peeling and diffusion effects after the test, the main parameters of the entire processing flow are determined. After the process parameters are selected, the process parameters need to be strictly controlled to achieve graphene exfoliation and carbon nanotube diffusion. Due to the change of process parameters, the results of delamination and diffusion will be quite different.

3.7. Graphene Detection Method

(1) At present, graphene characterization mainly includes graphene morphology characterization and thickness characterization. The UV spectrophotometer mainly measures the absorbance and concentration of the graphene dispersion obtained by the liquid phase separation method. XRD is used as a tool for measuring crystallinity and interplanar spacing. The 2θ angle of the crystal can be combined with the Bragg equation to calculate the interplanar spacing of the crystal, and the change in the crystal structure can be inferred from the change in 2θ. Graphite is a stable structure formed by stacking graphene sheets, $2\theta = 26.6°$, and the corresponding interplanar spacing is 0.335 nm. When graphite is exfoliated into graphene, the structure of graphite is destroyed, and the peak intensity of graphite at 26.6° is significantly reduced, the peak shape becomes wider, and the intensity and peak can be reduced. The Raman spectrum of graphene contains different D and G peaks. The degree of graphene defects can be judged by the ratio of the D peak to the G peak. The greater the ratio of the two, the greater the defect. XPS can measure the carbon and oxygen content of graphene. Generally speaking, the higher the oxygen content of graphene, the higher the degree of substitution of the original structure of graphene, and the larger the defects in graphene. The Raman and XPS characterization results are complementary to each other. Both SEM and HR-TEM can characterize the external shape of graphene nanosheets. Among them, SEM can measure the internal shape and area of graphene nanosheets and characterize the external shape of multiple graphene sheets, but because of the low resolution, the detailed internal structure of each graphene sheet cannot be clearly seen. HR-TEM's ultrahigh resolution technology can overcome this problem. In the HR-TEM graph, the shape and thickness of the graphene sheet can be clearly seen, and the number of internal grid patterns can be known by magnifying the edge of the graphene sheet and determining the number of graphene layers. At the same time, HR-TEM's selected area electron diffraction (SAED) technology can also make people distinguish single-layer, double-sided, and multilayer graphene. AFM can measure the internal thickness of graphene nanosheets. This function also makes it a powerful tool to characterize the number of graphene layers. By combining the thickness of single-layer graphene, the number of multilayer graphene sheets can be measured, and the distribution of the thickness and number of layers of the prepared graphene nanosheets can be calculated through mathematical statistics of specific numbers

1	500		15
2	1000	35	11
3	1500		7

(2) UV-Vis is one of the most commonly used methods to characterize the concentration of graphene. According to Lambert's law, the absorbance of a dilute solution is directly proportional to the thickness of the liquid layer and the concentration of the substance. The reason for being limited to dilute solutions is that the average distance between substances increases at high concentrations, and individual graphene particles are affected by neighboring particles and their charges, changing their ability to absorb specific radiation

4. Based on the Effect of Stripping Single-Layer Graphene from Dispersed Carbon Nanotubes

4.1. The Influence of Preparation Conditions on the Effect of Exfoliating Single-Layer Graphene

(1) The influence of various temperature and pressure variables on the performance of graphene is studied, and the experimental results are shown in Figure 4

As shown in Figure 4, at a high temperature of 250°C, the rate of graphene formation is about ten percent. When the high temperature rises to 450°C, the rate of graphene formation is reduced from 10% to 7%. When the high temperature exceeds 450°C, the solvent decomposes in a large amount. But facts have also proved that high temperature is not conducive to graphene peeling. Due to the increase in pressure, the utilization rate of graphene has increased. When the pressure rises by 26 MPa (the maximum operating pressure allowed by the reactor), the utilization rate of graphene will reach 12%. High pressure may also be thought to help exfoliate graphene.

(2) A brief study of the influence of speed on graphene output during centrifugation is shown in Table 2

It can be seen from Table 2 that under the same reaction conditions and the same separation time, the yield of graphene samples is 15% when the speed is 500 rpm, the yield of graphene samples is 11% when the speed is 1000 rpm, and the yield of graphene samples is 1500 rpm when the speed is 1500 rpm. The rate is 7%. The yield of graphene samples decreases as the rotation speed increases.
Figure 5: Influence of the amount of dispersing aids on the effect of exfoliating single-layer graphene.

Table 3: Calculated value of excess molar volume.

Water volume fraction (Vw)	Density	Excess molar volume
1.0	0.997	0.00
0.9	0.999	-0.10
0.8	1.002	-0.25
0.7	1.005	-0.44
0.6	1.008	-0.67
0.5	1.010	-0.96
0.4	1.011	-1.22
0.3	1.001	-1.61
0.2	0.998	-154
0.1	0.982	-1.23

4.2. The Influence of the Amount of Dispersing Aids on the Peeling Effect of Single-Layer Graphene.

The system was prepared with different concentrations of dispersing aids and peeled at 3500 rpm for 15 minutes and then centrifuged at 1100 rpm for 35 minutes to obtain a graphene dispersion. The law of concentration is shown in Figure 5.

It can be seen from Figure 5 that, as the concentration of the dispersant increases, the concentration begins to decrease and eventually stabilizes and no longer changes. The initial increase in the concentration of the dispersion aid is due to the fact that it provides more stabilizers for the adsorption of the graphene surface, resulting in an increase in the stability of the dispersed graphene. However, when the polymer concentration exceeds the critical value (2 mg/mL), the dispersed graphene concentration does not increase but decreases. This phenomenon is because the excess dispersant molecules entangle with each other to form supramolecular structures such as micelles. The supramolecules are too large to enter the outer layer of the space graphene sheet, and as a result, the amount of graphene dispersed does not increase. In short, the optimal dispersion concentration of 2 mg/mL is selected and then determined as a constant process parameter.

4.3. Stability of Graphene Dispersion.

Under normal circumstances, the stability of solute molecules (hereinafter referred to as graphene) in solution mainly depends on three kinds of interactions: the interaction between the solvent and the solute, the interaction between the solvent and the solvent, and the interaction between the solute. In the mixed solvent system, the solvent-cosolvent interaction also has a significant impact on the solvent-solute interaction and solute stability. Excess molar volume, as a kind of excess thermodynamic force, and excess molecular volume may reflect the interaction between molecules in the mixture. For a mixed system of water and TMU, the excess molecular weight can be calculated by the following formula. Table 3 shows the calculated value of excess molar volume.

$$V^E = [xM_1 + (1-x)M_2]\rho - xM_1\rho_1 - (1-x)M_2\rho_2. \quad (13)$$

In the formula, 1 and 2 represent the density of water, TMU and water-TMU and mixed solvent, respectively, and 3 and 4 represent the density of water and TMU, respectively.

It can be seen from Table 3 that when the volume fraction of water is 0.3, the excess molecular volume of the mixed solvent is the minimum, and the dispersion concentration of graphene is the maximum.

The concentration of the dispersion aid is selected as 2 mg/mL, and the relationship between the eccentricity of the graphene concentration (left) and the sedimentation time (right) is obtained. The initial graphite concentration is 80 mg/mL, the shear removal time is 15 minutes, and the solution is left for 6 hours. Remove the supernatant and centrifuge at different speeds for 35 minutes. Take the supernatant and measure the absorbance. After calculating the concentration, take the supernatant and observe the concentration of the graphene dispersion after different precipitation times. The results are shown in Figure 6.

