This paper studied the airflow cooling during blade surface processing and explained the applicable occasions of airflow cooling. The flat heat transfer model was used to study the characteristics of the cooling airflow during blade surface processing. The study of the model showed that the cooling coefficient of the airflow was affected by speed and pressure. Furthermore, the generation and strength of the autogenous cooling airflow were closely related to the physical properties of the grinding tool. In terms of processing heat generation, this paper used the Johnson-Cook material constitutive model to calculate the residual heat on the surface of the processed blade, and the surface temperature rise was within a controllable range. For the airflow intensity generated by the high-speed rotation of the tool, the airflow preset method was used to verify whether it meets the processing conditions.

1. Introduction

Due to the difficult processing of materials [1], the complexity of the shape, the diversity of materials, the diversity of various blade, etc., the difficulty of blade processing has been heavy. The key technologies of blade processing are thorny problems that the aviation industry urgently needs to overcome. Taking compressor blades as an example, they need to be forged or cast billet, milling, surface grinding, and other processes (such as manual polishing of the blade surface and dynamic balance adjustment of the blade) [2, 3] before they can be assembled to the shaft system; Figures 1 and 2 show a milled blade and its surface grinding technology. The machining accuracy of the blade has a great influence on the high-speed rotation accuracy of the shaft system and the performance of the whole machine [4–6]. In recent years, the development of blades with small aspect ratios and curved blades has put forward new requirements for blade processing accuracy and processing methods [7, 8]; the reason for this difficulty is that the geometry of the small aspect ratio blade is more complex than that of the general blade, which is difficult to complete with the existing processing technology. Such blades often need to undergo more complex surface grinding and surface coating layer process treatment. In summary, blade surface processing technology is the core technology of blade production.

Cooling during blade processing is a long-term concern. Due to the heat dissipation of titanium alloys, the surface of the blades will be ablated during the processing, and the local high temperature during the processing of nickel-based alloy blades will change the properties of the blade materials. The form of cooling and the control of cooling conditions are factors that cannot be ignored in blade processing technology.

2. Application of Airflow Cooling and Mathematical Model

There are many cooling methods for surface grinding [9–11]. In the grinding machine processing that uses a high-speed rotating hard grinding wheel as a grinding tool, coolant is usually used for cooling. This cooling method can not only take away the high temperature generated by

FIGURE 1: Blades formed by CNC milling.

FIGURE 2: Blade surface grinding technology.

FIGURE 3: Flat plate heat transfer model.

state of the workpiece will not be changed; third, the air flow launching device can be far away from the workpiece, thereby preventing interference in space; fourth, under the same power, the speed of the gas flow is higher than that of the liquid, which helps to increase the circulation frequency of the cooling gas. Obviously, the shortcomings of airflow cooling must be paid attention to and overcome. Due to the Brownian motion of gas molecules, the cooling airflow spreads quickly; therefore, a cooling airflow recovery device must be installed during the grinding process of the blade surface using airflow cooling. Since the recycled airflow is mixed with chips falling off the surface of the blade, abrasive particles dropped due to abrasive belt wear and various metal dusts, the processing environment must be ventilated, smoke and fire are prohibited, and employees must be equipped with breathing system protective masks.

The cooling air flow passes through the surface of the blade being processed and takes away the heat generated by the processing. This physical process can be illustrated by a flat plate heat transfer model. In the model shown in Figure 3, a certain microelement on the surface of the blade is taken as the research object. Since the selected microelement is small enough, its surface can be regarded as a plane approximately. The surface of the microelement is parallel, and the influence of the difference in the direction of the air movement can be corrected on this model. It is worth noting that according to the definition of fluid mechanics, the airflow velocity near the blade is distributed in a gradient, the airflow velocity closer to the blade is slower, and the airflow velocity farther away from the blade is faster. However, in this model, whether the blade or the airflow microelements are small enough that the airflow gradient distribution is very weak, which is ignored for the convenience of calculation.

The temperature distribution under this condition can be analyzed by the method of combining the N-S equation and the energy equation. When the cooling airflow and the processing speed reach a steady state, the governing equations of air flow heat transfer near the blade element should satisfy the following conditions.

Mass conservation equation:

$$\frac{\partial \rho}{\partial t} + \frac{\partial (\rho u_i)}{\partial x_i} = 0. \tag{1}$$

the processing heat, but it also can wash the surface of the workpiece and the surface of the grinding wheel at the same time and then take away the chips. In the abrasive belt grinding process, since the base material of the abrasive belt is a flexible material, it is not suitable to use a liquid cooling medium, and airflow is often used as a cooling medium. Compared with liquid, airflow cooling does not have particularly high cooling efficiency, but it has several obvious advantages.

First of all, the airflow cooling will not change the properties of the abrasive belt base material, the airflow cannot be attached between the abrasive belt base material and the contact wheel, and the movement form of the abrasive belt will not be changed; secondly, the airflow will not form residues on the surface of the workpiece and will not spread to the gap between the workpiece and the fixture, and the movement

Figure 4: Temperature distribution of the abrasive grain group passing through the highest peak of the blade.
Figure 5: Temperature distribution of the abrasive grain group leaving the blade.

Momentum conservation equation:

$$\frac{\partial(\rho u_i)}{\partial t} + \frac{\partial(\rho u_i u_j)}{\partial x_i} + \frac{\partial p}{\partial x_i} - \frac{\partial \tau_{ij}}{\partial x_j} + \rho g_i + S_i = 0. \qquad (2)$$

In the above two formulas, t is the cooling airflow density, p is the airflow pressure, u is the airflow velocity, τ is the viscous stress tensor, and S is the source term of the momentum equation.

The energy conservation equation in the cooling airflow region is

$$\frac{\partial(\rho c_p T)}{\partial t} + \frac{\partial(\rho u_i c_p T)}{\partial(x_i)} - \frac{\partial}{\partial x_i}\left(k_e \frac{\partial T}{\partial x_i}\right) - S_T = 0. \qquad (3)$$

The energy conservation equation in the microelement region of the processed blade is

$$\frac{\partial(\rho c_p T)}{\partial t} - \frac{\partial}{\partial x_i}\left(k \frac{\partial T}{\partial x_i}\right) - Q_T = 0. \qquad (4)$$

In the above two formulas, c_p is the specific heat capacity, Q_T is the heat source, k_e is the effective thermal conductivity, k is the molecular thermal conductivity, S_T is the source term of the energy equation, and k and k_e satisfy the following relationship:

$$k = k_e - k_r. \qquad (5)$$

The definition of k_r is

$$k_r = \frac{c_p \mu_r}{P_r}. \qquad (6)$$
Figure 6: Motion constraint of the stationary state of the blade.
Figure 7: Motion constraints in the case of both blade and abrasive belt movement.

In the above formula, μ_r is the turbulent viscosity coefficient, and P_r is the turbulent Prandtl number.

For the model in Figure 3, the following empirical formula can be used to calculate the heat transfer coefficient:

$$Nu = \frac{\alpha l}{\lambda} = 0.664 R_e^{1/2} P_r^{1/3}. \tag{7}$$

It can be seen from the above formula that the change of the turbulent Prandtl number of the cooling airflow is caused by the change of the turbulent viscosity coefficient, and the change of the Prandtl number causes the change of the plate heat transfer coefficient. However, the heat

transfer coefficient is not only affected by the Prandtl number, but also by the airflow Reynolds number. The definition of the turbulent Reynolds number shows that when the speed and pressure of the cooling airflow change, its Reynolds number will change, which will make the blades microelement's heat transfer coefficient changes.

3. Numerical Calculation Model for Processing Temperature

In this paper, the heat generated during the surface grinding of the blade microelement is simulated. The blade material is a new titanium alloy Ti6Al4V. The Johnson-Cook material constitutive model is a thermo-viscoplastic constitutive model suitable for this blade material. The reason for choosing the Johnson-Cook constitutive model is that this constitutive model can not only adapt to the thin-wall shape characteristics of the blade, but also is commonly used in titanium alloys. Research on the dynamic constitutive relationship of metals and mature numerical calculation programs can often achieve better results in grinding mechanism simulation. The mathematical expression of Johnson-Cook material constitutive model is

$$\sigma = (A + B\varepsilon^n) \left[1 + C \left(\ln \frac{\varepsilon}{\varepsilon_0} \right)^m \right] \left[1 - D \left(\frac{T - T_0}{T_0} \right)^k \right]. \tag{8}$$

In the above formula, A, B, n, C, and m are material constants, respectively, representing the yield stress intensity, strain strengthening coefficient, strain strengthening index, strain rate strengthening parameter, and temperature strain rate sensitivity under quasi-static conditions; σ is the flow stress; T_m is the melting point temperature; T is the temperature of the blade material, T_r is the reference temperature, usually designated as the ambient temperature of the simulation experiment; ε is effective plastic strain, and ε_0 is the reference strain rate. The Johnson-Cook material constitutive model parameters of Ti6al4v are shown in Table 1.

In addition to the constitutive model, the simulation of such problems must also define failure criteria. During the grinding process of the blade surface by abrasive particles, the blade material undergoes deformation similar to shear failure under the plowing action of the abrasive particles. Therefore, the failure parameters of the blade material can be defined as follows:

$$\omega = \sum \left(\frac{\Delta \varepsilon^{\mathrm{pl}}}{\varepsilon_{\mathrm{f}}^{\mathrm{pl}}} \right). \tag{9}$$

In the above formula, $\Delta \varepsilon^{\mathrm{pl}}$ is the increase in plastic strain, and $\Delta \varepsilon_{\mathrm{f}}^{\mathrm{pl}}$ is the amount of failure strain.

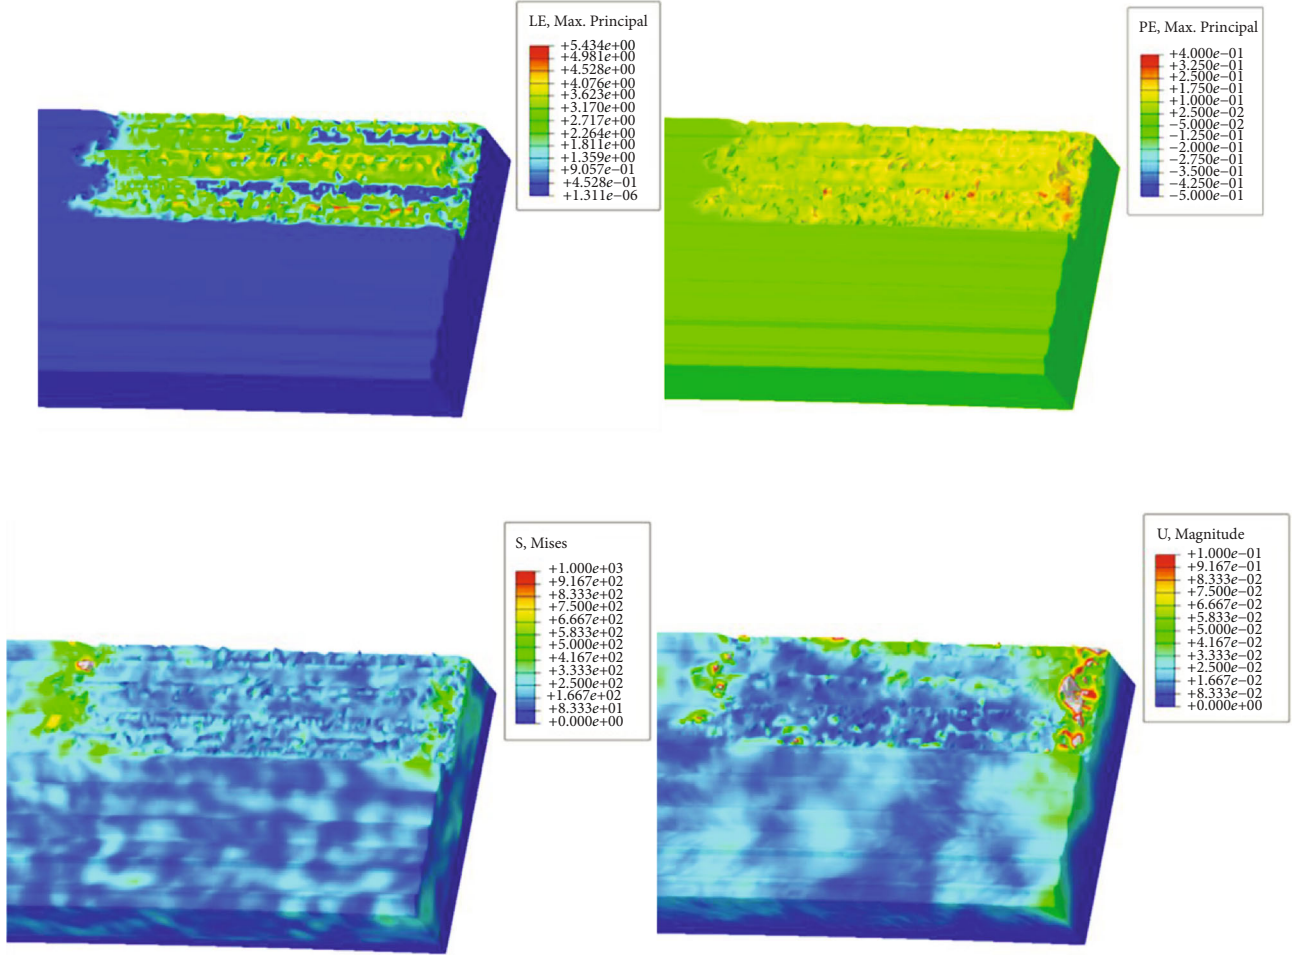
The failure strain $\Delta \varepsilon_{\mathrm{f}}^{\mathrm{pl}}$ is a function related to the strain rate, compressive stress deviator stress ratio, temperature,


FIGURE 8: Simulated calculated blade surface with blade feed motion when the abrasive belt is in the initial wear stage.

and other parameters, and its expression is

$$\varepsilon_{\mathrm{f}}^{\mathrm{pl}} = \left[\mathrm{d}_1 + \mathrm{d}_2 e^{(\mathrm{d}_3 (p/q))} \right] \left[1 + \mathrm{d}_4 \left(\frac{\dot{\varepsilon}^{\mathrm{pl}}}{\dot{\varepsilon}_0} \right) \right] (1 + \mathrm{d}_3 \theta). \quad (10)$$

The dimensionless strain rate in the above formula is denoted as $\varepsilon^{\mathrm{pl}\bullet}/\varepsilon_0{}^\bullet$, and the compressive stress deviatoric stress ratio is denoted as p/q, where p is the compressive stress and q is the Mises stress. For material Ti6al4v, d1, d2, d3, and d4 are invalid parameters, and their values are shown in Table 2.

4. Analysis of the Results of Numerical Calculations

The temperature change of the material during processing can be obtained after analysis using the finite element software ABAQUS. In this paper, The temperature cloud diagram of the processing process is used to analyze the temperature change during this process. The results are shown in Figures 4 and 5. It can be clearly seen from these two figures that the area where the temperature rises sharply is the area where the chips remain, that is, the valley area of

the milling texture. In the peak area of the milling texture, the temperature of the blade surface element does not rise sharply. The reason for this phenomenon is as follows: on the one hand, because the simulation analysis is a single grinding, the microelements on the blade surface are not constantly rubbed, which causes the temperature of the system to rise and accumulate. On the other hand, the large amount of heat generated during grinding is mostly attached to the chip body. The grinding simulation setting defaults that the cut chips are completely separated from the workpiece, so there is a significant temperature increase in the area where the chips remain. The areas where there are no residual chips, that is, those areas where the chips have been evacuated, will not cause a sharp rise in the surface temperature of the blade. The heat generated by mechanical friction during processing is removed with the removal of chips. It can be seen that it is very necessary to remove chips in time.

This paper distinguishes two different simulations and experiments in which the blade is at rest and the blade is in motion, in order to maximize the accuracy of the calculation. Figures 6 and 7, respectively, show the constraints of these two simulations; due to the different constraint conditions, the former cannot be simply defined as the state where the speed of the latter is zero. The simulation calculation amount of the blade and the belt at the same time is several

FIGURE 9: Cooling air flow velocity in the contact area during blade machining.

FIGURE 10: Cooling air flow velocity in the space near the processing area.

times that of the static and fixed state of the blade. In addition, the geometric characteristics of the original shape of the blade surface in the collection and distribution model should be as close as possible to the real blade blank surface.

Except that the setting of abrasive material parameter G_m is controlled by empirical value, other detailed parameters setting can be carried out as described below:

The hardness parameter H of the abrasive particle group is controlled by changing the parameters of the material. Change the speed of the reference point rotation (load-boundary condition) by setting the speed values of the six degrees of freedom in the boundary conditions, thereby controlling the movement frequency f of the abrasive particle group. On this basis, the linear velocity vs. of the abrasive particle group is controlled by changing the radius of gyration of the abrasive particle group movement (that is, the distance between the reference point and the abrasive particle group). Similarly, this control method is also adopted for the motion parameter v_w of the blade surface model,

We can control the normal force Fn between the blade and the abrasive particle group by changing the MPC contact option parameter (interaction-MPC constraint) in the constraint options. The definition of MPC is multipoint constraints; that is, the constraint point is not a single contact

form. The tangential force Ft between the blade and the group of abrasive particles is controlled by setting the interaction property-tangential behavior in the interaction property, and the number of revolutions N of the abrasive particle group in a period of time is controlled by setting the time step (step-time period). The cooling condition constant adopts the default preset value, that is, the reduced air flow rate (Kg/min) produced by the high-speed rotation of the grinding tool, so that the workpiece can be effectively cooled during processing.

Figure 8 shows a set of simulation results that meet the above settings. The results show that the machining results achieve the expected results under the cooling conditions of the air flow generated by the grinding tool. The cooling condition constant changes due to changes in various parameters of the tool, and the cooling effect brought about by this change is in line with the processing requirements.

5. Experiment and Analysis

According to the above calculation results, the airflow generated by the high-speed rotating grinding tool can meet the requirements of velocity and flow rate; meanwhile, the heat carried by the chips will not cause the local temperature of the blade surface to rise too high. This paper uses an air flow meter to measure the cooling air flow conditions in the actual process. Figures 9 and 10 show that when the machine rotates at a certain speed, the air velocity in the contact area of the blades and the contact wheel and the air velocity in the space near the processing area are, respectively, 7.413 m/s and 5.903 m/s, and the airflow temperature is about 15 degrees Celsius.

In an open situation, the total pressure ratio of the cooling airflow can be set to 1.1, the airflow temperature is 288 k, the atmospheric pressure is 0.101 Mpa, and the air density is 1.2 Kg/m3. At this time, the cooling airflow mass flow on the processing surface can be used as follows The formula shown approximates:

$$q_m = V\rho_0\Pi. \tag{11}$$

In the above formula, q_m is the mass flow rate of the cooling gas, ρ_0 is the air density, and Π is the total pressure ratio of the airflow.

If the area of the air flow around the processing area is 0.01m^2, then the air flow rates of the two are 5.75Kg/min and 4.57Kg/min, respectively. In the simulation calculation, it can be considered that the cooling airflow generated by the rotation of the grinding tool is equivalent to the flow rate of 5kg/min. More powerful ventilation air flow and cooling effect need to be achieved by generating cooling airflow through an air compressor. Obviously, the cooling effect of the airflow is closely related to the geometry of the tool. The research in this article can give such a processing idea: it is possible to design a processing tool that can not only conform to the blade surface grinding, but also generate high-speed cooling airflow due to the movement of the tool itself. This tool will change the shape of the contact wheel of the belt machine. These work will be carried out in further research.

6. Summary and Outlook

On the basis of the plate heat transfer model, the characteristics of the cooling airflow during the blade surface processing are studied. The cooling coefficient of the airflow is affected by the speed and pressure. The generation and strength of the self-generating cooling airflow are closely related to the physical properties of the grinding tool. In terms of processing heat generation, this paper uses the Johnson-Cook material constitutive model to calculate the residual heat on the surface of the processed blade, and the surface temperature rise is within a controllable range.

For the airflow intensity generated by the high-speed rotation of the tool, the airflow preset method is used to verify whether it meets the processing conditions. In the subsequent research, in addition to the plate heat transfer model, the conical capillary model can also be used as the cooling airflow model. It is necessary to improve the shape of the processing tool so that it can not only meet the requirements of blade surface processing, but also generate high-speed cooling airflow. Future research can be combined with cooling and lubrication, air flow types, etc. to increase the breadth and depth of research.

Spinal cord injury is a serious neurological injury disease. With the improvement of living standards in China in recent years, we began to develop sports hobbies, so the cases of sports spinal cord injury also increased. The main cause of spinal cord injury is the microenvironment after spinal cord injury, which prevents nerve regeneration. With the support of the state and the efforts of regenerative medical scientists in China, remarkable progress has been made in the reconstruction of microenvironment after spinal cord injury in recent years. The scaffold was combined with multifunctional nanoparticle repair technology to reconstruct the microenvironment of nerve regeneration by transplantation. The purpose of this paper is to carry out an experimental analysis on the repair of spinal cord injury after exercise based on multifunctional nanomaterial particles, and this paper takes badminton as an example to explore. The microenvironment of spinal cord injury was improved by implantation of multifunctional nanomaterial particles and nerve regeneration collagen scaffold. We found 48 patients with spinal cord injury after badminton and divided them into two groups. The pilot group was treated with a multifunctional nanomaterial granular nerve scaffold, whereas the treatment in the control group was with ordinary drugs. The experimental group was followed up for nine months, starting one month after the surgery. After nine months of experimental investigation, we found that the treatment of multifunctional nanoparticle nerve scaffold can not only reduce the injury area and scar formation but also promote the regeneration of nerve microenvironment and the recovery of body function and motor function of patients and reduce the inflammatory reaction caused by injury and pain.

1. Introduction

Spinal cord injury is the most serious complication of the spinal cord, which has the characteristics of high disability rate, high morbidity rate, high mortality rate, and many complications [1]. Spinal cord injury belongs to the central nervous system injury, and its repair after injury has always been a major problem in the international medical community [2]. At present, with the rapid development of high-altitude work, modern transportation industry, and the endless variety of difficult sports injuries, the incidence of this disease is increasing year by year. What follows is the highly degraded physical health and quality of life of the patients, as well as the heavy mental and economic burden to the patient's family and even the whole society, which greatly hinders the development of society [3].

Following spinal cord injury, some conduction tracts in the medulla spinalis, such as the corticospinal tract [4], can regenerate and grow into the medulla spinalis distal to the injury, but this does not significantly improve motor function after playing badminton in spinal cord injury patients. This is mainly due to the fact that after spinal cord injury, although some nerve fibers in the corticospinal tract can sprout and grow, they cannot form the correct neural

circuit with the motor center of the nerve loop originally dominated by the lower part of the injury. It affects the recovery of original nerve function.

With the continuous development of modern biomedical diagnosis and treatment technology, the original traditional disease diagnosis mode and treatment mode can no longer meet the needs of precision medicine and personalized medicine [5]. Multifunctional diagnosis and treatment mode, with its own accuracy, reliability, and the function of multiple examinations at the same time, has been highly praised by patients and medical workers. Multifunctional nanoparticle [6] technology, that is to integrate multiple components with different properties into one nanoparticle, can conduct real-time tracking and adjuvant treatment of disease diagnosis and treatment through its own physical and chemical properties at the same time of diagnosis and treatment. Therefore, in this paper, we applied the multifunctional nanoparticle technology to the treatment of spinal cord injury, combined the multifunctional nanoparticles with collagen nerve scaffold [7], and improved the wound site of patients with spinal cord injury due to badminton sports, as far as possible to reduce the pain of patients, shorten the recovery cycle, and reduce the burden of patients.

Multifunctional composite nanostructures are usually composed of two parts: the core and the outer shell [8]. Compared with the common simple nanostructures, core-shell nanostructures play a good role in protecting the core components, especially the easily oxidized or unstable components, and significantly improve the physical and chemical stability of multifunctional particles. In addition, the biocompatible shell outside the core can effectively reduce the biological toxicity of nanoparticles, improving the biological dispersion ability and phagocytosis efficiency of nanoparticles [9]. Core shell structure [10] can also effectively improve the connectivity of multifunctional nanoparticles with other biomolecules by changing the shell composition, so that the nanoparticles have better targeting and drug-loading capacity. In addition, the composition of the core and the shell can be selectively changed according to the specific application requirements, so that the multifunctional nanoparticles have the characteristics of both at the same time, so as to achieve a variety of biomedical diagnosis and treatment purposes. At present, core-shell nanomaterials with different functions have been widely used in electronic instruments, biomedicine, optics, and catalysis.

In this paper, we will analyze the pathological mechanisms of marrow injury from all aspects, starting from the physiological structure of the marrow, from chronic spinal cord injury to acute spinal cord injury. From the theme of this paper, the application of multifunctional nanomaterial particles in the treatment of spinal cord injury is described. The objectives are to analyze the research status and prospect of multifunctional nanomaterial particles in the treatment of spinal cord injury and combine the multifunctional nanomaterial particles with collagen nerve scaffold to maximize the efficacy of both in spinal cord injury.

2. Mechanism of Spinal Cord Injury

2.1. Physiology of the Spinal Cord. The medulla spinalis not only connects the brain to the peripheral nerves but also produces spinal reflexes [11]. The spinal cord begins in the medulla oblongata at the base of the brain, passing across the greater foramen and through the vertebral canal. In humans, the spinal cord ends at the level of the first lumbar spine, while in rats the spinal cord ends at the level of the third lumbar spine. In the process of growth, the growth rate of the lumbar spine is faster than that of the spinal cord, so the spinal nerve under the cervical spine passes through the intervertebral foramen under the corresponding vertebral body. From the inside to the outside, the spinal cord is covered by the leptomeningeal, arachnoid, and dural H-layer fibrous tissue. There is a subarachnoid space filled with cerebrospinal fluid [12] between the pia mater and arachnoid. There are fibrous connective tissue and adipose tissue between the dura mater and spinal plate. These structures, along with the spine, protect the spinal cord. The gray matter of the spinal cord is located in the center and surrounded by white matter. The gray matter is composed of interneurons, neuronal cell [13], dendrites, afferent nerve fibers, and glial cells. The peripheral white matter is mainly composed of multiple groups of myelinated axons. These axons with different functions are called fiber bundles or fiber pathways, which run longitudinally along the spinal cord. Some axons send information down from the brain to the peripheral nerves, while others transmit information from the peripheral nerves to the brain.

At present, spinal cord injury can be divided into three stages.

(1) Acute stage: in the first few days after injury, the main necrosis cells and then hematoma appear in the gray matter of the spinal cord, compressing the surrounding tissues, causing edema and microcirculation disorders, and aggravating the spinal cord injury

(2) Secondary reaction stage: injury after several minutes to a few weeks, including continuous ischemia and necrosis of cells, inducing or promoting apoptosis and necrosis of nerve cells, injured sites and surrounding areas

(3) Chronic stage: it can last for several days or even years, the range of apoptosis continues to grow, and scar formation, cystic regional expansion, and changes in nerve impulse transmission pathway were observed; some patients even have chronic central pain such as hyperalgesia and allergy

2.2. Primary Injury and Secondary Injury. When the spinal cord is severely injured, or the most common sudden impact, compression or vascular blockage, nerve injury has begun. We call it "primary injury." The primary injury is the mechanical injury of spinal cord caused by the injury itself, which results in necrosis of intramedullary cells and interruption of axons. It can be divided into spinal cord

concussion, spinal cord contusion and hemorrhage, spinal cord compression, cauda equina injury, etc. It can lead to permanent irreversible dysfunction of the spinal cord. The prognosis and rehabilitation were in direct proportion to the degree of injury at that time. At present, the local treatment of primary spinal cord injury is not effective. This is mainly because the local treatment of primary spinal cord injury is not suitable for primary spinal cord injury.

A series of harmful biological reactions caused by mechanical spinal cord injury are called "secondary injury." Secondary injury occurs after primary injury, sometimes more severe than primary spinal cord injury, leading to central hemorrhage and necrosis to edema and apoptosis area 2-3 cm long near the spinal cord, which is often replaced by glial scar tissue in the late stage. The mechanisms include microcirculation, free radical and lipid peroxidation, excitatory amino acid theory, calcium overload, electrolyte disturbance, and inflammatory reaction. It is one-sided to discuss one or more pathological injury mechanisms. Secondary injury is the result of multiple mechanisms. The interaction of various mechanisms affects the development of spinal cord injury. Secondary injury can occur within minutes to weeks after primary injury and last for several years. It can develop to both ends of the spinal cord, leading to more severe nerve damage, and eventually into a chronic phase.

It is very necessary to understand the biochemical and cytological mechanisms of primary and secondary spinal cord injury [14]. Therefore, we can study the treatment methods of these two periods to reduce the area of secondary injury and promote nerve regeneration. In 1911, Allen removed the inflammatory fluid from the spinal cord injury area in dogs and found that the motor function of dogs was significantly improved. Therefore, he proposed the concept of secondary spinal cord injury. With the development of research, Dr. Allen proposed that local hemorrhage at the injury site could lead to more severe spinal cord injury.

2.3. Apoptosis. Apoptosis [15] is a kind of programmed cell death that occurs under physiological or pathological conditions. Trauma can also lead to apoptosis. There is clear morphological and histological evidence that spinal cord injury can induce apoptosis. Apoptosis occurs in neurons, oligodendrocytes, microglia, and astrocytes. After spinal cord injury, oligodendrocytes in white matter die within weeks due to demyelination. Apoptotic cells were found in dentate and monkey and human spinal cord injury, which indicated that the active cell death aggravated the injury degree of central nervous system. The mechanism of apoptosis after spinal cord injury has not been fully studied, but the apoptosis of microglia and oligodendrocytes is closely related, suggesting that the activity of microglia may be related to apoptosis.

2.4. Inflammatory Response Theory. Inflammatory response theory: immune inflammatory response is the mechanism of self-defense and repair when the body is injured. Studies have shown that in spinal cord injury, the main inflammatory cells involved are neutrophils, monocytes, lymphocytes, and microglia in nerve cells. After spinal cord injury, resident microglia are activated, leukocytes rapidly infiltrate into the injured area and release unfavorable cytokines and reactive oxygen species, which leads to more leukocyte aggregation and more serious tissue damage. Secondary inflammatory reaction often plays a negative role in injuring spinal cord tissue, destroying and repairing, and promoting apoptosis and excessive hyperplasia of scar. A scholar believes that human intervention can control the development of secondary inflammatory response in favor of spinal cord repair; otherwise, inflammatory reaction will promote cell apoptosis and expand the scope of injury. Some studies suggest that inflammatory reaction is not completely harmful, it may play a beneficial role in the process of nerve tissue repair.

2.5. Chronic Stage of Spinal Cord Injury. The chronic stage of spinal cord injury includes slight demyelination of white matter, dissolution of gray matter, deposition of connective tissue [16], proliferation of reactive glial cells, and eventually formation of therapeutic scars. Glial scar [17] is mainly composed of reactive astrocytes, microglia (macrosatellite cells), extracellular matrix, and chondroitin sulfate polysaccharide. It acts as a barrier to prevent axons from passing through. About 25% of patients with spinal cord injury will form cystic cavity around glial scar [18]. Syringomyelia is usually caused by syringomyelia, which usually causes neuropathic pain. As a result, many patients develop pain syndrome, which eventually leads to depression. The mechanisms of pain and depression following spinal cord damage have not been clearly studied, but animal experiments have found that neurons from the back corners of the spinal cord are hyperexcitable for several weeks after injury, which could be associated with pain. In addition, studies have shown that chronic pain is related to the activation of the hypothalamic pituitary adrenal axis, and chronic pain is an inevitable stressor. The activation of HPA axis can also cause the release of glucocorticoid, which is closely related to depression.

3. Research on the Repair of Spinal Cord Injury with Nanomaterials

3.1. Research Background of Spinal Cord Injury. Spinal cord injury leads to partial or total loss of function below the wound. It not only brings great changes to patients and their families but also brings economic losses far beyond our expectation. The quality of life of patients with spinal cord injury is the lowest compared with other healthy people or disabled people. The average quality of life of patients with spinal cord injury is low, and their ability of self-care is low. They are eager to recover and to be able to take care of themselves. In this paper, we studied the changes of physical function of patients with spinal cord injury for nine months under two different treatment methods: multifunctional nanoparticle nerve scaffold and drug treatment, hoping to change the life status of patients with spinal cord injury.

3.2. Research Status. In view of the current high incidence rate and high disability rate of spinal cord injury, treatment

after onset has been a hot and difficult point in clinical research. At present, medical researchers divide the mechanism of spinal cord injury into two kinds: mechanical primary mechanism and biochemical secondary injury mechanism. We should choose appropriate treatment methods to block the two different injury mechanisms. At present, animal experiments and some clinical studies have confirmed the neuroprotective effects of surgery, drug therapy, and genetic engineering therapy on spinal cord injury. However, the specific surgical treatment and drug protection mechanism are not mature and controversial. It is expected that more research results will be translated into clinical practice to benefit patients with spinal cord injury.

3.3. Research Prospects.
As one of the world's medical problems, the research on the treatment of spinal cord injury has attracted the attention of researchers and clinical scholars. The number of clinical studies on spinal cord injury is increasing. However, there are still some key problems to be solved.

(1) Analysis of microenvironment of nerve regeneration: after spinal cord injury, injury will lead to local ischemia, hypoxia, edema, stem cell activation and other reactions, and then axon demyelination, glial cell proliferation, nerve cell necrosis, and other problems, and finally form a cavity or scar injury is not conducive to nerve regeneration microenvironment. The process of continuous dynamic change is accompanied by the dynamic changes of various signal molecules and cells in the microenvironment

(2) Regeneration and repair mechanism of complete spinal cord injury: spinal cord injury can be divided into complete injury and incomplete injury. After incomplete spinal cord injury, some axons with intact nerves can regenerate and recover their functions by means of springing. However, complete spinal cord injury can completely cut off the nerve, and its regeneration and repair mechanism were a key issue to be studied

(3) Clinical research path of spinal cord injury: although relevant clinical studies have been carried out, there are still some problems to be solved in the clinical research of spinal cord injury. For example, due to the existence of spinal cord shock, the current commonly used Asian classification is not suitable for judging the severity of acute spinal cord injury. How to judge a patient as a complete injury? The scars of old spinal cord injury in patients will inhibit nerve regeneration. It is difficult to distinguish the scar tissue of old spinal cord injury from normal nerve tissue in operation and to remove the scar

The repair of spinal cord injury is a complex process, which involves not only spinal cord injury but also peripheral nerve and muscle degeneration, as well as different psychological changes of patients. Therefore, it is necessary to establish a complete psychological rehabilitation plan for spinal cord injury, which is combined with the continuous development of regenerative medicine technology, and repair the spinal cord tissue and reconstruct the injured spinal cord through the combination of multifunctional nanoparticles and nerve regeneration scaffold. In the near future, nerve regeneration and motor function recovery of patients with spinal cord injury will be realized.

3.4. Research Methods.
First of all, we need to determine the purpose of the study and the content of the study and select the research object reasonably for the experiment. We selected 48 eligible patients with spinal cord injury after badminton. Under the condition of ensuring the patients' knowledge, we randomly divided the patients into two groups, 24 people in each group. From the patients' choice of treatment, the influence of nanoparticle nerve scaffold on body weight recovery, the promotion of motor function recovery by nanoparticle nerve scaffold, and the alleviation effect of nanoparticle nerve scaffold on inflammatory reaction were explored. Finally, the data were collected and sorted out to study the effect of multifunctional nanomaterials on the repair of spinal cord injury after badminton.

3.5. Experimental Process.
The microenvironment is not conducive to nerve regeneration after spinal cord injury, which mainly includes the following: (1) primary injury and secondary injury lead to nerve cell death; (2) lack of nutritional factors to promote nerve regeneration; and (3) cell proliferation forms scar tissue and some chemical molecules in scar, such as chondroitin sulfate proteoglycans (CSPGs), which act as physical and chemical barriers to nerve regeneration. On the one hand, they inhibit the growth of axons; on the other hand, they inhibit the differentiation of neural stem cells into neurons. With the deepening of research, scientists gradually realize that due to the complex microenvironment formed after spinal cord injury, single strategy is difficult to effectively promote the repair of spinal cord injury, and the combination of multiple strategies is the focus of spinal cord injury repair. It is the most suitable and effective method to reconstruct the microenvironment of spinal cord regeneration by using multifunctional nanoparticles.

At present, multifunctional nanomaterial particle collagen scaffold for nerve regeneration is used. It is a kind of polymer material. We prepared the nerve regeneration scaffold by coating the multifunctional nanoparticles on the collagen nerve scaffold and then implanted the scaffold into the spinal cord injury site of the experimental group. Due to the characteristics of the growth of spinal cord nerve cells, the ideal spinal cord injury repair material structure should be cell oriented, that is, it can guide the orderly growth of cell axons. According to the characteristics of longitudinal and orderly growth of spinal cord neurons, nerve fibers were guided to extend orderly. The results showed that compared with the control group, the function of the patients was significantly improved, and the basic movement of the patients showed coordination and mobility. Histological and immunocytochemical analysis showed that the recovery may be due to the decrease of tissue loss and glial scar. After 9

TABLE 1: General information of patients.

Project		Experimental group (N = 24)	Control group (N = 24)
Age	15-25	5	7

	Occasionally	8	8
	Rarely	6	4
	Never	6	7

months of follow-up, the patient had no obvious adverse reactions, which initially proved that nerve regeneration collagen scaffold transplantation was safe.

For the control group, we were on medication. Only two drugs, methylprednisolone and sialic acid tetrasaccharide ganglioside, were found to have significant effects on recovery from spinal cord injuries and have obvious effects on the rehabilitation of spinal cord injury. The dose and course of treatment determined by NASCIS should be strictly followed. There are many similarities between GM-1 and MP in pharmacological mechanism, such as reducing tissue edema, reducing lipid peroxidation, reducing the production of free radicals, and stabilizing membrane structure. GM-1 can also promote axon growth, stimulate synaptic formation, and improve nerve conduction function. GM-1 was given 48 hours after injury and lasted for several months. At the same time, they received medical observation together with the experimental group.

4. Results and Discussion

4.1. General Information Survey. As shown in Table 1, in order to improve the biological experimental study on the repair of spinal cord injury after badminton with multifunctional nanomaterial particles, we collated the general data of patients in the experimental group and the control group. From the above data, we can see that the age of patients with spinal cord injury due to badminton is mainly between 26 and 35 years old. However, no matter when the experimental group is still in the control group, the patients who often exercise are relatively few. From this, we know that as long as the 26-35 age groups are office workers, it is precisely because they usually lack exercise, so they are more likely to be injured in sports.

4.2. Selection of Treatment Methods for Spinal Cord Injury. At present, the common spinal cord treatment methods in China include multifunctional nanoparticle nerve scaffold, drug therapy, and stem cell therapy. We investigated the patients with spinal cord injury after badminton in a certain
FIGURE 1: Selection of current methods of spinal cord injury quality.

place from 2017 to 2019 and calculated the treatment method when treating spinal cord injury.

As shown in Figure 1, the current common clinical treatment of spinal cord injury is focused on nanoparticle nerve scaffold treatment, which accounts for 40% of the clinical treatment of spinal cord injury. The second is drug therapy. Compared with the surgical treatment of nanoparticle nerve scaffold, the clinical selection rate of drug treatment is less, but still accounts for 31%. And stem cell therapy accounts for 12%. In addition, other methods also accounted for 17%, which shows that some of these methods still have certain development prospects.

4.3. Weight Recovery of Patients after the Operation of Nanomaterial Nerve Scaffold. After some medical research, we know that the recovery of patients' body weight is closely related to the recovery of patients' body function.
Figure 2: Weight gain of patients after nerve stenting with nanomaterials.
Figure 3: Recovery rate of motor function promoted by nanoparticle nerve scaffolds.

Postoperative weight recovery of patients is conducive to speeding up the recovery of bodily functions.

As shown in Figure 2, we recorded and compared the weight of patients in the experimental group and the control group one month after operation. According to the research, the weight recovery of patients after surgery represents the recovery of patients' body function to a certain extent. From the comparison of our data, we can see that the weight of the experimental group and the control group in the observation period is rising, but relatively speaking, from the first to the third month, the body weight of the experimental group and the control group was almost the same, but from the fifth month, the body weight of the experimental group rapidly recovered, and the recovery speed was much faster than that of the control group.

4.4. Nanomaterial Nerve Scaffold Promotes the Recovery of Motor Function. During the 9-month follow-up treatment, we recorded not only the weight data of the two groups but also the recovery level of motor function. Motor func-

tion is very important for everyone, especially for patients with spinal cord injury due to badminton.

As shown in Figure 3, we started recording from the first month after surgery. In the first month, the motor functions of the experimental group and the control group were at the same level. In the third month, the motor function of patients in the experimental group decreased slightly due to some reasons after operation, but in the follow-up treatment, the motor function quickly caught up with the control group, and in the fifth month, the motor function of the experimental group recovered rapidly, while the recovery of the control group was relatively slow. It can be seen that nanoparticle nerve scaffold can promote the recovery rate of motor function.

4.5. Nanoparticle Nerve Scaffold Reduces Inflammatory Response. In the recovery process of the disease, no matter whether it is surgical treatment or delayed treatment, as long as there is a wound, there is the possibility of inflammation, so we also recorded the experimental group of patients in the
Figure 4: Inflammatory changes after nerve stenting of nanoparticles.

control group during the experimental period of inflammatory reaction.

As shown in Figure 4, we monitored the inflammatory response of the pilot and controlled patients from the first month after surgery. In the first month, the inflammatory response rates in the test and control arms were very similar. In the following eight months, the rate of inflammatory response in both groups decreased. But with the passage of time, the inflammatory response rate of the experimental group decreased much faster than that of the control group. After nine months, the inflammatory response rate of the experimental group decreased from 45% at the beginning to 8% at the ninth month. The control group was treated with drugs, from 47.85% at the beginning to 17% at the ninth month.

5. Conclusions

This paper mainly explores the repair of spinal cord injury after badminton sports with multifunctional nanomaterial particles. After spinal cord injury, patients will have a certain degree of movement disorders, and at the same time, various functions of the body will also have different degrees of problems, for example, urinary system infection, hydronephrosis, and dysuria. The follow-up treatment of spinal cord injury is not only a challenge to the patient's bearing capacity but also a heavy burden for the patient's family. Based on this point, we began to explore the use of multifunctional nanomaterial particle nerve scaffold for the treatment of patients. We found 48 patients with spinal cord injury after badminton exercise and divided them into two groups. The experimental group was treated with multifunctional nanoparticle nerve scaffold surgery, and the control group was treated with drug therapy. After nine months of treatment data recording, we compared the data and found the following three points: first, although the weight of the control group and the experimental group increased after operation,

the overall recovery rate and recovery rate of the experimental group were much higher than those of the control group. The weight recovery after the operation represents the recovery of body function to a certain extent. It can be seen that the surgical treatment of multifunctional nanoparticle nerve scaffold has great help for the recovery of body function of patients with spinal cord injury after badminton exercise. Second, we focus on the recovery of motor function of patients with nanoparticle nerve scaffold. From one month after the operation, we recorded nine months. Although motor function was recovering in both control and laboratory patients, it recovered quite quickly and increased in magnitude over time in the laboratory group versus the control group. Third, we observed the inflammatory response after the nanoparticle nerve scaffold surgery. In the first month, because of the surgical wound, the inflammatory reaction of the experimental group was slightly stronger than that of the control group. But in the follow-up treatment, the inflammatory reaction of the experimental group of patients quickly went down. Through the above three points, we found that the multifunctional nanoparticle nerve scaffold treatment can make the body function and motor function of patients recover quickly, shorten the treatment cycle, and greatly reduce the pain of patients and the burden of patients' families. At the same time, it can greatly and rapidly reduce the postoperative inflammatory reaction of patients. In addition, we also investigated the treatment options of spinal cord injury patients with badminton sports in a hospital from 2017 to 2019. Among them, 40% of the patients chose nanoparticle nerve stent surgery. To sum up, it is meaningful and promising to study the experiment of repairing spinal cord injury after badminton with multifunctional nanomaterial particles.

At present, cancer has become one of the main reasons that affect people's life and health. With the development of nanomaterials and nanotechnology, tumor phototherapy such as photodynamic therapy, photothermal therapy, and combination therapy has been developed rapidly. Based on this, this paper proposes to take gastric cancer, esophageal cancer, liver cancer, intestinal cancer, and pancreatic cancer as the starting point and apply the methods of network meta-analysis to comprehensively carry out the horizontal comprehensive evaluation of the efficacy and safety of traditional Chinese medicine injections. It is hoped that this article can provide high-quality evidence-based medicine for clinical decision-making and promote clinical rational drug use. The purpose of this paper is to study the meta-analysis of the main components of tumor treatment with nanophotodynamics combined with traditional Chinese medicine. The experimental results in this paper show that non-small-cell lung cancer has the largest number of evaluations, with 77 evaluations, accounting for 38.5% of the total frequency of tumor types. This may be related to the fact that lung cancer ranks first in the morbidity and mortality of malignant tumors. It is followed by the evaluation times of liver cancer and gastric cancer, which were 29 times and 25 times, respectively, accounting for 14.5% and 12.5% of the total frequency of tumor types. The therapeutic effect of SM-NP light therapy group on tumor was significantly higher than that of free Ce6 light therapy group, and its destruction and killing effect on tumor tissue was greater.

1. Introduction

The high recurrence rate, easy spread, and poor prognosis of tumors are the main challenges of clinical treatment. Currently, surgery, chemotherapy, and radiotherapy are the three main methods of clinical treatment of cancer. It has been widely used in tumor therapy, but it is difficult to inhibit it. It is effective in the treatment of malignant tumors. An ideal therapeutic strategy can not only effectively and safely remove tumors in situ but also prevent tumor metastasis by activating the body's immune system to recognize and remove tumor cells.

Chemotherapy is one of the important methods for the treatment of malignant tumors. However, traditional chemotherapeutic drugs lack tumor selectivity and have serious side effects. Photodynamic therapy is a new cancer treatment method developed in recent years. Photosensitive drugs enter the body and accumulate under the concentration and generate singlet active oxygen under the action of laser light of absorption wavelength, thereby producing cytotoxic effect. As a safe and efficient cancer treatment, photodynamic therapy can not only directly kill tumor cells but also potentially improve the immunogenicity of tumor cells. It induces an antitumor immune effect and meets the clinical demand for combined tumor therapy.

The innovation of this paper is to explore new research methods to comprehensively evaluate the efficacy and safety of different types of traditional Chinese medicine injections in the treatment of digestive system tumors, which has important academic significance and clinical value. This

paper evaluates the antitumor efficacy and biosafety of photodynamic nanodrugs by analyzing the data, which is the basis for clinical tumor treatment application method and data reference.

2. Related Work

In recent years, photodynamic therapy (PDT) has become a research hotspot in the field of tumor therapy due to its noninvasive and spatiotemporal controllable advantages. Synergistic therapy and precise drug delivery at the tumor site have emerged as a promising strategy to achieve tumor eradication. Here, Li et al. prepare smart near-infrared fluorescence imaging-guided nanoliposomes L@CY@DOX by encapsulating a chemotherapeutic drug (doxorubicin), liposome (L), and a near-infrared (NIR) photosensitizer (CY). It can enhance the therapeutic effect of chemotherapeutic PDT in cancer treatment [1]. Lack of selectivity of tumor cells and overproduction of glutathione (GSH) are two major challenges for efficient and safe cancer PDT, because they cause damage to normal tissues and scavenge ROS in cancer cells. Herein, Pan et al. report a GSH-responsive nanophotosensitizer based on CoOOH nanosheets for PDT of cancer. The current nanophotosensitizers represent a promising smart platform to synergistically improve the therapeutic index and safety of PDT [2]. Recently developed photodynamic therapy has received much attention for achieving effective root canal disinfection. It uses an optimized nontoxic photosensitizer (PS) such as indocyanine green (ICG). It is an integral part of this technology. Therefore, the aim of Akbari et al.'s study was to improve the photodynamic properties of ICG by incorporating ICG into nanographene oxide (NGO). It prepared NGO-ICG as a new PS and evaluated the antibacterial effect of NGO-ICG on Enterococcus faecalis after photodynamic therapy [3]. The application of traditional photodynamic therapy (PDT) is often limited by insufficient oxygen supply, and it is difficult to achieve high PDT efficacy. Herein, Qin et al. combine liposomes with photosensitizers indocyanine green (ICG) and perfluorooctyl bromide (PFOB) to develop a novel oxygen-enriched photodynamic nanospray for postoperative cancer therapy. This oxygen-enriched photodynamic nanospray strategy may open new avenues for clinically effective postoperative cancer therapy [4]. Photoimmunotherapy is a new treatment approach that is minimally invasive for malignant tumors. Here, Zhang et al. designed a targeted multifunctional black phosphorus (BP) nanoparticle, modified with PEGylated hyaluronic acid (HA) for photothermal/photodynamic/ photoimmunotherapy. In vitro and in vivo experiments demonstrated that HA-BP nanoparticles have good biocompatibility, stability, and sufficient efficacy in the combined photothermal therapy (PTT) and photodynamic therapy (PDT) treatment of cancer. Zhang et al.'s research expands the biomedical applications of BP nanoparticles, demonstrating the potential of modified BP as a multifunctional therapeutic platform for future cancer treatment [5]. Wang et al. design a versatile and powerful nanoplatform. They have cleverly integrated multiple molecules with therapeutic and diagnostic properties to stimulate the delivery of responsive drugs to lesions. This is still a huge challenge. Here, Wang et al. report a facile and ingenious cross-linked nanogel based on medicinal chemical cross-linking as a straightforward strategy to overcome assembly instability. This work provides a unique strategy for designing a series of prodrug nanogels as a universal drug delivery platform for precise disease therapy and diagnosis [6]. Deng et al. developed the mitochondria-targeted biodegradable polymer polylactic acid. The data suggest that X-PDT treatment has cytoreductive, antiproliferative, and profibrotic effects. The nanocarriers effectively enhance the radiosensitization effect, which makes it possible to enhance the radiation effect [7]. Lack of selectivity of tumor cells and overproduction of glutathione (GSH) are two major challenges for efficient and safe cancer PDT because they cause damage to normal tissues and scavenge ROS in cancer cells. Herein, Wei et al. reported a GSH-responsive nanophotosensitizer based on CoOOH nanosheets for PDT of cancer [2]. However, the shortcomings of these studies are that the model construction is not scientific enough and the data is limited to adapt to more complex situations.

3. Nanophotodynamic Therapy-Related Methods of Tumor

3.1. Advantages and Development Status of Photodynamic Therapy for Cancer

3.1.1. Photodynamic Therapy. Over the past few decades, photodynamic therapy (PDT) has undergone tremendous progress as a treatment modality. It includes age-related macular degeneration, psoriasis, atherosclerosis, and various malignancies. It mainly activates the photosensitizer (PS) accumulated at the tumor site by light with a specific wavelength. The activated PS transfers energy to surrounding oxygen molecules, resulting in the reduction of oxygen and the generation of reactive oxygen species (ROS) (Figure 1). Oxidation of biomacromolecules results in tumor reduction, vascular damage, local acute inflammation, and immune responses [8].

Compared with traditional treatment methods, PDT is due to its weak invasiveness, ideal convenience and flexibility, effective curative effect, and high patient acceptance. It has laid a solid foundation for the clinical application of PDT. Since the advent of the first approved PDT prodrug procarbazine in 1970, three photosensitizers, protoporphyrin, verteporfin, and 5-aminolevulinic acid, have been approved by the FDA. More than 16 drugs have subsequently entered clinical trials or are on the market. Compared with traditional treatments, PDT still has many limitations as a first-line clinical treatment due to the lack of effective photosensitizers, appropriate light doses, and effective photosensitizer delivery [9].

In drug delivery systems, light is a common external stimulus used to trigger drug release. Compared with complex and uncontrollable internal stimuli, light can control drug release in a more controllable time and space. Based on the process of PDT oxygen consumption and ROS generation, PDT can be combined with nanomedicines sensitive
FIGURE 1: Schematic diagram of a typical photodynamic reaction.

to the tumor microenvironment (such as ROS, hypoxia), and finally, it achieves a positive feedback and synergistic treatment effect [10].

3.1.2. Advantages of Photodynamic Therapy for Cancer. Photosensitizers, excitation light, and oxygen molecules are three important elements for PDT. The mechanism of action of photodynamic therapy is to utilize the selective enrichment of photosensitizers in tumor tissue. It converts oxygen into reactive oxygen species (ROS) that can kill cells through a laser-triggered photosensitizer with strong tissue penetration. It can oxidatively damage surrounding organelles and biomolecules, eventually inducing tumor cell necrosis and apoptosis, sealing tumor blood vessels, and causing vascular damage [11]. In addition, photodynamic therapy is often accompanied by the production of acute inflammation. Through the recruitment and activation of immune cells such as neutrophils and dendritic cells at the tumor site, acute inflammation in the local tumor is triggered, and an immune response is generated to further kill the tumor.

3.1.3. Tumor Phototherapy. In recent years, cancer, namely, malignant tumor, has become one of the important diseases threatening human health worldwide, although human beings have deeply researched on the mechanism and treatment of cancer for decades. However, the increasing number of new cases of cancer and the high mortality rate still pose a huge challenge to the current clinical cancer treatment

methods. Existing mainstream cancer treatments include surgical resection, chemotherapy, or radiation therapy, but these treatments have their own limitations. Although surgical resection has a good therapeutic effect on early-stage solid tumors, its therapeutic effect on metastatic tumors is limited. In addition, in order to ensure the curative effect during the operation, a large amount of normal tissue adjacent to the tumor is often removed, thereby causing significant damage to the patient's body. Chemotherapy is a commonly used clinical treatment method to control tumor growth through systemic administration. While killing cancer cells, it also kills a large number of normal cells, and it is easy to induce cancer cells to develop resistance to chemotherapeutic drugs, which often leads to the failure of treatment [12].

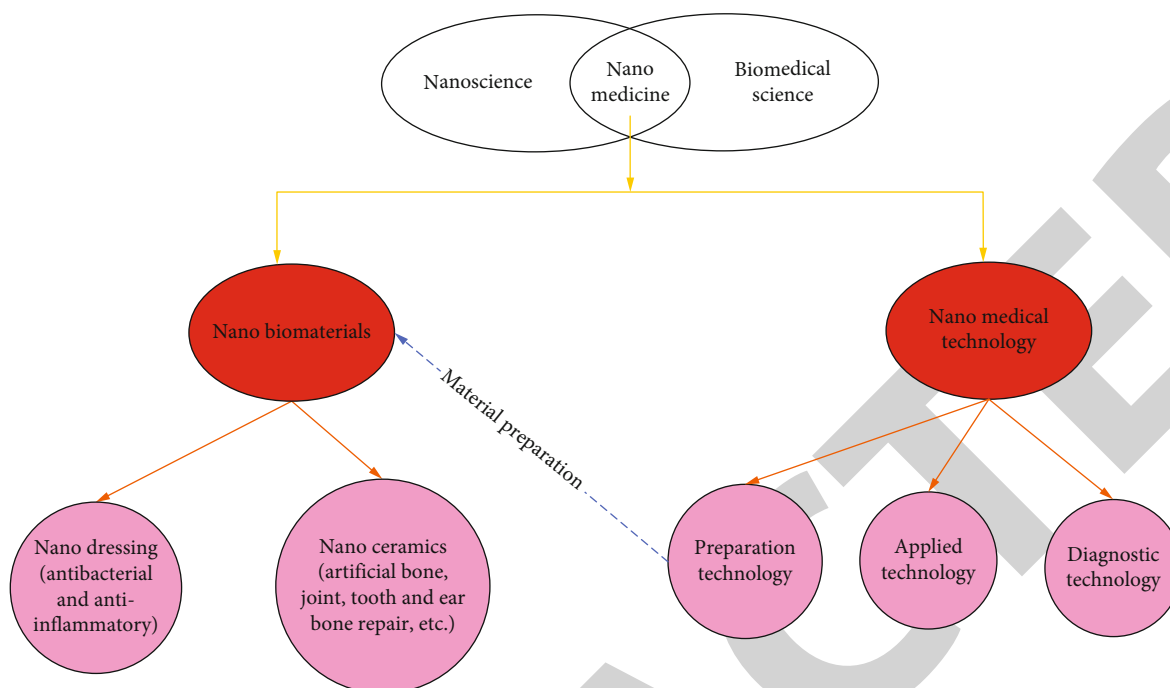
Radiation therapy is a common clinical cancer treatment method that induces cancer cell death by irradiating cancer cells with radionuclides or ionizing radiation. Due to the controllability of radiation, that is, the irradiation range, the systemic toxicity caused by radiotherapy is significantly lower than that of chemotherapy by systemic administration. However, radiotherapy still irradiates the normal tissues around the tumor to different degrees, causing obvious side effects. In view of this, on the basis of existing cancer treatment methods, combined with the advantages of multiple disciplines such as tumor biology, material science, and instrument manufacturing, new cancer treatments are developed. It has received more and more attention and research to meet the needs of current clinical cancer patients.


Figure 2: Overview of nanomedicine.

At present, a large number of studies have shown that many new cancer treatment methods (such as tumor immunotherapy, phototherapy, and gene therapy) and tumor treatment strategies under image navigation have good application prospects. At the same time, by combining with the commonly used clinical treatment methods, it also endows these traditional cancer treatment methods with new vitality and development opportunities and provides new options for the safe and efficient treatment of tumors [13].

3.2. Application of Nanomaterials. In the past few decades, nanomaterials have been extensively researched and developed and have been successfully applied in the fields of catalysis, medicine, sensors, and biology. In particular, it has also received extensive attention in water treatment and wastewater treatment. Moreover, the flow properties of nanomaterials in solution are very high. Nanomaterials have a relatively large specific surface area due to their small size, so they have strong adsorption capacity and reactivity. It has been reported that heavy metals, organic pollutants, inorganic anions, and bacteria can be successfully removed by many kinds of nanomaterials [14].

Due to the unique size-dependent properties of nanomaterials, they have a profound impact on various application fields such as the construction industry, products of daily life, and medical and healthcare. Figure 2 is an overview of nanomedicine.

Nano-antibacterial materials have attracted much attention due to their stable performance, good antibacterial effect, and low price. For example, nanotitanium oxide material has photocatalytic effect, which can decompose toxic gases such as formaldehyde and benzene and kill bacteria on its surface. Nanometer self-cleaning materials have great development

space. Nanomaterials also have many applications in catalysis. Catalysts play an important role in the field of chemistry. Catalysts can increase the reaction rate and shorten the reaction time. Most of the traditional catalysts have low catalytic efficiency and difficult preparation, resulting in waste of raw materials, reducing economic benefits, and polluting the environment. Nanomaterials have many active sites. It can greatly improve the reaction rate and control the progress of the reaction. It can even make chemical reactions that were previously inoperable go smoothly.

Nanoparticles used as catalysts are as follows:

(1) Metal nanoparticles

(2) Nanoparticles are supported on porous supports, which can further increase the selectivity of catalysts

(3) Compound nanoparticles

Nanomaterials are used in lithium electrical energy to improve cycle life. It can undergo some reactions that cannot occur in other materials, increasing the charge-discharge rate [15]. At present, nanomaterials can be well used as contrast agents in medical imaging. The mechanism by which nanobiomaterials promote the repair of damaged tissue is shown in Figure 3. Nanoparticles are widely used in biomedicine and can be used as biochips, bioprobes, etc. New medicines require new means of drug delivery so that side effects can be reduced and better efficacy can be achieved. Nanotechnology drug delivery can deliver drugs directly to cells and to targeted tissues.

3.3. Unsupervised Learning. The difference between unsupervised learning and supervised learning is that data does
FIGURE 3: Mechanism of nanobiomaterials to promote repair of damaged tissue.

not need to be identified in advance. According to different learning method rules and the clustering characteristics of the data itself, this paper finds the corresponding internal rules and finds useful hidden information in the complex and disordered data [16].

3.3.1. Clustering Algorithm. Clustering algorithm is a kind of classification and grouping of things with the same attributes. It classifies cluttered sets of data into meaningful clusters. The essence of a clustering problem is an optimization problem, but this optimization must satisfy certain clustering conditions or clustering rules. The advantage of clustering is that the processing time is fast, the operation is simple, and it is easy to explain; the disadvantage is that the parameters need to be set when using, and sometimes, the result may be locally optimal. The classification of clustering algorithms is shown in Figure 4 [17, 18].

(1) Data Standardization. In order to eliminate the influence of different dimensions of the original data, this paper adopts the cluster analysis method in the data preprocessing, and the original data needs to be standardized. The normalized formula is

$$A_{mn} = \frac{B_{mn} - \overline{B_n}}{\sqrt{\operatorname{var}\left(B_n\right)}} \quad (m = 1, 2, \cdots, j), \tag{1}$$

$$\overline{B_n} = \frac{1}{j} = \sum_{m=1}^{j} B_{mn}, \tag{2}$$

$$\sqrt{\operatorname{var}\left(B_n\right)} = \sqrt{\frac{1}{j} \sum_{m=1}^{j} \left(B_{mn} - B_n\right)^2}, \tag{3}$$

(2) Define the Distance. Assuming that there are j sample data in a b-dimensional space, the formula for calculating the distance between sample m and sample n is as follows:

$$D_{mn} = \sum_{k-1}^{b} |A_{mk} - A_{nk}|. \tag{4}$$

The formula calculates the absolute value distance.

$$D_{mn} = \sqrt{\sum_{k=1}^{b} \left(A_{nk} - A_{mk}\right)^2}. \tag{5}$$

The formula calculates the Euclidean distance.

$$D_{mn} = \operatorname{MAX}_{1 \le k \le b} |A_{mk} - A_{nk}|. \tag{6}$$

The formula calculates the Chebyshev distance.

Usually, the smaller the distance is, the closer the similarity of the sample objects of the study is.

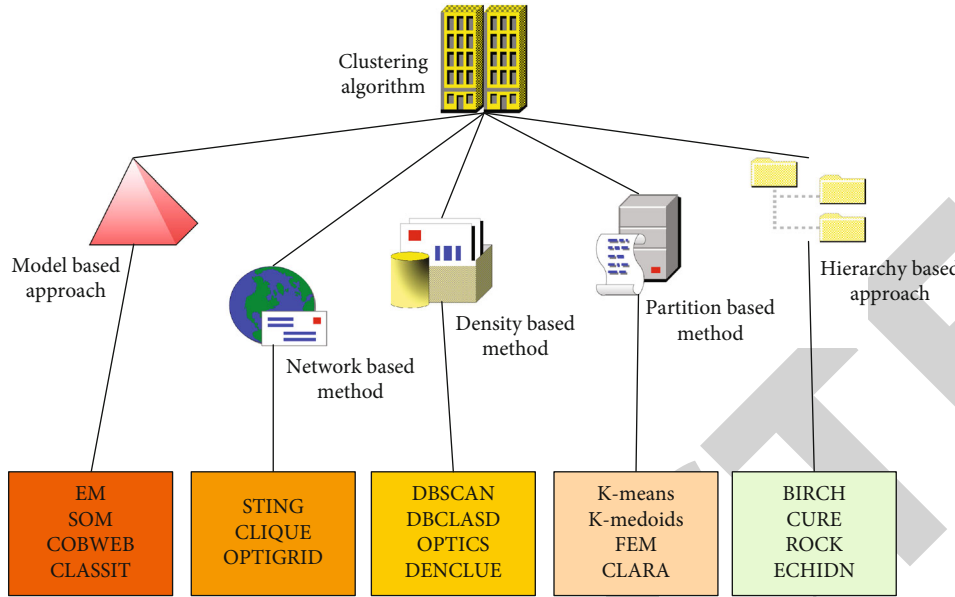
(3) Similarity Coefficient. The similarity coefficient of any two b-dimensional vectors can be used to measure the similarity of these two vectors in the b-dimensional space. The


FIGURE 4: Classification of clustering algorithms.

similarity coefficient C_{mn} is used to represent, where m and n are the two vectors to be compared. C_{mn} satisfies symmetry; that is, the two vectors to be compared satisfy $C_{mn} = C_{nm}$. In general, the cosine of the angle between two vectors is a common similarity coefficient:

$$\text{COS}(\theta_{mn}) = \frac{\sum_{k=1}^{b} A_{mk} A_{nk}}{\sqrt{\sum_{k=1}^{b} A_{mn}^2 A_{nk}^2}}. \tag{7}$$

3.3.2. K-Means Clustering

(1) K-Means Algorithm. The K-means algorithm is an unsupervised algorithm. As a classical clustering method, it is widely used to solve various partitioning and clustering problems, and it is still one of the most widely used clustering algorithms. At the same time, the K-means algorithm is also the basis for many more complex clustering techniques. While there have been many improvements to clustering methods today, the K-means algorithm is not outdated or obsolete and, in fact, may be more popular now than ever. The central idea of K-means clustering is to divide n data objects according to the number of categories K given in advance, so as to minimize the difference within each class and maximize the difference between classes. The flowchart of the K-means algorithm is shown in Figure 5 [19, 20].

The K-means algorithm is also known as the k-means algorithm. The algorithm idea is roughly as follows: it randomly selects k samples from the sample set as cluster centers and calculates the distances between all samples and the k "cluster centers." For each sample, it is divided into the cluster where the closest "cluster center" is located, and the new "cluster center" of each cluster is calculated for the new cluster.

According to the description, we can roughly guess the three main points for implementing the K-means algorithm: selection of the number of clusters k, the distance from each sample point to the "cluster center", and according to the newly divided cluster, updating the "cluster center."

(2) Key Points of K-Means Algorithm.

(1) Selection of k value

The choice of k is generally determined according to actual needs, or the value of k is directly given when the algorithm is implemented.

(2) The measure of distance

A sample is given:

$$M^i = \left\{ M_1^i, M_2^i, \cdots, M_p^i \right\}, \tag{8}$$

$$M^j = \left\{ M_1^j, M_2^j, \cdots, M_p^j \right\}, \tag{9}$$

where $i, j = 1, 2, \cdots, t$ represents the number of samples and p represents the number of features.

(a) Ordinal attribute distance measures (discrete attributes {1, 2, 3} or continuous attributes)

Minkowski distance

$$D_{\text{mk}}\left(M^{(i)}, M^{(j)} \right) = \left(\sum_{u=1}^{p} \left| M_u^i - M_u^j \right|^h \right)^{1/h}. \tag{10}$$
Figure 5: Flowchart of the classic K-means algorithm.

Euclidean distance refers to the Minkowski distance when $h = 2$:

$$D_{\text{ed}}\left(M^{(i)}, M^{(j)}\right) = \left\| M^{(i)} - M^{(j)} \right\|_2 = \sqrt{\sum_{u=1}^{p} \left| M_u^i - M_u^j \right|^2}.$$

$$(11)$$

Manhattan distance refers to the Minkowski distance when $h = 1$:

$$D_{\text{man}}\left(M^{(i)}, M^{(j)}\right) = \left\| M^{(i)} - M^{(j)} \right\|_1 = \sum_{u=1}^{p} \left| M_u^i - M_u^j \right|. \quad (12)$$

(b) Disordered attribute distance metrics (such as {airplane, train, ship})

VDM (Value Difference Metric)

$$\text{VDM}_h\left(M_u^i, M_u^j\right) = \sum_g^k \left| \frac{y_u, M_u^i, g}{y_u, M_u^i} - \frac{y_u, M_u^j, g}{y_u, M_u^j} \right|^h. \quad (13)$$

Among them, y_u, M_u^i represents the number of samples whose value is M_u^i on attribute u, and y_u, M_u^i, g represents the number of samples whose value is M_u^i on attribute u in the g th sample cluster. $\text{VDM}_h(M_u^i, M_u^j)$ represents the VDM distance between two discrete values M_u^i and M_u^j on attribute u.

(c) Mixed attribute distance metric, which is a combination of ordered and disordered:

$$\text{MinkovDM}_h\left(M^i, M^j\right)$$
$$= \left(\sum_{u=1}^{p_s} \left| M_u^i - M_u^j \right|^h - \sum_{u=p_s+1}^{p} \text{VDM}_h\left(M_u^i, M_u^j\right) \right)^{1/h} \quad (14)$$

Among them, p_s contains ordered attributes and $p - p_s$ unordered attributes.

The data set in this article is a continuous attribute, so the Euclidean distance is mainly used in the code to measure the distance.

(3) Update "cluster center"

For each divided cluster, calculate the mean value of the sample points in each cluster, and it uses the mean value as the new cluster center.

3.4. Genetic Algorithms

3.4.1. Overview. Genetic algorithm (GA) is a new global optimization algorithm developed in recent years. It is based on evolution theory and adopts design methods such as genetic combinatorial optimization technology, genetic variation, and natural selection.

Genetic algorithm is an optimization search algorithm based on biological evolution theory and molecular genetics. It first encodes possible solutions to a particular problem,

called chromosome-encoded solutions. This paper randomly selects N chromosomes as the initial group and then calculates the fitness of each chromosome according to the value of the evaluation function. It is predetermined that the best performance value of a chromosome is the highest fitness value, the chromosome with the highest fitness value is selected for replication, and a new set of chromosomes is created. These chromosomes are more customized to the environment through genetic operators. People will eventually adapt to the new environment, and forming a better group becomes the best solution to the problem [21, 22].

3.4.2. Basic Algorithm. The execution of the genetic algorithm involves many random operations, first considering the result of the selection. In standard genetic algorithms, selection criteria are based on the principle of proportionality. Therefore, through the action of the ith selector, the expected value of the number of people who will continue to exist in the next generation is $n(g_i / \sum g)$; then, there is

$$\bar{g}(P, t) = \frac{1}{n(P, t)} \sum g_i. \tag{15}$$

Then,

$$n(P, t + 1) = n(P, t) \cdot \frac{\bar{g}(P, t)}{g(t)}. \tag{16}$$

The equation shows that the effect of the selection operator will increase (decrease) the ability of a pattern above (below) the average to be applied across generations, improving quality.

Then, it analyzes the role of the crossover operator. This plan can obviously be maintained in the next generation if there is no intersection or if the intersection point is beyond the character positions specified on the left and right ends of the figure. Therefore, the probability R_s that the P mode will continue to exist in the next generation should satisfy

$$R_s \geq 1 - R_c \cdot \frac{\varphi(P)}{(L - 1)}. \tag{17}$$

Taking into account the effects of selection and crossover, there are

$$n(P, t + 1) \geq n(P, t) \cdot \bar{f}(P, t) \cdot \left[\frac{1 - R_c \cdot \varphi(P)}{(L - 1)/\bar{g}(t)} \right]. \tag{18}$$

Finally, because R_m represents the probability of the mutation operator acting, the constant probability is $1 - R_m$. If all the specified characters remain unchanged, the P pattern can naturally continue to exist in the next generation, the probability $(1 - R_m)^{O(P)}$; R_m is usually not large; then, under the action of the mutation operator, the probability of P continuing to exist is

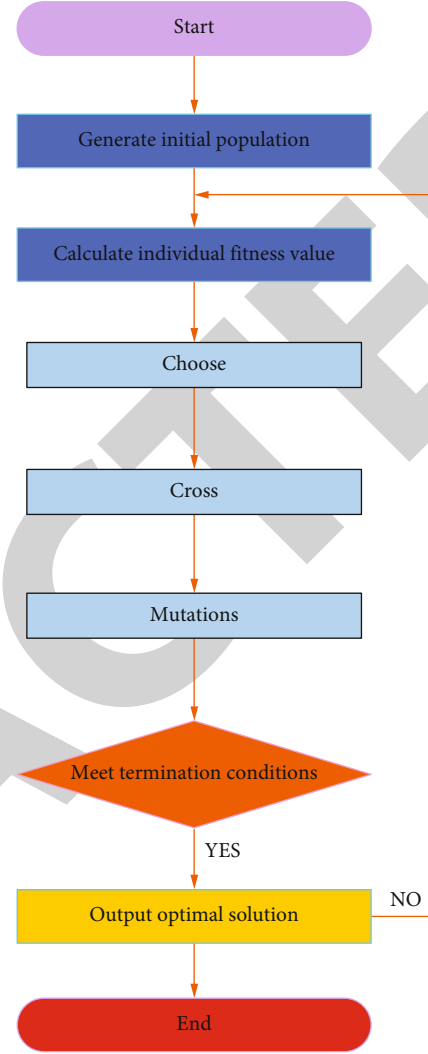
$$(1 - R_m)^{O(P)} \approx 1 - R_m \cdot O(P). \tag{19}$$


FIGURE 6: Genetic algorithm flowchart.

The probability of unreserved is about $O(P) \cdot R_m$. So, taking into account the functions of selection, crossover, and mutation operators, we end up with

$$n(P, t + 1) \geq n(P, t) \cdot \bar{g}(P, t) \cdot \frac{\left[1 - R_c \cdot (\varphi(P)/(L - 1)) \cdot R_m \right]}{\bar{g}(t)}. \tag{20}$$

Specifically, if $\bar{g}(P, t) = g(t)(1 + c)$, $c > 0$ is a constant, then

$$n(P, t) = n(P, t - 1)(1 + c) = n(P, O)(1 + c)^t. \tag{21}$$

The flowchart of the standard genetic algorithm is shown in Figure 6.

$y = 3.272x$
$R^2 = 0.855$

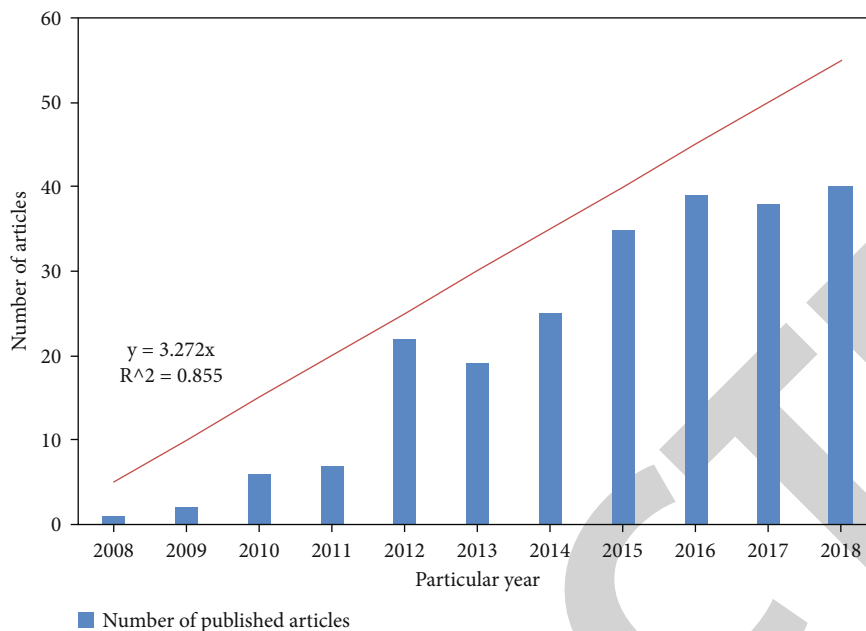
Number of published articles


FIGURE 7: 2008-2018 published status of systematic review and meta-analysis of traditional Chinese medicine injections in the treatment of tumor diseases at home and abroad.

4. Network Meta-Analysis Experiment of Traditional Chinese Medicine Injections in the Treatment of Digestive System Tumors

4.1. Current Status of Systematic Review/Meta-Analysis of Traditional Chinese Medicine Injections in the Treatment of Tumor Diseases. Since the publication of the first systematic review of TCM injections for oncology in 2008, with the increase of years, the number of publications of related systematic reviews/meta-analyses has also increased ($y = 3.272x$, $R^2 = 0.855$). As shown in Figure 7 3 papers were published before 2009, 35 papers were published from 2010 to 2012, 156 papers were published from 2013 to 2017, and 40 papers were published in 2018 [23].

4.2. Tumor Types Involved. Among the 198 systematic reviews/meta-analyses retrieved, 2 classic meta-analyses are aimed at the treatment of multiple tumors with a single variety of traditional Chinese medicine injections. In addition, the other 196 such systematic reviews/meta-analyses were all single-species or multispecies TCM injections for the treatment of a single type of tumor. The total frequency of occurrence of different types of tumors was 200. Among them, non-small-cell lung cancer has the most evaluation times, with 77 evaluation times, accounting for 38.5% of the total frequency of tumor types. This may be related to the fact that lung cancer ranks first in the morbidity and mortality of malignant tumors. The second was the evaluation times of liver cancer and gastric cancer, which were 29 and 25, respectively, accounting for 14.5% and 12.5% of the total frequency of tumor types. In addition, 17 studies only mentioned evaluating the disease as "tumor." It does not describe the type of tumor in detail. The types of tumors involved are shown in Table 1. The number of cases for different types of tumors is shown in Figure 8.

4.3. Involving Varieties of Traditional Chinese Medicine Injections. Among the 198 systematic reviews/meta-analyses included in this study, 14 network meta-analyses and 4 classic meta-analyses, respectively, evaluated multiple varieties of traditional Chinese medicine injections. The rest of the literature is only for a single variety of traditional Chinese medicine injections. A total of 14 TCM injection varieties were involved in the included systematic review/meta-analysis. The total occurrence frequency of different varieties of traditional Chinese medicine injections is 352 times. It accounted for 15.6% of the total frequency of Chinese medicine injections, followed by Shenqi Fuzheng injection and Aidi injection; the frequency of occurrence was 50 times and 45 times, accounting for 14.2% and 12.8%, respectively. For traditional Chinese medicine injections, there is a frequency of 10 or more occurrences, as shown in Table 2, for the varieties involved in the evaluation. It includes Fufang Kushen injection, Shenqi Fuzheng injection, Aidi injection, Kangai injection, Cinobufasu injection, Kanglaite injection, Brucea oil emulsion injection, Xiaoaiping injection, and Delisheng injection.

At the same time, this study summarizes the following 14 varieties of traditional Chinese medicine injection components and functional indications. It further analyzes the relationship between its components, efficacy and indications, and the treatment of tumors.

A summary of the dominant varieties of traditional Chinese medicine injections based on cluster analysis is shown in Table 3.

(1) To carry out the evaluation of clinical efficacy of traditional Chinese medicine injections in the treatment of gastric cancer, esophageal cancer, liver cancer, bowel cancer, and pancreatic cancer using network meta-analysis and the ranking of the

TABLE 1: Statistics of tumor types involved.

Serial number	Disease	Frequency of occurrence	Percentage
1	Non-small-cell lung cancer	77	38.5%
2	Liver cancer	29	14.5%
3	Gastric cancer	25	12.5%
4	Tumor	17	8.5%
5	Malignant pleural and peritoneal effusion	12	6%
6	Colorectal cancer	9	4.5%
7	Lung cancer	8	4%
8	Mammary cancer	8	4%
9	Esophageal cancer	8	4%
10	Cancer pain	4	2%
11	Lymphoma	3	1.5%

therapeutic effects. The ranking of different outcome indicators suggests that traditional Chinese medicine injections are the best drugs for the treatment of different digestive system tumors. The cluster analysis results show that (1) for the treatment of gastric cancer with traditional Chinese medicine injection combined with FOLFOX chemotherapy, in terms of improving the total clinical efficiency and improving the quality of life, astragalus polysaccharide combined with FOLFOX chemotherapy and Kangai injection combined with FOLFOX chemotherapy have more advantages than other traditional Chinese medicine injections. In terms of alleviating adverse reactions, astragalus polysaccharide combined with FOLFOX chemotherapy, sodium cantharidate, and vitamin B and FOLFOX chemotherapy have advantages over other traditional Chinese medicine injections. In addition, in the treatment of gastric cancer with traditional Chinese medicine injection combined with XELOX chemotherapy, Brucea chinensis oil emulsion and compound Sophora flavescens have more advantages than other traditional Chinese medicine injections in improving the total clinical effective rate and improving the quality of life indicators. Mushroom polysaccharide has more advantages than other traditional Chinese medicine injections in terms of alleviating adverse reaction indicators. (2) In improving the survival rate of patients with esophageal cancer, cinobufacini and Kangai injections combined with radiotherapy are dominant in the comprehensive ranking. Compound Sophora flavescens injection combined with radiotherapy has an advantage in the comprehensive ranking of the clinical total effective rate and the improvement of quality of life. (3) In the study of traditional Chinese medicine injection combined with

hepatic artery embolization in the treatment of liver cancer, compared with the cluster analysis results of other traditional Chinese medicine injections, Brucea oil emulsion and cinobufagin combined with TACE were dominant in the comprehensive ranking of survival rate. Kanglaite and astragalus polysaccharide combined with TACE are dominant in the comprehensive ranking of clinical total effective rate and quality of life improvement. Shenmai combined with TACE is dominant in the comprehensive ranking of adverse reactions. (4) Compared with the cluster analysis results of other traditional Chinese medicine injections, Xiaoaiping injection assisted by FOLFOX chemotherapy regimen in the treatment of colorectal cancer has the advantage in the comprehensive ranking of clinical efficacy and quality of life improvement

(2) In terms of safety, traditional Chinese medicine injections combined with radiotherapy or chemotherapy can alleviate the occurrence of adverse reactions. However, few adverse reactions caused by TCM injections have been reported in RCTs, so no definite conclusion can be drawn

4.4. Establishment of Animal Tumor Model. The experimental animals were BALB\c mice, 4.4-6.5 weeks old, weighing 11-16 g, female. In large-scale culturing of murine breast cancer cells 4T1, collecting 4T1 cells in the logarithmic growth phase, and counting them in a cytometer, the medium was used to prepare a cell suspension of 1×10^7 /mL. The $50 \mu L$ cell suspension was subcutaneously injected into the right back of BALB\c mice. After one week of culture, the tumor size was measured with a vernier caliper regularly. When the tumor volume was about $58 - 110 \text{mm}^3$, it could be used as a tumor model for in vivo research. Tumor volume was calculated according to the following formula:

$$V_{\text{Tumor volume}} = L_{\text{Tumor length diameter}} \cdot \frac{M^2_{\text{The widest diameter of a tumor perpendicular to the longest diameter}}}{2} . \tag{22}$$

(a)

(b)
FIGURE 8: Plot of the number of cases for different types of tumors.

In order to observe the histopathological changes of SM-NPs in photothermal/photodynamic synergistic treatment of tumors, a single dose of PBS, free Ce6, and SM-NPs was injected into tumor-bearing mouse via tail vein. The tumor tissue was irradiated with laser 24 hours after administration, and a nonirradiated control group was set, respectively. Six hours after laser irradiation, the tumor-bearing mice were sacrificed and the heart, liver, spleen, lung, kidney, and tumor tissues were taken out for H&E staining. It can be seen from Table 4 that sporadic areas of cell necrosis and infiltration of inflammatory cells can be observed in the tumor tissue of the free Ce6 light treatment group. In the SM-NP tumor tissue, obvious necrosis area and a large number of inflammatory cell infiltration can be seen. The results showed that the therapeutic effect of the SM-NP light therapy group on tumor was significantly higher than that of

Table 2: Statistics of traditional Chinese medicine injection varieties involved in the systematic review/meta-analysis of tumor diseases.

Serial number	Disease	Frequency of occurrence	Percentage
1	Compound Sophora flavescens injection	55	15.6%
2	Shenqi Fuzheng injection	50	14.2%
3	Aidi injection	45	12.8%
4	Kangai injection	35	9.9%
5	Cinobufacini injection	29	8.2%
6	Kanglaite injection	27	7.7%

12	Ginseng polysaccharide injection	10	2.8%
13	Shenfu injection	10	2.8%
14	Astragalus polysaccharide injection	9	2.6%

Table 3: Summary table of dominant varieties of traditional Chinese medicine injection based on cluster analysis.

Name of digestive system tumor	Intervention measures of the control group	Outcome indicators	The dominant varieties of traditional Chinese medicine injection obtained by cluster analysis
Gastric cancer	FOLFOX chemotherapy regimen	Total clinical effective rate, quality of life, and adverse reactions	Astragalus polysaccharide injection, Kangai injection, sodium pincer, and vitamin B injection
Gastric cancer	XELOX chemotherapy regimen	Total clinical effective rate, quality of life, and adverse reactions	Brucea javanica oil emulsion injection, compound Sophora flavescens injection, Lentinan injection
Esophageal cancer	Radiotherapy	Clinical total effective rate, quality of life, adverse reactions, survival rate	Compound Sophora flavescens injection, Shenqi Fuzheng injection, compound Sophora flavescens injection, Cinobufagin injection, Kangai injection
Esophageal cancer	Chemotherapy	Total clinical effective rate, quality of life, and adverse reactions	Compound Sophora flavescens injection
Liver cancer	TACE	Clinical total effective rate, quality of life, adverse reactions, survival rate	Brucea javanica oil emulsion injection, cinobufagin injection, Kanglaite injection, astragalus polysaccharide injection, Shenmai injection
Colon cancer	FOLFOX chemotherapy regimen	Total clinical efficiency and quality of life	Xiaoaiping injection
Pancreatic cancer	Chemotherapy	Total clinical effective rate, quality of life, and adverse reactions	Javanica oil emulsion injection, Kanglaite injection, Aidi injection

the free Ce6 light therapy group, and its destruction and killing effect on the tumor tissue was greater. Table 4 shows that the histopathology of the heart, liver, spleen, lung, and kidney tissue in each treatment group has no obvious changes. The results showed that although SM-NPs had a strong killing effect on tumor tissue, it was safe for the heart, liver, spleen, lung, kidney, and other tissues and had no obvious toxic and side effects.

5. Discussion

At present, malignant tumor has become one of the most serious diseases threatening human health. The World Health Organization's report on cancer in the world says there are 14 million new cancer cases and 8.2 million deaths worldwide each year. When malignant tumors occur, it increases the difficulty of treatment and the risk of life. Therefore, how to effectively prevent and treat cancer, especially to prevent tumor metastasis or recurrence, is an urgent problem to be solved in current scientific research.

There are three main methods of treating cancer: surgery, chemotherapy, and radiation. However, traditional treatment methods have disadvantages such as large trauma, large toxic and side effects, prone to multidrug resistance, damage to the immune system, and difficulty in avoiding tumor recurrence. In recent years, tumor immunotherapy has become one of the important research fields, an important breakthrough, and an important development direction of tumor therapy.

Phototherapy is a new way of thinking in current cancer treatment research. It is also one of the hottest research areas in biomedical applications, which is fundamentally due to the advantages of phototherapy with high treatment accuracy, minimal tissue damage, and no drug resistance. At present, the common phototherapy reagents mainly have shortcomings such as low absorbance, poor water solubility, easy aggregation, easy quenching of fluorescence, and poor dark toxicity. In this paper, combining the performance advantages of organic semiconductor nanoparticles and photosensitizers, a series of high-performance organic nano-phototherapy agents were designed, and their applications in tumor phototherapy were initially explored.

6. Conclusion

Organic semiconductor nanomaterials are nanostructured materials. Due to its strong light absorption, stable light, high brightness, and good biocompatibility, it has been widely used in bioimaging, antibacterial, antitumor, gene therapy, and drug release in the past decade. In this study, a network meta-analysis of traditional Chinese medicine injections in the treatment of digestive system tumors was carried out, and the clinical efficacy and safety of different varieties of traditional Chinese medicine injections were systematically, scientifically, and comprehensively evaluated. At the same time, Bayesian theory was used to identify the dominant varieties of traditional Chinese medicine injections and to optimize the program of adjuvant radiotherapy and chemotherapy for the treatment of digestive system tumors. It provides high-quality evidence-based medical evidence for clinical use.

Nanotechnology has become an important technology that cannot be ignored in high and new technology, and the application of nanomaterials is to design all aspects of life. With the more popularization of badminton, the blending of the two is also increasing. The purpose of this paper is to discuss the combination of sports health care and nanotechnology in badminton. This paper starts with the application of nanotechnology in badminton racket materials, hoping to explore the impact of nanotechnology on badminton sports health care. In this paper, 130 testers of different ages from different schools were selected for 17 weeks of badminton training. By comparing the physical fitness indicators before and after, this paper finds the impact of badminton on physical health. The experimental results show that badminton exercise training has an impact on human health and has a significant impact on human height, weight, and lung capacity.

1. Introduction

Badminton is a traditional Chinese sport. In recent years, the excellent performance of the national badminton team in international competitions has gradually brought the fitness function of badminton into the public's field of vision. It integrates social, entertainment, fitness, stress relief, and other attributes into one and improves the body's physical health and physical self-esteem. It makes badminton the best choice for contemporary teenagers to carry out extracurricular sports training activities. In addition, the continuous increase of badminton extracurricular training activities, the gradual rise of badminton club training, and the expansion of badminton teachers and referees and other professionals have not only laid a foundation for the extracurricular badminton sports training for senior primary school students. It also provides a guarantee for their physical health and the development of physical self-esteem.

The global science and technology and economy are in a stage of rapid development, and information technology, biomedical technology, and nanotechnology have become three important technologies side by side. And nanotechnology is a key basic technology. It lays a solid foundation for the development of information technology and biotechnology. Nanotechnology has also increasingly become the focus of competition in the world's high-tech fields. Nanotechnology is more and more deeply affecting and changing people's production, life, and thinking. Its impact on economy, politics, and society is more reflected in the fierce competition between countries for nanotechnology research and application.

This paper mainly has the following two innovations: (1) This paper is based on the research of value proposition generation in the process of nanotechnology commercialization from a layered perspective. This paper mainly analyzes the generation of value propositions in the process of nanotechnology commercialization from the industry level, company level, and specific business level. (2) About the research on the connection of value proposition generation in the process of nanotechnology commercialization, this paper mainly analyzes the influencing factors, typical obstacles, and targeted strategies in the process of value proposition generation in nanotechnology commercialization.

2. Related Work

The emergence of nanomaterials has greatly changed people's lives, and nanotechnology has penetrated into all aspects of life, and there are many studies on it. Mihail C examined progress in nanotechnology development since 2000, achievements over the past decade, and opportunities for research, education, innovation, and social outcomes worldwide by 2020 [1]. Duhan J S believed that nanotechnology is an interdisciplinary field of study. He discussed the potential uses and benefits of nanotechnology in precision agriculture. Tools and techniques based on modern nanotechnology have the potential to solve various problems of traditional agriculture [2]. Lee CH conducted research on the science and engineering of water purification, especially oil-water separation. His research goals are to provide a comprehensive review on oil-water separation by nanotechnology and organic chemistry and to improve understanding of the environmental issues of water purification using nanotechnology [3]. Reis CP believed that nanotechnology has developed alternative routes of administration, namely, those based on nanotechnology. Nanoparticles made of synthetic or natural materials have been shown to successfully overcome the inherent barriers to insulin stability, degradation, and absorption across the gastrointestinal tract and other mucosal membranes [4]. Mirkin CA discussed emerging nanotechnology-based tools. These tools have the potential to dramatically impact cancer research, diagnosis, and treatment. His research explains how nanotechnology exploits the size, shape, and composition-dependent properties of nanomaterials. It provides new tools for precision cancer medicine [5]. Weng Y highlighted the latest progress in nanotechnology-based system development. The system can deliver ocular drugs and genes to the eye through corneal absorption, periocular injection, and intravitreal injection for the treatment and diagnosis of ocular diseases. Then, he discussed and prospected the applications and challenges of nanosystems in ophthalmology [6]. Falagan-Lotsch P saw it as a nanoactivation method currently on the market or in development, such as antimicrobial food contact surfaces/packaging, nanoactivated sensors for rapid detection of pathogens/contaminants, and nanodelivery biocidal methods. It showed great potential in the food industry [7]. Michal reviewed the research progress of nanoantibacterial drugs in the past two years and introduced their unique properties, mode of action, and activity against multidrug-resistant bacteria and biofilms [8]. Since the launch of the US National Nano Initiative (NNI) in 2000, nanotechnology research has become the focus of global attention. Various countries have formulated nanotechnology plans relative to their national conditions. It strives to seize the commanding heights of science and technology strategy in the twenty-first century and to seize the initiative of future economic development [9].