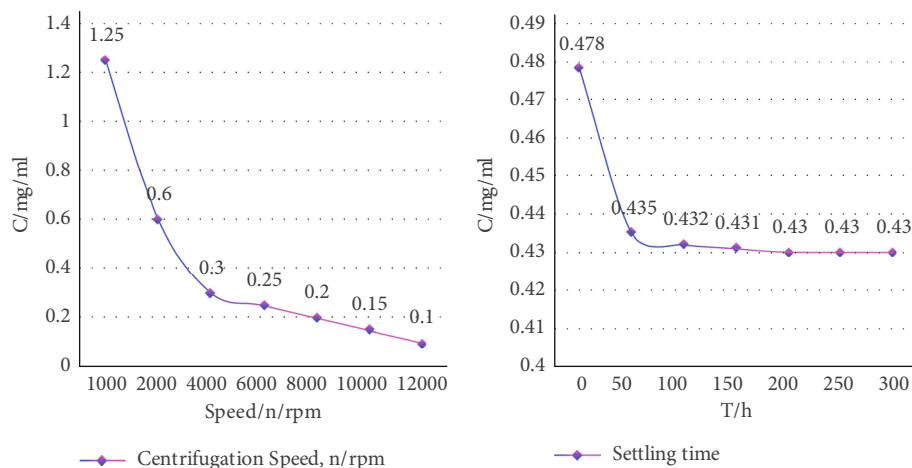
It can be seen from Figure 6 that the graphene concentration is inversely proportional to the eccentricity. If the centrifugation speed is slow, a high-concentration graphene


Figure 6: Stability of graphene dispersion.
Figure 7: Evaluation results of graphene peeling state.

dispersion can be obtained. On the contrary, the obtained graphene concentration is low. In the actual preparation process, the concentration and stability of the graphene dispersion are the most significant factors. At high eccentricity, the graphene dispersion is very stable, but the concentration is low. The obtained graphene has a high concentration, but the dispersibility is unstable. Precipitation experiments show that after 2 days at room temperature, about 96% of graphene is still stably dispersed in the system. This indicates that the entire system is in a stable state.

4.4. Evaluation of the Exfoliation State of Graphene. The AFM and TEM testing methods were used to characterize the exfoliation state of graphene, and the resulting sheet size distribution and thickness distribution are shown in Figure 7.

It can be seen from Figure 7 that more than half of the graphene sheets are 300-500 nanometers in size, and more than 80% of the graphene sheets are about 1.5 nanometers

in size. The thickness of a single layer of pure graphene is 0.6-0.9 nm, and the thickness of each layer is slightly larger than that of pure graphene, because the graphene sheet here adsorbs a dispersion aid. Thickness statistics show that most of the graphene obtained in the experiment is single-layer, double-layer, and a very small part of graphene with few layers.

5. Conclusions

This article focuses on the exfoliation of single-layer graphene based on dispersed carbon nanotubes. This paper establishes a mathematical model based on the high-speed centrifugal motion of the crushing ball in the crushing cavity and the motion trajectories of the collision ball and the shearing ball. According to the model, the centrifugal shear strength and the scattering limit length of the blind zone between the spheres are calculated, that is, the boundary scattering region. After understanding the relevant theories,

the exfoliated single-layer graphene based on dispersed carbon nanotubes is analyzed, and then, the exfoliated single-layer graphene based on this method is examined. The test results show that the thickness of each layer of the graphene stripped in this paper is slightly larger than that of pure graphene, because the graphene sheet here adsorbs the dispersion aid, and most of the graphene stripped in the experiment is in a single-layer and double-layer layers; very few of them are multilayered. Most of the data in this study are from data sources, but a small part of the data does not have sufficient evidence to prove that it is true and effective.

Cracks that are detected in concrete structures represent significant damage, and they can lead to a detrimental effect on the structure's durability. Their identification in a timely manner can help ensure structural safety and guide in-depth maintenance operation. Automatic detection of such cracks has been proposed using internal crack detection utilizing ultrasonic sensors in concrete. Cracks within the concrete can be detected using ultrasonic sensors. In this investigation, we introduced an intelligent method that is aimed at developing a crack detection scheme using ultrasonic sensors. These ultrasonic sensors are used for the detection of cracks in buildings which cannot be seen with our naked eyes; they are capable of alerting authorities via SMS message and providing the cracks' location via GSM and GPS modules. To monitor internal cracks in the concrete cubes and cylinders, the ultrasonic sensors can be fixed at the centre of the cube which will be used for interval crack monitoring based on crack detection technology. The grade of concrete used for testing is M_{25}, and it is well mixed with the ingredients of cement, fine aggregate, coarse aggregate, and water. The concrete is placed in the cube moulds having the dimensions $150\,\text{mm} \times 150\,\text{mm} \times 150\,\text{mm}$. The cylinders used in the case of the experimental analysis are of the dimensions of $150\,\text{mm}$ diameter and $300\,\text{mm}$ height. These specimens are cast and kept in the curing tank for 28 days to attain the maximum strength. After completion of the curing period, the specimens were taken out from the tank and weighed. After this weighing process, the cubes and cylinders are about $8.884\,\text{kg}$ and $13.399\,\text{kg}$, respectively. The information about the cracks can be displayed on the LCD, and also, the transmitted short message about the cracks can be exchanged between the devices using IoT.

1. Introduction

Concrete is the most often utilized material in the world for numerous civil infrastructure projects such as bridges and buildings. They are safely constructed by superimposing the various loads to the foundation, but their structural integrity is compromised by a variety of operating environmental factors. As a result, their strength is critical in nature, maintaining a high level of safety structures and durability, and their efficiency factors are critical because civil

infrastructure accounts for a significant portion of the national economy. The adopted ultrasonic sensor system can be classified into two major modules, namely, the hardware module and the software module. An ultrasonic sensor has two main parts, (a) the transmitter and (b) the receiver; the transmitter sends out a signal after it has been reflected off the surface or cracks [1, 2]. The principle of the ultrasonic sensor emits short bursts of high-frequency sound at regular intervals. Background interference is effectively suppressed by using ultrasonic sensors. Almost all materials which reflect the sound can be detected regardless of hue. Microultrasonic sensors are ideal for target distances ranging from 20 mm to 10 m, and they will record the time, pinpoint precision, etc. Some of the sensors can even resolve the signal to 0.025 precision [3, 4].

In this, the ultrasonic sensors play a major role in spotting the crack inside the concrete cube. Through ultrasonic ways, the cracks in the surface can be detected and the depth can be displayed. The GSM (Global System for Mobile Communication), GPS (Global Positioning System), and microcontroller-based broken bridge track detection are, when implemented, an efficient method for the detection of cracks which are present in the tracks. If a stretch is detected, then this sensor will send a signal to the Arduino UNO board which will activate the GPS receiver to exchange the information using IoT [5, 6].

In this paper, we proposed a low-cost, low-power IoT-based embedded technology to help and improve the safety standards for cylindrical concrete by preventing the cracks and impediments in the buildings. The testing crack prototype can identify fractures and impediments on buildings and cracks quickly. The findings indicate that this proposed technology will improve the dependability of safety systems [7–9]. By incorporating these characteristics into real-time applications, it can reduce the accidents by up to 70%. The major objectives of the paper are given below.

(1) The proposed IoT-based GPS and GSM for the internal crack detection system is an assisting unit that uses ultrasonic sensors to identify the cracks in cylindrical concrete available in buildings and bridges, etc.

(2) These sensors will check for the presence of a crack and displays the message on the LCD display if it exists. If the crack is detected, the data can be communicated using IoT

(3) As a result, the proposed method reduces automobile accidents and saves lives and also reduces the economic losses. This method is highly effective in reducing the need of human assistance in detecting cracks

2. Existing Method and Review of Literature

Crack detection is a telltale sign that a building is deteriorating. Crack detection is frequently required during the maintenance stage of a civil structure. In addition, inspection of the structural integrity based on crack analysis becomes substantial for the service life perdition of the structure. The process of determining the cracks using manual processes for large-scale structures is tedious and time-consuming, and many researchers are proposing their models based on image-processing concepts, which allows for a more rapid and efficient measurement of cracks in concrete [8, 9]. The general framework of these models is shown in Figure 1.