3. Nanotechnology Algorithms and Applications

3.1. Nanotechnology. Nanoscience and technology is one of the foundations of the new era of science and technology in this century. A nanometer is a unit of length and is one billionth of a meter. Studying the properties of materials and their applications in the range of 0.1 to 100 nm structure scale is what we call nanotechnology, and sometimes nanoscience and technology are also collectively referred to as nanotechnology. Nanotechnology is a technology to manufacture new materials, new devices, and research new processes based on nanoscience through new methods. The concept of nanoscience and technology is expressed differently in different literatures. But it will continue to improve as the discipline develops, and more detailed concepts will be drawn. Nanotechnology is based on advanced science and technology at the nanoscale and is the product of the combination of modern science and modern technology. Nanoscience and technology is the product of the interlaced and compatible theory and high technology, not just the expansion of a single discipline. Nanoscience and technology holds enticing prospects in terms of basic research. As a technology, nanotechnology will provide human beings with novel products and devices with specific functions. Nanoscience and technology are full of opportunities and challenges [10, 11].

Due to its unique properties, nanotechnology is widely used in military, medical, environmental energy, biological research, and other fields. It has brought great positive significance to national security and people's life, changed people's original production methods, improved production efficiency, and reduced energy consumption. And in the field of the environment, it is not far behind. The catalyst developed by it can effectively solve the problem of sewage and air quality [12, 13]. The huge positive significance of nanotechnology and some undiscovered potential values have made the world carry out crazy research on it, forming a "nanostorm" [14]. Among them, nanomaterials include four common forms of nanopowder, nanofiber, nanofilm, and nanoblock [15], as shown in Figure 1:

Nanotechnology contributes to the utilization of new energy sources. Hydrogen is abundant in nature. After burning, it will not pollute the environment, so it is regarded as a new type of energy in today's society. However, some previous technologies cannot achieve the best effect of hydrogen transportation and storage. The researchers discovered that carbon nanotubes are a material that can store hydrogen. The surface area of 1G carbon nanotubes can reach hundreds of square meters, and a large amount of absorbed hydrogen can be released by slight heating at room temperature. And this technology is expected to be included in the application stage in the future, when human beings can use hydrogen on a large scale to replace scarce fossil energy. Yet, the air we breathe will also change dramatically, as shown in Figure 2:

It is not difficult to see that the definitions of nanotechnology have different focuses on nanotechnology. The UNESCO definition highlights the convergence of nanoscale research at both theoretical and applied levels. The National Nanotechnology Innovation Organization's definition highlights the novel properties of materials and systems at the nanoscale. The NSF definition emphasizes convergent fusion at the nanoscale. The EU's seventh framework plan lists
Figure 1: Four forms of nanomaterials.
Figure 2: The economic impact of nanotechnology.

many areas related to nanotechnology. At the same time, these definitions have in common: First, they all reflect the scope of research at the nanoscale. Second, they all focus on the novel properties exhibited by matter at the nanoscale [16, 17], as shown in Figure 3:

3.2. Applications of Nanotechnology. Nanotechnology, like previous new technologies, was first used in the military field to prove its huge military value. When this technology emerged, people had glimpsed its broad prospects in the military field. The US Department of Defense clearly recognized the importance of nanotechnology a decade ago and has

played an important role in supporting this field. The US Department of Defense website reported in February 2001 that the US Department of Defense announced that in 2001, it awarded \$8.75 million to 16 nanometer research projects. It has also awarded 14 research institutions of \$15 million annually since 2002 to carry out nanotechnology research in 15 basic disciplines and engineering fields. Nanotechnology has brought global medical care to another level, and it has opened up new windows for biopharmaceuticals and chemical pharmaceuticals with its unique structure and properties. Because there is still a lot of work in the basic theory and application development, it is still in the research and development stage. Therefore, although a lot of research on the preparation, structure, and properties of nanobiomedical materials has been carried out, it is still in its infancy. Therefore, we look forward to people's further exploration. Experts pointed out that due to the introduction of nanotechnology in the future, the production of medicines and the delivery of medicines will undergo fundamental changes [18–19], as shown in Figure 4:

3.3. Application of Nanotechnology in Badminton Health Care. The application of nanomaterials has been very extensive and can be seen everywhere in our daily life. It has a lot of applications in light industry, chemical industry, machine manufacturing, electronic product manufacturing, and other fields. Nanomaterials will play a major role in future life, and
FIGURE 3: Nanotechnology.
FIGURE 4: Nanotechnology applications.

nanotechnology will bring more variety to our lives. The dominance of nanotechnology demonstrates its social value that cannot be ignored. It is widely and strongly applied to all fields of society with its unique properties, promoting the stable and orderly development of society [20–21].

In the field of badminton, with the excellent properties of nanomaterials, nanomaterials have in-depth applications in badminton rackets, protective gear, and others, as shown in Figure 5:

In this century, the nano industry must be one of the main industries leading the development of the science and technology industry. Nanotechnology and nanomaterials

have penetrated into various industries of the national economy, such as medical industry, environmental energy, computer industry, biological research, national security, and aerospace. It promotes the rapid growth of the national economy, and its economic impact will certainly exceed that of the information industry [22, 23].

3.4. Nanotechnology Hidden Markov Models. Hidden Markov model (hidden Markov model, HMM for short) is a statistical model, which is used to describe a Markov process with hidden unknown parameters. The difficulty is to determine the implicit parameters of the process from the

Nanotechnology racket   Nanotechnology ball net   Nanotechnology protective gear
FIGURE 5: Nanotechnology racket.

observable parameters. These parameters are then used for further analysis, such as pattern recognition.

Many properties of hidden Markov models are used to solve real-world practical problems. According to the different types of data processed, hidden Markov models can be divided into discrete hidden Markov models and continuous hidden Markov models. Discrete hidden Markov models are the basis of continuous hidden Markov models and are easier to understand. The remainder of this chapter will give a detailed introduction to discrete hidden Markov models and continuous hidden Markov models.

3.4.1. Elements of Hidden Markov Model. A hidden Markov model (HMM) can be described by five elements, including 2 state sets and 3 probability matrices:

The number of hidden states N is the number of unobserved states. The hidden states satisfy the Markov property, which is the actual hidden state in the Markov model. Implicit states are usually not available through direct observation.

The number of observable states M is the number of states that can be clearly observed. Its observable state is associated with the hidden state in the model. It can be obtained by direct observation. The number of observable states does not have to be the same as the number of hidden states (the number of different colored sticks thrown in the above example).

The implicit state transition probability matrix A describes the transition probability between states in the HMM (the probability of transitioning the person who throws a small stick in the example). It can be expressed as $a_{ij} \in A$. a_{ij} represents the probability of transitioning from state i to state j at time t, where $1 \le i$; $j \le N$.

The observation state radiation probability matrix B (the probability that the specified person throws the specified color stick in the example) can be expressed as $b_j(k) \in B$. $b_j(k)$ represents the probability of selecting the observation feature as x_k from the state j at time t, where $1 \le j \le N$; $1 \le k \le M$.

The initial state probability matrix π represents the probability matrix of the hidden state at the initial time $t = 1$. It can be expressed as $\pi_i \in \pi$; π_i represents the probability of selecting state i at time $t = 1$, where $1 \le i \le N$.

3.4.2. Training of Hidden Markov Models. When training an HMM for a given problem or specified dataset, consider the joint probability of the hidden state (S_i) and the observable state (O_i) and simplify it with the intrinsic properties of Markov chains for continuous data. The resulting joint probability:

$$\Pr(S, O) = \Pr(S_1) \prod_{t=2}^{T} \Pr(S_t|S_{t-1}) \prod_{t=1}^{T} \Pr(O_t|S_t). \quad (1)$$

3.4.3. Probability Calculation of Observable Sequences. To calculate the probability of observing the sequence $O = O_1, O_2, \cdots, O_T$, it is assumed that the model parameters λ are known, namely, the parameter values A, B, and π are all known. For a given λ, the computation is done by considering every possible sequence of states that can produce an observation sequence O. The sum of the obtained probabilities is the probability of producing the observation sequence O through the model parameters λ.

Supposing the implicit state sequence that may produce the observation state sequence O is

$$S = S_1, S_2, \cdots, S_T, \quad (2)$$

$$\Pr(O|S, \lambda) = \prod_{i=1}^{T} \Pr(O_i|S_i, \lambda), \quad (3)$$

$$\Pr(O|S, \lambda) = b_{S1}(O_1)b_{S2}(O_2), \cdots, b_{ST}(O_T). \quad (4)$$

Under the condition that the model parameter is λ, the probability that the hidden state sequence is S is calculated as follows:

$$\Pr(S|\lambda) = \pi_{S_1} a_{S_1 S_2} a_{S_2 S_3}, \cdots, a_{S_{T-1} S_T}. \quad (5)$$

Substituting formula (5) into formula (1), we get

$$\Pr(S, O) = \Pr(S|\lambda)\Pr(O|S, \lambda), \quad (6)$$

$$\Pr(O|S, \lambda) = \Pr(O|S, \lambda)\Pr(S|\lambda). \quad (7)$$

By considering every possibility that can produce an implicit state of the observation sequence O, the probability of obtaining the observation state sequence O from the model parameters λ can be obtained. The following formula is obtained

$$\Pr(O|\lambda) = \sum_{all\ S} \Pr(O|S, \lambda)\Pr(S|\lambda), \quad (8)$$

$$\pi = \begin{bmatrix} \Pr(Person\ 1) \\ \Pr(Person\ 2) \\ \Pr(Person\ 3) \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}$$

Prior probability matrix

	Person 1	Person 2	Person 3

Green	0.07	0.02	0.2
Black	0.6	0.17	0.01
White	0.01	0.08	0.02
Orange	0.1	0.05	0.06

Observation emission probability matrix

	Person 1	Person 2	Person 3
Person 1	0.2	0.4	0.3
Person 2	0.1	0.5	0.4
Person 3	0.4	1.5	0.1

State transition probability matri

Figure 6: Parameter matrix.

$$\Pr(O|\lambda) = \sum_{S_1, S_2, \cdots, S_T} \pi_{S_1} a_{S_1 S_2} a_{S_2 S_3}, \cdots, a_{S_{T-1} S_T} b_{S_1}(O_1) b_{S_2}(O_2), \\ \cdots, b_{S_T}(O_T). \tag{9}$$

In order to better explain the calculation method derived from formula (8) and formula (9), let us start from the beginning again with the example of a person throwing a small stick. With the parameter values given in Figure 6, the expression is used to calculate the probability of observing the sequence {red, green}.

Here, the sequence $O = \{red, green\}$ is observed. For all hidden state sequences S, the probability of finding the observation sequence O is

$$\Pr(O|\{person2, person1\}) = 0.6 \times 0.1 \times 0.07, \tag{10}$$

$$\Pr(O|\{person2, person3\}) = 0.6 \times 0.4 \times 0.2, \tag{11}$$

$$\Pr(O|\{person2, person2\}) = 0.6 \times 0.1 \times 0.02. \tag{12}$$

The total probabilities obtained are

$$\Pr(O|\lambda) = 0.0546. \tag{13}$$

In all possible states, the probability of observing the sequence O is calculated, and in formula (13), these calculated probabilities are summed, so that the probability of observing the sequence O of the HMM, the parameter λ, is obtained. The computational complexity of using formulas (2) to (9) to calculate the probability is quite high. For example, for an HMM with N hidden states, the time complexity of the exhaustive search is $2TN^T$, where T is the length of the observation sequence. Therefore, it is necessary to find some other alternative ways to calculate the probability of observation sequence.

3.4.4. Forward-Backward Algorithm. Forward-backward algorithm is a relatively less computationally intensive method that can calculate the probability of an observation sequence. The forward variable $\alpha_t(i)$ is defined as

$$\alpha_t(i) = \Pr(O_1, O_2, \cdots, O_t, S_{t=i}|\lambda), \tag{14}$$

where $\alpha_t(i)$ is the local observation sequence probability, which represents the probability that, for a given λ, the observation sequence is state i at time t. The specific steps of the forward-backward algorithm are as follows:

Initialization: For all states i, $\alpha_1(i) = \pi_i b_i(O_1)$, where $i \in \{1 \text{ to } N\}$.

Induction: For each time point t, a value of the forward variable $\alpha_t(i)$ can be obtained, and for each time point $t = 2, \cdots, T$ and all states j ($j \in \{1 \text{ to } N\}$) recursively calculate the forward variable $\alpha_t(j)$:

$$\alpha_t(j) = \left[\sum_i \alpha_{t-1}(i) a_{ij}\right] b_j(O_t). \tag{15}$$

Termination: For a given HMM, the probability of observing sequence O can be calculated by the following formula:

$$\Pr(O|\lambda) = \sum_i \alpha_T(i). \tag{16}$$

In this method, each state at time $t - 1$ is fully computed before considering the state at time t. Therefore, for a given HMM model λ, the last state in the operation constitutes the final probability of producing the observation sequence O. It can be found that the time complexity of the forward algorithm is $N^2 T$, where N refers to the number of hidden states and T refers to the length of the observation sequence.

The backward algorithm is similar to the forward algorithm and is used to calculate the probability of the observation sequence for a given λ. The backward variable $\beta_t(i)$ is defined as follows:

$$\beta_t(i) = \Pr(O_{t+1}, O_{t+2}, \cdots, O_T|S_{t=i}, \lambda). \tag{17}$$

As in formula (17), $\beta_t(i)$ represents the backward variable, which refers to S_i at time t, where λ is known and S_i is the hidden state. The final probability is as in

$$\Pr(O|\lambda) = \sum_i \pi_i b_i(O_1) \beta_1(i). \tag{18}$$

As described above, both forward and backward
FIGURE 7: Basic information of research objects.

algorithms can be used to compute $\Pr(O|\lambda)$ to evaluate problems. Forward and backward algorithms can also be used together to solve the problem of model parameter estimation.

4. Badminton Health Care

4.1. Objects and Methods. Constitution refers to the quality of human life. It is a comprehensive and relatively stable feature of the human body on the basis of heredity and acquisition in terms of human body shape structure, physiological function, physical quality, psychological quality, and adaptability. A healthy physique is the basis for ensuring people's normal life, study, and work. Among them, a healthy physique is characterized by normal development and symmetry in the human body morphological structure. In terms of physiological function, it shows that the physiological functions of various organ systems in the human body are normal. In terms of physical fitness, it is mainly reflected in strength, speed, and endurance to meet the physical needs of general labor and sports. On the level of psychological quality, it is manifested in having psychological characteristics suitable for its age and gender and being able to withstand corresponding psychological pressure. Adaptability is reflected in the body's natural adaptability and social adaptability to resist common pathogens and enable the body to integrate into society and interact with others normally.

In order to explore the different effects of students participating in badminton extracurricular training on physical health and physical self-esteem, three primary schools (JE Primary School, QS Primary School, and CT Primary School) were randomly selected. This article is based on the grouping criteria of only participating in extracurricular

training in badminton, basketball, and swimming, and not participating in any extracurricular sports training. Participation in various sports in the standard is in the range of six months to one year, and the level of sports ability is equal. Before the investigation, this article will visit and check the physical health status of all participants in the experiment. This article confirms that the participants are in good physical and mental health and explains the procedures for this experiment to the subjects. The data collectors introduced the purpose and precautions of this questionnaire
FIGURE 8: The improvement rate of badminton on physical function.

to the school physical education teachers and training team coaches in detail. It is convenient to answer the feedback information that is not understood during the questionnaire and data collection process in a timely manner. Physical education teachers and coaches in each school assist in distributing questionnaires, read out instructions, and explain filling requirements. It promises to keep the information filled in confidential and to fill in truthfully by the participants. In this paper, the fifth and sixth grade students of three primary schools are divided into four groups: no training, badminton, basketball, and swimming, and a total of 130 students in four groups are selected from each school. Later, due to the physical discomfort of 1 student and the failure of the assessment questionnaire for 3 students, 4 special subjects were excluded, and 126 students were retained as the research subjects of this experiment. The 126 study subjects were in good health and had no disease or other factors that would make them unfit to participate in the experiment. Among them, the number of students who participated in extracurricular training in badminton, basketball, and swimming and those who did not participate in the training were 34, 32, 30, and 34, respectively. In terms of gender distribution, there are 70 boys and 60 girls, and the proportions of each group are shown in Figure 7:

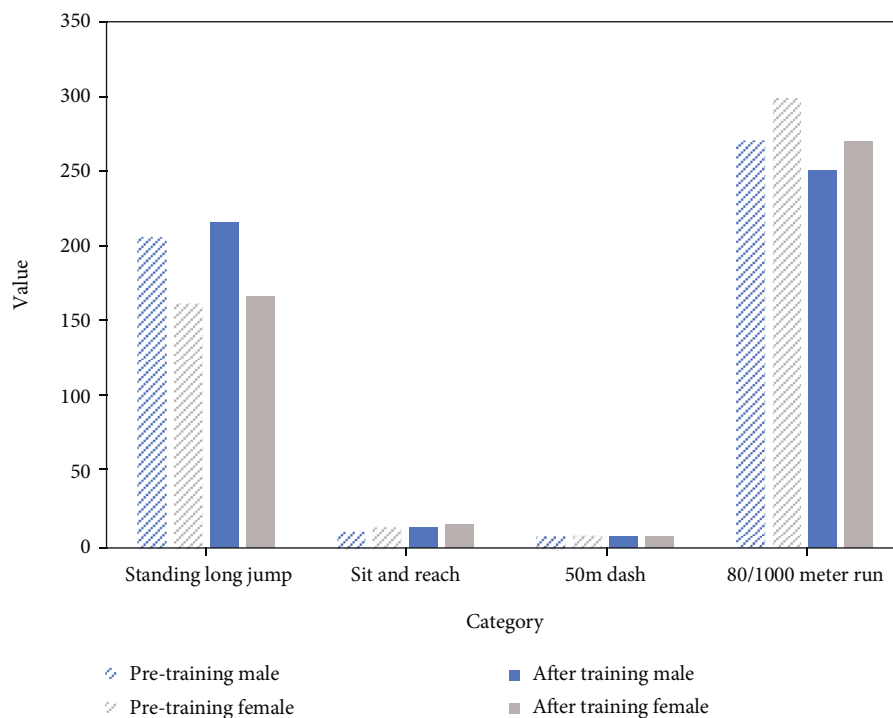
In order to explore the impact of badminton on the development of physical self-esteem among Chinese senior primary school students, this study uses the physical self-esteem scale to investigate the research subjects. The physical self-esteem scale for children is based on the PSDQ and PSPP and combines the characteristics of Chinese development and growth. It is divided into 12 different dimensions of health, appearance, strength, speed, flexibility, endurance, coordination, physical attractiveness, motor skills, physical activity, physical worth, and overall self-esteem. They collectively reflect the physical self-esteem of adolescents. The scale has a total of 78 items, and items 1, 13, 25, 37, 49, 61, 73, and 76 reflect the health subscale. 2, 14, 26, 38, 50, and 62 items reflect the physical attractiveness subscale. 3, 15, 27*, 39, 51*, 63, 74, and 77 items reflect the motor skills subscale. 4*, 16*, 28, 40, 52, and 64 reflect physical activity subscales and more. It takes about 20–25 minutes to fill in the answer, using a five-level scoring method; each subscale is scored separately and not included in the total score of the scale.


FIGURE 9: Analysis of the impact of badminton on physical fitness.

In view of the need to fill in the physical self-esteem scale questionnaire for the grouped students, the author conducted a physical fitness index test on 130 students participating in the experiment in three primary schools, and then, the paper distributed, filled in, and collected the questionnaire. After informing the students to fill in the requirements, they supervise the students to fill in the questionnaires according to their own specific conditions and subjective feelings within half an hour. Correlation analysis was performed on all questionnaires. A total of 130 questionnaires were distributed this time, 130 questionnaires were recovered, and the recovery rate was 100%. Among them, 126 are valid questionnaires, and the effective rate is 97.67%, as shown in Table 1:

The physique measuring instruments and test methods are shown in Table 2.

4.2. Physical Fitness Results. At the beginning of the design of the experiment, the body shape of the experimental subjects was changed. As the first indicator of the impact of badminton on the physique of middle school students, the reason is that height represents the growth and physical condition of human bones. Height is greatly affected by external and internal factors, including eating habits, age, and gender. Weight is a horizontal standard for judging health or not and determines a person's physical function. On this basis, the ratio of height to weight (i.e., BMI) is a long-standing internationally recognized standard for measuring body mass index. According to Chinese management, the standard is (18.5–23.9) kg/m², and the ideal body mass index is 22 kg/m². Through the experiments of the first stage, we observe the experimental results. As can be seen from Figure 8 and Table 3, through 15 weeks of badminton exer-

cise, the experimental data of the experimental group and the control group show that in terms of body shape, the boys have $P > 0.05$ in terms of body weight and BMI value, and there is no significant effect. The height is significant at $P < 0.05$ and has an effect. However, because the height growth rate of boys and girls is about 1.5%, this is normal growth, because middle school students are in the stage of physical growth and development. For girls, $P > 0.05$ for height and weight, and $P < 0.05$ for BMI, which has a significant effect. Therefore, it can be concluded that badminton has an impact on the height of boys' and girls' BMI in terms of body shape of high school students.

In this paper, strength quality, speed quality, endurance quality, and flexibility quality are used as the indicators of this experiment. The experiments corresponded to standing long jump, 50-meter sprint, 800/1000-meter run, and forward bending while sitting. It can be seen from Figure 9 that before and after training, regardless of gender and category, there is a certain improvement. Therefore, it can be concluded that badminton can improve the aerobic endurance of high school students.

4.3. Comparative Analysis of Different Exercise Modes. It can be seen from Figure 10 that there are differences in the physical health indicators of students participating in badminton extracurricular training and other groups. (1) The sit-up scores of the students who participated in the extracurricular badminton training were higher than those of other groups, and there was an extremely significant difference with the nontraining and basketball groups ($P < 0.01$). (2) The 50-meter running scores of the students who participated in the extracurricular badminton training were higher than those of the nontraining group, and there was a significant
FIGURE 10: Comparison of health care by different sports.

difference ($P < 0.05$). (3) The vital capacity scores of students participating in swimming training were higher than those of other groups, and there was a significant difference ($P < 0.05$). (4) There was no significant difference between the scores of students participating in extracurricular badminton training and the scores of other groups in terms of BMI, one-minute rope skipping, 50∗8 round-trip running, and sitting forward bending ($P > 0.05$). In addition, it can be seen from the average situation that the average scores of students participating in badminton extracurricular training in the 50-meter run and sit-ups are higher than those of other groups. It shows that the speed quality and muscle strength quality of students participating in badminton extracurricular training are better than those of other groups.

5. Conclusion

Through one-way statistical analysis on the physical self-esteem index and overall self-esteem of the fifth and sixth grade students participating in badminton extracurricular training and the scores of students in the no-training group, basketball group, and swimming group, we can see that students who participated in badminton training had extremely significant differences with other groups in the six scales of physical attractiveness, motor skills, appearance, flexibility, coordination, and physical self-esteem ($P < 0.01$). In addition, the multiple comparisons of the scores of the senior primary school students participating in badminton training and the students in the no training group, the basketball group, and the badminton group in these six dimensions can be clearly seen: In the multiple comparison of appearance subscale scores, the appearance scores of the senior primary school students in the badminton group (3.72 points)

were higher than those of the basketball group students (3.22 points). And there was a significant difference in the scores between the two groups ($P < 0.05$). In the multiple comparison of the scores of the flexibility subscale, the flexibility score of the senior primary school students in the badminton group (3.93 points) is much higher than that of the swimming group students (3.39 points) and the basketball group students' scores (3.08 points). There was an extremely significant difference in flexibility scores between the badminton group and the basketball group ($P < 0.01$), and there was a significant difference between the badminton group and the swimming group ($P < 0.05$).

The residual compressive stress of concrete members can offset the tensile stress caused by some external load and hinder the generation and expansion of surface cracks to enhance the flexural strength of concrete. In order to carry out this strengthening method, the single-layer and double-layer gradient coatings mixed by sulphate aluminium cement with different amounts of expansion agent on the surface of concrete specimens were discussed, and the theoretical calculation formula of surface compressive stress caused by this was deduced. Combined with experimental data, the influence of surface compressive stress on flexural strength of concrete was studied. The results demonstrate that the greater the surface compressive stress generated in the coating, the better the effect of improving the flexural strength of concrete. To obtain sufficient surface compressive stress, it is recommended that the cross-sectional product ratio of the substrate to the coating is more than 80; the higher the elastic modulus of the coating, the greater the surface compressive stress; the smaller the shrinkage rate of the coating, the greater the surface compressive stress. The improvement effect of double-layer gradient coating on the flexural strength of concrete is better than that of single-layer coating. Compared with the reference specimen without coating, the improvement rates of double-layer gradient coating on the early and late flexural strength of concrete are 57.7% and 45.7%, respectively.

1. Introduction

Concrete has become the most widely used civil engineering materials in practical construction projects due to its high compressive strength, low cost, easy access to raw materials, and convenient construction. It plays a key role in promoting the development of social economy. With the development of science and technology, concrete buildings will gradually develop in the direction of large scale, high layers and large span in the future. However, the low flexural strength of most concrete used nowadays can lead to surface cracking of large concrete structures (such as foundation slab, wall slab, floor slab and underground structure, etc.), and even affect the safety performance and service life of concrete structures. [1–3]. Improving the flexural strength of concrete through diverse ways has become one of the

urgent problems to be solved, so it has gradually become a research hotspot of experts and scholars.

The incorporation of reinforcement with high tensile strength in concrete is one of the first measures to enhance the flexural strength of concrete structures, and the premature cracking of concrete in the tensile area limited the use of reinforced concrete components in large span or bearing power load structures. The emergence of prestressed concrete solves this problem. It uses the high compressive strength of concrete to make up for its low flexural strength and utilizes the precompression method to indirectly improve the flexural strength of concrete. In essence, it changes the crack-prone characteristics of concrete, which is very effective for saving steel, reducing the size of the structural section, reducing the weight of the structure, preventing cracking, and reducing deflection. In addition, with

the further development of research and development work, various mineral admixtures, fibers, additives, and nanophase materials, polymer has been applied by scholars to improve the flexural strength of concrete and has achieved good results. The research status is as follows:

Tolmachov et al. [4] added water reducer, mineral admixture, and fiber into concrete to increase its flexural strength by 25.7%. Singh et al. [5] found that the flexural strength of RAP concrete could be increased by 10% by adding 10% (mass fraction) silica fume. Zhang et al. [6] found that when the fly ash content was 20% (mass fraction, the same below), the flexural strength of recycled concrete could be increased by 29.9%. On this basis, the flexural strength could be further increased by 11.4% by adding 1% water reducer, while the flexural strength of concrete could be increased by 30.7% by adding 10% silica fume. Somasekharaiah [7] showed that when 10% silica fume was added to the concrete, and 1% steel fiber and 0.25% polypropylene fiber were mixed in the concrete, the strength improvement rate reached 71.5%. Mahadik et al. [8] found that different dosages (volume fraction of 0.25%~1%) of steel fiber had different degrees of improvement effect on the flexural strength of concrete, and when the dosage was 0.75%, it was the best, and the improvement rate reached 43.3%. Bhat and Alam [9] found through a large number of tests in the concrete mixed with 0.5% to 2% (volume fraction) of steel fibers can improve its flexural strength, the flexural strength of concrete at the early age became the highest when the steel fiber content was 2%. Bi et al. [10] found that the flexural strength of polypropylene fiber with a length of 18 mm and a dosage of $0.6 \, kg/m^3$ was increased by 32.3% when it was mixed with concrete.

Turlapati and Chintapalli [11] suggested that the flexural strength of polypropylene fiber with a volume fraction of 1% could be increased by 35%. Wyrzykowski et al. [12] combined expansion agent, super absorbent polymer, and shrinkage-reducing agent to make the prestress of central concrete reach about 2.5 MPa~3.0 MPa. Yang et al. [13] found that when the content of expansive agent was 6% (mass fraction), the early and late flexural strength of concrete could be enhanced by 6.2% and 4.1%, respectively. Li et al. [14] found that when the content of nanosilica was 5% (mass fraction), the flexural strength of lightweight concrete could be enhanced by 17.5%. Saafi et al. [15] incorporated 0.35% reduced graphite oxide into cement-based composites, resulting in an increase of 134% in flexural strength. Wang et al. [16] found that the flexural strength of concrete could be increased by 12% by adding 0.5% carbon nanotubes and 1.0% polyvinyl alcohol nanosecond emulsion. Liu et al. [17] added 7% acrylic acid (AA) and 1-acrylamido-2-methylpropanesulfonic acid (AMPS) polymer into concrete to increase its flexural strength by 61.2%.

However, all of the above technical ways to improve the flexural strength of concrete have limitations. The production process of prestressed concrete members is complex, the technical requirements are high, and special tension equipment and professional technical operators are needed. At the same time, the construction cost of prestressed concrete structures is large, and the engineering cost of fewer components is high. The application of mineral admixtures in concrete provides a driving force for the sustainable development of resources, and its beneficial effect on the performance of concrete is no doubt. However, industrial waste residue used as mineral admixtures is after all an industrial byproduct, so there are also some problems. For example, silica fume will aggravate the shrinkage of concrete, and fly ash and slag will reduce the initial mechanical properties of concrete. At the same time, the measures taken to stimulate the activity of mineral admixtures may lead to hidden dangers such as alkali aggregate reaction, weak resistance to sulfate attack, and poor compatibility of admixtures [18–22]. The incorporation of fiber into concrete can significantly enhance the flexural strength of concrete, while studies have shown that the incorporation of steel fiber has no obvious enhancement effect on the compressive strength of concrete, and there are also problems such as high unilateral cost and construction difficulties. Basalt fiber production process energy consumption is enormous, and process control is not easy. Ordinary glass fiber is brittle and easy to break, easy to be damaged in the mixing process, and plant fibers have problems such as elevated water absorption, poor alkali resistance, and difficult processing [23, 24]. Nanomaterials are not only expensive but also need to consider the dispersion problem in the use process, and their application in concrete needs to be further studied [25, 26]. There continue to be some deficiencies in the overall performance of polymer concrete when it is modified by a single polymer. The incorporation of chemical admixtures will lead to changes in the structural quality of polymer membranes, which will have a negative impact on concrete [27, 28].

In addition to the abovementioned prestressed concrete, another successful application of prestressed reinforcement technology is the tempered glass. The tempered glass can improve the strength of the glass by 2~5 times by forming a layer of preloading stress on the surface of the ordinary glass, and at the same time, it can improve its thermal stability and safety performance, and it has been comprehensively promoted and popularized worldwide since the beginning of the 20th century [29–31]. Both in the field of concrete and glass, prestressed reinforcement design of macroscopic structure is adopted. The compressive stress is introduced into the material or component in advance to offset the external tensile stress, so as to increase the strain of the matrix cracking due to tension, and improve the fracture strength, reliability, and durability of the material. In recent years, a prestress design of high strength and high damage tolerance composite ceramics comparable to the prestress distribution of tempered glass has produced good results [32, 33]. In fact, as long as it can be realized, this method can be applied to any brittle material, and concrete is one of the typical brittle materials, with the property of compressive and tensile resistance. Therefore, this study introduces the idea of surface prestress design into concrete. By double-layer gradient coating of sulphate aluminium cement with different expansion agents, Because of the difference shrinkage rate between Coating 1 and Coating 2, Coating 1 and concrete, the surface residual compressive stress is formed on concrete surface to offset the flexural stress

caused by external load, so as to prevent or reduce the formation and expansion of surface cracks, thereby improving the flexural strength of concrete and extending its service life. The method is simple to operate, not limited by the component size and shape, and more economical, while the substrate does not need to consider the compatibility with the new material, which has good application prospects.

2. Theoretical Analysis

The principle of prestressed concrete to enhance the flexural strength of structural members is to produce precompression stress in concrete and pretension stress in steel through the reinforcement in the tensile zone. The precompression stress can reduce or offset the tensile stress caused by the external load, so that the tensile stress of structural members is not large or even in the compression state, so as to improve the flexural strength of concrete structural members. In turn, coating the surface of the tensile zone of concrete with coating shrinkage rate less than the shrinkage rate of the substrate will produce precompression stress on the surface of the concrete and produce a balanced pretension stress inside the concrete, which is the same as the principle of improving the flexural strength of prestressed concrete. Only one of the precompression stresses is generated inside the concrete, and one is generated on the surface of the concrete. If a double-layer gradient coating with different shrinkage rates is applied on the concrete surface, the second coating (coating 2) shrinkage rate < the first coating (coating 1) shrinkage rate, the surface residual compressive stress in both coating 1 and coating 2, the double-layer gradient coating, which can further enhance the flexural strength of the concrete. The residual stress distribution diagram of prestressed concrete, single-layer coated concrete, and double-layer gradient-coated concrete is shown in Figure 1.

To determine the feasibility of this idea, this paper first derived the theoretical calculation formula of the surface compressive stress generated by applying double-layer gradient coating, assuming the contraction ratio of coating 1 and coating 2 is α_{c1} with α_{c2}, and the shrinkage rate of concrete substrate is α_s, the cross-sectional diagram of the length direction of the test piece before and after the coating is shown in Figure 2. Assuming that no constraint exists in the ideal free shrinkage case, the shrinkage of coating and substrate is shown in the dashed line section of Figure 2, and the shrinkage rate of coating 1, coating 2, and substrate can be indicated by formula (1), (2) and (3).

$$\alpha_{c1} = \frac{\delta_{11}}{L}, \tag{1}$$

$$\alpha_{c2} = \frac{\delta_{12}}{L}, \tag{2}$$

$$\alpha_s = \frac{\delta_2}{L}. \tag{3}$$

In the formula, the amount of free contraction of the coating 1 and the coating 2 is δ_{11} and δ_{12}, δ_2 is the length direction of the substrate, and L is the initial length of the sample. In fact, because the tight binding of the interface has deformed the coating identical to the substrate, assuming that the overall amount of cooperative deformation of the composite sample is δ, and the overall shrinkage rate is $\bar{\alpha}$:

$$\bar{\alpha} = \frac{\delta}{L}. \tag{4}$$

The residual stress in the coating and the substrate is balanced, assuming the surface compressive stress in the coating 1 and the coating 2 are σ_{c1} and σ_{c2}, the tensile stress in the substrate to balance the surface compressive stress is σ_s, under the action of stress, the linear deformations of coating 1 and coating 2 are d_{11} and d_{12}, the linear deformation of the substrate is d_2. According to the relationship between stress and strain, formulas (5), (6), and (7) can be obtained:

$$d_{11} = \frac{\sigma_{c1}}{E_{c1}} \times L. \tag{5}$$

$$d_{12} = \frac{\sigma_{c2}}{E_{c2}} \times L. \tag{6}$$

$$d_2 = \frac{\sigma_s}{E_s} \times L. \tag{7}$$

The elastic modulus of the coating 1 and the coating 2 is E_{c1} and E_{c2}, respectively, E_s is the elastic modulus of the substrate, which is known or tested. To facilitate derivation and analysis, assuming the cross-section area of the coating 1 and the coating 2 is equal, known from the substrate tensile stress and the coating compressive stress in the cross section:

$$\sigma_{c1} S_c + \sigma_{c2} S_c = -\sigma_s S_s. \tag{8}$$

From Figure 2, d_{11}, d_{12}, δ_{11}, δ_{12}, and δ_2 has the following geometric relationship:

$$d_{11} = \delta - \delta_{11}, \tag{9}$$

$$d_{12} = \delta - \delta_{12}, \tag{10}$$

$$d_2 = \delta_2 - \delta. \tag{11}$$

Combined with formula (3), (4), (7), (8) and (11) can get formula (12):

$$\sigma_{c1} + \sigma_{c2} = \left(\frac{S_s}{S_c}\right) \cdot E_s \cdot (\alpha_s - \bar{\alpha}). \tag{12}$$

It can be seen by formula (12) that the surface compressive stress is not a material constant, and it is related to the cross-sectional product ratio of the coating to the substrate. In order to more intuitively evaluate the surface compressive stress of various shapes and dimensions, it is best to use the material constant instead of the unknown quantity, and the extraordinary parameters can be expressed in combination with the

layer gradient coating can be obtained:

$$\sigma_{c1} + \sigma_{c2} = \left(\frac{S_s}{S_c}\right) \cdot E_s \cdot \alpha_s \left\{ 1 - \left[\frac{E_{c1}\alpha_{c1}}{E_s\alpha_s} + \frac{E_{c2}\alpha_{c2}}{E_s\alpha_s} + \frac{S_s}{S_c}\right] / \left[\frac{E_{c1}}{E_s} + \frac{E_{c2}}{E_s} + \frac{S_s}{S_c}\right] \right\}.$$

(14)

Similarly, the formula for the surface compressive stress generated by a single-layer coating can be deduced as described above:

$$\sigma_c = \left(\frac{S_s}{S_c}\right) \cdot \left\{ 1 - \left[\frac{E_s S_s}{E_c S_c} + \frac{\alpha_c}{\alpha_s}\right] / \left[1 + \frac{E_s S_s}{E_c S_c}\right] \right\} E_s \cdot \alpha_s.$$

(15)

In the formula, σ_s is the tensile stress generated in the substrate and balanced with the surface compressive stress, S_c and S_s are the cross-sectional areas of coating and substrate, respectively. E_c and E_s are the elastic modulus of coating and substrate, respectively, α_c and α_s are the shrinkage of coating and substrate, respectively.

It can be seen from formula (14) that the magnitude of the surface compressive stress in the double-layer gradient coating is closely related to the cross-sectional area ratio, elastic modulus ratio and shrinkage ratio between the coating and the substrate. Therefore, the magnitude of surface compressive stress can be adjusted by these parameters to achieve the effect of optimal design. In this paper, the cross-sectional product of the concrete substrate has been determined, and its shrinkage rate and elastic modulus are also a fixed value (Obtained $\alpha_s = 330 \times 10 - 6$, $E_s = 28.1$ GPa through test), allowing qualitative analysis of surface compressive stress generated in double-layer gradient coating based on formula (14).

First, the elastic modulus value and contraction rate value of coating 1 are taken as the invariants, and when the shrinkage and elastic modulus of coating 2 are variables,
FIGURE 5: Schematic of the double-coated specimen.

the variation trend of the surface compressive stress generated in the double-layer gradient coating with the ratio of the cross-sectional area of the substrate to the coating is analyzed. It is assumed that the shrinkage ratios of coating 1 and coating 2 to substrate ($\alpha_{c1}/\alpha_s = 0.6$, $\alpha_{c2}/\alpha_s = 0.3$) are both fixed values. When the elastic modulus ratio of coating 1 to substrate is $E_{c1}/E_s = 0.6$, and the elastic modulus ratio of coating 2 to substrate is $E_{c2}/E_s = 0.6⊠ 0.9⊠ 1.2⊠ 1.5$, respectively, the variation trend of surface compressive stress in the double-layer gradient coating with the cross-sectional area ratio of substrate to coating is shown in Figure 3. It is assumed that the elastic modulus ratio of coating 1 and coating 2 to substrate ($E_{c1}/E_s = 0.8$, $E_{c2}/E_s = 0.5$) is a fixed value. When the shrinkage ratio of coating 1 to substrate is $\alpha_{c1}/\alpha_s = 0.6$, and the shrinkage ratio of coating 2 to substrate is $\alpha_{c2}/\alpha_s = 0.2, 0.3, 0.4, 0.5$, respectively, the variation trend of the surface compressive stress generated in the double-layer gradient coating with the cross-sectional area ratio of the substrate to the coating is shown in Figure 4.

Preparation of substrate ⟶ Preparation completed demoulding after 24h ⟶ Preparation of coating

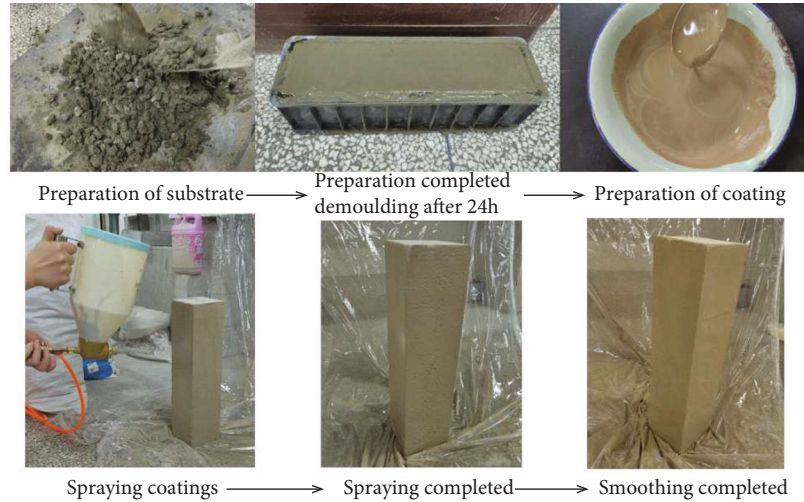
Spraying coatings ⟶ Spraying completed ⟶ Smoothing completed


FIGURE 6: Preparation process of coated concrete specimen.

As shown from Figure 3, when the elastic modulus of the coating 2 is a single variable, the surface compressive stress $(\sigma_{c1} + \sigma_{c2})$ increases with the increase of E_{c2}/E_s; according to Figure 4, when the shrinkage rate of the coating 2 is a single variable, the surface compressive stress $(\sigma_{c1} + \sigma_{c2})$ decreases with the increase of α_{c2}/α_s; Figures 3 and 4 show that the surface compressive stress $(\sigma_{c1} + \sigma_{c2})$ increases first with the increase of S_s/S_c, and plateaus after $S_s/S_c > 80$. Similarly, when the elastic modulus value of the coating 2 is taken as invariants, and the shrinkage rate value and the elastic modulus value of the coating 1 are the variables, the trend of surface compressive stress changes with the cross-sectional area ratio value of the substrate and the coating, which is completely consistent with the above.

Considering the above analysis: (1) on the premise of coating 2 shrinkage < coating 1 shrinkage < substrate shrinkage, the smaller the shrinkage of coating 1 and coating 2, the greater the surface compressive stress. (2) The higher the elastic modulus of coating 1 and coating 2, the greater the surface compressive stress. (3) In order to obtain enough surface compressive stress, it is suggested that $S_s/S_c > 80$.

3. Experiment

3.1. Materials. According to the above theoretical analysis, it can be seen that the shrinkage rate of coating 2 < that of coating 1 < that of substrate is the prerequisite for the generation of surface compressive stress, and the concrete will contract during the hardening process. Therefore, in this study, the slightly expanded sulphoaluminate cement was selected as the main component of the coating material, and the shrinkage rate of the coating material was adjusted by adding different amounts of concrete efficient expansion agent, so as to ensure the smooth generation of surface compressive stress.

Ordinary Portland cement (P·O42.5R) and sulphate aluminate cement (SAC42.5) were selected as cement in the concrete substrate and coating, respectively. Fine aggregate in substrate was medium sand with fineness modulus M_x

FIGURE 7: Flexural strength test.

FIGURE 8: Elastic modulus test of coating.
FIGURE 9: Schematic diagram of the loading method of the coating elastic modulus.

= 2.82, and the coarse aggregate was stone with continuous gradation of 5~30 mm in particle size. Calcium oxide-calcium thialuminite compound expansion agent (HME®-IV) was used for the expansion agent, and water was laboratory tap water. The chemical composition of the cement and the expansion agent is shown in Table 1, and the performance indicators of the expansion agent are shown in Table 2.

3.2. Design of Coating and Substrate. In order to facilitate the test of the shrinkage rate and elastic modulus of the coating material, the low content of expansion agent and sulphate aluminate cement was selected as the coating in this experiment, and five groups of test schemes were designed. Among them, the blank test group without coating had a total of one group; the single-layer coating consisted of three groups, which were composed of sulphate aluminate cement and 0%, 6%, and 10% expansion agent, respectively. There was a group of double-layer gradient coating, the first layer and the second layer were the substrate of sulphate aluminate cement and expansion agent with the contents of 0% and 10%, respectively, so that the shrinkage difference between the two layers reaches the maximum. The water-cement ratio of the coating is 0.5, and the mixture ratio of the reference specimen without the coating and the substrate with the coating were consistent. The mixture ratio of the coating and the substrate is given in Table 3.

3.3. Methods

3.3.1. Preparation of Coated Concrete Test Specimens. After the concrete substrate was poured, solid, and flattened, it shall be covered with plastic film and placed in the room with an ambient temperature of $(20 \pm 1)°C$. After 24 h, the concrete surface shall be cleaned and moistened with a wet rag. The prepared coating was evenly sprayed on the concrete surface (four faces in the length direction) and smoothed with a scraper. Double-layer gradient coating sprays the second coating immediately after spraying the first coating and smoothing with a scraper, and the test schematic diagram is shown in Figure 5, where k is a cross-section, h_1 for the thickness of the first coating, and h_2 for the

FIGURE 10: Elastic modulus test of substrate.

thickness of the second coating. The specific preparation process of coated concrete specimen is shown in Figure 6.

3.3.2. Flexural Strength Test. The prepared specimens were cured to 7d and 28d at $(60 \pm 5)%$ relative humidity and $(20 \pm 1)°C$, and then, according to GB/T 50081-2019 guidelines, the specimens of size $100\,mm \times 100\,mm \times 400\,mm$ were tested for measuring flexural strength by universal testing machine (Figure 7), and the controlled loading rate was 0.05 MPa/s. Take the average value of the flexural strength test results of a group of 3 specimens as the test result.

3.3.3. Coating and Substrate Shrinkage Rate Test. According to JC/T 313-2009 guidelines, the specimen size of 25 mm × 25 mm × 280 mm was tested for measuring shrinkage rate of the coating by JH-320 alkali aggregate specific length meter. Specimen size of $100\,mm \times 100\,mm \times 515\,mm$ was tested for measuring shrinkage rate of the concrete by HSP-540 shrinkage apparatus as per GB/T 50082-2009 guidelines. After the molding of the specimen, the initial length was measured after the curing condition of 1d under the above discount strength test, the specimen length changes after curing to 28d to calculate the shrinkage rate of 28d age, and the shrinkage rate of the coating and
FIGURE 11: Schematic diagram of the loading method of the substrate elastic modulus.

substrate was calculated as the formula:

$$S_{28} = \frac{(L_{28} - L_1)}{L_0} \times 100\%. \tag{16}$$

In formula, S_{28} indicates the shrinkage rate of 28d (positive expansion and negative contraction); L_{28} is the length of 28d, mm; L_1 is the initial length of the specimen, mm; L_0 is the effective length of the specimen (coating specimen 250, substrate specimen 485), mm. Take the average value of the shrinkage rate test results of a group of 3 specimens as the test result.

3.3.4. Coating and Substrate Elastic Modulus Test. In order to calculate the theoretical value of surface residual compressive stress generated in the coating, the elastic modulus of the coating and the concrete substrate at the age of 28d were tested by the dial indicator method. Specimen size of 70.7 mm × 70.7 mm × 220 mm was tested for measuring elastic modulus of the coating by TM-3 mortar elastic modulus tester as per JGJ/T70-2009 guidelines (Figure 8), and the loading speed was set to 0.5 kN/s. The schematic diagram of the loading method is shown in Figure 9, N_0 is the initial load at a stress of 0.3 MPa and $N_{0.4}$ is the pressure at 40% of the axial compressive strength.

Specimen size of 150 mm × 150 mm × 300 mm was tested for measuring elastic modulus of the concrete substrate by TM-2 concrete elastic modulus tester as per GB/T 50081-2019 guidelines (Figure 10), and the loading speed was set to 0.3 MPa/s. The schematic diagram of the loading method is shown in Figure 11, F_0 is the initial load with a stress of 0.5 MPa, and F_a is the load at 1/3 axial compressive strength. Take the average value of the elastic modulus test results of a group of 3 specimens as the test result.

3.3.5. Microscopic Test. The interface morphology and microstructure between coating and substrate were observed by JSM-6360LV scanning electron microscope. The sample preparation steps were as follows: after the flexural strength test of the specimen, a small sample was cut at the section of the specimen to be tested and then immersed in anhydrous ethanol solution for 24 h to stop the hydration reaction; finally, the test sample was placed in a 100°C oven for drying for 12 h. The surface of the sample to be tested needs to be sprayed with gold for 30 min before using scanning electron microscope to observe the sample, so as to increase the conductivity of the sample and make the observation of the interface microstructure clearer.

4. Results and Discussion

4.1. Theoretical Value Calculation of Surface Compressive Stress. According to the qualitative analysis in Section 2, the thickness of the coating should be less than 1.25 mm. Therefore, the thickness h of the single-layer coating and the thickness h_1 and h_2 of the double-layer gradient coating were both set to 1 mm in the test of this study, that was, the cross-sectional area ratio of coating to substrate remained unchanged. In order to verify that the surface compressive stress of the gradient coating is greater than that of the change of coating shrinkage rate and elastic modulus, the shrinkage rate and elastic modulus were tested (Table 4), and the theoretical values of the surface compressive stress

TABLE 5: Theoretical values of the surface compressive stress in the coating.

Sample no.	S_s/S_c	E_s/E_c	α_c/α_s	E_s/MPa	$|\alpha_s|$/%	σ_c/MPa
SC-0%	100	1.56	-0.61	2.81×10^4	0.330	9.48

Note: When the surface compressive stress is calculated, the shrinkage of the substrate is absolute value.
FIGURE 12: Flexural strength of uncoated specimens and coated specimens.

were calculated based on Equations (14) and (15), respectively. The calculation results are shown in Table 5.

According to Table 4, the shrinkage rate of all coating materials is positive and still expanding at 28d, while the concrete substrate is shrinking, and the shrinkage rate is coating 2 < coating 1 shrinkage rate, which shows that the coatings used in the test meet the prerequisite conditions for generating surface compressive stress.

The SC-0% group is the single-layer coating group without expansion agent in the coating, and the DC-0%-10% group is the double-layer gradient coating group with 10% expansion agent content on the basis of SC-0% group. It can be seen from Table 5, the surface compressive stress in the coating of DC-0%-10% group is 29.02 MPa, the surface compressive stress is increased by 206.1% compared with the SC-0% group. The coating of SC-10% in the single-layer coating group was the same as that of coating 2 in the double-layer gradient coating group, and the surface compressive stress in the coating of DC-0%-10% group was still higher than that of SC-10% group by 9.19 MPa. In the three single-layer coating groups, with the increase of the content of expansion agent in the coating from 0% to 10%, the shrinkage rate of the coating showed a downward
FIGURE 13: Interface morphology between coating and substrate.

trend, while the elastic modulus of the coating changed little, and the surface compressive stress in the coating increased.

The above analysis shows the following. (1) The surface compressive stress generated by the double-layer gradient coating group is significantly higher than that generated by the single-layer coating group, which also verifies the conclusion of the theoretical derivation of the double surface

(a)

(b)
Figure 14: Internal morphology of substrate at interface between uncoated specimen (a) and coated specimen (b).

compressive stress in Section 2. (2) When the cross-sectional area ratio of the coating to the substrate is a fixed value and the elastic modulus ratio changes little, with the decrease of the coating shrinkage, the surface compressive stress in the coating increases, which is consistent with the conclusion obtained in the qualitative analysis.

4.2. Experimental Verification of Improving Flexural Strength of Concrete. To further verify the improvement effect of the double-layer gradient coating on the flexural strength of concrete than the single-layer coating and to study the influence of the surface compressive stress on the flexural strength of concrete, the 7d and 28d flexural strength of uncoated and coated specimens were tested. The test results are shown in Figure 12.

It can be seen from Figure 12 that compared with the reference specimen without coating, whether single-layer coating or double-layer gradient coating can improve the 7d and 28d flexural strength of concrete, even the lowest group of 7d flexural strength in the coated specimen (SC-0%) also reached the 28d flexural strength of the reference specimen without coating (Control).

The effect of surface compressive stress on the early flexural strength of concrete was better than that on the later flexural strength. In the single-layer coating group, 7d and 28d flexural strength of concrete specimens increases with the increase of expansion agent content in the coating. The 7d and 28d flexural strength improvement rates of SC-0% group were 38.5% and 14.3%, respectively, the improvement rates of 7d and 28d flexural strength in SC-6% group were 50.0% and 25.7%, respectively, and the 7d and 28d flexural strength improvement rates of SC-10% group were 53.8% and 31.4%, respectively. The flexural strength of double-layer gradient coating group (DC-0%-10%) was better than that of the other three single-layer coating groups. The early and late flexural strength was 4.1 MPa and 5.1 MPa, respectively, and the strength improvement rate was 57.7% and 45.7%. This shows that the method proposed in this study to produce double surface compressive stress by coating double-layer gradient coating on the surface of concrete is feasible and effective for improving the flexural strength at early and late stages.

Combined with the theoretical values of surface compressive stress in Section 4.1 and the test results of flexural strength in this section, it can be found that the compressive stress on the surface of concrete and the improvement effect on the flexural strength of concrete with coated double-layer gradient coating are greater than those with coated single-layer coating. In the single-layer coating group, under the premise of small changes in the elastic modulus of the coating, with the increase of the content of expansion agent in the coating, the shrinkage rate of the coating decreases, and the surface compressive stress generated in the coating increases. The improvement effect on the flexural strength of concrete is also becoming more and more obvious. It can be seen that the greater the surface compressive stress generated in the coating, the better the effect of improving the flexural strength of concrete.

4.3. SEM Microanalysis. Good adhesion between the coating and the concrete substrate is the premise of the surface residual compressive stress, and it is also the key to the overall and common stress of the concrete components after coating. Figure 13 shows the micromorphology of the interface between the double-layer coating and the concrete substrate at the age of 28d. It can be observed from the figure that the boundary between the coating and the substrate is obvious and closely integrated, indicating that the cement slurry with expansion agent as the coating can better bond with the concrete substrate and further generate surface residual compressive stress.

Figure 14 shows the SEM comparison results of the concrete substrate at the interface between the double-layer gradient coating and the uncoated specimen at the age of 28d. Figure 14(a) shows that there are obvious cracks in the substrate of uncoated concrete, and the overall structure is uneven and irregular; compared with the uncoated specimen, the overall structure of the double-layer coated concrete substrate in Figure 14(b) is dense, and the internal cracks are significantly reduced.

This phenomenon may be due to the coating increases the wettability of the substrate surface and improves the water-cement ratio between the coating and the substrate, which promotes the hydration of the interface cement. At

the same time, the expansion agent reacts to generate a large number of AFt crystals that are interwoven to fill and cut off the capillary pores, so that the large pores are reduced and the total porosity is reduced, thereby improving the compactness of the microstructure at the interface [34]. The improvement of the pore structure at the interface by the coating reduces the overall moisture loss of the specimen, thereby reducing the shrinkage stress caused by the moisture loss of the pores, which is conducive to reducing the shrinkage cracking of concrete. In addition, the in-plane compressive stress of the surface itself is compressed and densified, which hinders the expansion of surface microcracks, and can improve the flexural strength of concrete [2].

The above microscopic analysis results show that the improvement effect of low shrinkage coating on the flexural strength of concrete is due to the fact that the generated surface compressive stress reduces the tensile stress caused by the external load and inhibits the generation and propagation of surface cracks. On the other hand, it is due to the improvement effect of coating on the structure of the interfacial transition zone.

5. Conclusions

(1) The theoretical analysis of double-layer gradient coating enhancing concrete flexural strength shows that the size of the surface compressive stress is related to the cross-section product ratio, elastic modulus ratio, and shrinkage rate ratio of the substrate and the coating, so through these parameters, the size of the surface compressive stress can be adjusted to achieve the optimal design effect. When the parameters of the substrate are unchanged, the higher the elastic modulus of the coating, the greater the surface compressive stress; the smaller the shrinkage of the coating, the greater the surface compressive stress; when the cross-sectional area ratio of substrate to coating is more than 80, the surface compressive stress is larger

(2) Coated on the concrete surface by double-layer gradient coating, the first layer is pure sulfate cement mixed with 10% expansion agent, Because the shrinkage rate of Coating 1 is between that of concrete and Coating 2, surface compressive stresses are formed between Coating 1 and Coating 2, and between Coating 1 and concrete, respectively, during the curing process. which effectively improves the early and later fracture strength by 77.7% and 45.7%, respectively, compared with the uncoated reference test

(3) By combining the theoretical value of surface compressive stress of the coating test and the flexural strength test results, it was found that the double-layer gradient coating test produces more surface compressive stress and higher flexural strength than the single-layer coating test; the smaller the shrinkage rate of the coating, the greater the surface com-

pressive stress, the higher the flexural strength. It can be shown that the greater the surface compressive stress generated in the coating, the better the improvement effect of the concrete flexural strength

(4) SEM test results show that the coating mixed with expansion agent and cement can be safely and stably attached to the concrete substrate. The coating can improve the density of the interface with the substrate and hinder the formation and propagation of surface cracks

The strengthening method adopted in this study can provide a new idea for improving the flexural strength of cement-based materials, but there are still some problems that need further study, mainly including the following:

(1) The more specific relationship between the ratio of different cross-sectional area, elastic modulus ratio and shrinkage ratio, and the flexural strength of specimens is taken as the focus of future research

(2) In the future research, various types of coatings can be selected for further study to further increase the effect of surface residual compressive stress on the flexural strength of concrete

(3) In the future research, the coating can be coated by machine, which can reduce the deviation of the test results caused by manual operation

Waterproof and impermeable problems seriously affect the safe use, normal structure, and working life of concrete projects. The waterproof performance of concrete can be improved by mixing with a proper amount of waterproofing agent; nevertheless, the early strength of concrete will be seriously affected. With the development of complex structures such as large spans in soil and water engineering and the increasingly complex engineering environment, people have put forward higher requirements for the working performance, strength, impermeability, durability, and intelligence of cement-based materials required. This article compares the changes in compressive strength, fluidity, and water permeability of mixed concrete by controlling the two variables of waterproofing agent and nanosilica. Combining the results of XRD microstructure analysis, the influence of nanosilica and waterproofing agent on the performance of concrete is explored. Moreover, it is hoped that other excellent properties of concrete can be improved, and a waterproof material with good opacity can be found. The test results show that after adding waterproofing agent alone, the 3 d compressive strength of concrete is decreased by 14.81%, the water permeability is reduced by 71.6%, and the depth of carbonic acid molecules at 28 d is also decreased by 37.3%. On the other hand, compared with concrete using waterproof coating alone, after adding in nanosilica, the 3 d compressive strength is increased by about 30%, and the water immersion height is decreased. The results show that the addition of polymer has a great influence on the compressive strength and carbonic acid resistance of concrete.

1. Introduction

Nanowaterproofing agent is a high-quality waterproofing agent that can maintain water resistance for a long time, with the functions of antimigration, water reduction, and performance improvement; this is a new generation of high-energy environmentally friendly products. Concrete can play a certain waterproof role in building structures, so it is widely used in waterproof buildings. However, in many engineering projects, concrete has not achieved the expected waterproof effect, resulting in serious water leakage in many building structures, which brings great inconvenience to production and life.

Because of the special properties of nanoparticles, some properties of the material can be changed after the addition of the nanoparticles, which can endow the material with special property required by the user, or make the special performance of the material more excellent [1]. At the same time, it can also help to open up the research road of material modification theory. Manufacturers and users of nanomodified materials put forward new requirements for material properties, such as stronger waterproof performance [2]. Frequent maintenance and leak repairs increase the economic expenditure and may not receive good results. With the development of modern society, the utilization of underground space has become popular, and the

requirements for waterproof technology are getting higher and higher.

Regarding the performance of concrete, relevant scientists have done a lot of research. Tanaka et al. had challenged the development of innovative asphalt mixtures, in view of the fact that the water stranded on the concrete deck of the highway bridge would significantly deteriorate and aggravate its damage. This asphalt mixture could ensure sufficient water resistance even during the limited time for concrete bridge repairs. After years of basic laboratory tests, a specially designed modified asphalt was developed, the performance of the mixture was specified, and its durability was checked using APT equipment, thereby obtaining a prototype mixture. Through the staged field test, the best construction method was finally obtained [3].

Sanytsky et al. were committed to the development of nanomodified cement-based composite materials in the field of self-cleaning building materials. The particle size distribution of the main components of multicomponent cement such as ultrafine zeolite and limestone, titanium dioxide, and kaolin additives was given. The interface degree of active surface in Portland cement and auxiliary cementing material was calculated. Studies had shown that due to the synergistic effect, anatase and rutile mixtures could be added to cement-based composite materials to improve the performance of self-cleaning gypsum. The mathematical programming method was used to study the effect of titanium dioxide and kaolin additives on the mechanical properties of nano-modified multicomponent cement. The results obtained by XRD and SEM methods showed that the addition of TiO_2 nanoparticles with a high specific surface area to the cement paste would result in the formation of a denser microstructure in the cemented matrix [4].

The purpose of Pacheco-Torres et al. is to evaluate the effect of surface roughness and bond strength between steel and concrete surfaces in two different ways. In this study, push-out tests were performed to evaluate the interface behavior between steel and concrete bonded using epoxy resin. Roughness is obtained by forming grooves on the surface of the specimen. From this study, it can be concluded that the epoxy resin used in the study can be safely used as an adhesive between steel sections and concrete bridge decks with a compressive strength of less than 50 MPa [5].

Regarding nanomodified materials, related scientists have done a lot of research. Li et al. studied the influence of nanosilica and silicone oil paraffin emulsion mixed with flue gas desulfurization gypsum on its water resistance. They mixed nanosilica with desulfurized gypsum, explored how the waterproof and mechanical properties of desulfurized gypsum were affected by the particle size and content of nanosilica, and analyzed its waterproof mechanism. They combined with the microscopic morphology analysis of the gypsum sample, the appropriate size of nanosilica filled the crystal pores and reduced the porosity, and this changed the structure and morphology of the gypsum crystals to a certain extent. The dense oil-hydrophobic film and nanosilica produced a compact gypsum structure, which prevented water molecules from entering the gyp-

sum, thereby improving the performance of FGD gypsum [6]. Xu et al. incorporated nano-ZrO_2 concentrate into phenolic epoxy resin to prepare a nanomodified coating system. They used a combination of electrochemical methods and surface characterization methods and evaluated the corrosion performance of the coating in a hot mixed acid solution, focused on the extent to which the corrosion performance of the coating was affected by the content of nano-ZrO_2. The results showed that the addition of 1% and 3% of nano-ZrO_2 could effectively improve the corrosion resistance of the coating, while the addition of 5% of nano-ZrO_2 reduced the corrosion resistance of the coating. The coating containing 3% nanometer ZrO_2 showed the smallest species diffusion, the lowest average roughness (5.94 nm), and the highest C/O ratio (4.55) and coating resistance and showed the best corrosion performance in the coating samples [7]. Liao et al. prepared aliphatic amine-modified layered silicate clay by n-octadecylamine intercalation method. It was an organically modified clay, which was a new type of phase change material. Through the ion exchange reaction, when the equivalent ratio of ODA-HCl to Na+-MMT was 1, and measured by X-ray diffraction (XRD) analysis, the interlayer corridor of the silicate-layered structure extended from 12 Å to 28 Å. The obtained organoclay could be used as a good heat storage and phase change material [8]. Irshidat and Al-Saleh studied the thermal and fire resistance properties of nanoclay-modified cement mortar. To prepare the modified mortar mixture, they replaced part of the cement with montmorillonite nanoclay (0-2% of the cement weight). The fire resistance was evaluated by comparing the residual mechanical strength of the heated sample and the control sample. Through XRD and SEM tests, the effects of nanoclay on the chemical composition and microstructure of the thermally damaged samples were evaluated, respectively. The experimental results showed that the nanoclay-modified cement mortar had higher compressive, tensile, and flexural strength than the control sample, especially at higher temperatures. Due to high-temperature exposure, the addition of nanoclay significantly reduced the degradation of the tensile and flexural strength of the cement mortar. SEM images showed that due to high-temperature exposure, the presence of nanoclay reduced the density and width of fine-line cracks that appeared along the cement matrix [9]. These methods provide some references for our research.

This article sets up a control group experiment, by controlling one variable unchanged and changing another variable; a comparative analysis study is carried out; and comparisons are made between groups. The changes in the cement-related properties after mixing various materials are studied, and the changes in the microanalysis of the cement are observed. By analyzing the crystal structure and chemical composition of concrete, the principles and laws of concrete performance affected by different components are summarized. The novelty of this experiment lies in the addition of new research content and research methods, while verifying the existing experimental results.

2. Methods for the Performance of Rigid Waterproof Concrete

2.1. Concrete Waterproofing Agent. Among the many chemical admixtures, there is a concrete waterproofing agent that can fill the capillary channels inside the concrete. And it has the ability to reduce the material's ability to attract water and the ability of water to penetrate concrete under hydrostatic pressure [10, 11]. Waterproofing agent can significantly improve the ability of concrete to repel water, so as to achieve the purpose of improving the durability of concrete [12].

Water-repellent active materials have a waterproof effect, reduce plasticity and surface tension, and reduce harmful holes that concrete can easily allow water to penetrate [13]. In the presence of colloids or other ingredients, use waterproof media to block and fill the pores, and the cement concrete will remain in the pores after hardening. Because the road blocking the pores is blocked, the way for water to penetrate into the concrete is reduced, so as to achieve the purpose of waterproofing [14]. Cutting the pores promotes the airflow in the waterproofing medium to be evenly distributed in the concrete, generating closed small bubbles, blocking the capillary channels, and increasing the density of the concrete. This makes the concrete from hydrophilic to hydrophobic [15]. There are active hydrophobic ingredients in the watertight area. After adding concrete, a hydrophobic layer can be formed on the capillary wall. This weakens the capillary adsorption and reduces the water absorption rate of concrete. This hydrophobic effect can effectively prevent water vapor and nonpressurized water from entering the concrete. From the research results of hydration products, after adding waterproof materials, almost no new hydration products are formed, and some new products formed by water-resistant active substances that may be colloids are formed [16].

The functions of concrete waterproofing agent include effectively enhancing the waterproof function and antiseepage function of concrete. Incorporating a watertight medium into the concrete promotes changes in the pore structure of the concrete and releases gel at the same time. The gel fills the internal pores of concrete, and the density is 6-9 times that of unimpregnated concrete [17]. It significantly improved the performance of mortar and reduced bleeding rate. It can replace limestone to a certain extent, overcome hollowing and scaling, reduce soil ash, save work, and improve efficiency; it can delay the heat release rate of cement and effectively prevent the fracture of concrete; it is also possible to store cement while maintaining the same strength and decline as the reference concrete [18–19].

The use of waterproofing agent has certain functions of water reduction, plasticization, and surface tension reduction, which can reduce the harmful pores in the concrete that easily seep water and at the same time make the concrete uniform and dense, thereby improving the ability of concrete to resist pressure water.

In the waterproofing agent, there are components that form colloid or other blocking and filling capillary pores. After the cement concrete hardens, it stays in the capillary pores, cuts off the capillary pores, and makes it difficult for water to enter, so as to achieve the purpose of waterproofing.

The air-entraining component in the waterproof profile produces some small and uniform closed air bubbles in the concrete, which blocks the capillary passage and improves the impermeability of the concrete.

Make concrete from hydrophilic to hydrophobic. There are active hydrophobic components in the waterproof profile. After adding concrete, a hydrophobic layer can be formed on the wall of the capillary, which weakens the adsorption of the capillary, thereby reducing the water absorption of the concrete. This hydrophobic effect is effective in preventing water vapor and unpressurized water from entering the concrete but has little effect on preventing the penetration of pressurized water.

2.2. The Impact of Nanomaterials on Concrete. Because of the special properties of nanomaterials, the mixing of nanomaterials into concrete will change some of the properties of the concrete. The specific performance is in the following important aspects:

(1) Cement stone is mainly composed of three parts: cement that has not reacted with water, the reaction product after the reaction between cement and water, and pores. Pores are the spaces that can be filled by the other two parts in the cement stone [20]. The strength of cement stone is inversely proportional to the number of pores and directly proportional to the density of cement stone. Adding nanomaterials to concrete can fill the remaining pores in the cement, making the overall structure of the concrete denser and stronger [21]

(2) Nanomaterials have the characteristics of small size, large surface, and high chemical activity. The addition of nanomaterials to the cement matrix not only directly involves the hydration process of the cement but also promotes the hydration process of the cement through the secondary hydration reaction with the hydration product. Especially, it improves the strength of concrete [22, 23]

(3) Nanomaterials accelerate the hydration reaction of cement and act as a catalyst, and the faster hydration of cement is beneficial to increase the initial strength of concrete. There are many chemical bonds on the surface of nanomaterials, and these chemical bonds are also very active, so there is no need to form a stable C-S-H phase during the hydration process [24]. The C-S-H phase is formed directly on the surface of the nanomaterial, and the loose hydrated cinnamic acid gel is transformed into a lattice structure centered on the nanoparticle. Thus, a general, uniform, and dense secondary interface can be formed in a good state [25, 26]

(4) Nanomaterials can significantly reduce the dense distribution and directional arrangement of calcium hydroxide at the interface between concrete cement

slurry and aggregate, which helps to improve the comprehensive performance of the interface, thereby improving the strength and durability of cement-based materials

Due to its special physical and chemical characteristics, nanomaterials have the following important roles in concrete: cement stone is composed of unhydrated cement particles, hydration products, and capillary pores. Capillary pores are the spaces in the cement stone that are not filled by cement particles and hydration products. The fewer the capillary pores, the denser the cement stone and the higher the strength. Nanomaterials can fill the capillary pores inside cement-based materials, making the internal structure of concrete more compact. Cement particles are equivalent to coarse aggregates, and nanomaterials play a good role in filling, which can reduce the total porosity in cement-based materials, effectively refine pores, and reduce critical pore size, thereby improving the compactness and durability of cement-based materials.. Nanomaterials are smaller in size, are larger in surface energy, and have great chemical activity. The addition of nanomaterials to cement-based materials can not only directly participate in the cement hydration process but also promote the process of cement hydration through secondary hydration reactions with hydration products, thereby improving the strength of concrete, especially cement-based materials' early strength.

2.3. Concrete Performance. Concrete has the following basic properties:

(1) Impermeability: the ability and performance of concrete materials to resist pressure penetration by water and oil not only reflect the ability of concrete to resist water flow. It also affects concrete performance, carbonization, and chloride ion penetration [27]

(2) Frost resistance: under the conditions of water adsorption and continuous low temperature, the concrete material has experienced multifrozen soil cycle, retaining its original properties or not significantly reducing the original properties

(3) Corrosion resistance: the ability to resist the corrosive and destructive effects of the surrounding environment is called corrosion resistance

(4) Fluidity: the concrete mixture flows under its own weight or mechanical vibration, and the mechanical vibration can flow evenly and densely on the formwork. It reflects the dilution consistency of the concrete mixture and the ability to fill the form [28]

(5) Compressive strength: when concrete is subjected to continuous and slowly increasing external pressure, the limit of pressure that the concrete can withstand per unit area at the critical point of destruction

From the research results of hydration products, few new hydration products formed crystals after the incorporation

of water repellent. The new products formed by some water repellents are likely to be colloids.

3. Experiments on the Performance of Rigid Waterproof Concrete

3.1. Preparation before the Experiment. Some raw materials that need to be prepared before starting the experiment:

(1) Cement. Use the data in Table 1 as a technical standard to ensure that the cement used in the experiment meets the standard

(2) Water repellent. For example, Table 2 is used as the performance standard of waterproofing agent, and the materials used in the study are all waterproofing agents with a cement content of 2%

(3) Nanomaterials. For example, Table 3 is used as the technical standard for nanomaterials

Trial mixing is carried out in the laboratory, and the mixed ingredients, proportions, and test mixing are obtained, such as the concrete materials shown in Table 4.

In order to better mix the concrete, the mixing process shown in Figure 1 is used in the lubrication process: first, wet the mixing drum of the concrete mixer, pour all the coarse aggregates during the mixing process, then pour the half sand, and then pour the cement (according to the test requirements, add different amounts of anticorrosion and hydrophobic substances). After the mixing is completed, reduce the amount of water and water pouring, and mix horizontally. Turn off the machine after the mixing is complete. If you find that the fluidity of the concrete is obviously low, add an appropriate amount of water-reducing agent and mix horizontally until the flow rate meets the requirements. Then, determine the amount of water-reducing agent, quickly load the mixed concrete into the test shell, and swing it firmly.

3.2. Experimental Process

3.2.1. Liquidity Test Experiment. To quantitatively analyze the fluidity of concrete, it is necessary to use the index of slump. According to the "Standard for Test Methods of Performance of Ordinary Concrete Mixtures," the experimental procedures and precautions for concrete test experiments are formulated. Before the test, take a clean water source and use a brush to moisten the inner wall of the slump cylinder and the tamping rod, and put a funnel of appropriate size on the top of the cylinder. Put it on the iron plate, step on the pedal with your feet, and slowly adjust and fix it. The mixed concrete is taken out and divided equally into three parts, and the three layers of space in the cylinder are filled with concrete, respectively. The height of each layer is set to 1/3 of the cylinder height, and the plug is inserted about

25 times in each layer. The stopper is injected into a spiral shape from the outside, and each penetration detection point is distributed as evenly as possible on the surface. Especially when printing the bottom, the tip of the knife must pene-trate the entire depth. When lightly impacting the second layer and the previous layer, the tip of the knife must penetrate the surface of the next layer. When inserting and punching the upper layer, make sure that the concrete of the upper layer is poured and lift it higher or with the top layer of the caving drum. After completion of cementing, the concrete is wiped with a knife. After removing the concrete on the floor by the side of the drum, the foldable pipe rises vertically and firmly. At this time, check the difference between the upper body point and the height of the cylinder, which is the slump.

3.2.2. Compressive Strength Test. When determining the compressive strength of concrete, strictly refer to the "Standard for Test Methods for Mechanical Properties of Ordinary Concrete." The main equipment includes the pressure tester, ruler, and brush as shown in Figure 2.

The specific steps of the experiment are as follows:

(1) Dry the test piece taken out from the curing site and the water on the upper and lower bearing plates, and start the experiment immediately

(2) The sample should be placed under the pressure plate or backing plate of the testing machine. If a sample is formed, the upper surface should be perpendicular to the storage area of the sample. The center of the sample should correspond to the center of the pressure plate under the testing machine. In the test mode or worksheet, adjust the ball position and adjust the contact balance

(3) When the specimen begins to deform, pay attention to it. When the specimen deforms sharply and reaches the critical point of being destroyed, stop adjusting the throttle, and record the load value when the specimen is broken

(4) Use the following formula to calculate the compressive strength of the test piece:

$$X_{CC} = \frac{M}{N}, \tag{1}$$

where X_{CC} is the compressive strength of test piece (MPa), M the destroy load of specimen (N), and N the pressure-bearing area of the test piece (mm^2).

3.2.3. Water Penetration Test. Based on the Standard for Test Methods of Long-term Performance and Durability of Ordinary Concrete, the water penetration test is carried out after preparing the materials required for the experiment. To quantify the water penetration resistance of concrete, the water penetration resistance of concrete is expressed by measuring the average water penetration height under constant water pressure. The water penetration testing machine used is shown in Figure 3.

The specific method of the test is as follows:

TABLE 4: Composition and proportion of each sample of concrete.

Group	Composition and proportion of admixture
P1	Ordinary concrete
P2	Ordinary concrete + 2%waterproof agent
P3	Ordinary concrete + 2%waterproof agent + 1%nanosilica
P4	Ordinary concrete + 2%waterproof agent + 1.5%nanosilica
P5	Ordinary concrete + 2%waterproof agent + 2%nanosilica
P6	Ordinary concrete + 2%waterproof agent + 1%nanosilica + 0.01%PowderA
P7	Ordinary concrete + 1.5%nanosilica + 0.01%PowderA
FIGURE 1: Schematic diagram of concrete pulling and mixing sequence.

FIGURE 2: Pressure testing machine.

(1) Take out the test piece one day before the curing time of the test piece is reached, and wipe it with a clean damp cloth. Air-dry the test piece or use other methods to dry it, and seal it after the surface of the test piece is completely dry

(2) Coat the side of the sample with a layer of molten paraffin containing a small amount of resin, and then, preheat the sample with a spiral pressure heating furnace or an electric furnace. In order to fix the sample on the bottom of the test model, release the pressure after the test model is completely cooled, and touch the test model with paraffin on the side of the test piece. When the paraffin slowly melts but does not flow, it indicates that the preheating temperature of the test model has reached the standard

(3) When the test piece meets the test standard, start the water penetration tester. Open the valve at the test position to make all the water seeping from the hole flow into the test pit. After the test pit is filled with water, close the gate and install the sealed test piece on the impermeability instrument

(4) After the test piece is installed, immediately open the valve under the test position to constantly control the water pressure in each time period, and control the pressurization time to no more than five minutes. When a stable pressure is reached, record this time as the start time of the experiment. Before the pressure reaches a stable level, always pay attention to the penetration of water on the end surface of the test piece. When water immersion occurs on the end face of the test block, the test block stops the test, the time is recorded as the end of the experiment, and the height of the test block is taken as the water penetration height of the test block. If the end surface of the test piece is not immersed in water, the test is terminated after the test is completed, and the test piece is taken out. During the test, when water is found to seep out from around the test piece, it must be sealed again

(5) Place the test piece taken out of the impermeable meter on the pressure plate. Diameter steel buffer sheets are arranged in the center of the upper and lower end surfaces of the test piece in the diameter direction, and check whether they are in the same vertical plane. Then, start pressing and divide the specimen into two halves along the longitudinal area. After dividing the test block, use the waterproof mark to trace the watermark

(6) The trapezoid plate is placed on the dividing surface of the test piece, and the water inlet height of each measuring point is measured at equal intervals along the water bottle with a steel ruler for accurate reading. When reading, if the measurement point is blocked with aggregate, the water penetration height near the two ends of the aggregate is measured and the average value is taken. The average value can be

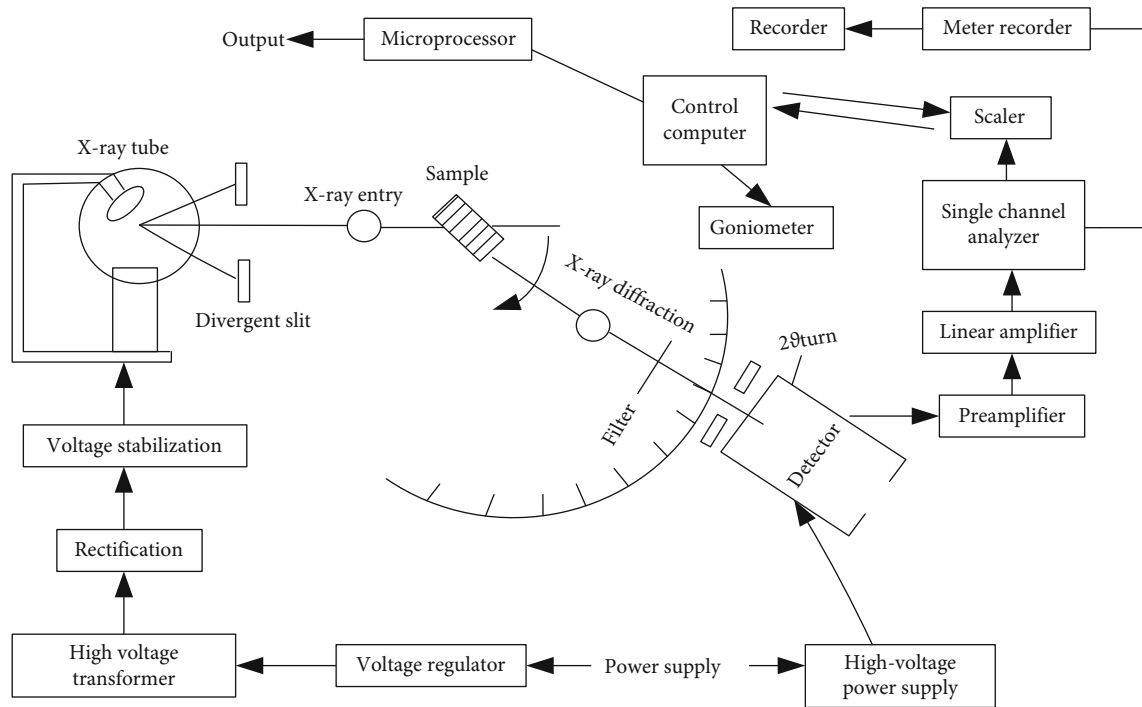
Figure 3: Water penetration resistance testing machine.


Figure 4: Block diagram of diffractometer composition.

used as the water immersion height of the measurement point

3.2.4. Phase Analysis-X-Ray Diffraction Analysis.

XRD is the abbreviation of X-ray diffraction. The material is diffracted by light to cause the transformation of atoms in the atomic layer and obtain a diffraction pattern. X-rays are a type of short-wavelength electromagnetic waves that can penetrate quite thick objects. Light crystals formed by electron transfer in the inner layer of X-ray molecules under the irradiation of high-speed moving electrons can act as photons. The coherent scattering formed by multiple atoms or ionic molecules causes an impact on the light, which in turn affects the intensity of the scattered rays. The maximum intensity of light formed by the overlapping of divergent waves from several molecules is called diffracted light of light. It can be obtained by the following formula:

$$2M \sin \theta = \alpha, \tag{2}$$

where M is the plane distance and α is the wavelength.

The measurement angle is based on rays of known wavelengths, and then, the crystal plane distance is calculated, which is mainly used for X-ray structure analysis. Another way to determine the angle is to use a known metal crystal to calculate the wavelength of the characteristic X-ray. The calculated characteristic X-ray wavelength can also be used to find the elements contained in the sample from existing data. Figure 4 is a block diagram of the diffractometer.

Prepare the test sample: after testing the compressive strength, take a specific test block, dismantle it, and put it in absolute ethanol to stop the final water. Before the test, use the mortar to mash the powder. After passing through the 80 square-hole sieve, it is double-sealed with a sealed bag and stored for later use.

3.2.5. Pore Structure Analysis.

In this test, a pressure system test is used to test the hole structure. The pump will not penetrate most pressure materials. The pump can be forced into the pores of the porous solid under the action of only external force. Generally speaking, the pressurized pressure is
FIGURE 5: Comparison diagram of compressive strength and concrete compressive strength.
FIGURE 6: Comparison diagram of water penetration height of each sample.

equal to the surface tension of the capillary orifice pump. The relationship between hole radius and external pressure is as follows:

$$M = -\frac{2m \cos \alpha}{N}, \tag{3}$$

where M is the capillary pore radius, N is the pressure applied to the pump, α is the wetting angle of the pump to the solid, and m is the surface tension of the pump.

4. Experimental Analysis of Waterproof Concrete Performance

4.1. Concrete Fluidity. In this test, different amounts of water-reducing agent are added to control the slump to

remain basically the same. During the mixing process, it can be clearly observed that after adding nanometers, the fluidity of the concrete is obviously affected, and the content of the required water-reducing agent increases. Finally, the slump of each test group is basically maintained at between, which meets the specification requirements.

4.2. Compressive Strength of Concrete. The compressive strength of each sample concrete is shown in Figure 5.

Through the analysis of the above data, it can be seen that the mixing of water-repellent agent seriously affects the early strength of concrete. This is because the fluidity of concrete is improved by the addition of organic water-repellent agent and has a retarding effect. The incorporation of nanomaterials solves the problem of low strength in the early stage, and the compressive strength in the later stage is also greater than that of the benchmark group. The incorporation of PowderA has an effect on the strength of concrete, and the early decrease is obvious. This is also because PowderA is an organic material, which is not good for the early strength.

In the compressive strength test, the 3 d strength of the P7 group concrete after adding KIM waterproofing agent decreased by 14.81%, and by 28 d, it only decreased by 3.94% with the P1 group. The strength of P3, P4, and P5 added with nanosilica increases significantly, especially the 3 d strength which increases by about 30%. However, the strength of the specimens doped with different amounts of nanosilica differed by less than 3%. Because nanosilica fills and refines a large number of pores in the concrete, it makes the apparent structure of the concrete denser, thereby

TABLE 5: Comparison of concrete impermeability test results.

Group	P2	P3	P4	P5	P6	P7
Reduction rate of each group relative to P1 group	71.6%	75.1%	76.9%	76.9%	74.4%	76.1%

TABLE 6: Peak value of main substances.

Sample	Crystal plane/crystal								
	(001)/CH			(101)/CH			C_3S		
	3 d	7 d	28 d	3 d	7 d	28 d	3 d	7 d	28 d

P2	988	978	1140	756	886	869	460	328	571
P3	1116	1150	640	700	717	645	480	339	307
P4	804	546	993	714	652	650	521	541	416
P5	753	822	862	677	708	578	578	348	340
P6	474	427	967	606	682	620	377	302	453
P7	586	604	736	649	653	749	541	374	683

promoting the development of concrete strength. The specimens with PowderA have lower early strength, reaching the level of P1 group by 28 d.

The incorporation of nanosilica will cause the loss of concrete slump. With the increase of nanosilica content, the slump drops sharply, and the fluidity of the concrete mixture will gradually decrease. In order to make up for the slump loss, the required water-reducing agent content increases. The specific surface area of nanomaterials is very large. Although their incorporation reduces part of the filling water, it greatly increases the surface adsorption water, which greatly increases the water consumption of standard cement consistency.

4.3. Concrete Anti-Water Penetration Test. The water penetration test was carried out after 28 days of curing of the specimen. The test result is shown in Figure 6.

By calculating the reduction rate of the permeable height in each group of samples relative to the P1 group, the effects of various composite waterproofing agents on the water permeation resistance of concrete were analyzed. The results are shown in Table 5.

From the above test data analysis, it can be seen that after adding KIM waterproofing agent, the ability of concrete to resist water penetration is greatly improved. On this basis, the density of concrete added with nanosilica is improved, and the water penetration resistance is further strengthened. In PowderA, a small amount of air will be introduced, so the impermeability of concrete will be slightly reduced. The combination of nanosilica and KIM waterproofing agent and the combination of nanosilica and PowderA have roughly the same waterproof penetration effect, but the combined effect of the three has a certain degree of impermeability.

4.4. X-Ray Diffraction Analysis. By analyzing the results of X-ray diffraction, it can be seen that the XRD diffraction spectra of each group are basically the same. Among them, 29.4° is selected, and 18.1° and 39.4° are selected as the characteristic peaks of calcium hydroxide. By comparing the

characteristic peaks, a semiquantitative method is used to determine the amount of the corresponding substance. The main substance peaks obtained by ray diffraction analysis are shown in Table 6.

First, analyze the content of C_3S, which can be seen from Table 6:

(1) Compare the P7 group with the P1 group; the content of C_3S in the sample was similar at 3 d; the content of P1 group was more than that of P7 at 7 d, and the content of the P7 group was more than that of the P1 group at 28 d

(2) Compare the P3, P4, and P5 groups; the content of c in the samples showed a decreasing trend at 3 d, 7 d, and 28 d, and the cement hydration continued to be uniform

(3) Compare the P6 group with the P4 group; the P6 group showed fluctuations similar to that of the P7 group. The content increased significantly at 28 d, even exceeding the content at 3 d, and it was quite low at 7 d

5. Conclusion

The effect of nanomodified waterproofing agent on the performance of underground rigid waterproof concrete was studied by designing the impermeability durability test of concrete with different proportions. Comparing with the case of adding the waterproofing agent only, the early strength of concrete was significantly improved by adding nanomodified waterproofing agent. The concrete modified by nano-SiO_2 showed good improvement in water resistance, seepage resistance, and chloride ion penetration resistance, nearly double the water resistance and seepage resistance of ordinary concrete; in addition, the chloride ion penetration resistance was better than that of single water repellent. There are still many deficiencies in this paper, such as the lack of analysis of the reasons for the influence of nanomodified materials on concrete and the incomplete perspective on the influence of nanomodified materials on concrete. Nanomaterials are the new materials of the century. They exhibit unique properties in physics, chemistry, structure, etc., which lead to their research and applications in various fields. In the field of construction engineering, researchers add nanomaterials to traditional building materials to improve the performance of traditional building materials and give new application value. More comprehensive research should be done on the specific influence and mechanism of nanomaterials on concrete properties, and all research results should be combined to classify the types of nanomaterials and the influence of nanomaterial dosage on concrete and formulate

corresponding standards, so as to provide a theoretical basis for the target concrete to select the corresponding nanomaterials and dosage according to the required performance index.

During sports, athletes' incorrect technical movements and direct physical confrontation can easily cause ankle injuries. Joint ligament injury is a common injury in sports. A ligament injury is an injury to the ligaments in a part of the body caused by varying degrees of injury. Clinical manifestations include localized swelling, pressure pain or joint instability, and pain that increases when pulled in the direction of violence. In order to further investigate the rehabilitation methods of nanomaterials for repairing the ankle Achilles tendon ligament injury in athletes, nanomaterials are materials in which at least one dimension in three-dimensional space is at the nanometer size (1-100 nm) or consists of them as the basic unit, which is approximately equivalent to the scale of 10 to 1000 atoms closely aligned together. In this paper, we found that the healing rate of patients was over 90% by the dynamic balance system combined with surface electromyography, surgical treatment, and extracorporeal shock wave. It can be seen that the dynamic balance system combined with surface electromyography (SEMG), surgical treatment, rehabilitation therapy of Taijiquan exercise, and extracorporeal shock wave therapy have significant effects on the rehabilitation of athletes' ankle and Achilles tendon ligament injuries and can effectively alleviate and resolve athletes' ankle Achilles tendon ligament injury.

1. Introduction

With the vigorous development of sports in China, people are more interested in participating in physical exercise. Not only professional athletes but also people who participate in physical exercise will inevitably suffer from ankle injury. Ankle sprain is a relatively common injury in sports, and injuries cause great pain to athletes. The saddle joint of the talus is wide in front and narrow in back, with the wider part entering the ankle point in dorsal extension and the narrower part entering the ankle point in plantarflexion. The anatomical and physiological characteristics of the ankle joint make it more prone to inversion and valgus sprains during plantarflexion. The ankle joint is composed of the articular surface of the lower end of the tibia and fibula and the talar pulley, so it is also called the talar calf joint. It is one of the important joints of the human body. It mainly depends on the ankle joint extension and plantar flexion.

The instability caused by ankle sprain is divided into lateral instability and medial instability. Clinical manifesta- tions of ankle sprains include pain and swelling at the site of the sprain immediately after the injury, followed by skin bruising and, in severe cases, immobility of the affected foot due to pain and swelling. The incidence of lateral instability combined with articular cartilage injury is 55%. It is mainly talar cartilage injury, most of which are located on the medial talar articular surface. The rate also increased signif- icantly, with a median instability associated with cartilage damage of 98%. Lateral collateral ligament injuries are common in the exercise population, and a comprehensive rehabilitation plan is a crucial outcome. Most literature on nonsurgical and postoperative rehabilitation includes observation reports and case studies, and primary studies comparing rehabilitation programs have not been published. The goal of an injured athlete is not only to return to the game without functional restrictions but also to address risk factors and prevent future injuries [1, 2].

Kyo Chul and others believe that nearly a century ago, a serious ankle sprain was considered to be an ankle ligament injury. With the advancement of imaging and surgical

techniques and the development of tools, the treatment of ankle sprains (including subtalar injuries) has greatly improved. The ankle ligament repair or reconstruction has been improved anatomically and has less trauma than before. Here, the term "'reconstruction" refers to nonanatomic reconstruction, which is a replacement reconstruction with a short fibular tendon, such as the Evans procedure, which significantly alters the biomechanical mechanisms of the ankle and subtalar joint under weight bearing. Rather, tendon transplantation to reconstruct ligaments has become the standard for treating severely injured ligaments, but it does not reproduce the original ultrastructure of the ankle ligaments [3]. The anatomical structure of the ligament includes a ligament with a distal end at both ends, and the structure should also have proprioceptive functions. To date, it is still impossible to reconstruct a fully functional anatomical ligament. The cooperation between regenerative medicine and surgical technology is expected to improve the reconstruction of ankle ligaments. However, we need more time to develop a technology to reconstruct the ideal ligament complex. Lee and Hogan believe that ligament sprain refers to the tearing of fibrous tissue in the ligament and is the main cause of foot and ankle complex injuries during field sports; external rotation of the foot is considered to be the main injury mechanism with ankle sprains. There are specific types of ligament damage; however, the effect of the magnitude and direction of the load vector on the in situ stress state of the ankle ligament has not been quantified in the literature. Finding the maximum injury tolerance of a human foot with an acceptable single ligament subfracture distribution, using a previously developed and fully validated foot and ankle joint model to reproduce a series of joint foot rotations experienced during high-risk athletic activities.

In view of the susceptibility of sprained ankle joints, on the basis of traditional treatment, special attention should be paid to prevention and rehabilitation during rehabilitation. This article analyzes and summarizes the causes, diagnostic methods, treatment measures, and prevention methods of athletes' ankle joint injuries, with a view to helping athletes train scientifically and actively cooperate with medical staff to effectively avoid and reduce the occurrence of ankle joint injuries and its adverse effects. Repairing ankle ligament injuries can relieve the patient's pain and for the athlete can lead to timely training and good performance.