Figure 1 depicts an image-processing methodology based on an automated methodology for concrete detection. This model numerically expresses the crack defects, and this method can also be used to detect the internal cracks [10–12].

Figure 1 depicts an image-processing methodology based on an automated methodology for concrete detection. This model numerically expresses the crack defects, and this method can also be used to detect the internal cracks [11, 13].

For identifying and analyzing concrete surface cracks, Hsieh et al. [8] developed an automated technique-based image-processing system. Crack detection is performed based on the crack analysis which is performed on a picture of a concrete surface, and the crack width, length, and area are calculated. A numerical model for crack flaws was created by Bao et al. [3], and the suggested technique is used to identify and quantify the cracks. Mak and Picken suggested an image-based automated crack identification model for postdisaster building evaluation; the authors show that the suggested method may provide considerable benefits in postdisaster building element analysis based on numerical tests [14].

Chidambaram and colleagues [15] offer a hybrid detection method that incorporates both digital picture correlation and acoustic emission. The Otsu method and Sobel's filtering in Talan et al.'s work made use of image-processing techniques to identify cracking flaws in digital pictures. A multifractal analysis of crack patterns was carried out by Gonzalez et al. [16] with applications in reinforced concrete shear walls. In [17], Otsu suggested the identification of surface cracks in tunnel linings based on infrared pictures, and it is an effective crack identification method. Low contrast, uneven light, and severe noise pollution are all prevalent problems in tunnel lining photos, and the proposed solution is capable of addressing them.

Furthermore, one of the most important tasks of pavement surveys is to detect cracks that occur on the pavement surface. It is because if cracks are found early and properly repaired, the cost of road reconstruction can be reduced by up to 80% [18]. As a result, numerous image-processing methods for detecting asphalt pavement cracks where fissures have been formed. Image thresholding algorithm-based road crack identification models by Subramanian et al. [19], Alam et al. [20], and Kogilavani et al. [21] have all provided solutions.

Furthermore, many scholars [22–24] have established models based on edge detection algorithms. Nonetheless, the above-mentioned crack detection models' performance is frequently hampered by the complex texture of asphalt pavement and the shading conditions of digital images [25]. As a result, more sophisticated methods such as to
FIGURE 1: Image-processing-based crack detection model.

boost fracture detection performance, beam let transform [21], and shadow reductions [22] have been applied. According to a survey of the literature, applying intelligent image-processing models for automatic crack identification and analysis is becoming more popular.

The mode input is the original image captured by the digital camera. The suggested enhanced Otsu technique is then used to apply the image-thresholding procedure on the original picture. The M2GLD algorithms, as well as the classic Otsu algorithm, were discussed in the previous section, which make up the suggested improved Otsu technique. Following the picture penalization procedure, the picture concentrated effort procedure is used to remove noisy pixels and the noncrack objects mentioned in Figure 2. The research work is considered an image-based automatic crack identification model for postdisaster building evolution; the authors show that the suggested method can provide significant benefits in postdisaster building element analysis based on a numerical experiment [26, 27]. Furthermore, one of the most important tasks of concrete surveys is to detect cracks that occur on the pavement surface. If the cracks are found at early stages and they can be properly repaired, the cost of road reconstruction can be reduced by as much as 80%. As a result, numerous image-processing methods for detecting asphalt pavement cracks have been developed. The image-processing procedure is divided into two steps: firstly, the area with less than a particular number of pixels (Np) are removed, and then, an axis is added to the image length of an object, where

$$ARI = \frac{L_M}{L_N}. \tag{1}$$

The major axis and minor axis lengths are measured using an object-circumscribed ellipse [11–15]. The major axis and minor axis lengths are L_M and L_N, respectively.

The limitations of the existing methods are as follows. This is the research gap identified in existing methods. The limitations are as follows:

(1) The existing method does not have an IoT-based GPS and GSM for internal crack detection system which is an assisting unit that uses ultrasonic sensors to identify the cracks in cylindrical concrete available in buildings and bridges, etc.

(2) The sensors used in the existing method are unable to detect the presence of a crack

(3) Due to these limitations, the existing method cannot reduce the automobile accidents and cannot reduce the economic losses. That is why the existing methods are not effective in reducing the need of human assistance in detecting cracks

3. Materials and Method

3.1. Proposed Method. The "GPS and GSM for internal crack detection" is an assisting unit that uses ultrasonic sensors to identify cracks in cylindrical concrete. The sensors are used to detect the presence of cracks and display the message on an LCD display if the cracks are detected [16–18]. As a result, this proposed method reduces the automobile accidents and saves lives and also reduces the economic losses [19]. The block diagram of the proposed method is shown in Figure 3. The objectives of the proposed method are given below.

(1) The proposed IoT-based GPS and GSM for internal crack detection is an assisting unit that uses ultrasonic sensors to identify the cracks in cylindrical concrete available in buildings and bridges, etc.

(2) Detect impediments trying to access the concrete structures (e.g., buildings, bridges, and dams)

(3) The sensors will check for the presence of a crack and displays the message on the LCD display if it exists. If the crack is detected, the data can be communicated using an IoT device

(4) As a result, the proposed method reduces automobile accidents and saves lives and also reduces the economic losses. This method is highly effective in reducing the need of human assistance in detecting cracks

3.2. Block Diagram for Proposed Method

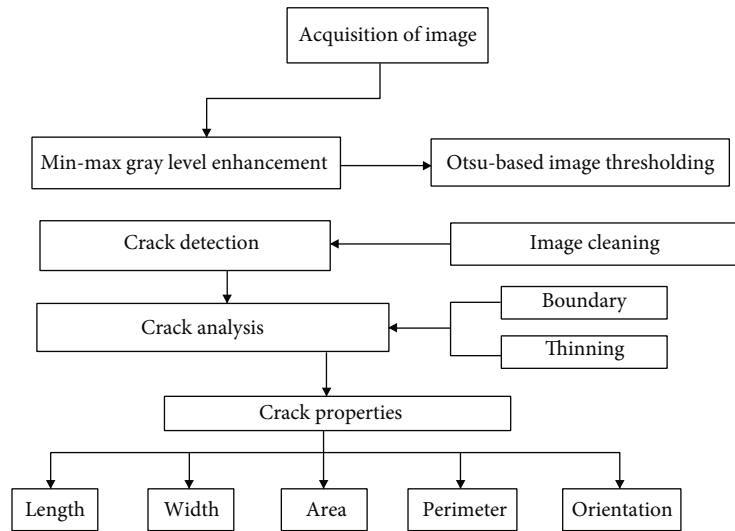
3.2.1. Arduino UNO. Arduino is a user-friendly hardware and software platform which is freely available, and it is an open source software. The Arduino board can detect input like light from a sensor, a button like in Figure 3, or a twitter tweet and convert them to outputs such as turning a motor, lighting and LED, or turning on a computer. Anything may be posted on the internet. The Arduino IDE (Integrated Development Environment) is a piece of software developed by Arduino that is used to write, compile, and upload code to Arduino devices. This is an open source programme, which is simple to install and use to start compiling code


FIGURE 2: Image enhancements with the proposed method.
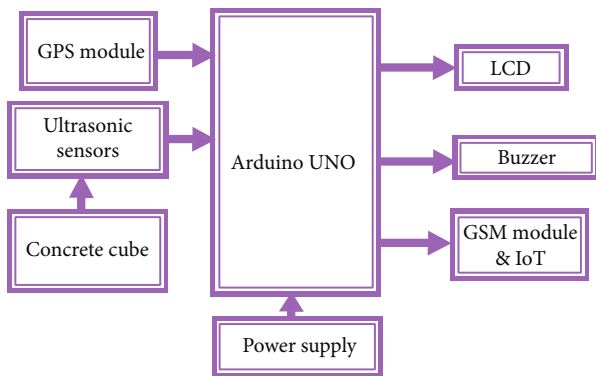

FIGURE 3: Block diagram of the proposed method.

FIGURE 4: Ultrasonic wave travel in air.

on the fly, and is compatible with almost all Arduino modules. The Arduino IDE is an open source software that is used to write and build code for the Arduino module. It is easily accessible for operating systems such as Mac, Windows, and Linux, and it is based on the Java Platform. This environment includes built-in methods and instructions for debugging, modifying, and compiling code.

3.2.2. GSM Module. A GSM modem is also known as a GSM module, and it is a hardware device which uses GSM technology used to connect remote networks. From the standpoint of the mobile phone network, they are substantially identical to a regular phone, including the requirement for a SIM card to identify themselves to the network.

3.2.3. Ultrasonic Sensor. Ultrasonic waves travel at a faster rate than normal sound waves (i.e., the sound that humans can hear). Ultrasonic sensors send ultrasonic pulses into the air and detect reflected waves from objects. Ultrasonic sensors contain a wide range of features such as intrusion alarm systems, automated door openers, and backup sensors for vehicles.

New application industries such as industrial automation equipment and automotive electronic industries are growing and will continue to rise in parallel with the rapid expansion of information processing technology. The research work [14] developed a unique piezoelectric ceramics manufacturing method to create several types of ultrasonic sensors which are small and have very high performance. The below-mentioned catalog's information will assist in making the best use of ultrasonic sensors.

3.3. HC-SR04 Sensor Features

(i) The operating voltage is +5 V

(ii) 2 cm to 450 cm theoretical measuring distance

(iii) 2 cm to 80 cm practical measuring distance

(iv) 3 mm precision

(v) Covered measuring angle: 15°

(vi) 15 mA is the operating current

(vii) 40 Hz is the operating frequency

3.4. HC-SR04 Ultrasonic Sensor: Working. This sensor is frequently used in a variety of applications including distance measurement or object detection. The ultrasonic transmitter and receiver are housed in two eye-like projections on the module's front. The sensor is based on the elementary concept

$$\text{Distance} = \text{Speed} \times \text{Time}. \qquad (2)$$

(a)   (b)
FIGURE 5: (a) Ultrasonic sensors are placed inside the concrete cube and its depth. (b) Wired connections after placing ultrasonic sensors in the concrete cube and cylinder.

The ultrasonic transmitter emits an ultrasonic wave that passes through the air and is reflected back toward the sensor if it comes into contact with any substance. The ultrasonic receiver module detects the reflected wave as depicted in Figure 4.

3.4.1. LCD Display (16 ∗ 2). A liquid crystal display (LCD) screen is a type of electronic display that can be used for a variety of purposes. A 16 ∗ 2 LCD display module is a low-cost module that can be found in a wide range of devices and circuits. A 16 ∗ 2 LCD has two lines and can display 16 characters per line.

3.4.2. Buzzer. A buzzer is also known as a beeper, and it is an auditory signaling device which is mechanical, electromechanical, or piezoelectric. Buzzer and beepers are commonly used in alarm clocks and timers and to validate human input such a mouse click or keyboard keystroke.

4. Result and Discussions

The ultrasonic sensors are placed in a concrete cube as shown in Figure 4, and after 24 hours, these cube specimens are taken out from the moulds and kept in a water tank for curing as shown in Figures 5(a) and 5(b). After 28 days, the curing process can be done, and the specimens are tested for compression under a compressive testing machine (CTM) as per IS 516:1959. If the cracks are not found in the specimen, then it shows no crack detected on the LCD as shown in Figure 6.

If the cracks are found in the concrete cube, the sensors detect the location and width of the crack present, and if the crack is not detected, this means that it does not send any message to the mobiles as shown in Figure 5. If the crack is detected, this means it sends via SMS to the mobile as shown in Figures 7–9. After detecting the crack, the message is displayed on the LCD. For reference, the sensors were named as left and right, where the depth is 11 for one concrete cube, and the data is communicated to the mobile along with the latitude and longitude. Figures 8(a) and 8(b) represent the depth of the cracks available in the right and left sides of the cube. The sensors are placed at the right and left sides of the cube. If the crack is detected by the sen-

FIGURE 6: Specimens kept under curing for 28 days.

FIGURE 7: Displayed message on LCD, when no crack is detected.

sors, then the message is displayed on the LCD connected to the system.

The left sensor is housed within a rectangular cube. As the pressure increases, fractures emerge inside the concrete, which are detected by the sensor and sent through SMS to a smart phone as shown in Figure 10. By not receiving the track's echo, the ultrasonic sensors can detect cracks in buildings and bridges. If the track's echo is received, then that gives the information that no crack is detected in the track. The output of the ultrasonic sensor is rounded and sent to a microcontroller that is linked to GPS and GSM.

To monitor internal cracks in the concrete cubes and cylinders, the ultrasonic sensors were fixed at the centre of the cube which will be used for interval crack monitoring based on crack detection technology. The grade of concrete used is M_{25} and well mixed with the ingredients of cement,

From Figures 11 and 12 and Tables 1, 2, 3, 4, 5, and 6, it is found that the cracks that are detected by the sensors are good enough, and these can be used in monitoring the health of structures. These sensors can be utilized such that a structure which is in a seismic zone can detect and monitor the vibrations that are coming from the earth, and these will be displayed on the screen. The cracks and the vibration sensors can be used for the structures which are under construction and which are already constructed. The sensors are placed in concrete structures for the detection of vibration alerts and cracks, and the information can also be exchanged

between the devices using IoT, so that this proposed method can save the lives of the people living in the buildings.

5. Conclusion

This paper describes the intelligent method for detecting the cracks and impediments in pillars of buildings. This method is cost effective, the reliability of safety measures in collapsing older structures can be improved as a result of this new creative technology, and also, this method is used to identify faults in tracks of the bridges. This helps to detect the cracks in buildings which are not visible to our necked eyes. It is capable of alerting authorities via SMS message and providing the cracks' locations via GSM and GPS modules. This method cannot cause any damage to nearby structures. The design is extremely efficient and user-friendly. The detection of fractures in a surface is very simple using this method. It is simple to use, and power consumption is also very low. Reduction of accidents can be effectively minimized by using this method. Therefore, it is concluded that this intelligent system is very effective and can minimize the accidents that can be caused during disasters by providing the information through mobiles and buzzer sounds.

China is a large agricultural country. With the development of industrial production, mechanized harvesting has become an inevitable development trend of agricultural material harvesting. In this paper, based on the latest technology of polycrystalline ferroelectric composite materials in the design of the shovel frame of the harvester's vibrating excavating shovel, the relevant theories of the polycrystalline ferroelectric composite material and the shovel frame of the harvester's vibrating excavating shovel are based on the literature. After understanding, the shovel frame structure of the vibrating excavating shovel of the harvester was designed, and the latest technology of polycrystalline ferroelectric composite material was introduced in the design of the shovel frame of the vibrating excavating shovel of the harvester to make the vibration system have better performance. The designed shovel frame structure is tested, and the test results show that the horizontal output force received by the shovel designed in this paper increases with the increase of speed and is minimized at 0.26 m/s. The vertical output force decreases first and then increases with the increase of speed. It is the smallest when the running speed is 0.39 m/s. The horizontal working resistance is always greater than the vertical working resistance, and it can be seen that the design of the shovel frame structure can be realized in actual work.