2. Proposed Method

2.1. Reasons for Ankle Injury. Ankle sprains usually occur when our body loses its center of gravity, causing damage to the soft tissues on the outside or inside of the foot, such as ligaments and joint capsules, during sports such as walking or running and jumping.

(1) More common in sports related to jumping

Sports events such as figure skating, alpine skiing, freestyle skiing, and basketball and gymnastics often require athletes to make jumping movements, and as the difficulty of the movement continues to increase, athletes engaged in these events have the possibility of ankle injury much higher than other athletes. The function of the ankle joint is mainly completed within a range of 70°-140° extension and flexion. When the ankle joint has excessive valgus and external rotation, varus and internal rotation, or the talus backwards, it violently impacts forward. When the tibial articular surface, the ankle joint is easily damaged, most of which are strains of the medial and lateral ligaments of the ankle joint [4]. The ankle joint is often subjected to excessive amplitude movements, so that the ankle points do not match the talar articular surface, which will cause ankle joint misalignment, which mainly refers to the medial and lateral or anterior and posterior displacement of the talus. Of these, the talar outward and forward are more common. When the ankle joint is sprained, the muscle ligaments are weak, and the joints are loose and unstable. During the activity, the lower end of the tibia and the inner and outer sides of the talus impact each other on the joints, which can also damage soft eyes, affect joint activities, and hinder normal activities.

(2) Insufficient preparation activities

The mechanism of ankle joint injury caused by insufficient preparation activities. In general sports, before doing exercises or competitions, do some activities that make the body heat and nervous system such as running and jumping, and then do some stretching of the limbs and joints. For amplitude activities, these activities can adjust the body parts to a state suitable for high-intensity exercise as soon as possible before normal sports training or competition. If the previous preparation activities are insufficient, the nervous system, the blood circulation system, and related muscle tissues are not fully mobilized, and the body lacks the necessary coordination, flexibility, and stretchability, and the ankle joint muscle ligament stretch may not be sufficient. Improved, the excitability of the nervous system is relatively low, the antagonist muscles cannot be fully relaxed in a timely manner, coupled with rushing into these exercises or competitions, sudden jump movements or landing instability; it is easy to cause ankle injury [5]. During training or competition breaks, sometimes due to venue, number of people, or other factors, the interval between two activities is longer, and athletes often ignore the proper preparation activities before entering the next exercise. The stretchability of the muscle has been reduced to a certain degree, but the physical strength has been restored to a certain degree. In the second exercise, the range and strength of the movement are relatively large and the speed is relatively fast. This has hidden the sprains of the ligaments of the joints or muscle tension. There is a high possibility of injury. In addition, a considerable part of the athletes only focused on improving the extensibility of large muscle groups and the amplitude of large joints in the preparation activities, while neglecting to improve the functional conditions of other small joints (such as the ankle joint) [6].

(3) Other factors

There are also other factors, such as training with injuries, excessive local load, paralysis of the mind, wrong technical movements, poor venues, excessive excitement, and

lack of protection, which can also cause ankle injuries. For example, the investigation center for the most common injuries in alpine skiing found that ankle ligament injuries were more caused by incorrect technical movements of athletes [7–9]. During training, if the venue is not good, it is easy to make the action fail. Poor weather conditions can also lead to injury accidents. In the summer, the temperature is too high, the athletes have difficulty concentrating, and their physiological adaptability is poor, which is prone to accidental injuries. In the cold winter, the muscles are stiff, the coordination of movements is not good, and it is easy to cause damage to the ankle muscle ligaments.

2.2. Rehabilitation Treatment of Ankle Achilles Tendon Ligament Injury. Rehabilitation gymnastics is a specially choreographed unarmed, or with the help of equipment, limb movement, and functional exercise gymnastics to enable the sick and injured to achieve the purpose of prevention, treatment, and rehabilitation.

(1) Rehabilitation gymnastic therapy

Action 1: take a sitting position and land on the edge of the calcaneus. Use the toe of the affected ankle to write 1 English letter at a time, and write 26 English letters once. Action 2: "Car windshield wiper" training. Take the seat with your feet flat on the ground, with your toes facing forward, and rotate the affected ankle to simulate the movement of the car's windshield wiper. Come out to touch the ground. Action 3: take a seated position to train the lower leg. In the sitting position, the ankle-limb limb is used for hoisting training. It is required to raise the calf as high as possible, and at the same time, keep the toes away from the ground. Then, put the heel back to its original position [10]. Action 4: stand on one leg (partially load-bearing). When standing, place one hand on the table, transfer part of the body weight to the side of the affected ankle, and hold it for 15 s. Increase the time for 15 s each time until you can use the ankle support for 45 s. Then, gradually increase the amount of body mass that can be supported until it can support all of its own body mass. Action five: training of varus and eversion of the affected ankle. Inversion training uses the outside of the affected ankle to rest on a fixed object, such as the edge of a table leg or door frame. Use the ankle to apply force for 2 s. Eversion training is to use the inside of the ankle's foot against a fixed object to push it inward for 3 seconds. Action six: use the training belt to train the ankle inside and out. Take a seated position, straighten your knees, use a training strap to fix one end to a heavy object (such as a table foot), and wrap one end around the inside of the ankle or the outside of the small toe. The ankle varus training is to rotate the foot away from the table foot with the foot, and then return to the initial position, count one training, be careful not to perform calf movements, external rotation training is to train the belt around the outside foot of the toe to turn out actions. Action seven: stand on one leg to support the whole, lifting training. Take the ankle-footed standing position, flex the knee on the healthy side, keep your feet away from the ground, and maintain a full body support for about 30s. Action eight: use a large towel to fold into a rectangle, the size is consistent with the size of the patient's feet. At the beginning of training, use both hands to support the support to ensure safety, gradually squat, and then stand up. With the progress of rehabilitation, gradually give up the help of supports, use their own muscle and nervous system to adjust the balance, and perform squat training. At a higher stage, the affected foot stands alone on the towel, and the rehabilitation teacher throws it to his body. Ball (you can change the direction and quality of the ball to increase the difficulty of training). For those athletes who are engaged in sports, conditions can be used for spa treatments, stepping, jumping, or kicking in various directions in waist-deep water [11].

(2) Traditional Chinese medicine therapy

(1) Mild ligament damage

Immediately after the injury, apply cold compresses to reduce the formation of hematomas. Local swelling can obviously be infused with cold water or externally applied with ice cubes. Replace once every 3 minutes for 30 minutes to constrict blood vessels and relieve local congestion. After 24 hours of sprain, switch to hot compress therapy, soak the towel with warm water or hot vinegar, hot wine, etc., and put it on the wound for 30 minutes. It can improve blood and lymph fluid circulation 1-2 times a day, which is conducive to blood stasis on the wound. And exudative absorption, in addition to self-reinforcing muscles and tendons, first slowly pull out and stretch the ankle joint, after a short time to do varus and eversion movements, do not use local manual rubbing in the early stage of injury, you can use Chinese medicine external application The rice dumplings are crushed into fine powder and mixed with frankincense into milk powder, which is adjusted to a paste with wine or egg white and applied to the wound, and the dressing is changed once a day [12].

(2) Severe ligament injury

Closed sticky plaster fixation method: the local drug is closed with a 2% lidocaine needle 1.5 ml and prednisolone acetate 0.5 ml. The ankle joint is placed in a mild valgus position with viscous fixation. If there is damage to the anterior fibula ligament and then slightly extended, the viscous paste passes from the inside of the foot through the plantar and lateral malleolus to the mid-anterolateral midsection of the calf. -4 strips, then use bandages to strengthen the fixation, usually 3 weeks can be fixed. Can be used 2% procaine 2 ml, plus acetic acid and acetaminophen 2 ml, for pain point closure, once a week, 3 times a course of treatment. Massage and acupuncture combined with fixed methods: acupuncture points such as Fengshi, Zusanli, Taixi, Kunlun, Qiuxu, Jueju, Jiexi, Taichong, and Ashi can be selected. Acupuncture (retaining needle for 15-30 min), once a day, to clear the qi of the meridians [13]. Restriction of ankle motion can be fixed with adhesive tape (rubber plaster) or bandages for 1-2 weeks. Those with medial collateral ligament injury should be inverted and fixed, those with lateral collateral ligament injury should be inverted and fixed to reduce the

tension of the injured ligament and accelerate the injury of the ligament. Repair. If the lateral collateral ligament of the ankle is damaged, take 3 pieces of 2.5-3 cm wide tape to valgus the affected foot. The first piece of tape starts from the inside of the foot and passes through the front of the lateral malleolus to the front of the calf and then behind the tape. Adhere the second and third tapes in parallel, and then apply bandages outside. It can also be treated with proprietary Chinese medicines. Sanqi injury pills, betta pills, Yunnan Baiyao, Qilisan, and conventional administration are used. It usually recovers in about 15 days [14].

(3) Tai Chi exercise

Patients are organized to participate in the study and exercise of prescribed Taijiquan movements. During exercise, attention is required to focus on activities that hurt the ankle. In the early treatment stage, surgical therapy is the main part, and some rehabilitation exercises are performed at the same time as surgical therapy. The focus of rehabilitation treatment during this stage is to prevent symptoms such as ankle instability or recurrent dislocation. After 3 weeks, patients with ankle ligament injuries were trained in Taijiquan, ranging from small to large. When the ankle was active, the two strengths penetrated each other, embracing each other, and running in parallel. During this period of training, it is required to increase the body's center of gravity. The body's center of gravity projection should be as close to or around the injured ankle as possible to prevent the injury from getting worse. It is not required to do the complete movement of Taijiquan. After 5-6 weeks, with the gradual recovery of the ankle injury, the body's center of gravity should gradually decrease when performing Taijiquan exercises, so that the distance of muscle work will increase accordingly. When playing Taijiquan, there is no need to focus on mental concentration. Under the control of consciousness, the mind of the practitioner always focuses on the injured ankle and the whole set of movements, eliminates the interference of other thoughts, and focuses on directing the functions of all organ systems throughout the body to cooperate with the injured ankle. Movement effectively prevents repeated ankle ligament injuries [15]. In the later stage of rehabilitation, in order to increase the left and right ankle ligament activity, perform "left cloud hand" or "right cloud hand" and other movements. Such movements can be moved laterally. Through training, the left and right ankle ligament activities can be guaranteed. In order to increase the full range of motion, "Left and Right Knee Staggers" is used. This move includes back and forth movements, left and right movements, outward abduction, inner buckle, lifting, and other movements to fully move the ankle ligaments; in order to make the ankle ligaments, the increase in the range of activity should be practiced in spiral-type arc movements, such as "left and right mustang split mane." The angle of body rotation is large, and the center of gravity gradually transitions to one foot. Because the center of gravity of the entire body moves smoothly, a certain height moves at a constant speed or constant speed, so that the ankle ligaments can be safely and fully exercised [11]. Regular exercise of this kind can not only promote the healing of ligaments

and shorten the recovery time but also enhance the flexibility and flexibility of the ankle ligaments.

(4) Extracorporeal shock wave therapy

Extracorporeal shock wave is a mechanical pulsed pressure wave transmitted through the medium of physics mechanism, which can produce good therapeutic effect on a wider range of human tissues where pain occurs through the positioning and movement of the treatment probe. Cavitation is the basis of ESW's effect on soft tissues. In the process, shock wave bubbles will be generated. Such bubbles will rapidly expand within a few microseconds and then burst after $100\,\mu$s, resulting in secondary, spherical shock waves, shearing. Tissue, release free radicals, target soft tissues that impinge on the lesion, resulting in axial damage, local bleeding, ecchymosis, hematoma, etc. When the energy of ESW is lower than $0.12\,$mJ/mm^2, the permeability of the cell membrane can be triggered, while when the energy of ESW is $0.5\,$mJ/mm^2, the changes of cytoplasm and mitochondria are mainly caused. Although the role of ESW in the treatment of soft tissue injuries is relatively clear, its mechanism of action is uncertain. Studies have found that ESW can promote the formation of new blood vessels, improve microcirculation, and promote the recovery of neural tissues by directly activating the healing process of soft tissues. Hausdorf et al. called the application of different ESW to the rabbit femoral end 10 days later and observed a decrease in local blood flow and bone metabolism. They believed that the process of ESW stimulation and promotion of tendon healing may be through local microfracture and damage to promote local growth factors and NO release to achieve tissue repair [12].

2.3. Nanomaterials. Nanomaterials are materials with nanoscale structures, which can be divided into zero-dimensional nanomaterials and one-dimensional nanomaterials according to their specific dimensions, and it has been asserted that when one can arrange and combine substances on very small dimensions, various materials of novelty will be obtained. The ratio of the number of surface atoms to the total number of atoms in a nanocrystal particle increases dramatically as the particle diameter becomes smaller. For example, at a particle diameter of 10 nm, the particle contains 4000 atoms and the surface atoms account for 40%; at a particle diameter of 1 nm, the particle contains 30 atoms and the surface atoms account for 99%. It was not until the end of the last century when the first International Conference on Nanoscience and Technology was held in the United States that theoretical research and contemporary science and technology were formally combined, which marked the official birth of nanotechnology. When the size of a material is at the nanometer level, the number of atoms on the surface of the material will increase dramatically, and this number will far exceed the number of ordinary materials, when the chemical activity of the material will be greatly increased. At the same time, nanomaterials are comparable to or smaller than the wavelength of light waves, the wavelength of de Broglie and the coherence length of superconducting

states, and the periodic boundaries of the materials are destroyed, resulting in "novel" optical, electrical, magnetic, acoustic, and thermodynamic properties; in addition, nanomaterials have quantum size effect and macroscopic quantum tunneling effect. These unique characteristics provide the conditions for the wide range of applications of nanomaterials. With the continuous in-depth development of theory and practice, nanostructures not called systems have been established at present. Along with the maturity of application, the uniqueness of nanomaterials plays a pivotal role in the field of biotechnology and advanced manufacturing.

3. Experiments

3.1. Dynamic Balance System Combined with Surface Electromyography (SEMG) Experimental Monitoring

(1) Wu, the research subject, suffered severe strain on the right ankle Achilles tendon, and developed strained periarthritis, which was manifested as local thickening, tenderness, and a feeling of induration. The right Achilles tendon still had a thickening of 5 cm in length. According to the degree of soft tissue damage, it was II degree, and some ligaments were lacerated. Zhang, the Achilles tendon side collateral ligament excessive pull, acute sprain, I degree injury, slight swelling, physical examination and early isokinetic strength test, neither of them suffered severe pain in the ankle, joint effusion and other phenomena. Wu's wound suture is located in the posterior midline incision. The tendon sheath has been separated and the degenerative tissue has been removed. The scar has a slight swelling. The pain arc is located at the fibula long and short muscle stops. Wu's pain point is located at the tibialis anterior muscle stop. The symptoms of the two patients were similar. Both suffered from weakness of the posterior ankle muscles, the range of motion of the joints and dorsiflexion was small, and there was a large difference in the muscle strength of the left and right ankle joints. Myasthenia gravis is mainly characterized by partial or generalized skeletal muscle weakness, easy fatigue, aggravation of symptoms after activity, and reduction of symptoms after rest and is generally serious, long-lasting, and difficult to treat

(2) Research method: the Biodexpro3 isokinetic force measurement system (according to the test standards specified by the Chinese Medical Association) was used to orient the heart slowly 60%/s X5 times, mainly to test the ankle joint dorsiflexor maximal muscle strength index; 180% fast/s X25 times, the main test of muscle endurance indicators, a total of 4 tests before and after rehabilitation treatment, and the comparative analysis of the measurement indicators. In the test, the two people stood with the affected leg in turn, flexed their knees about 90° on the healthy leg, and stood continuously for 30 seconds. According to the stability program set by

the system, they performed "8-1" levels in order from easy to difficult, with the soles of the feet as much as possible. It moves close to the center of the display screen and moves in the same part. It can perform various actions such as front collar back and back, inversion, and eversion as the platform rotates. Tested 2 times before and after treatment

3.2. Surgical Treatment Monitoring

(1) General information: 16 cases of ankle fractures with triangular ligament rupture were surgically treated, including 10 males and 6 females. X-ray examination of the ankle joint laterally and ankle points was performed routinely before operation. After the internal fixation of the lateral malleolus fracture is completed during the operation (if the posterior malleolus fracture needs to be fixed as well), if the ankle perspective shows that the ankle joint is in good position, the external rotation stress test of the ankle joint should also be performed, and those with negative tests do not need surgery. Triangular ligament. If it is positive, it needs to be explored to repair the triangular ligament. This group accounts for 14 cases; if the intraoperative perspective shows that the medial malleolus talar space has not recovered, it is considered that the insertion of the gap after the rupture of the triangular ligament results in poor reduction. Triangle ligament, this group accounted for 2 cases

(2) Surgical methods: after the ligament was exposed in 16 patients in this group, the fracture sites were as follows: 5 cases at the medial malleolus rupture, 6 cases at the middle rupture, and 5 cases at the talar rupture. The person who broke at the medial malleolus was screwed in two 2.8 mm absorbable anchors or metal anchors at the center of the malleolus for repair; the middle fracture was sutured directly with l-0 absorbable suture; screw in two 2.8 mm absorbable anchors or metal anchors at the dead center for repair. When knotting sutures, you should pay attention to shortening the length of the original ligament slightly. Observe under direct vision to maintain the appropriate medial space of the ankle joint. Do not overtighten the ligament to shorten too much and affect the later function recovery. For type AO type C fractures, the preoperative judgment may be associated with lower liver fat combined injury, and the lower liver fat combined should be fixed. In this group, 4 patients with type C fractures were still positive after the deep repair of the triangular ligament was completed. Therefore, the liver fat joint is fixed under the liver fat hook. Finally, the superficial layer of the fractured triangular ligament was sutured with 2-0 absorbable sutures, and the incision was closed layer by layer

3.3. Rehabilitation Monitoring of Taijiquan Exercise

(1) Research subjects: the research objects came from different groups such as teachers, students, and

workers in a university, and 76 patients with ankle ligament injuries were selected (average age: 30.47 ± 9.05 years). And randomly selected 41 cases (average age 31.42 ± 8.35 years old) as the experimental group, mainly Taijiquan exercise. The remaining 35 patients (mean age 29.35 ± 9.45 years) were used as the control group for routine rehabilitation training

(2) Research methods: the subjects were randomly divided into the control group and the experimental group and organized to participate in the study and exercise of the prescribed Taijiquan movements. During the exercise, the rehabilitants were required to focus on the activities of injured ankles. In the early treatment stage, both groups are mainly surgical treatment, and medical staff assists in some rehabilitation exercises at the same time of surgical treatment. At this stage, the focus of rehabilitation treatment is to prevent symptoms such as ankle instability or recurrent dislocation. After 3 weeks, 41 patients with ankle ligament injuries in the experimental group performed Taijiquan exercise, with a small amount of exercise. During the early training, the patient exercised under the guidance of an expert. With the help of Tai Chi during the ankle movement, the two strengths penetrated each other, embracing each other, and running in parallel. During this period of training, it is required to increase the body's center of gravity. The body's center of gravity projection should be as close to or around the injured ankle as possible to prevent the injury from getting worse. It is not required to do the complete movement of Taijiquan. During this period, the control group mainly carried out some conventional rehabilitation training, began to perform standing posture exercises, and then carried out partial weight-bearing exercises. After 5-6 weeks, with the gradual recovery of ankle injuries, the body's center of gravity during the Taijiquan exercise in the experimental group should gradually decrease, so that the distance of muscle work will increase accordingly, and the physiological pressure on the ankle ligaments will gradually increase. The control group began to carry weight-bearing walking training; and gradually extended the training time (maximum 45 minutes) and performed exercises such as running, jumping, and stepping up and down in the later stage of rehabilitation

3.4. Extracorporeal Shock Wave Therapy Monitoring

(1) Research subjects: 40 athletes with ankle ligament injuries were selected, including 22 males and 18 females; the course of disease was 3 months and 1 year. They were randomly divided into an external shock wave (ESW) treatment group of 25 cases (14 men and 11 women) and a closed control group of 15 cases (8 men and 7 women). Both groups were diagnosed by physical examination and ankle MRI before treatment. Inclusion criteria are as follows:

(1) aged 16 years or older, (2) no history of surgery and cardiovascular and cerebrovascular diseases, (3) the contralateral ankle is normal, (4) the range of motion of the ankle joint is the same on both sides before the injury, (5) preoperative X-ray examination confirmed no history of fractures, (6) local skin was free of infection, necrosis, allergies and other symptoms, and (7) all athletes had no midfoot and forefoot ligament injuries

(2) Treatment method

(1) ESW group: DolorClast radiation shock wave therapeutic apparatus produced by Swiss EMS company is used for treatment. The patient was placed in supine position, and the pain points at the ankle ligament injury were identified by palpation, and the blood vessels and nerve distribution areas were avoided. Then, the coupling agent was locally applied, and the ESW treatment head was vertically aligned with the tenderness site, and the pressure was set to 2.0-4.0 bar, impact frequency 6 Hz, impact pulses 2000 times at each part, handle pressure is medium. The impact energy is adjusted according to the patient's tolerance, and the impact treatment is performed with a larger pressure tolerated by the patient. 3 to 4 times is a course of treatment, with a maximum of no more than 2 courses, and the interval between the two treatments is 7 days

(2) Closed group: the same position as above, after the pain point of the ankle ligament was determined, the pain point was injected with triamcinolone 1 ml and 2% lidocaine 1 ml suspension, closed once every 5-7 days, 3 times as 1. The course of treatment should not exceed 2 courses at most, in order to prevent the accumulation of medicinal fluid in the local tissue and damage to the local tissue

4. Discussion

4.1. Dynamic Balance System Combined with Surface Electromyography (SEMG) Experiment Monitoring and Analysis

(1) Comparison of healthy and affected calf circumference and joint activity before and after treatment

Comparison of calf circumference and joint mobility between the two before and after rehabilitation is shown in Table 1:

It can be seen from Table 1 that the ankle and calf circumference of the two people increased rapidly in more than one month, while the range of joint activity increased significantly, almost doubled. Over time, it can withstand the normal amount of training, no adverse reactions, swelling at the Achilles tendon subsided, and pain has been significantly reduced. Comparative examination found no significant difference in calf circumference, and the sides tended to balance.

TABLE 1: A comparative study of leg circumference and joint mobility between the two before and after rehabilitation.

	Calf girth	Range of joint activity
Before treatment	-1.6 ± 0.5	$46.8° \pm 1.2$
After treatment	0.8 ± 1.0	$85.3° \pm 1.6$

Note: the positive sign indicates that the affected side is thicker than the healthy side, and the negative sign is opposite.

(2) Changes in muscle function before and after rehabilitation training

Due to the influence of individual differences, the maximum strength index mainly takes the ratio of peak torque to weight, also known as relative peak torque (PT/BW), which represents the relative muscle strength of muscle contraction; strength endurance is mainly through work fatigue (ER, unit (%)) to reflect its ability. It specifically represents the fatigue resistance of muscles during repeated contractions. The lower the endurance index, the stronger the muscle's resistance to fatigue, indicating that the endurance is better. Then, observe the two people's long-term muscle work to maintain muscle tension and stress. The maximum strength and strength endurance indicators are shown in Table 2 and Figures 1 and 2. Muscular endurance is the ability of the body to perform sustained muscular work for long periods of time, i.e., the ability to fight fatigue. Endurance includes two aspects, namely, muscular endurance and cardiovascular endurance.

From Table 2 and Figures 1 and 2, it can be seen that with the passage of time, the relative peak torque values of the right ankle plantar flexor muscle groups continued to increase, the dorsiflexor muscles were basically flat, and the work fatigue index decreased gradually, indicating that the strength level of the right ankle was significantly improved, and the antifatigue ability was improved. The right ankle even surpassed the uninjured left ankle in some strength levels.

In summary, after the rehabilitation treatment cycle, the calf muscle fibers of the two people increased, and the corresponding strength and muscle fatigue resistance were significantly improved, indicating that better results were achieved through rehabilitation treatment.

4.2. Surgical Treatment Monitoring Analysis

(1) All fractures have healed. The average healing time of fractures is l2.8 weeks (10 to 14 weeks). There were no cases of delayed fracture healing and fracture nonunion, and no wound complications occurred

AOFAS ankle-hindock function score: excellent in 8 cases, good in 8 cases, excellent and good rate was 100%, with an average of 93 points (85-100 points). The VAS pain score was 0.94 points (0-2 points). Specific patient information is shown in Table 3.

(2) Anatomy of the triangular ligament: the triangular ligament is a fan-shaped complex structure composed of multiple ligaments. The deltoid ligament is the main ligamentous structure that stabilizes the medial

aspect of the ankle joint and functions to maintain the normal anatomical position of the talus and prevent its exostosis and dislocation. The anatomy of the triangular ligament is still controversial. It is generally believed that the triangular ligament is composed of shallow and deep layers. Milner et al. believe that the main basis for distinguishing deep and shallow layers is the number of joints they cross. A joint, but sometimes it is not absolute

4.3. Monitoring and Analysis of Rehabilitation Treatment of Taijiquan Exercise

(1) Rehabilitation assessment results

After 76 patients with ankle ligament injury were subjected to follow-up, investigation, and statistics for 12-15 months (average of 12.5 months in the experimental group and 13.8 months in the control group), the following criteria were used to evaluate the effect of rehabilitation treatment shown.

As can be seen from Figure 3, the rehabilitation assessment results are as follows: excellent: no reinjury, no pain during walking, ankle dorsiflexion angle of 20°-30°, plantar flexion of 40°-50°, no lameness, easy squatting, and normal joint function; good: no reinjury, good function of the joint cavity and tendon sheath, back extension of 10°-20°, plantar flexion of 25°-40°, mild swelling and pain after walking a long distance, slightly lameness, more convenient to squat, and can maintain normal work; poor: there is reinjury, the injury recovers slowly, pain and lameness are obvious during walking, the ankle is swollen and unstable, back extension is 0°-5°, plantar flexion is 5°-15°, and it is inconvenient or difficult to squat.

(2) Comparison of rehabilitation effects

Compare the curative effect of the experimental group with the curative effect of the control group. The evaluation results are tested by x2, as shown in Figure 4.

As can be seen from Figure 4, the healing effect of the experimental group was significantly better than that of the control group ($P < 0.05$) (see Table 4). Tested by x2: $P < 0.05$.

The results show that the exercise of Taijiquan allows the ankle ligament to be exercised, which effectively prevents the occurrence of contracture, ankle instability, and recurrent dislocation. When playing Taijiquan, there is no need for mental attention. Under the control of consciousness, the mind of the practitioner always focuses on the injured ankle and the whole set of movements, eliminating the interference of other thoughts, and focusing on directing the functions of all organ systems throughout the body to cooperate with the injured ankle. Performing activities effectively prevents repeated ankle ligament injuries.

4.4. Monitoring and Analysis of Extracorporeal Shock Wave Therapy

(1) Comparison of VAS scores

The comparison of VAS scores is shown in Table 5.

TABLE 2: Comparison of four tests of right muscle strength (affected side) before and after two persons.

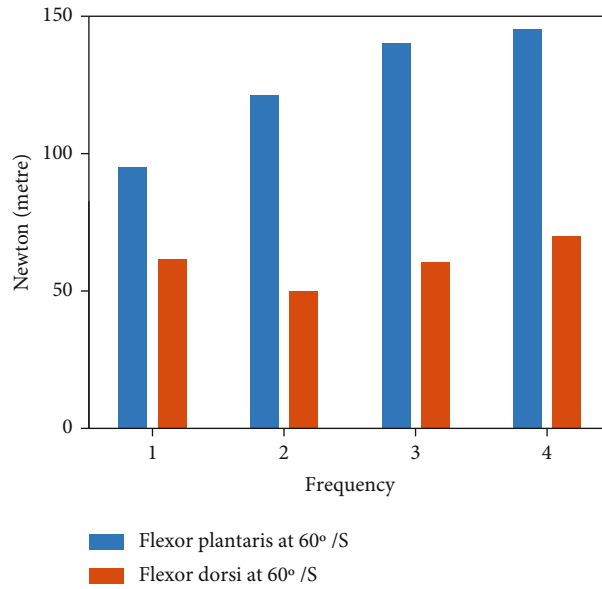
Test target	Flexor plantaris at 60°/s				Flexor dorsal at 60°/s			
	Right 1	Right 2	Right 3	Right 4	Right 1	Right 2	Right 3	Right 4
Peak moment (Newton A kind of rice)	75.7	97.9	111.1	116.3	52.1	41.9	49.0	56.8
Peak torque/weight (%)	94.6	122.4	138.9	145.4	65.1	52.4	61.3	71.0
Total work (joules)	136.5	224.5	260.9	270.9	157.1	140.6	181.7	218.0
Average power (Watts)	49.9	74.4	86.9	75.8	55.3	45.8	54.5	60.4
Work fatigue (%) (180°/s)	56.2	29.8	28.0	13.7	26.5	16.3	19.3	21.2


FIGURE 1: 4 relative peak moment changes before and after.
FIGURE 2: Change of fatigue degree before and after 4 times of work.

TABLE 3: Materials of 16 patients.

Case	Age (years)	Involved side	AOFAS score (pre/post)	VAS score (pre/post)	Follow-up Time/months
1	22	Left	100/100	0/0	30
2	35	Left	100/97	0/1	38
3	42	Left	90/90	0/1	48
4	48	Left	100/87	0/2	84
5	52	Left	100/97	0/0	32
6	68	Right	90/85	0/2	72
7	38	Right	100/97	0/1	64
8	52	Right	100/90	0/1	42
9	40	Left	100/97	0/0	34
10	40	Left	100/90	0/2	40
11	31	Right	100/97	0/1	65
12	64	Right	90/87	0/2	32
13	40	Right	100/90	0/1	36
14	41	Left	100/90	0/1	41
15	38	Left	100/97	0/0	40
16	30	Right	100/97	0/0	52
FIGURE 3: Rehabilitation evaluation results of the experimental group and control group.

As can be seen from Table 5, there was no significant difference in VAS scores between the two groups before treatment, at the end of treatment, and 4 weeks after treatment ($P > 0.05$), and there was a significant difference in VAS scores at 8 weeks after treatment ($P < 0.05$). At the same time, the VAS scores of the two groups before treatment were significantly different from those at the end of treatment, 4 weeks, and 8 weeks after treatment ($P < 0.05$).

(2) Kofoed score comparison

Kofoed score comparison is shown in Table 4.

It can be seen from Table 4 that there was no significant difference in the scores of the Kofoed observation indexes before treatment between the two groups ($P > 0.05$); the scores of pain, function, and activity of the ESW treatment group after treatment were significantly higher than those of the closed treatment group, with significant differences.
Figure 4: Comparison of rehabilitation effect between experimental group (41 cases) and control group (35 cases).

Table 4: Comparison of Kofoed scores between the two groups before and after treatment.

Kofoed observation index	Group ESW		Closed group	
	Preoperative	Postoperative	Preoperative	Postoperative
Pain	12.00 ± 8.66	40.60 ± 8.46	14.00 ± 10.56	26.67 ± 11.29
Function	7.08 ± 4.14	23.52 ± 3.64	8.40 ± 4.84	17.00 ± 4.63
Activity degree	4.52 ± 1.90	16.60 ± 2.47	5.07 ± 2.34	13.13 ± 3.00
Total	23.60 ± 14.70	80.72 ± 14.57	27.47 ± 17.74	56.80 ± 18.92

Table 5: VAS scores of patients in both groups before and after treatment.

Group	Number of cases	Before treatment	At the end of treatment	4 weeks after treatment	8 weeks after treatment
Group ESW	25	8.40 ± 1.19	3.72 ± 1.40	2.72 ± 1.37	2.40 ± 1.44
Closed group	15	8.53 ± 1.12	3.40 ± 1.12	3.33 ± 1.11	4.73 ± 1.98

Sexual significance ($P < 0.05$). The shortest recovery time for recovery training after treatment in the two groups: The shortest recovery time ($5.52 ± 1.36$ weeks) for athletes after training in the ESW treatment group was significantly shorter than that in the closed treatment group ($6.60 ± 1.76$ weeks) ($P < 0.05$).

5. Conclusions

For a long time, many sports workers and athletes have believed that "sports injuries are inevitable" and that "without sports injuries, high-level sports performance cannot be achieved," which has no scientific basis. The fundamental way to reduce exercise operations is to adhere to the principle of prevention. We must carefully analyze and study the various factors that are likely to cause injuries, summarize our experience, and gradually form the concept of injury prevention in ideology. With sufficient attention, the illness must not be delayed, and the acute injury gradually evolves into a chronic injury. To this end, this paper presents a study on rehabilitation and monitoring of Achilles tendon ligament injuries in athletes based on nanomaterial repair.

In this paper, we found that the dynamic balance system combined with surface electromyography (SEMG) experimental monitoring, surgical treatment monitoring, rehabilitation therapy monitoring of Taijiquan exercise, and monitoring of extracorporeal shock wave therapy. The dynamic balance system combined with surface electromyography (SEMG) treatment can increase the calf muscle fibers, increase the corresponding strength and muscle

fatigue resistance, and achieve good curative effects. Surgical treatment can accelerate fracture healing, with a cure rate of 93%. It has a significant effect on the rehabilitation of ankle ligament sprains; Taijiquan exercises can exercise the ankle ligaments and effectively prevent the occurrence of contractures, ankle instability, and recurrent dislocations; the analgesic effect of extracorporeal shock wave treatment on patients with ankle ligament injuries Compared with the traditional closed treatment, the effect is more durable and effective.

The results of this study indicate that ESW also has a strong analgesic effect on pain after soft tissue injury. In this article, immediately after treatment and 4 weeks after treatment, the VAS scores of the ESW group and the closed group were significantly lower than before the treatment, indicating that the two treatment groups had better analgesic effects in the early stage and there was no difference. The VAS score of the ESW group at 8 weeks after treatment was significantly lower than that of the closed group, indicating that the effect of closed treatment was less than 8 weeks after treatment, and the analgesic effect of ESW lasted longer. In addition, the total effective rate in the ESW group was also significantly higher than that in the closed group after treatment. Therefore, we believe that the analgesic effect of ESW on patients with ankle ligament injury is more durable and effective than traditional closed treatment.

With the improvement of people's attention to health, basketball is a sport that can strengthen the body and deeply loved by people. However, basketball involves a lot of physical activity and a quick stop technique, which increases the risk of arthritis. The reason for this paper is to concentrate on the utilization of nanotube joined restoration treatment in the treatment of knee joint pain in basketball players. This paper first introduces the structure and properties of carbon nanotubes, analyzes the pathology of knee arthritis and the causes of knee arthritis in basketball players, and discussed the knee arthritis rehabilitation treatment method. According to the diagnostic criteria of osteoarthritis and the significant incorporation and rejection measures, a sum of 50 patients with knee osteoarthritis were chosen as the review subjects and separated into test gathering and control bunch. The benchmark group was treated with conventional electroacupuncture, and the exploratory gathering was treated with nanotubes as repair materials for knee arthritis. The experimental results show that the application of nanotube combined rehabilitation therapy in the treatment of knee arthritis in basketball players is practical to a certain extent. The total score of WOMAC in the two groups after treatment decreased to a certain extent compared with that before treatment, but the difference in the experimental group was more obvious, and the difference was significant after statistical analysis ($P < 0.05$).

1. Introduction

Influenced by international high-level games, such as the NBA, basketball is gaining popularity among the general public. However, basketball players may suffer some sports injuries due to the influence of factors such as fierce confrontation, fierce competition, frequent physical contact, and playing environment. On the one hand, sports injury will not only bring physical inconvenience and pain to basketball participants but also affect their normal work and study. Serious injury will also make people physically disabled and even lose their lives. On the other hand, sports injuries have a negative impact on the smooth development of basketball.

As a normal one-layered nanomaterial, carbon nanotubes stand out because of their one of a kind construction and physical and synthetic properties. Carbon nanotubes have strong mechanical properties, stable chemical properties, special electronic structure, and optical properties and have a wide range of applications in material variation and environmental science, especially in the field of biomedicine. The discovery and development of special properties of carbon nanotubes is a very active research, which has laid a foundation for the treatment of knee arthritis patients.

Acrisio et al. reported theoretical studies on the structure and phonon properties of single-walled and double-walled carbon nanotubes under hydrostatic pressure. Their results confirmed a dramatic change in the volume of the single-walled carbon nanotubes at high pressures [1]. Their report did not address the real problem. Loredo-perez et al. aimed to quantitatively study the injurious spontaneity, knee edema, proinflammatory cytokines, bone mineral density, and microstructure of unilateral knee arthritis mice fed a high-fat diet. Their method was to give standard diets (SD) and HFD to male ICR mice starting at 3 weeks of age. The serum levels of il-1 and il-6 were first injected by CFA and then analyzed by ELISA for RANKL and microcomputed tomography [2]. Although they conducted quantitative

studies on mice fed with HFD, they still need to conduct qualitative studies. Straker et al. team found that arthritis of the hip and knee afflicts those who continue to pursue exercise as they age. They discussed mechanical measures to reduce joint load, including support, footwear, and foot orthotics/insoles. Biomechanical considerations of applying gait retraining and joint unloading techniques are proposed [3]. The method they proposed has no practical application value.

This paper first introduces the structure and properties of carbon nanotubes, analyzes the pathology of knee arthritis and the causes of knee arthritis in basketball players, and discussed the knee arthritis rehabilitation treatment method. According to the diagnostic criteria of osteoarthritis and the relevant inclusion and exclusion criteria, a total of 50 patients with knee osteoarthritis were selected as the study subjects. The control group was treated with ordinary electroacupuncture, and the experimental group was treated with nanotubes as repair materials for knee arthritis. The experimental results show that the application of nanotube combined rehabilitation therapy in the treatment of knee arthritis in basketball players is practical to a certain extent. Nanotube can withstand high temperature and is harder than steel, so it has a higher repair effect than traditional repair methods [4].

2. Treatment of Knee Arthritis with Nanotube and Rehabilitation Therapy

2.1. Nanotubes.
As typical one-dimensional nanomaterials, carbon nanotubes (CNTs) have unique physical, chemical, and electronic properties [5, 6]. Carbon nanotubes are one-dimensional hollow tubular nanomaterials formed by curling graphite sheet layers. Single-walled carbon nanotubes are framed by twisting a solitary layer of graphite, and multi-walled carbon nanotubes are shaped by twisting different layers of graphite [7, 8]. The specific structure formed by carbon nanotubes is related to the Angle and curvature when the graphite sheet is curled into a tube, so it may have different chirality, which are zigzag, armchair, and chiral.

Because of the unique and stable special topological structure of CNTs, CNTs will not break when subjected to bending but can achieve elasticity according to volume changes, with high strength and toughness [9]. It has excellent performance in physical mechanics, electricity, heat, and so on. When CNTs or their functionalized products are added to polymer or composite materials, their physical and mechanical properties, thermal properties, and electrical properties can be improved to a certain extent.

2.2. Basketball Players and Knee Arthritis

2.2.1. Knee Arthritis.
Osteoarthritis (OA) is a chronic osteoarthritis with prominent pathological features. OA is a kind of degenerative change of articular cartilage and secondary bone hyperplasia [10, 11]. Clinically, chronic joint pain, stiffness, swelling, and joint dysfunction are the main manifestations. As the knee joint is the most complex joint in the whole body with the highest load and the heaviest shear force, osteoarthritis (KOA) is most likely to occur at this joint [12, 13]. The symptoms of KOA are mainly manifested as knee swelling and pain when walking up and down stairs, sitting and standing up, knee pain and discomfort, etc. There will also be swelling, popping, and fluid accumulation in patients [14]. The clinical manifestations are degeneration of local cartilage tissue of knee joint, formation of osteophyte at knee joint edge, and changes of subchondral bone reactivity [15].

The entire course of disease development affects not only the articular cartilage but also the entire knee joint, including the subchondral bone, joint capsule, ligament, synovium, and the surrounding muscles of the knee joint [16, 17]. The onset of the disease is characterized by abnormal biochemical metabolism of the knee cartilage, and then damage to the structure of the knee joint, resulting in fibrosis, gap, ulcer, and damage to the entire knee joint surface, leading to knee joint pain and abnormal function [18].

2.2.2. Causes of Knee Joint in Basketball Players.
Basketball sports have a lot of physical activities and technical movements such as quick stop. When basketball players use these technical movements to play games, they are likely to cause great sports injuries to themselves. During the movement of the knee, the knee needs to bounce and squat continuously. This instantaneous explosive action keeps the knee in a bent state for a long time, which will cause the knee joint to bear a lot of extra load, thus causing sports injuries. The knee is the most vulnerable part during exercise. Once this part is damaged, the level of the athlete will be greatly affected, and this effect is not short-term, it will cause great harm to the athlete.

2.3. Knee Arthritis Rehabilitation Therapy

2.3.1. General Treatment.
If KOA patients' symptom is lighter, function is normal, should be given priority to with preventive measures and daily care, to related education and help the patients study, also should have the health-related behavior in daily life, to be able to slow the progress of the disease, and make the patient's quality of life improved, make the medical expenses of patients with lower [19, 20]. The contents of KOA education include posture, joint function, joint protection, disease, psychology, and so on. Patients should be allowed to understand the basic knowledge of the disease, to avoid catching cold or staying in a certain position for a long time, as well as excessive joint load. For obese patients, they should adopt such methods as diet control, weight loss, restriction of climbing activities, insistence on driving instead of walking, and reduction of activities when joints swell and should pay attention to the combination of work and rest, thereby gradually enhancing their physique. A systematic review of evidence-based medicine shows that therapeutic interventions based on patient education, exercise therapy, and weight control measures are not only cost-effective but also have good long-term efficacy and should be used as the core clinical treatment. Core treatments include self-management, health education, weight and information control, and psychological

intervention. Health education can significantly improve the short-term and long-term efficacy of KOA therapy.

2.3.2. Drug Therapy. Acetaminophen, nonsteroidal anti-inflammatory and analgesic drugs, traditional Chinese medicine, blood-activating and collateral-activating drugs or dialectical drugs, and external drugs can be used. Tramadol and other drugs can be used for severe pain [21, 22]. The use of acetaminophen (Max. 4 g/d, OTC single dose <650 mg) as the preferred therapeutic agent has been recommended in several guidelines. If full-dose acetaminophen is not effective in patients, ACR recommends oral or local administration of nonsteroidal anti-inflammatory or intra-articular injection of corticosteroids. Now, clinical also commonly used chondroitin sulfate, glucosamine, double reactine and vitamins, and other drug treatment. It has been reported that intra-articular injection of corticosteroids, sodium hyaluronate, deer and melon polypeptides, ozone, and joint cavity irrigation has been widely used and achieved good results. At present, there is still no strong evidence to prove that glucosamine, chondroitin, and other nutritional treatments can be used as the routine treatment of OA. Corticosteroids can relieve joint pain in the short term, but long-term repeated use can cause joint damage. Therefore, the authoritative guidelines are recommended to be used under certain conditions. Although there are many research methods for restoring articular cartilage, such as changing joint load and periosteum, perichondrium transplantation, chondrocyte and mesenchymal stem cell transplantation, artificial matrix, and growth factors, there is no method that can completely restore normal articular cartilage. Against glucosamine or chondroitin drugs, intra-articular injection of hyaluronic acid, duloxetine, and opioid painkillers is not recommended.

2.3.3. TCM Treatment. There are many methods such as internal administration of traditional Chinese medicine, external treatment, acupuncture and moxibustion, massage, acupotomy, and new treatment combining traditional techniques with modern science and technology. In the theory of the meridians, the meridians have the functions of articulation of limbs, restraint of bones, viro-body, and locomotion. Based on the theory of tendons, the special features and rules of tendons diseases were studied, and the tendon disease has carried on the thorough exploration, and it was concluded that pathological tendons were the pathogenic factors of tendons diseases, and a simple and feasible diagnostic method was put forward, which laid a solid theoretical foundation for the treatment. Silver needle therapy is beneficial to the communication and combination between the theory of biomechanic dynamic balance and the etiology and pathology of chronic soft tissue injury in the overall concept of traditional Chinese medicine and western medicine surgical treatment and has achieved good results. Acupuncture points in traditional Chinese medicine are closely related to vascular nerves. Under the stimulation of acupuncture points, blood supply of knee joint is improved and blood stasis is improved. Acupuncture can also directly stimulate the nerve tissue or pain source area conducting pain sensation, block the pain conduction in the nerve fiber, and inhibit the response of spinal dorsal horn cells to injurious stimuli. It may also effectively strengthen the function of muscle groups in various parts of the knee joint, consolidate the normal physiological function of the knee joint, and maintain the stability. The short-term and long-term effects of early knee arthritis were observed, and the results were more satisfactory than that of drug therapy. In the aspect of antiexercise fatigue, acupuncture therapy has advantages that other therapies do not have. The action mechanism of traditional Chinese medicine therapy is complex, and the study on the action principle is yet to be further studied. The traditional Chinese medicine therapy and the emerging Chinese medicine therapy have different standards in terms of treatment norms, which also need to be further developed.

2.3.4. Physical Therapy. Physical therapy was aimed at alleviating or eliminating the symptoms of KOA through the rational use of various physical factors. Such methods can improve local blood circulation, relieve muscle spasm, promote the absorption and dissipation of joint inflammation, and reduce bone pressure and pain. Compared with internal medicine and surgery, physical factor therapy is more economical in cost and can reduce medical costs. At the same time, it is additionally of incredible importance to work on patients' personal satisfaction and lessen family and social weight. Physical therapy generally uses physical properties such as sound, optics, electricity, or mechanics as well as cold and heat conduction to carry out corresponding treatment without sequelae [23]. The application of low-intensity pulsed ultrasound to promote cartilage repair in osteoarthritis has been found to have a good effect. The application of modulated medium frequency electrotherapy has a continuous and significant effect on relieving knee joint pain and is of great significance. The results of low-frequency thermal vibration magnetic therapy showed that the pain intensity score of the patients was significantly reduced after treatment. Low-intensity laser intravascular irradiation for elderly osteoarthritis can reduce the dosage of NSAIDS. Some scholars have summarized the physiotherapy scheme of KOA. If the acute knee joint swelling is obvious, the main method should be analgesia and detumescence. At the same time, cold therapy can be used to shrink the local blood vessels so as to reduce exudation and increase the pain area. In the chronic phase, ultrasound therapy and warm or micro heat ultrashort wave and microwave therapy should be used to enhance the local blood circulation. For example, if ligament and soft tissue are involved, medium frequency or low frequency electrotherapy should be used to release adhesion. If necessary, two physical factors can be combined to improve the therapeutic effect.

2.3.5. Exercise Therapy. Maintain normal composition and structure and mechanical properties of articular cartilage must make the joints have a certain weight, while maintaining the normal articular cartilage type, intensity, and frequency of the load there is a wide range, but when the intensity or frequency of the load above or below this range,

destroy the balance of the synthesis of articular cartilage degradation mechanism, composition, and ultrastructural changes of cartilage. Proper exercise is necessary to maintain the normal use of articular cartilage. Sports training has the advantages of noninvasive, efficient, and lasting and is favored by more and more doctors at home and abroad.

Through exercise training, the muscle strength around the knee joint is enhanced, and the symptoms of muscle atrophy are alleviated, so as to ensure the normal transmission of joint mechanics. At the same time, the stability of joints has been improved, so that the joints in a good state of protection can prevent the development of OA. Quadriceps strength training can steadily improve knee joint function and increase walking distance. Clinicians often use this training method to improve knee joint function. Routine quadriceps muscle strength training can relieve symptoms and slow down the progression of joint degeneration to a certain extent. Meanwhile, it can also increase the mobility and stability of the knee joint and inhibit or slow down the vicious cycle of joint instability in KOA. Although many scholars believe that training quadriceps muscle strength can relieve the symptoms of joint pain, strengthening quadriceps muscle strength training cannot improve the joint movement of the knee joint. Although quadriceps exercise improved muscle weakness, it did not achieve the desired effect of improving the symptoms of KOA. However, the researchers still agree that quadriceps rehabilitation exercise can be performed according to patients' different conditions and individual differences.

With the exception of the quadriceps, the stability of knee activity is determined by the ratio of muscle strength between the quadriceps and the hamstring. In patients with KOA, the extensor knee and the flexor knee muscles have the same loss of strength. Therefore, attention should be paid to both the knee extensor muscle strength training and the flexor knee muscle strength training. The results can improve the muscle strength, further coordinate the flexor and extensor muscle strength ratio, and increase the stability of the knee joint, thus effectively controlling or slowing down the development of KOA's disease. Constant speed muscle strength training requires the assistance of exercise equipment, through the equipment to adjust the resistance at a constant speed, and in the process of movement, the muscle in all angles can occur to maximum contraction and maximum tension, so as to achieve the best training effect. Isokinetic muscle strength training can effectively improve the muscle strength of quadriceps femoris and other muscle groups around the knee joint, significantly improve the stability of the joints of patients with KOA, and effectively improve the joint function of patients. However, isokinetic muscle training equipment has the characteristics of expensive, complicated operation, and high treatment cost, so it is still difficult to popularize at present. Chain of lower limb muscle training can effectively improve the limb motor function, muscle chain training emphasized to joint training of muscles, rather than a single muscle training, confirmed in the muscle chain theory emphasizes the balance between muscle in the chain and the importance of coordination, and lower limb muscle chain have positive

effects on KOA rehabilitation training. However, there is a difference between isokinetic muscle strength training and quadriceps muscle strength enhancement between male and female patients. Through isokinetic muscle strength training, the quadriceps muscle strength can be effectively enhanced in male KOA patients. However, this concept is not suitable for female KOA patients.

Insisting on isometric length, isometric tensioning exercise can make joint ache alleviate effectively, make joint stability increase, and make joint function improve, and its long-term effect is better than sodium hyaluronate. Because range of motion is positively correlated with the risk of injury and falls, increasing range of motion can help reduce pain. For KOA patients, emphasis should be placed on stretching the quadriceps, hamstrings, and triceps of the calf to increase the range of motion of the joint. Static stretch training had a significant therapeutic effect on KOA patients. Six weeks of static stretch training resulted in a significant decrease in WOMAC osteoarthritis index score. For the KOA patients treated with joint slackening, a medical procedure, the strolling velocity and step length of the patients altogether worked after therapy contrasted and before therapy, and the aggravation was essentially diminished. The effect was significantly better than that of the low-frequency pulse electric group, but the difference was not significant compared with the electric stimulation group 4 weeks after the end of treatment. Acupuncture combined with proprioceptive sensation training is conducive to the improvement of patients' proprioceptive sensation, which has a positive effect on the stability, flexibility, and self-control of the affected knee joints, and at the same time improves and consolidates the efficacy of acupuncture. In overweight patients, weight loss combined with exercise or even weight loss alone can achieve better results in alleviating pain, improving function, muscle strength, and quality of life. Therefore, weight control is strongly recommended as a necessary treatment. In addition to weight loss, joint stress reduction exercises can be performed by water movement or suspension. Patients with KOA must be trained with aerobic exercises due to lower limb dysfunction and decreased body capacity. Aerobic exercise can enhance heart and lung function. For the elderly, moderate and low-intensity aerobic exercise such as walking, gymnastics, tai chi, and swimming can be used in the remission period of KOA patients. After aerobic exercise, KOA patients not only effectively relieved their joint pain but also improved their body function, increasing their walking speed and walking distance and maintaining their body function for about 18 months. Therefore, to lower the intensity of the exercise, adhering to long-term training is able to obtain better results. Numerous studies have shown that exercise is not only a cure for KOA but also a way to prevent it. Should, therefore, on the basis of KOA patients to evaluate their physiological characteristics, the condition of monitoring of autologous, develop sustainable personalized safe, effective, strong adaptability of exercise prescription, make movement dysfunction in patients with improved, pain relief and disease development delay, delay or avoid surgery time and improve the quality of life.

TABLE 1: Comparison of distribution of gender, age, and disease course of patients.

Group	Number of cases	Male	Female	Age	Course of disease (month)
Experience group	25	14	11	26	6
Control group	25	13	12	25	5.8

TABLE 2: Comparison of WOMAC scores between the two groups before and after treatment.

Symptoms	Group	Integral	
		Experimental group	Control group
The pain	Before	11.21	10.78
	After	3.32	3.96
Stiff joints	Before	32.07	31.15
	After	46.61	45.89
Physiological function	Before	3.79	4.85
	After	2.14	2.93
The total score	Before	21.21	25.63
	After	27.14	33.41

3. Experiments of Nanotube Combined Rehabilitation Therapy

3.1. Subjects. In this paper, patients with KOA basketball players who were qualified for primary screening from January 2019 to June 2019 for diagnosis and treatment were selected for the observation of cases, and they were allocated to two groups by random number table in chronological order. The experimental group used nanotubes and electroacupuncture combined with rehabilitation therapy. Electroacupuncture is based on traditional acupuncture and moxibustion by adding low-frequency pulsed electrical stimulation, and through acupuncture and moxibustion to regulate qi, the human body's biological microcurrent is combined with acupuncture. The patients in the control group were treated with cupping. A total of 50 patients conforming to this study were included. The specific data are shown in Table 1.

3.2. Diagnostic Criteria. The analytic models of this study were intermittent knee torment in the knee over the most recent multi month; X-beam pictures (standing or weight-bearing) showed restricting of joint space, subchondral osteosclerosis or potentially cystic degeneration, and osteophyte arrangement at joint edges.

3.3. Experimental Methods. Each subject was given a two-week course of treatment as follows:

Hamstring training: In the prone position, perform the following movements: (1) straight knee and hip extension training; (2) bend the knee and bend the calf; (3) internal

and external rotation of the calves; and (4) internal and external rotation of lower limbs.

Acupuncture point selection is as follows: yinmen point, weizhong point, weiyang point, yingu point, heyang point, and chengshan point; the method of acupoint selection was in accordance with the national standards of acupuncture and moxibustion points. The depth and angle of acupuncture were also in accordance with the standards. After obtaining qi, the acupuncture was replenished and deflated, and the acupuncture was retained for 30 min.

Yk-2000a modulated if frequency therapeutic instrument was used, and the electrodes were placed in popliteal fossis-side juxtaposition. The osteoarthropathy prescription in the multistep treatment procedure was selected, and the treatment lasted for 20 min. The intensity of current output should be adjusted according to the patient's tolerance and comfort level.

3.4. Statistical Methods. Results statistical analysis was processed by statistical product and service solutions 20.0 statistical software. The comparison of measurement data met the t-test of normal distribution with homogenous selection of variance, while the t' test of nonhomogenous selection of variance did not meet the rank-sum test of normal distribution. The comparison of counting data was conducted by X^2 test, and the rank-sum test was conducted by rank data. All measurement data are represented by XSD. $P < 0.05$ indicated that the difference was statistically significant. The statistical analysis methods of measurement data can be divided into parametric test method and nonparametric test method.

4. Discussion of Nanotube Combined Rehabilitation Therapy

4.1. Comparison of WOMAC and VAS Scores between the Two Groups

4.1.1. Comparison of WOMAC Scores between the Two Groups before and after Treatment. Toward the finish of the one courses of treatment, the two gatherings acquired specific impacts on the WOMAC manifestation all out score. It was speculated that both the electroacupuncture group and the normal acupuncture group had treatable KOA, while the treatment group had better efficacy than the control group. WOMAC single symptom score, pain, joint stiffness, and physiological function under the two treatment methods have obtained a certain effect. Comparison of WOMAC scores before and after treatment is shown in Table 2 and Figure 1.

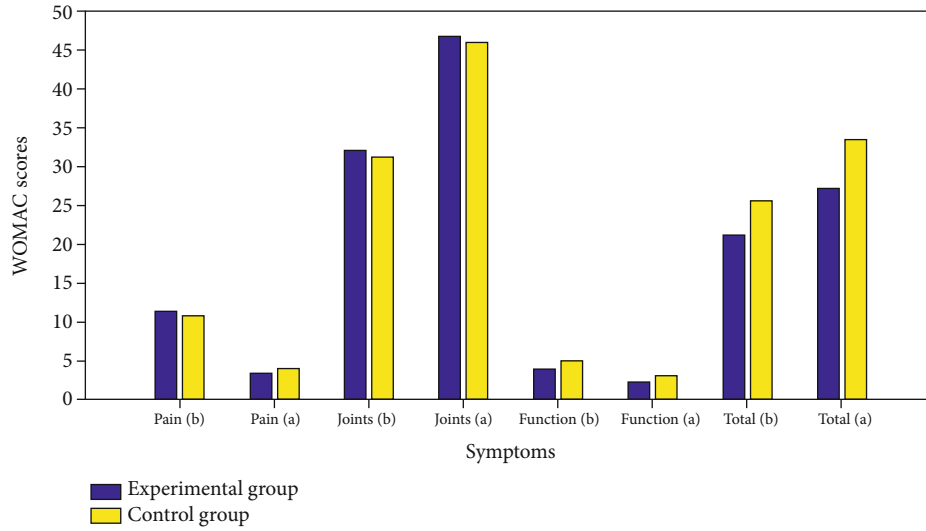
As should be visible from Table 2 and Figure 1, the all out WOMAC score of the test bunch changed essentially with the treatment, that is to say, $P < 0.05$, which was measurably critical. The complete score of WOMAC in the benchmark group changed essentially with the treatment, and the combined t-test showed $P < 0.05$, which was genuinely huge. In this way, it tends to be estimated that the improvement of absolute indications in the exploratory gathering and control bunch after treatment is superior to


Figure 1: Comparison of WOMAC scores between the two groups before and after treatment.
Figure 2: Comparison of VAS scores.
Figure 3: Comparison of knee joint mobility between the two groups.

that before treatment. The distinction in the absolute score between the two gatherings was huge ($P < 0.05$), so it very well may be viewed as that the test bunch was superior to

the benchmark group in working on the complete side effects. You can see the comparison between the control group and the experimental group, and the experimental group is significantly better than the control group.

According to the single symptom score, the pain score of the experimental group was significantly different before and after treatment, with statistical significance ($P < 0.05$). The changes of joint stiffness before and after treatment were significant ($P < 0.05$). There were significant differences in the scores of physiological function before and after treatment ($P < 0.05$). Therefore, it could be considered that the improvement of each single symptom in the treatment group was better than that before treatment. In the control group before and after treatment, the pain single score difference is obvious, with statistical significance ($P < 0.05$), joint stiffness score changes before and after the treatment, with statistical significance ($P < 0.05$), and physiological function score before and after the treatment, with statistical significance ($P < 0.05$), can be thought of as controlled in improving individual symptoms after treatment and was better than before treatment.

4.1.2. Comparison of VAS Scores. The VAS is a pain scale that gives pain a score of 10, with a score of 2 showing no aggravation, a score of 10 demonstrating serious agony, and a center score demonstrating changing levels of torment. Patients were approached to check the degree of agony on a size of 2 to 4 for gentle pain, 5 to 7 for moderate torment, and 8 to 9 for serious torment. Correlation aftereffects of VAS scores between the two gatherings are displayed in Figure 2.

As can be seen from Figure 2, there was a huge distinction in VAS score between the treatment bunch and the treatment bunch ($P < 0.05$). The VAS score of the benchmark group changed fundamentally with the treatment ($P < 0.05$). Along these lines, it tends to be presumed that the improvement of all out side effects in the treatment bunch and the benchmark group is superior to that before
FIGURE 4: Comparison of knee circumference between the two groups.

treatment. There was no critical distinction in VAS score between the two gatherings before treatment ($P > 0.05$). VAS scores of the two gatherings were viewed as equivalent before treatment, and the distinction in VAS scores between the two gatherings was critical after treatment ($P < 0.05$). It very well may be viewed as that the corrective impact of the treatment bunch is superior to that of the benchmark group. So you could argue that the treatment group was better at improving pain symptoms than the control group.

4.2. Comparison of Knee Joint Mobility and Circumference Diameter between the Two Groups

4.2.1. Comparison of Knee Joint Mobility between the Two Groups.
With the treatment, the scope of movement and the circuit breadth of the knee joint in the two gatherings was improved, and the thing that matters was genuinely huge. The impact of working on the scope of movement in the test bunch was superior to that in the control needle therapy bunch. Electroacupuncture has a solid pain relieving impact, and this study accepts that the scope of movement of the joint is generally impacted by torment, which makes it comprehended that the adequacy of the nanotube in working on the scope of movement of the joint is superior to that of the control group. The examination consequences of knee joint portability between the two gatherings are displayed in Figure 3.

As should be visible from Figure 3, the scope of movement of the joints when treatment was fundamentally divergent in the treatment bunch, with factual importance ($P < 0.05$). The scope of movement of the joints in the benchmark group was essentially different with the treatment ($P < 0.05$). Along these lines, it very well may be theorized that the improvement of absolute indications in the test gathering and control bunch after treatment is superior to that before treatment. There was no critical contrast in scope of movement between the two gatherings before treatment ($P > 0.05$), demonstrating that the scope of movement of the knee joint before treatment was equivalent between the two gatherings, and there was no huge distinction in scope of movement between the two gatherings after treat-

ment ($P > 0.05$). Along these lines, it tends to be theorized that the improvement of scope of movement in the test bunch is like that in the benchmark group.

4.2.2. Comparison of Periknee Diameter between the Two Groups.
With the treatment, the two gatherings of joint versatility and knee around the improvement, measurably critically contrast. The distinction between the two gatherings of changes around the knee joint was not measurably huge, showing that there was no distinction in the capacity of the two gatherings to switch up the knee joint. In other words, the experimental group has the same effect of reducing knee swelling as the control group. The comparison of the two groups of data is shown in Figure 4.

The data in Figure 4 represent the pathogenic causes of external causes to the knee joint. As should be visible from Figure 4, there was a critical contrast in the periwidth of the knee joint in the treatment bunch with the treatment ($P < 0.05$). The fringe distance across of the knee joint was altogether unique with treatment in the benchmark group ($P < 0.05$). Subsequently, it very well may be viewed as that the periknee breadth of the test bunch and the benchmark group is more modest than that before the treatment. There was no critical distinction in the peribreadth of the knee joint between the two gatherings before treatment ($P > 0.05$), showing that the periwidth of the knee joint before treatment was practically identical between the two gatherings, while there was no huge contrast in the perimeasurement of the knee joint between the two gatherings after treatment ($P > 0.05$). The outcomes showed that there was no distinction in the peribreadth of knee joint between the two gatherings after treatment, and the degree of progress in the periwidth of knee joint was something similar between the two gatherings.

5. Conclusions

In this review, the utilization of nanotube joined with recovery treatment in the treatment of knee joint pain was considered by noticing WOMAC and VAS scores with the treatment in the trial bunch and the benchmark group and looking at the scope of movement and periphery of knee joint in the two gatherings. The outcomes showed that the utilization of carbon nanotubes in the restoration treatment of knee joint pain was more powerful than the recovery treatment alone.

Albeit the pathogenesis of KOA cannot be completely explained in this review, biomechanical factors assume a significant part in the pathogenesis and treatment of KOA. Clinicians should lead a thorough and comprehensive evaluation and make treatment arrangements for joint security and personal satisfaction improvement in patients with KOA. In the treatment of KOA, consideration ought to be paid to the general insurance and thorough treatment of the knee joint.

The treatment time in this study was only 2 weeks, and knee osteoarthritis, as a chronic disease, requires a longer treatment time to improve its condition. Compared with its long treatment time, the treatment time of only 2 weeks

in this study is relatively short, and due to the different curative effects, the follow-up results of this study also have certain differences. There are still some deficiencies in the study of knee arthritis in this paper, which is expected to be made up for in future research.

With the rapid development of outdoor sports in our country, the condition of hip joint injury of athletes appears constantly. With the continuous progress of modern biotechnology and iatrotechnique, nanomaterials are also gradually used in the treatment of biological medicine. The purpose of this study is to use nanoscaffold materials in combination with athletics rehabilitation therapy to treat and analyze hip injuries in athletes. In this study, 290 patients with hip injuries in our hospital from June to October 2019 were studied. The hip joint injury patients were divided into the control group and the experimental group according to sex and age. The recovery of the hip joint injury in normal condition, the recovery in the pharmacotherapy, and the recovery in the combined therapy with the nanoscaffold material were compared. The function of nanoscaffold materials in experiments can be determined by detecting changes in related indicators in vivo. The results showed that there were 48 cases of ligament injury, accounting for 67.7% of hip joint injury. 22 cases had muscle and tendon injury, and 12 cases had articular cartilage injury and bursa injury. There was no significant difference in red blood cells, lymphocytes, and white blood cells after nanoscaffold material drug delivery therapy, while parathyroid hormone and osteocalcin changed greatly, which indicated that nanoscaffold material carrier therapy could promote the absorption and treatment of drugs in hip joint. Therefore, the research conclusions of this paper is that nanoscaffold material combined with rehabilitation therapy can effectively treat athletes with hip joint injury. It will contribute to the research and practical application of nanomaterials in modern medicine.

1. Introduction

1.1. Background Significance. Hip joint is the most important joint to support body weight in walking. It is very important for the standing position and movement of the body. However, the pain of hip joint activities will have a serious impact on the movement and function of the lower limbs of patients, especially the quality of life of patients including normal work and research. The incidence of hip joint deformation arthropathy, avascular necrosis of thigh head, hip heteromorphic syndrome, and hip joint pain caused by hip infection are high. In outdoor sports, the hip joint is more prone to injury.

The construction of titanium dioxide nanoscaffold materials not only is similar to the natural roughness of the artificial bone material of the artificial titanium but also has excellent hydrophilicity and greatly improves the cell adhesion and proliferation on the surface. Osteoblast-related cells can promote differentiation, proliferation, and induction. Titanium dioxide nanoscaffold materials have excellent adaptability to current biological fixation and embedding technology. Scanning electron microscopy (SEM) showed that osteoblasts have grown into tubular structures of titanium dioxide nanoscaffold materials that can immobilize bone cells. Microporous structures of specific size titanium dioxide nanopowders effectively reduce adhesion of bacteria

and promote growth and formation of bone tissue. Titanium dioxide nanoscaffold material coating is considered to be an excellent drug carrier because of its high surface area ratio. These excellent characteristics are widely used in biomedical fields.

1.2. Related Work. In the study of rehabilitation treatment of hip joint injury, Jana believes that the musculoskeletal model must adapt to the patient's unique geometry to predict the patient's specific hip load. His study compared the accuracy of anisotropic and isotropic scaled musculoskeletal models and hip force prediction from standard patient-specific skeletal geometry standards. His method is to analyze 356 hips of 250 adult pelvic radiographs. He applied three scaling methods: hip spacing anisotropic scale, iliac height, iliac width, lateral and inferior trochanter, isotropic scaling of pelvic width, and isotropic scaling of hip spacing. At the same time, he used the inverse static model to estimate the hip joint force when standing on one leg. The accuracy of his method is not high [1]. The Lopes et al.'s study compared the ROM of the hip joint between male patients with contact ACL injury and noncontact ACL injury. Their method was to compare the ROM of ipsilateral hip joint between 35 male patients with contact ACL injury (contact group) and 45 patients with non-contact ACL injury (noncontact group). In addition, imaging evaluation of the hip joint is also used to assess the presence of cam and clamp deformities. His method is unstable [2]. Morimoto et al.'s study measured the electromyographic activity of piriformis muscle in seven hip joint movements with a filament electrode. His method was to first select 11 healthy men without severe low back pain or lower limb injury. A filament electrode was inserted into piriformis muscle, and the surface electrode was attached to the hip muscle and the dominant brachial trunk muscle. Then, the EMG signal amplitudes of 7 kinds of hip joint movements were measured: hip neutral lateral supine abduction, hip neutral lateral supine abduction, hip joint internal rotation lateral supine abduction, hip joint external rotation prone extension, hip joint external rotation prone external rotation, hip joint pronation prone external rotation, and hip joint supine extension. They used repeated measurements of one-way ANOVA to examine the EMG of each of the seven hip movements. Their method is not practical [3].

1.3. Work of This Paper. In this paper, the structure of carbon nanoscaffold materials and the classification by layer number, chirality, and morphology are introduced. Then, the mechanical, electrical, and thermal properties of carbon nanoscaffold materials are described in detail. This study also describes hip injury and BASRI-hip score and gives examples of common sports injuries and events. This study describes the characteristics of hip joint movement of sports athletes. In this study, 298 patients in our hospital were divided into different groups according to age and gender. The experimental group was given drug therapy and nanoscaffold material combined rehabilitation therapy, respectively, and the control group was compared with the normal treatment. Observe the changes of blood indexes in the injured part of hip joint and the change of self-state to judge the therapeutic effect. According to the results, the therapeutic effects of hip patients of different genders are different. From the analysis of the treatment of hip joint injury with nanoscaffold material drug loading, the hip joint injury and the type and frequency of injury tissue structure are different in different age groups. The nanoscaffold material combination therapy in this study is very effective in the treatment of hip joint injury.

2. Carbon Nanoscaffold Materials and Hip Joint Injury of Sports Athletes

2.1. Structure of Carbon Nanoscaffold Materials. Carbon nanoscaffold materials (CNTs) are seamless tubular structures formed by single or multilayer graphite sheets wound around the same axis. The tube wall is a cylindrical surface composed of carbon atoms produced by SP2 hybridization and a hexagonal grid formed by three carbon atoms around it. The two ends are hemispherical rich rings composed of five rings and seven rings. This is formed by the coverage of lean molecules [4, 5]. It can be seen that the structure of carbon nanoscaffold material is a slightly complex one-axis multilayer structure. Carbon nanoscaffold materials (CNTs) are standard one-dimensional carbon nanomaterials because of their nanosized radial size and microscale axial size, showing a very large aspect ratio. In order to better understand the structure of carbon nanoscaffold materials, the academic community mainly uses the following three methods to classify carbon nanoscaffold materials.

2.1.1. Classification by Layers. Depending on the number of layers, the carbon nanoscaffold materials are divided into single and multilayer. The smaller the diameter of multi-walled carbon nanoscaffold materials, the larger the spacing between layers. The smaller the diameter, the larger the radius of curvature, the greater the spacing between layers, and the van der Waals force between layers [6, 7].

2.1.2. Classification by Chirality. The single-layer carbon nanoscaffold materials can be considered to be formed by curling the graphite sheet with hexagonal network structure [8, 9]. The graphite sheet structure is shown in Figure 1. Among them, a_1 and a_2 are the unit vectors of the 6-ring lattice with an included angle of 60°. In the figure, select point O as the origin and point OA as toward point A. This vector is the chiral vector of carbon nanoscaffold materials as shown below. Through point O, create the vertical vector ob of vector OA. This vector is the translation vector of carbon nanoscaffold materials as t. Through point B, the vector BB' is parallel to the vector OA. Secondly, OABB is the original unit of carbon nanoscaffold materials. The angle between vector OA and vector OD is the rotation angle, and the range is $0° \le |\theta| \le 30°$. The structure of SWCNTs can be expressed by chiral vector C_h

$$C_h = na_1 + ma_2 = (n, m). \tag{1}$$

n, m is an integer and $0 \le |m| \le n$. The rotation angle θ can be expressed by C_h and a_1
Figure 1: Schematic diagram of carbon nanoscaffold materials formed by graphene sheet.

$$\cos\theta = \frac{C_h a_1}{|C_h||a_1|} = \frac{2n+m}{2\sqrt{n^2+m^2+mn}}. \tag{2}$$

The rotation angle θ varies with n, m. When $\theta = 0°$ and $\theta = 30°$, the CNTs are not helical but chiral. Specific types are divided into armchair type and zigzag type. When $0° \leq |\theta| \leq 30°$ carbon nanoscaffold materials helix, they show chiral structure [10].

2.1.3. Classification by Morphology.

According to the various shapes of carbon nanoscaffold materials, in addition to the standard cylindrical shape, carbon nanoscaffold materials can also be divided into L-type, Y-type, or T-type and other different types. These different morphologies of carbon nanoscaffold materials are based on unique topologies. Moreover, there are uncertainties in the preparation process. Now, according to their morphology, carbon nanoscaffold materials can be classified into three types: blocking type, onion type, sea urchin type, variable diameter type, bamboo type, rosary type, spiral type, spindle type, and other abnormal types [11, 12].

2.2. Properties of Carbon Nanoscaffold Materials

2.2.1. Mechanical Properties.

The SP^2 hybridization of carbon atoms in carbon nanoscaffold materials makes the strength of carbon nanoscaffold materials very high. In ideal condition, the tensile strength of CNTs is about 800 GPa, and the shear strength is about 500 MPa. In addition, the strength of carbon nanoscaffold materials is about 100 times of steel, about 20 times of carbon fiber, the density of carbon nanoscaffold materials is one sixth of steel, and the weight is half of carbon fiber. The elastic modulus and hardness of carbon nanoscaffold materials are the same as those of diamond, and the CNTs have excellent softness and can keep the original shape after twisting, bending, and stretching. Due to the excellent mechanical properties of carbon nanoscaffold materials, it is called "super fiber" in the field of nanomaterials and has a very wide prospect [13, 14].

2.2.2. Thermal Properties.

Because CNT is large in aspect, heat is transmitted in the axial direction, and the thermal conductivity in the radial direction is average. In this study,

3000 K CNT extends only in the radial direction, and six ring structures remain on the wall of the tube. When the axial size of carbon nanoscaffold materials exceeds 10 nm, the thermal conductivity may reach 6000 W/m·k at room temperature and 280 W/m·k at low temperatures. In certain size ranges, carbon nanoscaffold material length and thermal conductivity are linear functions. Carbon nanoscaffold materials can be used as additives for composite materials and can help improve the thermal conductivity of composite materials [15, 16].

2.2.3. Electrical Performance.

The electrical properties of carbon nanoscaffold materials are very unique, which may show various conductive properties such as semiconductors and metals. The chiral classification of carbon nanoscaffold materials shows that the rotation angle of carbon nanoscaffold materials is determined by the integers n and M. the conductivity of carbon nanoscaffold materials is closely related to the rotation angle. In some studies, armchair carbon nanoscaffold materials exhibit excellent electrical conductivity when $n = M$. In the case of zigzag and chiral carbon nanoscaffold materials, $N - M = 3Q$ (q is an integer) denotes metallicity. When $nm = 3Q$ is not satisfied, the semiconductor property is indicated. The conductivity of carbon nanoscaffold materials is not only related to the size and rotation angle but also vulnerable to the influence of electric and magnetic fields. If the electric and magnetic fields are applied, carbon nanoscaffold materials will change from metal to semiconductor. The good conductivity and curvature radius of carbon nanoscaffold materials are very small, the open electric field is very low, and the field emission characteristics of carbon nanoscaffold materials are very good [17, 18].

2.3. Hip Joint Injury.

According to the BASRI hip scoring system for ankylosing spondylitis, >12 points were defined as radiation-induced femoral joint lesions. On the images, there are subchondral bone marrow edema, synovial fluid, abnormal synovial enhancement, or arthritis, which are considered to be signs of active inflammatory changes. Moreover, subchondral erosive destruction, articular cavity stenosis, sclerosis, and stiffness are considered to be the results of chronic inflammatory changes. Body fluid was defined as sufficient fluid around the neck of the leg or the inflated femoral joint capsule on T2 or stir images. Symptomatic femoral joint disease is defined as present or past pain or limitation of femoral joint motion [19, 20].

The hip joint with an abnormal X-ray was given a score of 1. The score of 0 indicates that the hip joint is normal; the score of 1 indicates that the hip joint may be abnormal; the score of 2 indicates that the hip joint is mildly abnormal and the joint space is narrowed significantly; the score of 3 indicates moderate abnormalities in the hip joint, and the joint space is >2 mm; the score of 4 indicates severe abnormalities in the hip joint, the bones have been deformed, and the contact range between the articular surfaces of the bilateral bones is >2 cm.

2.4. Common Sports Injuries and Events.

The following are the common sports injuries and events:

(1) Femoral head fracture: most of the complications of hip joint dislocation and easy injury items are white driving and car racing [21].

(2) Femoral neck fracture: the fracture of adduction or abduction is caused by osteoporosis and falling down, which is easy to be injured in the elderly who participate in sports.

(3) Femoral neck Palau fracture: race class periodic heavy load and easy to hurt events are long-distance runners and recruits.

(4) Hip joint sprain and synovium imbedding: sprained hind leg has "lengthening" phenomenon; you can easily get hurt in gymnastics [22].

(5) Dislocation of hip joint: anterior, posterior, and central dislocation and easy injury items are bicycle and car race [23].

(6) Femur tip slip: Sports injuries due to gymnastics and wrestling can easily lead to disorders of blood supply to the epiphysis.

(7) Osteoarthritis of the femoral head: excessive training in adolescence causes the bone supply disorder of the femoral epiphyseal; fragile events are gymnastics or long distance running.

(8) Hip joint disease: dancing too much can also cause hip injuries.

(9) Contracture and elastic effects of tibial tract: these may be associated with hip injections, and simple injury events are jumping [24].

(10) Iliopsoas key bounce and psoas muscle sliding: it is related to the slight over Zhong or "side leg" exercise, and the vulnerable items are gymnastics and dance.

(11) Bursitis: Gymnastics can also easily lead to iliac hematomas and femoral nerve palsy, hip hyperextension injuries or muscle strains when the buttocks hits the ground.

(12) Intertrochanteric fracture of femur and tendon strain and operation end disease: sprain or hip injury during hurdle and easy injury items are hurdle, gymnastics, and dance.

(13) Trochanteric bursitis of femur: the greater trochanter rubs against the iliotibial tract during running. The vulnerable event is middle and long distance running [25].

2.5. Hip Joint Movement Characteristics of Sports Athletes. The special physical characteristics of sports refers to the main physical characteristics shown in mechanics and biology for the purpose of maximizing sports efficiency under the permission of competition rules. In the new gymnastics, mastering the characteristics and training rules of sports is the precondition of physical training. Cognitive characteristic is an important link to improve the level of physical training. Understanding and mastering specific training rules is to improve training efficiency. Maintain the basic conditions of high-quality training for a long time. In the case of new sports, the flexibility of the hip joint can be improved more scientifically by correctly understanding the characteristics of the athletes' hip joint, correctly grasping the strength of the hip joint and understanding the characteristics of the hip joint. The wide movable area of the hip joint is one of the important sports characteristics of the player's hip joint [26, 27].

3. Nanoscaffold Material Preparation and Hip Joint Injury Treatment Experiment

3.1. Data of Experimental Objects. This data group collected 290 joint fractures and dislocation of sciatic nerve damage in my hospital from June to October 2019. They were 7-59 years old (average 32.83 ± 10.12 years). All patients have complete blood circulation, liver function, renal function, coagulation function, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and HLA-B27 gene determination, parathyroid hormone (PTH), osteocalcin, 25 hydroxyvitamin D3, end elongation peptide of N type I bone collagen, and B bone, as a result of reren's special placement determination test, Dr or joint CT examination of the pelvis, and iliac MRI results of the joint.

3.2. Preparation of TiO_2 Nanoscaffold Material Cladding Structure. Pure titanium is used for preheating, after removing the oxide film on the surface, grinding, cleaning, and drying. Electrochemical anodizing establishes an electrochemical anodizing system in which the titanium side is the anode and the platinum side is the anode. In the mixed solution system of the cathode, ammonium fluoride, and ammonium hydrogen phosphate, the oxidation voltage is controlled by a constant 15 V for 60 minutes. Scanning electron microscopy (SEM) confirmed that the coating structure of nanosized TiO_2 nanoscaffold material is TiO_2 nanoscaffold material. According to the various specifications required in the subsequent experiments, cylindrical titanium dioxide nanoscaffold material-coated titanium rods with a length of 30 mm and a diameter of 3 mm and a thin titanium dioxide nanoplate with a length of 10 mm and a width of 10 mm were fabricated. Put the sample into a steam pressure cooker at 120°C, kill the bacteria for 30 minutes, and then use it after ultrasonic cleaning and drying. Moreover, pure Ti metal samples are cut into the same size for use.

3.3. Preparation of TiO2 Nanoscaffold Material Coating Loaded with Gentamicin. A pipette was used to determine the concentration of 1 mg of the prepared intercontinental mycin solution (100 mg/mL), which was added to the prepared 10 mm × 10 mm TiO_2 nanoscaffold material-coated film and then removed. When the negative pressure device is opened in the dark, the suction value of negative pressure gradually rises, and the air pressure in the plastic pipe slowly drops to 0.01 KPa. After about 2 hours, the TiO_2 nanoscaffold material sheet was removed, and the surface of the TiO_2 nanoscaffold material sheet was cleaned with 20 mL

TABLE 1: Types of hip joint injury in sports.

Damage form	Male		Female	
	Number of injured	Proportion	Number of injured	Proportion
Muscle and muscle leg injury	22	20.3	30	48.5

Others	18	16.8	0	0

of 0.01 M phosphoric acid buffer, and the liquid used to detect ultraviolet light was recovered. The drug loading efficiency and mass of TiO_2 nanoscaffold materials with negative allergen were calculated according to the change of concentration of kanamycin in the solution. In the above experiments, the concentration of L-arginine solution was increased to 200 mg/mL and 300 mg/mL, and the experiment was continued under the same conditions. In the above experiments, the drug loading rates of TiO_2 nanoscaffold materials at various concentrations of rhizomycin were measured and compared.

3.4. In the Determination of Gentamicin Standard Curve, the Specific Steps Are as Follows:

(1) Weigh the allergen powder with a precision balance of 10 μ g, 25 μ g, 50 μ g, 100 μ g, 200 μ g, 500 μ g, and 1000 μ g, respectively, and dissolve them in 10 mL 0.01 M PBS buffer solution. Mix well, and use as standard solution for future use

(2) PBS buffer solution was prepared as blank control

(3) The UV absorption values of different concentrations of gentamycin standard solution were determined by UV spectrophotometer at 320 nm wavelength. The standard curve (UV absorption value and the concentration of gentamycin in the solution) was drawn between the two wavelengths, and the regression equation was established

(4) In the above experiments, 2 mL of intercontinental mycin solution measured in each round was completely vibrated. The ultraviolet absorbance value at 320 nm was measured, and the value was restored to the standard curve and regression equation to obtain the concentration of rhizomycin

4. Nanoscaffold Materials Combined with Rehabilitation Therapy for the Treatment of Hip Joint Injuries

4.1. Type and Frequency of Hip Joint Injury. According to the second standard of sports medicine, the types of injury are divided into muscle leg injury, joint injury, synovial fluid bag injury, bone injury, bone injury, and nerve injury. The types of hip joint injury tissue structure in sports are shown in Table 1.

According to the classification in Table 1 of the patients with femoral joint injury in our hospital, the histological types of hip joint injury of Chinese sports athletes were analyzed. The investigation shows that 48 of 290 sports athletes suffer from ligament injury, accounting for 67.7% of hip joint injury. 22 cases had muscle and tendon injury, and 12 cases had articular cartilage injury and capsule injury. Ligament injury ranks first in the type of tissue structure of hip joint injury. The main tissue structures of Chinese sports athletes are hip joint injury, ligament injury, muscle and tendon injury, articular cartilage injury, synovial fluid bag injury, and bone end injury. Some athletes were injured on the hip joint at the same time, which was very serious. The season of hip joint injury of athletes is shown in Figure 2.

According to Figure 2, 108 athletes who were injured in the femoral joint of the athletes were classified, and the injury season often occurred in winter and then continued in summer. And the spring and autumn players were injured. The main reasons are low temperature in winter, high muscle viscosity of athletes, poor preparation, and so on. In hot summer, athletes consume a lot of energy and can not supplement energy in time, and concentration force decreases.

4.2. Therapeutic Effect of Different Gender Hip Joint Patients Based on Nanoscaffold Material Combination Therapy. To exclude the impact of gender factors on the test results, we compared the differences between the two case groups. The distribution of hemoglobin, red blood cell, and red blood cell and the sedimentation rate of red blood cells were different statistically between men and women. In addition, the special arrangement of Austin starch ($t = 2.06$, $P = 0.041$), β-bone collagen ($t = 2.073$, $P = 0.040$), and t-pinp ($t = 2.070$, $P = 0.008$) also showed that these bone metabolism indexes were found to be statistically different between the two female groups There are no statistical differences. The experimental test results are shown in Table 2.

As can be seen from Table 2, although the number of cases in this survey is less than that of men, the possibility of hip joint injury is much higher than that of men.
Figure 2: Season of hip joint injury.

Table 2: Experimental results.

Project	Male		Female	
	Experience group	Control group	Experience group	Control group
Number of cases	67	108	34	24
WBC (10^9/L)	7.14 ± 3.29	8.43 ± 8.64	8.28 ± 6.52	7.36 ± 3.05
LYM (10^9/L)	1.86 ± 0.66	1.95 ± 0.63	1.88 ± 0.67	1.93 ± 0.77
RBC (10^9/L)	4.30 ± 0.62	4.52 ± 0.60	3.91 ± 0.75	4.05 ± 0.41
Hb (g/L)	116.36 ± 19.22	128.37 ± 22.14	104.76 ± 15.12	113.18 ± 13.31
PTH (pg/mL)	27.63 ± 12.47	30.76 ± 17.77	33.64 ± 11.85	37.67 ± 25.33
t-PINP (ng/mL)	84.57 ± 68.48	59.98 ± 52.73	56.74 ± 74.32	42.11 ± 30.07
Osteocalcin (ng/mL)	29.77 ± 19.25	22.54 ± 24.47	20.21 ± 15.35	20.21 ± 8.61

WBC: white blood cell; LYM: lymphocyte; RBC: red blood cell; Hb: hemoglobin; PTH: parathyroid hormone; t-PINP: amino extension end of total type I collagen; osteocalcin: osteocalcin.

The clinical symptoms of hip joint injury are typical groin pain and pain accompanied by dyskinesia of femoral joint. The pain may be caused by acute inflammation and changes of hip joint capsule and synovial nerve. In this study, hip symptoms and image observations were completely inconsistent. This may be related to the following reasons: hip pain and exercise restriction can affect personal subjectivity. The experimental results are shown in Figure 3.

In Figure 3, the number of red blood cells, hemoglobin, and distribution range of red blood cells have a great relationship with femoral joint injury, which can be seen that this is related to hip joint score. The red blood cell distribution width (RDW) and the component of red blood cell routine width reflect the variability of red blood cells in circulation. Traditionally, RDW is a reference index to determine anemia. In many studies, RDW is associated with many diseases, such as polycystic ovary syndrome, coronary artery disease, and heart failure. Inflammation may be the main reason for the

relationship between these diseases and RDW, and RDW can be used as an indicator of chronic inflammation.

4.3. Analysis of Hip Joint Injury in Different Age Groups. Through the investigation of the injury age of athletes, reflect the characteristics of injury age of athletes. As shown in Figures 4, 290 sports athletes were investigated. In the survey, the main age is 12-17 years and over 50 years, accounting for 34.8% and 37.6% of the players' questionnaire survey, a total of 72.4%. The age distribution of hip joint injury athletes is shown in Figure 4.

As can be seen from Figure 4, women aged 9 to 14 are more injured, while men aged 10 to 16 are more injured. This may be related to the athlete's puberty and joint flexibility. Adolescent athletes are prone to hip injuries due to long-term exercise because their bones are still growing. Over the age of 35, the number of patients with the disease continues to increase with age; both men and women are the same. This is because the physical strength of middle-aged and
FIGURE 3: Experimental results.
FIGURE 4: Age distribution of hip injury athletes.

elderly people decreases, the bones gradually relaxed, and a lot of problems are accumulated between joints.

4.4. Treatment of Hip Joint Injury with Nanoscaffold Material Drug Loading. Staphylococcus aureus was cultured for 4 hours, and Staphylococcus aureus was observed by a laser scanning confocal microscope on three different materials (pure Ti metal, titanium dioxide nanoscaffold material coating structure material without rhizomycin, and titanium dioxide nanoscaffold material coating structure material containing rhizomycin) on the surface. The colony number and density of Staphylococcus aureus on the surface of pure Ti metal and titanium dioxide nanoscaffold material coating structure material without sulfur group mildew increased significantly. The number of Staphylococcus aureus on the surface of titanium dioxide nanoscaffold material coating

structure material was less than that on pure Ti metal surface, but there were still a large number of Staphylococcus aureus appeared throughout the field of vision, but not more, which is obviously concentrated. There was no significant change in the number of Staphylococcus aureus on the surface of titanium dioxide nanoscaffold material coating with rhizomycin compared with that observed in 1 hour. The therapeutic effect of different materials of nanoscaffold material is shown in Figure 5.

It can be seen from Figure 5 that the colonies of Staphylococcus aureus on the surfaces of three different materials (pure Ti free, titanium dioxide nanoscaffold material coating structure material containing past mycin, and titanium dioxide nanoscaffold material coating structure material containing past mycin) after incubation for 1 hour and 4 hours were compared by using image Pro software under a laser
FIGURE 5: Therapeutic effect of different materials of nanoscaffold materials.

scanning confocal microscope. Regardless of the incubation time of 1 hour or 4 hours, the count of Staphylococcus aureus on the surface of titanium dioxide nanoscaffold materials coated with gentamicin was significantly lower than that of the information group, and the difference was statistically significant ($P < 0.5$). After 1 hour, the amount of S. aureus and S. aureus in the titanium dioxide nanoscaffold material coating material group was less than those on the pure Ti metal surface, but the difference was not statistically significant. After 4 hours of culture, the number of Staphylococcus aureus in the titanium dioxide nanoscaffold material coating structure material group was much lower than that of pure Ti metal surface, and the difference was significant.

5. Conclusion

The initial "explosive" release characteristics of TiO2 nanoscaffold material coating with rhizomycin can not play a long-term antibacterial effect in vivo. In animal experiments, Staphylococcus aureus is a common clinical bacterium, which has no obvious effect on the rare fungal infection after artificial joint replacement. In addition, the team has a small number of experimental animals, and the results may be biased. The clinics also have individual differences. Animal experiments alone cannot be extended to clinics. Through the company's internal experiments, it has been confirmed that the titanium dioxide nanoscaffold material coating structure material filled with rhizomycin can effectively inhibit the initial occurrence of infection around the artificial joint after artificial joint replacement, and it has a new therapeutic scheme significance for clinical prevention of infection around artificial joint after artificial joint replacement.

In this study, although there is no significant difference in age and disease course between patients with hip joint injury and those with normal hip joint, according to the Spearman correlation analysis, the degree of hip joint injury is negatively related to the age of onset; that is, the lower the age of onset, the more hip joint occurs. The possibility of damage will increase. There were fewer cases in women than

in men in this study, but the probability of hip injury was much higher than in men. The clinical symptoms of hip joint injury are typical inguinal pain and pain accompanied by hip joint dyskinesia. The pain may be caused by acute inflammation or changes in the hip capsule and synovial nerves. This conclusion has great reference significance for promoting the treatment of hip joint injury.

The injury rate of hip joint is 47%, which is the main injury site of Chinese sports athletes. There is a positive correlation between the training years of Chinese sports athletes and the incidence of hip joint injury. Training, talent selection, rules and technology development, nutrition, and other factors are the main causes of hip joint injury of sports athletes. Due to the coach's improper guidance on psychology, cultural quality, flexible sports, clothing, and venue equipment and other factors, it will also have different degrees of impact on sports athletes' hip joint injury. The main effective countermeasures to prevent hip joint injury are to pay attention to scientific and reasonable training methods, strengthen the muscle strength training around the hip joint of athletes, strengthen the standardization of technical sports, do a good job in proper preparatory activities, and establish a scientific Hip protection selection mechanism, improve the public's attention to hip protection, and promote the safety of outdoor sports.

The first-order phase transition compounds have attracted widespread attention from refrigeration enterprises and scientists due to their giant magnetocaloric effect and refrigeration temperature region spanning room temperature. Magnetic substances are crystal structures composed of magnetic ions or atoms with a certain thermal motion or vibration. This research mainly discusses the multisource coordination optimization of magnetic declination thermoelectric material efficient power generation device and distribution network. In this study, large doses of MnFe(P,Si) compounds with different ratios were prepared. The reason for choosing a large dose is that the properties and structures of the samples prepared in a large amount and a small amount will be more or less the same for the samples fired in the same proportion and in the same process. At the same time, mass production also prepares for future mass production. Thermomagnetic power generation described in this study is a form of power generation that converts thermal energy directly into electrical energy. The conversion of thermal energy to electric energy is realized by the change of magnetization in the closed coil by the thermomagnetic material in the magnetic field environment, and then, the change of the magnetic flux in the closed coil is realized. The distribution network refers to the power network that receives electrical energy from the transmission network or regional power plants and distributes it locally through distribution facilities or distributes it to various users step by step according to the voltage. It is composed of overhead lines, cables, towers, distribution transformers, isolating switches, reactive power compensators, and some ancillary facilities. A network that plays an important role in distributing electrical energy in the power grid. This research starts with the active distribution network scheduling priority and the distribution network scheduling coordination control framework. Combined with the scheduling and operation characteristics of each component in the distribution network, the coordinated optimization scheme of the distribution network and the source-network load-storage coordinated control framework are investigated and analyzed. The scheduling resources of the model include the power of the substation flowing into the distribution network, the output of the adjustable distributed power source, the output value of the energy storage element, the closing status of the tie switch, and the section switch. In the study, it was found that when the Fe content was 0.63, the Curie temperature of the compound could reach 273 K at the highest. Scientifically designing a thermomagnetic power generation demonstration device is an important part of the realization of thermomagnetic power generation. The magnetic declination thermoelectric materials designed in this study will help to improve the power generation efficiency.

1. Introduction

The rapid development of nanotechnology and advanced material synthesis technology provides convenience for the continuous improvement of the dimensionless thermoelectric figure of merit of thermoelectric materials. This in turn promotes thermoelectric power generation technology to play an active role in civil fields, such as automobiles and ships. Thermoelectric power generation technology has both social and economic benefits in the recycling and reuse of industrial waste energy.

Although the power generation efficiency of the energy system is reduced when the scale is reduced, its consequent reduction in transmission losses makes people see the feasibility of studying such systems. As a new microminiature energy source, the microthermoelectric power generation system has no moving parts, reliable operation, no noise, and low pollution. It can be an ideal solution as a miniature power supply for electronic systems. Compared with traditional energy, new energy has many advantages, but due to various technical defects, there is no new energy that can replace the dominant position of fossil energy in the energy structure.

It gives the temperature distribution function in the magnetic declination thermoelectric system structure according to the energy relation. It also uses the existing thermoelectric module parameters to establish continuous mathematical models for the one-dimensional symmetric and two-dimensional symmetric thermoelectric system structures. It also gives a discrete mathematical model for the distribution law of thermocouple pairs. On this basis, necessary parameter corrections were made to the model in combination with factors such as heat conduction process, structural gap, energy dissipation, and the adoption of porous structure. Thermocouples are temperature measuring elements commonly used in temperature measuring instruments. It is based on making full use of the continuity of the temperature distribution function of the system and discretizing the thermocouple pair. It performs multivariate optimization on the parameters of the thermoelectric system structure model. Based on the design goals, this paper proposes design indicators such as system efficiency function and volume energy density function and obtains the optimal value range of the system structure size and main model parameters.

2. Related Work

As a new microminiature energy source, the magnetic declination thermoelectric power generation system has no moving parts, no noise, reliable operation, and low pollution. It can be used as an ideal solution for the micropower supply of electronic systems. Magnetic declination refers to the angle between the magnetic meridian at any point on the earth's surface and the geographic meridian. Because compass and magnetic compass are the simplest devices to measure magnetic declination, the history of discovery and measurement of magnetic declination is also very early. Takahashi et al. believed that the power package dispatch system is expected to become one of the advanced distribution systems for controlling power, providing energy on demand, and reducing energy consumption. They designed and experimentally verified a power packet router to implement a networked power packet distribution system. Previously developed routers forwarded power packets directly to the load. And the new router forwards the packet to the other router with an information tag reattached to the power payload. In addition, new routers can adjust the start time of forwarding received power packets to other sites, thereby taking advantage of the router's integrated storage capacity

[1]. Wang and Lin studied the Minimum Distribution Cost Problem (MDCP) for a flow model of specialized manufacturing networks in order to simulate the distillation or decomposition of products in some manufacturing processes [2]. Ravadanegh et al. developed an integrated approach to the problem consisting of power distribution system reconfiguration, capacitor allocation, and simultaneous sizing and siting of renewable energy sources. It also improves the accountability and system performance parameters of the power system. They looked for solutions that are closer to the characteristics of reality. Load forecasts, market price errors, and uncertainties associated with variable output power of wind-distributed generators were all taken into account. They adopted NSGA-II combined with fuzzy set theory to solve the above multiobjective problem. The scheme they proposed ultimately resulted in a solution with minimum voltage deviation, maximum voltage stability, less contamination, and lower cost. Costs include new equipment installation cost, reconfiguration cost, power loss cost, reliability cost, cost of purchasing energy from the electricity market, line upgrade cost, and operation and maintenance cost of distributed generation [3]. Mehmood et al. believed that the life of a battery in a battery energy storage system (BESS) is affected by various factors such as the battery's operating temperature, depth of discharge, and the amount of charge/discharge current supplied to or drawn from the battery. They found the optimal location and size of the BESS for voltage regulation in power distribution systems [4]. Kulmala et al. believed that congestion management is one of the core drivers of smart power distribution systems. Distributed energy sources were used for network control for cost-effective network interconnection of distributed generation (DG) and better utilization of network assets. The main purpose of congestion management was to prevent voltage violations and overload the network. Congestion management algorithms can also be used to optimize network status. They proposed hierarchical and distributed congestion management concepts for future distribution networks with large-scale DG and other controllable resources in medium- and low-voltage networks. The control concept aims to run the network at the lowest cost while maintaining an acceptable network state. The hierarchy consists of three levels: the primary controller operates based on local measurements, the secondary control optimizes the set point of the primary controller in real-time, and the tertiary control utilizes load and production forecasts as its inputs. It implements network reconstruction algorithms and connections to the market. The primary controller is at the connection point of the controllable resource. The secondary controller is located in the primary and secondary substations, and the tertiary control is located in the control center. Therefore, the control is spatially distributed and operates on different time scales [5]. Mohtashami et al. proposed a multiyear distribution network planning optimization model. This was used to manage the operations and capacity of distribution systems with significant penetration of distributed generation (DG). Models take into account investments in traditional network and smart grid technologies. It includes dynamic line ratings, quadrature boosters, and

active network management. It also optimizes the settings of network control devices and takes into account their network cut DG output access arrangements (corporate or non-corporate) when necessary. They had carried out a series of studies on the UK 33 kV actual distribution network to test the model. The main purpose of the research was to evaluate and compare the performance of different investment methods, namely, incremental investment and strategic investment. The study also demonstrated the ability of the model to determine the optimal DG connection point to reduce the overall system cost [6]. Chen et al. through Matlab modeling and simulation proved that the algorithm was suitable for distributed generation (DG) distribution network fault location, which has a certain rapidity and fault tolerance [7]. The introduction of new energy will bring new problems and inconveniences in energy conversion, management, operation, etc., which requires the study of new supporting technologies for coordination. With the development of society, the depletion of fossil energy and the indiscriminate exploitation of resources has led to environmental deterioration, and the situation faced by human beings has become more and more severe. Under the current situation, many countries are vigorously developing green energy and have made considerable achievements. The introduction of new energy will bring new problems and inconveniences in energy conversion, management, operation, etc., which require the study of new supporting technologies for coordination. Therefore, how to comprehensively utilize new energy and traditional energy and realize the complementary advantages between the two is an important issue we are currently facing. As a developing country, China is developing rapidly, and energy consumption and heat emission are topics that cannot be underestimated. A large amount of heat energy emissions will not only bring environmental problems but also aggravate natural disasters such as the greenhouse effect and acid rain.

3. Methods for High-Efficiency Power Generation of Magnetic Declination Thermoelectric Materials

3.1. Thermoelectric Materials for Power Generation. Assuming that the internal load of a thermoelectric material module is R_L, a heat source q can also be added to provide heat so that the temperature difference between the two ends of the conductor is maintained by $T_1 - T_2$. The potential difference generated across the conductor is $(S_2 - S_1) * (S_1 - S_2)$, and the power generated is [8]

$$W = \left[\frac{(\beta_P - \beta_N)(T_1 - T_2)}{R_L - R} \right]^2 R_L. \quad (1)$$

Considering the heat flow provided by the heat source, most of the heat passes through the conductors by means of heat conduction. But there are parts of the heat flow that need to be balanced against the Peltier effect and Joule heating in general. The Peltier effect means that when a current passes through a loop composed of different conductors, in

addition to irreversible Joule heat, the junctions of different conductors will endothermic and exothermic phenomena with different current directions.

$$Q = k(T_1 - T_2) + (\beta_1 - \beta_2)IT_1 - \frac{I^2R}{2}. \quad (2)$$

The current density I is

$$I = \frac{(\beta_1 - \beta_2)(T_1 - T_2)}{(R_1 + R_2)}. \quad (3)$$

Therefore, the choice of load is generally to achieve maximum efficiency [9]

$$M = (1 + ZT)^{1/2}. \quad (4)$$

It gets the efficiency formula:

$$\eta = \frac{T_1 - T_2}{T_1} \cdot \frac{M - 1}{M + \chi T_1/T_2}. \quad (5)$$

It can be seen that the larger the M, the higher the efficiency. However, the size of M is mainly related to Z and temperature, so the value of ZT has a great influence on the efficiency of TEG materials.

For the design of thermoelectric sheets and the modeling of microminiature thermal structures, this paper is aimed at designing a microminiature thermoelectric conversion system as efficient as possible. Thermoelectric conversion systems are usually composed of thermal structures and thermoelectric conversion modules. Therefore, a thermoelectric unit model that comprehensively considers the thermal model and the electrical model is established. After that, it will build a complete thermoelectric conversion system model on this basis. The materials used to manufacture thermoelectric generators or thermoelectric coolers are called thermoelectric materials, which are materials that can realize the interactive transformation of electrical energy and thermal energy.

3.2. Principle of Thermomagnetic Power Generation Device. When the thermomagnetic power generation material (Mn, Fe)2(P, Si) is in a strong magnetic field, when the hot water passes through, when the temperature is higher than the Curie temperature of the thermomagnetic power generation material, the thermal motion of the atoms intensifies. The kinetic energy possessed by the thermal motion of atoms is sufficient to overcome the exchange between spin-magnetic moments. The spin moment of the magnetic atoms inside the material changes from parallel arrangement to disorder, and the magnetization becomes zero instantaneously. The thermomagnetic power generation material is transformed from a ferromagnetic state to a paramagnetic state, and the magnetic field becomes smaller. When the magnetic flux passing through the induction coil decreases, an induced current is generated in the induction coil. Conversely, when cold water passes through, the temperature of the thermomagnetic power generation material is lower than the Curie

temperature, and the atomic thermal motion weakens when the temperature decreases. The exchange action between the spin magnetic moments makes the magnetic atom spin magnetic moments return to the parallel arrangement from the disorderly arrangement. The magnetization changes from zero to a certain value instantaneously, and the thermomagnetic power generation material changes from a paramagnetic state to a ferromagnetic state. When the magnetic field increases, the magnetic flux passing through the induction coil increases, which will also generate a reverse induced current in the induction coil. Hot water and cold water alternately pass through the induction coil plastic tube thermomagnetic power generation material, and the ferromagnetic state and paramagnetic state of the thermomagnetic power generation material periodically transform each other near the Curie temperature. This will generate a periodic alternating induced current and realize the direct conversion of thermal energy into electrical energy. The principle of thermomagnetic power generation device is shown in Figure 1. For the design of thermoelectric power generation sheet, it is generally required that the larger the output power per unit volume, the better, that is, the larger the volume-specific power, the better. In the actual design process, when the area and other parameters of the thermoelectric power generation sheet are determined, and the length of the galvanic coupler arm is short to a certain extent; the output power of the power generation sheet will reach the maximum. If it continues to shorten, its power will show a downward trend [10].

For the energy storage devices connected in the network, the property rights are set to be owned by the distribution network operation and maintenance company, and they can participate in the operation and scheduling of the distribution network. Its scheduling cost C_t^E:

$$C_t^E = \sum \lambda P_t^E \Delta T \qquad (6)$$

For any distribution network node i, the power balance formula in polar coordinate form can be listed as follows [11]

$$P_i = U \sum U (G \cos \beta + B \sin \beta) \qquad (7)$$

$$Q_i = U \sum U (G \cos \beta - B \sin \beta) \qquad (8)$$

Among them: P_i and Q_i are the injected active and reactive power of node i, respectively [12].

When using Newton-Raphson's method to solve a nonlinear system of equations, it is necessary to write out its modified equations [13]

$$\Delta P_i = P - U_i \sum U (G \cos \beta + B \sin \beta), \qquad (9)$$

$$\Delta Q_i = P - U_i \sum U (G \cos \beta - B \sin \beta). \qquad (10)$$

3.3. $Mn_{1.23}FexP_{0.3}Si_{0.3}$ Compound Structure and Magnetic Test

3.3.1. Material Preparation.
The Mn flakes, Fe powder, P powder, and single-crystal Si block used in the experiment are calculated in a ratio of $Mn_{1.23}FexP_{0.3}Si_{0.3}$ ($x = 0.6$, 0.63, 0.63, 0.67, 0.7, and 0.73). It is weighed with an electronic balance. It was ball milled with a high-energy planetary ball mill (pulverisette-3) for 10 h under argon protection. It then precompresses the sample into a block under the pressure of 8 T and then puts it into a quartz tube for vacuuming (vacuum degree < 10-3 Pa), fills it with argon gas to 2×10^3 Pa, and seals the quartz tube. The sealed samples were placed in a vertical annealing furnace for sintering at 11009°C for 2 h and then lowered to 830°C for 20 h and then quenched.

3.3.2. Sample Characterization and Performance Measurement.
The X-ray diffraction (XRD) spectrum of the sample was measured with a Philips PW-1830 X-ray diffractometer (Cu-Kα, $h = 0.134184$ nm) at room temperature (293 K), the measurement step was 0.01°, and the collection point time was 4 s. It measures the magnetic properties of compounds with a LakeShore 7407 vibrating sample magnetometer [14].

Voltage constraints:

$$V_{K,\min} < V_K < V_{K,\max}, \qquad (11)$$

where V_k is the voltage at node k [15].
Line current constraints:

$$I \leq I_{l,\max}, \quad l \in n_l. \qquad (12)$$

In the formula, I_l is the number of branches in the power supply island network after the power supply is restored. $I_{l,\max}$ is the maximum current value allowed for line I.

Microgrid output constraints [16]

$$P_{j,\min} \leq P \leq P_{j,\max}. \qquad (13)$$

$P_{j,\max}$ and $P_{j,\min}$ are the upper and lower limits of the active power sent by the microgrid j, respectively [17].

Charge load available capacity constraints [18]

$$EV \leq EV_{k,\max}. \qquad (14)$$

$EV_{k,\max}$ is the upper limit of the available capacity of the charging power [19].

The dispatch model takes the total operating cost of the distribution network in a single dispatch period as the objective function.

$$\min F = \sum \left(C_t^g + C_t^{DG} + C_t^{ESS} + C_D^t \right). \qquad (15)$$

In the formula, time t represents the current time period [20].

The cost of purchasing electricity from the grid:

$$C_b = \sum_g^{NG} CP \Delta T. \qquad (16)$$
Figure 1: Principle of thermomagnetic power generation device.

Among them, g represents the feeder at the exit of the b substation, and NG represents the total number of substation feeders connected to the distribution network.

3.4. Design of Thermomagnetic Power Generation Device.
The thermomagnetic power generation device is composed of six parts: magnetic field system, cold and heat source system, automatic control electronic switch, induction coil, sensitive ammeter, and thermomagnetic power generation material.

(1) Magnetic field system: the strong magnetic material NdFeB is used to make a cylindrical strong permanent magnet as the driving magnetic field. The length is 20 cm, the inner diameter is 9 cm, the outer diameter is 20 cm, and the maximum magnetic induction intensity is $B = 0.8$ T. The direction of the magnetic field is radial. The plastic tube with the magnetic material placed in the outer coil is placed in the inner magnetic field area of the cylindrical strong magnet, and its function is to make the thermomagnetic power generation material reach saturation magnetization

(2) Cold and heat source system: the heat source is a domestic water heater, the maximum temperature can reach 100°C; the cold source is tap water

(3) Automatic electronic switch: the two electronic switches are, respectively, connected with the heat source and the cold source water inlet pipe. The electronic switch is controlled by a single-chip microcomputer. The hot and cold water passes through the thermomagnetic power generation material in the plastic pipe alternately, and different times can be set according to needs. The thermomagnetic power generation material periodically changes in cold and heat

(4) Induction coil: the induction coil is wound on a plastic tube by a hand-winding machine, and the wound coil is painted with insulating paint to protect the coil. After the thermal-magnetic power generation material is installed inside the plastic pipe, the two ends are cut with nylon rods and the outside is sealed with a rubber sheet

(5) Microammeter: measure the thermal-magnetic power generation current, and use wires to connect the induction coil and the microammeter [21]

(6) Thermomagnetic power generation material: the annealed thermomagnetic power generation material is cut into 1.3 mm thin slices with a wire cutting machine. The thin copper wires are used to connect them, leaving a gap in the middle to facilitate the passage of water and improve the heat exchange capacity between the material and water. The cut thermomagnetic power generation material can also be turned into small particles. The thermomagnetic power generation device designed in this study is shown in Figure 2

3.5. Multisource Optimization Model for Microgrid Power Supply Recovery.
After the distribution network fails, the real-time monitoring of the DMS is used to obtain the sum of the power available for all microgrids in the outage area $\sum L_i$ and the total power $\sum MG_j$ of the load in the outage area, and the microgrid power supply recovery scheme is selected [22].

$$\sum L_i \le \sum MG_j. \tag{17}$$

After the power distribution network fails, the real-time monitoring of DMS is used to obtain the sum of the external power of all microgrids in the nonfault outage area $\sum MG$
FIGURE 2: The thermomagnetic power generation device designed in this paper.

and the total power of the load in the outage area $\sum L_i$.

$$\sum L - \sum EV \leq \sum MG \leq \sum L_i. \qquad (18)$$

The multilevel rapid power supply restoration scheme proposed in this study considers the economics of network operation after the power supply of the distribution network is restored. Therefore, in the optimal power flow mathematical model, the optimization objective is to minimize the active network loss of the power supply island after the power supply is restored [23]

$$\min M = \min \sum I^2 R, \qquad (19)$$

where I is the line transmission current; R is the line resistance.

The theoretical output power of a single thermocouple pair tends to increase with the increase of the temperature difference between its two sides in a large range and also tends to increase with the increase of the current. In comparison, the effect of temperature difference on the thermocouple's power generation efficiency is more obvious. Tide constraints:

$$U \sum_{J=1} YU = P + Q, \qquad (20)$$

where P and Q are the values of active power and reactive power injected by node i, respectively.

4. Multisource Coordination Optimization Results of Thermoelectric Material Efficient Power Generation Device and Distribution Network

Figure 3 shows the XRD spectrum of the $Mn_{1.23}Fe_xP_{0.3}Si_{0.3}$ series compounds. It can be seen from the XRD spectrum that when the Fe content is 0.63, it is a single Fe_2P-type hex-agonal structure. The impurity phase of this series of compounds is one of $(Mn, Fe)_3Si$ or $(Mn, Fe)_3Si_3$. With the increase of Fe content, the first impurity phase is $(Mn, Fe)_3Si_3$. Then, the peak intensity decreased gradually until the Fe content was 0.67, the $(Mn, Fe)_3Si$ impurity phase appeared, and then the peak intensity gradually increased.

It can be seen from Table 1 that when x is between 0.6 and 0.63, the unit cell volume V and the lattice constant a gradually increase. When x is between 0.63 and 0.73, the change rule of the unit cell volume V is not obvious. The lattice constants and unit cell volumes of the $Mn_{1.23}Fe_xP_{0.3}Si_{0.3}$ series compounds are shown in Table 1.

The change of magnetization with temperature of $Mn_{1.23}Fe_xP_{0.3}Si_{0.3}$ ($x = 0.6, 0.63, 0.63, 0.67, 0.7,$ and 0.73) series compounds is shown in Figure 4. The cooling and heating curves do not overlap, indicating that there is thermal hysteresis. When the Fe content is 0.63, the thermal hysteresis of the compound is at least 1 K. When the Fe content is 0.6, the maximum thermal hysteresis of the compound is 21 K. The Curie temperature (Tc) of a compound can be determined by taking the partial derivative of the M-T heating curve. It can be seen that when the Fe content is 0.63, the maximum Curie temperature of the compound is 273 K. When the Fe content is 0.6, the minimum Curie temperature of the compound is 207 K.

$Mn_{1.23}Fe_xP_{0.3}Si_{0.3}$ samples were prepared and cut into 1.3 mm thin slices by a wire cutting machine. The samples were taken with masses of 30 g, 100 g, 130 g, and 200 g, respectively, and put into a thermomagnetic power generation device with $N = 1030, 2000, 2700,$ and 3300 coil turns, and the hot water temperature was about 80°C. Through the analysis of the measurement data, whether it is a flake sample or a particle sample, the induced current increases with the increase of the sample mass. The reason is that the mass increases, the total number of magnetic atoms increases, the total magnetic moment increases, and the change rate of the total magnetic flux of the sample around the Curie temperature increases. For samples of the same mass, the induced current produced by the granular sample
Figure 3: XRD spectra of $Mn_{1.23}FexP_{0.3}Si_{0.3}$ series compounds.

Table 1: Lattice constant and unit cell volume of $Mn_{1.23}FexP_{0.3}Si_{0.3}$ series compounds.

x	a (nm)	c (nm)	V (nm^3)
0.6	0.6030	0.3414	0.1082
0.63	0.6064	0.3399	0.1083
0.63	0.6063	0.3404	0.1083
0.67	0.6060	0.3407	0.1084
0.7	0.6048	0.3407	0.1079
0.73	0.6012	0.3480	0.1089

is greater than that produced by the flake sample. The variation of the induced current is shown in Figure 5.

When a sample of the same mass is placed in the coil, the induced current I increases with the increase of the number of turns N of the coil. According to Faraday's law of electromagnetic induction, the induced electromotive force is proportional to the number of turns of the coil. The relationship between the induced current and the number of coil turns is shown in Figure 6.

Figure 7 shows the XRD diffraction of Sn-bonded M $n_{1.23}Fe_{0.63}P_{0.3} - xSi_{0.3} + x$ series composite compounds. Through qualitative analysis of XRD patterns, it can be known that the compound and the main phase are still Fe_2P-type structure of MnFe(P,Si).

This shows that the main phase structure of the bonded compound has not changed (A ($Mn_{1.23}Fe_{0.63}P_{0.48}Si_{0.32}$), B ($Mn_{1.23}Fe_{0.63}P_{0.46}Si_{0.34}$), C ($Mn_{1.23}Fe_{0.63}P_{0.44}Si_{0.36}$), and D ($Mn_{1.23}Fe_{0.63}P_{0.42}Si_{0.38}$)). There is an impurity peak around 43° which is Fe_3Si_3. After data comparison, it is found that the peaks at 31.7° and 32.3° belong to metal Sn. Both metallic Sn and impurity peaks have negative effects on the magnetocaloric properties of the compounds themselves.

The lattice constants and unit cell volumes of the M $n_{1.23}Fe_{0.63}P_{0.3} - xSi_{0.3} + x$ series bonding compounds are

shown in Table 2. From Table 2, we can see that the lattice constants a and b and the unit cell volume V have no significant changes. It can only be seen that the lattice constant a slowly decreases, b increases slowly, and the unit cell volume V gradually increases. The lattice constants and unit cell volumes of the $Mn_{1.23}Fe_{0.63}P_{0.3} - xSi_{0.3} + x$ series bonding compounds are shown in Table 2.

The output results of the nonlinear active distribution network multisource collaborative optimization scheduling model are shown in Table 3.

Because this model is linear, the linear programming solver CPLEX is used to solve it. The calculation time is 2.9 s, and the total running cost is 27728.922 yuan. It can be seen that the fast calculation method can greatly improve the solution speed while maintaining high accuracy. The improvement of computational efficiency brought by the linear algorithm is more obvious in solving large-scale systems with multiple nodes and multiple times. The planned output power of the substation within 24 hours is shown in Figure 8.

Based on the multisource collaborative optimization nonlinear scheduling model of network reconfiguration, the SBB mixed integer nonlinear programming solver is called in GAMS, and the optimal collaborative scheduling scheme of active distribution network energy storage, flexible load, and tie switch position control is obtained. Compared with the operation results obtained by the dispatching model without considering dynamic reconfiguration, it can verify the effective application of dynamic reconfiguration in the coordinated optimal operation of the distribution network system. The planned output of the substation is shown in Table 4.

Strategy 2 considers energy storage factors more than strategy 1. The total operating cost of the active distribution network is reduced by 3383.42 yuan, and the electricity sales revenue from the distribution network to the main network
FIGURE 4: Magnetization of $Mn_{1.23}FexP_{0.3}Si_{0.3}$ ($x = 0.6, 0.63, 0.63, 0.67, 0.7$, and 0.73) series compounds as a function of temperature.
FIGURE 5: Variation of induced current.

is 996.03 yuan, an increase of 734.13 yuan compared with strategy 1. The operating costs of the distribution network under different dispatching strategies are shown in Table 5.

The operator's distributed power parameters are shown in Table 6.

The matching and optimization process of each parameter inside the thermoelectric power generation device is an extremely comprehensive problem. It is not only related to material technology but also related to factors such as structure selection and layout. Therefore, another important research direction to improve the system thermoelectric power generation efficiency is to balance the influence of various parameters on the output power and thermoelectric conversion efficiency to seek the optimal matching. The load state of the active distribution network is shown in Figure 9.

5. Discussion

In the past few hundred years, with the rapid development of industrialization and urbanization all over the world, the demand for energy has also increased rapidly. The excavation and utilization of large-scale fossil energy have resulted in a sharp decrease in energy reserves, and at the same time, the harmful substances produced during energy consumption also directly lead to the deterioration of the environment. At this stage, adjusting the energy structure transformation is an effective way to solve the current global energy and environmental problems.

The access of distributed power sources changes the power flow direction and network structure of the distribution network. When its penetration rate is too high, it may

cause the voltage limit of multiple distribution network nodes mainly access nodes to be exceeded, and the power flow will be sent back to the upper-level power grid. In addition, the randomness and intermittency of the distributed power supply itself will also cause problems such as voltage

fluctuations in the distribution network. In the military, the use of a microthermoelectric power generation system can greatly improve the combat effectiveness of the army. Microthermoelectric power generation systems can provide

the biggest weakness of the existing technology, storage battery, fuel cell, etc., is that the time that can provide electric energy is short. The microthermoelectric power generation system can provide a relatively long power supply in a small volume.

Distributed power generation is an important way to utilize new energy. With the advancement of energy transformation and the increase of energy demand, the penetration rate of distributed power generation in the distribution network is gradually increasing. The large-scale access of DG has changed the structure of the original distribution network. Coupled with the uncertainty of DG's own output, when it is connected to different capacities and different locations, it will have different effects on the operating characteristics of the distribution network such as voltage distribution. Combined with the distribution law of the temperature field and its potential field, comprehensively considering the output characteristics and structural reliability of thermoelectric power generation, the parameters of the thermoelectric power generation device are optimized and matched, and a reasonable structural layout scheme is designed. It improves the thermoelectric conversion efficiency while reducing reliability problems caused by mechanical stress and environmental factors.

power drives for military robots or military electronic equipment. When military robots are used for reconnaissance, their volume is generally relatively small due to the need for concealment. In field operations, the conventional power system has been unable to ensure the smooth flow of military communications, which requires the miniaturization of the power system. In these cases, energy supply is very important. In addition to the characteristics of large volume,

FIGURE 9: Load status of active distribution network.

In addition to increasing the temperature of the heat source, improving the heat dissipation conditions of the cold source and rationally arranging the cooling system are also effective ways to improve the thermoelectric conversion efficiency of the system and improve the performance of the system. First of all, choosing a reasonable heat exchange method and heat exchange medium, such as oil cooling, air cooling, water cooling, or phase change heat, can improve the performance of the system to a certain extent. Secondly, optimizing the shape and structure of the radiator components and increasing the heat dissipation area of the radiator components are important measures to improve and maintain the system temperature difference.

The characteristics of thermoelectric power generation devices make such devices play a more important role in plateau weather stations, outposts, and other places where electricity is difficult to use. When natural gas or oil pipelines pass through desolate areas, the combustion heat of natural gas or oil can be used to provide them with a temperature difference working environment. The performance of magnetic declination thermoelectric materials is also related to temperature difference. This means that both the thermal conductivity and the electrical conductivity of the material will affect the thermoelectric conversion efficiency of the material.

6. Conclusion

The thermal conductivity and electrical conductivity of magnetic declination thermoelectric materials are realized by the movement of internal carriers. Metal Sn and metal Zn are light metals with low melting point and good electrical conductivity. The powder compound of metal Zn or metal Sn and MnFe(P, Si) material is mixed uniformly, sealed in a quartz tube under the protection of high-purity argon gas, and sintered near the melting point of metal Zn or metal Sn. This makes the metal Sn or the metal Zn dissolve rapidly

to function as a metal bond. The efficiency of the thermoelectric power generation device also depends on the heat dissipation and heat conduction device matched with it, as well as the thermoelectric coupling effect inside the thermoelectric power generation device. Therefore, the efficiency of thermoelectric conversion device is also related to parameters such as temperature difference, load resistance, loop current, and internal resistance of power generation devices. Therefore, the optimal matching between the load and the internal structural parameters of the thermoelectric power generation device is also an important issue to improve the thermoelectric conversion efficiency of the system.

Nanoscience is a comprehensive, interdisciplinary course based on many advanced sciences and technologies that has developed rapidly in recent decades. Nanotechnology has been widely used in biomedicine, materials science, chemistry, physics, information and electronic engineering, and other fields. Nanomaterials have been widely used in various research fields because of their many excellent properties, such as quantum size phenomenon, small size phenomenon, and quantum mechanics. Surface effects and tunneling phenomena have now become the focus of scientific research. Controlled release means that the drug is released quantitatively and uniformly through the controlled release coating film, so that the concentration of the drug in the blood remains unchanged. This paper is aimed at studying the application and performance of nanoparticles in the controlled release system of anticancer drugs. This paper addresses the issue of the controlled release of anticancer drugs. This question is based on nanoparticles. Therefore, it was elaborated around supramolecular polymer nanoparticles, and a case design and analysis of its use in the controlled release system of anticancer drugs was carried out. The experimental results showed that when laser irradiation and GSH coexisted, the dissolution rate and cumulative dissolution rate of DOX were the highest, and the total release within 3 h was close to 53%. This result indicates that the release of DOX from DOX@HMPB@PEI-SS-HA is both photosensitivity and redox responsive, and the photosensitivity predominates.

1. Introduction

Chemotherapy plays an important role in various cancer treatments, but traditional chemotherapy cannot achieve key goals such as stable drug delivery, targeting, stabilization point, and timely release. We hope these issues will be resolved. In recent years, the controlled stimulated release of nanomedicines has been a research hot spot. Since artificial intelligence and production planning were proposed, genetic algorithm, as a global optimization algorithm, has been widely used. It has comprehensive applications in image processing, machine learning, computer-aided design, and other fields.

Cancer is one of the main culprits that endanger human health and threaten human life, which has always been the focus of doctors. By controlling drug release, it can be achieved through membrane control systems and in vivo diffusion systems. Targeted drug release functions can be achieved through biorecognition mechanisms, permeation mechanisms, and in vitro control. This series of means ensures that the blood drug concentration remains stable, and the patient can get the best effect by taking the drug.

The innovation of this paper is the following: (1) This paper combines drug controlled release with a decision tree algorithm and genetic algorithm and introduces the theories and related methods of the two algorithms in detail. (2) In the face of drug controlled release, this paper divides the experimental samples into four groups. Through the evaluation of the experimental results, this paper compares the performance of nanoparticles in it. It is concluded that nanoparticles play a positive role in the controlled release of anticancer drugs.

2. Related Work

At the end of 1959, the concept of the nanometer was first proposed by a Nobel Prize winner. But really effective nanoscale research began in the 1960s. In the past decade, scientists have begun to shift their focus to the study of related nanomaterials. And it has achieved fruitful research results in the preparation process. Kumar et al. discuss the structure, morphology, and optical properties of the prepared samples. Its refinement revealed a single-phase hexagonal wurtzite structure without any impurity phase. It enhances the understanding of the structural and optical properties of Co/Mn codoped nanocrystals. However, their data is less [1]. Chevigny et al. investigated the dispersion mechanism of nanocomposites composed of polymer-grafted nanoparticles mixed with free chains of the same polymer. Through the analysis of the interparticle structure factor, they extracted the thickness of the spherical crown of the grafted brush and correlated it with the degree of dispersion: the aggregation of the particles was associated with a significant collapse of the grafted chains. However, their conclusions are not comprehensive enough [2]. Ammari et al. work on the mathematical modeling of plasmonic nanoparticles. They analyze how plasmonic resonances change and broaden as nanoparticles change in size and shape. By analyzing the imaginary part of Green's function, it was shown that super-resolution and superfocusing can be achieved using plasmonic nanoparticles. However, their analysis process is relatively simple [3]. Son et al. report on the nonvolatile memory characteristics of bistable organic memory (BOM) devices. Transmission electron microscopy (TEM) images show an isotropic distribution of gold nanoparticles around the PVK colloidal surface. However, their content is not novel enough [4]. Cabezón et al. conducted a series of experiments to explore the potential of anti-transferrin receptor 8D3 monoclonal antibodies (mAbs) to transport neurotherapeutics in the BBB. They also discuss the trade-offs of using this technique in their application and draw conclusions. Along with other volume electron microscopy imaging techniques, SBF-SEM is a powerful method worth considering for studying drug transport across the BBB. However, the influencing factors of their experiment are not single [5]. Examination of surface morphology by Han et al. revealed rod-like PANI nanoparticles encapsulated with ATP clay particles, confirming their Pickering emulsion stabilizer properties. They examined the ER performance of PANI@ATP nanoparticles dispersed in silicone oil under different electric field strengths. ER fluid flowing in particles PANI@ATP exhibits typical electrorheological behavior, and its shear stress curve is in good agreement with the Cho-Choi-Jhon model of the rheological formula of state. However, their data are not accurate enough [6]. Ke et al. reported the photothermal energy transfer efficiency of gold nanoparticles of different sizes by evaluating the temperature distribution of laser-activated particle suspensions in water. The results show that the photothermal properties of gold nanoparticles are size-tunable. However, they did not proceed from reality [7]. Sheikholeslami and Bhatti investigated the forced fusion heat transfer of nanoparticles in a porous half-ring under the action of a uniform magnetic field. Ultimately, they concluded that the velocity of nanoparticles increases with Darcy and Reynolds numbers and that the heat transfer rate is highest for flaky particles. The Nusselt number increases with increasing nanoparticle volume fraction, Darcy number, and Reynolds number and decreases with increasing Lorentz force [8, 9]. However, their process is more complicated.

3. Methods for Drug Controlled Release

3.1. Application of Nanomaterials in Drug Controlled Release Systems. The rise of nanotechnology in the 1980s was a very horizontal and rapidly growing field of research. The fusion of nanotechnology with biology, materials science, and medicine has created a new branch of nanomedicine. The specific application of "nanomedicine" in disease diagnosis, treatment, and monitoring has revolutionized the treatment methods of traditional medicine, which can alleviate the suffering of patients and improve people's health [10]. Due to their unique chemical and physical properties, nanomaterials have many advantages in drug management and have been extensively evaluated and studied by scientists and clinicians.

The drug release behavior of traditional chemotherapy methods is uncontrollable. After the drug molecule enters the blood, it is distributed throughout the body through the diffusion mechanism. The drug molecule usually needs to undergo protein binding, metabolism, excretion, and other steps, and the drug concentration decreases rapidly. Only a small amount of the anticancer drug eventually reaches the tumor site. The use of nanomaterials as drug carriers in this paper can effectively transfer drugs to the site of injury. It achieves targeted release and controls the drug release rate.

Most polymeric nanomaterials are biodegradable and biocompatible. It can control the metabolic kinetics of drugs through surface chemical modification [11]. Therefore, they are very suitable as drug carriers: they are commonly used to make nanocarrier polymers, both natural and synthetic polymers. Natural polymers include chitosan, albumin, heparin, dextran, gelatin, sodium alginate, and collagen. Synthetic polymers include polyethylene glycol (PEG), polyglutamic acid (PGA), polylactic acid (PLA), polycaprolactone (PCL), polylactide-co-glycolide (PLGA), and N-(2-hydroxypropyl)-methacrylamide copolymer (PHPMA) [12].

3.2. Decision Tree Algorithm

3.2.1. Overview. Decision tree learning algorithms are inductive learning algorithms based on a set of sample data sets (data samples can also be referred to as examples), focusing on conclusions drawn from disturbed and irregularly sampled data sets (concepts). It represents the classification rules, where the data samples should be able to be embodied in the form of "attribute inference."

A decision tree is a tree structure that automatically sorts data. It is a tree-structured knowledge representation that can be directly transformed into classification rules. It can

be thought of as a tree-based predictive model. Among them, the root node of the tree is the entire space of the data set, and each child node corresponds to a separation problem. It is a test on a single variable that splits a spatial data set into two or more parts; each worksheet node is a data separator with sorted results. Decision trees can also be interpreted as a special form of rule sets, which are characterized by a hierarchical organization of rules. The decision tree algorithm is mainly aimed at the learning method of "classifying discrete variables into feature types," and for continuous variables, they must be discrete in order to learn and classify [13, 14].

The learning decision tree adopts the object detection method. It compares the eigenvalues of the internal nodes of the decision tree and judges that the branch conclusion of the next node is in the leaves of the node decision tree according to different eigenvalues. Figure 1 briefly describes the process of creating a decision tree.

3.2.2. Basic Algorithm.
The internal nodes of the decision tree are features or feature sets, the leaf nodes are the categories or conclusions of learning differentiation, and the features of internal nodes are test attributes or separation attributes.

After a decision tree is created by learning from a sample data set, a new set of unknown data can be sorted. When using decision trees to sort data, top-down backtracking is used. It judges and compares the eigenvalues of the internal nodes of the decision tree and decides which branch will be switched according to the different attribute values obtained from the leaf nodes.

According to the description, it can be seen that the path from the root node to the drawing node corresponds to the connection rules, and the entire decision tree corresponds to the combination selection of the rules. For example, Figure 2 represents a decision tree; A, B, C in the figure are attribute names; and $a_1, a_2, b_1, b_2, c_1, c_2$ are the values of attributes A, B, C, respectively. When the value of attribute A is a_1 and the value of attribute B is b_2, it belongs to the second category.

According to various attributes of the internal nodes of the decision tree, decision trees can be divided into the following types.

When each internal node of a decision tree contains only one attribute, it is called a univariate decision tree. But when the inner nodes of a decision tree contain many variables, it is called a multivariate decision tree. Each internal node can have two or more branches, depending on the number of different feature values for the tested feature.

(1) ID3 Algorithm.
On the basis of the CLS learning algorithm, later generations have proposed a variety of decision tree learning algorithms, the most important of which is the ID3 algorithm proposed in 1979. The ID3 algorithm is a decision tree learning algorithm based on information inheritance, which is the representative of the decision tree algorithm. Most of the algorithms have been improved and applied on top of them. The information theory is introduced into the decision tree algorithm, and the divide and

conquer strategy is adopted [15]. When selecting features at all levels of a decision tree, all features are identified, and the feature with the largest information gain is selected as the decision tree node, which is determined by the different values of the feature [16, 17]. Finally, this paper adopts a decision tree to classify the new samples.

In this paper, the sample data set is set as S, and the purpose is to divide the sample data set into m categories. Assuming that the number of sample data belonging to class a is X_a and the total number of sample data in S is $|S|$, then the probability that a sample data belongs to class a is $p(X_a) \approx X_a/|S|$. At this time, the uncertainty degree of the decision tree for dividing X (that is, the information descendant) is

$$H(S, X) = H(S) = -\sum_{a=1}^{m} p(X_a) \log_2 p(X_a). \tag{1}$$

If attribute c is chosen for control (assuming attribute i has n distinct values), the uncertainty (conditional continuity) is

$$H\left(\frac{S}{X}\right) = -\sum_{a=1}^{m}\sum_{b=1}^{n} p(X_a, c = c_b) \log_2\left(\frac{X_a}{c} = c_b\right). \tag{2}$$

Then, the amount of information provided by attribute c for classification is

$$I(S, c) = H(S) - H\left(\frac{S}{c}\right). \tag{3}$$

In the formula, $I(S, c)$ represents the reduction degree of information entropy after selecting feature c as the classification feature. Therefore, it should choose to maximize feature $i(S, c)$. As a categorical feature, decision trees that do this have the greatest certainty.

It can be seen that the ID3 algorithm chooses to retain the CLS algorithm, a sentence of information theory, and it is recommended to select the attribute maximizing $I(S, c)$ as the criterion for selecting the classification attribute test feature. Figure 3 shows the specific process of the ID3 algorithm.

When the ID3 algorithm is used as the discriminant model, the number of samples in the experiment, that is, the discriminant results, is shown in Table 1.

(2) C4.5 Algorithm.
The C4.5 algorithm was proposed in 1993. It evolved from the ID3 algorithm, inherits the advantages of the ID3 algorithm, and adds new methods and functions [18]. The main body of the algorithm consists of three parts: C4.5 tree, pruning algorithm C4.5 pruning, and rule generation algorithm C4.5 rules.

The C4.5 tree algorithm selects the feature with the highest information gain rate in the current sample set as the test feature. It is based on the theory of information genetics and finally builds a complete decision tree. For continuous

FIGURE 2: Simple decision tree.

features, separate first, that is, divide the values of continuous features into different intervals, which is convenient for processing. C4.5 pruning uses an error-based pruning method to prune the entire decision tree to obtain a simplified decision tree. C4.5 rules converts a complete decision tree into a set of if.then rules and then simplifies them. Both simplified decision trees and rule sets resulting from pruning or rule creation processes can be used for classification.

2000	0.728
2500	0.715
3000	0.694

Its basic idea is the following: for the sample set W, it is assumed that the variable i has m features, that is, the eigenvalues i_1, i_2, ... The number of samples i_1 in which i_k corresponds to the value of i is m_1, respectively. $m_1 + m_2 + \cdots + m_k = m$ should be present if m is the total number of samples. The entropy value $H(S, i)$ of the feature i is used to determine the cost of obtaining the information of the sample feature i, namely,

$$H\left(\frac{S}{i}\right) = -\sum_{a=1}^{k} p(i_a) \log_2 p(i_a) \approx -\sum_{a=1}^{k} \frac{m_a}{m} \log_2 \frac{m_a}{m}. \quad (4)$$

The information acquisition rate is defined as the ratio of the average mutual information to the cost of acquiring information, namely,

$$E(S, i) = \frac{I(S, i)}{H(S, i)}. \quad (5)$$

That is, the information acquisition rate refers to the amount of information acquired from the unit cost, which is a measure of the relative uncertainty of the amount of information. Taking the information gain rate as the criterion for selecting the experimental characteristics, the characteristic i with the largest $E(S, i)$ should be selected as the experimental characteristic [19].

The pruning strategy adopted by the C4.5 algorithm is pessimistic error correction, and the misclassification rate is estimated as

$$W(j) = \frac{q(j)}{P(j)}. \quad (6)$$

The continuity corrected error rate is

$$W'(j) = \frac{q(j) + 1/2}{P(j)}.$$ (7)

Accordingly, the misclassification rate of subtree J_j is

$$W(J_j) = \frac{\sum q(a)}{\sum P(a)},$$ (8)

where i takes the leaves of the subtree, so the corrected misclassification rate is

$$W'(J_j) = \frac{\sum (q(a) + 1/2)}{\sum P(a)}.$$ (9)

Then,

$$W'(J_j) = \frac{\sum \left(q(a) + P_{J_j}/2\right)}{\sum P(a)},$$ (10)

where P_T is the number of leaves on the node.

Using the training data, child nodes always produce fewer errors than their respective nodes, but when the correct numbers are used, this does not happen, because they depend on the number of cards, not just the number of errors [20].

The standard deviation is calculated as follows:

$$SE\left[u'(J_a)\right] = \sqrt{\frac{u'(J_j) * \left(P(a) - u'(J_a)\right)}{P(a)}}.$$ (11)

Among them, for nodes, there are

$$u'(a) = q(a) + \frac{1}{2}.$$ (12)

And for the subtree, there are

$$u'(J_j) = \sum q(a) + \frac{P_{J_j}}{2}.$$ (13)

The flowchart of the C4.5 algorithm is shown in Figure 4.

When the C4.5 algorithm is used as the discriminant model, the number of samples in the experiment, that is, the discriminant results, is shown in Table 2.

3.3. Genetic Algorithms

3.3.1. Overview. The genetic algorithm (GA) is a new global optimization algorithm developed in recent years. Based on the viewpoint of biological genetics, the self-adaptive optimization of individuals is realized through natural selection, inheritance, mutation, and other mechanisms. This reflects the evolutionary process of "natural selection and survival of the fittest" in nature. It is based on the theory of evolution

and adopts design methods such as genetic combinatorial optimization technology, genetic variation, and natural selection.

The genetic algorithm is an optimization search algorithm based on biological evolution theory and molecular genetics. It first encodes possible solutions to a particular problem, called chromosome-encoded solutions. It randomly selects N chromosomes as the initial group and then calculates the fitness of each chromosome based on the value of the evaluation function. It is predetermined that the best performance value of the chromosome is the highest fitness value, and the chromosome with the highest fitness value is selected for replication. It creates a new set of chromosomes. These chromosomes are more tailored to the environment through genetic operators, and people will eventually adapt to the new environment. Forming a better group becomes the best solution to the problem [21, 22].

3.3.2. Basic Algorithm. The execution of the genetic algorithm involves many random operations, first considering the result of the selection. In standard genetic algorithms, selection criteria are based on the principle of proportionality. Therefore, through the action of the ith selector, the expected value of the number of people who will continue to exist in the next generation is $n(f_i/\sum f)$; then, there is

$$\bar{f}(P, t) = \frac{1}{n(P, t)} \sum f_i.$$ (14)

Then,

$$n(P, t + 1) = n(P, t) \cdot \frac{\bar{f}(P, t)}{\bar{f}(t)}.$$ (15)

The formula shows that the effect of the selection operator will increase (decrease) the ability of a pattern above (below) the average to be applied across generations, improving quality.

Then, it analyzes the role of the crossover operator. This plan can obviously be maintained in the next generation if there is no intersection or if the intersection point is beyond the character positions specified on the left and right ends of the figure. Therefore, the probability R_s that the P mode will continue to exist in the next generation should satisfy

$$R_s \geq 1 - R_c \cdot \frac{\varphi(P)}{L - 1}.$$ (16)

Taking into account the effects of selection and crossover, there are

$$n(P, t + 1) \geq n(P, t) \cdot \bar{f}(P, t) \cdot 1 - R_c \cdot \frac{\varphi(P)/(L - 1)}{\bar{f}(t)}.$$ (17)

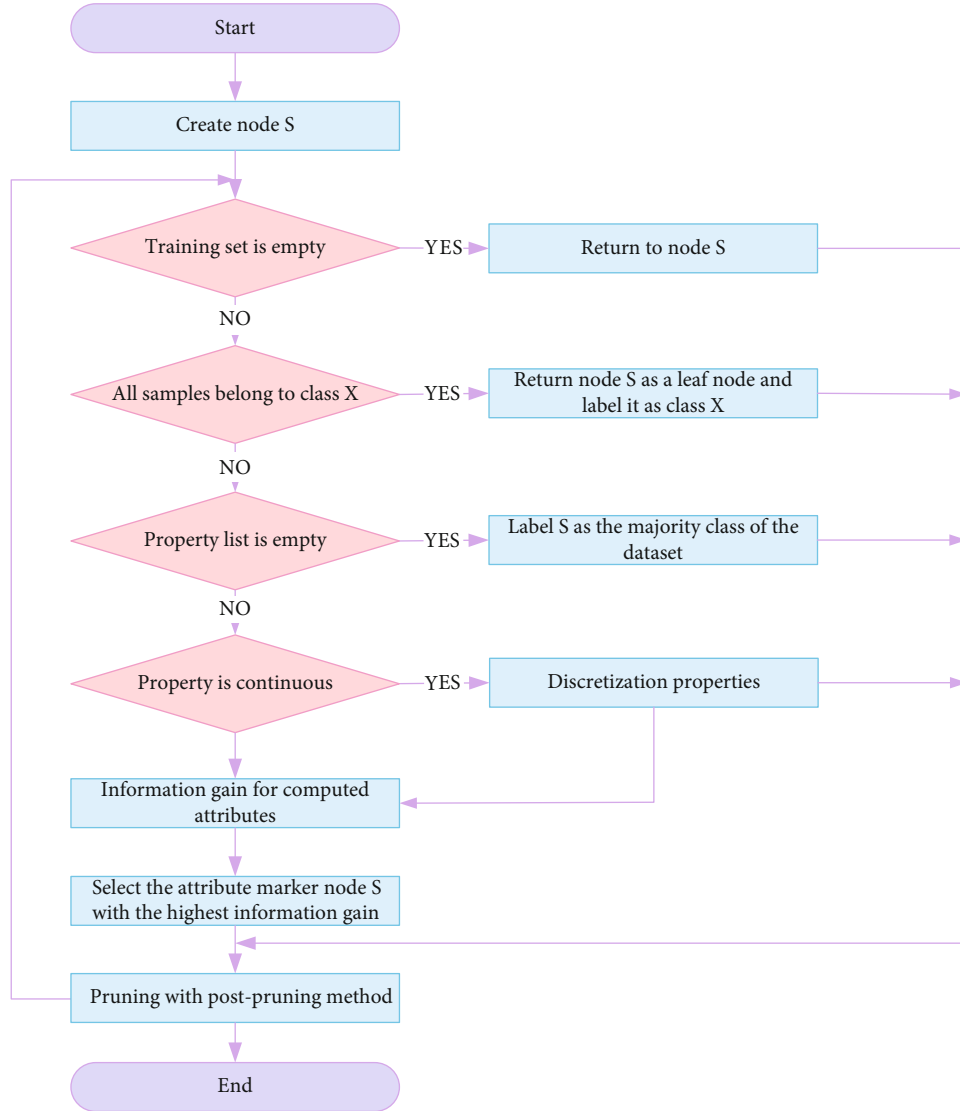
Finally, because R_m represents the probability of the mutation operator acting, the constant probability is $1 - R_m$. If all the specified characters remain unchanged, the P pattern can naturally continue to exist in the next


FIGURE 4: C4.5 algorithm flowchart.

TABLE 2: Discrimination accuracy of C4.5 algorithm when data sources are different.

The amount of data	Legacy C4.5
500	0.757
1000	0.732
1500	0.680
2000	0.629
2500	0.652
3000	0.705

generation, the probability $(1 - R_m)^{O(P)}$, R_m is usually not large, and then under the action of the mutation operator, the probability of P continuing to exist is

$$(1 - R_m)^{O(P)} \approx 1 - R_m \cdot O(P). \quad (18)$$

The probability of unreserved is about $O(P) \cdot R_m$. So, taking into account the functions of selection, crossover, and mutation operators, we end up with

$$n(P, t + 1) \geq n(P, t) \cdot \bar{f}(P, t) \cdot \frac{1 - R_c \cdot \varphi(P)/L - 1 \cdot R_m}{\bar{f}(t)}. \quad (19)$$

Specifically, if $\bar{f}(P, t) = f(t)(1 + c)$, $c > 0$ is a constant, then

$$n(P, t) = n(P, t - 1)(1 + c) = n(P, O)(1 + c)^t. \quad (20)$$

The flowchart of the standard genetic algorithm is shown in Figure 5.

Coding and initial population: since the algorithm itself cannot directly deal with the number of solutions, it is necessary to pass the coding form of the genotype string structure.
FIGURE 5: Genetic algorithm flowchart.

It can be represented by binary and other forms, such as 11001. And it generates n initial groups according to the encoding form, and n is usually set according to the actual situation.

Fitness calculation: fitness calculation is to evaluate the individual's pros and cons through an evaluation function. It is the main basis for the next round of operation of the genetic algorithm, so the design of the fitness algorithm is very important.

Choosing an action.

Crossover: crossover is to exchange some information with each other for two individuals that are successfully paired randomly to form a new individual and then calculate the fitness. If the fitness data of the new individual improves, it means that the individual is optimizing in the desired direction.

Variation: in order to make the individuals in the population diverse, it prevents the problem of generating local solutions. In this paper, some parts of the individual are manipulated and changed, so that the group can survive and develop better.

4. Experiment and Analysis of Polymer Nanoparticles in Drug Controlled Release

4.1. Experiment Preparation. At present, nanodrug carriers have been widely used in cancer therapy, oral drugs, gene carriers, intracellular targeted drug delivery, quantitative drug delivery, immune-enhancing vaccines, and the prevention and treatment of vascular retention [23]. Figures 6(a) and 6(b) belong to the type of polymer nanomaterials.

Anticancer drug release experiments were divided into four groups: (1) pH 7.4, (2) pH 7.4+GSH, (3) pH 7.4+NIR laser irradiation, and (4) pH 7.4+GSH+NIR laser irradiation. The dissolution medium of the corresponding two groups (1) and (3) was PBS at pH 7.4. The dissolution medium of both groups (2) and (4) was pH 7.4 PBS containing 20 mM GSH.

First, 1 mg of DOX@HMPB@PEI-SS-HA was uniformly dispersed in 1 mL of the corresponding dissolution medium and transferred to a dialysis bag (MWCO = 3500 Da). Then, the dialysis bags were put into 5 mL of the corresponding dissolution medium, respectively, and the culture was continued in a constant temperature environment of 37°C. For groups (1) and (2), the system needs to be placed in a dark environment with a constant temperature of 37°C; for groups (3) and (4), the system must be irradiated with an 808 nm laser (power density is 1.5 W/cm^2). It is illuminated 10 min before each sampling. When the preset time points are reached, 2 mL of the samples to be tested are removed and 2 mL of the same dissolution medium is quickly replenished. According to the absorbance curve of the tested sample, the absorbance of the tested sample was calculated, and the cumulative DOX dissolution rate corresponding to different time points was determined.

The in vitro dissolution experiment of each system needs to be repeated three times, and the average value of the three times is the release amount of DOX.

In this experiment, two methods of CLSM and FCM were used for detection, and two methods of MTT and Live-Dead were used for analysis. In this paper, the cytotoxicity of HMPB@PEI-SS-HA and DOX@HMPB@PEI-SS-HA was evaluated, respectively.

4.2. Experimental Results. The PVP-coated solid PB NPs were etched by HCl to form HMPB NPs. We then combined electrostatic layer-by-layer self-assembly and chemical cross-linking to selectively adsorb PEI-SH and HA-SH onto the surface of HMPB NPs. PEI-SH and HA-SH can react to generate disulfide bonds, and HMPB@PEI-SS-HA can be obtained (as shown in Figure 7).

(a) Polymeric micelles

(b) High polymer
Figure 6: Polymer nanomaterials.

(a)

Figure 7: Schematic diagram of HMPB@PEI-SS-HA.

Table 3: Particle size of products at different stages of preparation.

Name	Hydrodynamic diameter (nm)
PB	103.52
HMPB	111.60
HMPB@PEL-SH·	125.49
HMPB@PEI-SS-HA	142.83

Zeta potential and particle size of products at different preparation stages were detected by DLS. With the progress of the assembly process, the particle size of the NPs also gradually increased, and the results are shown in Table 3.

HMPB is a hollow mesoporous structure with a huge specific surface area and pore volume. It becomes an ideal carrier for loading anticancer drugs. When DOX was loaded into HMPB@PEI-SS-HA, when the mass ratio of the two was 1/1.2, the drug loading reached 46%, and the encapsulation efficiency was close to 94%. In addition to the structural characteristics, the reasons for the high loading capacity, the electrostatic interaction between the positively charged DOX and the negatively charged HMPB@PEI-SS-HA, and the formation of coordination bonds between Fe(II) and DOX in HMPB play a positive role in the drug loading capacity.

Next, we investigated the release rule of DOX from DOX@HMPB@PEI-SS-HA. The results in Figure 8 show that the release of DOX has both redox and light responsiveness. Figure 8(a) is the dissolution curve of the control group at 24 h in Figure 8(b). In the environment with neither NIR laser irradiation nor GSH, the release rate of DOX from DOX@HMPB@PEI-SS-HA was very slow, the dissolution basically reached equilibrium within 24 h, and the total release amount was around 20%. This result can be attributed to the particularly low exchange efficiency of the inner charge and the outer dissolution medium through the pores of the HMPB. This is beneficial for minimizing toxicity and side effects in healthy tissue. At the same time, it also shows that DOX@HMPB@PEI-SS-HA is very stable and will not burst suddenly during the blood circulation process, resulting in the sudden release of anticancer drugs.

As shown in Figure 8(b), when there was only GSH, the dissolution rate of DOX was faster than that of the control

(a) Dissolution curve of control group at 24 h

(b) Comparison of dissolution rates of four groups
FIGURE 8: In vitro drug release behavior of DOX@HMPB@PEI-SS-HA.

group, and the cumulative dissolution rate was about 22% at 3 h. It shows that the disulfide bond in the carrier is broken under reducing conditions, destroying the PEI-SS-HA part in its structure. It makes the internal DOX and the water phase medium in closer contact, and the exchange efficiency is improved. In the environment with only NIR laser irradiation, compared with the control group, the dissolution rate of DOX was significantly accelerated, and the cumulative release at 3 h exceeded 40%. It is mainly because of the strong photothermal properties of HMPB itself.

On the one hand, the laser irradiation significantly increased the temperature of the system, which increased the solubility of DOX in the dissolution medium. It simultaneously accelerates the DOX exchange efficiency between the inner space of the nanocapsule and the outer environment. On the other hand, because HMPB is inside the carrier, NIR irradiation directly destroys the structure of HMPB. Therefore, the overall structure of the carrier will collapse, resulting in a significant increase in the DOX release rate. When laser irradiation and GSH coexisted, the dissolution rate and cumulative dissolution rate of DOX were the highest, and the total release within 3 h was close to 53%. This result indicates that the release of DOX from DOX@HMPB@PEI-SS-HA is both photosensitivity and redox responsive, and the photosensitivity predominates.

4.3. Experimental Analysis. In the experiments, a NDDS with both NIR and redox responsiveness, DOX@HMPB@PEI-SS-HA, was designed and synthesized. Due to the hollow mesoporous structure of HMPB, the DOX drug loading reached 46%. Anticancer drug release experiments showed that the strong photothermal properties of HMPB accelerated the release rate of DOX from DOX@HMPB@PEI-SS-HA when irradiated with an NIR laser. In addition, DOX dissolution also has redox responsiveness, but photosensitivity dominates. Cell uptake experiments also confirmed that DOX@HMPB@PEI-SS-HA could target and bind to the CD44 receptor. The results of the cytotoxicity evaluation further confirmed the positive effect of the photothermal properties of HMPB on accelerating the release of anticancer

drugs and killing cells. HMPB@PEI-SS-HA can not only load DOX but also deliver other anticancer drugs. Due to its high drug loading capacity, low toxicity, and excellent photothermal properties, it has broad application prospects in the field of photochemical combination therapy.

5. Discussion

First of all, through the study of the relevant knowledge points of the literature works, this paper has initially mastered the relevant basic knowledge. This paper analyzes how to study the application of nanomedicine in the controlled release of anticancer drugs based on the decision tree algorithm and genetic algorithm. This paper expounds the concepts and related technical algorithms of the two algorithms and explores the application of polymer nanomedicines. In this paper, the applicability of nanomedicines in the controlled release of anticancer drugs is analyzed by experiments.

Nanoscience is a comprehensive, multidisciplinary discipline based on many advanced scientific technologies that have developed rapidly in recent decades. Nanotechnology has been widely used in biomedicine, materials science, chemistry, physics, information and electronic engineering, and other fields. Nanomaterials have been widely used in various research fields because of their many excellent properties, such as quantum size phenomenon, small size phenomenon, and quantum mechanics. Surface effects and tunneling phenomena have now become the hot spots of scientific research. However, scientific researchers still face great challenges in the preparation of nanomaterials with different shapes and properties and their applications. Researchers hope to better understand the microstructure of nanomaterials and control their shape, structure, composition, and others [24, 25].

In this paper, the experimental analysis shows that the organic-inorganic composite nanocapsules are prepared by polymer nanoparticles, and the DOX drug loading reaches 46%. The in vitro release rate and total nanoparticle release rate were significantly improved. Cellular uptake and

cytotoxicity experiments further confirmed the positive role of supramolecular polymer nanoparticles in controlling the release of anticancer drugs and cell death.

6. Conclusion

Today, functional nanodrug carriers have become a necessary and important means for cancer diagnosis and treatment. Therefore, the preparation and application of functional nanocarriers have become the focus of chemical and biomedical workers. The key to producing functional nanocarriers is the functionality of their materials. Supramolecular polymers with multiple stimuli-responsive properties are compared to conventional covalent polymers. Because of its nonhomogeneity, it is harmonized and repairable. The superior performance and time-synchronized and seeded copolymers have unique advantages in functional modification and self-assembly due to more side chains. There are many reports on the self-assembly of supramolecular polymers and graft copolymers, but their application in the fabrication of functional nanodrug carriers remains to be further developed. In addition, it is necessary to change the manufacturing method of polymers to find polymers through simple modification or reversibility to improve the function of preparation and performance of drug carriers.

Engineering design can be regarded as an iterative optimization process. This process is difficult because of two main problems: the first is that computer-aided engineering (CAE) is time-consuming in terms of evaluating design solutions, while the second is the high dimensionality of design solutions. In the research community, a surrogate model is proposed to deal with the first problem while an evolutionary algorithm is adopted for the second. In this work, we develop a new method with only sparse scattered data, which is very common in many practical scenarios. The surrogate model can also assign a penalty factor for the predicted value, and this penalty factor can be used as one of the targets of the evolutionary algorithm to balance global exploration and local exploit. We also adopt a new evolutionary strategy, which can search high-dimensional space. Three groups of experiments are conducted to validate the proposed methods. The experimental results show that the surrogate model can predict performance and the corresponding penalty factor, the evolutionary strategy is better in terms of searching high-dimensional space compared with other evolutionary strategies, and the whole method can generate new design solutions that are near to the known design solutions. The experimental results show that this method can be used in practical scenarios, especially where they only have sparse scattered data.

1. Introduction

Engineering design is a complex process involving different design activities, and it can be generally regarded as the iteration of design and validation. Currently, with the help of well-developed computer-aided design (CAD) and computer-aided engineering (CAE) systems, the design model can be parameterized and the validation process can be simulated computationally. Therefore, engineering design can be regarded as an optimization problem [1], and different aspects of product can be optimized, such as shape optimization [2] and reliability optimization [3].

$$\hat{x} = \arg \max \ f(\mathbf{x}), \tag{1}$$

$$\mathbf{x} \in \Omega, \tag{2}$$

where $\mathbf{x} = [x_1, x_2, \cdots, x_n]$ is a parameter vector representing a design solution, Ω is the feasible solution space of $\mathbf{x}$, $\hat{x}$ is the optimal solution, and $f(\mathbf{x})$ is the evaluation function of design solutions. CAE has played the role of $f(\mathbf{x})$ successfully in engineering design for many years. However, two characters of such function make the optimization extremely complex and difficult. The first is derivative unavailable, which means the gradient-descent methods are invalid [4]; the second is time-consuming [5], which means the evaluation of the function requires extensive computational resources. In addition to above difficulties, the high dimensionality of the design space is another problem making the optimization difficult.

A response surface model (RSM) [6] is a method adopted to deal with the first two difficulties, and it is a statistical method that explores the relationships between design variables $\mathbf{x}$ and one or more response variables $f(\mathbf{x})$ [7]. The RSM method is also called as a surrogate model, metamodels, or emulators in different scenarios [8], and the underlying idea is to replace the computationally expensive model with a computationally cheaper one [8, 9]. In this

work, we use the terminology of "surrogate model" referring to the latter one.

Many technical methods can be used to build a surrogate model, such as linear or nonlinear interpolation, Kriging [10], neural network, radial basis function [11], and Gaussian process [12]. Although these methods have been successfully applied in solving many engineering problems, some remaining problems are hindering the applications of the surrogate model in engineering design. In many scenarios of applying the surrogate model successfully, either the available data is sufficient or the method of data collection is deliberately designed, such as "grid" data or "orthogonal" data. However, there are many different scenarios where the data is "sparse," which means the amount of available data is small, and "scattered," which means the data is located randomly in the feasible design space.

The main contribution of this paper is to propose a surrogate model method and a high-dimensional design space exploration method, respectively. We first attempt to build a surrogate model based on "sparse scattered" data and then use a new evolutionary strategy to explore and exploit the high-dimensional space. The combination of the two can realize the rapid generation from sparse scattered point data to a design scheme. The rest of the paper is structured as follows. Section 2 provides some related works for this study. Section 3 explains the technical details of both building a surrogate model and the evolutionary strategy. Section 4 conducts several groups of experiments to validate the proposed method. Section 5 summarizes this research and identifies some possible future works.

2. Related Works

In this section, some existing key techniques related to this work will be explained, including the surrogate model and evolutionary strategies.

2.1. Surrogate Model. There are many methods for building a surrogate model, and these methods can be categorized based on different criteria. From the perspective of data characteristics, there are methods for both grid data and scattered data. If the data is collected through Design of Experiment (DOE) [13], we can get regular grid data, and the surrogate model is easy to build. For low-dimensional problem, the Delaunay triangulation [14], natural neighbor interpolation [15], spline interpolation [16], and so on can be used to build the surrogate model, while for high-dimensional problems, the simple nearest-neighbor interpolation [17], Kriging [10], and so on can be used to build the surrogate model. Zhou et al. presented the nearest-neighbor value (NNV) interpolation algorithm for the improved novel enhanced quantum representation of digital images (INEQR). Experiments show that the proposed interpolation method has higher performance in high-resolution image recognition [18]. Qian et al. proposed a general sequential constraint updating approach based on the confidence intervals from the Kriging surrogate model (SCU-CI). Results illustrate that the proposed SCU-CI approach can generally ensure the feasibility of the optimal solution under a reason-

able computational cost [19]. If the data is collected randomly, we can only get irregular grid data, which are also called scattered data. In this situation, the surrogate model becomes difficult to be constructed. There are already some methods to deal with this problem, such as triangulated irregular network, radial basis function [20, 21], and Kriging [10]. de Oliveira et al. proposed a new approach for occlusion detection—the surface-gradient-based method (SGBM) applied to a triangulated irregular network (TIN) representation. Experimental results demonstrated the feasibility of the SGBM for occlusion detection in the true orthophoto generation [22]. She et al. present a novel battery aging assessment method based on the incremental capacity analysis (ICA) and radial basis function neural network (RBFNN) model [23].

From the perspective of key techniques, the methods can also be categorized as interpolation and fitting. The former attempts to build a hypersurface that exactly passes the existing data, while the latter treats existing data as noise-contained data and attempts to find a hypersurface that minimizes the errors, and the hypersurface is unnecessary passing existing data. From the perspective of complexity, the methods can be categorized as a linear model or nonlinear model.

Although the surrogate models have been used widely in many domains, the successful applications always rely on either grid data or sufficient data. However, in many practical scenarios, the existing data is neither grid data nor sufficient. The data is sparse and scattered, and methods that fit for such situations should be developed.

2.2. Evolutionary Computation. Evolutionary computation is a commonly used method to search optimal solutions from design space. Most of the evolutionary computation methods follow the same framework, but they improve the algorithm by developing different evolutionary strategies, including crossover, mutant, and selection.

Many evolutionary strategies are developed to improve the algorithm from two perspectives. The first perspective is developing a new crossover and mutant method to generate new offspring, such as differential evolution- (DE-) based method [24, 25], immune-based method [26], particle swarm optimization- (PSO-) based method [27], and probabilistic model-based method [28]. The second perspective is developing a new selection method, such as decomposition-based method [29], preference-based method [30], indicator-based method [31], and hybrid method [32]. Although the above improvements contribute to solving many design problems, there is also requirement for developing evolutionary strategies for optimizing a high-dimensional problem.

3. Methodology

In this section, we will explain the proposed method in detail. Generally, the method has two main parts, including surrogate model construction and design solution searching. In the first part, a surrogate model, which receives design solutions as input and return performances as output, will be constructed based on a two-stage interpolation process. In the second part, we adopt a new

mutant strategy, to search the high-dimensional space. The two parts will be detailed in the following two sections, respectively.

3.1. Surrogate Model Construction.

We first define the data structure used to build a surrogate model and then explain the underlying ideas of the two-stage interpolation process, and finally, we explain the technical detail of this method. The mathematical symbols used in this work are summarized in Table 1.

3.1.1. Data Structure.

Typically, there are two kinds of data in many engineering design problems, and they are design solution and the corresponding performance. A design solution can be represented by a vector $\mathbf{x} = [x_1, x_2, \cdots, x_d]$, in which $x_1, x_2, \cdots, x_d$ are parameters that determine the design solution, and d is the dimensionality of the design solution $\mathbf{x}$. A performance is a measurement of design solution $\mathbf{x}$, and design solution $\mathbf{x}$ commonly has several performances for evaluation. Besides, the performance can be different under different working conditions $\mathbf{c} = [c_1, c_2, \cdots, c_l]$, in which $c_1, c_2, \cdots, c_l$ are parameters that determine the working conditions, such as temperature and velocity which can jointly define a two-dimensional $l = 2$ working condition. Therefore, the performance can be represented by a $k \times m$ matrix where k is the kinds of performances and m is the total number of working conditions.

$$\mathbf{p} = \begin{bmatrix} p_{11} & p_{12} & \cdots & p_{1m} \\ p_{21} & p_{22} & \cdots & p_{2m} \\ \vdots & \vdots & \vdots & \vdots \\ p_{k1} & p_{k2} & \cdots & p_{km} \end{bmatrix}. \tag{3}$$

Generally, we have a $n \times k \times m$ matrix as database D for building the surrogate model, where n is the number of known design solutions. As shown in Figure 1, we know the k kinds of performance under m different working conditions of n known design solutions. It is noteworthy to say that the n known design solutions are scattered in the high-dimensional space.

3.1.2. Underlying Considerations and Assumptions.

Based on the above data, the goal is to construct a surrogate model that receives a design solution $\mathbf{x}'$ and a group of working conditions $\mathbf{c}'$ as input and outputs the corresponding performances of the design solution $\mathbf{x}'$ under working conditions $\mathbf{c}'$. It is noteworthy that the design solutions $\mathbf{x}'$ and working conditions $\mathbf{c}'$ are generally not contained in the database D.

We can regard the surrogate model as a function $\mathbf{p} = f(\mathbf{x}, \mathbf{c})$. This function maps value from $d + l$ dimensional space R^{d+l} to k dimensional space R^k, and this high-dimensional mapping requires more data to train. Since we only have sparse scattered data, two critical assumptions are drawn before learning the surrogate model.

TABLE 1: The mathematical symbols used in this work.

#	Symbols	Explanation
1	$\mathbf{x}$	A design solution
2	x	A parameter of the design solution $\mathbf{x}$
3	d	The dimensionality of the design solution $\mathbf{x}$
4	$\mathbf{c}$	A working condition
5	c	A parameter of the working condition $\mathbf{c}$
6	l	The dimensionality of the working condition $\mathbf{c}$
7	$\mathbf{p}$	The performance of a design solution
8	k	The total kinds of performance
9	m	The total number of working conditions
10	n	The total number of known design solutions
11	D	The training database
FIGURE 1: The data structure of the existing training data.

Assumption 1. For different design solutions, the mappings from working condition to performance are identical.

Based on Assumption 1, we do not need to learn a dedicated mapping (maps from working condition to performance) for different design solutions, which is necessary if the surrogate model is built, like $\mathbf{p} = f(\mathbf{x}, \mathbf{c})$. Therefore, we can divide the surrogate model into two stages, of which the first stage maps design solution $\mathbf{x}'$ to performances $\mathbf{p_c}$ under existing working conditions $\mathbf{c}$ by $\mathbf{p_c} = g(\mathbf{x}')$, while the second stage maps $\mathbf{c}'$ to performance under unknown working condition by $\mathbf{p} = h(\mathbf{c}')$. By this assumption, some dependences among design solutions, working conditions, and performance are ignored, and this loses the data requirement for training the surrogate model.

Assumption 2. The design solutions that are like existing design solutions are more feasible.

Based on Assumption 2, we make the surrogate model to assign a penalty factor for the predicted performance. If the new design solution $\mathbf{x}'$ is far from the known design

solutions, the penalty factor should be high and vice versa. This penalty factor will be used during the design optimization process, and it helps to shrink the searching space and keeps the design solution close to the regions where some design solutions are known.

3.1.3. Two-Stage Interpolation. The surrogate model can be implemented by two-stage interpolation. In both two stages, the inverse distance weighting (IDW) [33] is adopted to implement the interpolation, which computes an unknown value based on the following equation:

$$\widehat{y} = \frac{\sum_{i=1}^{Q} w_i \times y_i}{\sum_{i=1}^{Q} w_i}, \tag{4}$$

where Q is the total number of data points used to predict new value $\widehat{y}$ and w_i is the weight of the ith data point. In the IDW method, the weight is calculated by

$$w_i = \frac{1}{\left\| x / - x_{\mathbf{i}} \right\|^{P/2}}, \tag{5}$$

where $\mathbf{x}'$ is the data point that the performance is unknown; $\mathbf{x}_i$ is the ith data point; $\| \ \|$ is to calculate the distance between two data points in the high-dimensional space R^n; P is the order the distance, and this is a metaparameter to control the weights.

Based on this, given an unknown design solution $\mathbf{x}'$ and unknown working condition $\mathbf{c}'$, we can first interpolate to get the performances of the design solution $\mathbf{x}'$ under known working conditions $\mathbf{c}$ and then further interpolate to get the performances of the design solution $\mathbf{x}'$ under unknown working conditions $\mathbf{c}'$. We also need to assign penalty factors to the predicted performances of unknown design solutions and working conditions. In this work, we simply use the Euclidean distance as a measurement of penalty factors, and the value can be calculated by

$$\text{PF} = \text{PF}_1 + \text{PF}_2, \tag{6}$$

where PF_1 is the penalty factor of the first stage and it can be obtained by (7), while PF_2 is the penalty factor of the second stage and it can be obtained by (8).

$$\text{PF}_1 = \frac{1}{Q} \sum_{i=1}^{Q} \left\| x' - x_i \right\|^{P/2} \tag{7}$$

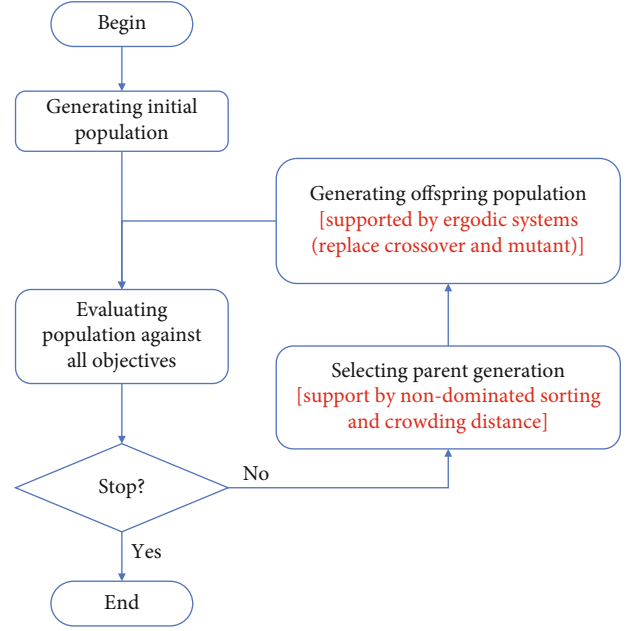
where Q is the total number of design solution used to predict the performance; $\mathbf{x}'$ is the data point that the performance is unknown; $\mathbf{x}_i$ is the ith data point used to predict the performance; $\| \ \|$ is to calculate the distance between two data points in the high n dimensional space R^n; P is the order of the distance, and this is a metaparameter to control the weights.


FIGURE 2: The main framework of ergodic evolution.

$$\text{PF}_2 = \frac{1}{R} x \sum_{j=1}^{R} \left\| c' - c_j \right\|^{P/2} \tag{8}$$

where R is the total number of known working conditions used to predict the performance of unknown working conditions, $\mathbf{c}'$ is the working condition that the performance is unknown, and $\mathbf{c}_j$ is the jth working condition used to predict the performance.

3.2. Design Solution Searching. Based on the method of surrogate model construction in Section 3, a surrogate model can be obtained, which receives design solution and working conditions as input and predicts performances and its corresponding penalty factor as output. Based on this surrogate model, we will adopt an evolutionary algorithm to explore the design space. The penalty factor will be taken as one of the fitness functions during the evolutionary process.

Basically, most evolutionary algorithms follow the same framework. As shown in Figure 2, the critical difference is the operation of "generating offspring population," which is marked by a bold rectangle. The traditional crossover and mutant operations are replaced by a simple ergodic system. The detail can be found in Algorithm 1. As shown in the algorithm, the ergodic system adopted in this work is a logistic map, and it is used to generate a random number for generating new offspring. The ergodic evolution method has the advantages of ergodicity and regularity and performs better in dealing with high-dimensional design space.

4. Experiment

In this section, we conduct three groups of experiments to validate the proposed method. The first group is to test whether the surrogate model can predict the performance;

Generate an initial population. Evaluate the fitness for each individual.
/* D and EP **initialization***/ **for** i =1 to PS **do**
for j =1 to Dim **do**
/* DR **as a random value***/ **if** $rand$ [0, 1) < DR **then**
$D_{i,j} = -1$

FIGURE 7: The evolutionary process of the two targets of 20 runs.

During the experiments, we use a small dataset provided by a research institute of aerodynamic. This dataset includes 20 known design solutions with 4 design parameters in each design solution and 4 kinds of performance under 28 working conditions. Since the 4-dimension design solutions cannot be shown in a figure, we process the 20 design solutions by Principal Component Analysis (PCA) and plot the first two components in a figure. From Figure 3, we can find that the data is sparely scattered in the design space. We regard the data with less training data and sparse distribution of the main parameter data points in the problem as sparse scattered data.

4.1. Experiment on the Surrogate Model. Based on the method illustrated in surrogate model construction of Section 3, a surrogate model based on sparse scattered data can be constructed. This section conducts several experiments to test the model and find the optimal metaparameters of the surrogate model, such as Q in (4) and P in (5).

Since the proposed method involves two stages, we test the two stages, respectively. For the first stage, we conduct experiment based on the 10-fold crossvalidation method. This method splits all 20 data into 10 groups and uses 9 groups as training data and uses the last group as test data in each experiment. In each experiment, we calculate an

averaged error by (9), and after 10 times of experiment, the error of the first stage is averaged again.

$$e = \frac{1}{2} \times \sum_{i=1}^{2} \sqrt{\frac{1}{28} \times \sum_{j=1}^{28} \left(\widehat{p}_{ij} - p_{ij} \right)^2}, \qquad (9)$$

where P_{ij} is the value of the ith predicted performance under the jth working condition, while the P_{ij} is the real value of the ith performance under the jth working condition. Table 2 shows the results of different configurations of Q and P, and we can find that the surrogate model has the smallest error when $P = 1$ and $Q = 5$.
FIGURE 8: The 2-dimensional representation of the 20 known design solutions.

For the second stage, we also conduct experiment based on the 10-fold crossvalidation method. In each experiment, we calculate an averaged error by (9), and after 10 times of experiment, the error of the second stage is averaged again. Table 3 shows the results of different configurations of R and P, and we can find that the surrogate model has the smallest error when $P = 1$ and $R = 2$.

4.2. Experiment on Ergodic Evolution. In this section, we validate the ergodic evolution algorithm in terms of the capability of searching high-dimensional space. In this experiment, 16 benchmark functions are adopted as the test problems, including SCH, FON, POL, KUR, ZDT1, ZDT2, ZDT3, ZDT4, ZDT6, DTLZ1, DTLZ2, DTLZ3, DTLZ4, DTLZ5, DTLZ6, and DTLZ7. These benchmark functions are well known, and the detail can be found in [34].

We compare the performance of ergodic evolution with NSGA-II, which is a well-known evolutionary algorithm proposed in [35], and random evolution (RE), which is the same as Algorithm 1 except that the ergodic system is replaced by a general random generator. The crossover rate and mutation rate of NSGA-II are set to 0.9 and 0.1, respectively.

For each benchmark function, we run the three algorithms 30 times. For each run, the algorithms run 1000 generations with 100 individuals in each generation. After all experimental results are obtained, we conduct nondominant analysis. First, all individuals in the same generation of the three algorithms are combined, and then, count the number of individuals in the nondominant frontier after nondominant analysis. Figure 4 shows the averaged result (30 runs) of the top 100 generations. From the figure, we can clearly see that the proposed method is superior to NSGA-II and RE for most of the benchmark functions except DTLZ2, DTLZ4, and DTLZ5.

In addition, we plotted the Pareto frontiers of 5th, 10th, 20th, 50th, 100th, 200th, 500th, and 1000th generation of the three algorithms. Considering the length limitation, we only

show the figures of ZDT3 (Figure 5) and DTLZ2 (Figure 6) in this paper.

4.3. Experiment on the Whole Method. In this section, we validate the proposed method. For the ergodic evolution, two targets are adopted. The first is a function of the 4 performances provided by the aerodynamic institute, while the second is calculated by equation (5). The surrogate model is constructed with $P = 1$, $Q = 5$, and $R = 2$.

We run the whole algorithm 20 times, and Figure 7 shows the evolutionary process of the two targets. For each run, the algorithm evolves 200 generations, and there are 100 individuals in each generation. The figures include 20 lines indicating the evolutionary process of the 20 runs, and each point in the line indicates the minimum value of targets in one generation. As we can see, the algorithm converges to minimum targets almost within 100 generations.

We randomly select 4 runs and list 20 design solutions in the nondominated Pareto front in Table 4. We plot the generated design solutions and known design solutions in a single figure, and both are proceeded by PCA. From Figure 8, we can find that most of the generated design solutions are near to known design solutions, which prove that the proposed method can achieve rapid exploration of high-dimensional space. This result is reasonable since the second target of the CE restricts the algorithm to exploit new design solutions in the space near to the known design solutions.

From the extensive experiment results above, we find that (1) the adoption of some basic assumptions or prior knowledge can relax the requirement of data for training the surrogate model. The prior knowledge here represents views of designers on design problems. In this work, we simply adopt two basic assumptions, and the whole model is divided into two parts, and some unimportant relationships are ignored by the surrogate model. Therefore, we think transferring basic assumption or prior knowledge into a computational manner and integrating it with the surrogate model are feasible ways to build a surrogate model with only

sparse and scattered data. (2) The simple IDW method can train the surrogate model. However, in different scenarios, IDW may not always be feasible, and some advanced methods like Kriging and RBF network should be adopted and validated. (3) One of the merits of the proposed method is that the searching space can be expanded with the addition of more known design solutions. This means that this method is fit for both sparse and scattered data and relatively bigger data.

5. Conclusion

To train a surrogate model with only sparse and scattered data and find new design solutions based on this surrogate model, this work proposed a two-stage interpolation-based method for the surrogate model and adopts CE to explore the high-dimensional space. This paper uses PCA to reduce the dimension of data and prove the characteristics of sparse and scattered data. Then, combining the two-stage interpolation and ergodic evolution method, the sparse scattered point data is generated into the design method. Three groups of experiments show that the surrogate model can predict performances, and the CE is efficient in terms of exploring high-dimensional space.

Although this work proposes a feasible method to deal with the problems, some remaining problems require extensive research works. In the future, we will enhance the method from the following aspects.

(i) This work only adopts basic assumptions to relax the data requirement, and the data requirement can be further relaxed by incorporating prior knowledge, such as experts' experience and physical law. The main problem will be the technique of embedding prior knowledge into surrogate models

(ii) In this work, the penalty factor is important and the simple Euclidean distance is used. In the future, some nonlinear function of the Euclidean distance can be used to measure the penalty factor. The difficulty will be how to predefine or learn a nonlinear function for the penalty factor

Preparation and Performance Study of Carbon Fiber Composite Electroplated Carbon Badminton Racket

Ziying Sheng and Kai Wen 🆔

School of Physical Education, Wuhan Business University, Wuhan, 435600 Hubei, China

Correspondence should be addressed to Kai Wen; 20150740@wbu.edu.cn

Driven by the slogan of "Fitness for All", more and more people are participating in sports, which also promotes the popularity of the sports equipment market, of which badminton rackets are an important part. With the improvement of people's economic level, there are higher requirements for the materials of various sports equipment. It is expected that badminton rackets will not only be light, but also bearable, and the electroplated carbon in carbon fiber composites has such properties. Therefore, the purpose of this paper is to study the preparation of badminton rackets by electroplating carbon with carbon fiber composite materials and to study its performance. In this paper, the properties of carbon fiber composites are tested and analyzed, and the relevant chemical formulas are used to explain them. The experimental results of this paper show that after using the same pressure to conduct experiments on wooden, iron, steel, steel-aluminum, carbon-aluminum, and carbon bats, it is found that the bearing capacity of wooden bats is only 28%, the damage degree of badminton racket is 54%, while the bearing capacity of carbon racket is 89%, and the damage degree of badminton racket is 12%. This fully shows that the badminton racket made of electroplated carbon material not only has a much higher bearing capacity than badminton rackets of other materials, but also has a much lower damage degree than badminton rackets of other materials. Therefore, badminton rackets made of electroplated carbon are more durable and more popular.

1. Introduction

The demand for high-performance composite materials, especially in the fields of defense, military, and aerospace, has contributed to the rapid development of science and technology. Carbon fiber composite material is one of the most widely used composite materials, and the properties of carbon fiber directly determine the properties of the composite material. Scientific researchers in various countries have conducted many studies on the composition and structure of carbon fibers and their properties. Since the beginning of the twenty-first century, the properties of carbon fibers have been continuously optimized and improved, and the research on the manufacturing process of composite materials has also deepened, striving to make composite materials more efficient and simpler to manufacture.

A further study of carbon fiber materials is the study of their composite materials. In the molding process of carbon fiber composite materials, including hand molding and stretching. The resin conveying molding process is to perform the reinforcement material into a closed shape and solidify it under vacuum and pressure conditions. This process is simple and convenient and is widely used. In the aerospace field, in addition to the excellent properties of the composite material itself, it is also found that the carbon fiber composite material containing some shape memory effect maintains the shape memory ability.

The innovations of this paper are as follows: (1) This paper introduces the theoretical knowledge of carbon fiber composite materials and electroplated carbon and uses carbon fiber composite material and electroplated carbon to analyze how carbon fiber composite material and electroplated carbon play a role in the preparation and performance research of badminton racket. (2) This paper expounds the properties of carbon fiber materials and electroplated carbon. It is found through experiments that the

badminton rackets made of carbon fiber materials and electroplated carbon are of better quality and more popular.

2. Related Work

With the increasing emphasis on sports in China, the number of people participating in sports is also increasing rapidly. Mizuno found that people developed fully automatic badminton robots that could catch and serve in the same environment as a human badminton player. In the system he invented, the robot could automatically move to where the shuttlecock would fall and hit it back with a normal badminton racket. Mizuno gave a general introduction to a fully automatic badminton robot, but did not describe it with a practical example [1]. Park believes that shoulder and elbow injuries account for a considerable proportion of injuries in badminton. Because badminton requires repetitive, high-velocity overhead movements that place high loads on the upper body joints, badminton players often experience shoulder and elbow pain and decreased function. His research is mainly to evaluate the abnormality of the shoulder and elbow tendon in badminton players and to explore its correlation with clinical symptoms. Forty-nine badminton players participating in the leisure badminton club were invited to the sports training center for experiments. Park only introduced the object of the experiment, and did not explain the process of the whole experiment, resulting in no corresponding conclusions [2]. Duncan's study examines the impact of changes in physical and psychological arousal on badminton short serve performance in competitive and practice environments. He experimented with 20 badminton players (10 males and 10 females), with short serve measured at rest, midway, and end of a badminton-specific training program. The results showed that the performance of the short serve in practice was significantly better compared to the game, while the performance of the short serve in the real game was not very good. This is because in the real game, the athlete will have anxiety and tension, which will affect the performance. Although he conducted experiments on 20 athletes and analyzed the results of the experiments, there was no solution to the experimental results [3]. Minkai found that despite the well-known importance of badminton in sports, badminton is poorly defined and lacks research. In contrast to general training typically used to improve a badminton player's on-court agility, Reactive Initiation Training (RIT) challenges perceived speed, requiring only quick steps in the direction of the shuttlecock. His research explores comparing the speed of body reflexes to reaction initiation exercises to determine whether these exercises are effective in improving on-court agility. 20 badminton novices were divided into two halves and received physical reaction speed and reaction initiation training on the court. Before and after training, they took on-court agility tests with pre-judgment and without pre-judgment. The results showed that both training methods reduced the average running time, but only the reaction initiation training additionally reduced initiation time

and its proportion in those time-consuming positions. He designed and practiced the process of the whole experiment, but there is no specific experimental data to prove the authenticity of the experiment [4]. Yuan found that the loading of gold nanoparticles (AuNPs) onto environmentally sensitive polymer microgels is increasingly used to tune their optical properties and catalytic activities. Here, he synthesized composite polymer microgels with a core-shell structure and controllably loaded AuNPs onto the network chains of the polymer microgels. The results show that the prepared AuNPs composites have good pH sensitivity; thus, the electromagnetic coupling between AuNPs can be regulated by polymer microgels under various acidic conditions. But he did not explain in detail why this study was done [5]. Akhtar discovered that cellulose, a natural biopolymer commonly used as a support agent, has enhanced applicability and properties. The cellulose he isolated from the waste was used for silver nanoparticle (Ag-NPs) impregnation by a simple and reproducible method. Cellulose (Ag-Cel) prepared from Ag-NPs was characterized by powder X-ray diffraction, Fortier transform infrared spectroscopy, and scanning electron microscopy. Its thermal stability was investigated by thermogravimetric analysis. Although the scholar has carried out detailed experiments, no corresponding conclusions have been drawn [6].

3. Test Method of Carbon Fiber Composite Material Electroplating Carbon Performance

3.1. Application of Carbon Fiber Composite Materials. In carbon fiber composites, if the carbon fibers in the matrix are stretched along the fibers, the strain capacity of all fibers is the same, and some fibers will not affect the effect of other fibers after failure [7]. The broken fibers did not play a role, but the other fibers played their part as usual. According to this characteristic, if the material is damaged, especially in the use of sports equipment, it will not cause serious performance degradation. According to this characteristic, the personal safety of the athlete can be ensured [8].

Badminton is a sport suitable for all ages. In sports, the hardness and durability of badminton rackets have a great influence on the sports performance [9]. For example, some sub-rackets are prone to breakage, which can affect an athlete's level. The structure diagram of the badminton racket made of electroplated carbon material is shown in Figure 1.

As shown in Figure 1, with the development of science and technology, electroplated carbon badminton rackets have appeared in the sporting goods market. Carbon fiber has the characteristics of high hardness and toughness. In specific applications, carbon fiber and other substances are usually combined to form carbon fiber composite materials [10]. At the same time, the electroplated carbon should have excellent mechanical properties after curing, and in addition, it should have good fluidity, which is convenient for curing and molding. The application fields of carbon fiber composite materials are shown in Figure 2.

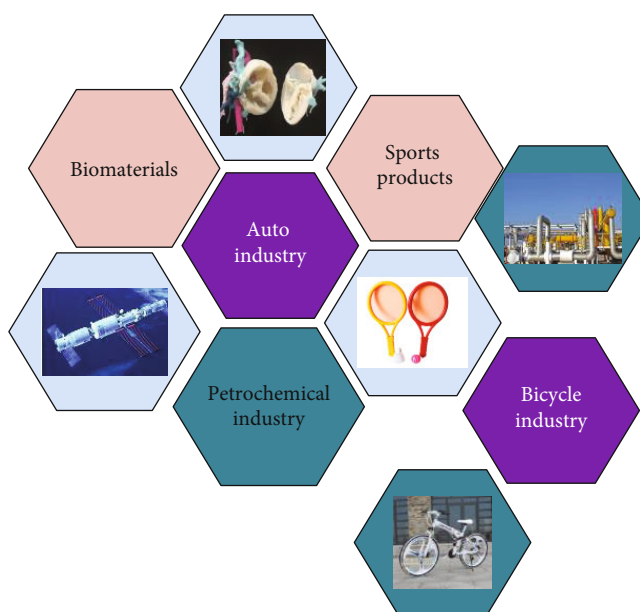
As shown in Figure 2, in the structure of carbon fiber composites, fiber reinforcement takes on the heavy
FIGURE 1: Electroplated carbon badminton racket.