1. Inductions

Nowadays, because China's grain crop harvesting work is still labor-based and the level of mechanization of crop production is relatively low, a large amount of labor intensity, labor, and time plus huge costs have significantly reduced agricultural output. Production has had a great negative impact [1, 2]. At present, although some places have adopted mechanical harvesting of crops, they are only used for trenching, and engineers are required to participate in excavation, harvesting, and installation at the same time. Therefore, the degree of mechanization is relatively low. So, harvesting must be mechanized to increase labor efficiency and reduce labor intensity [3, 4].

In the harvester, the vibration function of the harvester is also the main part of the harvester's work. The vibration equipment is also the basic equipment for harvesting. Its

structure and motion parameters have a significant impact on the crop damage rate and the labor intensity of manual drilling [5, 6]. Therefore, optimizing and improving the performance of the shock absorber are very important for improving the working efficiency of the harvester.

Aiming at the research on the vibrating shovel of the harvester, some researchers have developed a cassava harvester with a drilling excavator with a built-in main knife structure. The principle is that the main knife penetrates the bottom of the tuber to completely separate the potato soil during harvest. The combine harvester includes harvesting tools, tuber cleaning/traction device, and collector/combiner. In addition to the lifting/loading device, it also has a device to loosen the soil around the cassava tubers, pull the tubers smoothly off the ground, and then use the device to load them onto the truck. Compared with previous harvesters, an advanced feature of this type of machine is the

integration of conveyor and harvester from separation to loading. However, the research on excavation parts and vibrating screens is still in the preliminary test stage, and the relevant research theories are not yet mature. Most cassava harvesters cannot carry out fully mechanized harvesting operations, and more research work is required to use the machines, especially the subsequent finishing operations. In addition, due to different geography and planting conditions, these machines are not completely suitable for cassava harvesting in our country. For this reason, it is necessary to develop a cassava harvester suitable for China's production conditions in accordance with the actual development of cassava in China [7]. Some researchers also pointed out that among the various combined harvesters produced at home and abroad, the excavator screen excavator is particularly suitable for peanut harvesting and film waste collection operations in China. It has the advantages of a low fruit drop rate, the recovery of residual film, the whole film, and the above-ground/underground broken film that can be recovered at the same time, and the recovery rate of residual film is high. However, the traditional single-screen excavator has problems such as large vibration and low soil cleaning effect. In recent years, China has invested a lot of manpower, material, and financial resources in the research and development of film waste-recycling machines, but the current film waste-recycling machines on the market have a single function and low economic performance and commercial value. These are all factors restricting the development of agricultural mechanization in China [8]. Some scholars believe that the excavation and harvesting of most agricultural products have gone through three main stages: shoveling, farming, and mechanical harvesting. Nowadays, the most developed countries have achieved almost mechanized harvesting, but in economically underdeveloped areas, manual harvesting is still the main harvesting method. Digging harvesters generally include digging, soil separation, placement (or collection), and other processes. Among them, excavation equipment and separation and transportation equipment are important components that determine the quality of excavation and harvesting [9]. In the study of polycrystalline ferroelectric composite materials, relevant researchers pointed out the characteristics of polycrystalline ferroelectric composite materials [10]: ferroelectric materials have strong spontaneous polarization, and the iron-based material of the bismuth layer has a high Curie working temperature. In the inspection of the entire bismuth ferroelectric layer material, it does not involve the extraction of the bismuth oxide layer produced by the B-based iron material, the lanthanide A site, and the relaxation type, and the high Curie of most bismuth layer iron materials' working temperature is above 500. At the same time, the ferroelectric material with the bismuth layer has good temperature stability in terms of high dielectric and piezoelectric properties, and the ferroelectric material with the bismuth layer also has an ultrahigh mechanical quality coefficient that reduces the dielectric constant and dielectric loss (2000-7200). Because of the high nonpolarization and low insulation effect of the bismuth oxide layer, the iron-bonded bismuth layer material also has an ultrahigh temperature coefficient of resistivity. This is due to the role of the bismuth peroxide layer in the defect, which

makes the perovskite layer more stable, so the contour structure of the bismuth layer ferroelectric material has better fatigue resistance [11]. Other researchers pointed out that multi-iron composites are materials that combine two or more custom-made iron materials in different ways. Among them, composite magnetic electrical materials are a hot research topic. Compared with single-phase magnetic materials, composite magnetic materials have a higher magnetic coupling coefficient, and the temperature of the Curie ferroelectrics and ferromagnets is much higher than at room temperature. Because of these advantages, composite magnetoelectric materials have been extensively studied [12]. In summary, with the development of mechanized production, more and more people begin to pay attention to the design of harvesters, but most of them stay in the theoretical part, and the mechanical applications of the design are not extensive.

This paper studies the shovel frame structure of the vibrating excavating shovel of the harvester, which is the latest technology of polycrystalline ferroelectric composite materials, and analyzes the characteristics of the polycrystalline ferroelectric composite material and the shovel frame structure of the vibrating excavating shovel of the harvester on the basis of literature data. We prepare the theoretical foundation for the following structural design, then design the shovel frame of the harvester's vibrating excavating shovel on the basis of these theories, test the designed structure, and draw relevant conclusions through the test results.

2. Shovel Frame Structure of the Polycrystalline Ferroelectric Composite Material and the Vibrating Shovel of the Harvester

2.1. Characteristics of Polycrystalline Ferroelectric Composite Materials. In addition to the macroscopic characteristics of the electrical group, iron materials have two important characteristics: the structure of the electrical domain and the Curie temperature.

(1) Electric domains refer to small regions with the same spontaneous polarization direction of ferroelectric materials. The boundaries between electrical regions are called domain walls [13]. If the angle between the polarization directions of adjacent electrical regions is 180°, then this region is called a field 180°. If the angle between the polarization directions of adjacent electrical regions is 90°, it is called a field of 90°, as shown in Figure 1. The electric field can be reversed under the action of external force and electric field. This is called electric field change. Applying an electric field opposite to the direction of spontaneous polarization to a ferroelectric substance can reverse the sector by up to 180°, but applying a compressed voltage or a voltage parallel to the direction of spontaneous polarization can reverse the sector by 90°

(2) The spontaneous polarization phenomenon of ferroelectrics only exists in a specific temperature range,
FIGURE 1: Schematic diagram of domain structure.

and the spontaneous polarization disappears if the temperature exceeds a certain temperature. The ferroelectric has undergone a phase change process from the ferroelectric phase to the normal dielectric phase [14]. That is, the temperature of the corresponding ferroelectric phase transition is called the Curie Tc temperature. Near the Curie temperature, ferroelectrics have many properties, such as dielectric response, piezoelectric response, and pyroelectric effect. Therefore, the Curie temperature change is one of the important means to adjust the physical properties of ferroelectrics

2.2. Application of Polycrystalline Ferroelectric Composite Materials

(1) Research on iron scale effect: due to the development of the thin iron film and ultrafine iron powder technology, the phenomenon of iron size has become a practical problem, so it must be studied in depth in time. Humans first theoretically predicted the changes of spontaneous polarization, phase transition temperature, and dielectric sensitivity of materials with time scales and measured the critical electric strength of typical ferroelectrics [15]. The above results have not only led to the design of a large number of integrated steel electrical components and thin composite materials but also promoted the development of modern polycrystalline ferroelectric composite material theory under limited time scale conditions

(2) Basic research and application research on ferroelectric liquid crystals and ferroelectric polymers: studies have confirmed that the liquid crystals in the inclined laminar flow phase composed of iron chiral atoms have ferroelectricity. In terms of performance, ferroelectric liquid crystals are very advantageous in electrooptical display and nonlinear optical applications. The electrooptical display is mainly through the reversal of polarized light, and its speed is several orders of magnitude higher than that of ordinary filamentary liquid crystal [16]. For nonlinear optics, the effect of second or high-frequency harmonic output exceeds the usual inorganic constitutive nonlinear optics application crystals. Ferropolymers were only recognized more than ten years ago and have a long history with thermoelectrics and piezoelectrics [17]. However, some new types of ferroelectric

polymers did not appear until ten years ago. After research, the iron polymer discovered has a wider range of compositions and different structures, so more ferroelectrics appeared later, which expanded the research field of ferroelectric physics and developed new applications

(3) Research on integrated ferroelectrics: the combination of the thin iron film and semiconductor is called integrated ferroelectric, and the research on this material is very extensive [18]. The basic form of ferroelectric memory is random access ferroelectric memory. It was initially considered to be the main purpose of research, and it was not commercialized until 2000 [19]. Compared with the 1950s and 1960s, modern materials and technologies have solved some important problems. First, the use of thin films helps to reduce the depolarization voltage and integrate with standard silicon or circuits, and the fatigue performance is significantly improved, resulting in multiple inverted iron films, which have gradually realized important uses in memory. At the same time, the application of ferroelectric thin films is not limited to the storage field but also includes ferroelectric effect transistors and ferroelectric random access memories. In addition to memory, the built-in ferroelectrics can also be used in infrared detection and imaging equipment, ultrasonic and surface acoustic equipment, and optoelectronic equipment. It can be seen that the built-in thin film devices have huge application prospects

2.3. The Shovel Frame Structure of the Vibratory Excavating Shovel of the Harvester

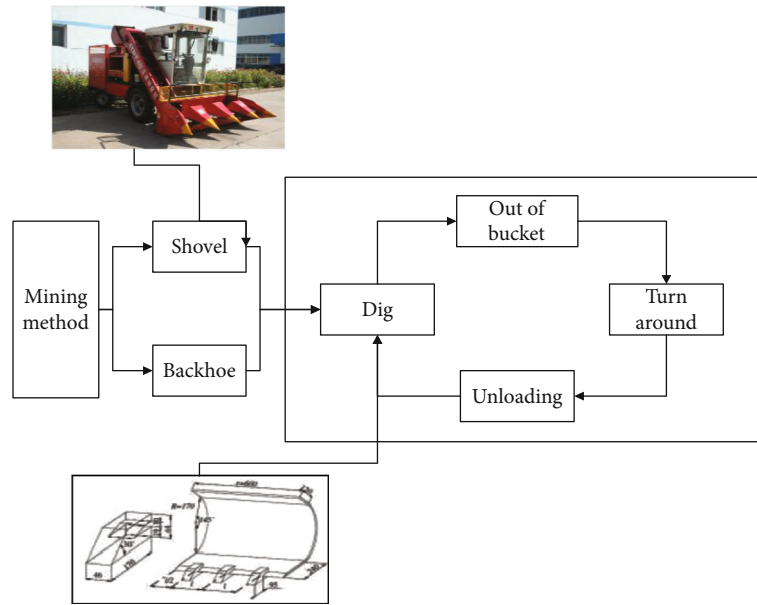
2.3.1. Working Principle of Harvester. As shown in Figure 2, the excavator operation process has typical cyclic characteristics, whether it is a front excavator or a reverse excavator drilling method. The cycle process mainly includes five stages: drilling, emptying the bucket, rotating, unloading, and drilling. The important stage of drilling design energy consumption is also the stage when the working device is subjected to drastic random load changes. During the entire drilling phase, very complex physical and mechanical phenomena occur between the bucket and the soil, that is, the soil is destroyed. The bucket is the first tangent to the ground at a specific initial speed and cutting force. If it is a forward drilling method, the main purpose is to destroy the integrity of the accumulated soil. After being completely destroyed, gravity causes the soil to roll into the shovel. At


FIGURE 2: Working principle of the harvester.

the same time, the bucket continues to cut deeply until the bucket is full. This mode of operation mainly occurs in open-pit mining and mineral blasting. The main purpose of excavator drilling is to destroy the soil structure.

2.3.2. The Relevant Parameters of the Shovel Frame of the Vibratory Excavating Shovel of the Harvester

(1) The Surface Inclination of the Vibrating Shovel of the Harvester. The vibrating shovel is also one of the main parts of the digging harvester, which directly affects the efficiency of the whole machine, and the shovel surface angle a is the main reason that affects the quality of the excavator [20]. Inappropriate viewing angles can cause soil retention and increase operating power. The design principle of angle a is to make the excavated material rise to a certain height along the surface of the bucket machine to prevent the excavated material from falling in the middle direction. At the same time, the excavation object should also do the following: the excavation is smooth, and it is transferred to the rear vibrating screen to gradually eliminate soil dirt.

According to design experience, if the angle a is larger, the crop soil mixture will be scattered on both sides and trapped in the digging shovel. In fact, the angle a is determined by many factors, such as the ability to loosen the soil, the height of the drilling material lifted by the excavator, and the characteristics of the soil. The larger the angle a, the weaker the ground, but it also increases the digging resistance and tends to maintain the ground. The smaller the angle a, the smaller the digging resistance of the excavator, the better the ground, and the higher the penetration efficiency, but the crushing effect of the shovel on the ground is reduced. At $a = 25°$, the moderately hard sandy loam is obviously blocked. So, in summary, the inclination value of the shovel surface is initially set in the range of 18°-26°.

2.3.3. Vibration Drive Device.
The drive unit is mainly used to drive vibration. The drive unit is mainly composed of a drive shaft, a front-drive joint, a rear-drive joint, a cam-drive arm, and a cam block. The transmission structure transmits power from the power output shaft of the tractor to the drive shaft. The drive shaft drives the cam to reciprocate. The front-drive connector and the rear-drive connector move forward and backward at the same time under the influence of the eccentric drive arm during driving [21].

The design of the drive camshaft arm is mainly used for the reverse movement of the two vibrating rods. The mass of the eccentric transmission vibrating arm is 2.67 kg, the eccentricity is 9 mm analyzed by the 3D software center of gravity analysis unit, and the calculated moment of inertia is 0.024 kg m. When the eccentric drive arm rotates, the inertial force will be generated, which will cause the whole machine to vibrate and affect the stability and service life of the machine tool. Therefore, it is necessary to balance the vibration. Therefore, it is necessary to install an eccentric mass with the moment of inertia such as an eccentric drive arm on the drive shaft. The mass is 1.78 kg, and the eccentricity (the distance from the center of the camshaft to the drive shaft) is 13.5 nm. The eccentric block of the eccentric transmission arm and the camshaft are symmetrical about the axis of the transmission shaft and are both located on the transmission shaft to neutralize the moment of inertia generated during operation.

2.4. Related Calculation Model.
The discrete element method (DEM) is a numerical simulation method for calculating complex discrete systems, mainly used to calculate the mechanical and kinematic properties of granular materials [22]. When analyzing mechanical problems, many mechanical or motion systems are usually involved. The laws and states of each system can be expressed and calculated through the interaction of mathematical analysis functions.

For the more complicated problems when using this mathematical analytical function method, new arithmetic methods have emerged, such as the finite element method (FEM) and the discrete element method. The finite element method divides the system to be analyzed into microscopic units, approximates each unit with a simple mathematical analysis function with limited degrees of freedom, and calculates the increase of the entire system through each microscopic unit. Similar to the idea of the finite element method, the discrete element method treats the entire system as a collection of interacting discrete units, analyzes the interaction between the discrete units, and then combines the mechanical action and exchange of energy between the units to obtain the analysis results of the entire discrete system and the mechanical influence on the external structure [23].

In summary, this paper uses the Hertz-Mindlin model to carry out discrete element numerical simulation experiments [24]. Suppose there are two spheres with radii of R_1 and R_2, and δ_n is the amount of normal overlap:

$$\delta_n = R_1 + R_2 - \left| \vec{r}_1 - \vec{r}_2 \right|, \tag{1}$$

where $\vec{r}_1$ and $\vec{r}_2$ are the vector positions of the centroids of the two particles.