FIGURE 2: Application areas of carbon fiber composites.

responsibility of the mechanical properties of the composites. The electroplated carbon is responsible for the task of fixing and strengthening and protects the carbon fiber from damage from the external environment. Therefore, the electroplated carbon and carbon fiber reinforcement of composite materials need to have excellent wettability and adhesion [11]. The good performance of carbon fiber self-recovery after deformation is shown in Figure 3.

As shown in Figure 3, the performance of the composite material depends on the ratio of reinforcement to matrix and the performance of the individual components. The general reinforcing materials are carbon fibers, glass fibers, plastic fibers, etc. In addition to metals, ceramics, and other materials, the matrix is mainly a resin material. Reinforcing materials can increase material strength and improve mechanical properties [12].

3.2. Characteristic Analysis of Electroplated Carbon in Carbon Fiber Composites. In the process of glass transition of electroplated carbon, the mechanical properties of the

resin will be quite different before and after. As the ambient temperature gradually increased, the free volume of the electroplated carbon molecules began to expand. When the temperature reaches the glass transition temperature, the free volume of the electroplated carbon molecules is sufficient, so the configuration of the electroplated carbon molecules is fully changed and adjusted, and the movement of the molecular chain is very active [13]. The analysis of electroplated carbon with different formulations is shown in Figure 4.

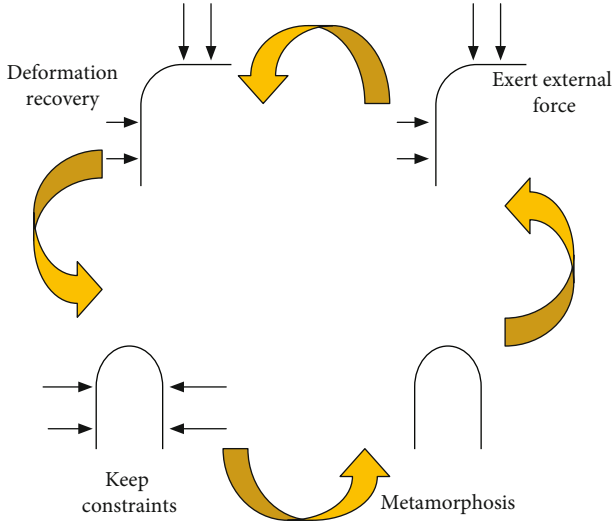
As shown in Figure 4, because the #20 formula has too little electroplating carbon, the performance in the DMA test is not ideal. Therefore, in the DSC test, it is no longer necessary to test the #20 type electroplated carbon, and only the DSC test of the #40, #60, and #80 samples is required. The three proportioned samples were scanned at different constant heating rates, and the apparent activation energy E_a was calculated according to the Kissinger formula; apparent activation energy can give a clearer physical meaning to elementary reactions, that is, the difference between the average


FIGURE 3: Good performance of carbon fiber self-recovery after deformation.

energy of the activated molecule and the average energy of all molecules [14], as shown as follows:

$$-\frac{E_a}{R} = \frac{dIn\left(\Phi/T_P^2\right)}{d(1/T_P)}, \tag{1}$$

where Φ represents the temperature rise rate, T_P represents the peak temperature, E_a represents the activation energy, and R represents the molar gas constant. According to the Kissinger method, when using the Kissinger method to determine the activation energy of crystallization of amorphous materials, it should be ensured that the crystallization fractions corresponding to the selected temperature are not very different; otherwise, large errors will be introduced, and the kinetic formula can be approximated as

$$H = A \cdot \exp\left(-E_a/RT\right) \tag{2}$$

Among them, the pre-entropy factor A is

$$A = \frac{\Phi E_a \exp\left(E_a/RT_P\right)}{RT_P^2} \tag{3}$$

The corresponding peaks of the three exothermic peaks in the DSC scan at different heating rates are shown in Table 1.

As shown in Table 1, the second exothermic peak disappeared when the temperature increased. Because the reaction rate was too fast, the reaction was not sensitive enough to temperature, so it was incorporated into the third peak, which was used to test the viscosity of electroplated carbon as a function of temperature using the temperature ramp mode of rotational rheology. The time-sweep mode was used to test the relationship between the viscosity and time of electroplated carbon at a constant temperature [15]. The kinetic parameters of the curing reaction are shown in Table 2.

It can be seen from Table 2 that solidification is a Chinese word, which chemically refers to the process of transforming substances from low molecules to high molecules, and also refers to the process of forming certain fixed views and viewpoints on things [16]. When the specific gravity of electroplating carbon increases, both E_a and A of the curing reaction of the system will increase. This is because the energy required for the electroplating carbon homopolymerization reaction is larger than the other two curing reactions [17]. With the increase of carbon content in electroplating, the difference between #60 and #80 is an order of magnitude from #40, while the difference between #60 and #80 is not obvious, indicating that the addition of electroplating carbon can prolong the service life of the mixed resin [18]. Electroplating carbon under different vision is shown in Figure 5.

As shown in Figure 5, the ability of a metallic material to resist permanent deformation or fracture under static load, and it can also be defined as proportional limit, yield strength, breaking strength, or ultimate strength. In order to ensure the full progress of the curing reaction, the curing temperature needs to be higher than the glass transition temperature, which can ensure good mechanical properties and curing degree of the electroplated carbon after curing [19].

3.3. Density Test. In this paper, the method of electroplating is used to electroplate the carbon fiber with nickel, and the metallization modification is carried out. The effect of nickel on the wettability of the carbon fiber interface was investigated by observing the high temperature spheroidization of the copper plating layer during the heat treatment process. By testing the thermal shock resistance of the carbon fiber composite wire, the bonding force between the carbon fiber and the copper coating was studied [20].

Archimedes' principle generally refers to Archimedes' law. An important principle of hydrostatics, which states that an object immersed in a stationary fluid, experiences a buoyant force equal to the weight of the fluid displaced by the object, directed vertically upward and through the centroid of the displaced fluid [21]. The actual density of carbon fiber copper composites is measured using Archimedes' principle:

$$F = pgv \tag{4}$$

p represents the density of distilled water and g represents the volume of distilled water displaced by immersion of the composite in distilled water. The volume V of the composite material at this time is

$$V = \frac{m_1 - m_2}{p} \tag{5}$$

Then, the density p of the composite material is

$$p = \frac{m_1 p}{m_1 - m_2} \tag{6}$$

(a) Storage modulus

(b) Loss modulus
FIGURE 4: Electroplated carbon with different formulations.

TABLE 1: Corresponding peak temperature (Tp) of exothermic peak of electroplated carbon curing system at different heating rates.

System	Heating rate (K/min)	$T_{P1}(K)$	$T_{P2}(K)$	$T_{P3}(K)$	$T_{P4}(K)$
#40	6	420.4	457.0	470.3	486.9
	12	453.0	462.1	483.2	489.0
#60	6	431.7	460.9	498.5	505.6
	12	458.9	465.6	480.3	489.3
#80	6	439.6	462.5	492.4	499.5
	12	460.8	470.1	498.8	505.8

TABLE 2: Curing reaction kinetic parameters.

System	E_a(kJ/Mol)	A(min-1)	H_{25}(min-1)
#40	62.5	3.43×10^7	4.75×10^{-6}
#60	73.2	4.65×10^8	5.46×10^{-7}
#80	81.6	1.96×10^9	1.63×10^{-7}

Then, the density p_r of the composite material is

$$p_r = \frac{p_1}{p_2} \tag{7}$$

Among them, p_1 is the actual density of the composite material, and p_2 is the theoretical density of the composite material.

3.4. Test of Thermal Conductivity.
Raman spectroscopy is a type of scattering spectroscopy. Raman spectroscopy is an analysis method of Raman scattering effect, which analyzes the scattering spectrum with different frequencies from the incident light to obtain information on molecular vibration and rotation, and is applied to the study of molecular structure. Raman spectroscopy is an important means to study the structure of carbon materials, which reflects the changes in the structure of carbon materials from the perspective of chemical structure [22]. The thermal conductivity K is measured by a laser thermal conductivity meter, and the thermal conductivity calculation formula is

$$K = \alpha \cdot \rho \cdot C_\rho \tag{8}$$

where K is the thermal conductivity, α is the thermal diffusivity, ρ is the density, and C_ρ is the specific heat capacity.

In recent decades, many outstanding research results have emerged in China in the field of materials, among which carbon fiber composite materials have been widely used in modules ranging from module shells and cabinets to aircraft fuselages [23]. However, how to objectively and quantitatively evaluate the electromagnetic pulse protection performance of this new type of composite material, such as the radio frequency impedance characteristics of the composite material, the electrical conductivity of the composite material under the action of a magnetic field, and the impedance characteristic of the composite material under the action of lightning pulse, it involves multidisciplinary knowledge such as mechanical structure, electromagnetic field propagation, instrument measurement, and materials. At present, there are not many people engaged in research in this field in China, which restricts the development and improvement of new materials [24].

3.5. Nickel Electroplating and Electroplating Carbon on Carbon Fiber Surface.
The pretreated carbon fibers are electroplated with nickel. The carbon fiber content in the plating solution was kept at about 0.2 g/L, and the short carbon fibers were put into the nickel plating solution for ultrasonic

Normal multiples of
electroplated carbon

500 times of
electroplated carbon
FIGURE 5: Electroplated carbon under different vision.

stirring. When the short carbon fibers are all settled on the bottom cathode copper plate, the power is turned on, and the thickness of the nickel layer is controlled by the electroplating time. The reaction that occurs at cathode Ni during nickel plating is

$$Ni^{2+} + 2e = Ni \tag{9}$$

The main reaction that occurs at anode Ni^{2+} is

$$Ni\text{-}2e = Ni^{2+} \tag{10}$$

If the anode current density is too large, anode passivation is likely to occur, accompanied by the progress of the side reaction $O_2\uparrow$ as

$$2H_2O - 4e = O_2\uparrow + 4H^+ \tag{11}$$

Therefore, in the process of electroplating, the current density is strictly controlled to ensure the quality of the coating.

The nickel-plated carbon fibers were repeatedly ultrasonically cleaned with distilled water, and then copper-plated. The carbon fiber content in the plating solution was maintained at about 0.4 g/L. When the nickel-plated carbon fibers were ultrasonically stirred in the solution, the power was turned on. The temperature of the plating solution was 40 °C and the current density was 2.5 A/dm. The reaction that occurs at cathode Cu during copper plating is

$$Cu^{2+} + 2e = Cu \tag{12}$$

The main reaction that occurs at anode Cu^{2+} is

$$Cu\text{-}2e = Cu^{2+} \tag{13}$$

In the process of copper plating, it is still necessary to control the current density. Excessive current density will also be accompanied by side reactions.

The electroplated copper-plated and nickel-plated copper carbon fibers were taken out, repeatedly washed with distilled water for 3 times, then filtered and cleaned with anhydrous alcohol on a suction filter, and finally placed in a vacuum drying box for drying.

Since metal is easily oxidized in the air, it is inevitable that some coatings will be oxidized to form oxides during the cleaning and drying process of carbon fibers. The coating of the oxide is relatively poor, which will affect the subsequent experiments, so the copper oxide must be reduced. The carbon fiber is put into a vacuum tube furnace for reduction, and the reaction that occurs is

$$H_2 + CuO \longrightarrow H_2O \tag{14}$$
Electroplating time is an important factor to control the thickness of the coating, and the method of determining the thickness of the carbon fiber surface layer by metallographic method is difficult to implement. Therefore, this paper uses the weighing method to estimate the average thickness of the coating. The weighing method is the method recommended by the International Organization for Standardization. It is only suitable for gases that do not react between components, components and the inner wall of the cylinder, and condensable components that are completely gaseous under experimental conditions. The calculation formula of the average thickness of the coating is

$$\Delta r = \left(\sqrt{1 + \frac{\rho_c \Delta G}{\rho_c N_i G}} - 1 \right) d \tag{15}$$

In the formula, ΔG is the weight gain rate of carbon fiber before and after nickel electroplating; ρ_c and $\rho_c N_i$ are the density of carbon fiber and nickel, respectively; and d is the diameter of carbon fiber.

Many studies have shown that there are two main factors that affect the thermal shock resistance of coatings. The first is the difference between the thermal expansion coefficient of the coating and the base material. The thermal expansion coefficient of the metal copper coating is larger, while the thermal expansion coefficient of the matrix carbon fiber is smaller. Due to the difference in thermal expansion coefficient, thermal stress will be generated between carbon fiber and copper during the cooling and heating cycle. The calculation formula of thermal stress is

$$\sigma th = \frac{E_f}{1 - \nu} \cdot (\alpha_r - \alpha_s) \cdot (T_s - T_r) \tag{16}$$

FIGURE 6: Application of carbon fiber composites in sports equipment.

In the formula, α_r and α_s are the thermal expansion coefficients of the substrate and the coating, respectively, and T_s and T_r are the temperatures of the coating and the substrate, respectively. It can be seen from the formula that the smaller the thermal expansion coefficient between materials, the smaller the thermal stress will be. The greater the interfacial bonding strength, the better the thermal shock resistance of the coating.

Since carbon fiber is a carbon material, it has a lower theoretical specific capacity ae^-. In general, researchers improve the actual cycle Li_aC of carbon fibers through surface modification, biological preparation of carbon fibers, etc., so that it can approach the theoretical capacity to the greatest extent:

$$aLi^+ + C(carbon fiber) + ae^- \leftrightarrow Li_aC \qquad (17)$$
4. Experiment and Analysis of Carbon Fiber Composite Material Electroplating Carbon

4.1. Experiment and Analysis of the Properties of Carbon Fiber Composites. In many sports, athletes hope that the equipment can meet the characteristics of light weight and high strength at the same time, while the density of carbon fiber composite materials is only 1.76 to 1.80 g/cm^3, and the density of metal materials is several times that of carbon materials. For example, steel has a density of 7.87 g/cm^3 and aluminum has a density of 2.7 g/cm^3. These materials do not meet certain special sports needs. The application of carbon fiber composite materials in sports equipment is shown in Figure 6.

As shown in Figure 6, therefore, the carbon material is lightweight and high in strength and is very suitable for

TABLE 3: Physical properties of different reinforcement materials.

Reinforcing material	Density/ g·cm-3	Tensile strength/ GPa	Elastic modulus/ GPa	Elongation/ %
Carbon fiber	1.69	3.47	232	1.48
Glass fiber	2.58	3.47	69	2.56
Boron fiber	2.39	1.38	378	0.37

Lightweight carbon fiber	309	47.8	8.9

use in sports equipment. Carbon materials are widely used in some sports such as bicycles, sailboats, poles, golf, and rackets. The physical properties of different reinforcing materials and the comparison of badminton rackets made of different materials are shown in Table 3 and Table 4.

As shown in Table 3, carbon materials have high fatigue resistance compared with metals and are very suitable for the manufacture of large rackets. As the competition in

FIGURE 8: The expansion ratio of composites with different carbon fiber volume fractions as a function of temperature.

sports becomes more and more intense, the requirements in the field of rackets are also increasing.

As shown in Table 4, the interface problem of metal matrix composites has always been a hot and difficult problem in research, and the bonding state between the interfaces has an important impact on the performance of the composites. The interface between carbon fiber and copper has high interfacial energy, which will lead to poor wettability between carbon fiber and copper. This poor wettability

results in the simple mechanical bonding of the interface between carbon fiber and copper, and it is difficult to prepare carbon fiber composites with good interfacial bonding, which limits its performance.

The sintering temperature also has a great influence on the thermal conductivity of the composites, and the thermal conductivity changes with the increase of the sintering temperature, and the density is the same. With the increase of sintering temperature, the thermal conductivity first

(a)

(b)
FIGURE 9: Bearing capacity of badminton rackets of different materials under the same force. (a) Bearing capacity of badminton racket made of ordinary material. (b) Bearing capacity of badminton racket made of electroplated carbon material.

increases and then decreases and reaches the maximum value at 950°C. The effect of sintering temperature on the composites is shown in Figure 7.

It can be seen from Figure 7 that when the test temperature is relatively low, the thermal expansion difference between the composite materials formed by different sintering temperatures is very small, and as the test temperature increases, the difference becomes larger and larger. The average thermal expansion of the samples sintered at 950°C is the largest, and the average thermal expansion of the samples sintered at 850°C is the smallest.

It can be seen from Figure 7 that the density has an important influence on the thermal conductivity of the composite material; the higher the density p, the higher the thermal conductivity of the material. The effect of porosity λ on composites is

$$\lambda = \lambda_s (1 - p) \tag{18}$$

The relationship between the expansion ratio and temperature of the composites with different carbon fiber volume fractions is shown in Figure 8.

It can be seen from Figure 8 that with the increase of the volume fraction of carbon fibers, the expansion rate of the composite material shows a decreasing trend. Objects

TABLE 5: Comparison of the bearing capacity of badminton rackets of different materials.

	Pressure	Affordability	Level of damage
Wooden racket	30	28%	54%
Iron beat	30	32%	58%
Steel and aluminum	30	40%	43%
Carbon aluminum racket	30	65%	28%
Carbon racket	30	89%	12%

expand and contract due to changes in temperature. The change in length magnitude caused by a unit temperature change is expressed by the thermal expansion coefficient. When the volume fraction of carbon fiber volume fraction increases, the thermal expansion coefficient of the composite becomes smaller. On the other hand, the addition of carbon fiber to the matrix will form the interface and internal stress, which will affect the thermal expansion of the composite. With the increase of carbon fiber content, the interface and internal stress will increase, and the influence on thermal

expansion will be greater, so the thermal expansion coefficient will also decrease.

Direct electroplating-hot pressing is a good method for preparing short carbon fiber composites. Carbon fibers overlap each other in the process of electroplating and maintain uniform dispersion in the subsequent cleaning, drying, and hot pressing processes and can prepare composite materials with uniform distribution of carbon fibers.

4.2. Experiment and Analysis of Electroplated Carbon Badminton Racket. After the electroplated carbon badminton racket is produced, its durability needs to be tested through actual use. Hardness, bearing capacity, etc. all need to be verified. In order to enhance the scientificity of the test, this paper conducted an experiment on a badminton coach to let him use badminton rackets of different materials and test the endurance of badminton rackets under the same force, so as to compare their hardness and draw conclusions. The bearing capacity of badminton rackets of different materials under the same force is shown in Figure 9.

As shown in Figure 9, when testing the flexibility, mechanical bending equipment can be used to apply pressure to badminton rackets of different materials and compare their ability to withstand the same pressure. In this paper, experiments were carried out on wooden, iron, steel, steel-aluminum, carbon-aluminum, and carbon bats, as shown in Table 5.

As shown in Table 5, the bearing capacity of wooden, iron, steel, steel-aluminum, carbon-aluminum, and carbon beats under the same pressure was analyzed. It is found that only the carbon racket has a relatively high bearing capacity and a relatively low degree of damage, so now the mainstream material of the racket is mainly carbon racket. The racket made of this material is of good quality and light weight, which can make athletes swing faster and use less effort. Due to the influence of other factors, such as users, use environment, and frequency of use, the results of this experiment are not completely reliable, and there are certain differences.

5. Conclusions

With the development of science and technology, people's quality requirements for various things are getting higher and higher. The development of China's aviation industry is inseparable from the contribution of carbon fiber composite materials. Carbon fiber composites have been widely used in many fields because of their good properties. This article first gives a general introduction to carbon fiber composite materials and electroplated carbon so that people can understand the properties and principles of the two and then use the relevant chemical formulas to analyze their properties. Finally, it is found that both have super-strength properties. In the experimental part, this paper compares the physical properties of electroplated carbon and different reinforcing materials and draws the conclusion that the fatigue strength of carbon fiber composites is much higher than that of metal materials. Then, the hardness and bearing capacity of electroplated carbon badminton rackets were compared. Under

the same force and pressure, the electroplated carbon badminton racket is not only more durable, but also harder than other badminton rackets. Therefore, it is very necessary to study the preparation and performance of electroplated carbon badminton rackets.

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

This article takes the application of nanomaterials in new concrete materials as the research object and explores the defects of nanomaterials in improving the toughness and tensile capacity of traditional concrete by analyzing the effects of nanomaterials on the structure and properties of new concrete. This article takes the application of nano-SiO_2 in new concrete materials as an example. Firstly, the experiment of preparing nanoconcrete was carried out, and then, aiming at the experimental results, a detailed analysis and discussion on the effects of nano-SiO_2 on the shrinkage, mechanical properties, and microstructure of the new concrete materials were carried out. The research results show that the cement paste with nano-SiO_2 is much better in chemical shrinkage than the cement paste without admixture, and the chemical shrinkage value of the cement paste with nano-SiO_2 increases significantly in the early setting stage. The chemical shrinkage values are 11.4%, 26.7%, 53.9%, and 94.2%, respectively, according to the amount of nano-SiO_2 added. With the extension of the setting period, the growth rate of the shrinkage value of cement paste slows down; nano-SiO_2 can improve the compressive capacity and strength of concrete, and with the increase of the amount of compressive strength, the value of compressive strength is also increasing. In the early stage of coagulation, when the nano-SiO_2 dosage is 1.6%, the compressive strength of the coagulation for 3 days is 39.02%. With the prolongation of the setting period, the increase in compressive strength continues to increase, but the growth rate slows down; the addition of nano-SiO_2 has changed the microstructure of concrete. Nano-SiO_2 has high pozzolanic activity, which can promote the hydration process of cement, and because of the small particles, it can fill the voids of concrete, thereby improving its compactness and mechanical strength.

1. Introduction

1.1. Background and Significance. In recent years, with the rapid development of the social econoour, the process of industrialization and urbanization has also been accelerating, which is manifested in the construction and improvement of various infrastructures. Concrete, as the most widely used construction material in the construction industry, has also been used in the largest amount. In recent years, its demand has also increased exponentially. However, due to the problems of insufficient toughness and tensile resistance caused by the components of concrete materials, many projects have collapsed and damaged, which has a major impact on casualties and property losses. Seeking new building materials and improving the quality of building materials are the demands of many parties.

Nanomaterials were born in the 1960s and have been widely used since the 21st century. For example, it has played a huge application value in medical, chemical, electronic industry, and biochemical fields. It is a new type of material with excellent physical and chemical properties, which is different from the atomic and molecular characteristics of microscopic particles and different from macroscopic objects. Nanomaterials are mesoscopic structural materials with singular characteristics [1]. Because of their small size, they exhibit strange properties that neither

microscopic particles nor macroscopic objects possess. The development of nanomaterial technology is a revolution in the history of materials science and construction engineering [2]. Its unique properties of light, electricity, heat, and magnetism have had a huge impact on the development of the construction industry and civil engineering. Adding nanomaterial into traditional concrete and other building materials to change the composition structure of traditional concrete can greatly improve the mechanical properties and durability of new concrete, thereby improving its toughness and tensile capacity [3].

1.2. Related Work. Since the advent of nanomaterials in the 1960s, more and more experts and scholars have paid attention to it due to its special properties. Huang and Lovell pointed out that nanomaterials have been widely used as reagents for therapeutic and diagnostic (therapeutic) applications. They note that research efforts in nanomaterials have changed beyond the in vitro investigation of emerging substances to the conception of substances that work on more contextually relevant patterns of animal disorders, thus multiplying the opportunity for therapeutic clinical conversion. Common categories of nanoscale biomaterials, consisting of magneto nanoparticles as well as volume particles, upswitched granules, dielectric silica granules, charcoal-based granules, and organochromatic dye-based granules, exhibit the diagnostic and therapy applications of biomaterials. Changes like dimensional manipulation and process surface modification allow for regulation of ecological compatibility and interaction from the intended organization. Demands for better treatment for testing disorders and intensified chemical therapies, as well as practical thoughts on the need for climatologically scalable nanomaterials, are set to be crucial drivers [4]. Xiangzhen et al. have also stated that temporary structural failures frequently occur in dynamic tension (e.g., spalling) when reinforced structures are loaded by detonating and impact velocity charges. The precise forecast of structural failure due to static forces is known to be a competitive issue. In their study, they suggest a nonlocal damage-dependent modelling to forecast temporary elastic failure of specific concrete material building on the relatively recently developed localized porous square product model. In this nonlocal pattern, the interference fields diminish as the extent of insolation grows, and this results in an ideal characterization of the total damage area and the free surface localization, i.e., the lack of localization disappears in such areas. The statistical illustrations of one-dimensional peel tests and two-dimensional dynamic tension tests on concrete slabs show that a less damage-dependent nonlocal model can address the full range of restrictions of the primal nonlocal market. A general model predicated on nonlocal injuries was then validated on the basis of two experiments, the divided Hopkinson extension lever test and the adapted divided Hopkinson lever (scattered) trial. Mathematical demonstrations indicate that the suggested nonlocal induction model can provide a sensible estimate of the location of mechanical dynamic tension failure. However, the topographic example does not properly forecast dynamic tension failure, while the primitive nonto-

pographic model does not forecast several cracks at high load rates [5]. The advantages of nanomaterials in construction have only emerged in recent years. Therefore, there is not much research on nanomaterials in the construction industry. Based on this, it is very meaningful to study the application of nanomaterials in new concrete materials.

1.3. Innovation in This Article. The innovations in this article are mainly reflected in the following aspects: (1) It is proposed to apply nanomaterials to new types of concrete. The excellent properties of nanomaterials can effectively improve the defects of traditional concrete toughness, tensile strength, compression, and insufficient durability. (2) Take nano-SiO_2 as an example through experiments to specifically explore the influence of nanomaterials on the performance and structure of concrete, turn abstraction into concrete, and make the article easy to understand. The article provides a suggestion for optimization and improvement of concrete materials in the construction industry and can also provide new ideas for the research of nanomaterials.

2. Nanomaterial and Their Application in New Concrete Materials

2.1. Nanomaterials. Nanomaterials are a new and hot new material science in the past two years and have received extensive attention and research from all walks of life since its inception. It refers to a material that is at least one-dimensional in the three-dimensional space at the nanometer level. Because of its small size, it exhibits singular characteristics that are very different from the atoms and molecules of microscopic particles and macroscopic objects. The form of particles between microscopic atoms and macroscopic individuals. The size of nanomaterials is in the range of 1-100 nm, which is equivalent to the scale of 10-1000 atoms closely packed together [6, 7].

2.1.1. Characteristics and Effects of Nanomaterials. Nanomaterial particles are small and larger than the surface volume. When the diameter of the nanoparticle is 10 nanometers, the body of the nanoparticle contains more than 4000 atoms, and the atoms on the surface account for 40%; when the diameter of the particle drops to 1 nanometer, the particle body contains 30 atoms, and the body surface atoms will account for 99%, which means that almost all the atoms are concentrated on the surface of the particle [8, 9]. The number of atoms on the surface of the nanoparticles and the total number of atoms increase dramatically with the reduction of the diameter of the nanoparticles. This strange characteristic has led to the nanomaterials having many special properties that are not available in general materials, manifested in various effects, as follows:

First: surface and interface effects. The so-called surface and interface effects are manifested in the phenomenon that the number and total number of surface atoms of nanomaterial particles will increase sharply and violently as the diameter of nanoparticles becomes smaller. When the diameter of the nanoparticle is 10 nanometers, the number of atoms on the surface of the particle will occupy 40%, and as the

diameter of the particle continues to decrease, the percentage of its surface atoms will increase significantly; when the diameter of the nanoparticle continues to decrease to about 1 nanometer, the percentage of atoms on the surface will increase to more than 90%, and then, all the atoms contained in the particles will be concentrated on the surface. Due to the violent increase in the number of surface atoms, particles will have extremely high surface energy, easily combine with other atoms, and will have high stability and chemical activity [10].

Second: small size effect. The external morphology of nanomaterials is a tiny crystalline particle. In terms of individual particle morphology, nanomaterials are similar to atoms and molecules in the microscopic world, but from the surface of the entire nanomaterial, it has the ability to be compared with macroscopic objects. It has a huge body surface area. Therefore, nanomaterial is a kind of special material body which is different from microscopic particles and macroscopic individuals. For ultrafine particles such as nanomaterials, the size becomes smaller and the body surface area increases, which produces various peculiar properties and also significantly improves its strength, toughness, and hardness, showing greater than other materials. The advantages are reflected in its acoustic, optical, electrical, thermal, and magnetic properties. For example, the combination of nanomaterials and metal materials makes the nanometals much harder than normal normal metals; the combination of calcium fluoride and nanomaterials can bend flexibly at room temperature without breaking, etc. [11, 12].

Third: quantum size effect. When a nanomaterial with a large specific surface area is split into discrete energy levels from the continuous energy band, the spacing between energy levels will increase as the particle size decreases. When the spacing between energy levels is greater than thermal energy, electrical energy, or magnetic field energy, nanomaterial particles will produce a series of anomalous properties that are different from macroscopic and microscopic particles, that is, the quantum size effect of nanomaterials [13].

Fourth: macro quantum tunnel effect. The ability of microscopic particles to penetrate the barrier is called tunneling. And for ultrafine particles such as nanomaterials, due to their special magnetization, it also has this kind of tunneling effect. The ability of nanomaterials to penetrate the barriers of the macroscopic system but change their own special properties is called the macroscopic quantum tunneling effect of nanoparticles [14].

Fifth: volume effect. The volume of nanomaterial particles is very small, and the number of atoms contained in the body is very small. Therefore, it is impossible to describe many phenomena with the mass of infinite atoms. This is the volume effect of nanomaterials [15].

2.1.2. Classification of Nanomaterials. With the deepening of research, nanomaterials are now mainly divided into the following categories:

First: nanoceramics. Nanoceramics use nanotechnology to incorporate nanopowder into ordinary engineering ceramics to change the properties of ordinary ceramic materials, so that the finished ceramic products have higher flexibility, hardness, and strength and overcome the problems of traditional ceramics that are brittle and fragile [16, 17].

Second: nanopowder. Nanopowder refers to powder or particles with a diameter of less than 100 nm and is a solid particulate material between microscopic particles and macroscopic objects.

Third: nanofibers. Nanofiber is a linear material with a diameter between 1 and 100 nm and a long length. It is mainly used for the manufacture of components of quantum computers and photonic computers in the future.

Fourth: nanofilm. Nanofilm is divided into granular film and dense film. A particle film is a thin film that sticks to nanoparticles with a small gap in the middle; a dense film refers to a film with a tight film layer and a particle size of nanometers.

Fifth: nanoblock. Nanoblocks are nanocrystalline materials that are shaped by nanopowder by high pressure or crystallized by metal liquid. It is mainly used for ultrahigh strength materials and smart metal materials [18, 19].

2.2. New Concrete Materials. It is the most widely used and most used building material in the construction industry. The traditional concrete is mainly made of cement, with the addition of aggregates such as water, stones, and sand. If necessary, chemical admixtures and mineral admixtures (such as fly ash and mineral powder) are added, and they are evenly distributed according to the appropriate ratio. The condensed artificial stone made of agitation is a basic building material. For a long time in the past, concrete has been used for the construction of housing infrastructure projects due to its fire resistance, compression resistance, and extremely convenient characteristics in production and use. It has also been used to this day. However, with the development of social technology and the continuous improvement of people's requirements for the quality of building materials, some problems of traditional concrete, such as poor toughness and weak tensile capacity, have gradually been exposed. Traditional concrete can no longer meet the needs of the current society. Looking for new energy materials or new technologies to improve the performance of traditional concrete has become an important research direction in the construction industry and civil engineering and other fields [20, 21].

New concrete is based on traditional concrete materials using modern technological means or adding new material energy, so that the structural composition and performance of traditional concrete can be changed, and its aspects such as toughness, tensile strength, mechanical properties, and durability are improved. Performance of an improved building material [22]: compared with traditional concrete, the new type of concrete shows more powerful performance advantages. At present, new concrete is mainly made of nanotechnology and nanomaterials to improve traditional concrete [23].

2.3. Application of Nanomaterials in New Concrete Materials. Due to its small particle size and large body

surface area, nanomaterials can show strong hardness, strength, and toughness when combined with other atoms. The combination of concrete and nanomaterials can well solve its lack of toughness and tensile strength problem. As mentioned earlier, there are different classifications of nanomaterials, and nanomaterials used in concrete materials are also diverse. The main applications are mainly the following:

First: *the application of nanometer ore powder in new concrete materials.* Nanomaterials have special properties such as surface and interface effects, small size effects, quantum size effects, macroscopic quantum tunneling effects, and volume effects. Therefore, when combined with other materials, they can give the combined materials different properties from traditional materials. The nanometer ore powder added to the new concrete mainly includes nanometer SiO_2, nanometer CaCO3, and nanometer silicon powder. Using nanotechnology to add nanometer ore powder to the concrete makes its atomic structure into nanometer level, which can greatly improve the strength and hardness of the concrete, toughness, and durability [24].

Second: *the application of nanometal powder in new concrete.* Nanometal powder has the characteristics of high strength, high hardness, and good plasticity. At the same time, because of its surface effect and good activity, it can be added to concrete to produce functional electromagnetic shielding concrete. However, since there are many types of nanometal powders, to make the best electromagnetic shielding concrete, the appropriate nanometal nonpowder must be selected [25, 26].

Third: *the application of nanometal oxides in new concrete materials.* The use of nanometal oxides can make smart cement concrete, such as self-alarm devices. The addition of nanometal oxides can make the concrete have a strong conductive function. If a sensor made of nanometal oxides is inserted into the concrete, then the concrete will be able to realize the alarm and monitoring functions of the outside world [27, 28].

Fourth: *the application of nanocomposites in new concrete materials.* Nanocomposite is a new type of material developed based on the combination of basic nanomaterials and other materials. Adding nanocomposites to concrete can not only improve the compressive strength, tensile strength, and ductility of concrete but also improve durability of concrete [29, 30].

3. Preparation Experiment of Nanoconcrete

Nanomaterials are widely used in new concrete materials. Based on the different types of nanomaterials, the nanoadditives mixed in concrete materials are also different, and different nanoadditives have shown to improve the performance of concrete materials. In order to specifically analyze the improved performance of nanomaterials on concrete properties, this paper selected nano-SiO_2 as a nanoadditive added to new concrete materials for experimental research.

3.1. Experimental Object and Purpose. In this experiment, the application of nano-SiO_2 in new concrete materials was taken as the research object and theme of the experiment, and the purpose was to explore the effects of nano-SiO_2 on the shrinkage performance, mechanical properties, internal structure, durability, and other aspects of the new concrete materials.

3.2. Raw Materials Used in the Experiment

3.2.1. Cement. Cement is the basic material of concrete, accounting for the largest proportion. The cement used in this experiment is ordinary Portland cement, and its main components and properties are shown in Tables 1 and 2.

3.2.2. Aggregate. The aggregate of concrete is composed of coarse aggregate and fine aggregate. The coarse aggregate used in this experiment is broken limestone, and the fine aggregate is siliceous natural river sand.

3.2.3. Chemical Admixture. The chemical admixture is added to improve the performance of the concrete and make it more suitable for the external service environment. Commonly used chemical admixtures are water reducing agents, which are divided into fatty acid salt series, naphthalene sulfonate series, melamine resin series, sulfamate series, and polycarboxylate series. The naphthalene sulfonic acid is used in this experiment. Water reducer, swelling agent, and UEA swelling agent are also used in this experiment.

3.2.4. Mineral Admixture. Whether the concrete has good tensile strength, durability and corrosion resistance has a decisive relationship with its mineral admixture. The performance of the mineral admixture can directly affect the performance of the concrete, so the mineral admixture added to the concrete is selected. Mixing is very important. The mineral admixtures used in this experiment are ore powder and fly ash, and their chemical composition is shown in Table 3.

3.2.5. Nanomaterial. The nanomaterial used in this experiment is nano-SiO_2 in nanoore powder. Its example diameter is between 6 and 50 nm, the specific surface area is 250⊠/g, and the purity is greater than 99%.

3.2.6. Water. It is general civilian tap water.

3.3. Experimental Steps and Methods

3.3.1. Measuring the Density and Specific Surface Area of Cement, Mineral Powder, and Fly Ash. *Step 1.* Place the cement, ore powder, and fly ash samples in an oven to dry, and then, put them in a desiccator to cool to room temperature.

Step 2. Pour appropriate amount of anhydrous kerosene into the pycnometer, the volume is between 0 and 1 ml, then close the lid tightly and place it in a constant temperature water bath, and take out the recorded reading V_1 after 20 minutes.

Step 3. Wipe the upper part of the pycnometer not in contact with kerosene, then pour 60 g of cement, mineral powder, and fly ash samples, and use ultrasonic vibration until there are no more air bubbles in the bottle.

TABLE 1: Chemical composition of cement.

Chemical composition (%)	SiO$_2$	CaO$_3$	Al$_2$O$_3$	MgO3	Fe$_2$O$_3$	SO$_3$
Content	21.3	52.14	6.52	3.18	3.77	4.98

TABLE 2: Properties of cement.

Setting time		Stability	Compressive strength (MPa)		Flexural strength (MPa)	
Initial setting	Final setting	Qualified	4D	27D	4D	27D
2.5 h	3.5 h		25.7	50.0	5.5	8.7

TABLE 3: Chemical composition of mineral powder and fly ash.

Chemical composition (%)	SiO$_2$	CaO$_3$	Al$_2$O$_3$	MgO3	Fe$_2$O$_3$	SO$_3$
Mineral powder	31.12	34.45	14.23	11.45	0.31	2.47
Fly ash	61.34	2.13	28.12	0.82	5.04	0.36

Step 4. Put the pycnometer in the constant temperature water bath again, read V2 after 20 minutes, and then use formula (1) to calculate the density of cement, mineral powder, and fly ash.

$$\rho = \frac{P}{V_2 - V_1}, \tag{1}$$

where ρ stands for density, P stands for mass, V_1 stands for the first reading, and V_2 stands for the second reading.

Step 5. Use the density of cement, mineral powder, and fly ash calculated in the above steps and formula (2) to calculate the quality of the sample, and then, place the sample in the automatic specific surface area measuring instrument to measure the specific surface area, a total of three measurements. Then, go to the average.

$$W = \rho V (1 - \varepsilon), \tag{2}$$

where W represents the sample mass of cement, mineral powder, and fly ash, ρ represents the sample density, V represents the volume of the particle film layer, and ε represents the porosity of the film layer.

3.3.2. Measuring the Packing Density and Porosity of Sand and Gravel. Step 1. Take a 3 L sample of sand and stone in an oven and dry it; then, cool to room temperature.

Step 2. Remove the excessively large sand and gravel, and then, divide the rest into two parts of the same quality.

Step 3. Take one of them and put it into the volume cylinder twice before and after. Each time it is installed, a cylindrical steel pipe with a diameter of 10 mm is put into the cylinder to hit the ground. The steel pipe is perpendicular to the ground during the impact, about 20-25 hits.

Step 4. After the impact is completed, load another sample into the cylinder until it exceeds the mouth of the cylinder, and smooth the cylinder mouth with a ruler.

Step 5. Weigh the total weight of the sample and the volumetric cylinder to calculate the packing density and porosity of the gravel.

3.3.3. Mixing Cement. Step 1. Nano-SiO$_2$ is placed in water and dispersed with ultrasound for 5 minutes.

Step 2. Put cement, mineral powder, fly ash, and chemical admixture weighed according to a certain proportion into the pure paste mixing pot and stir slowly for 3 minutes.

Step 3. Put the ultrasonically treated nano-SiO$_2$ into the stirring pot, stir slowly for 1 minute and a half, then let it stand for 10 s, and then stir quickly for 1 minute.

Step 4. Put the well-mixed clean mud into the mold, and let it stand after setting.

Step 5. To prepare concrete, first, put nano-SiO$_2$ into water and disperse it with ultrasonic wave for 5 minutes.

Step 6. Put cement, mineral powder, fly ash, chemical admixture, and coarse and fine aggregate weighed according to a certain proportion into the concrete mixing pot and mix slowly for 6 minutes.

Step 7. Pour in nano-SiO$_2$ treated with ultrasonic wave and stir for 5 minutes.

Step 8. Pour the mixed concrete into the mold and set it under high pressure and then let it stand for curing.

4. Analysis of the Influence of Nanomaterials on the Performance of New Concrete Materials

In the third part of the article, we used nano-SiO$_2$ as a specific example to conduct the preparation experiment of nanoconcrete. The experimental results show that the addition of nano-SiO$_2$ changed the chemical composition of the original traditional concrete, greatly improved its chemical and physical properties, and showed the excellent performance that traditional concrete does not have. In this chapter, we will make a specific analysis and discussion on
FIGURE 1: Chemical shrinkage of cement paste after 4 days of setting.
FIGURE 2: Chemical shrinkage of cement paste after 27 days of condensation.

TABLE 4: Concrete mix ratio.

NS content	Water	Cement	Gravel	Water reducer and swelling agent	Mineral powder and fly ash
NS0%	165	623	650	12.65	114
NS0.4%	165	621.7	650	12.65	114
NS0.8%	165	617.8	650	12.65	114
NS1.2%	165	624	650	12.65	114
NS1.6%	165	619.55	650	12.65	114

the improvement of nano-SiO$_2$ on the performance of new concrete materials.

4.1. Effect of Nano-SiO$_2$ on Chemical Shrinkage of Cement Paste.

Nano-SiO$_2$ has high pozzolanic activity. Adding it to cement paste can shorten the setting time of cement paste and reduce its fluidity, which is very helpful for improving the strength of cement. In order to deeply analyze the effect of nano-SiO$_2$ on the chemical shrinkage of cement paste, we mixed four different amounts of nano-SiO$_2$ (0.4%, 0.8%, 1.2%, and 1.6%) into the preparation of cement paste and record the chemical shrinkage value of each setting period and compare it with the cement paste without nano-SiO$_2$. The results are shown in Figures 1 and 2.

From Figure 1, we can see that the cement paste added with nano-SiO$_2$ has a much faster chemical shrinkage value than the cement paste without nano-SiO$_2$, and the chemical shrinkage effect is significant. The chemical shrinkage value of cement paste of SiO$_2$ increases rapidly, and the chemical shrinkage value gradually increases with the increase of the amount of nano-SiO$_2$ added. When the cement paste was set for 3 days, the amount of nano-SiO$_2$ added was 0.4%, 0.8%, 1.2%, and 1.6%. The corresponding chemical shrinkage values increased by 11.4%, 26.7%, 53.9%, and 94.2%, respectively. From Figure 2, we can see that the chemical shrinkage value of the cement paste doped with nano-SiO$_2$ increased significantly in the early stage, but with the increase of the setting time, the growth rate of the chemical shrinkage value slowed down, but it was still increasing. At 27 days of coagulation, the chemical shrinkage values of the cement pastes with nano-SiO$_2$ dosages of 0.4%, 0.8%, 1.2%, and 1.6% increased by 3.5%, 17.6%, 31.2%, and 58.9%, respectively. The cement paste doped with nano-SiO$_2$ has a significantly increased chemical shrinkage value than the undoped cement paste, and its chemical shrinkage value continues to increase with the increase of the added amount. This shows that nano-SiO$_2$ can affect the chemical shrinkage effect of cement paste and reduce its setting time, and because of its high pozzolanic activity, it is also conducive to improving the compactness and uniformity of cement paste.

4.2. Effect of Nano-SiO$_2$ on the Compressive Capacity of New Concrete.

In order to study the effect of nano-SiO$_2$ on the compressive capacity and strength of new concrete, after keeping the water, aggregate, chemical admixture, and mineral admixture constantly, we make four kinds of nano-SiO$_2$ (0.4%, 0.8%, 1.2%, and 1.6%) instead of cement to add to concrete, the compressive strength of the setting time on the 3rd, 7th, 28th, and 60th days was tested, and at the same time, it is compared with the compressive strength of concrete without nano-SiO$_2$. The combination of concrete with different amounts is shown in Table 4, and the compressive strength of concrete in each setting period is shown in Table 5 and Figure 3.

It can be seen from Table 5 and Figure 3 that the addition of nano-SiO$_2$ can significantly improve the compressive strength of concrete in the early setting stage, and as the amount of admixture increases, the compressive strength

TABLE 5: Increased value of nano-SiO$_2$ content in concrete compressive strength.

NS content	3D	7D	28D	60D
NS0.4%	9.67	5.67	5.75	5.60
NS0.8%	18.25	11.25	12.13	12.11
NS1.2%	37.88	18.04	12.5	12.34
NS1.6%	39.02	20.19	13.01	12.86

increase value also continues to increase. When nano-SiO$_2$ is added, the amount is 1.6%, the compressive strength of the coagulation period is 3 days and 7 days, respectively, increased by 39.02% and 20.19%, but with the extension of the coagulation period, the increase in compressive strength is not large, and when the coagulation period is on the 60th day, its compressive strength increased by only 12.86%. This shows that nano-SiO$_2$ can improve the early resistance of concrete, but with the extension of time, its compressive performance becomes less obvious. The reason is that the nano-SiO$_2$ particles have a small volume and a large specific surface area, have high pozzolanic activity, and can react with calcium hydroxide produced by the hydration of cement in concrete to promote the hydration process of cement, thereby improving its coagulation. Because of its small volume, nano-SiO$_2$ can fill the voids in the concrete, improve the density of rice concrete, and thus improve the early compressive capacity and strength of concrete. However, as the amount of nano-SiO$_2$ added increases, its chemical shrinkage value will also increase, which slows the cement water process of the concrete, resulting in a decrease in the growth rate of the compressive strength of the concrete in the later period.

4.3. Effect of Nano-SiO$_2$ on the Microstructure of New Concrete.

Nano-SiO$_2$ has a variety of specific properties, and it can change the internal structure and composition of concrete materials when combined with new concrete materials. In order to explore the microstructure changes of concrete doped with nano-SiO$_2$, we have drawn the XRD pattern of the concrete before and after nano-SiO$_2$ is added, as shown in Figure 4.

Figure 4 is the XRD pattern of the concrete before and after the nano-SiO$_2$ is added. From the figure, it can be seen that the diffraction peak of the internal structural components of the concrete changes greatly, which shows that after the nano-SiO$_2$ is added, the microstructure of the concrete has changed a lot. It promotes the hydration process of concrete cement, narrows the pores between concrete systems, makes the concrete components more closely connected, and is conducive to improving its mechanical strength.

5. Conclusions

In recent years, econooour has developed rapidly. Various real estate industries and infrastructure construction units have developed rapidly. Concrete, as the largest and most extensive building material, has become a very promising project. However, in today's modernized society, the
FIGURE 3: Compressive strength of concrete with different nano-SiO$_2$ content at each setting time.
FIGURE 4: XRD pattern of concrete before and after incorporation of nano-SiO$_2$.

application requirements of concrete are getting higher and higher. Due to its structural composition, traditional concrete often shows poor toughness, insufficient compression and tensile capacity, and poor endurance in engineering construction. Unable to adapt to more severe service environment and other issues, it is particularly important to strengthen the improvement of the traditional concrete performance structure.

Nanomaterials are a new type of high-tech materials. Because of their small particle size and large specific surface area, they have special properties that many other materials do not have. The combination of nanomaterial and new concrete materials on the market can produce concrete materials with better performance effects, which have a great influence and help to improve the mechanical, chemical, and physical properties of concrete.

This study obtained through experimental analysis that nano-SiO$_2$ can significantly improve the chemical shrinkage value and compressive strength of concrete. Due to its high pozzolanic activity and small particle volume, it can fill the pores of concrete, improve its interface structure, and promote the compactness and compressive capacity of the concrete system. In short, the addition of nano-SiO$_2$ has greatly improved the performance of concrete and obviously improved its previous defects. Although the optimization of traditional concrete materials has been deeply studied in this paper by using nanomaterials, there are still many deficiencies. The depth and breadth of the research in this paper are not enough. In the process of this research, the selection and acquisition of experimental data are absolutely ideal. The completeness and effectiveness are not enough. Some interference factors involved in the experimental process are not considered. My academic level research is also limited. The research on the application of nanomaterials is still in the preliminary stage. In the future, in our work, we will study appropriate methods and means from more perspectives based on the existing technology and level and continuously improve the research content.

The authenticity of calligraphy and painting is an important knowledge in the collection and research of Chinese painting and calligraphy. The identification of folk painting and calligraphy is usually conducted by experts and scholars engaged in cultural relics, archaeology, painting and calligraphy, and ancient buildings. Relying only on the identification of experience and literature and history, there are certain limitations, and it is difficult to form convincing. Spectroscopic technology mainly uses the characteristic spectral lines of molecules or atoms to judge the chemical composition and relative content of substances, so that different molecular structures of substances can be determined and distinguished; thus, it becomes an effective tool for exploring the molecular structure of substances; therefore, it has been widely used in nanomaterials, biomedicine, cultural relic identification, and other fields. Raman spectroscopy is the most common spectroscopic technique in scattering spectroscopy. When light passes through a material surface, in addition to light transmission and light absorption, light scattering can also be observed. In addition to the original incident light frequencies (Rayleigh scattering and Tyndall scattering), the scattered light also includes some new frequencies, which are called Raman scattering, and its spectrum is Raman spectrum. In this paper, Raman spectroscopy is used to study nanomaterials and calligraphy and painting, and the Raman spectra of real and fake calligraphy and painting, as well as the light absorption rate and degradation rate of nanomaterials at different temperatures, are analyzed experimentally. The results show that the Raman spectrum of the authentic calligraphy reaches the maximum when the wave number is 1000; the peak of the Raman spectrum of the authentic fresco reaches the maximum when the wave number is 1400. The average light absorption rate of nanomaterials in was 47.2%, and the average catalytic degradation rate was 53.6%; the average light absorption rate of nanomaterials was 68.9%, and the average catalytic degradation rate was 62.4%. There are obvious differences in peak shape, peak intensity, peak frequency, etc. between genuine and fake calligraphy and painting. The spectrum of genuine works has good consistency, so the authenticity of calligraphy and painting can be distinguished according to the difference between the spectrums.

1. Introduction

Indian scientists discovered the Raman scattering effect in 1928 [1]. In the following decades, due to the weak intensity of Raman scattered light and the low energy of the excitation light source mercury arc lamp, it has not been widely used in practice. Until the emergence of laser Raman spectrometer and Fourier transform technology, people can use laser as a light source to study the vibrational state of molecules more comprehensively and provide more information on molecular

structure, which greatly improves the detection sensitivity of Raman spectroscopy. Subsequently, the application fields of Raman spectroscopy have become increasingly extensive, and special seminars on Raman spectroscopy in various disciplines (medicine, geology, biology, etc.) will be held at the biennial International Raman Spectroscopy Conference. The application range of Raman spectroscopy covers optics, quantum mechanics, electromagnetism, group theory, molecular spectroscopy, and other disciplines and has been widely used in materials, chemical industry, petroleum, polymer, biology,

environmental protection, geology, and other fields. This paper mainly focuses on the application of Raman spectroscopy in the identification of calligraphy and painting and nanomaterials.

The art of Chinese painting and calligraphy is the crystallization of five thousand years of Chinese civilization and a historical treasure in the process of Chinese social development. It reflects the real life of ancient Chinese people from many fields, embodies the unique philosophical concepts and aesthetic concepts of the Chinese nation, and is a material for studying the history of human society. Through the analysis of calligraphy and painting works, we can understand the background information of the era of calligraphy and painting creation, brush and ink skills and drawing methods, as well as the subjective emotions that the author wants to convey, thereby inferring the era of painting and calligraphy, the development of painting technology, and the identification and restoration of painting and calligraphy. When analyzing calligraphy and painting works, the first task is to protect the integrity of the calligraphy and painting. The structure of some works is very complex, and the old ones have even been worn and faded, which makes it difficult to identify calligraphy and painting works. Raman spectroscopy reflects the molecular properties of substances, which will not cause any damage to the object, and requires a small amount of samples. It has the characteristics of fingerprint rapidity, sensitivity, and simplicity. Therefore, Raman spectroscopy has been widely used in the identification and research of calligraphy and painting. In this paper, Raman spectroscopy was used to identify Chinese paintings and calligraphy and to study the light absorption properties and catalytic activity of nanomaterials. Combining traditional Chinese painting and calligraphy with modern advanced technology, new concepts and ideas are used in the current calligraphy and painting appraisal, so that calligraphy and painting can be appraised and appreciated more accurately and objectively, and the authenticity of calligraphy and painting can be identified, to make a reasonable value judgment on the artistry of calligraphy and painting and improve the overall level of the appraisal and appreciation of calligraphy and painting. It provides some feasible references for calligraphy and painting researchers and has certain positive significance for the collection, protection, and research of calligraphy and painting.

2. Related Work

In terms of theoretical research, experts and scholars at home and abroad have discussed the application and development prospects of spectroscopy technology in various fields and have done related research in the application of nanomaterials. Gallas et al. investigated five silica samples by infrared spectroscopy and a homemade thermogravimetric infrared spectroscopy (TG-IR) apparatus to quantify and compare the affinity of these five silicas for water. TG-IR measurements allow precise determination of the molar absorption coefficient, which is independent of the source of the sample and the concentration of silanol groups on the silicon. Experiments showed that the accessibility decreased with the increase of alcohol content, and the silica samples changed linearly with the concentration of adsorbed water [2]. Gibson et al. analyzed

NICMOS transmission spectra using a residual permutation algorithm and found that previously published transmission spectra could be restored when the same model was used for system effects, and that the transmission spectra changed considerably when the instrument model was changed slightly. They concluded that NICMOS transmission spectroscopy is highly influenced by the system model and cannot be used as a robust detection of molecules [3]. Bunker et al. studied the long K-band spectrum to measure the star formation rate in the system, searching for eight damped absorber emission values for $z > 2$. Under two different simplifying assumptions, (1) assuming a large disk, the spatial density of DLA at $z = 2.3$ is equal to the spatial density of present-day spiral galaxies. (2) In the layering hypothesis, the DLA size at $z = 2.3$ is the same as the gas size of the current spiral galaxy. They search for compact emission sources within a solid angle of 11×2.5 arcsec2 for each system. Compared to the previous most sensitive spectral searches, the studied samples were twice as large, the limit was twice as deep, and the measured solid angles were three times larger [4]. Crowther et al. studied the ISO-SWS spectrum of the Wolf-Rayet galaxy NGC 5253 to provide estimates of its stellar population. They used photoionization models and the latest theoretical O star flux distributions to derive the effective stellar temperature and ionization parameters. They assessed the distribution of highly ionized nebula lines in Wolf-Rayet galaxies in an evolutionary synthesis model, distinguishing regions where different infrared fine structure lines are formed [5]. Sasaki et al. used scanning electron microscopy and Fourier transform infrared spectroscopy to analyze the morphological features and chemical composition (Er) of the bone surface after YAG and CO_2 laser ablation. The experimental group was irradiated with continuous YAG and CO_2 lasers, and the position of the conventional micromotor drilling was used as the control group. Fourier transform infrared spectroscopy showed that the chemical composition of the bone surface after YAG laser ablation was basically the same as that after motor drilling. And after laser irradiation, no toxic substances were detected [6]. Yamada et al. investigated the kinetics of room temperature ionic liquid 1-butyl-3-methylimidazolium bis (trifluoromethylsulfonyl) imide (BmimNTf2) using two-dimensional infrared vibrational echo spectroscopy and polarization-selective pump probe. They observed the long-time-scale structural spectral diffusion components at 600 ps, as well as short- and intermediate-time scales for selenocyanate anion (SeCN–) measurements. Experiments have shown that 2-SeCN-Bmim+ is sensitive to local motions in the ionic region, which affect the spectral diffusion and redirection of small, anionic, and neutral molecules [7]. Yan et al. studied solid-phase redox transitions with X-ray spectroscopy and he used high-resolution X-ray spectroscopy (HR-XPS) to observe multivalent arsenic reacting nZVI particles with aqueous As(III). They believe that the morphology of arsenic in the nanoparticles depends largely on the loading of nZVI. Most of the arsenic is found in the reduced state in the nZVI environment, resulting in rapid depletion of Fe(0) cores and arsenic sequestration in oxide formation. Encapsulation of arsenic in most of the solid phase suggests that nZVI is a more powerful arsenic scavenger [8].

3. Spectroscopy and Nanomaterials

3.1. Raman Spectroscopy. Raman scattering effect is an inelastic scattering phenomenon caused by crystal structure, symmetry, charge, and other factors [9]. Raman spectra are significantly different in different substances, so Raman spectra are also called "fingerprints." Based on the Raman effect, qualitative, quantitative, and structural analysis can be performed on the Raman peak position, peak value, line type, line width, and number of spectral lines of the sample. When light enters the surface of an object, most of the light will be transmitted or absorbed, and only 0.1% of the photons will be scattered [10, 11]. During scattering, after the molecule absorbs energy, it will transition from the ground state to the virtual energy level and then drop from the virtual energy level to a lower energy level and release the scattered light. Raman spectroscopy includes optics, quantum mechanics, electromagnetism, molecular structure, molecular spectroscopy, and other disciplines and its applications in chemistry, physics, biology, medicine, environmental science, and other fields. These applications vary in nature, from purely qualitative to highly quantitative.

Light scattering is another natural phenomenon besides light absorption, light reflection, light transmission, and light emission, and it is an interaction between light and matter. Light scattering is caused by the collision of incident photons with objects in a certain direction, and the incident photons are shifted from the original incident direction [12]. Scattered light generally contains information about the structure of matter and is accompanied by changes in energy. It can be divided into elastic scattering and inelastic scattering according to the size of its fall back to the lower energy layer. The so-called elastic scattering, also known as Rayleigh scattering, means that when the excited molecule is deexcited, its energy level returns to the initial energy level, and the scattering energy is equal to the excitation energy. On the other hand, inelastic scattering is Raman scattering. When the excited molecule is deexcited, its energy level returns to the noninitial energy level, and the scattering energy is not the same as the excitation energy. There are two types of Raman scattering: Stokes scattering and anti-Stokes scattering. The energy of Stokes scattering is less than the energy of excitation, and the molecule is deexcited and falls back to an energy level higher than the initial energy level. On the other hand, the energy of anti-Stokes scattering is greater than the energy of excitation, and the molecule falls back to an energy level lower than the initial energy level. Generally, the Stokes scattering intensity is larger than the anti-Stokes intensity [13], and this process is shown in Figure 1.

It can be seen from the transition diagram of the energy level that both Raman scattering and Rayleigh scattering are caused by the transition of the ground state electrons to the virtual state under the excitation of the incident light and then to the ground state and emitting scattered light [14]. In Rayleigh scattering, since the electron does not interact with the phonon, its energy does not change, that is, its scattering frequency does not change with the frequency of the incident light. In Raman scattering, when electrons enter the virtual state, they will interact with phonons, which will cause the loss of phonon energy, resulting in the scattered light energy being smaller or greater than the incident light energy. That is, the frequency of scattered light decreases or increases by $\Delta \nu$ compared with the frequency of incident light, which corresponds to the Stokes or anti-Stokes Raman scattering process, respectively.

Raman scattering spectrum is a form of reflecting Raman shift, that is, the wavenumber difference between excitation light and scattered light. Raman scattering, unlike Rayleigh scattering, is a type of inelastic scattering, and in this case, Stokes light as the wavelength increases, and when the wavelength is reduced, it is anti-Stokes light. The principle of Raman scattering is shown in Figure 2. By detecting the scattered photons, Raman spectra can be obtained. Different bands correspond to the vibrational frequencies of different functional groups. Each molecule has a unique spectrum, called a "fingerprint," based on its chemical bonds and its specific vibrational frequency.

Raman spectroscopy is a type of molecular vibrational spectroscopy. It corresponds to the change of intramolecular vibrational energy level, carries information, such as the composition and structure of the substance itself, and has high specificity. It is a good spectral detection method [15]. One of the advantages of Raman spectroscopy is that the excitation light source can be selected at will. From the principle of Raman scattering, it can be seen that the frequency shift of the Raman spectrum has nothing to do with the frequency of the light source, and different light sources can be selected according to different samples. Secondly, Raman scattering is generated by the laser, which has strong directivity and can measure tiny samples in a very small area, thereby realizing long-distance noncontact detection. Since the laser has good monochromatic properties, good orientation ability, and high energy density, using it as an excitation light source can greatly improve the excitation efficiency. Raman spectroscopy does not need to prepare samples and can directly measure the measured objects, such as ancient painting pigments and traces left at crime scenes, so that they can be preserved intact [16]. Third, Raman spectroscopy can identify the chemical composition of cells. This method does not require labeling and staining and allows semiquantitative analysis of proteins, lipids, and DNA through vibrational spectroscopy, which can visually display their intracellular distribution. Fourth, Raman spectroscopy has a wide detection range. Since both polar molecules and nonpolar molecules can form Raman spectra, the detection objects of Raman spectra are very wide, including inorganic substances, organic substances, polymers, minerals, animal and plant tissues, and catalysts.

In spectroscopy, the grating resolution is usually defined as

$$R = \frac{\lambda}{\Delta\lambda} = m \times N. \tag{1}$$

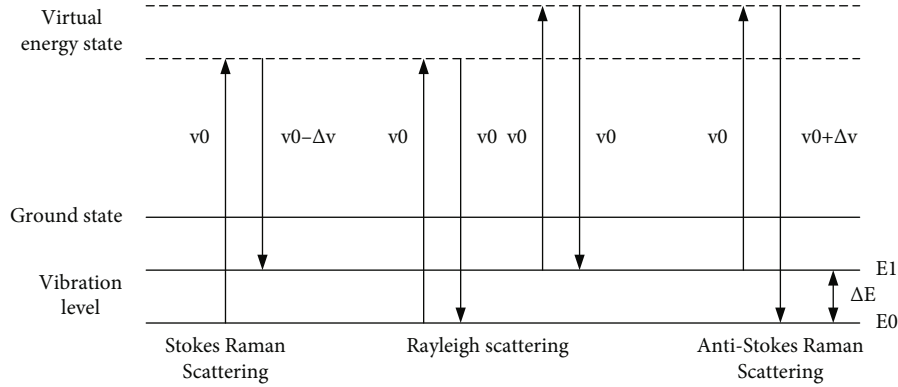
Among them, $\Delta\lambda$ refers to the minimum wavelength difference that the wavelength λ can resolve. m refers to the spectral order, and N is the total number of grating scales. Here, $\Delta\lambda$ depends not only on the resolving power of the dispersing element but also on the construction parameters


Figure 1: Energy level diagram for scattering process.
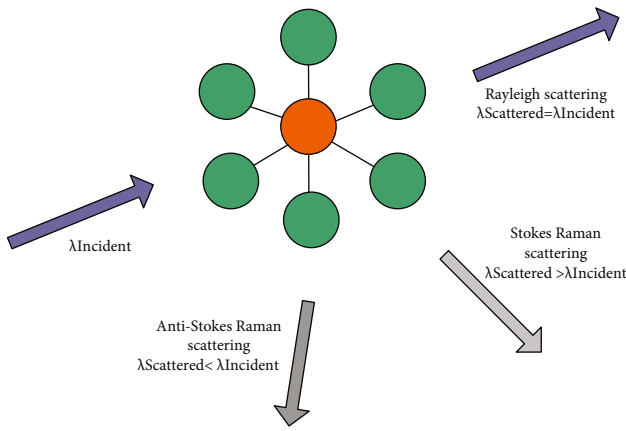

Figure 2: Principles of Raman scattering.
Figure 3: Crystal structure of rutile.

and diffraction angle, respectively. Clearly, when the incident angle and the diffraction angle are equal, the increase of the incident angle makes the spectral order increase.

At present, to evaluate the quality of Raman spectra, there are mainly methods for estimating the standard deviation of noise, which are discussed below. The random noise in the Raman spectrum is formed by the superposition of many random noise sources, which can be considered to satisfy the Gaussian distribution and belong to the Gaussian noise. Assuming that the Gaussian noise in the original signal is N, its standard deviation is σN, the signal filtered by a high-pass filter G is N', the standard deviation is $\sigma N'$, and the unit impulse response sequence of the high-pass filter is $g(n)$. Then, the power spectral density of N and the spectrum of the high-pass filter are the following formulas, respectively:

$$P(w) = \sigma_N^2, \tag{3}$$

$$G(w) = \sum_{n=-\infty}^{+\infty} g(n) e^{-jnw}, \tag{4}$$

where w represents the digital angular frequency, $w \in [-\pi, \pi]$.

N' is N obtained after being filtered by high-pass filter G, which should satisfy

$$N' = N * G, \tag{5}$$

where a represents a convolution, and its spectrum satisfies

$$F'(w) = F(w) \cdot G(w). \tag{6}$$

Among them, $F(\omega')$ and $F(\omega)$ represent the spectrum of N' and N, respectively. For the power-limited signals N' and N, they are limited in the range of $[-T/2, T/2]$, and their spectrums are $F_T'(\omega)$ and $F_T(\omega)$, respectively, which satisfy

$$F_T'(w) = F_T(w) \cdot G(w). \tag{7}$$

When T tends to infinity, the following formula is obtained:

such as the slit size, the focal length of the spectrometer, and the optical quality of the optical components. Increasing the total number of grating lines or increasing the spectral order can improve the spectral resolution. The optical properties of a grating can be described by the following formula:

$$m\lambda = d(\sin i + \sin r). \tag{2}$$

Here, λ refers to the diffraction wavelength, d refers to the grating constant, and i and r refer to the incident angle

	1.980 (2)	1.965 (2)
O-Ti-O bond angle	81.2°	77.7°
	90.0°	92.6°
FIGURE 5: Light reaction mechanism.

$$\lim_{T \to \infty} F_T'(w) = G(w) \cdot \lim_{T \to \infty} F_T(w). \tag{8}$$

The power spectral density of N' is shown in

$$P'(w) = |G(w)|^2 \cdot \lim_{T \to \infty} \frac{1}{T} |F_T(w)|^2. \tag{9}$$
FIGURE 6: Process flow chart for preparing.

It can get

$$P'(w) = |G(w)|^2 \cdot P(w). \tag{10}$$

Since the autocorrelation function and the power spectrum function are mutual Fourier transforms, the autocorrelation function $R(\tau')$ of the filtered signal N' is shown in

$$R'(\tau) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} P'(w) e^{-jw\tau} dw. \tag{11}$$

Moreover, defined by the power-limited signal autocorrelation function, the following formula is obtained:

$$R'(\tau) = \lim_{T \to \infty} \frac{1}{T} \int_{-T/2}^{T/2} N'(t) N'(t + \tau) dt. \tag{12}$$

Let $\tau = 0$, and formula (12) can be transformed into

$$R'(0) = \lim_{T \to \infty} \frac{1}{T} \int_{-T/2}^{T/2} |N'(t)|^2 dt. \tag{13}$$

Since the mean value of the high-pass filtered signal N' is zero, the following formula can be derived.

$$R'(0) = \sigma_N'^2. \tag{14}$$

Combining formulas (3), (4), (9), (10), (14), it can be deduced that

$$R'(0) = \sigma_N^2 \sum_{n=-\infty}^{+\infty} g^2(n) = \sigma_N^2 \|g\|^2. \tag{15}$$

It can be concluded from the above derivation that the noise variance filtered by a high-pass filter is equal to the noise variance in the original signal multiplied by the square of the modulus of the filter's response vector.

The core idea of the noise standard deviation estimation method is to use the high-pass filtered noise standard deviation to estimate the noise standard deviation in the original signal. Gaussian noise is mainly concentrated in the high-frequency domain. After the original signal is high-pass filtered, the low-frequency signal is filtered out. The high-frequency signal that passes through is mainly noise, and the interference of the signal is very small. At this time, it is more

TABLE 2: The relationship between hydrolysis reaction temperature and gel time.

Hydrolysis temperature	Gel time
20°C	48~72 h
30°C	30~35 h
40°C	18~20 h
50°C	<8 h

TABLE 3: Relationship between calcination temperature and average particle size of TiO.

Calcination temperature	Particle size
400°C	48~72 h
500°C	30~35 h
600°C	18~20 h
700°C	<8 h

accurate to calculate the standard deviation of the filtered noise, and then, the standard deviation of the noise in the original signal can be estimated by formula (15).

The specific operation is as follows: set the wavelet coefficients on two adjacent small scales to be $wc_1(n)$、$wc_2(n)$, respectively, and their correlation coefficient to be $Cor_1(n)$, $n = 1, 2, \cdots L$, where L represents the length of the discrete signal. The correlation coefficient $Cor_1(n)$ satisfies the

$$Cor_1(n) = wc_1(n) \cdot wc_2(n). \tag{16}$$

Normalizing the energy of $Cor_1(n)$ so that the energy of the new correlation coefficient $Cor_2(n)$ is equal to the energy of $wc_1(n)$. Let the energies of $Cor_1(n)$ and $wc_1(n)$ be E_{Cor_1} and E_{wc_1}, respectively, and formulas (17) and (18) are as follows:

$$E_{cor1} = \sum_{n=1}^{L} |Cor_1(n)|^2, \tag{17}$$

$$E_{wc1} = \sum_{n=1}^{L} |wc_1(n)|^2. \tag{18}$$

The new correlation coefficient $Cor_2(n)$ can be expressed as

$$Cor_2(n) = Cor_1(n) \cdot \sqrt{E_{wc1}/E_{cor1}}. \tag{19}$$

Comparing $Cor_2(n)$ with $wc_1(n)$, if the position n_0 satisfies the formula (20), the wavelet coefficient $wc_1(n_0)$ at n_0 is considered to be caused by the signal, and it is set to zero, thus obtaining the small-scale wavelet coefficient $wc'_1(n)$ with the signal interference removed, using formula (15) again, the noise standard deviation of the original signal can be estimated.

$$Cor_2(n_0) \geq |wc_1(n_0)|. \tag{20}$$

3.2. Nanomaterials. Nanomaterials are an emerging material that appeared in the 1980s, usually referring to the particle structure with nanometer size. Because nanoparticles have special properties that are significantly different from individual materials and single molecules, such as size effect, surface effect, volume effect, quantum effect, and macroscopic quantum tunneling effect; therefore, it has a wide range of applications in the fields of electronics, optics, chemical industry, ceramics, biology, and medicine [17, 18]. The preparation, structure, properties, and photocatalytic mechanism of TIOZ materials has been an important topic in the field of photocatalysis since it was discovered in the early 1970s that TIOZ electrodes have the function of splitting water under sunlight. After entering the 1990s, with the rapid development of nanotechnology, nanophotocatalysis technology has been widely used, and its particle size, surface area, and other technologies have also been further developed, and to a certain extent, the improvement of its quantum efficiency is achieved through the design of materials.

Photocatalysis technology is through photocatalysis, and the electrons in the valence band of the semiconductor are excited to transition to the conduction band to form a pair of electrons and holes and react with O_2 and H_2O/OH^- on the surface of the catalyst to generate free radicals, so that the organic compounds are gradually decomposed into small molecular substances such as CO_2 and H_2O. Since the research of semiconductor photocatalytic oxidation technology, many semiconductor catalysts with catalytic effect have been discovered, such as TiO_2, ZnO, SnO_2, Fe_2O_3, $BiVO_4$, Cu_2O, CdS, and C_3N_4 [19]. Among them, TiO_2 is in a leading position among many semiconductor catalysts due to its nontoxic and harmless, strong stability and strong redox ability.

It is a white powder in nature, TiO_2 mainly rutile, anatase, brookite, and $TiO_2(B)$ phase. Generally speaking, the crystalline titanium dioxide prepared at low temperature is anatase and brookite phases, while the rutile phase is stable at high temperature. Among them, the rutile and anatase forms TiO_2 are the most widely used in the field of photocatalysis, and the two crystal forms TiO_2 exhibit different properties due to structural differences. Both rutile type and anatase type TiO_2 are composed of octahedrons with Ti as the center and O as the corner, TiO_6 as the basic unit, and both phases belong to the tetragonal crystal system. The main difference lies in the connection mode between the octahedrons and the degree of lattice distortion [20]. The crystal structure is shown in Figures 3 and 4. The connection between octahedrons is mainly connected by common edges and common corners. In the anatase type TiO_2, each octahedron is connected with the surrounding eight octahedrons (four common edges and four common corners), whereas in the rutile type TiO2, each octahedron is connected to ten surrounding octahedra (two common edges and eight common corners). Because the crystal connection method is different, the degree of crystal distortion of the anatase type is also stronger, so the symmetry and stability of the rutile type TiO_2 lattice are higher than those of the anatase type TiO_2, and in the crystal coordination structure, the more the number of common edges, the worse the stability of the crystal structure. Therefore, the most stable crystal phase of titanium dioxide is the rutile phase, both
FIGURE 7: Raman spectra of authentic and fake calligraphy. (a) shows the Raman spectrum of the authentic calligraphy, and (b) shows the Raman spectrum of the calligraphy fake.

FIGURE 9: Optical absorptivity of nanomaterials at different temperatures. (a) is the light absorption rate of nanomaterials, and (b) shows the light absorption rate of nanomaterials.

anatase phase and brookite phase can be transformed into rutile phase during high temperature treatment, and this process is generally irreversible at a phase transition temperature of 500-600°C.

Table 1 presents crystallographic data for rutile and anatase types, The Ti-Ti bond distance (3.57 Å) in the rutile phase structure is larger than that in the anatase phase structure (3.79 Å). The Ti-O bond distance (1.949 Å) in the rutile phase structure is shorter than that in the anatase phase structure (1.939 Å). The density of rutile phase TiO_2 material

(4.25) is greater than that of anatase phase TiO_2 material (3.89).

Titanium dioxide is a wide-band semiconductor material. The forbidden band width of the anatase phase grain is 3.2 eV, the forbidden bandwidth of the rutile phase grain is 3.02 eV, and the forbidden band width of the brookite phase grain is 2.96 eV. The valence band of TiO_2 includes the 3d orbital of Ti and the 2p orbital of O, while the conduction band only includes the 3d orbital of Ti [21]. When TiO_2 is irradiated with a light beam with a wavelength below
Figure 10: Photocatalytic activity of nanomaterials at different temperatures. (a) shows the photocatalytic degradation rate of nanomaterials, and (b) shows the photocatalytic degradation rate of nanomaterials.

Table 4: Photocatalytic reaction rates at different voltages.

TiO_2	Voltage	2 h	4 h	6 h	8 h	10 h
	25 V	1.12	1.46	1.71	2.27	2.70
Reaction speed	35 V	1.29	2.05	2.11	2.65	2.34
	45 V	1.69	2.23	2.50	2.23	2.06

387 nm, the electrons in its valence band are excited into the conduction band, thereby forming an energy-efficient electron e^- with a negative charge, and form a hole h^+ with a punctual point in the valence band. The reaction principle is shown in Figure 5.

The sol-gel method uses titanium alkoxides or inorganic salts as precursors to form sols through the hydrolysis reaction of the precursors, and the hydrolyzed precursors are further condensed to form gels, and finally, the desired materials are prepared by drying and heat treatment. The process is shown in Figure 6. Tetrabutyl titanate is hydrolyzed in water or alcohols to form oligomers, and the oligomers interact and polymerize to form a three-dimensional network structure with Ti-O-Ti as the polymer unit. At the beginning of the chemical reaction, a large number of small molecules are formed by hydrolysis and polymerization. They form long molecular chains through polymerization, and cross-linking and branching occur between the long molecular chains and small molecules, forming two-dimensional, three-dimensional, and even multidimensional networks and then forming gels. Among them, the morphology, size, crystallinity, and surface properties of the gel particles are affected by the components of the solution, pH, reaction temperature, and other factors. The size, morphology, crystallinity, and surface properties of nano-TiO_2 particles can be regulated by controlling the experimental conditions. The relationship between the hydrolysis reaction temperature and the gelation time is shown in Table 2.

Finally, the organic components of the gel are removed through heat treatment processes such as drying and calcination to obtain nano-TiO_2. The relationship between the calcination temperature and the average particle size of TiO_2 is shown in Table 3. Generally speaking, when the polymer chain has obvious branching and cross-linking, there are a lot of holes in the colloid, and it has good structural stability. However, when the branching and cross-linking of the colloid chain is not obvious, the pores in the colloid are not large, the structure will be relatively fragile, and it is easy to break during the calcination process.

4. Experiment of Spectroscopic Technique in Chinese Painting Identification

Using Raman spectroscopy technology, two authentic calligraphy and mural paintings and their fakes during the Song Dynasty were analyzed, and their respective Raman spectra were obtained, as shown in Figures 7 and 8. Figure 7 shows the Raman spectra of genuine calligraphy and fakes. Figure 8 shows the Raman spectra of the original and fake murals.

Through the analysis of Figure 7, it can be seen that the Raman spectra of genuine and fake calligraphy are significantly different. The calligraphic authentic Raman spectrum has peaks at 200, 400, 600, 800, 1000, 1200, 1400, and 1600 in the 0-1800 cm^{-1} wavenumber range. And when the wave number is 1000 cm^{-1}, the peak is the largest, followed by the peaks at 1400 and 1600 cm^{-1}. The Raman spectrum of the calligraphic fake also has peaks at 200, 400, 600, 800, 1000, 1200, 1400, and 1600 in the wavenumber range of 0-1800 cm^{-1}. Different from the real one, the fake Raman spectral peaks are concentrated between 800 and 1200 cm^{-1}.

By analyzing Figure 8, it can be seen that the Raman spectra of the authentic and fake murals are significantly different. The authentic Raman spectrum of the fresco has peaks at 200, 400, 600, 800, 1000, 1200, 1400, and 1600 in the 0-1800 cm^{-1} wavenumber range. When the wave number is 1400 cm^{-1}, the peak value is the largest, followed by the peak value at 1200 and 1600. The Raman spectrum of the fresco fake also has peaks at 200, 400, 600, 800, 1000, 1200, 1400, and 1600 cm^{-1} in the wavenumber range of 0-1800 cm^{-1}. Unlike the real one, the fake Raman spectrum peaks around 1000 cm^{-1}.

By selecting Rhodamine B as a typical photocatalytic degradation research object, the test of the degradation ability of the nanomaterial TiO_2 sample is characterized. The test results are shown in Figures 9 and 10. Figure 9 shows the light absorptivity of nanomaterials at different temperatures. Figure 10 shows the photocatalytic degradation rates of nanomaterials at different temperatures.

Through the analysis of Figure 9, it can be known that the absorption rate of TiO_2 with light is different at different temperatures. When the temperature is 400°C, the light absorption rate of TiO_2 with a wavelength of 800 nm is the highest, reaching 64.9%. The light absorption rate for the wavelength of 400~600 nm is basically the same, which is maintained at about 42.1%; the light absorption rate for the wavelength of 600~800 nm increases steadily. When the temperature is 600°C, TiO_2 has the highest absorption rate of light with a wavelength of 780 nm, reaching 80.4%. The absorption rate of light with a wavelength of 400 nm is 48.7%, and the absorption rate of light with a wavelength of 450 nm is 61.2%; the absorption rate of light with a wavelength of 550~750 nm increases from the initial 53.2% to 79.5%.

From the analysis of Figure 10, it can be seen that the catalytic degradation rate of TiO_2 to light varies greatly at different temperatures. When the temperature is 400°C the catalytic degradation rate of light with a wavelength of 450 nm is 41.7%, and the catalytic degradation rate of light with a wavelength of 650 nm is 58.3%. When the temperature is 600°C the catalytic degradation rate of light with a wavelength of 450 nm was 54.6%, and the catalytic degradation rate of light with a wavelength of 650 nm was 64.3%.

Exploring the photocatalytic activity of nanomaterials involves two parameters: photocatalytic degradation rate and reaction rate. In addition to the photocatalytic degradation rate, the reaction rate should also be studied. Table 4 shows the photocatalytic reaction rates of nanomaterials at different voltages.

It can be seen from Table 4 that when the voltage is 25 V, the best photocatalytic activity appears in the TiO_2 nanomaterials prepared under the condition of 10 h, and its reaction rate constant is 2.70×10^{-3} min^{-1}. When the voltage is 35 V, the best photocatalytic activity appears in the TiO_2 nanomaterials prepared under the condition of 8 h, and the reaction rate constant is 2.65×10^{-3} min^{-1}. When the voltage is 45 V, the best photocatalytic activity appears in the TiO_2 nanomaterials prepared under the condition of 6 h, and its reaction rate constant is 2.50×10^{-3} min^{-1}. At the same voltage, the reaction rate constant first increases and then decreases with time.

5. Conclusion

An important part of the identification of calligraphy and painting is to identify the authenticity, and the identification of the authenticity of calligraphy and painting has always been a major subject of Chinese painting and calligraphy collection and research. In the identification of calligraphy and painting, Raman spectroscopy is used increasingly. Using Raman spectroscopy to assist in the identification of cultural relics can not only speed up the identification but also reduce the artificiality and subjectivity in the identification process, improve the accuracy and objectivity of identification, reduce the probability of errors in identification, and shorten the identification time. After spectral analysis, the spectra of genuine and fake calligraphy and painting have great differences in peak shape, intensity, and frequency, and the spectrum of genuine works shows good consistency, so that the authenticity can be distinguished from the difference in the spectra. The use of spectral technology can not only ensure the accuracy of identification but also prevent damage to calligraphy and painting. Therefore, Raman spectroscopy is a nondestructive and accurate in situ analysis method, which is suitable for the precise analysis of antiques, calligraphy, and painting. The application of Raman spectroscopy technology in cultural relics, calligraphy, and painting has enriched the identification methods of cultural relics, calligraphy, and painting and improved its scientificity and credibility. With the advancement of science and technology, spectroscopic technology will be an important method of calligraphy and painting identification. However, in-depth study of calligraphy and painting identification requires research on this paper. By observing the scanning electron microscope image of the rice paper, we can analyze the general proportion of leather and grass in the paper from the structure of the surface of the rice paper or the number of long and short fibers in the paper and further use this method to identify the year and type of the rice paper.

Nowadays, the rapid development of sports science and technology has brought about the vigorous development of the sports industry, which is worth studying for a long time in the future. This article aims to use metallurgical sintering technology to prepare high-performance iron-based powder materials and apply them in the traditional sports industry to produce new sports equipment. This article proposes a metallurgical sintering method, that is, the use of a process of powdered iron-containing materials through a series of operations to finally obtain a new agglomerate and to obtain the required new physical and mechanical properties of materials or products. A new type of material is made and used in the traditional sports industry to meet the high-quality needs of sports equipment in the current era. According to survey statistics, my country's sports industry has been developing rapidly in the past five years. It has increased from 1,901.13 billion yuan in 2016 to 2,869.35 billion yuan in 2020. Sports investment and financing events have also dropped from 313 to 105, but the entire sports industry's investment is getting bigger and bigger. The number of employees in the national sports industry has also exceeded the 2 million mark. In the future, the sports industry is also an industry with great potential for development.

1. Introduction

At present, traditional sports equipment mostly uses wood or metal materials. The physical properties of these materials limit the strength of sports equipment to a large extent. With the development of science and technology, new materials are widely used in various sports equipment and even become a key factor in determining the outcome of competitive sports. Based on the excellent characteristics of various new materials, such as high strength, specific modulus, light weight, wear resistance, good damping performance, and strong design ability, the performance of sports equipment has been significantly improved, and it has been widely used. Traditional exercise equipment has a short life span, low safety, and significant limitations. In this paper, sintering technology is used to prepare high-performance iron-based powder metallurgy materials, which are used in the traditional sports industry to manufacture fitness, rehabilitation, sports, and other sports equipment. In our country, science and technology have always been the primary productive forces, but in the sports industry, the rapid development

and progress of sports science and technology are the primary productivity of the sports industry. Since 1992, my country has vigorously developed sports science and technology, and with the continuous development of the times, sports science and other related sciences have gradually merged, which has led to the continuous production of new interdisciplinary subjects and the development of new science and technology and materials. In this context, the technology of this paper may be widely used in daily life in the future.

Through the preparation of high-performance iron-based powder metallurgy sintered materials, the traditional sintering technology is used to produce new high-performance iron-based powder materials, which are used in the sports industry to realize high-performance iron-based materials and the theory of sports fields. At the same time, the preliminary integration of the levels also preliminarily promotes the application research of high-performance iron-based materials and sintering technology in the field of sports equipment. In the follow-up, corresponding products can be produced and put into daily life

applications. Sports goods produced by applying advanced sports science and technology and materials are also very important in our daily lives. Not only is that, in competitive sports, sports equipment is also the top priority, which can completely affect a person's strength. Nowadays, with the rapid development of sports science and technology, the current sports industry is increasingly dependent on sports science and technology. As an emerging field of science and technology, high-performance iron-based powder metallurgy materials will be used in sports and even other fields in the future. Therefore, this article is based on this, with the topic of the application of high-performance iron-based powder metallurgy materials in the sports industry, theoretically studying the feasibility of this technology, and laying the groundwork for possible future development.

Shui et al. introduced a method of preparing iron-based friction materials directly from vanadium-containing titanium magnetite concentrates using in situ carbothermal reaction and sintering. The influence of Ni content (1-4%, mass fraction, the same below) on the microstructure and the mechanical properties and wear properties of iron-based friction materials were studied. The results show that the sintered sample is composed of iron matrix, graphite lubricating phase, and hard particles (mainly TiC). The former is mainly in the form of reflected electromagnetic wave energy to attenuate electromagnetic radiation, so that the transmitted electromagnetic wave energy is reduced; the latter is mainly in the form of absorption of electromagnetic wave energy to attenuate electromagnetic radiation, so that the electromagnetic wave return reflection energy is reduced. The matrix is mainly composed of layered pearlite with higher strength and higher hardness than ferrite. Compared with the sintered samples without Ni, the structure and performance of iron-based friction materials with different Ni content are improved to different degrees. The low Ni content (1%-2%) promotes the sintering process, exhibiting reduced pores and uniform distribution of lubricating graphite phase and hard particles. In addition, the hardness and wear performance are significantly improved. As the Ni content increases, when the Ni content exceeds 2%, not only the number of pores increases but also the graphite phase and hard particles segregate in the microstructure, resulting in a decrease in material hardness and wear resistance. In summary, when the Ni content is 2%, the structure and performance are the best. But he did not experiment with detailed data on other metals, compared the structure and properties of several different metals, and finally reached a conclusion [1]. Due to low cost, high availability, and high strength, iron-based composite materials have been widely used in many industrial applications such as bearings, camshafts, connecting rods, pulleys, various valves, and oil pump gears in automobiles and other industries. Mahdi and Mahmood aim to prepare Fe-10 vol. % Cu-(0–5) wt. % nano-Y2O3 composite materials through powder metallurgy technology and study its physical and mechanical properties. The powder was mixed in a ball mill for 30 minutes and then uniaxial compacted at a 700 MPa room temperature for 3 minutes. The green sample was sintered at 1000°C for 1 hour. Not only is the absorption intensity greater

(-16.9 dB) but the absorption bandwidth is also wider (4.2 GHz). The results of Mahdi and Mahmood's research show that nanoyttrium oxide has a significant effect on the physical and mechanical properties of Fe-10%Cu composites. As the content of nanooxides increased from 0% to 3%, the bulk density increased by 0.92%, and the true porosity decreased by 6.4%. Mahdi and Mahmood increased Y2O3 to 1%, the Vickers microhardness increased by 5.9% and then gradually decreased when it further increased by more than 1%. As the content of nanooxides increases from 0% to 3%, the wear rate is reduced by 21%. On the other hand, increasing Y2O3 to 5% reduces the compressive strength by 47%. However, his research results do not have specific examples of combining with other industries to support his theoretical research results [2]. Over the years, technological development has had a huge impact on sports performance and has promoted the development of specific materials and manufacturing processes for sports-related products. In this context, Ribeiro et al. used the internal coupling effect of fiber-reinforced plastic (FRP) to design and develop a new snowboard technology using anisotropic layer design. This work involves the technical, economic, and environmental assessment of skis made of three alternative materials, namely, carbon, glass, and flax fiber-reinforced plastics. It shows how life cycle analysis can support product design and development by using innovative technologies to apply life cycle engineering methods to the ski design process. In this case, the material selection and fiber placement angle will have a significant impact on the stiffness of the resulting FRP, so in the three dimensions of the analysis, namely, cost, environment, and technology. Natural fiber is the most environmentally friendly choice, glass fiber is the best economically, and carbon fiber is the best in terms of technical performance. Therefore, Ribeiro et al. consider and weigh the importance attributed to each analysis dimension to allow aggregate analysis of alternatives and make informed decisions. His research is to use plastics for the manufacture of sports equipment and does not use metal to make a comparison to prove the diversity of experimental results [3, 4].

In this paper, metallurgical sintering technology is used to prepare high-performance iron-based powder materials and apply them in the traditional sports industry to produce new sports equipment. The sintering method refers to adding various iron-containing powdery substances to a certain amount of solvent, fuel and water, after stirring, fusion and granulation, it is put into the sintering equipment, so that the material undergoes a series of physical and chemical changes, and finally presents a dense combination.. It can be seen that the impedance matching and attenuation characteristics of absorbing materials are mainly determined by the values of dielectric constant and magnetic permeability of the materials. In addition, the material matrix ratio, material thickness, geometric effect, and other factors also affect the absorbing effect of the absorbing material. In the traditional sports industry, most of the metal and wood materials are used for the production of sports equipment. Such products are not only bulky but also have certain disadvantages in other properties. And the sports equipment made of the

new high-performance iron-based powder material we use has the characteristics of light weight, good quality, and good torsion resistance and can even be used in professional competitions. Through the rapid development of the sports industry in recent years, coupled with the continuous innovation of sports science and technology, various disciplines, industries, and sports are blended with each other, and newer technologies are used in the sports industry.

2. Preparation Method of High-Performance Iron-Based Powder Metallurgy Sintered Material

2.1. Sintering Method. The sintering method is a traditional handicraft process, that is, a traditional firing process that converts the original powdery raw material into a dense combination. In the early days, people have begun to use the sintering process to produce many things, such as porcelain, powder metallurgy, refractory materials, and high-temperature materials. These products are widely used in our daily lives. Under the general production situation, after the powdery object is formed, a polycrystalline material can be obtained after a sintering method, which is a dense combination. It can increase the loss of electromagnetic waves inside the material and thus improve the wave absorption performance of the material, which provides a guiding direction for designing the composition and structure of wave-absorbing composites. Under microscope observation, it can be seen that its structure includes pores and crystals. [5]. The sintering process may affect the properties of the original material, because it will affect the size of the pores of the object, the size of the crystalline particles, and the distribution and shape of the grain boundaries. The specific process of the sintering method is shown in Figure 1.

Since the particle size is related to the sintering temperature and the holding time of the peak temperature, SEM is used to observe the microstructure of sintered silver under different process conditions, and the particle size is counted according to the linear interpolation method [6]. With the increase of sintering current or energization time, the size of silver particles after sintering increases significantly. The effect of different cladding layer thicknesses on the magnetic properties was investigated by varying the experimental cladding silicon oxide process with the help of a silane coupling agent for the activation of iron-nickel alloys of micron size. It was found that the saturation magnetization strength of the material decreased with increasing the cladding layer thickness, while the effect on the coercivity was not significant. Since grain growth is caused by grain boundary migration, the grain boundary migration rate can be expressed by the following formula:

$$V_a = M_a \times F_a. \tag{1}$$

Among them, M_a represents the mobility of the grain boundary; F_a represents the driving force. And the relationship between M_a and temperature can be expressed by the

following formula:

$$M_a = \frac{(D_a * \omega)}{(K * T * W_a)}. \tag{2}$$

Among them, D_a is the diffusivity of the grain boundary; W_a is the boundary width; ω is the atomic volume; K is the Boltzmann constant; T is the absolute temperature [7]. The driving force F_a can be expressed as follows:

$$F_a = A \times \frac{\sigma_a}{D_g}. \tag{3}$$

Among them, σ_a is the surface energy; D_g is the average particle size. Grain boundary diffusion can lead to grain growth, as described in the above formula. Therefore, the grain boundary migration rate is proportional to the grain growth rate, that is, dD_g/dt.

$$\frac{dD_g}{dt} = \frac{A \times \sigma_a \times D_a \times \omega}{(K \times T \times W_a \times D_g)}. \tag{4}$$

After formula integration, you can get

$$D_g{}^2 - D_{g0}{}^2 = k \times t. \tag{5}$$

Among them, D_{g0} is the grain size when t is equal to zero? Therefore, we can conclude that when the energization time is extended or the sintering current is increased, the migration rate of the grain boundary will increase, resulting in an increase in the grain size. Especially when the electrification time is 180 s, it can be found that the silver particles have obvious coarsening [8].

Although the current sintering peak temperature is high, the very short sintering time inhibits the growth of sintered silver particles. Formulated by haulage:

$$\sigma = \sigma_0 + kd^{-a}. \tag{6}$$

Among them, σ is the shear strength; σ_0 and k are constants independent of size; d is usually between 0.5 and 1.

The Heywang-Jonker model proposes that the barrier height (ϕ) and acceptor state density (N_s) of the sample can be estimated from the resistance temperature $R - t$ curve. According to semiconductor theory, the relationship between barrier height (ϕ) and grain boundary resistance:

$$\rho = \rho_0 \exp\left(\frac{e\varphi}{kT}\right). \tag{7}$$

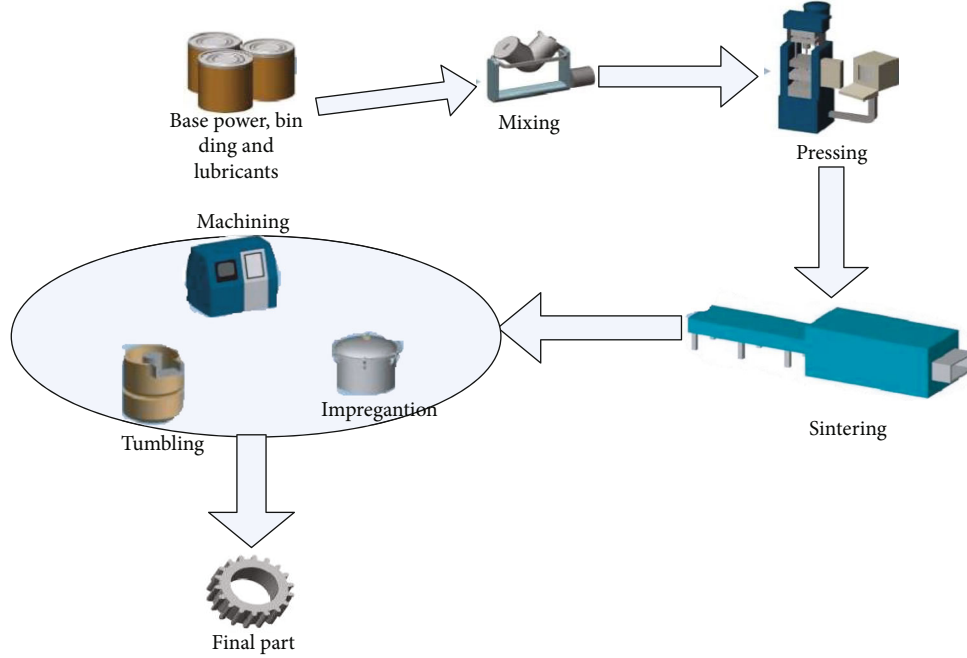
Among them, ρ_0 is a constant, e refers to the basic charge, T is the Kelvin temperature, and k is the Boltzmann constant [9]. When the sample temperature is lower than the Curie temperature T_C, the potential barrier is offset by the spontaneously polarized electrons of the ferroelectric phase. When the temperature rises above the


FIGURE 1: Preparation process of sintering method.

Curie temperature T_C,

$$\varphi = \frac{eN_S^2}{8\varepsilon_0\varepsilon_r N_d}. \tag{8}$$

N_S is the acceptor state density, Nd is the donor doping concentration, ε_r is the relative permittivity, and ε_0 is the vacuum permittivity. By (7) and (8), the resistance ρ can be expressed as

$$\rho = \rho_0 \exp\left(\frac{eN_S^2}{8\varepsilon_0\varepsilon_r N_d kT}\right). \tag{9}$$

2.2. Powder Metallurgy Methods. Powder metallurgy is a traditional process that uses metal powder or a mixture of metal powder and nonmetal powder as raw materials for smelting and uses technical means such as sintering and forming to finally produce metal materials, composite materials, and various other types of products. Mean is as shown in Figure 2. Powder metallurgy is a kind of powder sintering technology; ceramic firing in daily life also belongs to this technology, so most of the powder metallurgy methods or techniques can also be applied to the production of ceramic materials. The powder metallurgy method has many advantages and benefits. However, in high-frequency field applications, on the one hand, due to the skinning effect of soft magnetic alloy materials, the electric field is mainly concentrated on the surface of the material, which can create uncontrollable hazards. It can solve the problem of the urgent need to develop new materials to replace the original materials. Soft magnetic metal nanoparticles have gained wide interest in applications such as catalysts, biosensors, clinical medicine, super-

capacitors, water treatment, and microwave absorbing materials due to their potential properties. It will play a very important role in future life [10].

The Archimedes drainage method is used to detect the density ρ of each sample, and the surface is treated with wax to improve the accuracy of the test. Use BSM-200.4 electronic analytical balance to measure the quality [11]. Calculate the sample density according to formula ((10), where m_1 is the mass of the sample in air (g), m_2 is the mass (g) after sealing wax, m_3 is the suspended mass in water (g), and ρ_w is the density of water (g/cm^3). ρ_{wax}Is the density of paraffin wax (g/cm^3).

$$\rho = \frac{m_1}{m_2 - m_3/\rho_w - m_2 - m_1/\rho_{\text{wax}}}. \tag{10}$$

The porosity of the sintered matrix is the key parameter of the infiltration amount in the subsequent copper infiltration process. After the density of the sintered matrix is measured, the matrix porosity ε can be calculated according to formula (11) [12]. ρ_0 is the theoretical density of the sintered matrix (g/cm^3), and ρ is the measured density of the sintered matrix (g/cm^3).

$$\varepsilon = \left(1 - \frac{\rho}{\rho_0}\right) \times 100\%. \tag{11}$$

The material composition of the working layer and the nonworking layer of the bimetal valve seat ring is different, and the thermal expansion coefficient is different. Therefore, the radial shrinkage rate k of the two layers of materials needs to be tested before and after copper infiltration [13]. A screw micrometer (accuracy: 0.01 mm) is used to measure
FIGURE 2: Detailed production steps of powder metallurgy method.

the size of the sample before and after the copper infiltration and calculated according to formula (12), d_1 is the diameter before copper infiltration (mm), and d_2 is the diameter after copper infiltration (mm).

$$k = \left(\frac{d_2 - d_1}{d_1}\right) \times 100\%. \tag{12}$$

The strength of ring-shaped powder metallurgy parts is often tested by crushing test. The ring-shaped sample is subjected to radial load until it is crushed to obtain the maximum load F, and the crushing strength is calculated by formula (13). Among them, F is the maximum load (N), D_1 is the outer diameter of the ring (cm), h is the height of the ring (cm), and e is the thickness of the ring (cm).

$$K = \frac{F(D_1 - \mathrm{h})}{eh^2}. \tag{13}$$

In order to detect the interface bonding strength of the two layers of the bimetal seat ring, a tensile strength test is required [14]. Calculate the tensile strength according to formula (14). F_b is the maximum load (N) that the sample bears when it is broken, and S_0 is the original cross-sectional area of the sample (mm).

$$\sigma = \frac{F_b}{S_0}. \tag{14}$$

Collision theory collision-contact reaction is a necessary condition for the reaction between molecules. The higher the concentration of the substance participating in the chemical reaction is the greater the probability of collision, and the faster the chemical reaction. Therefore,

there are

$$v = kC_A C_B. \tag{15}$$

Pulverization and products are two items included in powder metallurgy technology. Pulverizing is mainly a metallurgical process, that is, its literal meaning; while products are through metallurgical processes, and finally, products are obtained [15]. The powder products in our daily life are often beyond the scope of ordinary metallurgy and materials. Usually, they are combined with multiple disciplines of technology, which may include machinery, mechanics, materials, and environment, and are multiple disciplines. Especially in this era, 3D printing technology is very developed, and current metallurgical technology often includes CAD, mechanical engineering, control engineering, materials science, and computer technology, which makes metallurgical technology a very demanding and professional knowledge. Powder metallurgy technology is now very common and widely used in factories, as shown in Figure 3 for the powder metallurgy process.

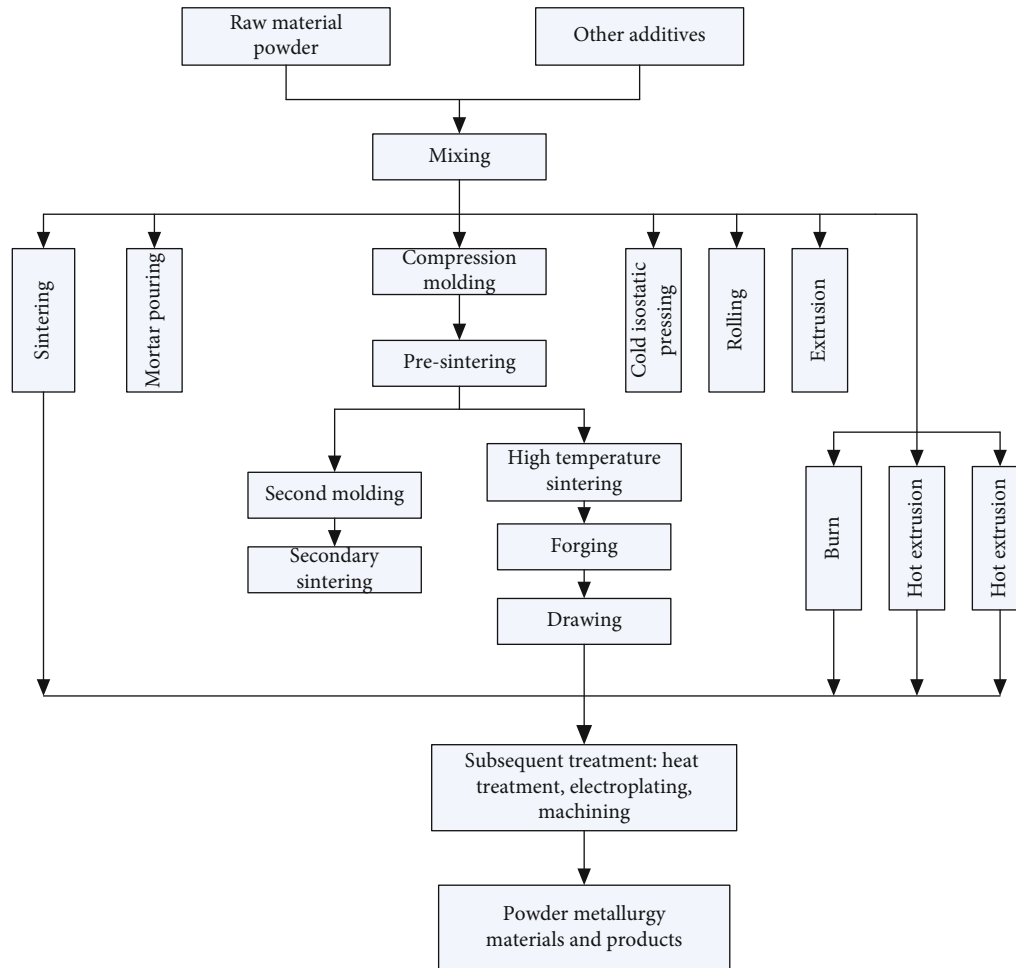
2.3. Sports Industry. The sports industry is a whole industry that integrates the provision of sports products for the society, the organization of sports activities, and the economic sector that includes sports. The sports industry is a very important sector in our country and an indispensable part of the national economy. Like other industries, the sports industry focuses on market performance and economic benefits. But at the same time, it also has its own unique characteristics different from other industries [16]. For example, the important function of their products is to enhance the physical quality of the people, promote the development of social production, promote the national spirit, and ultimately realize the overall development of individuals and the overall progress of social culture. In a broad sense, the


FIGURE 3: Brief introduction diagram of powder metallurgy process.

sports industry includes all business activities related to sports, including the production and management of sports equipment products and sports service products; in a narrow sense, sports products refer to the "sports service industry" or "energy Some sports companies that enter the market but are also profitable" [17]. The industrial chain of the sports industry is the lifeblood of it. It is the general idea of all sports and its derivative industries. All sports industries are developed around it. The sports industry chain is shown in Figure 4.

3. Experiments of Metallurgical Materials in the Sports Industry

3.1. Hardware Design. This experiment is to apply high-performance iron-based powder through sintering technology and finally successfully prepare the material for application in the sports industry. In the experiment, the current sintering technology was used to realize the connection process between the IGBT chip and the silver-plated copper substrate and the DBC substrate [18]. Therefore, 99.95% of the copper purchased in this paper is cut into a substrate with a size of 22 mm ×15 mm ×1.5 mm according to the size of the matching chip. In order to avoid the oxidation problem of the bare cop-

per substrate during the sintering process, the cut copper is electroplated, and 5 μm silver is plated in each direction [19]. As shown in Figures 2 and 3, the processed silver-plated copper and DBC substrate and the IGBT chip are used in the experiment, the IGBT chip size is 6.5 mm × 4.87 mm × 0.12 mm. The IGBT chip and the DBC substrate are quickly sintered and connected by an integrated device to realize the connection between the IGBT chip and the substrate. Among them, the power supply adopts AC-DC-AC-DC conversion technology (IGBT inverter technology), microcomputer control technology, and modern power electronic technology; the time control can reach millisecond precision; and the control response and control accuracy are greatly improved. Due to the use of DC output, its manufacturability is significantly improved [20]. Sintering is one of the most critical parts. The process flow chart of the sintering system is shown in Figure 5. It can process powdered metal or nonmetal materials through specific methods such as firing and finally successfully obtain a dense combination and successfully applied to sports equipment [21].

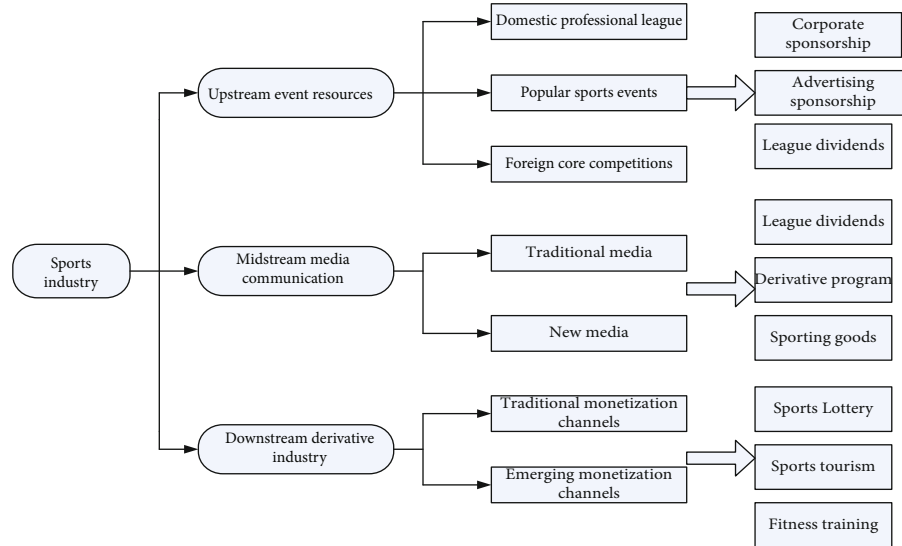
3.2. Software Design. This experiment also carried out corresponding data collection, data analysis, data processing, and summary work on the computer system, combined with


FIGURE 4: Overall block diagram of the sports industry chain.
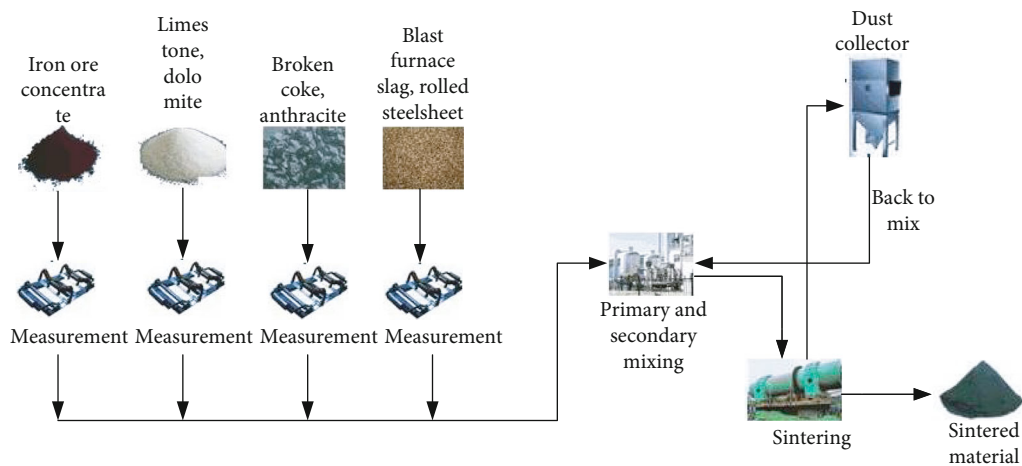

FIGURE 5: Schematic diagram of the process flow of the sintering system.

computer technology, communication technology, network technology, etc., and finally successfully prepared a high-performance iron-based metallurgy that meets the requirements [22, 23]. The transient thermal resistance value of the connection sample between the IGBT chip and the substrate is used to characterize the thermal performance of the sintered silver joint. Transient thermal resistance is characterized by a transient thermal resistance test system independently developed by our laboratory. This system includes a test circuit board that drives and controls IGBT chips, an oscilloscope (TektronixDPO4104B) for real-time monitoring of IGBT output waveforms, and a test circuit for IGBT chips. Collector-emitter programmable DC power supply (RIGOLDP1116A) with heating current, high-efficiency water-cooled heat sink, PVC still air box to avoid the influence of air disturbance on the test results, integrated test control, data acquisition, and data processing software pack-

age and computer carrier [twenty three]. In order to verify the feasibility of the nanosilver connection sample between the IGBT chip and the substrate obtained by the current-assisted sintering method, this paper uses a double-pulse test device for electrical switching characteristics to characterize the electrical switching performance of the IGBT postwelded sample connected with the nanosilver solder paste, as shown in Figure 6 below.

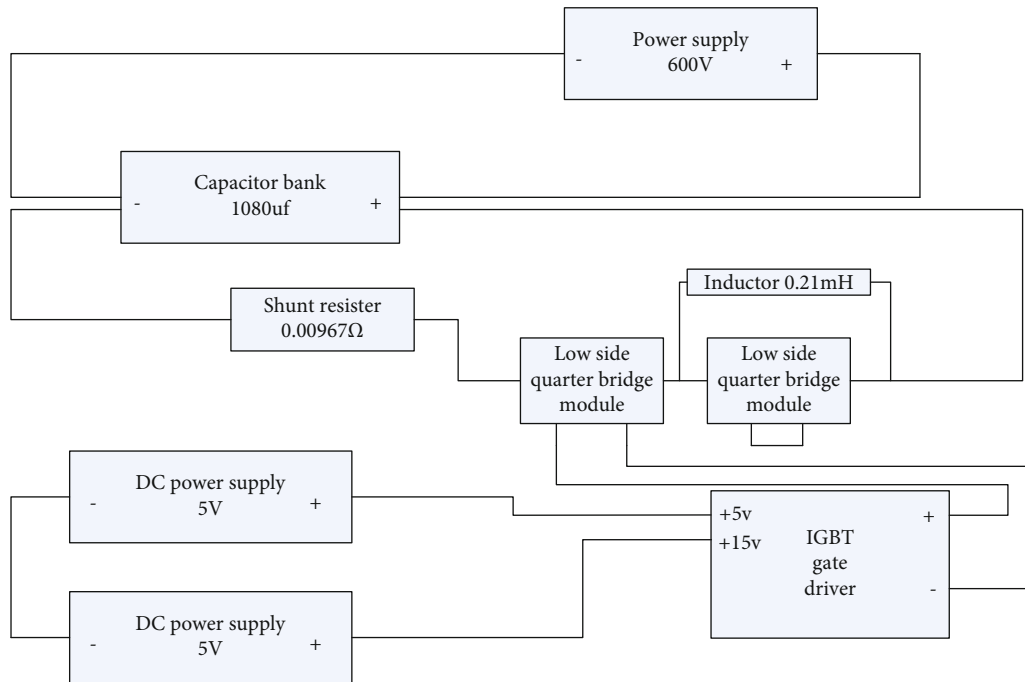
3.3. Overall Design. This article is in the traditional sports industry, in the field of sports equipment and sports equipment, the use of high-performance iron-based powder metallurgy materials through traditional sintering technology, and finally a composite polymer material [24]. Up to now, most of the sports, fitness, and entertainment equipment we use in our daily life are designed and manufactured by metal materials or wood, but the physical characteristics of


FIGURE 6: Circuit diagram of the double pulse test device.

these materials themselves have led to the strength of the manufactured appliances. With the continuous advancement of science and technology and the continuous successful research and development of various new materials, various new materials have also been widely used in the production of various sports equipment, even in some sports competitions [25]. According to the excellent properties of various new materials, such as high strength, special measurement, light weight, good wear resistance, strong damping performance, and strong design, various materials are widely used in the production of sports equipment.

4. Data Analysis and Discussion Based on Experiments

4.1. Data Analysis Based on Sintering Technology. With the progress of the times and the continuous discovery and utilization of various new materials, and the continuous development of various manmade materials in daily life, the scope of cemented carbide continues to develop and expand. And the performance requirements of cemented carbide are constantly improving. In the 1990s, the research and preparation of cemented carbide with extremely small nanostructured carbides became a huge hot spot. After many inspections, people found that without changing the binder phase content, when the grain size of tungsten carbide is less than $1\,\mu m$, the hardness and strength of the cemented carbide can be significantly improved. And the growth rate has also declined. This leads to a significant reduction in grain size, especially the carboxyl groups of nanocrystalline cement. Hardness and durability will evolve a lot. The German Dust Metallurgical Company has established a grading standard for cemented carbide according to the particle size, as shown in Table 1.

The specific production stages of sintering technology: (1) low-temperature presintering stage. At this stage, it is necessary to produce metal or nonmetal recovery and absorb gas and volatilize water and then carry out the exclusion and decomposition of the embossing; (2) at this stage, there will be a chemical phenomenon called recrystallization. The deformed crystals in the particles will recover and produce a new type of crystal. At the same time, oxides on the surface will be reduced and sintering will be formed at the interface is the completion stage of high-temperature insulation. At this stage, a large number of closed pores will be formed, and at the same time, the full flow and diffusion of the gas will be completed, so that the size and number of small pores will decrease, but the density of the entire sintered body will be greatly increased. The specific situation is shown in Figure 7.

The stacking fault energies of some metals and alloys are shown in Table 2. Through detailed data, it is found that iron is a typical face-centered cubic crystal structure with low stacking fault energy. During the fusion process, the nanoiron grains follow the grain boundary moves and develop, so the nanoiron paste has the matching conditions during the fusion process. Many twins were found in the joint made of silver nanoiron alloy. The nanoiron glue was continuously irradiated with an electron beam at about 200°C. According to TEM observation, a large number of twins were formed at the edges of the iron particles. However, the number of twins will decrease over time until they disappear completely.

The conversion rate between different metals is different. In this experiment, we used several metals and alloys, such

TABLE 1: Cemented carbide grain size classification standards of the society of powder metallurgy.

Stacking fault energy (mj)	400	200	18	70	60	20	15

as gold, silver, copper, iron, and stainless steel. The conversion rates between them are high and low. In the experiment, we are studying high-performance iron-based metallurgical materials, so we value the conversion rate of iron or the conversion rate of iron-containing alloys. The conversion rates of different metals at different temperatures are shown in Figure 8.

Preliminary study on the preheating time of fusion pressure the preheating temperature, sintering current, and excitation time basically determine the range of parameters to be discussed in the fusion process. On this basis, the mechanical and thermal properties of the interface between the IGBT chip and the substrate are mainly investigated. The microstructure of the gold-plated copper

rods with different fusion current activation time preheating temperature and different preheating time is shown in Table 3 to ensure the reliability of the experimental data. At least 5 samples are repeated for each group of experiments, and finally, the average value of each group of experimental data is taken as the final result.

In the traditional sports industry, most of the materials used are heavy, wear-resistant, and cheap, such as iron, aluminum, wood, and other materials. The sports equipment made in this way is very heavy, and resistant to torsion, the performance such as hitting feedback is not very good, but the price is cheap, so many people may discard it after using it once, which also causes a certain degree of pollution. However, in this research, we used the new technology to produce high-performance iron-based metallurgical materials. This material is used in the production of sports equipment, making the new sports equipment light in weight, wear-resistant, and resistant to torsion. And many other features, and when damaged, we can also recycle the secondary production. After in-depth research on the application scenarios of high-performance iron-based materials, I calculated the expected improvement (p) of this material in the field of sports equipment for other projects, as shown in Table 4, that is, under
FIGURE 8: Comparison of conversion rates of different metals.

theoretical conditions, calculate the sports performance of using high-performance iron-based materials in the direction of improving the performance of a certain aspect based on previous data, and compare them with the sports performance of sports equipment using existing composite materials, expressed as a percentage. A theoretical expected value is called the expected lift.

The sports industry is a very important sector in our country and an indispensable part of the national economy. Like other industries, the sports industry focuses on market performance and economic benefits. But at the same time, it also has its own unique characteristics different from other industries. For example, the important function of their products is to enhance the physical quality of the people, promote the development of social production, promote the national spirit, and ultimately realize the overall development of individuals and the overall progress of social culture. With the daily needs of people for sports, sports are not only for physical health. With the rapid development and improvement of sports and related industries, sports have also become a consumer product for people's daily leisure and entertainment. Sports investment and financing have become more and more frequent with the improvement of the sports industry. Figure 9 shows the actual situation of my country's sports industry investment and financing in the past five years.

The sports industry is a very promising industry, and damage to sports and fitness equipment in our daily lives is also a very important aspect. As shown in Table 5, according to estimates, in 2019 alone, the total output value of the national sports industry was 2,948.3 billion yuan, a very significant increase compared to 2018. The construction of daily sports facilities reached more than 20 billion yuan, and the current price increased by 41.7%, accounting for 1.9% of the added value. According to data, from 2016 to 2020, the output value and added value of my country's sports industry are increasing year by year, and many new brands and emerging sports are produced in my country every year. The specific data is shown in Figure 10.

TABLE 4: Comparison of high-performance iron-based materials and traditional alloys.

Sports	Sports equipment	Expected lift
Single parallel bars	High-performance iron-based materials	52.3%
Single parallel bars	Traditional alloy	51.3
Dumbbells	High-performance iron-based materials	17.7%
Dumbbells	Traditional alloy	17.3%
Shot put	High-performance iron-based materials	28.0%
Shot put	Traditional alloy	27.4%

Category name	Total (100 million yuan)		Structure (%)	
	Total output	Value added	Total output	Value added
Sports industry	29483.4	11248.1	100.0	100.0
Sports service industry	14929.5	7615.1	50.6	67.7
Sports goods and related products manufacturing	13614.1	3421.0	46.2	30.4
Sports facilities construction	939.8	211.9	3.2	1.9

4.2. Discussion. Sintering technology is a traditional handicraft process, that is, a traditional firing process that converts the original powdery raw material into a dense combination. This article uses sintering metallurgy to produce high-performance iron-based powder materials and then applies them to the sports industry. Its ferrite grains are very small and can only be embedded in amorphous carbon, which makes the ferrite not play the role of lower coercivity. These are two unrelated industries, but through the rapid development of the sports industry in recent years, coupled with the continuous innovation of sports science and technology the integration of various disciplines, industries, and sports make this topic very meaningful for research. For different applications, it is necessary to choose different substances to be compounded with FeNi alloy to meet the application requirements. In the early days, people have already begun to use the sintering process to produce many things, such as porcelain, powder metallurgy, refractory materials, and high-temperature materials. These products are widely used in our daily lives and widely used in our daily lives. In this experiment, we applied this method to produce a new type of material for sports equipment, which can enable the industry to produce new sports equipment with good quality and strong functionality for use in our daily lives, and
FIGURE 10: Statistics on the scale and increase of China's sports industry from 2016 to 2020.

possibly used in sports equipment. In professional competitions, according to recent trends, this situation is very possible.

5. Conclusions

This article is based on the traditional sports industry, using the sintering method to produce high-performance iron-based powder metallurgy materials, which are used in the development of related sports equipment in the current sports industry. The sintering metallurgical method is a very traditional method, which has been widely used in daily life by our working people since ancient times. Since the beginning of the 21st century, various emerging industries have developed vigorously. As one of the pillars of our country, the sports industry has also begun to develop rapidly. At this stage, it continues to integrate with all walks of life to develop new sports science and technology. Traditional sports equipment basically uses materials such as metal or wood, which are not only cumbersome but also of low quality. In this era of rapid development, they are on the verge of being eliminated. Based on this, we want to design and develop a new type of material for the production of sports equipment, using traditional technology and the current rapid development of the industry. Although our research is still in the theoretical stage, as long as we develop it and realize it, it is believed that it will be widely used in the sports industry for a long time in the future.

Wrist joint plays an indispensable role in our daily life. The injury of wrist joint has a great influence on the fine movement of the hand and upper limb. For example, you cannot do joint movements, you cannot carry things, and life is very inconvenient. It is necessary to distinguish the types of wrist disorders and take effective rehabilitation methods in time. Wrist joint has a great impact on people's life and work, and the rehabilitation of wrist joint has become a research hotspot in rehabilitation medicine and medical engineering. Carpal tunnel syndrome is the most common peripheral nerve entrapment disease in clinical practice, with a very high incidence. According to data, the incidence of carpal tunnel syndrome in the general population abroad is 1%-5%, while that in special populations is as high as 14.5% above. In order to solve the problem of rehabilitation of wrist joint, using electrospinning technology, the polymer solution is prepared into nanofiber materials with strong adsorption and good filterability under the action of high-voltage electric field. And using some small-sized nanofibers that are similar to organs in shape and structure, as well as their excellent degradability and biocompatibility, this material is used in the research of wrist joint movement rehabilitation. In this paper, sports rehabilitation training is carried out on the wrist joint of basketball players, and the nanofiber material is effectively combined with sports rehabilitation training. By comparing the rehabilitation of athletes who did not use nanofiber materials, the role of nanofiber materials in sports rehabilitation was studied. This article analyzes the three parts of the radial joint, the wrist joint, and the ulnar joint before and after the sports rehabilitation training for basketball players with functional impairments and compares the sports rehabilitation of the basketball players without nanofiber materials. This article analyzes the three parts of the radial joint, the wrist joint, and the ulnar joint before and after the sports rehabilitation training for basketball players with functional impairments and compares the sports rehabilitation of the basketball players without nanofiber materials.

1. Introduction

1.1. Background Meaning. Wrist joint is the most flexible joint in human upper limb, which can complete various complex and accurate movements. It is not only used frequently in life but also bears the largest load in the process of supporting, pushing, and pulling. The wrist joint is a complex joint composed of multiple joints, including the radiocarpal joint, the intercarpal joint, and the carpal metacarpal joint. In a narrow sense, the wrist joint refers

to the joint between the lower end of the radius and the first row of carpal bones (except the pisiform bone), that is, the radiocarpal joint; but from a functional point of view, the wrist joint should actually include the radiocarpal joint, the intercarpal joint, and the radioulnar joint. The lateral joints, which are unified in motion, the wrist joint is located deep in the carpal tunnel. The wrist joint is the main part to complete the function of the upper limb, and it is easy to cause injury in daily life. It plays an indispensable role in our daily life. Once the wrist joint is damaged, people's life and work

will be greatly affected. Especially for basketball players who need to use it frequently, if their wrist joint is injured, and the untreated and unreported injury will continue to reduce their ability and lead to poor team performance [1]. In the rehabilitation of wrist joint injury, early and correct functional exercise is very important for the recovery of wrist joint function. It can promote blood circulation, accelerate metabolism, prevent muscle atrophy, and enhance muscle strength through muscle movement. Rehabilitation medicine of wrist joint involves many aspects, and there are many methods of wrist rehabilitation training, such as electrocardiography signal control method, AR method, thermotherapy, occupational therapy, mechanical movement, and exercise therapy. However, due to the complexity of wrist joint, the rehabilitation treatment of wrist joint has always been one of the difficult problems in rehabilitation medicine and medical engineering, and it is also a hot research topic in medical field. In recent years, with the emergence of electrospinning technology and nanofiber materials, researchers have seen a new research idea of wrist rehabilitation training.

Electrospinning is a special form of electrostatic atomization of polymer fluids. At this time, the atomized and split substances are not tiny droplets, but tiny polymer jets, which can run for a long distance and eventually solidify into fibers. Electrospinning is a special fiber manufacturing process in which a polymer solution or melt is jet-spun in a strong electric field. Under the action of the electric field, the droplet at the needle changes from a spherical shape to a conical shape (that is, a "Taylor cone") and extends from the tip of the cone to obtain fiber filaments. In this way, polymer filaments with nanometer diameters can be produced.

Some nanofiber materials are very useful in biomedicine. They are similar to human organs in morphology and structure and have excellent degradation and biocompatibility. The smaller the size of the nanofiber particles, the larger the surface area. Because the surface particles lack the coordination of adjacent atoms, the surface energy is extremely unstable, and it is easy to combine with other atoms, showing strong activity. Human organs are similar. These nanofibers can replace biological organs for organ transplantation, repair, and treatment. Because of its small grain size, the size of internal pores or defects is greatly reduced, and it is not easy to break through the crystal and has unique super plasticity. It is mainly used in artificial bone and artificial joint. Carbon nanofibers have good biocompatibility and strong adsorption. They play an important role in the strength and toughness of artificial organs and can be used in the blood purification system. The application of nanopolymer materials has been involved in immunology, drug-controlled release carrier, and interventionism diagnosis and treatment. Due to the various characteristics of these nanomaterials, researchers will make great breakthroughs in biomedical research.

1.2. Related Work. The rehabilitation training of wrist joint and the application of electrospinning technology and nanofiber materials have always been the research hot spot in the academic field. Erben prepared nanofibers and microfiber mats through a new combination of alternating current (AC) electrospinning and bubble electrospinning, Nanofiber refers to a wire-like material with a diameter of nanometer scale and a large length with a certain aspect ratio. In addition, the fibers that are modified by filling nanoparticles into ordinary fibers are also called nanofibers. In a narrow sense, the diameter of nanofibers is between 1 nm and 100 nm, but in a broad sense, fibers with a fiber diameter below 1000 nm are called nanofibers. Microfiber mat refers to nonwoven sheet scrap functional fibers with a fiber diameter of less than 5 μm [2]; however, the practicability of this method is not as good as that of this paper. Warzoha et al. studied the effect of randomly oriented grapheme nanofibers on the overall thermal properties of organic paraffin PCM [3], but the amount of data that this method needs to collect is too large. Iida et al. studied the stability of the distal radioulnar joint (DRUJ) at different wrist joint positions and examined the relative contribution of each ligament component of the triangular fibrocartilage complex (TFCC) to the stability of DRUJ [4], but the research object of this method is too one-sided. Wu et al. studied the effects of processing parameters such as rotation speed, working pressure, carbonation, and SPS temperature on the diameter of nanofibers [5], but the data needed to be calculated by this method is too complicated. Yan et al. prepared a beaded nanocomposite Li3V2(PO4)3(LVP) grown on carbon nanofibers (CNF) through electrospinning and heat treatment. The preparation method is more precise and simple [6]; however, the operation steps of this method are too many and the operation is too complicated [7], but the cost of this method is too high. Pujari et al. studied the potential benefits of vibration stimulation as a motor intervention and its application in exercise rehabilitation [8], but this method is not suitable for all patients. Han's research is aimed at investigating the current sports rehabilitation industry and finding out the possibility of improving rehabilitation policies [9]; however, the experimental results of this study are not accurate, and there are some errors. Although the relevant research of the above scholars has achieved some results to some extent, most of them are theoretical exploration, with few practical applications, and there is no conflict for the research content of this paper, so the research of this paper is of great significance.

1.3. Innovation of This Article. This article uses nanofiber materials produced by electrospinning technology to improve the sports rehabilitation training of athletes' wrist joints and combines nanofiber materials with sports rehabilitation to make the effect of sports rehabilitation better. The innovations of this article are mainly reflected in the following: (1) using the method of comparative analysis, according to whether nanofiber materials are used in sports rehabilitation training and observe the rehabilitation of the two athletes within five weeks; (2) this article links nanofiber materials with sports rehabilitation and obtains further innovations in sports rehabilitation programs, while expanding the application fields of nanofibers; and (3) this article conducts a comparative analysis from various aspects of

the athlete's wrist joints to ensure the comprehensiveness of the data and the accuracy of the experimental results, including the ruler and wrist angle, the first moon angle, and the ship moon angle, and other aspects of the related indicators for analysis.

2. Proposed Method

2.1. Electrospinning Technology. Electrospinning technology is a technology that overcomes surface tension and viscosity force in a non-Newtonian polymer solution under the action of a high-voltage electric field to obtain nano- to submicron fibers by stretching and bending. Fluids that satisfy a linear relationship between shear stress and shear strain rate are called Newtonian fluids, and those that do not satisfy the linear relationship are called non-Newtonian fluids. Electrospinning technology has changed people's understanding of materials and their properties by manufacturing optimized one-dimensional nanostructures, that is, nanofibers [10]. In recent years, electrospinning has become a promising method to obtain long and continuous fibers with nanometer diameter from a variety of polymers [11]. As a perfect combination of high voltage and nanotechnology, it has injected fresh blood into traditional high-voltage technology. The current background of international research has identified the electrospinning process as one of the key technologies for obtaining nanofibers [12]. Electrospun fibers have attracted attention in many fields, such as tissue engineering, coaxial cables, and drug release due to their huge specific surface area and high porosity. The experimental device of electrospinning technology consists of a high-voltage DC power supply, a sample tube with capillary tube, and a collection plate. The positive pole of the power source output by the DC power supply is connected to the metal electrode inserted into the sample tube, and the negative pole is connected to the receiving plate. With the in-depth research on electrospinning technology in recent years, the laboratory has designed a variety of electrospinning devices that can control the behavior of fiber properties, geometry, and arrangement.

Electrospinning is a modern and effective method that uses an electric field to produce fine fibers whose diameter can be reduced to nanometers [13]. The experimental process of electrospinning technology is as follows: Firstly, the polymer solution is loaded into the sample tube, and the tilt angle of the spinneret is adjusted to make the droplets hang on the spinneret. Turn on the power, and a gradient electric field is formed between the nozzle and the receiving plate. At this time, the electric field force experienced by the nozzle droplets will counteract the surface tension of the liquid. When the two are equal, a "Taylor cone" is formed at the spinneret. Further increase the voltage and the electric field can overcome the surface tension of the liquid. A Taylor cone is formed by the illusion of a liquid under an electric field (or a gravitational field or a pressure field). The Taylor cone is sharp and unusual, and no weapon in the world can match it. And from the tip of the cone is a jet of liquid as thin as a hair. The cone is named after a generation of fluid mechanics guru Taylor, because he used the theory to calcu-

late the angle of the cone. At this time, the tiny stream of dotted liquid is ejected from the spinneret in the form of fiber bundles and moves toward the negative electrode. In this process, the fiber bundle undergoes a series of bending instability processes and electric field stretching processes. The fiber bundles gradually split, and the diameter continuously decreases. At the same time, the solvent gradually evaporates from the fiber surface, and the dried nanofiber falls on the collecting plate. The positive charge of the fiber is partially neutralized by the negative charge accumulated on the negative electrode, forming multiple layers of positively charged nanofibers. The applied voltage, the flow rate, and the distance from the injector to the collector have a moderate effect on the fiber diameter, while the needle gauge has a small effect on the fiber diameter [14].

Electrospinning technology can be regarded as a special case of electrospray technology. Its principle and related formulas are as follows. The droplet at the top of the spinning tube is convex hemispherical under the action of surface tension. When a voltage of a certain potential is applied in the liquid, the curvature of the droplet surface will gradually change. When the potential reaches the critical value of V_c, the droplet is gradually elongated by a Taylor cone with an angle of 49.3 degrees. The small droplets split by the jet at the tip of the Taylor cone have high monodispersity, and the drug is integrated into the droplets. After the droplets are dried, highly monodisperse nanodrug particles can be obtained, and the obtained nanodrug particles can reach ERP. The effect of targeted drug delivery effectively enhances the efficacy of the drug. The data here comes from actual tests by relevant scientists. The value V_c of the critical potential can be determined by the following formula:

$$V_c = \left(\frac{2H}{L}\right)^2 \left[\ln\left(\frac{2L}{R}\right) - 1.5\right](0.117\pi\gamma R). \tag{1}$$

In the formula, H represents the distance between the capillary and the earth pole, L represents the length of the capillary, radius R represents the radius of the capillary, and γ represents the surface tension of the liquid.

For the hemispherical droplet suspended on the end of the capillary, the solution electrospray/electrospun voltage V is similar to the formula of V_c in formula (1), and its value can be expressed as

$$V = 300(20\pi\gamma r)^{0.5}. \tag{2}$$

The r in the formula represents the radius of the droplet suspended at the end of the capillary. The premise of satisfying formula (2) is that the droplet is surrounded by air. and the fluid in the droplet is a simple molecule. The strength and conductivity of the liquid play a vital role in the dynamics of electrospinning.

2.2. Nanofibers. Nanofibers are linear materials with a nanometer scale diameter and a large length with a certain aspect ratio. Its diameter is between 1 nm and 10 nm. The smaller the diameter of the nanofiber, the higher the tensile strength

[15]. Nanofibers are classified into two categories according to their types: fibers having a nanometer diameter and fibers modified by filling conventional fibers with Na-no particles. So far, there are many methods for preparing nanofibers, such as stretching method, template synthesis method, self-assembly method, electrostatic spinning method, and solution jet spinning method. Pass nanofibers have larger surface area and smaller pore size than other materials and have stronger adsorption, good filterability, and barrier ability and excellent adhesion and heat preservation.

The advantages of nanofibers are as follows: First, due to their small diameter, they have a very large size effect, including excellent electrical, magnetic, optical, and thermal aspects. Secondly, the regular arrangement of molecules allows self-organization, thus exhibiting a unified function. Third, in biomedicine, it can be combined with cells to make nanofibers with specific structures. Due to these advantages of nanomaterials, in recent years, nanofibers have found markets in the fields of healthcare, energy, and defense [16]. At the same time, the improvement of the practical value of nanofibers has also promoted the rapid development of its preparation technology.

Based on the unique characteristics of nanofibers, researchers have conducted corresponding research in the following areas: First, in biomedicine, small-sized nanofibers are similar to organs in morphology and structure. Some fibers have excellent degradability and biocompatibility, so cell scaffolds can be cultured. It can be used for tissue and organ repair, as a carrier for drug-controlled release systems and wound coverings [17]. Secondly, about the environment, due to the fiber membrane, the diameter of the fiber is small, the porosity is high, and the uniformity is good. These characteristics of electrospun nanofibers can be used to prepare adsorption materials and filter materials, which can be effectively combined with submicron filtration, and can be applied in atomic industry, aseptic room, precision industry, finishing and other industries, and greatly improve its filtering effect. When nanofibers are used as barrier materials, they can be used as separators between positive and negative electrodes of batteries, because they can prevent the movement of particles and specific ions. For example, the fiber network made of vinyl chloride acrylonitrile copolymer resin by air injection method has high density and high blocking efficiency. As a special battery separator, it can also work in acid and alkaline medium for a long time. In the field of sensor, nanofiber membrane has high specific surface area and excellent structure controllability, which makes it an ideal material for improving sensor performance and preparing high-performance sensor. Nanofiber mats usually exhibit high particle capture efficiency, but due to their more compact structure, they may also lead to higher air flow resistance than macrofiber materials [18]. Due to its hydrophilicity, nontoxicity, and biocompatibility, electrospun nanofiber mats can be used in tissue scaffolds and wound dressings [19]. In addition, researchers have also used nanofibers in protective clothing, aerospace, energy, and magnetic fields and have made significant progress.

2.3. Wrist Joints.

The wrist joint is an important joint of the human arm. It can make up for the lack of freedom of the shoulder and elbow joint. It is a typical elliptical joint. The wrist joint connects the hand and the forearm, is an important part of the upper limb support and thrust, and can withstand heavy loads. Wrist joints, including radiowrist joint, interwrist joint, and ulnar joint, are the most complex joints in the human body. This complex mechanism is conducive to the functioning of the hand. The radiowrist joint is an elliptical deformed ball-and-socket joint, which is a hinge-like motion system with the wrist bone. The radiocarpal joint transfers the load from the forearm to the hand and promotes the fine work of the hands and fingers by providing a considerable degree of stability [20]. Due to different hand movements, the carpal bone is divided into three kinematic chains according to the articular surface of the distal radial carpal. The central chain contains the moon bone, skull, and radius. The side chain is mainly boat-shaped, which can stabilize the wrist bone. The internal measurement chain controls the rotation of the hand, including the triangular fibrocartilage disc, the triangular bone, and the hook bone. Damage to any of the anatomical structures, or even fractures, will affect the function of the entire wrist joint.

In a narrow sense, the wrist joint refers to the joint formed between the lower end of the radius and the proximal row of the wrist bone (not including the pea bone). However, from a functional point of view, wrist joints include the following: (1) the proximal articular surface of the scaphoid, lunate and triangle bones are used as the joint head, and the wrist joint surface of the articular disk below the radius and ulna is used as the joint; (2) distal radioulnar joint; and (3) wrist joints: construct adjacent carpal bones in stages. The bones are intertwined and in contact with each other, connected to each other by complex ligaments and tendons, and have varying degrees of mobility. Due to the complex structure, many joints, and ligaments, the wrist joint is highly flexible. The anatomical properties of the wrist joint allow the wrist joint to move in two planes, frontal uplift offset (abduction and adduction) and surface flexion/extension (palm flexion and extension). The stability of the wrist joint is mainly caused by the wrapping of the joint capsule and the traction of the intercarpal ligaments.

Most of the wrist joint movement is done by the radiowrist joint. In biomechanics, the ulna may be regarded as the pillar of radius activity [21]. It has three degrees of freedom for flexion, extension, contraction, and a certain limit of circular motion. Among them, turning the palm toward the center of the hand is called wrist flexion, also called palm bending; turning to the back of the hand is called wrist extension, also called palm extension; movement in the direction of the thumb is called radial bending. Movement in the direction of the little finger is called ulnar flexion; movement to the outside of the body is called outward rotation; movement to the inside of the body is called internal rotation. There are many kinds of wrist motion theory: the traditional two-row theory, Taleisnik wrist column theory, Gilford's hinge theory, etc.

2.4. Sports Rehabilitation.

Sports rehabilitation is a noninvasive and effective treatment method for sports injuries [22]. In recent years, due to social leisure behaviors, sports rehabilitation after joint or other parts of the body has been injured

and has become more and more important [23]. The purpose of sports rehabilitation training is to improve the patient's physical function and athletic ability. Patients can be assisted by rehabilitation therapists or train their own muscle strength. Sports rehabilitation originated in the sports world and is used for rehabilitation exercises for athletes injured. Sports rehabilitation is a new "trinity" cross-discipline where sports and health medicine overlap, and it is an important part of modern rehabilitation [24]. With the development of medicine, exercise rehabilitation is also suitable for certain diseases, such as stroke, Parkinson's disease, high blood pressure, heart disease, diabetes, and lung diseases.

For sports players, it is important to determine strategies to prevent injuries, optimize rehabilitation, and improve performance [25]. In a sense, the key to the success or failure of sports rehabilitation also depends on the implementation of personal prescriptions and exercise prescriptions. Its content mainly includes form, intensity, time, frequency, and matters. The most important forms of exercise are appropriate resistance exercises and conditioning exercises, as well as aerobic exercises. They can also perform some powerful physical tasks, such as housework and indoor fitness exercises. Exercise intensity is mainly divided into low intensity, medium intensity, and high intensity. It is necessary to comprehensively evaluate the patient's general condition and medical condition according to the patient's risk category and select and exercise the appropriate exercise intensity. It should be noted that the exercise intensity, duration, and exercise frequency of different patients are not exactly the same. Exercise intensity setting methods mainly include age prediction method, heart rate reserve method, resting heart rate+20 method, peak oxygen uptake method, and anaerobic threshold method. When planning an exercise, the main requirement is to ensure patient safety first. Based on this, the intensity and time will gradually increase, and the time of each exercise depends on the situation, ranging from 30 minutes to 1 hour.

Sports rehabilitation training mainly focuses on joint mobility, muscle strength, and functional sports exercises. Rehabilitation treatment requires the participation of the therapist and his family. The therapist will teach the patient's family how to recover and what to pay attention to during the training process. This allows the family to perform simple rehabilitation after returning home to maintain the patient's athletic performance. Family rehabilitation can not only improve the rehabilitation effect but also reduce the economic pressure of the family and form a joint rehabilitation model of hospital and family. During the exercise, the principles of science, applicability, long term, and regularity must be followed, and the frequency should be at least three times a week. Therefore, in order to consider the exercise rehabilitation process to better perform rehabilitation exercises, according to the consensus of the medical profession, exercise rehabilitation is divided into three stages, the first stage is the hospitalization period, and the second stage is the initial discharge period and outpatient rehabilitation. The third stage is the maintenance stage of outpatient rehabilitation. Standardized exercise rehabilitation can not only alleviate the pain and discomfort of patients but also improve exercise endurance, improve mental state, improve overall quality of life, and reduce patients' medical expenses.

3. Experiments

3.1. Test Subject. This article selects two basketball players' sports rehabilitation data before and after wrist joint damage in different periods for experiments. The athlete who uses nanomaterials in wrist exercise rehabilitation is called Athlete A, and the other is called Athlete B. Rehabilitation training was carried out for two athletes, and the specific conditions of the radial joints, wrist joints and ulnar joints, were observed before and after the training, so as to analyze the role of nanomaterials in wrist joint sports rehabilitation.

3.2. Experimental Data. For the statistics on the degree of wrist joint damage of two basketball players before rehabilitation, the collected wrist-related data include the flexion and extension angles of the radius palm inclination angle, radius ulnar deflection angle, ulna carpal angle, radial moon angle, head moon angle, boat moon angle, carpal angle, radial head angle, and radial boat angle. Table 1 shows the degree of damage to the wrist of the two athletes.

The wrist joint damage data of the two athletes in Table 1 were collected in different periods. In the existing medical data, we can know that the normal angle of each carpal joint is shown in the rightmost column of Table 1. In addition, the medical data shows that the angle change of the palmar inclination angle of the radius indicates the fracture of the distal radius; the change of the ulnar deflection angle of the radius indicates the dislocation of the wrist joint or the fracture of the distal radius; the change of the ulnar angle indicates the fracture of the wrist or the dislocation of the wrist joint; radial-lunar flexion > 15° indicates unstable palm flexion, and dorsal extension > 10° indicates unstable back extension; head-lunar angle > 20° indicates wrist instability; boat moon angle > 70° indicates unstable wrist dorsal extension, and <30° indicates instability of wrist flexion; radial head angle > 26° indicates instability of the wrist joint; radial boat angle > 75° indicates instability of the wrist joint.

4. Discussion

4.1. Rehabilitation of the Radial Joint. We analyze the rehabilitation of the wrist joints of two basketball players and compare the rehabilitation of the radial joints of the two athletes with and without nanomaterials for sports rehabilitation training. In order to analyze the effect of nanomaterials on the exercise rehabilitation of the radial joint. With 7 days as a check cycle, we check the extension and flexion angles of the athlete's radius and ulnar angle, radial moon angle, radial head angle, and radial boat angle within 35 days. The final result is shown in Figure 1.

The broken line in Figure 1 represents the recovery of the radial ulnar angle and the radial moon angle of the radial joint within five weeks of athlete A and athlete B. The bar graph shows the recovery of the radial head angle and radial boat angle of the radial joints for athlete A and athlete B in five weeks. The data of radius ulnar angle and radial moon angle are subject to the data of the left main axis, and the data of radial head angle and radial boat angle are subject

TABLE 1: Wrist damage data table.

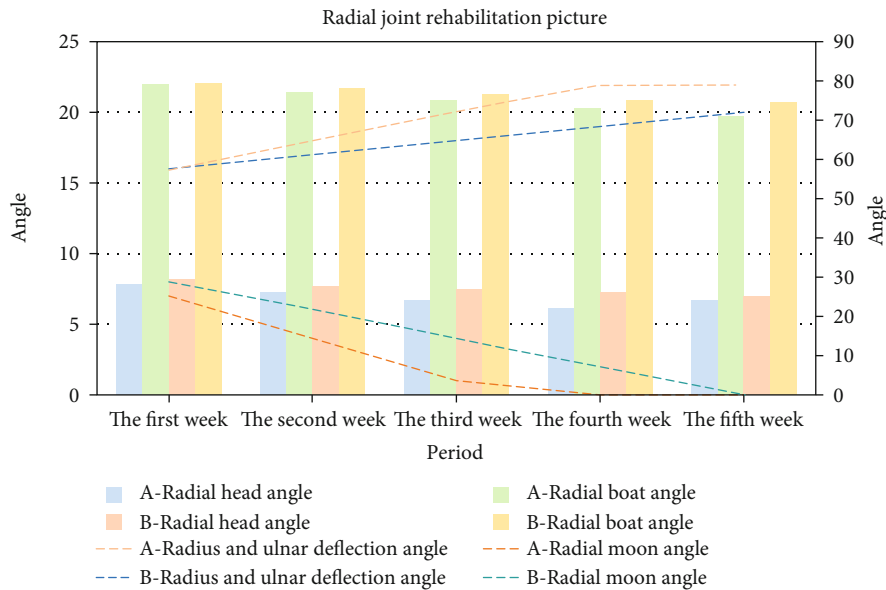
	Athlete A	Athlete B	Normal
Radial pal-mar angle	Normal	Normal	10-15°
Radius and ulnar deflection angle	15°	15°	21-25°
Ulnar angle	18°	18°	21-51°
Radial moon angle	Buckling15° Back stretch10°	Buckling13° Back stretch10°	0°
Head moon angle	25°	25°	0-15°
Boat moon angle	Buckling20° Back stretch75°	Buckling20° Back stretch75°	30-60°
Carpal angle	Normal	Normal	130°
Radial head angle	30°	30°	6-26°
Radial boat angle	80°	80°	55-75°


FIGURE 1: Comparison of the rehabilitation of the radius joint.

to the data of the right secondary axis. According to the data in Figure 1, it can be seen that athlete A's radial joint recovered faster than athlete B's in the same cycle. Therefore, the rehabilitation effect of sports rehabilitation training using nanofibers is better than that of sports rehabilitation training without nanofibers, and the recovery ability is stronger.

4.2. Rehabilitation of Other Parts of the Wrist. With 7 days as an inspection cycle, we check the recovery of the ulnar wrist angle, head moon angle, and boat moon angle of the two athletes within 35 days after sports rehabilitation training. The final result is shown in Figure 2.

According to Figure 2, the wrist joint recovery of the two athletes in five weeks can be seen, athlete A who uses nanofibers for sports rehabilitation has a faster recovery speed, and the time required for rehabilitation training is shorter. Athlete B who does not use nanofibers requires a longer period of time for sports rehabilitation and a slower recovery speed.

4.3. Comparison of Rehabilitation Effects between the Two. After five weeks of sports rehabilitation training for two athletes and observation, we can understand that nanofiber materials have a certain influence on the rehabilitation effect of wrist joint sports rehabilitation training. By comparing the degree of wrist joint recovery of the two athletes in five weeks, the final result is shown in Figure 3.

According to the data in Figure 3, it can be seen that the rehabilitation effect of athlete A who uses nanofiber materials for sports rehabilitation training is better than that without nanofiber materials. And before the end of the rehabilitation, the average degree of rehabilitation per week was 0.3 faster than that of athletes who did not use nanofiber materials. Ordinary sports rehabilitation training is about 2 times faster than wrist joints without rehabilitation training, and sports rehabilitation training using nanofiber materials is about 3 times faster than wrist joints without rehabilitation training.

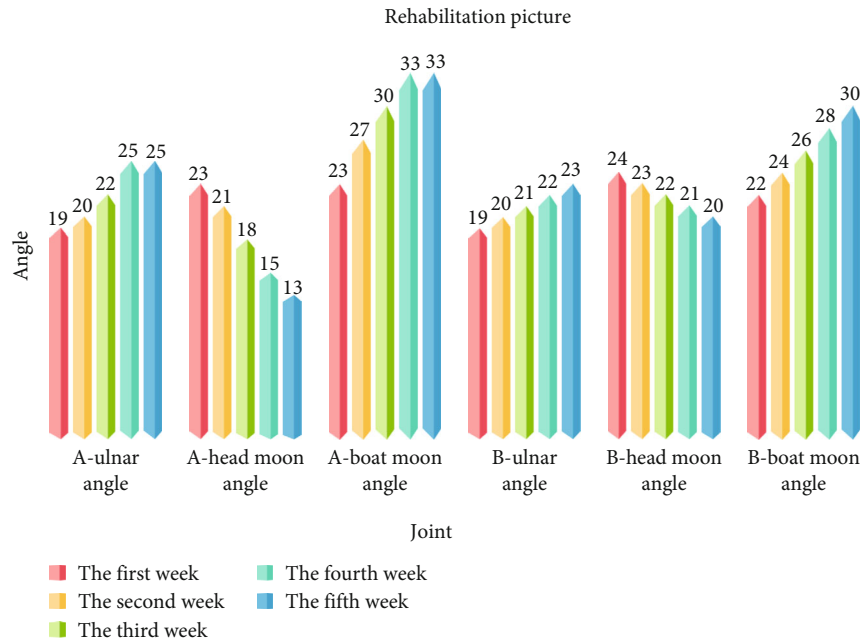
Rehabilitation picture


Figure 2: Rehabilitation of other parts of the wrist joint.

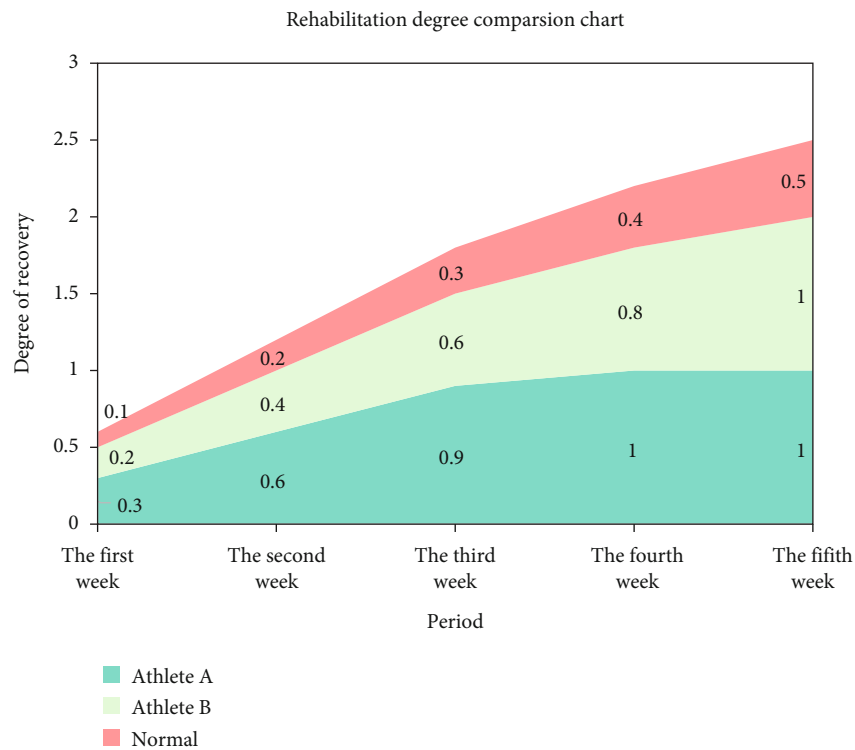
Rehabilitation degree comparsion chart


Figure 3: Comparison chart of rehabilitation degree.

4.4. The Application of Nanofibers in Sports Rehabilitation.
By collecting data on sports rehabilitation in the past 5 years, we can understand the use of nanofiber materials in sports rehabilitation in recent years and analyze the proportion of nanofiber materials used in sports rehabilitation. The final result is shown in Figure 4.

It can be known from the data in Figure 4 that in the early years, the application of nanofiber materials in sports rehabilitation was relatively small, and it was in a state of research and development. Later, with the progress of science and technology and the mass production of nanofiber materials, as well as scholars' research on nanofiber materials. Nanofiber materials
Figure 4: The use of nanofibers in sports rehabilitation.

have become more and more widely used in various fields. As many experiments have proved that nanofiber materials have good rehabilitation effects in sports rehabilitation, the application of nanofiber materials in sports rehabilitation is also increasing year by year.

This article has made corresponding research results on the application of nanofiber materials based on electrospinning technology in the rehabilitation of basketball athletes' wrist joints. However, due to the limited time, the experiment still has many areas to be improved and perfected. This experiment is based on the wrist joint as the research object. In the follow-up experiments, other parts can be combined with nanofiber materials for sports rehabilitation training, so as to understand the role of nanofibers in sports rehabilitation more comprehensively and concretely. Since this study only studied the inclination angle of each part of the wrist joint and did not consider other causes of damage to the wrist joint, the different degrees of damage to the wrist joint can be studied in future studies to ensure the integrity of the experiment.

5. Conclusions

The wrist joint is one of the more important joints on the human body. It connects the two parts of the arm and the palm and plays a vital role in the movement of the human hand. If the wrist joint is damaged; then, people's daily life will also be greatly affected, causing great inconvenience to people. Since the internal structure of the wrist joint in the human body is relatively complex, effective and rapid exercise rehabilitation is the focus of medical researchers.

This article conducts sports rehabilitation training on the wrist joints of basketball players and effectively combines nanofiber materials with sports rehabilitation training. By comparing the rehabilitation of athletes who did not use nanofiber materials, the role of nanofiber materials in sports rehabilitation was studied. Finally, the five-week experimental data of two athletes proved that the combination of nanofiber materials and sports rehabilitation can make the athlete's wrist joint rehabilitation faster and has a better rehabilitation effect than ordinary sports rehabilitation training.

With the improvement of the socio-economic level and the continuous popularization of health concepts, more and more people have increased their attention to physical health and often go to physical examinations to protect their health. Nanotechnology, also known as nanotechnology, is a technology for studying the properties and applications of materials with structural dimensions in the range of 1 nm to 100 nm. The rapid development of nanotechnology has provided an important guarantee for healthy physical examination and nursing methods. Therefore, it is necessary to conduct research on the development of health examination and nursing technology based on nanotechnology. Nursing safety means that nursing staff should strictly follow the nursing system and operation procedures in carrying out nursing work, execute medical orders accurately, and implement nursing plans to ensure that patients are physically and mentally safe during treatment and rehabilitation. Based on the development and research of health examination nursing technology under nanotechnology, 220 physical examinees in our hospital were selected and divided into experimental group and control group according to whether nanotechnology-based physical examination nursing method was applied, and then, the physical examination time, physical examination efficiency, and the coincidence degree of physical examination results were compared. The results showed that the physical examination time of the experimental group was 58.94 ± 31.40 min, while that of the control group was 73.74 ± 38.95 min; the difference between the two groups was 14.8 ± 7.55 min, with statistical significance ($P < 0.05$). Therefore, it can be seen that the development and research of health examination nursing technology based on nanotechnology can effectively improve the level of medical care service and the satisfaction of physical examinees.

1. Introduction

With the development and progress of human society, people pay more and more attention to health. People no longer feel satisfied with pure material life but pay more attention to how to improve their quality of life. Early treatment of disease and disease-free prevention has become the life philosophy that people pursue. Regular health checkups can help detect early signs of disease and prevent or delay the onset of disease. Therefore, annual inspections have become a health choice for more and more people.

Physical examination refers to the process of examining subjects through medical means and methods to understand the health status of subjects, early detection of diseases or health damage, and a comprehensive assessment of the health status [1]. The physical examination includes clinical items such as internal medicine, surgery, ophthalmology, otorhinolaryngology, anorectology, and gynecology routine. The purpose of the health check is to assess the health of people, screen for diseases and risk factors, and provide one-way preventive consultation and intervention measures to prevent the onset of diseases or aggravate existing diseases to achieve the purpose of prevention [2]. In other words, medical examinations are aimed at most subjects in society who have no subjective symptoms [3]. Compared with others, this emphasizes the initiative of the subjects and replaces mandatory physical examination with active physical examination. Health is one's own, health is dynamic, health is social, and health is proactive. Regular comprehensive health checkups are required to understand one's health

status, to adopt the best approach and intensity, to improve immunity and resistance to disease, and to detect health risk factors early.

Wider uses the cations released by the cation exchange reaction of nanocrystals to induce fluorescent dyes and detect trace amounts of biomolecules, with good results. This shows the great potential of using portable point-of-care testing equipment to detect biomarkers [4]. Harrison uses polyethylene glycol glucose gold nanoparticles (PEG-Glu-GNP) as the imaging probe for CT and PET scans. Mice injected with gold nanoparticles can be examined by high-resolution micro-CT, and the gray density and CT can be determined [5]. PET-CT is a perfect integration of the functions of the highest-grade PET scanner and advanced spiral CT equipment, which is mainly used clinically for the early detection and diagnosis of major diseases in the fields of tumor, brain, and heart. Farrar used reverse microemulsion technology to further prepare core-shell quantum dot fluorescent nanoparticles with amino and phosphate groups, thereby successfully identifying liver parenchymal cells [6]. van Houwelingen et al. pointed out that the specific distribution of superparamagnetic iron oxide magnetic nanoparticles in biological tissues can help improve the MRI contrast between tumors and normal tissues at that site. MRI, also known as magnetic resonance imaging, uses the magnetic resonance phenomenon to obtain electromagnetic signals from the human body and reconstruct information about the body. It can be applied to MRI to diagnose tumors and other diseases [7]. Murphy uses magnetic iron oxide particles as a carrier to immobilize protease A and uses its ability to specifically bind hepatitis B virus surface antigen antibodies to achieve the purpose of measuring hepatitis B virus [8]. The microfluidic biochip based on nickel oxide nanorods prepared by Ridley et al. can determine the total cholesterol concentration in human blood through electrochemical detection method [9]. Cholesterol is actually an important substance indispensable to human tissue cells. High-density cholesterol has a protective effect on blood vessels; if low-density cholesterol is high, the risk factor for coronary heart disease will increase.

Compared with the previous research on health examination and nursing technology literature, the innovative content of this article is roughly divided into the following points: The first point is the application of nanotechnology as the main aspect. The previous literature mostly introduces human factors such as physical examination and nursing. The second point is to clarify the huge effect of nanotechnology on health examination and nursing technology, because the literature has paid less attention to this in the past.

2. Theory of Health Checkup

Health checkups include medical examinations using medical methods and methods to understand people's health status and find clues to diseases and health risks early. Health checkup is a health-centered physical examination, which refers to the medical examination of the subject through medical means and methods to understand the health status of the subject and to detect disease clues and hidden health problems at an early stage. This includes special medical examinations required by the state, such as occupational medical examinations, medical examinations for practitioners, enrollment, enlistment, marriage registration, medical examinations provided by basic public health services, and new types of local cooperation examinations [10]. But it does not include people who use union medical funds or participate in new rural joint medical care.

Health check is a diagnosis and treatment measure [11]. Secondly, the quality of diagnosis and treatment is the core element of quality control in health examinations. Therefore, the core of medical examination quality control is the quality of supervision and treatment. The central determinant of the quality of diagnosis and treatment is the skill level of medical staff and the composition of related medical devices [12]. In general, the survival and development of a hospital depends on quality, which in turn depends on talents and management. Therefore, there is no doubt that the quality of diagnosis and treatment is an eternal topic in the quality control of health examinations.

There are still some misunderstandings about the health check in some areas, such as Japan, so the local people take the health check late [13]. In pursuit of economic benefits, they sacrificed the quality of diagnosis and treatment and ignored the quality of management. Health checks are becoming more and more important, but they have not attracted enough attention from managers. For example, some excellent managers do not want to go to the health check center for management work, and some do not want to go to the health check center of the health check center [14]. All these hinder the transition from medical experience management to scientific management. Health checks require internal, external, female, eyes, ears, nose, throat, oral cavity, ultrasound, radiology, and laboratory department checks. It can be said that the physical examination center is the epitome of outpatient clinics [15]. Its quality is closely related to people's health and life. Without a sound management system as a guarantee, the quality of the test is also questionable. Health management is a process of holistic management of health risk factors of an individual or a population. Its purpose is to mobilize individual and collective initiatives to effectively use limited resources to achieve maximum health outcomes. Good management quality can not only mobilize the enthusiasm, initiative, and creativity of medical staff but also promote healthy external competition among medical laboratories. At the same time, by continuously attracting outstanding medical staff to engage in health examination work, the professional development of health examination can be promoted.

Physical examination and medical services have some things in common and have their own characteristics. Health check is an action to pursue health and a process of obtaining comprehensive health information [16]. Candidates are usually healthy or unhealthy people who have higher requirements for service quality. Therefore, the quality control of a health examination organization is not only the professional level of medical personnel inspection and the performance of the equipment used in the diagnosis and treatment process but also the evaluation of the health

examination management system of the organization and the implementation of the processing technology platform. The level of service is reflected in the workflow. Due to the lack of advanced science and technology and effective management methods in the past, medical staff had to spend a lot of manpower and material resources to process various inspections and inspection reports, and their work efficiency was very low. Today, the rapid development of science and technology provides technical support for the computerization of medical examinations. The health check has realized the computerization of the health check by establishing the foundation of network technology and introducing information management software [17]. Many application results show that the introduction of information management software for physical examination work can not only improve work efficiency, reduce errors and accidents, and reduce the waiting time of subjects but also make the stored information an ideal for scientific research and optimization of decision-making management select. As shown in Figure 1, to do a good job of health examination and nursing should start from the following points.

Make good training and work arrangements for nursing staff. Reasonably arrange the working hours of nursing staff, conduct batch retraining, improve the quality and ability of nursing staff, and continuously improve their work ability. They are trained on emergency handling capabilities every month, and emergency plan training is conducted on emergency situations to improve the actual combat capabilities of nursing staff [9]. The head nurse organizes the work reasonably according to the nurse's skills and position and improves the reward system according to the level of completion of the nurses to encourage work. The chief nurse will arrange the positions of the nurses reasonably and ensure that there is a staff member for each position, depending on the number of daily inspections. In daily work, in order to ensure the smooth progress of the physical examination, two nurses are required at the front desk, and the nurses will carefully answer the questions of each enquirer with the patient to improve their satisfaction.

Make preparations for each link of the physical examination. Nursing staff should strengthen contact with the health department to avoid having multiple auditors in the long-term testing department, thereby extending the testing time. In one link, the nursing staff brings the medical examiner to the place and procedure of the examination to avoid delays caused by unfamiliar situations [18]. When telling the doctor to complete each examination, the corresponding doctor must sign on it to prevent leakage. In order to improve the efficiency of nursing work, improve compliance, and shorten the inspection time, the examination room of the medical center needs clear signs to guide the examinee to conduct various examinations. Not only that, but various physical examination procedures need to be improved to avoid emergencies such as blood fainting, needle fainting, and low blood sugar.

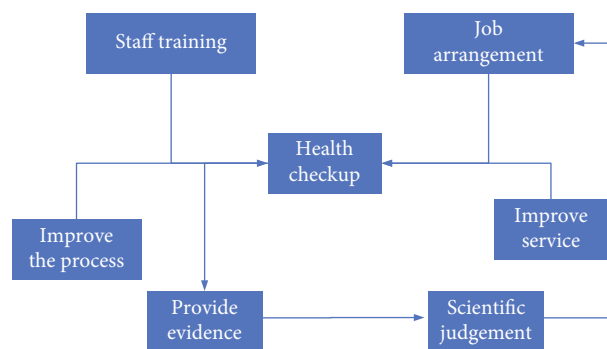
Improve service methods to ensure a quiet and comfortable environment in the examination room, and separate the examiners from patients with other diseases. Establish a reasonable and convenient path for medical examiners, install


FIGURE 1: Important criteria for health checkup.

all medical examination items on the same floor, and provide one-stop service for the entire medical examination to shorten the time for medical examiners to go up and down the stairs [19]. Paste the relevant knowledge flow chart of the interview on the stairs and walls to ensure that the inspected personnel complete all the exams in the shortest time. After the physical examination, assess the health of the examiner. If there is any problem, we will promptly notify the medical examiner and make appropriate arrangements for the medical examiner's follow-up visit or entry.

3. Application of Nanotechnology in Medicine

Nanotechnology is a high technology with a wide range of disciplines and interdisciplinary development developed in 1980 [20]. When the material reaches the nanometer size, its characteristics will change, thus showing special characteristics, such as small size effect, surface effect, quantum size effect, and macroscopic quantum tunneling. In recent years, bio-related nanobiotechnology has developed rapidly and has become a frontier and hot spot in the international biotechnology field. When nanobiology develops to a certain technology, nanobiological cells with recognition ability can be made from nanomaterials, and biomedicine that can absorb cancer cells can be injected into human body and can be used for targeted killing of cancer cells. It has broad application prospects and clear industrialization prospects in the field of medicine and health. Technologies such as nanomedical carriers, nanomedical materials, nanobiosensors and imaging technologies, and microsmart medical devices will lead to new developments in diagnosis and treatment methods.

Nanodiagnostic technology is the application of nanobiotechnology in molecular diagnosis, which is very important for the development of personalized therapy. At present, research on nanobiotechnology in clinical diagnosis mainly focuses on nanobiosensors and imaging technologies, manufacturing nanorobots at the cellular level for repair, biomarker extraction and measurement, and applications in other fields [21]. Nanodiagnostic technology aims at early diagnosis of diseases and improvement of treatment effects. The application of nanotechnology in health examinations is shown in Figure 2.

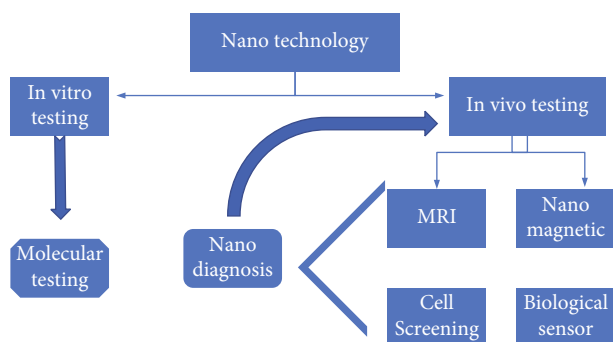
Nanotechnology is used in in vitro molecular detection projects. Nanobiomolecule detection methods can be used


Figure 2: Application of nanotechnology in physical examination.

for clinical diagnosis. Due to the very low content of the detected molecules, the detection sensitivity of this method is very high [22]. The unique properties of nanomaterials greatly improve the sensitivity and convenience of molecular detection. Various signal amplification methods for detecting ultrasmall biomolecules have been studied. A change in the properties of a particle caused by a sharp increase in the ratio of the number of surface atoms to the total number of atoms as the particle diameter becomes smaller. For example, at a particle diameter of 10 nm, the particle contains 4000 atoms and 40% of the surface atoms; at a particle diameter of 1 nm, the particle contains 30 atoms and 99% of the surface atoms. For example, the detection performance of cation exchange amplifiers based on ZnS nanoclusters is better than enzyme-linked immunosorbent assay (ELISA), with a detection limit of 1/1000.

Nanotechnology is also used in in vivo molecular detection projects. Gold nanoparticles are nontoxic and biocompatible nanomaterials. The synthesis method is simple, the particle size is controllable, the surface is chemically active, it is easy to modify or adsorb other substances, and it has unique photoelectric properties [23]. There are many researches on the application of gold nanoparticles in the field of biology. After the injection of gold nanoparticles, the mice were examined by high-resolution micro-CT to determine the gray density, and the attenuation value of particle excretion over time was determined by CT [24]. After injection of PEG-Glu-GNP, the outline of the tumor is easily distinguished from the surrounding tissues. This complex probe can diagnose diseases in the body early and help detect cancer or cancer metastasis early. In addition, the development of neurotransmitters in the body and participation in brain chemistry monitoring help us better understand the pathological and physiological effects of biomolecules. In this study, a new type of glass capillary encapsulated in gold nanoparticles is reported, which can sense dopamine in the brain. The results showed that Au/GCNE modified by perfluorosulfonic acid can be successfully used to monitor striatal dopamine in anesthetized rats. The high quantum dot is a core-shell nanobody with Cd Se as the core and Cd S or Zn S as the shell and has excellent spectral characteristics. Water-soluble quantum dots provide a very broad application prospect in research fields such as biochemistry. It has low cytotoxicity and can be used for ultrasensitive detection of living cells and nonisotopically

labeled biomolecules in vivo. The unique labeling characteristics of quantum dot technology will undoubtedly make it a leading technology for DNA detection (DNA chip), protein detection (protein chip), and the detection of biomolecules in protein-protein interactions. This provides a new method for the preparation of antigen and antibody and the principle of body-receptor (enzyme-substrate) reaction. At the same time, it will greatly promote the rapid development of bioimaging and biopharmaceutical technology, which will bring huge progress in the diagnosis and treatment of diseases.

The emergence of nanomaterials has completely changed the medical detection technology, making it one of the frontier areas of public concern. Nanodiagnosis is the use of the extremely high sensitivity of nanotechnology for early diagnosis of diseases [25]. The tools needed for nanodiagnostics include quantum dots, gold nanoparticles, and cantilevers, where quantum dots have high photostability. This requires the molecules being detected to interact with the nanoparticles to generate a strong signal to detect the sample. (1) Nanomaterials exhibit many excellent physical properties in biomedical imaging applications. In the field of nanoimaging, small superparamagnetic iron oxide nanoparticles coated with biomolecules provide anatomical details and help achieve real-time monitoring of treatment. Magnetic resonance imaging (MRI) to detect cancer is widely used as a contrast agent. Compared with traditional diagnostic methods, certain cancer cells can be detected earlier (months or years). Nanoimaging technology can also be used to detect residual or metastatic cancer cells after chemotherapy. (2) Since magnetic nanoparticles have the advantages of easy handling and large specific surface area, the application of functionalized magnetic nanoparticles is very attractive. Current magnetic separation research involves many aspects of the biological field, such as the removal of metal ions from the blood, the concentration of proteins and nucleic acids, and the recovery and repetition of immobilized enzymes. (3) When there is a small amount of cancer cells in the tissue or blood, they can be accurately detected by specific techniques, which can provide early diagnosis and treatment of patients and indeed provide patients with valuable treatment time and improve the cure rate [26]. Therefore, cell screening is very important. The immunomagnetic bead cell screening method can separate high-purity cells from complex cell mixtures within minutes. Nanotechnology can improve accuracy by enhancing or even completely transforming the screening of biomarkers in tissues and body fluids. (4) Nanobiosensors in the field of cancer research and sensors based on nanotechnology are expected to achieve early diagnosis of various cancers. The sensitivity of the nanosensor is very high. During blood testing, when a specific cancer cell antibody preset in the sensor encounters the corresponding antigen, the sensor current will change, and the change in the current can identify cancer cells in the blood, type, and concentration. At present, more and more venture capital invested in this field, but this technology still has technical problems that need to be solved in practical applications. In the future, various nanosensors will be integrated and placed in the human body to allow early detection of various diseases.

4. Experiments on Health Examination and Nursing

4.1. Experiment Preparation

4.1.1. Subject.
There was a selection of 220 medical examiners in our hospital from March 2018 to March 2019, of which 116 were males and 104 were females. The age ranged from 18 to 65 years old, with an average of 33.67 ± 5.73 years old. A total of 60 medical staff, 18 doctors, 4 chief nurses (senior nurses), 11 intermediate, 10 junior, and 17 nurses participated in the medical examination center. For inclusion criteria, all subjects underwent physical examinations and signed all informed consent forms. For exclusion criteria, there are serious communication problems. The conditions of the experimental subjects are shown in Table 1.

4.1.2. Experimental Group.
Magnetic nanoparticles with a particle size of less than 20 nm usually exhibit superparamagnetic and can be widely used in clinical diagnosis. At present, the more mature and rapidly developing application in clinical diagnosis is mainly magnetic resonance imaging. Therefore, magnetic resonance imaging of nanomaterials was used as the standard to distinguish the experimental group from the control group. The experimental group will use MRI technology applied with magnetic nanoparticles, and the control group will use traditional imaging technology for physical examination. 110 people per group, the ratio of male to female in each group is 58 : 52.

The porous $Fe_3O_4@SiO_2$ nanoparticles have uniform morphology, ordered pore size distribution, and good acid response. At the same time, the nanocarrier has excellent biocompatibility, strong antipain drug loading capacity, and excellent nutrition-guided fan orientation. In addition, the relaxation rate of $Fe_3O_4@SiO_2$ nanoparticles in an acidic environment is significantly improved, which provides a more direct method for detecting cancer tissues by magnetic resonance imaging. Therefore, $Fe_3O_4@SiO_2$ nanoparticles can target and deliver therapeutic agents loaded into tissues in the body and monitor the therapeutic changes in the tissues in real time through magnetic resonance imaging.

4.1.3. Preparation of $Fe_3O_4@SiO_2$ Core-Shell Nanoparticles.
According to the classic hydrolysis method, the core-shell structured silica-coated Fe_3O_4 nanospheres were synthesized. A specific method is to uniformly disperse 0.1 g of synthetic Fe3O4 nanospheres in a mixed solution of 140 ml of ethanol and 20 ml of distilled water to form a colloidal solution and then add 2 ml of concentrated ammonia to the solution. Stir mechanically for 10 minutes. Then, a mixed solution of 1.5 ml TEOS and 10 ml ethanol was gradually added to the colloidal solution, stirred at room temperature for 30 hours, collected with a magnet, washed several times with ethanol and distilled water, and dried in vacuum.

Disperse 0.1 g of the synthesized core-shell $Fe_3O_4@SiO_2$ nanoparticles uniformly in distilled water, add 10 g 8 g/L NaBH4 ice water solution, and pour the mixed solution into the PTFE hydrothermal reaction solution and heat it at 80°C. The reaction was kept at °C for 12 hours. Finally, the product

was collected on a magnet; washed 3 times with propanol, ethanol, and water; and dried in a vacuum drying oven at 30°C overnight. Add $Fe_3O_4@SiO_2$ as a contrast agent to the magnetic resonance device.

4.1.4. Experimental Instruments and Reagents.
The experimental instruments and reagents are as follows: automatic blood analyzer, EDTA-K2 vacuum anticoagulation tube, automatic urine analyzer, magnetic resonance meter, electrocardiograph, and CT detector.

4.2. Experiment Content.
Before the experiment, fully understand the needs of examinees, solicit opinions from relevant experts, and strive to meet the needs of medical examiners at all levels, and refer to literature. It is necessary to combine the characteristics of the physical examination center and the characteristics of the examinee to establish a physical examination path diagram to learn and understand the meaning and standards of the clinical nursing path.

Use the nursing service satisfaction questionnaire and various nursing quality work questionnaires compiled by our hospital to collect statistics on the health examination and nursing work quality scores. Develop complete rules and regulations based on different scores. Health check contents are as follows: internal medicine, surgery, otolaryngology, oral cavity, 5 items of hepatitis B, blood test, urine test, electrocardiogram, chest X-ray, thyroid B ultrasound, prostate B ultrasound (male), uterus, and appendix B if necessary. Endoscopy will be performed, such as ultrasound (for women), B-ultrasound of the liver and pancreas, and CT. Coordinate the reasonable examination sequence and scientific physical examination process of each group of medical examiners, and ensure that every link in the physical examination path can operate normally. Each physical checkpoint has one or two full-time staff to provide nursing services.

4.2.1. Routine Blood Test.
Both groups of patients were collected at 9 o'clock in the morning. The experiment used venous blood collection. The patient's cubital vein was selected as the venous blood collection site. After cleaning and disinfecting the skin, the disposable blood collection needle was connected to a vacuum anticoagulant. Collect the blood in a test tube with a blood volume of 5-8 ml. After the blood is collected, add a diluent to the anticoagulation tube to dilute the sample, and shake it gently to mix well. The control group adopted the peripheral blood sampling method. The left hand of the patient was selected, the skin of the index finger was cleaned and disinfected, and then, the blood was collected with a disposable lancet and placed in an anticoagulation tube. After the blood samples of the two groups were shaken well, the blood analyzer was used for routine blood tests. All samples are tested within 2 hours after blood collection. Strictly follow the operating

TABLE 1: Basic situation of experimental subjects.

Number	Age	Sex ratio	Number of medical staff
220	33.67 ± 5.73	116 : 104	60

TABLE 2: Health physical examination and nursing service level.

Group	Knowledge propaganda	Care etiquette	Communication skills
Control group	8.46 ± 0.87	9.56 ± 0.69	8.02 ± 0.35
Trial group	8.51 ± 0.76	9.64 ± 0.74	7.97 ± 0.28

procedures of the automatic blood analyzer, and perform regular maintenance and quality control on the instrument before use. Strictly follow the instructions of the kit to keep the equipment stable and check and maintain blood cells to ensure stable operation of the equipment. Under the condition of continuous operation for 24 hours, the instrument is automatically cleaned and calibrated according to the program, and the values of various parameters are controlled within the normal measurement range.

4.2.2. Urine Routine. All women need to clean their vulva and collect specimens. After the specimens are sent to the laboratory, they are inoculated with fully mixed urine in a 35°C incubator using a 1 μL loop and cultured for 18-24 days to colonize colonies. Liquid forming element analysis can quantitatively calculate white blood cells and bacteria. After mixing the urine sample, use an automatic urine forming element analyzer to detect the number of bacteria and white blood cells in the urine, and report it in "units/μL."

4.2.3. Evaluation Criteria. After the physical examination is completed, a statistical score will be made on the length of the physical examination, the efficiency of the physical examination, the reliability of the physical examination, the satisfaction of the medical examiner, and the degree of interest in statistical treatment. Use t-test and $\chi 2$ test, and use the SPSS 10.0 software package to process and analyze all data. The inspection level is $\alpha = 0.05$.

5. Results of Health Checkup Care

5.1. The Development and Research Effect Comparison of Health Examination and Nursing Technology Based on Nanotechnology. The core of high-quality services is to provide customers with safe, high-quality, efficient, and satisfactory nursing services and to integrate the "patient-centered" nursing service concept into physical examination. High-quality service is an inevitable product of the development of the times and social progress. Innovating the physical examination path model and creating a standardized physical examination path are specific signs of improving quality services. With the implementation of the physical examination certificate, the nursing staff of the physical examination center must be enthusiastic about their work, have a good service attitude to the candidates, and have good nursing skills. "From passive service to active service, from active service" service concept "to touching service" provides all nursing staff with beautiful, more common problems, more information, and more detailed services. As shown in Table 2, there is basically no difference in the level of health examination and nursing service of different groups.

As shown in Table 2, the health knowledge preaching score of the nursing staff in the control group was 8.46 ± 0.87 points, and the nursing etiquette and communication skills were 9.56 ± 0.69 and 8.02 ± 0.35 points, respectively. The scores of health knowledge presentation, nursing etiquette, and communication ability of the experimental group were 8.51 ± 0.76, 9.64 ± 0.74, and 7.97 ± 0.28 points, respectively. In general, the two sets of data are not statistically significant.

Nanobiotechnology has great development potential. It can be used as a more sensitive and rapid response clinical diagnostic reagent, providing a valuable basis for the advancement of disease prevention and treatment. Taking into account the heterogeneity between patients, personalized medicine combining nanoclinical medicine and molecular biomarkers can ensure excellent efficacy and safety. Therefore, health checkup and nursing technology based on nanotechnology can effectively reduce checkup time and improve checkup efficiency.

As shown in Figure 3, after applying the health checkup and nursing technology under nanotechnology, the time of the physical examination of the experimental group was significantly reduced. The time of the physical examination of the experimental group was 58.94 ± 31.40 min, and that of the control group was 73.74 ± 38.95 min; the difference between the two is 14.8 ± 7.55 min, and the two groups of data are statistically significant ($P < 0.05$). The physical examination efficiency score of the experimental group physical examination subjects was 8.72 ± 0.68 points, and the physical examination time of the control group physical examination subjects was 7.29 ± 1.23 points. It is obvious that the health examination and nursing technology based on nanotechnology are more mature, saving a lot of time in the physical examination.

The detection accuracy of physical examination items is also an important criterion for measuring health examination and nursing technology. Therefore, the credibility scores on the physical examination items are compared to determine which group has the higher accuracy of the physical examination. Comparing the experimental group using nanotechnology health examination and nursing technology with the control group, the data is statistically significant, $P < 0.05$.

As shown in Figure 4, the reliability scores on the physical examination items of the experimental group using nanotechnology health examination and nursing technology are distributed in the range of 6.57-8.69. In contrast to the control group, the reliability scores on the physical examination items are distributed at 5.28—within the 6.85 interval. This also shows that due to the application of nanotechnology, the experimental group has significantly improved the health examination and nursing technology and can have a very clear judgment on the health of the examinee. At this point, the health examination and nursing technology of nanotechnology have been applied. The experimental group has a very big advantage.

5.2. Analysis on the Satisfaction of Medical Examiners Based on the Health Examination and Nursing Technology Based on Nanotechnology. During the physical examination, the
FIGURE 3: Comparison of physical examination results between the two groups.

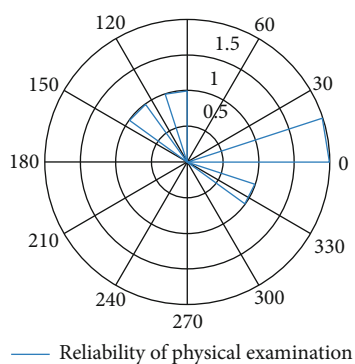
FIGURE 5: Comparison of satisfaction values between the two groups.


FIGURE 4: Comparison of physical examination reliability scores.
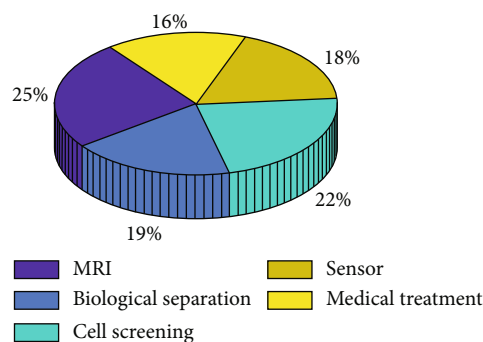

FIGURE 6: Classification of nanotechnology in health checkup.

nursing staff will actively communicate with the patient and their family members according to the patient's psychological endurance and understanding ability and explain the current medical technology used to treat and treat the disease. Nursing staff should conduct some tests on patients who may have depression and then provide counseling and psychological counseling to them to reduce the psychological pressure of patients and seek to win their trust in order to establish a good nurse-patient relationship. While carrying out necessary communication, compare the medical examination satisfaction of the two groups of examinees to observe whether the application of nanotechnology can be favored by the examinees.

As shown in Figure 5, the satisfaction value of the experimental group continues to rise with the increase in the number of people undergoing physical examinations, from the initial 87.67% to the final 88.97%. In the control group, the satisfaction value fluctuates greatly. This shows that the experimental group based on nanotechnology-based health examination and nursing technology has achieved more satisfaction with the examinees by virtue of less examination time and accurate examination results. In contrast, the control group experienced fluctuations in satisfaction, and the high probability was related to its poor physical examination experience.

Nanotechnology-based physical examination and nursing technology not only provide advanced clinical diagnostic methods, such as magnetic resonance imaging during physical examination, bioisolation, and cell screening, but also provide the convenience provided by nanorelease drugs and nanobiosensors. Therefore, the position of nanotechnology in health examination and nursing is very important. In order to see the specific application of nanotechnology in health examination and nursing more intuitively, it is expressed as a percentage.

As shown in Figure 6, the main application of nanotechnology in health checkup care is magnetic resonance imaging (MRI), which accounts for 22%. The special properties of nanoparticles make them an excellent contrast agent, which can make the imaging clearer and more intuitive, so as to understand the internal structure of the examinee more clearly, and achieve the purpose of protecting health.