Then the size of the contact radius a is equal to

$$a = \sqrt{\delta_n R^*}. \tag{2}$$

In the formula, R^* is the equivalent radius of the particle, and the derivation formula is as follows:

$$\frac{1}{R^*} = \frac{1}{R_1} + \frac{1}{R_2}. \tag{3}$$

The normal phase force between particles F_n is

$$F_n = \frac{4}{3} E^* (R)^{1/2} \delta_n^{3/2}, \tag{4}$$

$$\frac{1}{E^*} = \frac{1 - \lambda_1^2}{E_1} + \frac{1 - \lambda_2^2}{E_2}, \tag{5}$$

where E^* is the equivalent elastic modulus between particles, E_1 and E_2 are the elastic modulus of two spherical particles, respectively, and λ_1 and λ_2 are the Poisson's ratio.

The normal damping force calculation formula is

$$F_n^d = -2\sqrt{\frac{5}{6}}\beta\sqrt{S_n m^*} v_n^{rel}, \tag{6}$$

$$m^* = \frac{m_1 m_2}{m_1 + m_2}, \tag{7}$$

$$v_n^{rel} = \left(\vec{v}_1 + \vec{v}_2 \right) \times \vec{n}. \tag{8}$$

Among them, m^* is the mass equivalent, m_1, m_2 is the mass of the two particles, and v_n^{rel} is the relative velocity of the normal phase between the two particles.

The calculation formula of the tangential force between particles is

$$F_t = -S_t d_t, \tag{9}$$

$$S_t = 8G^* \sqrt{R^* \alpha}, \tag{10}$$

$$G^* = \frac{2 - \nu_1^2}{G_1} + \frac{2 - \nu_2^2}{G_2}, \tag{11}$$

where G^* is the gravitational velocity.

The calculation formula of tangential damping force is

$$F_t^d = -2\sqrt{\frac{5}{6}}\beta\sqrt{S_t m^*} v_t^{rel}. \tag{12}$$

In the formula, v_t^{rel} is the tangential relative velocity between the two particles.

3. The Shovel Frame Structure Design of the Vibratory Excavating Shovel of the Harvester

3.1. Application of the Latest Technology of Polycrystalline Ferroelectric Composite Materials.
The shovel frame structure of the excavating shovel of the harvester should be applied to the ferroelectricity of the polycrystalline ferroelectric composite material to realize good control of the shovel frame structure. This article expands the application of the polycrystalline ferroelectric composite material in the vibration system.

3.1.1. Principle of Vibration System.
The excavator designed in this research adopts the principle of vibration. When the vibrating excavator is working, the control unit adopts a pulse generator (motor, rotary valve). The structure of the oil circuit of the vibrating cylinder retracts the piston rod of the vibrating cylinder, and the shovel mounted on the piston rod vibrates and destroys the soil. Since the shovel returns through the return spring, it can drive the shovel to vibrate back and forth in a balanced position [24].

3.1.2. Vibration Structure.
The vibrating shovel is driven by a ZL50G loader and provides a hydraulic drive. The hydraulic system of the vibrating excavator is powered by a gear pump connected in series with the main pump of the loader ZL50G. The gear pump drives four parallel vibrating oil cylinders to move, and the excavating shovel moves under each vibrating oil cylinder. The vibrating cylinder periodically provides active vibration, and the return spring provides a specific pressure to reset the shovel [25]. The excavating shovel is made of a 65Mn steel plate and is fixed on the component with bolts, which can be easily replaced after wear.

Based on the above analysis, the control during the vibration process is very critical. Therefore, in order to have a better control capability of the vibration system, an integrated ferroelectric is used to design the system circuit.

3.2. Design of the Opening Angle of the Shovel Surface of the Shovel.
The design of the opening angle of the drilling shovel directly affects the resistance of the drilling. If the opening
FIGURE 3: Geometry diagram of the blade edge.

angle of the digging shovel surface is too large, the stems, leaves, and weeds are not easy to be cut during the operation of the digging shovel, and the movement resistance is large, which will increase the power consumption of the machine and increase the manufacturing cost [26]. Therefore, it is necessary to adjust the opening angle r of the digging shovel blade so that the stems, leaves, and weeds can slide smoothly along the edge of the shovel blade to reduce the digging resistance.

In the structural design of the second-order curved shovel, the opening angle of the shovel surface directly affects the digging resistance of the shovel surface during excavation. If the opening angle of the shovel surface is too large, the shovel blade will be difficult to cut stems, leaves, and weeds and will be easily tangled, resulting in a sharp increase in drilling resistance and increased energy consumption. Therefore, it is necessary to effectively control the opening angle of the shovel surface. To achieve the purpose of cutting stems, leaves, and weeds, reduce the resistance to drilling. According to the geometric relationship shown in Figure 3, the total resistance p of the stem, weeds, and soil at the end of the leaf is decomposed along the direction of the leaf and perpendicular to the direction of the leaf. The geometric relationship is as follows:

3.2.1. Design of Inclination Angle of Shovel. In order to study the change law of convex curved shovel resistance with the inclination of the shovel face and the length of the shovel body, the virtual shovel face inclination is introduced into the resistance calculation formula to realize the approximate calculation of the curved shovel. When the virtual shovel surface inclination and the length of the shovel body are unknown quantities, the calculation results are shown in Figure 4.

The comprehensive analysis in Figure 4 shows that under various combinations of the virtual shovel surface length and the subsurface inclination angle, the drilling resistance increases with the increase of the drilling depth. In addition, the length of the virtual surface of the shovel also has a certain influence on the resistance of the shovel. Under the same combination of digging shovel surface inclination angle, as the virtual length of digging shovel surface increases, the digging resistance tends to decrease, but the effect is not significant. In the actual design, the surface

length of the excavating shovel should not be too long; otherwise, the soil-blocking phenomenon will be more serious when harvesting crops. On the other hand, it is unfavorable for the soil separation of the next vibrating device, and the load capacity of the tool alone is increased to increase the power consumption.

In order to study the variation of convex curved shovel resistance with the height of the shovel surface, the virtual shovel surface height is introduced into the resistance calculation formula to realize the approximate calculation of the curved shovel. When the virtual shovel surface height is an unknown quantity, the calculation results are shown in Figure 5.

The analysis of the change curve of top resistance with the height of the primary shovel (Figure 5) shows that the resistance of the shovel decreases with the increase of the height of the primary shovel. It can be seen that the height of the stepped excavating shovel has a great influence on the excavation resistance. Therefore, when designing the excavating shovel, the height of the stepping excavating shovel must be appropriately selected so that the digging resistance will not become too high. The resistance of the shovel is also closely related to the combination of shovel inclination. Analyzing Figure 5, it can be seen that even if the slope of the main shovel changes, the slope of the auxiliary shovel will not change. When the shovel resistance changes and the inclination of the front surface of the main shovel is determined, if the inclination of the auxiliary shovel surface increases, the resistance of the shovel surface increases sharply. Therefore, the change of the inclination angle of the secondary excavator has a great influence on the resistance, and it is more obvious. The difference in the inclination angle of the two steps can be used to measure the crushing ability of the surface of the secondary excavating shovel. The greater the difference, the higher the crushing capacity, but the greater the surface resistance of the shovel.

After analyzing and studying the relationship between the inclination angle of the secondary surface curve and the drilling resistance, it may be found that the inclination angle of the main excavator surface must be smaller than the secondary inclination angle, and the difference between the two inclination angles cannot be too large or too small. If the value is too high, if the surface soil compressibility of
FIGURE 4: The relationship curve between digging depth and resistance when combined with different inclination angles.
FIGURE 5: Change curve with the height of the primary excavating shovel.

the digging shovel is low, the surface resistance of the digging shovel will increase sharply. If the value is too low, the soil will not have enough compressibility, but the resistance will be relatively low. Based on the above situation, the combined inclination angle of the convex surface of the excavating shovel pair is 15° and 30°.