6. Conclusions

(1) The research background of this article is that with the improvement of socio-economic level and the continuous popularization of health concepts, more and more people have increased their attention to physical health and often participate in physical

examinations to protect their health. The rapid development of nanotechnology has provided an important guarantee for healthy physical examination and nursing. Nanotechnology plays an important role in health examination and nursing. Therefore, it is necessary to conduct research on the development of health examination and nursing technology based on nanotechnology

(2) The purpose of this article is to start with the development and research of health examination and nursing technology under nanotechnology. 220 physical examination patients in our hospital are selected and divided into experimental group and control group according to whether the physical examination and nursing method under nanotechnology is applied. The experimental group prepares Fe3O4@SiO2 core-shell nanoparticles as the MRI contrast agent for detection. The control group does not use it by default. Data statistics are made on the physical examination time, physical examination efficiency, and physical examination results, and then, the physical examination time, physical examination efficiency, and physical examination results coincide with each other

(3) The experimental data shows that after applying the health checkup nursing technology under nanotechnology, the checkup time of the experimental group's checkups is significantly reduced, the checkup time of the checkups in the experimental group is 58.94 ± 31.40 min, and the checkup time of the checkups in the control group is 73.74 ± 38.95 min; the difference between the two is 14.8 ± 7.55 min, and the two groups of data are statistically significant ($P < 0.05$). The physical examination efficiency score of the experimental group was 8.72 ± 0.68 points, and the physical examination time of the control group was 7.29 ± 1.23 points. This clearly shows that the health examination and nursing technology based on nanotechnology are more mature, saving a lot of time in the physical examination

With the popularization of oral health knowledge, people have gradually realized the importance of orthodontic treatment in oral health, so the number of patients undergoing orthodontic treatment has increased significantly. To improve the effect of orthodontic treatment, this article mainly studied the application of adhesives loaded with amorphous nanocalcium phosphate in the prevention of enamel demineralization in orthodontic patients. In the experiment, we used spray-drying technology to synthesize NACP. The collected dry particles were dispersed with absolute ethanol, sonicated for 10 minutes, dropped on a 200 ordinary carbon support film, and then dried and observed with a transmission electron microscope (TEM). Prevention of enamel demineralization in orthodontic patients was by adhesive-loaded amorphous nanocalcium phosphate. In this experiment, the membrane dialysis method was used to release the drug-loaded nanoparticles. The MH-5 microhardness tester was used to randomly select 3 positions on the buccal area of the enamel surface to measure the microhardness. After measuring the microhardness of each point, take the average of the readings of the 3 positions. Before and after the experiment, the difference of the enamel surface microhardness before and after the experiment was statistically analyzed. Before the scanning electron microscope observation, to avoid contamination of the window area of the enamel surface, which will cause interference with the scanning electron microscope observation, we use acetone to remove the acid-resistant nail polish coated on the enamel surface. Clean the attachments on the surface of the teeth first, then fix, dehydrate, and dry. When the release time reaches 52 h, the cumulative release rates of Cur in pH 5.4 and pH 7.4 buffers are 85.84 and 64.68%, respectively. The results show that by adjusting the concentration of PAA, it is possible to configure a mineralized liquid that can not only use the fluidity of NACP to penetrate into the collagen fibers but also transform into HAP within a suitable time, to achieve the purpose of repairing demineralized dentin.

1. Introduction

In recent years, inorganic nanoparticles have attracted much attention due to their unique materials and size dependence. In addition to its good stability, easy control of morphology, and size, it also has optical, magnetic, and other physical properties and has a wide range of applications in drug delivery and tumor imaging. The chemotherapeutic drugs are loaded on the surface and pore structure of inorganic nanoparticles through physical, chemical action, or surface functional groups, and the drugs are transported into the organism through the cell membrane to achieve the therapeutic effect. Calcium phos-

phate is a typical inorganic nanoparticle, which has good biocompatibility and will not cause rejection in the organism, so it has obvious advantages in drug delivery, bioceramics, and bone repair. In organisms, ACP has better osteoconductivity and biodegradability than HAP and TCP, and some of its properties can be adjusted by changing its components. Amorphous calcium phosphate (ACP) is a general term for short-range ordered and long-range disordered calcium phosphates. ACP can be classified as having a variable chemical composition (the Ca/P ratio can vary from 1.0 to 2.0), a class of calcium phosphate salts with similar chemical properties to glass. ACP is an amorphous intermediate phase of calcium

phosphate found during the synthesis of hydroxyapatite (HAP) under neutral or acidic conditions, so X-ray diffraction analysis shows amorphous features.

Among calcium phosphate materials, ACP exhibits better osteoconductivity and biodegradability and has been widely used in the demineralization and remineralization of tooth enamel, bone defect treatment, and drug carriers. However, ACP is a metastable phase, it is very easy to transform into a crystal form, and it has poor dispersion in solution and is easy to agglomerate, which seriously affects the application of ACP in organisms. CPP-ACR (casein phosphopolypeptide-amorphous calcium phosphate) can effectively prevent enamel demineralization and promote the remineralization of enamel demineralization that has occurred.

Jiang et al. prepared stable nanoamorphous calcium phosphate (NACP) with polyethylene glycol as a stabilizer to obtain nanosized amorphous adsorbents [1]. Feng et al. explored the effect of a novel bioabsorbable stent composed of PLLA and ACP nanoparticles on inflammation and calcification of surrounding tissue after stent implantation in porcine coronary arteries [2]. Zhang et al. performed 20 cycles of hypophosphite adsorption-desorption on the polymer-supported ferric iron nanocomposite HFO@201 [3].

When fluoride is used alone, remineralization mainly occurs on the surface of tooth enamel caries. Once fluoride ions contact calcium and phosphorus ions, fluorapatite will quickly form on the surface of the tooth, preventing mineral ions from continuing to enter the caries. The deep layer hinders the remineralization of the deep layer. When CPP and fluoride ions exist at the same time, the entire layer of enamel caries can be remineralized. CPP can prevent the rapid transformation of calcium phosphate stage, and the mineral components can diffuse in the form of ions. Below the surface of the carious lesion, an active gradient is formed, which promotes remineralization throughout the entire layer of enamel carious lesions. This in vitro remineralization model after enamel acid etching strongly illustrates that lysozyme can stabilize a higher concentration of calcium and phosphorus ions into an amorphous state. Under the degradation of sodium hypochlorite and the induction of glycine, it can promote the remineralization of early enamel caries.

2. Method and Experiment

2.1. Experimental Equipment and Materials.

The main instruments are incubator, microhardness tester, laboratory PH meter, bt25s electronic scale, anaerobic culture tank, 61MXW-80A vortex oscillator, GSP-9050MBE constant temperature water-proof incubator, complete automatic biochemical analyzer, scanning electron microscope, energy spectrum analyzer, etc. [4].

The main materials used in the experiment are dipotassium hydrogen phosphate, calcium chloride dihydrate, 4-hydroxyethylpiperazine, ethanesulfonic acid, 1% sodium hypochlorite rinse, 37% phosphoric acid gel, etc. [5].

2.2. Subjects.

100 patients were randomly selected from the fixed orthodontic patients, 50 males and 50 males, aged between 12 and 16 years old, with permanent teeth. All patients were treated with the standard square wire arch technique, and the average treatment period was 20 months, which was set as the observation group. The control group consisted of a random selection of 200 normal people aged 12-16 years without fixed correction, 100 men and women each.

Inclusion criteria. The experimental group had normal tooth morphology, well-developed enamel, and no hard tissue diseases such as enamel demineralization, fluorosis, and tetracycline. The control group was those with normal tooth morphology, no enamel development defects, and no enamel demineralization.

Exclusion criteria. The experimental group was unable to follow up on time and adhere to treatment, and the control group were tetracycline teeth, fluorosis teeth, and other enamel development defects [6].

2.3. Synthesis of Nanometer Amorphous Calcium Phosphate (NACP).

Spray-drying technology was used to synthesize NACP. 1.5125 g anhydrous acetic acid was added to 500 mL distilled water to prepare a spray solution. Then, 0.8 g calcium carbonate ($CaCO_3$) and 5.094 g anhydrous calcium hydrogen phosphate ($CaHPO_4$) were dissolved in acetic acid solution. Add distilled water to the solution until the total volume of the solution reaches 1 L. The concentration of acetic acid is 25 mmol/L. The solution is sprayed by a nozzle located in a spray chamber with hot air flow at 10 mL/min feed rate. The collected dry particles were dispersed with absolute ethanol, vibrated with ultrasonic for 10 minutes, dropped on a 200 ordinary carbon support films, and observed by transmission electron microscope (TEM) after drying. The powder specific bet (Brunauer-Emmet-Teller) specific surface area was analyzed using a physical/chemical adsorption analyzer [7]. The preparation of NACP nanoparticles is shown in Figure 1.

Amorphous calcium phosphate (ACP) is generally considered a transition phase in the formation of calcium phosphate in aqueous environments. Generally speaking, ACP may be the first phase in the precipitation and crystallization process of calcium phosphate solution, which can be obtained by the rapid mixing of calcium and phosphorus solutions. The chemical composition of ACP is not fixed and is often related to the calcium and phosphorus concentrations and pH values in the reaction solution. As for the structure of the ACP, there is no clear conclusion so far. The IR spectrum of ACP shows a broad absorption peak for phosphate radicals. XRD results show that the compound is amorphous Through electron microscopy, it can be observed that ACPs are generally round spheres with diameters between 20 and 200 nm. ACP appears to have the short-range structure of apatite, but due to the very small size of the crystals, it shows an amorphous phase on the XRD pattern. This conclusion has been confirmed by X-ray absorption spectroscopy.

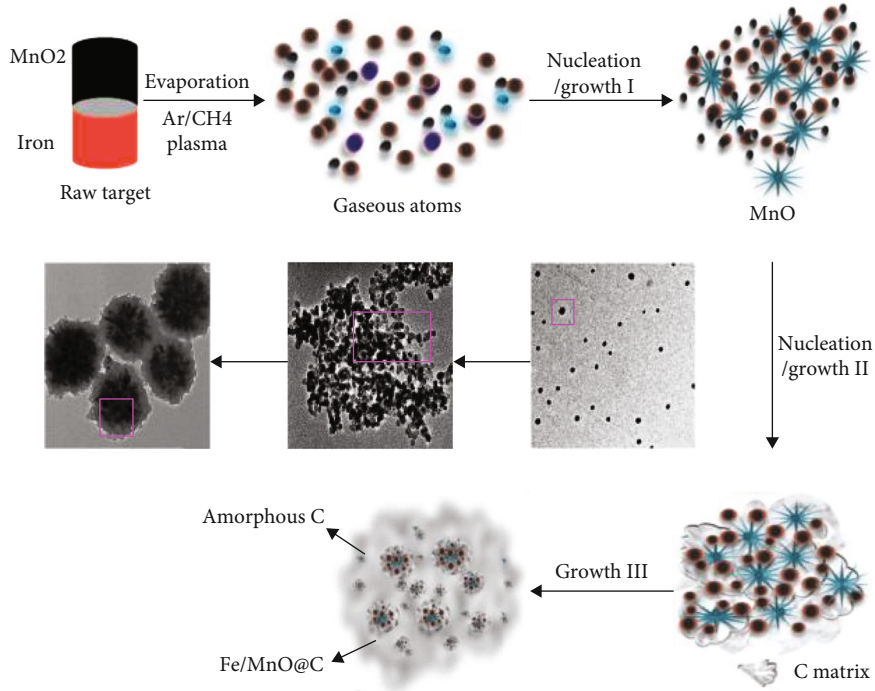
Sodium cyclopentadienyl is a colorless solid, but the sample will appear pink due to oxidation. Solutions of sodium cyclopentadienyl in THF are commercially available. It can be prepared by treating cyclopentadiene with sodium. The reaction is usually carried out by heating sodium to a molten state in dicyclopentadiene. Previously common practice was to use "sodium wire" or "sodium sand," which was obtained


FIGURE 1: Preparation of NACP nanoparticles.

in the form of fine dispersion by melting and refluxing sodium in xylene with rapid stirring.

Define a binary comparison criterion [8]:

$$\tau(p\,;x,y) = \begin{cases} 1, & p(x) < p(y), \\ 0, & p(x) \geq p(y). \end{cases} \quad (1)$$

The formula is as follows [9]:

$$Z = \iint_w g(X)g^T(X)dX,$$

$$G(i,j) = \sqrt{G_x^2(i,j) + G_y^2(i,j)}, \quad (2)$$

$$\theta(i,j) = \text{arc}\left(\frac{G_x(i,j)}{G_y(i,j)}\right).$$

When the image is blurred and the noise is small, the working state of the gradient operator is a satisfactory continuous image $f(x,y)$, and the position gradient (x,y) can be expressed as a carrier [10]. If G_x and G_y are used to represent the gradient change of $f(x,y)$ along the X and Y directions, the gradient vector can be expressed as follows [11]:

$$f(x,y) = \begin{bmatrix} \dfrac{\partial f(x,y)}{\partial x} \\[2mm] \dfrac{\partial f(x,y)}{\partial y} \end{bmatrix}. \quad (3)$$

A transformation method based on the tangent function is as follows [12]:

$$D_o = \frac{D_M}{2}\left[1 + \frac{\tan\left(\alpha\pi(x/D_M - 1/2)\right)}{\tan\left(\alpha\pi/2\right)}\right]. \quad (4)$$

The specific steps of the BP neural network algorithm are as follows: each connection has a weight. If the j-node is in the exit layer or the hidden layer [12], the net input to the j-node E_j is as follows:

$$E_j = \sum_i w_{ij}S_i + \theta_j. \quad (5)$$

Given the net input E_j of node j, the output of S_j of node j is as follows [13]:

$$S_j = \frac{1}{\left(1 + e^{-I_j}\right)}. \quad (6)$$

As the burden and bias representing the prediction error of the network are continuously updated, the error propagates backwards [14]. For the node of the output layer j, the error Err_j calculation formula is as follows:

$$\text{Err}_j = S_j\left(1 - S_j\right)\left(G_j - S_j\right). \quad (7)$$

Computing the error of j nodes on the hidden layer requires a weighted sum of j-related node errors on the next layer [15]. The error of the hidden layer of the j node is as follows:

$$\text{Err}_j = S_j\left(1 - S_j\right)\sum_k \text{Err}_k w_{kj}. \quad (8)$$

w_{jk} is the connection weight from node k to node j in the next higher layer [16], and Err_k then is the error of node k.

The propagated errors are reflected by updating the weights and biases [17, 18]. The formula for weight update is as follows, where Δw_{ij} is w_{ij} the weight change amount.

$$\Delta w_{ij} = (1)\mathrm{Err}_j S_i,$$
$$w_{ij} = w_{ij} + \Delta w_{ij}. \tag{9}$$

The offset is updated by the following equation, where $\Delta \theta_j$ is θ_j the offset change.

$$\Delta \theta_j = (1)\mathrm{Err}_j,$$
$$\theta_j = \theta_j + \Delta \theta_j. \tag{10}$$

2.4. In Vitro Drug Release. In this experiment, membrane dialysis was used to release the drug-loaded nanoparticles. First, put 5 mL Cur-ACP nanoparticles (2 mg/mL) in a pretreated dialysis bag with a molecular weight cut-off of 34 kDa, immerse the dialysis bag in a 100 mL beaker (protect from light), and place the beaker in a shaker (37°C, 70 rpm) [19, 20]. The in vitro drug release process is shown in Figure 2.

2.5. Antioxidant In Vitro. In this determination, 1 mL of samples with various concentrations (2, 4, 6, 8, and 10 μg/mL) was mixed with 2 mL of 0.1 mM DPPH solution [21]. After that, the mixed solution was kept at room temperature and protected from light for 30 minutes [22].

$$\mathrm{Inhibition}(\%) = \frac{A_0 - A_1}{A_0} \times 100\%. \tag{11}$$

Among them, A_0 is the absorbance of the control group, and A_1 is the absorbance of the sample.

2.6. Preparation of New Antibacterial Remineralization Functional Orthodontic Adhesive. As shown in Table 1, the first new type of orthodontic adhesive was prepared by adding 5% by mass of MAE-DB to PEHB resin. MAE-DB and NACP with mass ratios of 5% and 40% were added to PEHB to prepare the second new type of orthodontic adhesive, referred to as PND. Adding more than 40% of NACP to the resin will affect the adhesive properties and mechanical properties of the resin, so the addition concentration of 40% is selected. The whole preparation process is carried out in a dark room, and the resin mixture is mixed evenly with a mixing knife, and the air bubbles are removed by vacuum. The adhesive is prepared within 0.5 h before each use, and the unused ones are discarded after the test and no longer used [23, 24].

Take 0.5 g of mussel shell powder in a 100 mL beaker, add 40 mL of propionic acid with a concentration of 5% to make it fully react, take the supernatant after centrifugation, dilute the obtained solution to 50 mL, and then dilute the concentration to 0.06 M 50 mL of phosphoric acid solution was added dropwise to the beaker. After the dropping was

completed, 0.6 mmol of sodium tripolyphosphate was added to the beaker. After 30 min of reaction, 6 g of urea was added. After stirring to fully dissolve the urea, the beaker was placed at 90°C. In a water bath, it was stirred for 3 min and then allowed to stand until precipitation appeared. The precipitate was centrifuged, washed twice with deionized water and twice with ethanol, and dried at 70°C for 24 h to obtain ACP white powder.

2.7. Testing of Mechanical Properties of New Orthodontic Adhesives. Transbond XT paste (TB), a commonly used orthodontic adhesive in clinical practice, was selected as a commercial control, and three adhesives (TB, PD, and PND) were used to make test pieces with a size of 25 mm × 2 mm × 2 mm. The surface was cured with LED light curing lamp (output light intensity is 1200 mW/cm^2) for 60 s. After fully curing, the specimen was placed in a constant temperature water bath at 37°C for 24 h. Each group has 5 test pieces. A three-point bending test was carried out on a computer-controlled universal testing machine with a span of 20 mm and a pressing speed of 1 mm/min, to test the flexural strength and elastic modulus of the material. The flexural strength is calculated by the following formula [25]:

$$S = 3P_{\max} \frac{L}{(2bh^2)}. \tag{12}$$

Among them, $P_{\max}$ is the breaking load, L is the span, b is the width of the specimen, and h is the height of the specimen.

The modulus of elasticity is calculated by the following formula:

$$E = \left(\frac{P}{d}\right)\left[\frac{L^3}{(4bh^3)}\right]. \tag{13}$$

The load P divided by the displacement d is the slope of the load-displacement curve in the linear elastic region [26].

2.8. Microhardness Measurement. In this experiment, the MH-5 microhardness instrument was used to randomly select 3 positions on the buccal test area of the enamel surface to measure the microhardness. After measuring the microhardness of each point, the average of the readings of the 3 positions was taken. Use this method to calculate the final surface microhardness value of the tooth enamel. Nanohardness and elastic modulus are measured by a nanoindenter. The test uses a continuous hardness measurement method. The depth of pressure is 600 nm. The calculation formula of hardness and elastic modulus is as follows:

$$S = \beta\sqrt{\lambda} E_r h,$$
$$\frac{1}{E_r} = \frac{(1 - v_i^2)}{E_i} + \frac{(1 - v_s^2)}{E_s}. \tag{14}$$

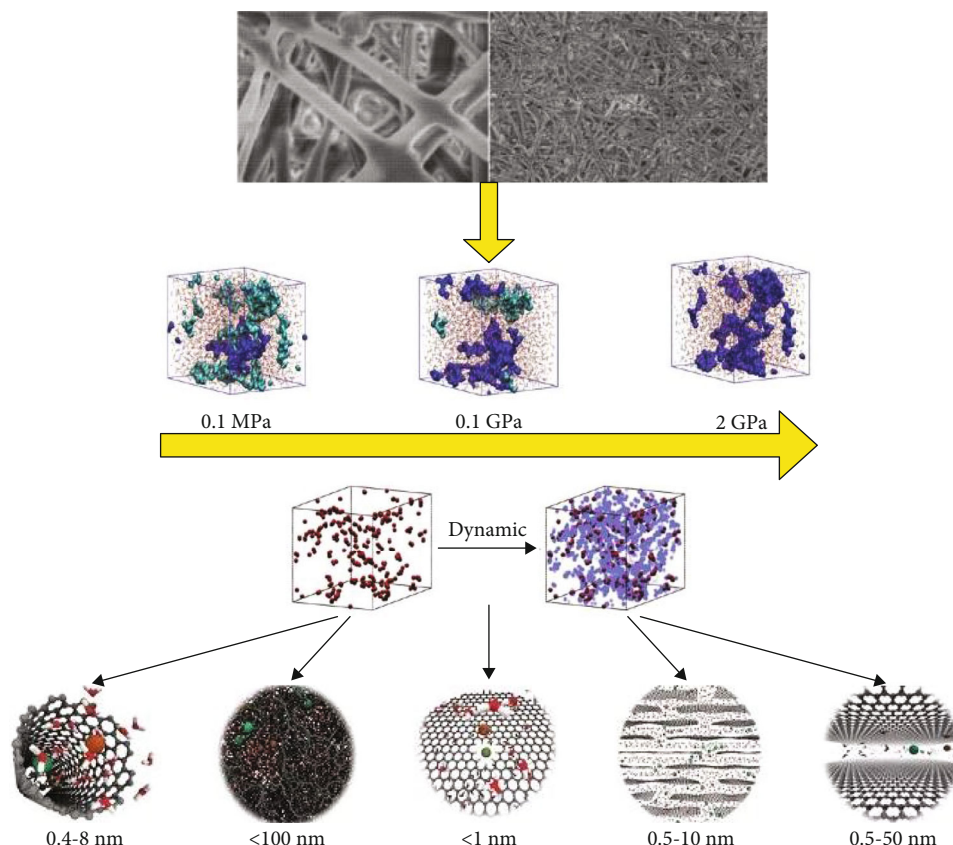
In the formula, S represents the contact hardness, h represents the depth of pressure measurement, E_r is the reduced


FIGURE 2: In vitro drug release process.

Glue	PEHB	MAE-DB	NACP
PD	95	5	0
PND	55	5	40

Young's modulus, and E_i and E_s are determined by the Young's modulus of the probe and the sample.

2.9. Scanning Electron Microscope Surface Observation. In this experiment, two samples were drawn from each group according to the random number table for scanning electron microscopy (JEOLJSM-6390LV) observation in the window area of the tongue and palate. Before the scanning electron microscope observation, to avoid contamination of the window area of the enamel surface, which will cause interference with the scanning electron microscope observation, we use acetone to remove the acid-resistant nail polish coated on the enamel surface. Clean the attachments on the surface of the teeth first, then fix, dehydrate, and dry. Because the surface of the tooth is not charged, its electrical conductivity is also relatively poor, so the charging effect and discharge effect will be caused when observing with a scanning electron microscope, which will affect the observation of the image of the enamel surface. Therefore, it is necessary to check

the sample before observing the sample. The surface of the sample is sprayed with gold to increase the conductivity of the test surface of the sample. Finally, the samples are placed to the sample stage according to the original grouping order. When observing the image for collection, each experimental group can be distinguished according to the quadrant.

2.10. Statistical Analysis. All data were entered into the computer through EXCEL, and single-factor analysis was used to compare whether the enamel surface roughness values and microhardness values of each group were statistically different. The test standard was $P = 0.05$. The statistical results are completed by the SPSS13.0 statistical software.

3. Results

The comparative analysis of the labial surface pH of the upper and lower anterior teeth is shown in Figure 3. The results showed that no matter which group of patients, the pH was lower than that of the mandibular teeth, and the difference was statistically significant ($P < 0.05$).

Table 2 shows the comparison of the teeth between the anterior teeth of the same name. Table 3 shows the comparison of the labial pH of the teeth between the anterior teeth of the same name. It can be seen from the results that no matter the upper and lower jaws, there is no statistically significant difference in pH ($P > 0.05$).
FIGURE 3: Comparative analysis of the labial pH of the upper and lower anterior teeth.

TABLE 2: Comparison of the labial pH between the left and right sides of the upper jaw with the same name anterior teeth.

Tooth	Left	Right	t	P
I1	6.64 ± 0.22	6.71 ± 0.15	1.92	>0.05
I2	6.40 ± 0.12	6.46 ± 0.20	1.37	>0.05
C	6.89 ± 0.18	6.91 ± 0.17	0.94	>0.05

TABLE 3: Comparison of pH between the anterior teeth of the same name on the left and right sides of the mandible.

Tooth	Left	Right	t	P
I1	7.29 ± 0.28	7.34 ± 0.21	1.29	>0.05
I2	7.33 ± 0.23	7.30 ± 0.14	0.87	>0.05
C	7.07 ± 0.16	7.10 ± 0.26	0.73	>0.05

Calcium phosphate remineralization method contributes to the prevention of enamel leukoplakia lesions and promotes remineralization of demineralized enamel. Dental resin materials containing calcium phosphate can release calcium and phosphorus ions, which become calcium and phosphorus ion reservoirs for plaque neutralization and tooth surface, preventing enamel demineralization and promoting remineralization.

The N_2 adsorption-desorption isotherm and BJH pore size distribution of NACP nanoparticles are shown in Figure 4. The sample shows an IV-type isotherm of H1 hysteresis loop, which is a typical mesoporous structure. From the measured data, it can be seen that the BET surface area of NACP nanoparticles is $41.414 \, m^2/g$, and the total pore volume and average pore diameter are about $0.165 \, 6cm^3/g$ and 10.5 nm, respectively.

Figure 5 shows the slow release process of NACP nanoparticles in vitro at 37°C and different pH. There was no sig-

nificant difference in the cumulative release of drugs in different pH buffers 5 h before release. However, as time increases, the drug release rate of Cur-ACP nanoparticles in pH 5.4 is faster than the release rate in pH 7.4. This is because NACP will gradually decompose in an acidic environment, thereby causing the loaded drug will be released slowly. When the release time reaches 52 h, the cumulative release rates of Cur in pH 5.4 and pH 7.4 buffers are 85.84 and 64.68%, respectively.

The quartiles of the proportion of Actinomycetes at different stages of treatment are shown in Figure 6. After wearing the fixed appliance, the proportion of some bacteria in the total flora also changed. Three kinds of bacteria (Streptococcus mutans, Lactobacillus, and Actinomycetes) accounted for the proportion of total bacteria. Kruskal-Wallis H rank-sum test analysis of multiple independent sample comparisons found that the proportions of Streptococcus mutans and Lactobacillus exist between group differences ($P < 0.05$). For the proportion of Actinomycetes in the total flora, there was no significant change among the groups ($P > 0.05$). Further use of pairwise comparison found that, compared with individuals who did not receive orthodontic treatment, the fixed appliance worn for less than 1 year, 1-2 years, and more than 2 years showed Streptococcus mutans and mutant in the local plaque of the tooth surface. The proportion of Lactobacillus in the total flora was significantly increased ($P < 0.05$), but the Kruskal-Wallis H rank-sum test analysis of multiple independent sample comparisons found that the proportion of Streptococcus mutans and Lactobacillus in the flora increases but does not occur continuously with the extension of the treatment time (the proportion of Streptococcus mutans and Lactobacillus in the partial plaque with the tooth surface after the fixed appliance is worn for less than 1 year, 1-2 years, and more than 2 years. The difference in proportion is not significant, $P > 0.05$).

The surface roughness of the seven different samples is shown in Figure 7. In the first month of the experiment, the
FIGURE 4: N^2 adsorption-desorption isotherm and BJH pore size distribution of NACP nanoparticles.
FIGURE 5: The slow drug release process of NACP nanoparticles in vitro at 37°C and different pH.

enamel surface roughness of the D group was significantly lower; two and three months of the experiment, the enamel surface roughness of each treatment group was significantly reduced. Compared with group G, the difference was significant ($P < 0.05$), the enamel surface roughness of group B was significantly lower than that of other groups ($P < 0.05$), and group C was significant compared with group D, group E, and group F difference. It can be seen that different influencing factors will have various effects on the surface roughness of different samples.

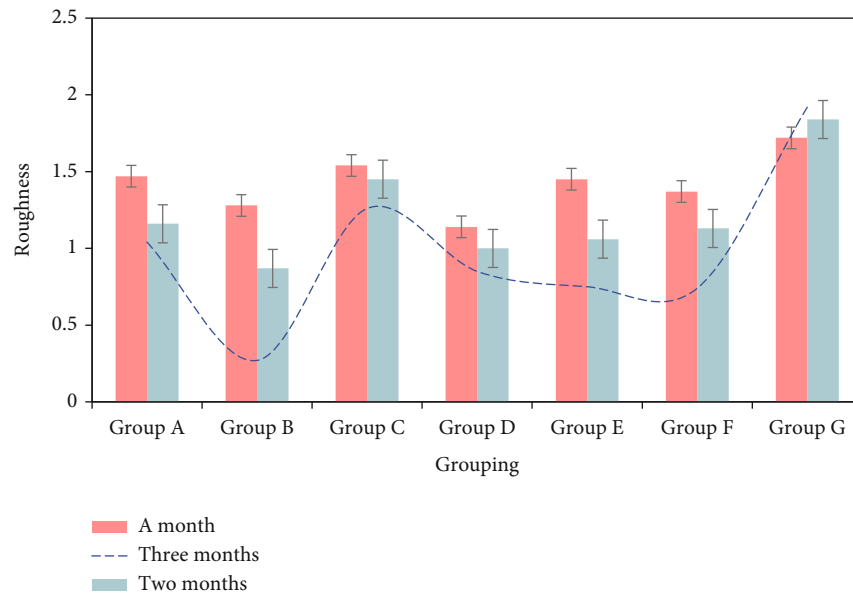
The scanning electron microscope situation is shown in Figure 8. In a dry environment, after the treatment of 37% phosphoric acid and GC treatment agent, the enamel cracks or enamel peeling of the GC adhesive group after two unloadings all showed different degrees of enamel cracking or enamel peeling, especially the second unloading was more prominent. In the area covered by the enamel adhesive, there are residual resin protrusions embedded in the micropores of the enamel after removing the brackets, and the bonding is tight, and the bonding surface has no obvious cracks.
FIGURE 6: Quartiles of the proportion of Actinomycetes at different stages of correction.


FIGURE 7: The surface roughness of seven different samples.

According to the analysis of the bonding process, these protrusions are mainly caused by no fillers. The liquid component of the enamel adhesive with good penetration and physical bonding properties is formed. This protrusion is considered beneficial to tooth health and still has an anticaries effect and does not need to be removed. Moreover, its anticaries effect compensates for the side effects caused by the improved bonding method to expand the acid etched area.

The comparison of the demineralization rates is shown in Table 4. Comparison of enamel demineralization rates between groups A, B, and C is as follows: group B and group A are different in demineralization rate, group A is higher than group B ($\chi^2 = 19.227$, $P \leq 0.01$); group C is demineralized compared with group A. The rate is different in group A than in group C ($\chi^2 = 21.892$, $P \leq 0.01$); there is no difference in demineralization rate between group B and group C ($\chi^2 = 0.053$, $P = 0.818$). The new composite material based on the binder-loaded amorphous nanocalcium phosphate can effectively seal the open dentinal tubules, and its effect has a certain resistance to abrasion and acid, which provides
FIGURE 8: Scanning electron microscope situation.

TABLE 4: Comparison of the demineralization rate of the three groups A, B, and C.

	Demineralization rate	χ^2 value	P value
Group A and group B			
Group A	26.41	19.227	≤0.01
Group B	14.35		
Group A and group C			
Group A	26.41	21.892	≤0.01
Group C	13.82		
Group B and group C			
Group B	14.35	0.053	0.818
Group C	13.82		

a new experimental basis for the clinical treatment of dentin hypersensitivity.

The averages of the three groups of EDI indexes A, B, and C are shown in Figure 9. It can be seen from the figure that the average of the EDI index of the group A is the highest. Comparison between group B and group A is as follows: $t = 2.929$, $P = 0.008$, group A is higher than group B, which is statistically significant; comparison between group C and group A is as follows: $t = 2.911$, $P = 0.008$, group A is higher than group C, and there is statistical significance; comparison between group B and group C is as follows: $t = 0.340$, $P = 0.737$, and there is no statistical significance.

The comparison of the numbers and proportions of the two groups of Streptococcus mutans and Actinomycetes is shown in Table 5. The number of Streptococcus mutans in the demineralization group was significantly increased compared with the nondemineralization group.

4. Discussion

The crystalline phase transition of ACP is an autocatalytic process, and its crystallization curve is s-shaped. Phase transition is the process in which a substance changes from one phase to another, so the crystallization process is a phase transition process. There are many factors that affect the phase transition of ACP, mainly including the pH value of the solution, the temperature of the system, and the addition of foreign ions or molecules. Under alkaline conditions, ACP finally phases into hydroxyapatite in aqueous solution, and the phase transition rate is very slow (pH = 9.00). The increase in acidity increases the speed of amorphous intersecting. At pH = 3.4, the amorphous phase only exists for a few minutes, but the phase becomes calcium-deficient hydroxyapatite (DCPD) instead of apatite, and ACP evolves to calcium-deficient under physiological pH conditions. And phosphate hydrolyzed apatite. Temperature has a great influence on the phase change of ACP. It takes about three days for the phase change at 10°C, two hours at 25°C, and complete phase change within 30 minutes when it rises to 37°C. The influence of foreign ions and molecules on the phase transition of ACP is also essential. In fact, organisms use the interaction of biological macromolecules with calcium ions and phosphate ions to control the amorphous as the precursor of biomineralization.

The change in the gloss of the tooth surface is one of the manifestations of demineralization. It will become caries if it develops further without treatment. Generally, tooth enamel demineralization can be divided into two forms, namely, surface demineralization and subsurface demineralization. After the remineralization of early enamel caries, mineral salts can stay in part of the enamel that has been demineralized in a certain form, resulting in an increase in the microhardness of the caries area and a decrease in porosity. The histomorphology shows that the surface layer and dark zone are widened, the area of caries is reduced, and the negative birefringence of the glazed surface is enhanced under the polarized light microscope. In the caries lesion area, the positive birefringence tends to the negative birefringence, and the microscopic X-ray shows an increase in density. In addition, remineralization not only refers to the deposition of
FIGURE 9: The average of the three groups of EDI indexes A, B, and C.

TABLE 5: Comparison of the numbers and proportions of the two groups of Streptococcus mutans and Actinomycetes.

Bacteria	Number		The proportion	
	Demineralization group	Undemineralized group	Demineralization group	Undemineralized group
Streptococcus mutans	11.13 ± 0.72	10.63 ± 0.91	1.20 ± 1.07	0.44 ± 0.48
Actinomycetes	12.08 ± 0.24	12.11 ± 0.57	6.50 ± 4.57	8.59 ± 10.51

minerals in the oral cavity on the surface of the tooth and the diseased part under normal conditions but also can occur during the formation of dental caries.

The anterior teeth of the same name are similar in shape, and the contact surfaces and methods of the left and right anterior teeth of the same name and the toothbrush are similar when individuals perform daily oral cleaning such as brushing their teeth. This may also be one of the reasons. In the same dental arch, there is a statistical difference in the pH of the labial surface of the teeth without the same name. In the maxillary arch, the pH of the labial surface of the canine teeth is higher than that of the central incisor ($P < 0.05$), and both are significantly higher than that of the lateral incisor ($P < 0.05$); this may be related to the position of the teeth in the oral cavity and the distance of the salivary gland opening. For example, the pH of the labial surface of the maxillary lateral incisor is lower than that of the canine. Plaque is easy to accumulate, especially after bonding and fixing the appliance, it affects its cleaning and makes the pH of the lip surface lower than the central incisor. There is no significant difference in pH between mandibular lateral incisors and central incisors. Therefore, the central incisors and lateral incisors of the mandibular incisors receive the washing and buffering effect of saliva resemblance. This is similar to the difference in enamel demineralization in fixed orthodontics.

Due to the low compliance of patients, topical fluoride regimens are usually difficult to work. Calcium and phosphate ions released from calcium phosphate biomaterials form ion reservoirs in dental plaques. The supersaturated calcium and phosphorus ion pool helps prevent demineralization and promote enamel remineralization. In traditional calcium phosphate materials, the diameter of calcium phosphate fillers is mostly about 55 microns, which leads to restrictions on the filler addition ratio and the release of calcium and phosphorus ions. The new type of amorphous calcium phosphate nanoparticles (NACP) has a diameter of about 110 nm. Because of its small particle size and large specific surface area, it has a high level of Ca and P ion release ability and the ability to promote tooth enamel remineralization. In addition, resin composites containing this type of NACP filler can "smartly" release high concentrations of calcium and phosphorus ions in an environment with a pH value close to 4 (cariogenic environment and enamel demineralization environment), and increase the local pH to above 5.5. Reduce the enamel demineralization rate, and after the pH rises above 5, the release of ions will be significantly reduced, preserving the effectiveness of the internal filler of the material.

The copolymer has a large difference in solubility between the hydrophilic and hydrophobic segments and can self-assemble into nanomicelles with a fairly narrow size

distribution and typical core-shell structure in water. Polyethylene glycol (PEG) is often used as the hydrophilic segment of polymer micelles, and the hydrophobic segment is polylactic acid (PLA), chitosan (CS), polycaprolactone (PLC), etc. The inner core can be loaded with poorly water-soluble drugs to increase the solubility of the drugs in aqueous solutions, while the hydrophilic outer shell can maintain the steric stability of the micelles. Polymer micelles can escape the nonspecific uptake of the reticuloendothelial system (RES) due to their small size distribution; the preparation methods of micelles are simple and diverse, and the conditions are mild; targeting molecules can be coupled on the surface of the micelles to enable the drug to achieve the target to deliver, thereby improving the efficacy of drugs. These advantages make polymer micelles have broad application prospects in the delivery of poorly soluble drugs.

5. Conclusions

Enamel demineralization of orthodontic teeth is a very serious problem, especially for patients with poor oral hygiene, and it is necessary to take active preventive measures as soon as possible. The self-etching bonding technology breaks through the traditional phosphoric acid etching and combines a variety of research results to reduce enamel damage and demineralization. It has special advantages in preventing enamel demineralization and is worthy of further research. The surface of the enamel after acid etching demineralization is rougher, and the porosity is greater, which is conducive to the penetration and fitting of the adhesive. The nanoactive filler contained in the adhesive is easier to combine with the demineralized enamel, thereby enhancing the hardness. Over time, the loss or increase of minerals ultimately determines whether WSL or even dental caries will advance, stabilize, or degenerate. Therefore, improving the ability of tooth enamel to resist demineralization and promoting its remineralization is an effective method to inhibit WSL and dental caries. In the experiment, the synthetic peptide at the C-terminus of enamel protein improved the directional connection of the nanoparticles and promoted the orderly transformation of the nanoparticles into enamel-like HAP crystals. Ordered particle arrangement may be a preparatory step before crystal formation and growth, which is in line with the concept of particle-attached crystallization (CPA) in the nonclassical mineralization theory. In this study, CMC and PA are used to simulate proteins related to biomineralization, and ACP is stabilized and arranged by forming CMC/ACP nanocomposites, and then, small particles are arranged in a queue and specifically bound to the enamel surface.

In order to reasonably reduce the energy consumption of automotive LCD instrument and improve the display quality, a new local dimming algorithm is proposed in this paper. Firstly, the gray image of the input image is obtained by using the maximum principle, and then, the LED backlight brightness value is obtained by using Otsu method and maximum entropy method. The BMA backlight smoothing algorithm is improved by combining bilinear interpolation algorithm, and the dimming image is obtained by using pixel compensation algorithm based on logarithm. Then, for low brightness images, high brightness images, low contrast images, and high contrast images, typical algorithms are used to simulate and compare, and the image processing effects of various local dimming algorithms are analyzed. Finally, the entropy weight method is used to objectively evaluate the local dimming algorithm. The results show that the new local dimming algorithm reduces the energy consumption and improves the display quality, which verifies the effectiveness of the proposed algorithm.

1. Introduction

LCD in automobile liquid crystal instrument is different from OLED. It is a nonautonomous light-emitting display device, which needs to rely on backlight module to provide backlight [1]. Because LED has the characteristics of energy saving, environmental protection, and long service life, the straight down LED backlight module is widely used as its backlight in automotive LCD instruments. However, the output brightness of the traditional backlight is constant, resulting in high energy consumption, poor contrast, and light leakage of the display. In order to solve this series of problems, researchers proposed a local dimming algorithm. The local dimming algorithm divides the image into several partitions, and the backlight source changes accordingly according to the pixel content of the corresponding partition. More basic local dimming algorithms include max method, average method, sqrt method, and standard deviation method [2]. Max method takes the maximum gray value of the corresponding partition as the backlight brightness value, which will not cause obvious loss of details, but the energy-saving effect is poor. The average method takes

the average gray value of the corresponding partition as the backlight brightness value. Compared with the max method, the average method has better energy-saving effect, but it is prone to gray truncation. Sqrt method and standard deviation method obtain the backlight brightness value of the corresponding partition on the basis of average method. Compared with average method, sqrt method retains more image details and reduces energy consumption to a certain extent compared with max method, but it is also prone to gray truncation. At the same time, there are typical local dimming algorithms such as error correction method, CDF threshold method, and IMF method [3, 4]. In the error correction method, the weighting coefficient before the correction value is fixed, resulting in some images cannot get the ideal LED backlight brightness value, and the scope of application is limited. Both CDF threshold method and IMF method are suitable for high brightness images and can enhance the contrast of images, but for images with a large proportion of dark scenes, the LED backlight brightness obtained by the two algorithms is low, which is easy to cause excessive pixel compensation and is easy to lose details. In recent years, some scholars have proposed better local

dimming algorithms. Wu [5] proposed a new local dimming algorithm that uses the improved hybrid leapfrog algorithm to extract the backlight brightness, which improves the image contrast. Song et al. [6] proposed a local dimming algorithm based on deep learning that directly generates a compensation image from the input image without any backlight dimming level information. Zhang et al. [7] proposed a new adaptive local dimming method to change the backlight brightness value in combination with human visual characteristics. Zhao [8] proposed a local dimming algorithm based on image local brightness. Although some scholars at home and abroad have proposed some local dimming algorithms, there is still much room for improvement in energy saving and improving display quality. This paper presents a local dimming algorithm for automotive LCD instrument, which improves the display quality and reduces the energy consumption.

2. A New Local Dimming Algorithm

Otsu method has good processing effect for bimodal image and image edge region in gray histogram. It has the characteristics of simple calculation, high real-time performance, and relatively good processing effect. It is often used to obtain the initial threshold in the field of threshold segmentation. However, because Otsu method only considers the maximization of target and background segmentation when doing threshold segmentation, it is often difficult for Otsu method to obtain a better segmentation threshold for some images whose gray value of target and background is close. Otsu method has a good processing effect for the image with obvious distinction between the background layer and the target layer, that is, the image with double peaks in the gray histogram, and also in the edge area of the gray value of the image. The maximum entropy method and Otsu method have a good complementary effect. They have a good recognition and segmentation effect in the region with low discrimination between the background and the target boundary, while the processing effect in the edge region of gray image is poor [9]. By comprehensively analyzing the advantages and disadvantages of existing local dimming algorithms, this paper proposes a local dimming algorithm based on OTSU and maximum entropy, including local dynamic backlight extraction algorithm, backlight smoothing algorithm, and pixel compensation algorithm.

2.1. Backlight Extraction. The specific steps of the new backlight region extraction algorithm are as follows:

(1) Convert the input image into a gray image by using the maximum principle

Firstly, this paper uses the maximum principle to gray the input image to obtain the gray image; that is, the maximum value of the red, green, and blue primary colors of each pixel is taken as the gray value of the pixel. By using the maximum principle to obtain the gray value, it can ensure that the brightness value of LED backlight calculated in the subsequent backlight extraction algorithm will not be too
Figure 1: Schematic diagram of gain region.

Figure 2: Block effect simulation diagram.

low, so as to avoid the impact on the image display effect due to excessive pixel compensation to a great extent. At this time, the three primary colors of red, green, and blue are represented by eight channels, which is 256 levels; the quantization range of the gray value is 0-255, as shown in

$$\text{gray}(x, y) = \max\left(R(x, y), G(x, y), B(x, y)\right). \quad (1)$$

In the formula, $R(x, y)$, $G(x, y)$, and $B(x, y)$ are the three primary color components of red, green, and blue at the pixel.

(2) Obtain the first level target value by using Otsu method

After obtaining the gray image of the input image, the Otsu method (maximum inter class variance method) is used to adaptively select the first level target value according to the gray image of each image partition. The specific steps are as follows:

For an image with a resolution of $A \times B$, it contains M gray levels $\{0, 1, 2, \cdots, M - 1\}$, and N_i is the number of pixels with gray level i, as shown in

$$P_{Oi} = \frac{N_i}{AB}. \quad (2)$$

In the formula, P_{Oi} is the gray probability corresponding to the gray level i, where $\sum_0^{M-1} P_{Oi} = 1$ and $P_{Oi} \geq 0$.

If the segmentation threshold is f, the gray image pixels are divided into $[0, f]$ and $[f + 1, M - 1]$, that is, corresponding to background Back1 and target Back2. $P_1(f)$ and $P_2(f)$ are the total pixel probabilities of background Back1 and

target Back2, respectively, and $\mu_1(f)$ and $\mu_2(f)$ are the average gray values of background Back1 and target Back2, respectively, as shown in

$$\mu_1(f) = \sum_{i=0}^{f} i \frac{P_{Oi}}{P_1(f)},$$
$$\mu_2(f) = \sum_{i=f+1}^{M-1} i \frac{P_{Oi}}{P_2(f)}, \tag{3}$$

where μ_0 is the average gray value of the input image and C is the inter class variance, as shown in

$$C(f) = P_1(f)(\mu_1(f) - \mu_0)^2 + P_2(f)(\mu_2(f)\text{-}\mu_0)^2$$
$$= P_1(f)P_2(f)(\mu_1(f) - \mu_2(f))^2, \tag{4}$$
$$C(G1) = \max_{1 \leq f \leq M-1} C(f).$$

In the formula, $C(G1)$ is the maximum interclass variance and $G1$ is the target threshold.

(3) Obtain the secondary target value by using the maximum entropy method On the basis of Otsu method

Within the range of [90%, 110%] of the primary target value obtained by Otsu method, the secondary target value is obtained by maximum entropy method. The specific steps are as follows:

Taking the segmentation threshold f_2 as the boundary, it is divided into two parts: Back3 and Back4, which correspond to gray areas $[0, f_2]$ and $[f_2 + 1, M - 1]$, respectively. $P_{e1}(f_2)$ and $P_{e2}(f_2)$ are the probability sum of gray levels in two gray areas, respectively.

The sum of information entropy th_{total} of Back3 and Back4 is

$$\text{th}_{\text{total}}(f_2) = \text{th}(\text{Back3}) + \text{th}(\text{Back4})$$
$$= -\sum_{i=0}^{f_2} \frac{P_{Oi}}{P_{e1}} \ln \frac{P_{Oi}}{P_{e1}} - \sum_{i=f_2+1}^{M-1} \frac{P_{Oi}}{P_{e2}} \ln \frac{P_{Oi}}{P_{e2}}. \tag{5}$$

For the flat part of the curve in the gray histogram of the input image, the information entropy is large; the steep region with less gray level information is the region with low complexity and low information entropy. By traversing f_2 in the gray range of $[0.9G1, 1.1G1]$, the gray level $G2$ corresponding to the maximum value of $\text{th}_{\text{total}}(f_2)$ is the secondary target value.

(b) Average

(c) Sqrt

(d) SD

(e) ECM

(f) CDF

(g) IMF

(h) New

FIGURE 7: High brightness image simulation diagram.

(4) Calculate the target segmentation threshold

The target segmentation threshold G_final is obtained by comprehensively considering the primary target value and secondary target value in steps (2) and (3).

$$G\_\text{final} = \frac{G1 + G2}{2}. \tag{6}$$

(5) Calculate the backlight brightness value

The area where the gray value is greater than G_final is regarded as the gain area gain, as shown in Figure 1.

After obtaining the gain region, the relevant idea of error correction method is used, as shown in

$$\begin{aligned} \text{BL}_\text{gain} &= \text{mean}(\text{gain}), \\ K &= \frac{\text{BL}_\text{gain} - G\_\text{final}}{\text{BL}_\text{max}}, \\ \text{BL}_\text{new} &= \text{BL}_\text{avg} + K \times \frac{\left(\text{BL}_\text{max} - \text{BL}_\text{avg}\right)^2}{255}. \end{aligned} \tag{7}$$

In the formula, BL_gain is the average gray value of the gray image gain area; K is the gain coefficient. Cor is the correction amount obtained by introducing the error correction method, and BL_new is the backlight brightness value of LED lamp obtained by applying the new local dynamic backlight extraction algorithm.

2.2. Backlight Smoothing. Due to the light diffusion of LED lights in adjacent zones, it will affect adjacent zones. If the pixel is compensated directly, there will be obvious "block effect" in the image. Therefore, before pixel compensation, backlight smoothing is needed to eliminate the "block effect." The simulation effect of block effect is shown in Figure 2. At present, LSF algorithm and BMA algorithm are widely used for backlight smoothing. Compared with LSF algorithm, BMA algorithm has the advantages of simple operation, less hardware resources, and better backlight smoothing effect. However, because the traditional BMA algorithm uses a simple surrounding image processing when expanding the matrix for smoothing filtering, it will cause some loss to the final backlight smoothing effect. The algorithm adopts bilinear interpolation expansion method when expanding the matrix. This method effectively considers the image information of the original matrix, and the performance of the algorithm is improved.

FIGURE 8: Low contrast image simulation diagram.

The core idea of the improved BMA algorithm is as follows:

(1) The surrounding mirror image is only a simple copy of the boundary, resulting in a large error. The bilinear interpolation algorithm is used to expand the matrix, which fully considers the nearest four vertices around the pixel to be calculated. In the initial matrix expansion, the bilinear interpolation algorithm is used to replace the traditional method of surrounding mirror image to expand the matrix to obtain the expansion matrix BL_{exp}, as shown

$$
BL_{exp} = \begin{bmatrix}
BL_{bil_{1,1}} & BL_{bil_{1,2}} & BL_{bil_{1,3}} & L & BL_{bil_{1,c}} & BL_{bil_{1,c+1}} & BL_{bil_{1,c+2}} \\
BL_{bil_{2,1}} & BL_{bil_{2,2}} & BL_{bil_{2,3}} & L & BL_{bil_{2,c}} & BL_{bil_{2,c+1}} & BL_{bil_{2,c+2}} \\
BL_{bil_{3,1}} & BL_{bil_{3,2}} & BL_{bil_{3,3}} & L & BL_{bil_{3,c}} & BL_{bil_{3,c+1}} & BL_{bil_{3,c+2}} \\
M & M & M & M & M & M & M \\
BL_{bil_{r,1}} & BL_{bil_{r,2}} & BL_{bil_{r,3}} & L & BL_{bil_{r,c}} & BL_{bil_{r,c+1}} & BL_{bil_{r,c+2}} \\
BL_{bil_{r+1,1}} & BL_{bil_{r+1,2}} & BL_{bil_{r+1,3}} & L & BL_{bil_{r+1,c}} & BL_{bil_{r+1,c+1}} & BL_{bil_{r+1,c+2}} \\
BL_{bil_{r+2,1}} & BL_{bil_{r+2,2}} & BL_{bil_{r+2,3}} & L & BL_{bil_{r+2,c}} & BL_{bil_{r+2,c+1}} & BL_{bil_{r+2,c+2}}
\end{bmatrix}. \tag{8}
$$

(a) Max

(b) Average

(c) Sqrt

(d) SD

(e) ECM

(f) CDF

(g) IMF

(h) New
FIGURE 9: High contrast image simulation diagram.

(2) The backlight smoothing initial expansion matrix BL_{exp} is smoothed by equation (9) to obtain the initial smoothing filter matrix BL_{filt}

$$
\begin{aligned}
\mathrm{BL}_{\mathrm{filt}_{i,j}} = {} & 0.32 \times \mathrm{BL}_{\mathrm{bil}_{i,j}} + 0.1 \times \left(\mathrm{BL}_{\mathrm{bil}_{i,j\text{-}1}} + \mathrm{BL}_{\mathrm{bil}_{i,j+1}} \right) \\
& + 0.1 \times \left(\mathrm{BL}_{\mathrm{bil}_{i\text{-}1,j}} + \mathrm{BL}_{\mathrm{bil}_{i+1,j}} \right) + 0.07 \\
& \times \left(\mathrm{BL}_{\mathrm{bil}_{i\text{-}1,j\text{-}1}} + \mathrm{BL}_{\mathrm{bil}_{i\text{-}1,j+1}} + \mathrm{BL}_{\mathrm{bil}_{i+1,j\text{-}1}} + \mathrm{BL}_{\mathrm{bil}_{i+1,j+1}} \right).
\end{aligned}
\tag{9}
$$

(3) After smoothing the matrix, the nearest neighbor interpolation algorithm is replaced by bilinear interpolation algorithm to double the size of the matrix

(4) Repeat steps (1)~(3) twice. Finally, the bilinear interpolation algorithm is used to expand the smoothing filter matrix to the size of the original image. The comparison of algorithms is shown in Figure 3

2.3. Pixel Compensation. If the brightness value of LED backlight obtained by the local dynamic backlight extraction algorithm is too small, the traditional pixel compensation algorithm will lead to overcompensation of image pixels,

which will lead to gray truncation and poor reliability of the algorithm. This paper proposes a pixel compensation algorithm based on logarithm, which can stretch the low brightness region and enhance the high brightness region, which reduces the distortion of the image to a great extent, as shown in

$$
V(x, y) = \ln \left(\left(\frac{\mathrm{gray}_{\max}}{g(x, y)} \right)^{0.2} \times e \right),
$$
$$
\begin{cases}
R'(x, y) = V(x, y) * R(x, y), \\
G'(x, y) = V(x, y) * G(x, y), \\
B'(x, y) = V(x, y) * B(x, y).
\end{cases}
\tag{10}
$$

In the formula, $\mathrm{gray}_{\max}$ is the maximum gray value of each image partition gray image; $g(x, y)$ is the backlight smoothing value at pixel (x, y) obtained by backlight smoothing of LED backlight brightness matrix; $V(x, y)$ is the pixel adjustment coefficient.

The comparison between traditional pixel compensation algorithm and logarithm-based pixel compensation algorithm is shown in Figure 4.

3. Effect Verification of Local Dimming Algorithm

On the MATLAB platform, different local dimming algorithms are used to simulate low brightness image, high brightness image, low contrast image, and high contrast image. The resolution of the test image is 1920×1080, and image partition is 16×9. The sample image is shown in Figure 5, and the simulation results are shown in Figures 6–9.

According to the simulation results, six testers are invited to subjectively evaluate the simulation images according to the five grades of excellent, good, general, substandard, and inferior in the closed dark light environment. The results are shown in Table 1.

4. Algorithm Evaluation

4.1. Evaluation Index. Based on the comprehensive analysis of the classical objective evaluation methods, this paper proposes to take the energy-saving rate (SER), overflow rate (OFR), and contrast (CR) as the objective evaluation indexes for the regional dimming algorithm, as shown in Table 2.

In the formula, BL_AVG is the average brightness of all LED backlights corresponding to an input image, and the value range is $[0 - 255]$; OF_{sum} is the total number of pixel overflow after pixel compensation; MAX(BL) and MIN(BL) are the maximum and minimum brightness of LED back-

light obtained by using the regional dynamic backlight extraction algorithm.

4.2. Result Analysis. Three objective evaluation indexes of energy saving rate, overflow rate, and contrast are extracted from the backlight brightness value and backlight compensation pixel value. In this paper, the entropy weight method based on objective indexes is used to evaluate and score the algorithm, eliminate the interference of subjective factors, give weights to each objective evaluation index, and then convert it into the quantification of the quality evaluation of regional dimming algorithm.

The evaluation results obtained by entropy weight method are shown in Table 3.

Table 1 evaluates the image from the subjective visual perception of the tester, and Table 3 analyzes the processing effect of the algorithm from the objective indicators. The consistency between Tables 1 and 3 is good, which verifies the excellent processing effect of the algorithm proposed in this paper on reducing energy consumption and improving display quality.

5. Discussion

(1) A new local dimming algorithm for automotive LCD instrument is proposed, which can reduce energy consumption and improve display quality. It mainly

includes the comprehensive use of Otsu method and maximum entropy method to determine the brightness value of LED backlight, the improvement of BMA backlight smoothing algorithm by bilinear interpolation, and the pixel compensation algorithm based on logarithm

(2) The new local dimming algorithm and other local dimming algorithms proposed in this paper are simulated and analyzed on four typical images. It is found that the local dimming algorithm proposed in this paper can effectively improve the display quality, which shows that this algorithm has wide applicability

(3) The entropy weight method is used to objectively evaluate the quality of the algorithm, which proves that the local dimming algorithm proposed in this paper can effectively reduce energy consumption and improve the display quality

Composite material is a new material prepared by several raw materials with different forms or properties through new processing methods. The composite not only maintains the advantages of the properties of each component but also can obtain the comprehensive properties that cannot be achieved by a single component through the complementarity and correlation of the properties of each component. The purpose of this paper is to study the effect of wet and hot conditions on the interlaminar fracture toughness and durability of composites. In this paper, the interlaminar fracture toughness and durability are studied, and the prediction and analysis method under wet and hot conditions is carried out. The effects of hot and humid conditions on interlaminar fracture toughness and durability were analyzed. The experimental results show that the longitudinal compressive strength of the unidirectional composite at 120°C and 1.00% moisture absorption is 29.53% lower than that at 20°C and 0.50% moisture absorption. Due to the high moisture absorption of aramid fiber, the longitudinal compressive strength of unidirectional aramid composite fiber will be significantly reduced in the humid and warm environment.

1. Introduction

Due to the special properties of nanomaterials, they are regarded as new materials in the 21st century. Advanced composites have been more and more used in aerospace and cycle fields because of their excellent properties, such as high special strength. The vulnerability and nonuniformity of the composite material itself make the failure of the hinge part of the composite material more complex, and the failure characteristics of the damage are also more complex. Its fracture performance is very different from that of metal materials. In addition, the connecting parts of composites are also very different. However, due to the complexity of composites and the continuous emergence of various new fibers and matrix materials, the influence of the humid and hot environment on the mechanical and fatigue properties of composites is not obvious. At present, there is no complete and accurate evaluation system.

Advanced composites are increasingly used in the main structures of aircraft and automobiles. Due to the low inter-laminar strength, delamination is one of the most serious failure modes in composites and their structures. It is widely used in the cohesion model and virtual crack closure technology to predict the delamination of composites and their structures under tensile, compressive, or impact loads [1, 2]. Therefore, the interlaminar fracture toughness of composites is very important for the design and analysis of composites and their structures. Interlaminar fracture toughness is generally considered an inherent property of composites, which needs to be obtained by a delamination test. Therefore, it is very important to develop a simple and accurate test method to determine the interlaminar fracture toughness.

The innovations of this paper are as follows. (1) This paper combines damp-heat conditions with composites and introduces the relevant methods of interlaminar fracture toughness considering damp-heat conditions in detail. (2) In the face of hot and humid conditions, the fracture toughness and durability of composites are studied in this paper. By evaluating the experimental results and comparing the data

changes, it is concluded that the longitudinal compressive strength of unidirectional aramid composite fiber will be significantly reduced in the humid and hot environment.

2. Related Work

The influence of the environment is complex. For example, high temperature and moisture absorption will increase the plasticity of the matrix and increase the delamination toughness. On the other hand, it will cause microcracks in the matrix, will affect the bonding strength between the fiber matrix, may reduce the toughness, and will have different effects on different types of resins. Zhang et al. studied the effects of lime content, slag content, and moisture content on the thermal and wet properties of lime slag/soil composites by the response surface method and lime preparation process. The results showed that the lime content, slag content, and moisture content will affect the overall thermal and wet properties. Under the action of alkaline excitation and micro aggregate, the optimized lime slag/soil composite has the advantages of compact structure, reasonable mechanical properties, and comprehensive properties of heat and moisture. However, their data is less [3]. Zong et al. adopted the uniform experimental design and multiple nonlinear regression formula. They studied the Ce-La dose results (Ce-La molecular ratio and tetrabutyl titanate). The effects of the volume ratio of tetrabutyl titanium to tetraethyl orthosilicate on the hygroscopicity and photocatalytic properties of Ce-La/TiO_2 hollow microspheres were studied. The results show that these four factors have an effect on hygroscopicity. However, their research is not comprehensive enough [4]. Kasaragadda et al. applied superhydrophobic coatings to the surfaces of carbon, Kevlar, and glass fiber composites to eliminate the absorption of water by the composite structure. The test results show that when the composite surface is coated with a superhydrophobic coating, the moisture absorption is much smaller than that of the uncoated composite sample. However, their influencing factors are not single [5]. Yu et al. used the strong van der Waals force between superaligned carbon nanotubes (SACNT) to design a self-supporting 3D CNT/$CaCl_2$ radiator, which has better heat dissipation performance than aluminum fins. This high-efficiency refrigerator provides another heat management method for electronic products. However, their content is not novel enough [6]. Tanaka et al.'s study measured the specific volume and softening point of the resin by a single fiber drawing test at room temperature, 40°C, and 80°C. It was used to evaluate the fiber/matrix interface characteristics of the CF/PA9T composite model, and the results were compared with those of the CF/PA6 and CF/PA12 composite models. The resin expansion and interfacial shear strength of CF/PA9T model composites decreased with the increase in temperature, and the decreased range of interfacial shear strength of CF/PA9T model composites was less than that of CF/PA6 and CF/PA12 model composites. The reduction of high-temperature residual stress below 80°C does not cause chemical modification and softening of the resin but reduces the interfacial shear strength of the fiber matrix.

However, their process is more complicated [7]. Liu et al. expanded its application in the electronics and membrane industry. It is aimed at developing radiation with heat resistance, conductivity, and moisture resistance by using PCT as the reactive reinforcement and applying the solid-state interface reaction (SSIR) between PCT and PA6. According to the results, SSIR occurred between PA6 and PCT. However, their research is not specific enough [8]. Chen et al. mixed natural corn starch with galactomannan (NS-GM) to produce the starch-galactomannan complex after wet heat treatment (HMT). They studied the in vitro digestibility and physicochemical properties of starch and starch-galactomannan complex. Their study found that the resistant starch content of HMT NS-GM composite granules was related to the galactose/mannose residue ratio of galactomannan. However, their conclusion is not comprehensive [9]. Han et al. synthesized a unique amino-functionalized metal-organic skeleton (sN-MIL) with a small pore size and low specific surface and developed a new heat-resistant and moisture-resistant bismaleimide (BD) resin with ultralow dielectric loss and high toughness. They discussed in depth the reasons behind these attractive properties of sN-MIL/BD composites. However, their content is not detailed enough [10].

3. Interlaminar Fracture Toughness Method considering Wet and Hot Conditions

3.1. Composites in Hot and Humid Conditions

3.1.1. Composite Material. Composite material is a new material prepared by several raw materials with different forms or properties through new processing methods. The new material processed and prepared by composite means has a clear interface between the organizational components in the material, which not only maintains some excellent characteristics of the original material components but also has superior characteristics that the original material components do not have. Composite materials include the matrix and reinforcement. Among them, the reinforcement plays an important role in bearing the external load in the composite, and the static properties of the composite are mainly determined by the characteristics of the reinforcement [11, 12].

The matrix of another main part of the composite mainly plays the role of coordination with the added solid. The solid added plays the role of supporting and fastening the solid added, and the load transfer between the solid added and the solid added protection. Matrix materials can also improve some properties of composites. In this paper, resin is selected as the base material because of its low density and ceramic as the die material because of its high-temperature resistance, and metal as the die material must obtain higher hardness and shear properties. As we all know, polymer matrix composites have another name in engineering applications, also known as resin matrix composites. In practical engineering applications, we use more thermoplastic resins and thermosetting resins. Among thermosetting resins, epoxy resin has the advantages of strong adhesion

and good corrosion resistance. It has been widely used in engineering applications, with good fiber surface permeability and convenient processing, preparation, hardening, and casting. Thermoplastic resin has good processability [13, 14]. Therefore, when the heating temperature reaches the transition temperature, they will soften again. Based on this excellent performance, it is easier to manufacture cast composites, and this resin has very good fracture resistance and high hardness. The drawback is that the coefficient of this resin is not high and the heat resistance is not very good.

3.1.2. Influence of the Damp and Hot Environment on Composites.

During the use of composite materials, they will encounter the changing atmospheric environment. They will be used in nature with changing temperature T and relative humidity RH for a long time. When the natural environment's temperature and humidity are relatively high, water molecules may enter the polymer components and further diffuse. In view of the tiny cracks and gaps in the composite structure and the defects contained in the internal interface of the composite, the penetration rate and saturated moisture absorption rate of water in the material will be improved. The mechanical properties and electromagnetic properties of composites are bound to be greatly affected by them. In the end, the utilization efficiency of composites will be reduced and even the products will be damaged [15]. Water molecules penetrate into the tissue between the fiber and the matrix, causing the glue of these parts to lose viscosity and be transmitted to the fiber through the interface, resulting in fiber damage.

It is generally believed that glass fiber and carbon fiber do not absorb moisture, while aramid fiber has greater moisture absorption. It can be seen from Table 1 that the hygroscopicity of the glass fiber- and carbon fiber-reinforced composites is significantly lower than that of the resin matrix. The hygroscopicity of the aramid fiber-reinforced composites is four times that of the resin matrix. The phenomenon of water corrosion of glass fiber is found.

The influence of the liquid and warm environment on fiber-reinforced resin matrix composites is the synergistic effect of humidity and temperature, which is mainly due to the different degrees of damage to the resin matrix and the connection interface between reinforced fiber and resin/fiber. Heating can accelerate the moisture absorption rate, increase the moisture absorption balance of the material, and reduce the equilibrium time.

3.2. Fracture Mechanics Solution of Composite DCB.

Due to the low interlaminar strength of laminates, delamination is the most common and main failure form.

From the point of view of mechanical fracture, separation belongs to the propagation behavior of the interlayer crack. According to the classification of cracks in fracture mechanics, their separation is mainly divided into three ways: I, II, and II, which depend on the stress at the edge of the crack. Type I separation, with the edge stress perpendicular to the crack surface, belongs to the open type. Type II

TABLE 1: Water absorption of the material after immersion in water for 7 days (10^{-2} g/cm^3).

Material temperature	22°C	60°C	100°C
Epoxy resin	0.24	0.39	1.12
Glass fiber-reinforced composites	0.13	0.24	0.68
Carbon fiber-reinforced composites	0.24	0.33	0.82
Aramid fiber-reinforced composites	0.48	0.68	4.78

separation, with the edge stress parallel to the crack surface, belongs to the shear type. Type III peeling, with the peak voltage on the crack surface perpendicular to the crack, tears in the propagation direction. In engineering practice, the stress state at the crack tip is often a complex stress state, which is the composite of the three basic types [16, 17].

3.2.1. Griffith's Energy Release Rate.

According to Griffith's law, the energy release rate refers to the energy consumed per unit of the newly generated surface area during fracture, as shown in Figure 1.

The mathematical form of the energy release rate can be expressed as follows:

$$G = \frac{\delta \prod}{\delta M} = \frac{\delta(W - U)}{\delta M} = \frac{1}{N} \cdot \frac{\delta(W - U)}{\delta m}, \quad (1)$$

where u represents the total strain energy, w represents the external force work, M represents the surface area of the newly generated crack surface, n represents the specimen width, and DM is the crack growth increment. Using the following relationship: $C = \varepsilon/P$, $W = P\varepsilon$, and $U = 1/2P\varepsilon$, formula (1) can be transformed into the following form:

$$G = \frac{1}{2N} P^2 \frac{\delta C}{\delta m}, \quad (2)$$

where P and ε are the applied load and opening displacement, respectively. C represents the flexibility of the DCB specimen.

3.2.2. Fracture Mechanics Solution Based on the Beam Theory.

The energy release rate of the DCB sample shown in Figure 2 can be analyzed by the basic beam theory.

According to Euler's beam theory, the opening displacement of DCB sample δ and the force P applied at both ends have the following relationship:

$$\varepsilon = \frac{2Pm^3}{3E_{xx}A}, \quad (3)$$

where E_{xx} represents the elastic modulus of the sample along the fiber direction, M represents the crack length, h is the thickness of the single cantilever beam, a represents the section moment of inertia of the single cantilever beam, and $A = 1/12Nh^3$.
FIGURE 1: Schematic diagram of Griffith's energy release rate.
FIGURE 2: DCB sample.

By introducing formula (3) into formula (2), the expression of the energy release rate based on Euler's beam theory can be obtained:

$$G = \frac{1}{N} \cdot \frac{P^2 m^3}{3E_{xx}A}. \tag{4}$$

Using formula (3) and its transformation form, the energy release rate G in formula (4) can be rewritten as follows:

$$G = \frac{9E_{xx}A \cdot \varepsilon^2}{4Nm^4}, \tag{5}$$

$$G = \frac{3P\varepsilon}{2Nm}, \tag{6}$$

$$G = \frac{1}{N} \cdot \sqrt{\frac{9P^4 \cdot \varepsilon^2}{4E_{xx}A}}. \tag{7}$$

Theoretically, the energy release rate calculated by formulas (4)–(7) should be the same. However, if the load and displacement obtained from the finite element are used and the energy release rate is calculated by the four formulas, the accuracy of their results is different. The reason is that the load-displacement relationship of the DCB sample given in formula (3) is an approximate solution.

3.2.3. Two-Dimensional Elastic Solution. Formula (3) introduces some simplified assumptions when calculating the load-displacement relationship of the DCB sample: the energy in the DCB sample is only stored in arms ABCD and AIHG. As shown in Figure 2, strain energy is also stored in the noncracked region DEFG, but this is not considered in formula (3). In addition, the uncracked region is deformed and not completely rigid as required by the simple cantilever theory. Therefore, formula (3) used to calculate the load-displacement relationship of the DCB sample is inaccurate [18]. In order to overcome the shortcomings of the simple beam model, the researchers used the orthogonal scaling method and finite element analysis (FEA) to give the solution of the energy release rate of the two-dimensional orthotropic DCB:

$$G = \frac{P^2 m^2}{N \cdot E_{xx}A} \left(1 + 2\alpha \frac{h}{m} + \alpha^2 \frac{h^2}{m^2}\right), \tag{8}$$

where

$$\alpha = \left[0.677 + 0.146(\beta\text{-}1) - 0.0178(\beta\text{-}1)^2 \right. \\ \left. + 0.00242(\beta\text{-}1)^3\right] \cdot \left(\frac{E_{yy}}{E_{xx}}\right)^{-1/4}, \tag{9}$$

$$\left(\frac{E_{yy}}{E_{xx}}\right)^{-1/4} \beta = \frac{\sqrt{E_{xx}E_{yy}}}{2G_{xy}} - \sqrt{v_{xy}E_{yx}}. \tag{10}$$

E_{xx}, E_{yy} and G_{xy} are Young's modulus and the shear modulus, respectively; v_{xy} and v_{yx} are Poisson's ratios. For isotropic materials, $\beta = 1$ and $\alpha == 0.677$, which is consistent with the two-dimensional elastic solution of isotropic DCB. For the case of $M/H \gg 1$, the energy release rate given by formula (8) is very close to that obtained by formula (4) based on the simple beam theory.

3.2.4. Finite Element and Verification. A two-dimensional finite element model is established to verify the accuracy of formulas (4)–(8) in calculating the energy release rate of orthotropic DCB. The boundary conditions of the finite element model are shown in Figure 3, in which the lower left hinge point is fixed ($u_x = u_y = 0$), and the concentrated force P is applied at the upper left point. The mechanical proper-
FIGURE 3: Finite element model network planning and boundary conditions.

ties of the composites used in the finite element model are as follows: $E_{xx} = 110$ GPa, $E_{xx} = E_{yy} = 8.07$ GPa, $G_{xy} = G_{xz} = 3.79$ GPa, $G_{yz} = 3.28$ GPa, $v_{xy} = v_{xz} = 0.32$, and $v_{yz} = 0.45$. Through the linear elastic finite element analysis, the opening displacement required to calculate the energy release rate in formulas (5)–(7) is obtained. It is difficult to obtain the solution of $x = -2$ at the point of $y = -H$, because it is difficult to obtain the singularity of the displacement at the point of $y = -M$.

3.3. Double Flexibility Method for Determining Interlaminar Fracture Toughness

3.3.1. Method Overview. It can be seen from Figure 3 that most solutions of Euler's beam theory (except formula (7)) are not accurate enough when actually calculating the energy release rate of the DCB sample. Therefore, these formulas need to be modified before they can be used. The researchers studied the complex deformation of the crack edge and proposed the concept of equivalent crack length $m_{\text{eff}} = m + \Delta$, i.e., modified beam theory (MBT), whose compliance type can be expressed as follows:

$$C = \frac{8(m + \Delta)^3}{E_{xx}Nh^3}. \tag{11}$$

E_{xx} is Young's modulus, and H is the thickness of the single cantilever beam.

According to the ASTM standard, the Δ can be assured. The linear regression method is used to linearly adjust the compliance cube root $C^{1/3}$ related to the crack length M. The intersection of the straight line and the M axis is m, as shown in Figure 4.

By replacing formula (11) with formula (2) and through appropriate transformation, the formula of the critical energy release rate is as follows:

$$C_{\text{AC}} = \frac{3P\varepsilon}{2N(m + |\Delta|)}. \tag{12}$$

Similarly, the flexibility calibration method (CC) and the modified flexibility calibration method (MCC) can also correct the flexibility. The flexibility expressions are formulas (13) and (14), respectively:

$$C = Mm^r, \tag{13}$$
Figure 4: Modified beam theory.

$$C = \frac{1}{M_1^3}\left(\frac{m}{h} - M_2\right)^3. \tag{14}$$

Among them, R and M_1 are also obtained by the linear regression adjustment method similar to Δ. By introducing formulas (13) and (14) into formula (2), respectively, the corresponding expression of the critical energy release rate can be obtained:

$$G_{AC} = \frac{rP\varepsilon}{2Nm}, \tag{15}$$

$$C_{AC} = \frac{3P^2 C^{2/3}}{2M_1 Nh}. \tag{16}$$

According to formulas (12), (15), and (16), the three methods proposed by ASTM must record the crack propagation length and the corresponding force and displacement and determine the correction coefficients a, R, and M_1 in real time. This process is troublesome, and if tested in the high- and low-temperature environment, the method of the ASTM standard will be very difficult to achieve. Based on the contents, we propose a double flexibility method for the fracture resistance of composite DCB specimens without real-time recording of the crack length.

3.3.2. Theory of the Double Flexibility Method. In fact, if there is a highly accurate relationship between the applied load P, the crack length m, and the opening displacement ε, it is not necessary to measure the crack length, the applied load, and its corresponding displacement at the same time. In this paper, a high-precision relationship between force-displacement-crack length is established by using the solution of the high-precision energy release rate given by predecessors [19]. In this paper, the energy release rate solution formula (8) obtained from the two-dimensional elastic analysis is adopted, and formula (8) is brought into formula (2) for indefinite integration. The relationship between the

applied load P and the displacement ε of orthotropic DCB can be obtained as follows:

$$C = \frac{\varepsilon}{P} = \frac{24}{NE_{xx}}\left(\frac{m^3}{3h^3} + \alpha\frac{m^2}{h^2} + \alpha^2\frac{m}{h}\right). \tag{17}$$

In this paper, the finite element model is used to verify the accuracy of formulas (3) and (17) in calculating DCB flexibility. When m/h is not used, the relative difference between formulas (3) and (17) and the finite element results are shown in Figure 5. It can be seen that formula (3) obtained from Euler's beam theory is too simple to calculate the flexibility of DCB, but the flexibility formula (17) obtained by integration is quite accurate.

For isotropic DCB, α is a constant value, equal to 0.677. Therefore, Young's modulus E_{xx} required in formula (7) can be obtained by the following method: the DCB test is conducted to obtain the force-displacement curve of the linear elastic loading section so as to obtain the DCB flexibility under the initial crack, which is brought into formula (17) to finally determine Young's modulus E_{xx}. After E_{xx} is determined, the fracture toughness of isotropic DCB can be calculated directly from formula (7) without measuring the crack length.

For anisotropic DCB, E_{xx} and α are unknowns. In order to determine these two parameters, a double flexibility method is proposed in this paper; that is, the flexibility C_0 loaded in the DCB test curve and the flexibility C_1 unloaded are used. The crack lengths corresponding to flexibility C_0 and C_1 are m_0 and m_1, respectively, which can be easily obtained by ultrasonic M-scan. It brings the two groups of crack lengths and corresponding flexibility into formula (17) to obtain the following:

$$C_0 N = \frac{24}{E_{xx}}\left(\frac{m_0^3}{3h^3} + \alpha\frac{m_0^2}{h^2} + \alpha^2\frac{m_0}{h}\right), \tag{18}$$

$$C_1 N = \frac{24}{E_{xx}}\left(\frac{m_1^3}{3h^3} + \alpha\frac{m_1^2}{h^2} + \alpha^2\frac{m_1}{h}\right). \tag{19}$$

It takes into account α as a positive number, where α and E_{xx} are as follows:

$$\alpha = \frac{-Y - \sqrt{Y^2 - 4XZ}}{2X}, \tag{20}$$

$$E_{xx} = \frac{24}{NC_1}\left(\frac{m_1^3}{3h^3} + \alpha\frac{m_1^2}{h^2} + \alpha^2\frac{m_1}{h}\right), \tag{21}$$

where

$$X = \frac{m_1}{h}C_0 - \frac{m_1}{h}C_1,$$

$$Y = \frac{m_1^2}{h^2}C_0 - \frac{m_0^2}{h^2}C_1, \tag{22}$$

$$Z = \frac{m_1^3}{3h^3}C_0 - \frac{m_0^3}{3h^3}C_1.$$
FIGURE 5: Formulas (3) and (17) calculate the relative difference between the botulinum toxin and finite element results.

TABLE 2: Composite material performance.

Material			Compound material				
Stretch	Strength (MPa)	84.76				Glass transition temperature T_g (°C)	218
	Modulus (GPa)	3.29	Impact strength (kgcm/cm^2)	14.0			
	Elongation at break (%)	3.34				Heat distortion temperature (°C)	198
Compression	Strength (MPa)	167.18				Density ρ (g/cm^2)	1.256
Bending	Strength (MPa)	134.47	Fracture toughness GIC (J/m^2)	95			
	Modulus (GPa)	3.66				Saturated moisture absorption in boiling water (%)	3.3

After determining α and E_{xx}, determine the relationship between flexibility C and crack length M. Using formula (17), the crack length m can be expressed as follows:

$$m = \sqrt[3]{\alpha^3 + \frac{\varepsilon N E_{xx}}{8P}} \cdot h - \alpha h. \tag{23}$$

That is, when the P force and ε displacement are known, the crack length can be calculated without additional measurement.

By introducing formula (23) into formula (8), the expression of the energy release rate without the crack length can be obtained:

$$G = \frac{P^2 h^2 \left(\alpha^3 + (\varepsilon N E_{xx}/8P)\right)^{2/3}}{N E_{xx} A}. \tag{24}$$

The significance of the formula is that the crack propagation length and fracture strength can only determine the duration of the test procedure from the force and displacement information during the test. It avoids measuring the crack propagation length during the test and makes it

suitable for the hardness test environmental conditions of the type I interlayer under test conditions, such as low temperature [20, 21].

4. Experiment and Analysis of Interlaminar Fracture Toughness and Durability in the Humid and Hot Environment

4.1. Interlaminar Fracture Toughness Test

4.1.1. Materials. In this study, the hardness and heat resistance of the composite used are relatively good, and some of its main properties are shown in Table 2.

All the 24 ply unidirectional plates used in the test are about 4 mm thick. The cut specimen is 165 mm long and 30 mm wide. In one section of the test piece, a layer of Teflon film with a length of about 35 mm is prepaved in the middle layer as a prefabricated layer. The shape and geometric dimensions of the test piece are shown in Figure 6. After cutting, the test piece shall be dried and hygroscopic.

4.1.2. Load-Displacement Curve. Under normal temperature and dry conditions, the typical load-displacement curve of
FIGURE 6: Shape and size of the test piece.

(a) Load-displacement curve of the MMF test under the normal temperature and dry state

(b) Test load-displacement curve with moisture absorption of 1.15% at 120°C
FIGURE 7: Comparison diagram of the load-displacement curve of the MMF specimen test.

the hybrid test is shown in Figure 7(a). Before crack propagation, the load-displacement curve is linear. When the crack propagates, it enters the nonlinear section. This is because the crack propagates, the crack length m increases, the stiffness of the beam decreases, the load-displacement curve of the crack propagation thickness is different from that before the crack propagation, and the slope of the straight-line section of the unloading curve decreases. In this environment, the unloading line is always straight and points to the origin. It can be seen that the linear relationship is established and there is no permanent deformation. It can be inferred that there is no plastic deformation problem [22]. In fact, from the shape of the unloaded specimen, there is no residual deformation.

In the high-temperature and high-humidity environment, the load-displacement curve of the MMF specimen has entered the nonlinear response section before crack propagation. This is most prominent in the test at 120°C and 1.15%, as shown in Figure 7(b). It is inferred that there is a certain plastic deformation at the tip of the crack before the crack propagation, and the crack propagates only after the plastic deformation. In terms of mechanism, the glass transition temperature of the interlayer resin decreases at high temperature after moisture absorption. The ambient temperature is very close to the glass transition temperature of the material after moisture absorption [23]. With the increase of material fluidity and high stress at the crack tip, plastic flow and plastic deformation easily occur. From the

test piece after the test, there is indeed permanent deformation.

In addition, the unstable propagation of cracks can be observed during the test.

It can be seen from the load-displacement curve that in the initial stage of crack propagation, when the crack is small, the load increases with the increase of crack length, and the crack propagation is steady; in the later stage of crack propagation, the crack is long. Under the displacement loading mode, the load decreases and the propagation belongs to an unsteady state.

4.1.3. Fracture Failure Criterion. According to the test results, the type I and type II component values of pure type I and type II interlaminar fracture toughness and mixed type interlaminar fracture toughness are calculated by using the previous calculation formula. The criterion of crack (delamination) propagation under the complex load can be traced, and the scatter diagram of G_I-G_{II} can be made. The pure type I action state is regarded as the special state of G_{IIa}, and the pure type II action state is regarded as the state of $G_{IIa} = 0$ and $G_{IIa} = G_{IIc}$. The layered G_I-G_{II} scatter diagram of specimens with different moisture contents under different temperature conditions is shown in Figure 8.

By comparing these figures, it can be found that in the dry state, whether at room temperature of 30°C or high temperature of 120°C, the dispersion of measured data is very small, and the envelope characteristics of delamination
(a) G_I-G_{II} diagram of the dry specimen at 30°C

failure are obvious. Except G_{Ic}, other points are basically in a straight line. Therefore, it can be determined that the delamination criteria of composite unidirectional plates in the dry state are straight lines. However, G_{Ic} is not on this straight line, which shows that there are inconsistencies between the calculation formula of pure type I and that of type I stratification in mixed stratification. In particular, the value of G_{Im} is larger than that of G_{Ic}. This is difficult to explain from the perspective of energy.

4.2. Durability Test. The relative strength of the composites after aging at 95°C and heat was 88%. However, the humid and hot environment will have a great impact on the resin matrix and interface. The change of the resin matrix or interface properties will change its failure mechanism and failure mode and affect the longitudinal tensile strength. For brittle resin or carbon fiber composites with a strong interface, the mild liquid and thermal environment can increase their longitudinal tensile strength. For the flexible resin or weak interface, the liquid and thermal environment will reduce the strength. It can be seen from Table 3 that liquid heat has little effect on the longitudinal strength and measurement of unidirectional composite carbon fiber. For unidirectional glass fiber composites, the tensile strength decreases significantly because the glass fiber is corroded by the liquid and thermal environment. The surface treatment of glass fiber and its combination with resin directly affect the effect of protecting glass fiber from water corrosion, which has a great impact on the tensile strength of glass fiber composites.

Because the warm and humid environment will lead to the softening of the resin matrix, when the resin matrix softens, its coefficient will be significantly reduced. This will significantly reduce the longitudinal compressive strength of unidirectional composites, and the performance will degenerate into nonlinearity. Under high temperature and humid-

ity, the compressive strength decreases, but the compressive strength under room temperature and humidity is basically unchanged. With the increase in temperature, the hygroscopicity increases, and the strength and coefficient decrease significantly. It can be seen from Table 3 that the longitudinal compressive strength of unidirectional composites at 120°C and 1.00% moisture absorption is 29.53% lower than that at 20°C and 0.50% moisture absorption. Due to the high moisture absorption of aramid fiber, the longitudinal compressive strength of unidirectional aramid composite fiber will be significantly reduced in the humid and warm environment [24, 25].

4.3. Accumulation of Mechanical Property Degradation. The hygroscopic environment of composites is constantly changing. When the hygroscopic environment conditions change, the hygroscopic characteristics of composites also change. The mechanical properties will further change on the basis of the influence of the previous wet and hot environment, and the changes in properties will accumulate. In this process, the mechanical properties of the material may be reduced or partially recovered under wet and hot conditions. As shown in Figure 9(a), the performance of the composite decreases after time Δt_1 in humid and hot environment 1. In the process of time Δt_2, the mechanical properties of the composites recovered due to the decrease in moisture absorption or the change in temperature.

As the hygroscopic characteristics of the materials will change after the change in the humid and hot environment, the change law of the mechanical properties of the composites will also change. Therefore, this paper adopts the equivalent of the performance degradation amount. As shown in Figure 9(b), it is assumed that the performance degradation amount of composite material after time Δt_1 is equal to the performance degradation amount after time t_{21} under humid and hot environment 1.

TABLE 3: Effect of damp-heat conditions on the resistance of composites.

Moisture absorption (%)	Temperature (%°C)	E_x (GPa)	E_y (GPa)	X' (MPa)	X (MPa)	Y (MPa)	Y' (MPa)	S (MPa)
0.50	-30	183	10.60	1510	1507	42	261	71
0.50	20	180	10.10	1490	1490	38	244	66

5. Discussion

Firstly, through the study of relevant knowledge points of literature works, this paper has preliminarily mastered the relevant basic knowledge. This paper analyzes how to study the interlaminar fracture toughness and durability of composites in the humid and hot environment. This paper expounds on the concept and related methods of interlaminar fracture toughness, explores the composites in the humid and hot environment, and analyzes the interlaminar fracture toughness and durability through experiments.

After absorbing water, the mechanical properties of polymer matrix composites will change. The mechanical properties of liquid will also change due to the change in moisture absorption. Generally speaking, the axial properties of unidirectional composites are not greatly affected by moisture absorption, while the transverse and shear properties of materials are reduced due to the influence of the liquid and thermal environment on the matrix and interface [26]. When the moisture absorption reaches saturation, the hydrodynamic properties of the composites also tend to have a constant value.

The experimental analysis shows that moisture absorption has no obvious effect on the breaking resistance of the material at room temperature. At high temperatures, moisture absorption will increase the dimensional hardness of the composites. The temperature has the least effect on the mixed dimension fracture hardness of the dry sample, and

the moisture absorption of the sample is relatively high. When the temperature is lower than 60°C, the hardness changes slightly. When the temperature is higher than 60°C, the hardness increases with the increase in temperature. Through the microfracture analysis, it is found that the single action of moisture absorption or high temperature makes the matrix toughness enhanced, and the fracture presents a ductile fracture morphology. The two work together to enhance the viscosity of the resin matrix.

6. Conclusion

Because polymers will age under the influence of external environmental factors, moisture and heat are the most important factors leading to the aging of composites. Therefore, the design and use departments in this paper pay special attention to the possible damage and mechanical properties of such composites in the humid and warm environment, which is an important guarantee and premise to promote their reasonable and effective implementation. The research on wet aging of composites is a research topic with theoretical and practical significance. Although some progress has been made, its important role in guiding practical engineering applications still needs to be further studied. The work of this paper is only a preliminary exploration, and there are still many topics that need further research.

With the development of aerobics, more and more college students participate in this sport, but more and more sports injuries of students. Sports injuries directly or indirectly affect the normal study and life of college students. Therefore, it is very important to study the sports injuries of college students and their causes for improving the sports level of college students and promoting their healthy growth. And it provides proper precautions. This paper presents the investigation of nanomaterials, deep learning, and MRI images of meniscal injuries and concludes that the injury rate of high-level competitive aerobics athletes is 100%, and the top 4 injured parts are the wrist, ankle, waist, and knee. It can be seen that the meniscus injury occurs more frequently.

1. Introduction

Physical exercise is the best way to enhance physical fitness and improve the quality of life. In particular, sports such as aerobics, which are full of passion and vitality, are more and more sought after by more and more people. Aerobics is a sport that integrates gymnastics, dance, and music; is based on aerobic exercise; and is characterized by health, strength, and beauty. It is not only a popular fitness method for body building and cultivating sentiment but also an item of competitive sports. However, the problem of sports injury caused by high-level aerobic exercise has become an important problem affecting the normal training of athletes. Therefore, it is very urgent to study the injury causes and preventive measures of high-level athletes.

With the improvement of the competitive level of competitive aerobics athletes, the functions and coordination of various organs and body systems have not only reached a high level but also approached the physiological limit. Although competitive aerobics is a non-Olympic event, the state's support is relatively weak and there is no dedicated team of doctors. Therefore, improving the injury prevention and control ability of high-level aerobics teams has important guiding significance.

The innovation of this paper lies in the application of nanomaterials to study the repairing effect of aerobics-induced meniscus injury, which has a certain clinical trial and innovation.

2. Related Work

The 21st century is an era of rapid progress in biological and medical research. Nanotechnology has a particularly obvious interdisciplinary nature. Many scholars have conducted research on nanotechnology. Yin et al. thoroughly characterized the Pt10 clusters through a combination of experimental techniques and theoretical analysis, showing the highest CO oxidation activity per platinum atom of CO oxidation catalysts, and this catalytic system presents a coherent interdisciplinary picture [1]. Shivakumar et al. verified by nearly unchanged PureB diode I–V characteristics and microscopic examination of the deposited layers. In order to obtain this result, it is required that the silicon surface must be cleaned before B deposition [2]. Here, Hu et al. introduced a new method based on two-dimensional electron resonance and thermal displacement measurements to measure the two-dimensional energy loss temperature of a sample by combining these measurements

with first-principle modeling [3]. Zhao et al. used a new model to analyze the hydrogenation kinetics of Mg-Ce-Ni nanocomposites during the synthesis process and established a hydrogenation reaction rate control mechanism in the range of 300-680 k [4]. Ross and Yamaguchi described the effect of mechanical properties and polishing tool structure on tool-target surface contact during polishing. In addition to abrasive type and size, this also affects polishing characteristics, especially material removal at grain boundaries, grain enhancement, grain displacement, and nanoscale geometry of the polished surface [5]. Nanoimprint lithography (NIL) is an emerging high-resolution parallel patterning method that targets areas where e-beam and high-end lithography are expensive and cannot provide sufficient resolution at reasonable throughput. Currently, structures with feature sizes smaller than 5 nm have been achieved, and the resolution is limited by the ability to make reliefs. For historical reasons, the term nanoimprint lithography refers to a thermal imprint process. In ultraviolet (UV) NIL, photopolymerizable resins are used with UV clear stamps. In both of these processes, film squeeze flow and capillary action play a central role in understanding the NIL process. Kam and Torres provided an overview of NIL, focusing on general principles and concepts rather than specific process issues and state-of-the-art tools and processes. They also discussed the material aspects of printing and resists. Kam and Torres gave some specific applications where the imprint method had significant advantages over other construction methods. Finally, areas where further development in this field is needed are discussed [6]. Recently, large plastic deformations have been observed in compressive tests of biotemplated, anisotropic, and hierarchically structured silica monoliths. Based on the nanoscale structure of the material, Opdenbosch and Zollfrank fabricated a dynamic model in which parallel silica struts are compressed and sheared longitudinally. The resulting interfacial shear forces lead to continuous plastic deformation during cyclic loading with a gradual increase in force, matching the observations from mechanical tests. Opdenbosch and Zollfrank report physical parameter values obtained by fitting model curves to measured curves, their relationship to previous structural observations, and their utility in tailoring the complex mechanical behavior of this novel material [7]. However, the shortcomings of these studies are that the model construction is not scientific enough and the conditions are limited to adapt to more complex situations.