3.3. Shovel Body Length Design. The length design of the shovel body should follow this principle. The length of the shovel body cannot be too long or too small. The length of the shovel body of the digging shovel is so long that the resistance between the soil body and the shovel surface is very small. However, when harvesting, the rear edge of the digging shovel surface is seriously blocked, which makes the crop fragile and affects the harvesting effect. The length of the shovel body is too small to cause the crops to be brought to the vibration chain of the conveyor before break-
FIGURE 6: Schematic diagram of the length of the shovel body.

ing, it is also difficult to break due to vibration, and the energy consumption of the vibration chain of the conveyor increases sharply. Therefore, the length design of the shovel
FIGURE 7: The bucket material quality change curve with time.

body should comprehensively consider the above factors and carry out a reasonable design.

The length of the shovel body is determined as shown in Figure 6, l_0 is the virtual shovel face length, l_1 is the first shovel face length, l_2 is the second shovel face length, a is the virtual shovel face inclination, a_1 is the first shovel face inclination, a_2 is the inclination angle of the second-stage shovel surface, h is the height of the rear end of the shovel body, and h_1 is the height of the first-stage shovel surface.

The actual design of the shovel body length should ensure that the speed is not zero when moving to the rear end of the first section; otherwise, the soil cannot be transported in time, causing a blockage.

3.4. Design of the Number of Teeth. For the bucket model for three different numbers of teeth (the number of teeth is 0, 2, and 4), a three-dimensional numerical model of the natural accumulation of noncohesive minerals during bucket drilling was established, the bucket manipulation process was visualized, and the bucket load during the entire drilling period was extracted. Compared with the previous model test and overall test method, the numerical simulation method guarantees the consistency of the test to a large extent, avoids the reproducibility and reproducibility of the model test, improves the reliability of the results, and reduces the influencing factors. The test cost and test cycle are reduced [27]. The experimental results are processed, and three types of hopper material quality curves that change with time (Figure 7) are extracted to explain the filling information and flow of the hopper material.

Through the processing of the test results, as shown in Figure 7, three types of bucket material quality changes that

TABLE 1: Discrete element simulation parameters.

Parameter	Numerical value
Soil particle radius (m)	0.001~0.003
Number of simulated soil particles	400000
Soil density (kg/m^2)	1540
Soil Poisson's ratio	0.3
Soil shear modulus (Pa)	$1.01e + 06$
Digging shovel density (kg/m$'$)	7890
Poisson's ratio of digging shovel	0.269
Shear modulus of shovel (Pa)	$8.2e + 10$
Time step (s)	$2.65e - 05$
Total simulation time (s)	52~53

change over time are extracted, and the filling information and flow of the materials in the bucket are described. The figure shows that the quality curves of the three buckets tend to be the same but have different widths and different final constant values. From 0 to 15 seconds, the quality of the three buckets will be significantly improved. Within 0-4 seconds, the gradient becomes smaller, indicating that the integrity of the material has been destroyed by the bucket teeth, and it begins to flow into the bucket. Starting from 4 seconds, the slope of the curve increases sharply. Large means that the material starts to enter the bucket quickly in large quantities. The slopes of the three curves are similar, but due to the difference in the number of bucket teeth, the quality of the bucket begins to vary. This difference is maximized in 6 seconds. The mass of the four-tooth bucket is

Table 2: Discrete element simulation results 1.

Working speed (m/s)	Horizontal force of the shovel (N)	Vertical force of the shovel (N)
0.26 m/s	55.91	55.65
0.37 m/s	62.21	47.89
0.48 m/s	66.12	52.34

Table 3: Discrete element simulation results 2.

Working speed (m/s)	Horizontal force of the shovel (N)	Vertical force of the shovel (N)
0.26 m/s	55.91	55.65
0.39 m/s	66.99	44.21
0.52 m/s	89.43	59.76

Table 4: Discrete element simulation results 3.

Working speed (m/s)	Horizontal force of the shovel (N)	Vertical force of the shovel (N)
0.35 m/s	55.81	55.52
0.37 m/s	66.99	44.89
0.39 m/s	89.43	59.76

43.40 tons. Compared with the teeth in bucket 0, the mass of the 2,964-ton bucket is almost 46.4% higher.

Observe the change of each curve from the maximum mass of the entire bucket to the final speed. The less the number of bucket teeth, the more stable the quality of the bucket and full bucket, that is, the more stable the maximum mass and final speed. The fewer the number of teeth, the lower the quality of the spilled material when the material quality in the bucket is maximized. Therefore, from the test results, it may be a reasonable choice to place less or no teeth on the nonsticky drilling material.

4. The Shovel Frame Structure Test of the Vibrating Excavating Shovel of the Harvester

In this chapter, using the EDEM discrete element modeling software, according to the physical and mechanical parameters of the soil, a soil particle model was established, combined with field test conditions, and a 3D model of the harvester for simulation adjustment was created. A particle factory will be built to simulate the work of the harvester. The movement of the ground and the power of the shovel were observed in the process. The harvester uses discrete data methods to simulate working resistance at six different operating speeds (0.26 m/s, 0.35 m/s, 0.37 m/s, 0.39 m/s, 0.48 m/s, and 0.52 m/s). A discrete data method is used to study the feasibility of harvester, and a new digital design research method is provided for this.

4.1. Establishment of Discrete Element Model. Use the EDEM software to simulate and analyze the working resistance of the harvester. In addition to obtaining the physical and material parameters of the soil and harvester in advance, it is also necessary to select the correct contact model and create a soil particle model. Create geometry for the shovel model, set limits for the simulation area, create a particle factory, and run the simulation.

4.2. Selection of Discrete Element Simulation Parameters. The closeness of the discrete simulation results to the actual field test results mainly depends on the choice of discrete simulation parameters. The selection of parameters is to consult relevant documents and make adjustments according to the simulation process. The specific simulation parameter values are shown in Table 1.

4.3. Discrete Element Simulation Results and Analysis. The simulation test adopts a single-factor test, which only changes the forward speed of the excavating shovel along the negative direction of the X-axis. The forward speed of the excavating shovel is adjusted in the six simulation tests. The negative direction along the X-axis is 0.26 m/s, 0.35 m/s, 0.37 m/s, 0.39 m/s, 0.48 m/s, and 0.52 m/s, respectively. The simulation results are divided into three groups. The specific data results are shown in Tables 2–4.

Analyzing the above simulation test data table, if other simulation parameters are consistent, changing the forward speed of the excavating shovel in the negative direction of the X-axis increases with the increase of the horizontal force of the excavating shovel. The increase first decreases and then increases. The working speed is 0.39 m/s, and the horizontal working resistance is always greater than the vertical working resistance.

5. Conclusions

This paper studies the shovel frame structure of the vibratory excavating shovel of the harvester with the latest technology of polycrystalline ferroelectric composite materials. After understanding the relevant theories, the shovel frame structure of the vibrating excavating shovel of the harvester is designed. In the shovel frame structure, the latest technology of polycrystalline ferroelectric composite material is introduced to make the vibration system have better performance, and the designed shovel frame structure is tested through actual tests. The test result shows that when the minimum speed is 0.26, the vertical resultant force first decreases and then increases with the increase of speed. The operating speed is 0.39 m/s, and the horizontal operating resistance is always greater than the vertical operating resistance. Therefore, the shovel frame structure designed in this paper is feasible in actual work. However, there are still some shortcomings in the research process of this article, which are mainly manifested in the absence of an actual field experiment.