3. Nanomaterials and Related Methods

3.1. Nanomaterials

3.1.1. Definition of Nanomaterials. Generally speaking, nanomaterials refer to materials whose size is between 1 and 100 nm. Because nanomaterials have nanoscale dimensions, their properties, such as physical, electrical, optical, and magnetic properties, are significantly different from conventional materials. Many nanomaterials are catalytic, adsorptive, and highly reactive [8].

3.1.2. Application of Nanomaterials. In the past few decades, nanomaterials have been extensively researched and developed, and have been successfully applied in the fields of catalysis, medicine, sensors, and biology. In particular, it has also received extensive attention in water treatment and wastewater treatment. Due to their small size, nanomaterials have a relatively large specific surface area, so they have strong adsorption capacity and reactivity, and the flow properties of nanomaterials in solutions are very high. It has been reported that heavy metals, organic pollutants, inorganic anions, and bacteria can be successfully removed by many kinds of nanomaterials [9]. Due to the unique size-dependent properties of nanomaterials, they have a profound impact on various application fields such as the construction industry, products of daily life, and medical and healthcare. Figure 1 is an overview of nanomedicine.

Nano antibacterial materials have attracted much attention due to their stable performance, good antibacterial effect, and low price. For example, nanotitanium oxide material has photocatalytic effect, which can decompose toxic gases such as formaldehyde and benzene, and kill bacteria on its surface. Nanoscale self-cleaning materials have great development space [10]. Nanomaterials also have many applications in catalysis. Catalysts play an important role in chemistry because they can increase reaction rates and shorten reaction times. Most of the traditional catalysts have low catalytic efficiency and difficult preparation, resulting in waste of raw materials, reducing economic benefits, and polluting the environment. Nanomaterials have many active sites, which can greatly improve the reaction rate, control the progress of the reaction, and even make the chemical reaction that could not be carried out smoothly [11].

Nanoparticles used as catalysts are as follows: (1) metal nanoparticles; (2) nanoparticles are supported on porous supports, which can further increase the selectivity of catalysts; and (3) compound nanoparticles. Due to its small size, high voltage, and low self-discharge rate, lithium batteries are widely used in portable electronic devices such as mobile phones, notebook computers, power tools, and electric vehicles

Nanomaterials are used in lithium electric energy to improve cycle life and can take place in some reactions that cannot occur in other materials and increase the rate of charge and discharge. At present, nanomaterials can be well used as contrast agents in medical imaging. The mechanism of nanobiomaterials to promote the repair of damaged tissue is shown in Figure 2 [12]. Nanoparticles are widely used in biomedicine and can be used as biochips, bioprobes, etc. New medicines require new means of drug delivery so that side effects can be reduced and better efficacy can be achieved. Nanotechnology drug delivery can deliver drugs directly to cells and to targeted tissues [13].

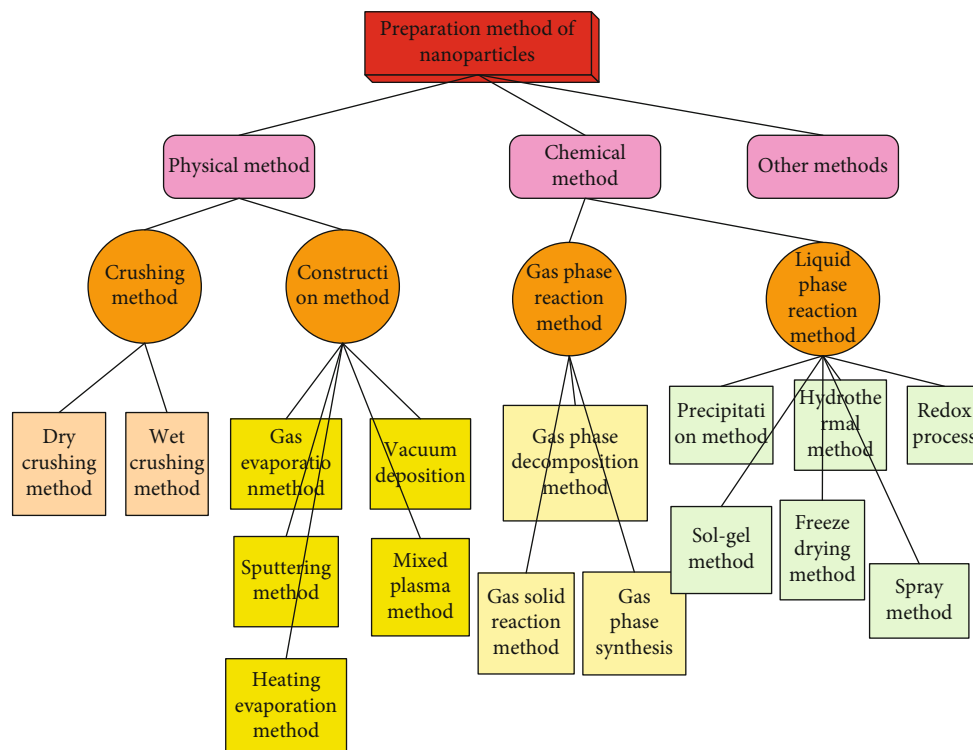
3.1.3. Synthesis of Nanomaterials. The preparation methods of nanomaterials can be roughly divided into physical methods, chemical methods, and other methods. Among
FIGURE 1: Overview of nanomedicine.
FIGURE 2: Mechanism of nanobiomaterials to promote the repair of damaged tissue.


FIGURE 3: Nanoparticle preparation method.

them, physical methods include the pulverization method, deposition method, and sputtering method. Chemical methods include the sol-gel method, precipitation method, evaporative solvent pyrolysis method, redox method, and solvothermal method. Figure 3 shows the nanoparticle preparation method [14].

3.1.4. Characterization of Nanomaterials. In order to explore the mysteries of the nanoworld, the structure and properties of nanoparticles must be characterized. The characterization of nanomaterials is the modern analysis and detection technology and related theoretical knowledge about particle composition, structure, morphology, etc. Usually, we obtain the composition, particle size, morphology, structure, and interface of nanoparticles by inductively coupled plasma emission spectroscopy, scanning electron microscopy, transmission electron microscopy, atomic force microscopy, X-ray diffraction, and X-ray photoelectron spectroscopy. The average particle size, particle size distribution, composition, and interface of nanomaterials all affect their physicochemical properties. Figure 4 shows the commonly used characterization methods for nanomaterials [15].

3.2. Overview of the Development of Finite Element Analysis Based on MRI

3.2.1. Medical Imaging Technology. With computer assistance, in order to complete the construction of accurate physical and geometric models of anatomical organs, how to accurately extract the information contained in images (CT, MRI) is the key to current computer-assisted surgical guidance and treatment [16].

3.2.2. MRI Nuclear Magnetic Resonance Imaging Technology. With the development of imaging and the continuous improvement of surgical methods, the choice of surgical treatment of breast cancer has also changed. The range of surgical indications has also expanded, but it is limited to accurate diagnosis and surgery. It has a better therapeutic effect and therefore has a more prominent clinical significance in MRI examinations [17]. Figure 5 is a meniscus segmentation device based on a magnetic resonance image, and Figure 6 is a process of obtaining a meniscus segmentation result from an MRI image.

3.3. Introduction of Deep Learning Based on the Repairing Effect of Meniscus Damage. Deep learning is a very popular method in machine learning, covering a wide range of theoretical perspectives. In order to achieve more intelligent human-computer interaction, researchers imitate the human brain and thinking and establish various neural network models; deep learning is one of them. Deep learning is a multilevel representation learning method, learning data features by creating models, and finding a better data representation is the primary purpose of representation learning, as shown in Figure 7 [18].

The processing method of deep learning is nonlinear, and the processed data can be speech, images, text, etc., which can be learned from low-level to high-level abstract features [19].

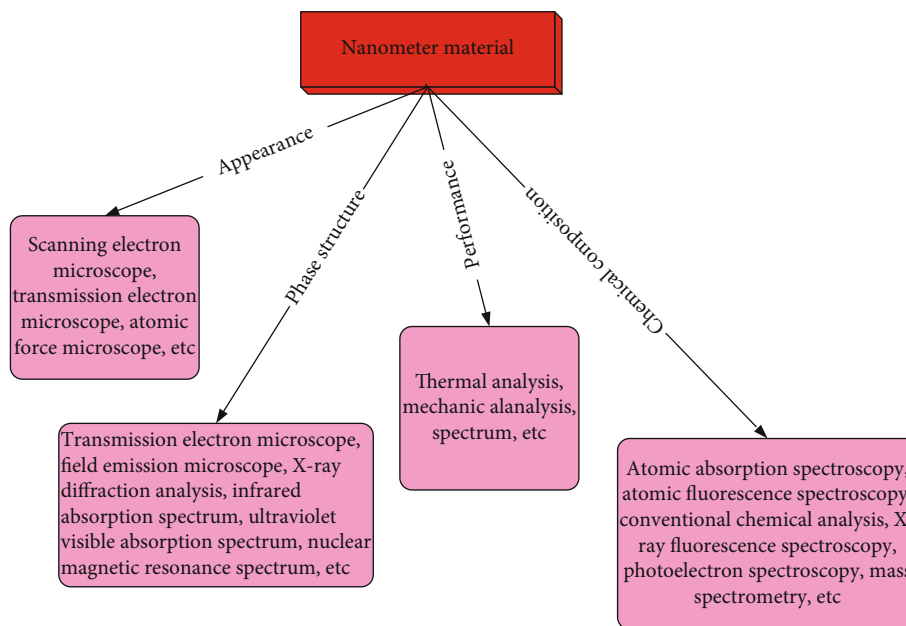
3.4. Supervised Deep Learning Algorithms. In regression analysis, it is subdivided into various types according to the number of independent variables, dependent variables,


Figure 4: Nanomaterial characterization techniques.
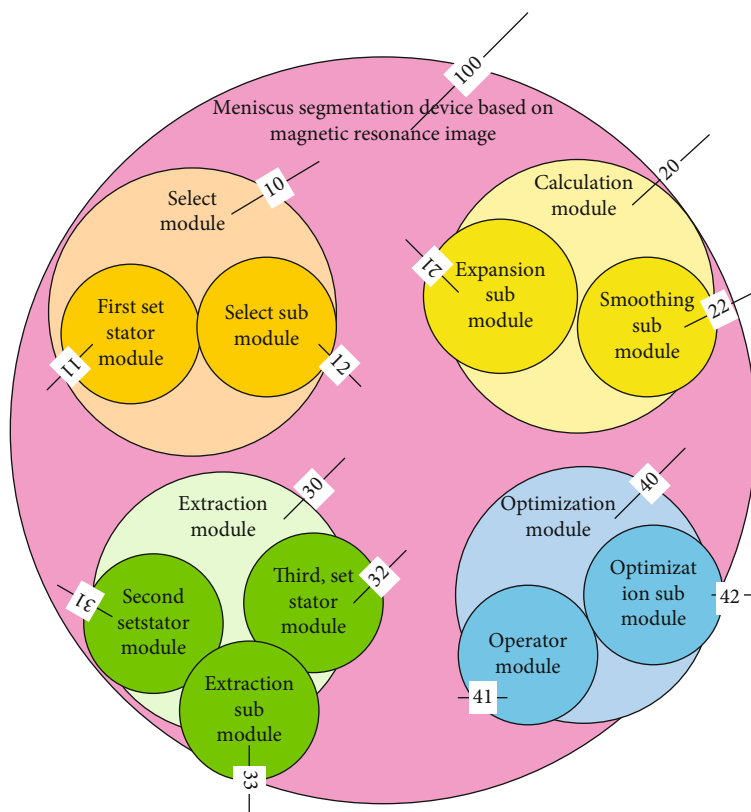

Figure 5: Meniscus segmentation device based on magnetic resonance images.
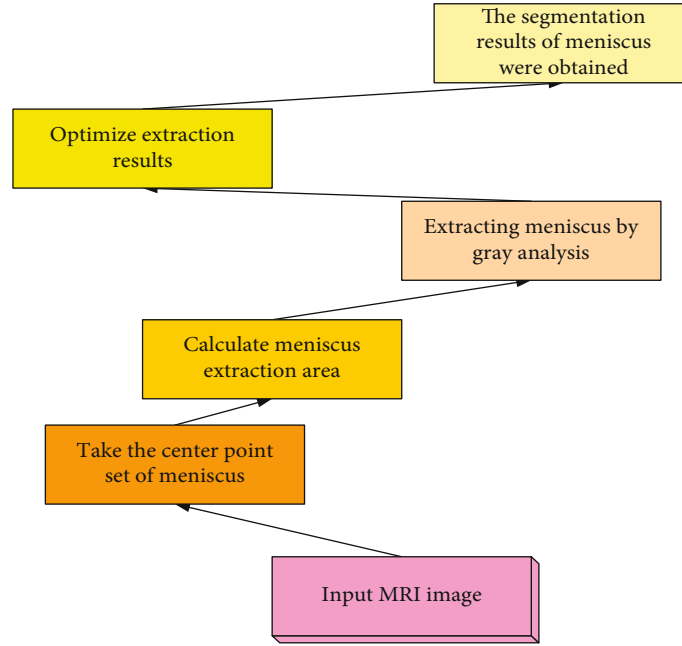

FIGURE 6: The process of obtaining meniscus segmentation results from MRI images.
FIGURE 7: Deep neural network.

and the relationship between them. Regression methods in classification include logistic regression (LR), Softmax as an LR model is generalized on multiclassification problems, and Softmax regression is often used as the final classifier

layer in supervised deep learning. The following is a detailed introduction from Softmax to convolutional neural networks [20].

3.4.1. Softmax Classifier. Before introducing Softmax regression, it is necessary to introduce logistic regression. Logistic regression is a simple binary classification algorithm that implements classification by fitting the classification boundaries of the data and uses optimization methods such as gradient descent to determine the best regression coefficients. One of the more important formulas in logistic regression is the step function: $Q(X) = 1/(1 + E^{-\theta^Z X})$; its waveform is as follows, the value range is $[0, 1]$ [21].

Its corresponding negative log-likelihood loss function is defined as

$$Q(\theta) = -\frac{1}{u}\left[\sum_{m=1}^{u} Y^m \log f_\theta(X^m) + (1 - Y^m) \log (1 - f_\theta(X^m))\right]. \tag{1}$$

LR is a special case of Softmax when dealing with binary problems. Two probabilities need to be solved in LR: $T(Y = 1|X; \theta)$ and $T(Y = 0|X; \theta)$. In Softmax regression, there are J probabilities, and its general function representation

$$T(i) = \frac{\exp\left(\theta_m^Z X\right)}{\sum_J^{J=1} \exp\left(\theta_m^Z X\right)}. \tag{2}$$

The negative log-likelihood loss function at this time is

$$Q(\theta) = -\frac{1}{u} \left[\sum_{m=1}^{u} \sum_{n=1}^{J} M\{Y^m = n\} \log \frac{E^{\theta_n^Z X^m}}{\sum_{l=1}^{J} E^{\theta_l^Z X^m}} \right], \quad (3)$$

where $M\{\bullet\}$ indicates that when its value is true and the result of the function is 1; otherwise, it is 0; then, the objective function is optimized by gradient descent [22].

3.4.2. Convolutional Neural Network. The convolutional neural network (CNN) is a kind of deep learning network structure, which is characterized by a large number of convolution operations in the network structure. In addition, activation functions and pooling layers are also its basic structures. These three basic structures make it have better local perception characteristics and feature abstraction ability than multilayer perceptron (MLP). At present, CNN has been widely used in many subdivisions of image processing and computer vision, such as image classification, image semantic segmentation, and visual object detection [23].

(1) Calculate the Output. For the l layer of the fully connected layer, the output is

$$\begin{cases} A^x = g(C^x), \\ C^x = T^x A^{x-1} + P. \end{cases} \quad (4)$$

Among them, T^x and P are the weights and biases, and $g(\bullet)$ is the sigmoid activation function, and the output range of this function is in $[0, 1]$. Assuming that d is the current sample number, the dth sample error is E^d:

$$E^d = \frac{1}{2} \sum_{k=1}^{l} \left(S_k^d - B_k^d \right)^2 = \frac{1}{2} \left\| S^d - B^d \right\|_2^2. \quad (5)$$

In the formula, S^d is the expected output value of the dth sample, and B^d is the actual output value of the dth sample after the network operation.

(2) Backpropagation. The data is calculated layer by layer through the network, and the error between the actual output and the expected output is obtained, which can be regarded as the sensitivity of the neuron base. The formula is

$$\frac{\partial E}{\partial P} = \frac{\partial E}{\partial C} \frac{\partial C}{\partial P}. \quad (6)$$

The formula for the sensitivity of layer x in the backpropagation stage is

$$\delta^s = \left(T^{x+1} \right)^S \delta^{x+1} \bullet g'(C^s). \quad (7)$$

The sensitivity of the output layer node is

$$\delta = g'(C^x) \bullet \left(B^d - S^d \right). \quad (8)$$

(3) Weight Update. The derivation of the error for the x layer weight of the fully connected layer is the cross product of the x layer input and its sensitivity. The weight update formula is

$$\frac{\partial E}{\partial T} = A^{x-1} (\delta^x)^S, \quad (9)$$

$$\Delta T^x = -\eta \frac{\partial E}{\partial T^x}. \quad (10)$$

The specific training process of the convolutional layer is as follows:

We input the data to the convolution layer for convolution calculation and get

$$A_n^x = g \left(\sum_{m \in W_n} A_m^{x-1} \bullet T_{mn}^x + P_n^x \right), \quad (11)$$

where T is the weight, P is the bias, and 1 is the set of input feature maps [24].

As shown in formula (17), it is shown that the computation is the gradient of the convolutional layer:

$$\delta_n^x = \beta_n^{x+1} \left(g'(C_n^x) \bullet \text{up}(\delta_n^{x+1}) \right), \quad (12)$$

where up($\bullet$) is the upsampling calculation.

Through the above calculation, the gradient of the given feature map was gotten. The following equation shows the gradient of the bias basis obtained by summing the sensitivity of the feature map nodes in the x layer:

$$\frac{\partial E}{\partial P_n} = \sum_{i,j} (\delta_n^s)_{ij}. \quad (13)$$

The gradient of the convolution kernel weights is calculated as follows:

$$\frac{\partial E}{\partial K_{mn}^x} = \text{rot180} \left(\text{conv2} \left(A_m^{x-1}, \text{rot180}(\delta_n^x), '\text{valid}' \right) \right). \quad (14)$$

The same is true when updating the weights and biases with the above formula.

The pooling sampling layer training process is as follows:

$$A_n^x = g \left(\beta_n^x \text{down} \left(A_n^{x-1} \right) + P_n^x \right). \quad (15)$$

Among them, down($\bullet$) is the pooling function and β and P represent the weight and bias, respectively.

The difficulty of the pooled sampling layer is also the calculation of the gradient. If the pooled sampling layer is followed by a fully connected layer, its sensitivity can be calculated by the BP algorithm; if the pooled sampling layer is

followed by a convolutional layer, the sensitivity meter calculation formula is

$$\delta_n^x = g'(C_n^x) \bullet \text{conv2}\left(\delta_n^{x+1}, \text{rot180}(K_n^{x+1}), 'full'\right). \quad (16)$$

The calculation process of the bias in the pooled sampling layer is the same as that in the convolutional layer, but the calculation formula of the weight β is as follows:

$$\frac{\partial E}{\partial P_n} = \sum_{i,j} (\delta_n^x \bullet f_n^x)_{ij}. \quad (17)$$

In the formula,

$$f_n^x = \text{down}(A_n^{x-1}). \quad (18)$$

Finally, the weights are updated by formulas (17) and (18).

3.5. Knee MRI and Meniscus Characteristics. In recent years, deep learning has made breakthroughs, and its application in the field of data analysis has grown rapidly. At present, deep learning has become the main application tool of machine learning in the field of image recognition and computer vision. In the biomedical field, deep learning is rapidly becoming the state-of-the-art in computer-aided diagnosis, resulting in increasing diagnostic accuracy. In the field of medical images, deep learning methods are applied everywhere from lesion detection, image segmentation, image registration to classification.

The meniscus is an important part of the knee joint and is a soft tissue structure, as shown in Figure 8. It consists of two crescent-shaped structures, which are located between the femur and the tibia and play a role in joint cushioning. The one near the inside of the knee joint in the leg is called the medial meniscus and has a larger opening that resembles a crescent; closer to the outside is the lateral meniscus, which has a smaller opening and is a crescent close to the full moon, which is wrapped in the middle by the medial meniscus. The sharp corners on the front side are called front corners, and the rear corners are called rear corners. At the knee joint, the femur, tibia, and meniscus are surrounded by peripheral ligament connections, one part is connected at the angle of the meniscus, and one end is on the leg bone. Its structure is relatively complex. If it is not presented in the form of a section, the meniscus is wrapped in it, making it difficult to observe.

4. Repair Experiment and Analysis of Nanomaterials on Meniscus Injury Caused by Calisthenics Exercise

4.1. Information on Meniscal Injury

4.1.1. Cause

(1) Traumatic injury: when the knee is in flexion, the medial and lateral menisci can move forward and backward with the femur due to rotation. When this paradoxical movement is outside the normal range, a tear of the meniscus can occur [25]

(2) Degenerative injury: due to age and exercise factors, such as excessive walking, it may cause frequent stimulation of the meniscus and frictional loads beyond the normal physiological range. As a result, the pathological changes such as tissue degeneration and minor damage of the meniscus are gradually aggravated to the degree of tearing

4.1.2. Clinical Manifestations

(1) Pain

Severe pain occurs immediately after trauma. The pain is worse with activity, but not as severe as before.

(2) Swelling

At the time of the injury or a few hours after the injury, the knee joint may swell and sometimes bruise under the skin.

(3) Sound

There is a sound in the knee joint during activities, which is mostly caused by the abnormal friction and bounce of the ruptured meniscus with the tibia and femur when the knee joint is active.

(4) Interlock phenomenon

During the extension and flexion activities of the knee joint, there is often a phenomenon of sudden "stuck" resulting in the inability to extend and flex the knee joint, which is called interlocking phenomenon.

4.1.3. Check

(1) MRI

MRI, the imaging method of choice for detection of meniscal injuries, also observes the condition of the collateral and cruciate ligaments. The nature of the pain can be

(a) Front view of the knee joint

(b) Top view of the meniscus
FIGURE 8: Schematic diagram of the structure of the knee joint and meniscus.

tugging, tearing, or colic-like persistent pain, and the pain range occurs on the side of the injury. Over time, the pain will gradually reduce and focus on the local area.

(2) McFarland's sign test

It has a high reference value for diagnosis. Subcutaneous congestion is the result of bleeding due to ligament damage.

(3) Extrusion test

When the knee is nearly straight, passively abduct or adduct the calf to squeeze the torn meniscus and cause pain.

(4) Arthroscopy

This is the basis for the final diagnosis. When the knee joint is actively or passively moved, this phenomenon can be relieved by itself, and the activity returns to normal. There are also cases where the interlock does not recover and the joint is permanently unable to straighten and flex.

4.2. Characteristics and Analysis of Injury Rate of High-Level Competitive Aerobics Athletes. In this survey, "a specific time" is the moment of filling out the survey form as the end of time and 12 months from this. In this paper, according to the research needs, the statistical number of sports injuries is limited to the frequency of injuries in the last year after the athlete achieved the corresponding level. Considering that the time continuity and cumulative effect of chronic injury will have a great impact on the statistical effect, therefore, the chronic injury is only counted once for the injury nature column in the questionnaire, and the sum of the actual numbers for acute injury is calculated. Statistics show that the injury rate of high-level competitive aerobics athletes is 100%. This shows that the investigators have suffered from sports injuries in the past year. Table 1 was prepared based on the frequency distribution data of the incidence frequency obtained by the questionnaire.

It can be seen from Table 1 that with the improvement of the level and the length of training years, the number of inju-

ries will gradually increase. In the early stage of high level, there may be about 3 injuries, but in the later stage of high level, the number of injuries is mainly 6 or more. It can be seen that injuries are a common occurrence for high-level athletes and must be experienced all the time. Injuries seem to be an unavoidable problem associated with high-intensity training and daily high-intensity training as skill levels improve and develop.

It can be seen from Figure 9 that the most frequently treated parts of the national team are the waist, knee, and wrist, followed by the shoulder, hip, ankle, elbow, and back. Among them, most of the waist is lumbar muscle strain, and microwave or thermal magnetic therapy is often used for physiotherapy. Most of the back is fatigued after training. All athletes who perform back treatment use low-frequency electrical stimulation and relaxation instruments, which are equivalent to electrotherapy massage. Both the knee and the wrist belong to joints, and their injury prevention measures are very similar, so the knee joint is used as the representative to discuss. Actions of competitive aerobics jumps, body jumps, flexion and split jumps, twists, high kicks, Ilyushin, Kossack jumps, side split jumps, exchange jumps, scissor kicks, scissor jumps, etc. have a strong impact on the knees. This can easily cause knee pain, swelling, flexion and extension disorders, etc., and then atrophy of the quadriceps femoris and imbalance of the thigh and calf muscles. To prevent the disease from worsening in the case of uninterrupted training, it can be strengthened to prevent from the following aspects:

(1) The use of sports protective support belt can effectively prevent the aggravation of injury

(2) They should perform functional exercises, including strength, flexibility, motor sensory, and proprioceptive training. Flexibility has high requirements in competitive aerobics. Special functional exercises can not only prevent injuries but also improve sports performance, killing two birds with one stone. The common way is PNF exercises, specifically participating in primary prevention. The exercise of

TABLE 1: Incidence frequency of high-level competitive aerobics athletes in China in the past year.

Sport level frequency	1-2 times	3-5 times	≥6 times
National level	40%	37%	23%
National master	20%	38%	42%
International master	10%	12%	78%

TABLE 2: Comparison of age, height, and weight between healthy group and patients.

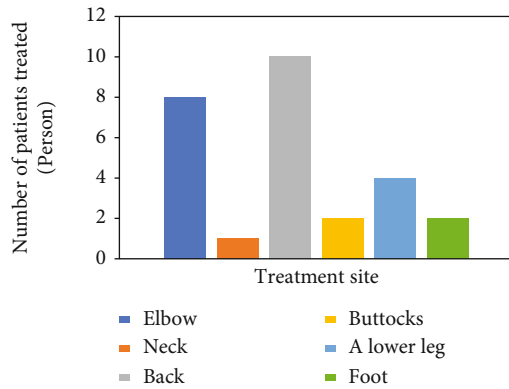
Group	Health group	Patient group	Inspection value	P value
Number of cases	20	20		
Age	30.52 ± 5.33	32.52 ± 5.02	-1.592	0.110
Weight	74.38 ± 14.08	73.18 ± 11.69	0.422	0.680
Height	176.02 ± 5.84	174.89 ± 3.88	1.240	0.226


FIGURE 9: Distribution map of treatment sites for aerobics national training team during 2020\11-2021\11. Note: the statistics take one month as a small unit. If someone has performed multiple treatments on the same part within a month, it will be counted only once. However, the same parts of the same object in different months of the 12-month period are accumulated on the basis of the above. Such statistics not only reduce the interference of the injury healing process on the overall injury characteristics but also reduce the interference of the individual injury characteristics of the same subject with multiple treatments on the overall injury characteristics.

balance ability can greatly improve the neuromuscular control ability of the body and promote the coordination and stability of the body. The recovery of the athlete's balance ability and proprioceptive control ability is the key to reducing the risk of reinjury. Balance pads, active boards, and other balance exercise equipment can be used to enhance limb stability. The trampoline exercise used by the national aerobics training team is actually a functional exercise to enhance the sense of movement and proprioceptive training

(3) Physiotherapy. Any injury has the ability to repair itself, but research shows that the biochemical composition of tissue repaired by itself is different from that of uninjured tissue. Therefore, active stimulation by external means is helpful for the recovery of structure and function and also helps to improve the ability to respond to exercise and prevent the occurrence of injury. The commonly used physiotherapy methods for chronic knee injuries include microwave therapy, thermomagnetic therapy, ultrashort wave therapy, and ultrasonic therapy. Among them, ultrasound is mainly used for the removal of

scar tissue and adhesions. The efficacy of microwave, thermomagnetic, and ultrashort mainly lies in the deep penetration of thermal effect, which can focus on promoting blood circulation in the affected area and promoting damage repair. During the treatment of the national team members, a total of 9 people have used the above methods, of which 7 people showed significant improvement, and continued to maintain a large amount of exercise training without any suspension of training. To sum up, the overall tertiary prevention of injuries for high-level athletes can enable athletes to fully and actively deal with sports injuries that accompany the improvement of competition, which is conducive to improving the body's ability to withstand high-intensity training, resulting in a good training adaptation

4.3. Comparison of Gender, Age, and Weight of Patients. Table 2 shows that the age comparison between the healthy group and the patient group was not statistically significant ($T = -1592$, $P = 0.110 > 0.05$); there was no statistical significance in height ($T = 1.240$, $P = 0.226 > 0.05$) and no statistical significance in weight ($T = 0.4226$, $P = 0.680 > 0.05$).

Table 3 shows the comprehensive score comparison made by the back-end algorithm layer of the Internet cloud of the foot space posture evaluation and analysis system based on all the gait data of the testee's feet within one minute. It is mainly assessed from four aspects: gait stability, bipedal symmetry, initiation ability, and deceleration ability. The results show that

(1) In patients with unilateral meniscus injury, the stability, symmetry, and starting ability of gait before surgery were significantly lower than those of the healthy group and the gait data obtained after surgery, which indicates that meniscus injury has a significant impact on gait stability, symmetry, and startup ability. Factors such as uneven force on both lower extremities and the patient's own fear caused by factors such as knee instability, knee flexor muscle weakness, and pain in the affected limb after meniscus injury were considered

(2) There was no statistical difference in the stability, symmetry, and starting ability of the gait after surgery and the healthy group, indicating that the comprehensive evaluation of the gait after meniscus

TABLE 3: Comparison of gait comprehensive score between the healthy group and patient group.

Group	Health group	Patients before operation	Postoperative patients	F value	P value
Stability	98.67 ± 0.68	95.01 ± 1.56	98.70 ± 0.69	145.99	<0.01
Symmetry	95.60 ± 2.78	91.29 ± 3.61	95.29 ± 2.89	19.91	<0.01
Starting ability	89.05 ± 5.66	76.61 ± 4.41	88.11 ± 3.21	66.55	<0.01
Deceleration capacity	88.77 ± 5.78	84.99 ± 5.88	86.55 ± 5.01	1.24	0.28

surgery was close to the normal gait, the kinematic data was generally normal, and the surgical effect was more reliable

(3) There was no statistical difference in the deceleration ability between the patients before and after surgery and the healthy group, which may be related to the lower requirements of knee joint stability and muscle strength for gait deceleration exercise. It cannot be ruled out that the result error is caused by the small number of times of reentry and the large error of deceleration movement data collection in this experiment

5. Discussion

The research on sports injuries in advanced aerobics is a step that cannot be ignored in the scientific development of aerobics. At present, with the rapid development of science and technology, people are no longer satisfied with using "sports performance" as an index to evaluate the effect of training but pay more attention to evaluating the effect of training, that is, the relationship between the input and output of training.

Nanomedicine is also a promising drug, as it is not easily absorbed by the human body when prepared in nanopowder or suspension. Nanomedicine is pasted on the affected area and can be absorbed directly through the skin without injection. But in aerobics, strength quality is a very critical link, so it is necessary to have excellent strength quality.

During training, athletes continue to work hard to achieve better results and keep crossing borders. To break themselves, they cause multiple sports injuries. How to improve the effective prevention of aerobic injury has become a major problem faced by coaches and athletes. At present, the clinically preferred treatment for meniscal injury is arthroscopic surgery, which can well complete the trimming and shaping of the damaged meniscus. It can eliminate the pain, noose, joint instability, and other symptoms caused by meniscus injury and significantly improve the function of the knee joint.

6. Conclusions

This study found that the loss of postoperative muscle strength of the affected limb had a significant impact on postoperative gait. Postoperative muscle strength of the affected limb, especially the decrease of knee flexor muscle strength and postoperative pain are the two main causes of

postoperative gait abnormalities in patients with meniscus injury. Another study has shown that muscle tension can be improved by exercising the muscle strength around the knee joint. The release of fascial adhesions has great benefits and is helpful for improving joint stability and internal circulation. Combined with the above data, patients with meniscus injury should be given appropriate lower extremity functional exercises after surgery to improve the muscle strength around the joints. It should be an equally important measure to eliminate postoperative pain, edema and other conventional treatments.

Force-Electric Coupling of Nanoscale Ferroelectric Domains Based on Piezoelectric Force Microscopy (PFM)

Xusheng Wang [ID] **and Chenchen Feng**

Xi'an University of Technology, Xi'an, 710048 Shaanxi, China

Correspondence should be addressed to Xusheng Wang; xswang@xaut.edu.cn

Piezoelectric and ferroelectric materials are widely used in various types of microelectronics due to their excellent mechanical and electrical coupling characteristics. In recent years, piezoelectric force microscopy has developed into a powerful tool for analyzing nanoscale ferroelectric materials. However, quantitative analysis based on PFM is difficult to properly study it. This article studies the related issues of PFM quantitative analysis. First, the relationship between the effective piezoelectric coefficient and piezoelectric coefficient of different materials is analyzed from the PFM nanometer scale to analyze the force-electric coupling effect. The study found that the effective piezoelectric coefficient is closely related to the intrinsic electroelastic constant of the material. Secondly, the analysis of the nanoscale piezoelectric deformation of ferroelectric materials shows that under the conductive SPM probe, as the clustering with the probe increases, the in-plane displacement first increases and then decreases, and the out-of-plane displacement gradually decreases. Finally, the half-width region of the nanoscale ferroelectric response domain was analyzed by PFM. Taking the in-plane and out-of-plane domains of 180° and 90° domains as examples, the relationship between the response boundary domain and the tip radius was analyzed, and the results showed that whether the PFM can effectively solve the problem of detection and analysis depends on the half-width of the response boundary domain, and the resolution of the vertical PFM is higher than that of the lateral PFM.

1. Introduction

Because PFM has the ability to be highly sensitive to the local detection of piezoelectric sensors, PFM has been widely used to study the microstructure and properties of new ferroelectric materials. By using PFM nanoscale detectors to perform image scanning on ferroelectric materials, not only can the domain structure signal be grasped more efficiently, but also special iron structure domains can be established, and the changes related to the performance of the brake can be studied. In some materials containing more iron elements, because ferroelectric domains and ferromagnetic domains are closely connected, it is important to process iron and manipulate the iron domains through PFM. However, due to the unbalanced characteristics of the electric field, the high-load electric field caused by the PFM conductive probe, and the complex and long-term electromechanical interaction between the test materials, the quantitative

analysis of the PFM test is still very difficult. Nanoscale electromagnetic coupling hinders the research of ferroelectric materials and delays the development of electronic components produced by nanoscale electromagnetic coupling.

Many scholars at home and abroad have studied the analysis of the electromechanical coupling of nanoscale ferroelectric domains based on piezoelectric force microscopy (PFM) and have achieved certain research results. For example, Chen et al. proposed functional materials, which refer to the continuous or gradual change of single or multiple superimposed properties of materials in a certain direction, which are used to adapt to different environments and develop distinctive functional materials. As the material parameters of functional materials gradually change, the thermal and stress mismatch in the material structure is greatly alleviated. The size and spatial distribution of all constituent materials are optimized, so that the advantages of all constituent materials can be effectively used, and the most advanced materials'

needs for multifunctional technology can be met [1]. But the complex structure of ferroelectric materials can affect the PFM technique to analyze the electromechanical coupling effect. After comparing and analyzing several separate models, Kuerban et al. finally decided to adopt a combined forecasting model. Combined forecasting is the weighted average of forecasts obtained by different forecasting methods to reach the final forecast result. The forecast result is generally better than that the prediction results of each single model are an effective way to improve the prediction accuracy of the model, and the results are more reliable [2]. Xing and other scholars combined the comprehensive load statistics of the formatting module and the overall module load of the module to carry out applied research on the power load and carried out the composite model characteristics, influencing factors and evaluation indicators of the power load indicators of the subindustry of my country's power system. According to the time-sharing principle, a load composition model for different industries is proposed. According to the characteristics of short-term load forecasting and combined with domestic and foreign engineering experience, various solutions to the load forecasting problem are comprehensively analyzed [3]. In the 1940s, a scientific researcher discovered a piezoelectric ceramic material with excellent performance and easy to make and store. This material can change the chemical composition and polarization phenomenon in a targeted manner. According to its advantages in piezoelectric coefficient, electrical coupling coefficient, and stable performance, the application of piezoelectric ceramics has been rapidly expanded [4]. Capeli et al. conducted a tip crack fracture experiment on single crystal niobium. This experiment observes and examines the morphological characteristics of interface cracks and further measures the fracture hardness and atomic separation requirements. This experiment finally showed that although niobium is a flexible material and has many variants, the cracks at the interface of the two materials remain as sharp atomic cracks, and no extreme cracks will appear [5]. Although researchers have carried out a lot of related work in this area, quantitative analysis based on PFM will encounter many difficulties, that is, the complex structure of ferroelectric materials will affect the PFM technology to analyze the effect of force-electric coupling.

This article introduces the characteristics of piezoelectric and ferroelectric materials and analyzes the relationship between the effective piezoelectric coefficient and the piezoelectric coefficient of different piezoelectric materials under the decoupling and full coupling methods based on the working principle of PFM; comparing the effective piezoelectric coefficients of different materials under decoupling and full coupling, comparing the time-induced in-plane and out-of-plane displacement responses of single-domain ferroelectrics with PFM detection. Then, take PZT-4 as an example according to the genetic algorithm optimization; the piezoelectric coefficient is inversely optimized to obtain the optimal piezoelectric coefficient; then, the single-domain and complex ferroelectric domain nanoscale piezoelectric deformation are analyzed, and finally, the $BaTiO_3$ ceramic piezoelectric ceramic material is used as an example

to analyze the half-width of the domain boundary response of the in-plane and out-of-plane domains of 180 degrees and 90 degrees varies with the radius of the tip. Through these experiments, it can be known that PFM technology is an important nanoscale ferroelectric material analysis tool in the study of ferroelectric domains.

2. Introduction of Piezoelectric Force Microscopy and Performance Analysis of Ferroelectric Domain Materials

2.1. PFM Working Principle. When a ferroelectric crystal exerts a mechanical force in a certain direction, confinement charges are formed on the corresponding crystal surface. The amount of charge is related to the amount of mechanical stress applied. This phenomenon is called the positive piezoelectric effect. On the other hand, if an external electric field is applied to the ferroelectric crystal, the ferroelectric crystal will also deform, which is called the piezoelectric inverse effect. PFM is a novel scanning probe microscope (SPM) based on the inverse piezoelectric effect of ferroelectric samples. Its working principle diagram is shown in Figure 1.

As shown in Figure 1, during PFM operation, an alternating voltage was applied to the SPM conductive probe to generate an electric field between the conductive probe and the bottom electrode. According to the inverse piezoelectric effect, the detection sample changes its shape under the action of an electric field, causing the material surface to displace, thereby pushing the cantilever beam to twist. The twist signal is reflected from the laser to the spectral detector and then sent to the amplifier lock. Computer-generated PFM signals include signal amplitude and phase signals. The amplitude depends on the local mechanical and electrical coupling of the sample, and the phase is related to the internal polarization direction. In the multisample power tracking detection experiment, regions with different polarization directions have different degrees of electric field, which triggers the conduction effect of the probe, so that the piezoelectric images show different response resolutions. On the other hand, the feedback signal determines the distance between the probe and the specimen, so the interaction force between the probe and the model remains constant. At this time, special specimens can be developed according to the size of the specimens [6, 7].

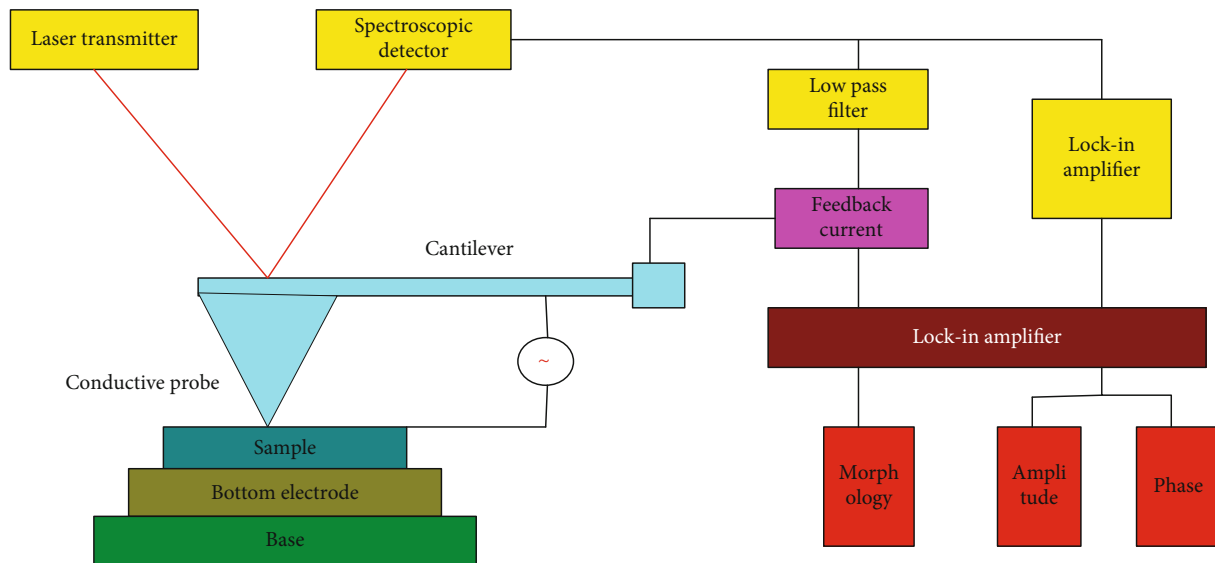
2.2. Characteristics and Applications of Piezoelectric and Ferroelectric Materials. Piezoelectric material is a special type of intermediate electrical material. Due to its piezoelectric properties, it can identify the conversion between electricity and electricity. This conversion will produce changes under external loads such as mechanical force, electric field, temperature field, and light, thereby having piezoelectric, ferroelectric, pyroelectric, and nonlinear optical characteristics. When the electric domain changes the electric structure under the action of the medium thermal field, the electric heat generated by the ferroelectric material can provide the ferroelectric material for the infrared detector; when the applied stress field changes, the electric domain structure will also change, and the ferroelectric material will produce


FIGURE 1: Working principle diagram of piezoelectric force microscope.

the piezoelectric effect which makes the application of ferroelectric materials in sensors and energy maps have a variety of research types. The polarization and conversion of the ferroelectric crystal produce a typical hysteresis model with the change of the applied electric field, which has the characteristics of the reverse polarization electric field and can be applied to the ferroelectric memory. The discovery of these properties has led to the production of ferroelectric materials in various microelectronic components, such as thermal elements and electrical transducers [8].

The positive piezoelectricity of piezoelectric materials is simply the ability to convert force into electricity. Specifically, it refers to the internal polarization when the external force is increased in a certain direction by the special structure of the dielectric material, which causes the material structure to deform. At this time, positive and negative charges are generated on the two opposite surfaces. The other is the inverted piezoelectric effect, in layman's terms, it converts electricity into a force that causes deformation. When the electric field is removed, the deformation of the dielectric will return to its original shape [9]. Therefore, the polarization direction of piezoelectric materials is also a very important research part.

Since the polarization phenomenon can occur in the ferroelectric material itself, and the ferroelectric material usually exists in multiple regions, each region has the same polarization direction. The regions with uniform polarization directions are called electrical domains, and the boundaries between domains are called wall domains. Generally speaking, each domain has an "end-to-end" polarity, so that there is no constrained charge at the boundary between domains, and the electrostatic energy in the boundary area is not reduced. The introduction of domains reduces the energy and electrostatic energy of the system, but introduces the energy of the wall domains, making the ferroelectric structure correspond to the minimum static energy in the

system [10, 11]. Since the center of the positive and negative charges does not enter the ferroelectric material, the relative arrangement of the positive and negative charges changes under the change of the external thermal field, causing spontaneous changes in polarization. The charge filtered by the surface of the ferroelectric material cannot maintain complete free movement on the road surface and the accumulated material, thereby generating a potential difference between the surface of the ferroelectric material and the surface of the material. This phenomenon is called the thermoelectric effect. Since all four sides of the material are heated at the same time, the positive and negative center displacements of the corresponding symmetry are the same, which is different from the piezoelectric effect. It shows that pyroelectric materials must have a greater range and spontaneous polarity, so pyroelectric materials have piezoelectricity. Driven by an electric field with a strong optical frequency or a DC electric field, ferroelectric materials will produce photoelectric effects and nonlinear optical effects. The refractive index of the ferroelectric material changes with the change of the additional charge, and the secondary fiber effect is generated with the regular change of the electric field. The secondary electro-optic effect refers to the birefringence of the isotropic material under the action of an external electric field, resulting in a change in the refractive index, and the change in the refractive index is proportional to the square of the electric field intensity. The material with central symmetry has no primary electrostatic effect, and the secondary fiber effect is very common in any dielectric material. The refractive index change is not only related to the external electric field but also the refractive index of the ferroelectric material can be changed by increasing the mechanical force. High-energy light is the source point light that radiates ferroelectric materials, generating bipolar electric pulses that can be driven by electromagnetic waves of a certain frequency.

2.3. Point Charge and Its Electric Field. In the PFM test, the SPM conductive probe is similar to a moving electrode [12]. By adding a certain voltage to the SPM conductive probe, a nonuniform electric field is induced in the virtual electric field space. Compared with the test sample, the SPM probe is very small, and the tip size can reach the nanometer level. By comparing the different shapes and thicknesses of the SPM probe and the test sample, people can regard the electric field caused by the SPM probe as an electric field caused by a point charge or a series of mirror charges, where the equivalent charge can also be used the equivalent capacitance between the SPM probe, and the sample is judged [13, 14]. The SPM conductive probes used in the experiment have different shapes, but mainly include conical, spherical, and disc shapes.

During the working process of PFM, a quantitative voltage is applied to the SPM probe, and an electric field probe is introduced. Compared with the SPM probe, the test material can be considered as a semi-infinite body. Therefore, the spatial electric field shaped by the conductive probe can be equal to the electric field induced by a point charge. According to the charge imaging method, it can be assumed that there is a mirror charge Q above the test sample from the sample surface. It can be seen from the singularity theorem of the mirror image method that the introduced image charge is outside the required field, and its introduction does not change the boundary conditions of the required field. Therefore, we can use the electric field generated by the charge Q to balance the space electric field shaped by the SPM probe, thereby simulating the distribution of the space electric field [15].

During PFM operation, a quantitative voltage is applied to the SPM probe, and an electric field probe is introduced. Compared to the SPM probe, the test material can be regarded as a semi-infinite body. Therefore, the space electric field created by the conductive probe can be equal to the electric field induced by the point charge. According to the charge imaging method, the charge imaging technique refers to the method of monitoring the calcium ion concentration in the tissue using a calcium ion indicator. In nervous system research, calcium ion imaging technol-ogy is commonly used to monitor the changes of calcium ions in neurons, indicating neuronal activity. With calcium imaging technology, the originally silent electrophysiological activity has become a vivid, colorful, and flickering spectacular image. It can be assumed that, viewed from the sample surface, there is an image charge Q above the test sample. It can be seen from the singularity theorem of the mirror image method that the introduced image charge is outside the required field, and its introduction does not change the boundary conditions of the required field. Therefore, we can use the electric field generated by the charge Q to balance the space electric field formed by the SPM probe, thereby simulating the distribution of the space electric field [15].

2.4. The Electroelastic Field Method between the Conductive Tip and the Sample

(1) Decoupling method

The essential idea of the force electrolytic coupling method is to separate the electrostatic field and the elastic electric field and evaluate them separately. The specific ideas are as follows: first, the finite electrostatic field model is used to calculate the internal piezoelectric electric field distribution of piezoelectric materials without considering the influence of the force-electric coupling; second, the internal pressure is considered to be the pressure generated by the electric field, so elasticity and stress can be solved by the rebound relationship; finally, the Green's function of the decoupling of the ferroelectric surface is used to obtain the piezoelectric displacement on the surface of the ferroelectric material. For the balanced distribution of ferroelectric materials detected by the SPM conductive probe, assuming that its polarization direction is perpendicular to the horizontal direction, the SPM conductive probe can be treated as a loading point for loading Q, where h is the height from the sample surface [8]. Using the loading image method, the potential $\varphi(\rho, z)$ distribution of the entire space can be obtained.

$$\varphi(\rho, x_3) = \begin{cases} \dfrac{Q}{2\pi\lambda_0(k+1)\sqrt{\rho^2 + (x_3 + h)^2}}, & x_3 \geq 0, \\[4mm] \dfrac{Q}{4\pi\lambda_0}\left[\dfrac{1}{\sqrt{\rho^2 + (x_3 + h)^2}} - \dfrac{k-1}{k+1}\dfrac{1}{\sqrt{\rho^2 + (x_3 - h)^2}}\right], & x_3 < 0. \end{cases} \tag{1}$$

Among them, $\rho = \sqrt{x_1^2 + x_2^2}$ and λ_0 are the vacuum permittivity, $k = \sqrt{\lambda_{11}\lambda_{33}}$ is the effective pressure permittivity, $\gamma = \sqrt{\lambda_{33}/\lambda_{11}}$ is the dielectric anisotropy factor, which reflects the difference between in-plane and out-of-plane dielectric properties, and x_1 represents the horizontal direction in the three-dimensional coordinate axis. In the right direction, x_3 represents the vertical downward direction, and x_2 is perpendicular to x_1 and x_3, respectively. The electric field is the gradient of the electric potential, namely,

$$E_i = \frac{-\partial \varphi}{\partial x_i}. \tag{2}$$

Assuming that the voltage applied to the needle tip is φ_o and the radius of curvature of the needle tip is R_o, the effective point charge model shows:

$$Q = \frac{2\pi \lambda_o R_o \varphi_o (k+1)}{k}, \tag{3}$$

$$d = \frac{R_o}{k}. \tag{4}$$

The charged probe causes an electric field to form inside the piezoelectric material, and the piezoelectric material produces strain under the action of the electric field due to the inverse piezoelectric effect. This piezoelectric accessory can be seen as an internal filter, namely,

$$s_{mn}^T = d_{mnk} E_k. \tag{5}$$

Among them, d_{mnk} is the piezoelectric tensor component on the three-dimensional image, and the repetition index k ($k = 1, 2, 3$) satisfies the weighted summation. Because piezoelectric tension destroys the dynamic equilibrium state of the system, internal stress e_{mn} and stress σ_{jl} are generated:

$$e_{mn} = s_{mn} - s_{mn}^T, \tag{6}$$

$$\sigma_{jl} = C_{jlmn} \left(s_{mn} - s_{mn}^T \right). \tag{7}$$

Among them, C_{jlmn} is the stiffness sensor component of the elastic component. By comparing the displacements of piezoelectric and elastic structures and introducing half-space elastic Green's function $G_{ij}(x, x')$, the surface displacement of the material can be obtained as:

$$u_i(x) = \int_0^\infty dx_3' \int_{-\infty}^\infty dx_2' \int_{-\infty}^\infty dx_1' C_{jlmn} d_{mnk} E_k\left(x'\right) \frac{\partial G_{ij}\left(x, x'\right)}{\partial x_l'}. \tag{8}$$

For a uniform ferroelectric material and the polarization orientation are perpendicular to the surface of the material, the Fourier transform can be used to solve the surface displacement to obtain the analytical form of the surface in-plane and out-of-plane displacement:

$$u_1(\rho, 0) = \frac{Q}{2\pi \lambda_o (k+1)} x_1 \frac{[d_1 g_1(\gamma) + d_2 g_2(\gamma) + d_3 g_3(\gamma)]}{\sqrt{\rho^2 + h^2} \left(\sqrt{\rho^2 + h^2} + h \right)}, \tag{9}$$

$$u_2(\rho, 0) = \frac{Q}{2\pi \lambda_o (k+1)} x_2 \frac{[d_1 g_1(\gamma) + d_2 g_2(\gamma) + d_3 g_3(\gamma)]}{\sqrt{\rho^2 + h^2} \left(\sqrt{\rho^2 + h^2} + h \right)}, \tag{10}$$

$$u_3(\rho, 0) = \frac{Q}{2\pi \lambda_o (k+1)} \frac{[d_1 g_1(\gamma) + d_2 g_2(\gamma) + d_3 g_3(\gamma)]}{\sqrt{\rho^2 + h^2}}. \tag{11}$$

Among them, d_1, d_2, and d_3 are voltage coefficients, $g_1(\gamma) = 2 + \gamma + 2(1 + \gamma)v/(1 + \gamma)^2$, $g_2(\gamma) = -\gamma/(1 + \gamma)^2$, $g_3(\gamma) = \gamma/(1 + \gamma)^2$, and v is Poisson's ratio.

(2) Fully coupled method

Since the force-electric coupling between the needle tip and the sample is axisymmetric, it can be solved by the Hankel integral transformation method [16, 17]. The Hankel integral transformation pair defined for any function $F(r, z)$ is:

$$\tilde{F}(\xi, z) = \int_0^\infty F(r, z) r J_p(\xi r) dr, \tag{12}$$

$$F(r, z) = \int_0^\infty \tilde{F}(\xi, z) \xi J_p(\xi r) d\xi. \tag{13}$$

Among them, in the three-dimensional coordinate axis, r represents the horizontal axis to the right, z represents the vertical axis downward, $J_p(\xi r)$ is the first-type Bessel function of order p, and ξ is the polar axis in the Fourier space.

3. Analysis and Research on the Electromechanical Coupling of Nanoscale Ferroelectric Domains Based on Piezoelectric Force Microscopy (PFM)

3.1. Research Content. There are three main research contents in this article. First, when using the PFM technology to quantitatively analyze the nanoscale piezoelectric coefficients, it is discussed whether the effective voltage coefficient under the decoupling method and the fully coupled method is compared with the actual voltage coefficient, and whether the two methods will overestimate or underestimate the conductive SPM probe [18] surface displacement caused by the needle. The second is to analyze PFM to detect nanoscale piezoelectric deformation of single-domain ferroelectric materials and complex ferroelectric domains. The third is to analyze the half-width of the domain boundary response half-width of the in-plane domain and the out-of-plane domain of the vertical angle and the lateral angle and discuss the effect of the PFM vertical resolution and the lateral resolution [19].

3.2. Research Methods. This article mainly uses the literature data method and the comparison method to obtain the relevant properties and research directions of ferroelectric materials by searching literature, compare the effective piezoelectric coefficients of different materials under decoupling and full coupling, and compare PFM to detect single-domain ferroelectric samples the in-plane and out-of-plane displacement response caused by the time, and

4. Based on Piezoelectric Force Microscopy (Pfm) Nanoscale Ferroelectric Domain Force-Electric Coupling Analysis

4.1. Quantitative Analysis of Nanoscale Piezoelectric Coefficients Based on PFM

(1) Effective piezoelectric coefficient based on decoupling method

In order to quantitatively analyze the relationship between the effective piezoelectric coefficient and the inherent parameters of the material, select $BaTiO_3$, $PbTiO_3$, PZT (Zr/Ti = 48/52), PZT-8, and PMN-42%PT as examples, and the corresponding inherent material parameters are shown in Table 1. In order to clearly see the difference between the effective piezoelectric coefficient and the inherent piezoelectric coefficient, the correction factor f of the material is defined. The results show that the correction factor of PZT-8 is the smallest with a value of 0.72, while the correction factor of PMN-42%PT is the largest at 2.65. There is no obvious trend in the correction factor between different materials. In addition, for different materials, the correction

factor may be greater than 1 or less than 1, which indicates that the piezoelectric coefficient of the PFM test may be overestimated or underestimated, which makes the quantitative analysis of the piezoelectric coefficient of the PFM technology more difficult.

Figure 2 shows the relationship between the effective piezoelectric coefficient of different materials and the piezoelectric coefficient and dielectric anisotropy factor. Fixing all other material parameters and changing only the piezoelectric coefficient d_3, then the linear relationship between the effective piezoelectric coefficient $d*_3$ and the piezoelectric coefficient d_3 can be obtained. Although there is a linear relationship between $d*_3$ and d_3, the slopes of $d*_3$ and d_3 are different for different materials, which means that the piezoelectric coefficients of other materials cannot be accurately obtained by calibrating with reference to the material. The effective piezoelectric coefficient of different materials and the dielectric anisotropy factor r are obviously nonlinear, especially for PMN-42%PT, the corresponding effective piezoelectric coefficient increases sharply as r increases. The obvious nonlinear characteristics of $d*_3$ and r in PMN-42%PT are mainly due to its large d_2. It is worth noting that although the piezoelectric coefficient is fixed, the effective piezoelectric coefficient still changes with the elastic constant and the dielectric constant. This shows that the quantitative analysis of the piezoelectric coefficient for the PFM technology requires all other material parameters to be known.

TABLE 2: Properties of piezoelectric ceramics.

Material	Elastic constant (GPa)	Piezoelectric coefficient (C/m^2)	Dielectric constant (10^{-9} F/m)
PZT-4	138.67	12.8	6.521
PZT-5A	124.00	12.6	8.127
BaTiO$_3$	150.14	11.5	9.842
(Ba$_a$Ca$_b$)TiO$_3$	158.33	10.8	8.786

FIGURE 3: Effective piezoelectric coefficients of different materials.

(2) Effective piezoelectric coefficient based on the full coupling method

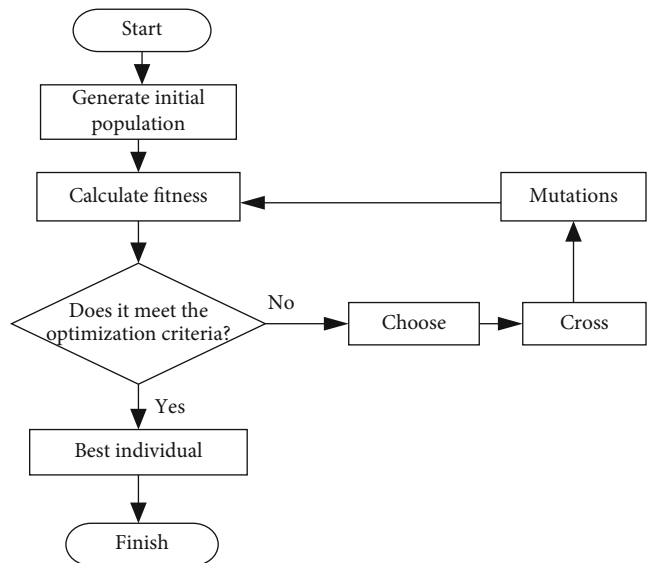
This paper selects five different piezoelectric materials, namely, PZT-4, PZT-5A, BaTiO$_3$, (BaaCab)TiO$_3$, and PZT (Zr/Ti = 48/52), and the comparative analysis is based on the full coupling method and the decoupling method. The difference of effective piezoelectric coefficient, further analyze the relationship between effective piezoelectric coefficient and material inherent parameters. The actual material parameters corresponding to the selected materials are shown in Table 2. The elastic constant of PZT-4 material is 138.67 GPa, the piezoelectric coefficient is 12.8 C/m^2, and the dielectric constant is 6.521×10^{-9} F/m; PZT-5A material the elastic constant is 124.00 GPa, the piezoelectric coefficient is 12.6 C/m^2, and the dielectric constant is 8.127×10^{-9} F/m; the elastic constant of BaTiO$_3$ material is 150.14 GPa, the piezoelectric coefficient is 11.5 C/m^2, and the dielectric constant is 9.842×10^{-9} F/m; the elastic constant of (BaaCab)TiO$_3$ material is 158.33 GPa, the piezoelectric coefficient is 10.8 C/m^2, and the dielectric constant is 8.786×10^{-9} F/m; PZT (Zr/Ti = 48/52); the elastic constant of the material is 124.74 GPa, the piezoelectric coefficient is 5.92 C/m^2, and the dielectric constant is 4.812×10^{-9} F/m.


FIGURE 4: Basic flow chart of genetic algorithm.
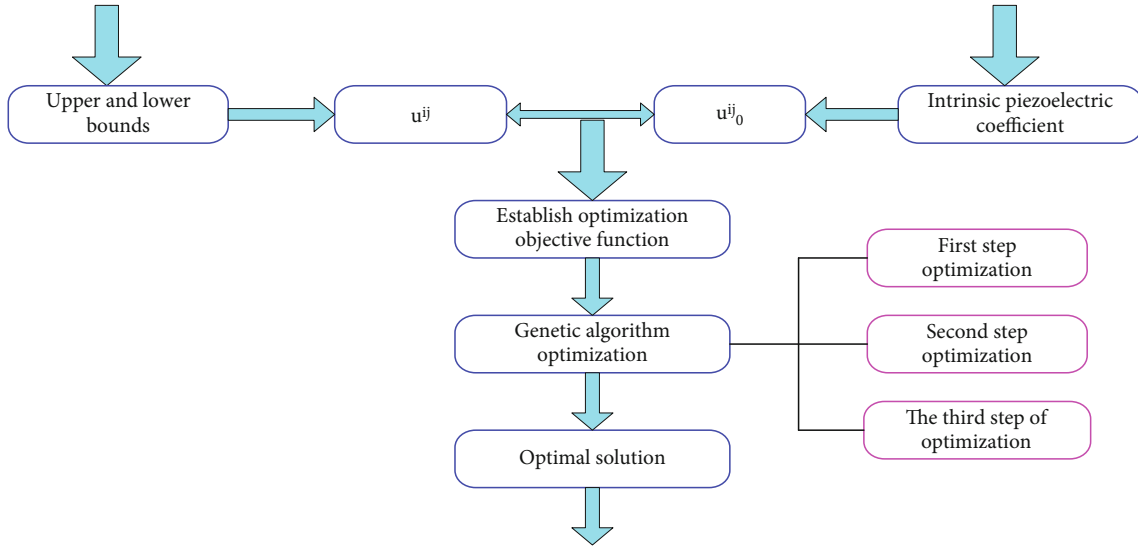

FIGURE 5: Piezoelectric coefficient optimization process.

Analyzing the difference of the effective piezoelectric coefficients of the two theories, the effective piezoelectric coefficients obtained by the two theories for different materials are summarized as shown in Figure 3. The effective piezoelectric coefficient of PZT-4 material in decoupling mode is 267.24 (pm/V), and the effective piezoelectric coefficient in full coupling mode is 252.13 (pm/V); PZT-5A material is effective in decoupling mode the piezoelectric coefficient is 325.46 (pm/V), the effective piezoelectric coefficient in the fully coupled mode is 305.37 (pm/V); the effective piezoelectric coefficient of the $BaTiO_3$ material in the decoupling mode is 167.95 (pm/V), fully coupled the effective piezoelectric coefficient in the mode is 167.81 (pm/V); the effective piezoelectric coefficient of $(Ba_aCa_b)TiO_3$ material in the decoupling mode is 133.14 (pm/V), and the effective piezoelectric coefficient in the fully coupled mode is 132.78 (pm/V); the effective piezoelectric coefficient of PZT (Zr/Ti = 48/52) material in decoupling mode is 148.23 (pm/V), and the effective piezoelectric coefficient in full coupling mode is 147.36 (pm/V). It can be seen from these data that compared with the actual piezoelectric coefficient, whether it is a decoupling method or a fully coupled method, the corresponding effective piezoelectric coefficient may be overestimated or underestimated. Moreover, compared with the fully coupled method, decoupling analysis tends to underestimate the surface displacement caused by the conductive SPM probe.

(3) Inversion of piezoelectric coefficient

There is an obvious nonlinear relationship between the effective piezoelectric coefficient and the intrinsic material constant. Therefore, we propose a method to inversely optimize the electroelastic constant of the material under different test conditions. It is based on this idea, focusing on the inversion of piezoelectric coefficients based on genetic algorithm (GA). The idea of genetic algorithm originates from the most suitable survival process in biological evolution, and its basic process is shown in Figure 4. They first randomly generate

populations and evaluate the suitability of the main population; then, select parent individuals based on suitability, such as roulette selection method, traversal sampling, and competitive bidding; secondly, transfer or reorganize the selected parent individuals; transfer or after reorganization, in order to prevent the optimization result from appearing a local minimum, the population will change with a small probability; finally, if the newly generated population reaches the optimization of the termination condition, the optimization result is output; otherwise, the second step is returned.

The inversion optimization of piezoelectric coefficients uses PZT-4 material as an example, and the three piezoelectric coefficients are optimized through multistep optimization. The optimization process is shown in Figure 5. The first step is to consider the three piezoelectric coefficients e_1, e_2, and e_3, and perform simultaneous optimization. The three piezoelectric coefficients obtained by the first optimization are recorded as e^1_1, e^1_2, e^1_3, and $e_1 = e^1_1$ in the second optimization. Only optimize the other two piezoelectric coefficients e_2, e_3, and then, you can get e^2_2, e^2_3. In the third step of optimization, $e_3 = e^2_3$, and $e_1 = e^1_1$, and only e_3 is optimized separately.

The piezoelectric coefficient results obtained by the three-step optimization are shown in Table 3. The intrinsic piezoelectric coefficients e^0_1, e^0_2, and e^0_3 of the three steps are 11.5, -5.4, and 14.7. After the first step of optimization, the optimized voltage coefficients e_1, e_2, and e_3 are 11.486, -5.346, and 14.822, respectively; after the second step of optimization, the optimized voltage coefficients e_1, e_2, and e_3 are 11.487, -5.428, and 14.604, respectively; after three-step optimization, the optimized voltage coefficients e_1, e_2, and e_3 are 11.532, -5.398, and 14.676, respectively.

4.2. Analysis of Nanoscale Piezoelectric Deformation of Ferroelectric Materials

(1) Nanoscale piezoelectric deformation of single-domain ferroelectric materials

TABLE 3: Optimal piezoelectric coefficient and intrinsic piezoelectric coefficient of PZT-4.

	Intrinsic piezoelectric coefficient (C/m^2)			Optimized piezoelectric coefficient (C/m^2)		
	e^0_1	e^0_2	e^0_3	e_1	e_2	e_3
1	11.5	-5.4	14.7	11.486	-5.346	14.822
2	11.5	-5.4	14.7	11.487	-5.428	14.604
3	11.5	-5.4	14.7	11.532	-5.398	14.676

- 180 degree out-of-plane domain
- 90 degree in-plane domain
- 90 degree out-of-plane domain
FIGURE 7: Comparison of the half-width of the domain boundary response of the 90-degree and 180-degree in-plane and out-of-plane domains of BaTiO$_3$ ceramics as a function of the tip radius.

The surface displacement of a single-domain ferroelectric sample is calculated by the nanoscale piezoelectric response displacement equation. Figure 6 shows the spatial distribution of the surface displacement caused by PFM detecting a single-domain ferroelectric sample. (a) shows the in-plane displacement response. (b) The figure shows the out-of-plane displacement response. From the results shown in the figure, it can be seen that the deformation displacement is highly concentrated and uneven. The out-of-plane displacement under the conductive SPM probe has a maximum value of 0.165 nm. As the distance from the conductive SPM probe is

farther, the out-of-plane displacement under the conductive SPM probe gradually decreases; while the in-plane displacement is farther away from the conductive SPM. In the process of the probe, it increases first and then decreases, with a maximum value of 0.032 nm at 16 nm away from the probe. The nanoscale piezoelectric deformation of single-domain ferroelectric samples will lay the foundation for the analysis of complex ferroelectric domain structures.

(2) Nanoscale piezoelectric deformation of complex ferroelectric domains

Ferroelectric materials usually contain complex microdomain structures, such as 180-degree electrical domains and 90-degree electrical structures. Due to this unbalanced microdomain structure, it is difficult to quantitatively analyze the piezoelectric response of nonferrous metal materials, which brings great difficulty to the PFM test and analysis work. Compared with a single nonferrous metal material, the polarization vector of a ferroelectric material is not uniformly distributed in the multiple fusion structure, but three nonuniform distribution dimensions are known, which determines the inherent piezoelectric coefficient of its tensor coefficient and also leads to the local intrinsic piezoelectric coefficient tensor which also presents a complex distribution. However, there is a uniformly distributed intrinsic piezoelectric coefficient tensor in a single electric domain region, and independent and uniform piezoelectric coefficient sensors are internally distributed in individual regions. This can be obtained by the spatial coordinates of the piezoelectric coefficient tensor in a single coordinate domain.

4.3. Domain Boundary Response Half-Width Analysis. In this experiment, the $BaTiO_3$ ceramic material was used as an example to compare the change of the half-width of the domain boundary response of 90-degree and 180-degree in-plane domains and out-of-plane domains with the tip radius. An angle of 90 degrees represents PFM vertical detection, and an angle of 180 degrees represents PFM lateral detection. It can be seen from Figure 7 that whether it is a 180-degree domain or a 90-degree domain, whether it is an in-plane or out-of-plane domain, the domain boundary broadening increases with the increase of the tip radius. It shows that the linear curves corresponding to the 180-degree domain and the 90-degree domain are very close, and the anisotropy of the in-plane polarization has little effect on the results of the PFM measurement of the domain boundary thickness. Under the same tip radius, the domain boundary response half-width of a 180-degree in-plane domain is larger. For example, when the tip radius is 25 nm, the corresponding domain boundary response half-width of a 180-degree out-of-plane domain is 11.9 nm, but 180 degrees the domain boundary response half-width corresponding to the in-plane domain is 20 nm, which means that the lateral PFM has a worse resolution than the vertical PFM.

5. Conclusion

The continuous improvement of the requirements of multifunctional materials has promoted the continuous development of functional composite materials and multifield coupling materials, making more and more materials have multifield coupling characteristics. The continuous development of nanotechnology has led to the emergence of various new SPM technologies, which have prompted everyone to study the multifield coupling behavior caused by various SPM probes. The quantitative analysis of experimental data is very important for the study of nanoscale ferroelectric materials. To this end, this paper established a nanoscale piezoelectric deformation method for analyzing complex ferroelectric domain structure, explained a series of PFM test results of nanoscale deformation of complex ferroelectric domain structure, and analyzed the nanoscale pressure of ferroelectric materials for PFM quantitative test. The electrical response provides a good guide plan and provides a reference for the experimental preparation of ferroelectric materials with strong electrical coupling performance, thereby promoting the application of nanoscale ferroelectric materials.

Retraction

Retracted: Application of Nanoscaffold Material Combined with Exercise Rehabilitation Therapy in the Treatment of Athletes with Hip Injuries

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

A nanoscaffold is a porous scaffold. It injects antibiotics, cells, and polymer particles into damaged cavities in the form of injectables and forms hydrogels after the molecules self-assemble at the injection site. Sports rehabilitation is a new frontier field integrating sports, health, and medicine, also known as physical therapy. It is the use of various sports methods for the injured or disabled, so that they can fully recover their physical functions and spirits, and can make them reintegrate into society. It mainly studies the relationship between sports and health. Among the tissue engineering scaffolds used as seed cell carriers, nanomaterials are playing an increasingly important role in the study of joint injury and repair due to their unique effects such as cell adhesion and proliferation. The purpose of this paper is to study a reliable nanoscaffold material for the treatment of patients with hip injuries in athletes and to observe its actual effect in combination with sports rehabilitation therapy. In this paper, an electrospinning method was proposed to prepare nanoscaffold materials, and the nanoscaffold materials were applied to the exercise rehabilitation process of two groups of hip patients, and the data of the patients' rehabilitation were calculated. The results showed that the OD value of the cells in the exercise rehabilitation therapy using nanofiber scaffolds increased significantly, and the average daily growth rate of the OD value was 0.112. And the rehabilitation after 5 months was 19.8 points higher in hip range of motion score, 11.3 points higher in overall function score, and 6.2% lower in complication rate compared with ordinary exercise rehabilitation therapy. Therefore, it can be concluded that the therapy of the nanofiber scaffold material combined with exercise rehabilitation can more efficiently help patients with hip joint injury to recover, and the probability of complications is lower compared with the traditional exercise rehabilitation therapy.

1. Introduction

With the development of science and technology, nanomaterials have become important materials used in many fields, including the production of materials for medical equipment. Because athletes are too intense in the process of exercise, they often cause joint damage, especially for the hip joint. The hip joint is the most critical part of the movement of the lower limbs of the human body, and the treatment of the hip joint is particularly important. Although traditional

exercise rehabilitation therapy can help patients recover to a certain extent, its efficiency is not high, and it is more dependent on the exercise method of physician medical treatment, so it is necessary to propose a more efficient exercise rehabilitation therapy. In this way, hip patients can relieve hip pain and restore normal movement of the hip joint as soon as possible. With the advancement of the pathological research of hip joint injury, some progress has been made in the mechanism of treatment of hip joint injury. Many factors combined with exercise rehabilitation therapy

can promote the effect of treatment. However, these are only some single substances that promote treatment. How to integrate these accelerators to better improve the expression of nutritional factors, and whether there will be countermeasures, need to be explored and studied. In addition to expressing neurotrophic factors to repair hip joint injury, the treatment of hip joint injury can also regulate the expression of genes, which can play a role in repairing damaged tissue.

The innovation of this paper is that (1) an electrospinning method was proposed to prepare nanoscaffold materials, and the nanoscaffold materials were applied to the exercise rehabilitation process of two groups of hip patients, and the data of the patients' rehabilitation were calculated. (2) Using the control method, the OD value of the cells and the postoperative rehabilitation effect of the two groups of patients were compared. (3) Conduct in-depth theoretical research on the subject content, and analyze the research status of the subject-related content of this paper.

2. Related Work

Regarding the research on exercise rehabilitation therapy, many scholars in China have carried out related research. Among them, Buckthorpe et al. described how the properties of water support the functional recovery process after ACLR (anterior cruciate ligament reconstruction). Buckthorpe et al. recommended that if the main properties of hydrotherapy (density, hydrostatic pressure, buoyancy, and viscosity) are properly applied to rehabilitation practice, then it can be used to achieve the six main goals after ACLR, namely, (1) help reduce pain and swelling, (2) support gait recovery, (3) support the maintenance and/or development of cardiovascular health, (4) help accelerate and optimize movement pattern retraining, (5) allow earlier introduction of plyometric and strength training, and (6) support the relationship between session recovery and optimal load management [1]. Li et al.'s study employed an effective motion measurement method based on inertial sensor networks to measure children's motor abilities to verify the effectiveness of systemic CP rehabilitation. Li et al. proposed a new skeletal vector-based dynamic model to reconstruct the posture of children during exercise training to evaluate the effect of exercise rehabilitation. An Extended Kalman Filter (EKF) is used to fuse sensor signals to measure the motion of body parts, the accuracy of which is verified by the OptiTrack optical system. Li et al. used statistical analysis methods to analyze the motor function rehabilitation of SD children. The results are reassuring, and the lower extremity motor function of some children has been improved after rehabilitation training [2]. Flaherty provided research-based evidence to support the use of these modalities in pain management and to reduce the use of pain medications, including opioids. Mechanisms of action, applications, contraindications, and adverse effects of cryotherapy, pulsed electromagnetic field therapy, transcutaneous electrical nerve stimulation, and laser therapy are reviewed. It has been shown that adding one or more of these therapies to an anaesthetic pain management regimen can improve outcomes and reduce potential drug side effects [3]. Temkin-Greener et al. conducted data surveys based on methods such as minimal data set assessments, vital statistics, nursing home comparison websites, LTCFocus, and district health resource files. Findings suggest that facilities with for-profit missions and more therapists may be more motivated to maximize treatment utilization, even among the sickest residents [4]. They evaluated the therapeutic techniques and rehabilitation used by physical therapists in the treatment of patients with plantar fasciitis. Based on a retrospective review, Fraser et al. concluded that although plantar fasciitis is a common musculoskeletal disorder, a small proportion of patients with plantar fasciitis are treated by a physical therapist. Most patients evaluated by a physical therapist received manual therapy and supervised rehabilitation sessions as part of their care plan [5]. Murray et al.'s study systematically assessed the evidence supporting the efficacy, prescribing, and progression patterns of vestibular rehabilitation therapy (VRT) in concussion patients. Nine of the studies reported improved outcomes. However, level I evidence from only 1 study showed that when VRT (in combination with cervical treatment) was compared with usual care, heterogeneity in study type and outcome precluded meta-analysis. Eight studies used habituation and adaptation exercises, 9 studies used balance exercises, and there was a lack of standardization in prescribing and progression patterns. It was then concluded that there is currently limited evidence on the optimal prescribing and efficacy of VRT in patients with mTBI/concussion. The available evidence, though weak, shows promise in this population. This requires further high-level studies to evaluate the effect of VRT in patients with mTBI/concussion with vestibular and/or balance dysfunction [6]. The research of the above scholars has promoted the application of sports rehabilitation therapy to a certain extent and, at the same time, has done some practical tests, but most of them are based on theoretical research. And the joint nanoscaffold material for sports rehabilitation treatment of patients with hip joint injury is also less involved, so the research in this paper is of pioneering significance.

3. Exercise Therapy Based on Hip Joint Nanoscaffold Materials

3.1. Nanoscaffold Materials. Nanomaterials are materials that have at least one dimension in three-dimensional space on the nanometer scale (1-100 nm) or are the basic units built around them. This corresponds to a dense scale of about 10 to 1000 atoms. Nanomaterials are an important part of nanotechnology. Nanotechnology refers to the general term for manufacturing technologies whose processing precision reaches the limit value of one order of processing size, and its crystal lattice spacing is about 1 to 100 nanometers [7, 8].

Since the advent of nanoparticle materials in the 1970s, the development process can be divided into three stages in terms of research connotation and characteristics. The first stage (before 1990) mainly explored the preparation of nanoparticle powders or synthetic blocks of various materials by various methods in the laboratory, studied the methods for evaluating and characterization, and explored the special properties of nanomaterials that are different

from ordinary materials. The research objects are generally limited to single materials and single-phase materials, which are usually referred to as nanocrystalline or nanophase materials internationally. The second stage (1990~1994). The focus of attention is how to use the physical and chemical properties of nanomaterials to design nanocomposite materials. The synthesis and physical property exploration of composite materials once became the dominant direction of nanomaterial research. The third stage (1994-present). Nanoassembly systems and artificially assembled nanostructured material systems are becoming a new hotspot in nanomaterial research. Internationally, such materials are called nanoassembled material systems or nanoscale patterned materials. Its basic connotation is that nanoparticles and their nanowires and tubes are the basic units assembled in one-dimensional, two-dimensional, and three-dimensional spaces to form a system with nanostructures.

Nanomaterials can be divided into nanofilms, nanopowders, nanofibers, nanoblocks, and nanoceramics according to their material properties, as shown in Figure 1.

Nanostructure is a new system constructed or constructed according to certain rules on the basis of nanoscale material units. It includes a nanoarray system, mesoporous assembly system, and thin-film mosaic system. Research on nanoarray systems has focused on binary systems formed by the alignment of metal nanoparticles or semiconductor nanoparticles on an insulating substrate. The nanoparticle and mesoporous solid assembly system has some new effects due to the characteristics of the particle itself and the coupling with the matrix at the interface.

Nanomaterials can be divided into nanocomputers, nanosensors, nanobiomaterials, nanosemiconductor materials, and other fields according to their application scope, as shown in Figure 2.

Nanobiomaterials can also be divided into two categories, one is the nanomaterials that are suitable for the interior of the organism, such as various nanosensors, which are suitable for disease monitoring, early diagnosis, and later treatment. These nanoscale mechanical systems can quickly identify the location of the disease and can accurately guide the drug into the diseased location without damaging other normal body parts or clearing the deposits in fat and removing the thrombus in the cardiovascular and cerebrovascular. At the same time, they can also be used to kill viruses and eliminate cancer cells [9, 10].

The preparation methods of nanomaterials include (1) the evaporation condensation method under inert gas. It is usually formed by high pressure forming of particles with a particle size of 1-100 nm with a clean surface, and nanoceramics also need to be sintered. A variety of nanosolid materials has been successfully developed abroad by the above-mentioned inert gas evaporation and vacuum in situ pressurization methods, including metals and alloys, ceramics, ionic crystals, amorphous, and semiconductor nanosolid materials. This method has also been successfully used in China to make nanomaterials such as metals, semiconductors, and ceramics. (2) Chemical method: (i) hydrothermal methods, including hydrothermal precipitation, synthesis, decomposition, and crystallization, are suitable for the prep-

aration of nanooxides; (ii) hydrolysis methods include sol-gel method, solvent volatilization decomposition method, latex method, and evaporation separation method. (3) Comprehensive method. A preparation method is formed by combining the physical vapor method and chemical deposition method. Other methods generally include ball milling and jet processing.

A nanoscaffold is a porous scaffold. It injects antibiotics, cells, and polymer particles into damaged cavities in the form of injectables and forms hydrogels after the molecules self-assemble at the injection site. Figure 3 shows the use process of the nanoscaffold material. It is now believed that this type of fine particle can be assembled by combining traditional controlled release systems with surface engineering and self-organization via growth factors and other signaling molecules. Superior biomimetic scaffolds, especially biopolymer self-assembled hydrogels, are formed for this purpose. Nanoscaffolds have great prospects for drug control and regenerative medicine [11, 12].

Nanotechnology basic theoretical research and new material development and other applied research have developed rapidly and have been widely used in traditional materials, medical equipment, electronic equipment, coatings, and other industries. With the increasing investment in nanotechnology application research in various countries, the process of industrialization of new nanomaterials will be greatly accelerated, and the market size will increase in volume. Several products such as nanocalcium carbonate, nanozinc oxide, and nanosilicon oxide in nanopowder materials have formed a certain market scale. Nanopowder widely used nanoceramic materials, nanotextile materials, nanomodified coatings, and other materials have also been successfully developed, and industrial production has been initially realized. The application of nanopowder particles in medical diagnostic preparations and microelectronics is shifting from experimental research results to industrialized production of products.

3.2. Exercise Rehabilitation Therapy. Sports rehabilitation is a new frontier field integrating sports, health, and medicine, and it mainly studies the relationship between sports and health. Particularly for some adult hip bones, the damage is mostly caused by high-energy violence. This kind of high-energy violence also often causes damage to the distal articular surface of the hip bone and the surrounding tissues, ligaments, skin and soft tissues, nerves, blood vessels, and other injuries. Fractures are prone to redisplacement after manual reduction, and it is difficult to restore the integrity of the articular surface. External fixation of the elbow joint is required in the early stage after manual reduction, which may easily lead to the loss of elbow joint function. Strong internal fixation provides a prerequisite for the early postoperative functional rehabilitation training of patients [13, 14]. Immobilization of the affected limb for too long can easily lead to obstruction of lymphatic and venous return, fibrin deposition, and serous fibrous exudation in the tissues around the joint. This can cause fibrous adhesions, edema of the joint capsule and surrounding muscles, fibrosis, and
Figure 1: Nanomaterials.
Figure 2: Applications of nanomaterials.

contractures, resulting in impaired elbow mobility, resulting in elbow stiffness.

The soft tissues around the hip joint, such as fascia, muscle bonds, and muscles, determine the high lateral stability of the hip joint. However, the sagittal flexion and extension range of motion is also larger, and while improving its flexion and extension range of motion, it is also necessary to pay attention to strengthening its lateral stability.
Figure 3: Application process of nanoscaffold materials.

Sports rehabilitation therapy: 3-5 days after surgery, perform leg movement, lift, and leg contraction training. After 2-4 weeks, begin to perform hip flexion and extension exercises. After 6-8 weeks, traditional functional rehabilitation training with muscle strength training for the affected limb is the main method.

Commonly used traditional sports rehabilitation equipment includes training beds, stationary bicycles, and suspension frames, as shown in Figure 4.

Table 1 shows the safety assessment scale of sports rehabilitation for fracture patients. Evaluate the patient's rehabilitation exercise score, and formulate a personalized rehabilitation prescription based on the score. The table has a total score of 100. Rehabilitation exercise is safer for more than 60 points; 40-60 minutes of rehabilitation exercise should be cautious and closely observed; 0-40 points are mainly muscle isometric contractions, and early isotonic contractions are not suitable.

3.3. Patients with Hip Injury. With the aging of the population, the incidence of hip diseases in the elderly will also increase significantly, such as femoral head necrosis, fractures, and femoral arthritis. The pain and joint dysfunction caused by it have become an important factor affecting the quality of life in the elderly. At the same time, due to trauma and improper lifestyle, the incidence of hip disease among young people has increased. Particularly for athletes who have been doing leg exercises for a long time, the use of the hip joint is more frequent, and various injuries of the hip joint are more likely to occur [15, 16]. The emergence

of these hip diseases makes more and more patients have to accept hip treatment. The specific parts of the hip joint are shown in Figure 5.

The main causes of hip injury are trauma; vascular plunger, deformity, and tumor of the hip; hip compression; hip inflammation; and others such as deformity, demyelinating degenerative diseases. The pathological process mainly includes primary injury and secondary injury. The final result will have a large negative impact on the physiological function of the hip joint due to neuronal and glial cell death, axonal degeneration and formation of myelin sheaths, cystic cavities, etc. The specific situation is shown in Figure 6.

Common treatments for hip injuries include decompression therapy with surgery or prevent the use of large doses of drugs. This method has a neuroprotective effect on acute hip injury. Expression of factors that inhibit axon regeneration can be blocked. There is rehabilitation through exercise, or injection of neurotrophic factors to repair damaged myelin. At present, the use of nanoscaffold materials combined with exercise rehabilitation therapy to treat hip joint injury is a new hot research direction [17, 18]. Table 2 shows the evaluation method of functional rehabilitation after hip injury.

At present, the mechanism of bone marrow mesenchymal exercise rehabilitation therapy in the treatment of hip injury is not very clear. It is known that the characteristics of bone marrow mesenchymal cells are as follows: self-replication ability, asymmetric division ability to differentiate into other cells, surface markers with primitive cells, and homing. With these characteristics, the treatment of hip joint injury can have better results by selecting the appropriate exercise rehabilitation therapy approach and

FIGURE 4: Commonly used sports rehabilitation equipment.

TABLE 1: Exercise rehabilitation safety evaluation form.

Score	Fixed reliability	Integrity of soft tissue
60 to 80	Strong immobilization for immediate weight bearing	——————
40 to 60	Postoperatively with the help of	Reasonable surgical approach (less trauma)
20 to 40	Brace function active movement	The ligament solution is fixed and repaired firmly
1 to 20	Can resist body gravity but not resistance	The ligament of the joint is sutured, and the tension is partially resisted during the operation
0 marks	To maintain alignment, external fixation, traction, etc.	The ligaments of the joint are sutured, and the tension cannot be resisted during the operation

the appropriate time. The pathological mechanism of hip joint injury is mainly the damage of the hip joint barrier caused by the hip joint injury, which leads to the entry of some bacteria into the hip joint injury site. And because of cytotoxicity, ischemia and hypoxia-induced apoptosis are initiated.

The biggest problem with sports rehabilitation therapy for hip injury lock is that the details of its operation are not fully understood. According to the current research, it may be derived from the following aspects: exercise rehabilitation therapy can migrate to the injured site autonomously and differentiate into nerve cells; the mediating role of exercise rehabilitation therapy; exercise rehabilitation therapy can inhibit the activation of certain apoptosis factors. However, the specific causal mechanism remains to be studied.

The research trend of exercise rehabilitation therapy in the treatment of hip injuries will develop towards the synergistic effect of multiple factors. That is to say, the effect of simple exercise rehabilitation therapy is not ideal, and various promoting factors need to be integrated, and the target gene that can promote axonal repair should be transfected into the hip joint. Although there are still many problems to be solved, with the deepening of research, the details of sports rehabilitation therapy for hip injuries will eventually be fully understood. At that time, more treatment methods will also be applied in the clinic, and by combining various methods and taking advantage of their advantages, a convenient, stable, and less traumatic treatment method will surely be found, so as to overcome the problem of repairing hip joint injury [19, 20].

4. Test of the Assisted Rehabilitation Effect of Nanoscaffolds

4.1. Exercise Rehabilitation Efficacy Algorithm. In order to facilitate the calculation of the movement process, this paper establishes the coordinate system of the lower limbs of the human body as shown in Figure 7. The hip joint is the key driving part of the movement of the entire lower limb, which is the origin of the coordinate system, and the hip joint and the knee joint are regarded as articulations.

For the motion process of the thigh system, set the angle in the horizontal direction and its corresponding angular

TABLE 2: Hip joint function evaluation table.

Flexion	Pain and dysfunction	Score
Loss of extension < 15°, flexion > 130°	No pain and functional impairment	Excellent
Loss of extension < 30°, flexion > 120°	Mild functional impairment	Good
Loss of extension < 40°, flexion > 90°	Pain with activity, moderate functional impairment	Generally
Loss of extension < 40°, flexion > 90°	Frequent pain, severe functional impairment	Not good
FIGURE 7: Human lower limb coordinate system.

velocity and angular acceleration to x_{1i}, x_{2i}, and x_{3i}; then, the motion equation is

$$
\begin{aligned}
x_{1i}(k) &= \theta_1, \\
x_{2i}(k) &= \dot{\theta}_1 = w_1, \\
x_{3i}(k) &= \ddot{\theta}_1 = \dot{w}_1 = \beta_1.
\end{aligned}
\tag{1}
$$

Among it, k represents the kth motion situation.

$$
\begin{cases}
\theta_1(k+1) = \theta_1(k) + w_1(k)t_s, \\
w_1(k+1) = w_1(k) + \beta_1(k)t_s, \\
\beta_1(k+1) = \beta_1(k).
\end{cases}
\tag{2}
$$

The equation of state can be obtained:

$$
\begin{cases}
x_{1i}(k+1) = x_{1i}(k) + x_{2i}(k)t_s, \\
x_{2i}(k+1) = x_{2i}(k) + x_{3i}(k)t_s, \\
x_{3i}(k+1) = x_{3i}(k).
\end{cases}
\tag{3}
$$

Output equation:

$$
\begin{cases}
y_{1i}(k) = g \cos x_{1i}(k) + x_{3i}(k)d_1, \\
y_{2i}(k) = -g \sin x_{1i}(k) - x_{2i}{}^2(k)d_1.
\end{cases}
\tag{4}
$$

In the equation, g is the acceleration of gravity.

Similarly, for the movement process of the calf system, let its variable be x_{12}, x_{22}, and x_{32}.

$$
\begin{aligned}
x_{12}(k) &= \theta_2, \\
x_{22}(k) &= \dot{\theta}_2 = w_2, \\
x_{32}(k) &= \ddot{\theta}_2 = \dot{w}_2 = \beta_2.
\end{aligned}
\tag{5}
$$

The equation of state is

$$
\begin{cases}
x_{12}(k+1) = x_{12}(k) + x_{22}(k)t_s, \\
x_{22}(k+1) = x_{22}(k) + x_{32}(k)t_s, \\
x_{32}(k+1) = x_{32}(k).
\end{cases}
\tag{6}
$$

Output equation:

$$
\begin{cases}
y_3(k) = g \cos x_{1i}(k) + x_{3i}(k)(l + d_2), \\
y_4(k) = -g \sin x_{1i}(k) - x_{2i}{}^2(k)(l + d_2).
\end{cases}
\tag{7}
$$

According to the Kalman filter principle, the Kalman filter is a linear minimum variance filtering algorithm. By making certain assumptions about the statistical characteristics of the input signal and noise, the state space method is used to describe the system. According to the current measured value and the estimated value of the previous moment, the signal can be processed in real time through recursive calculation. It can not only process stationary random signals but also process multidimensional and nonstationary random signals. It is an important method for solving state estimation and filtering problems in various dynamic systems. The nonlinear state-space model is obtained:

$$
\begin{aligned}
X_k &= f(X_{k-1}, k-1) + W_{k-1}, \\
Z_k &= h(X_k, k) + V_k.
\end{aligned}
\tag{8}
$$

Among them, X_k is the multidimensional state set, Z_k is the multidimensional observation set, and W_k and V_k are the noise state set and observation set. h represents a nonlinear function.

Expand h by Taylor series, leaving only the first-order term, then:

$$
Z_k = h(\widehat{X}_{k,k-1}, k) + \left.\frac{\partial h}{\partial X_k}\right|_{\widehat{X}_{k,k-1}} (X_k - \widehat{X}_{k,k-1}) + V_k.
\tag{9}
$$
Figure 8: Electrospinning method.

Assume:

$$\left.\frac{\partial h}{\partial X_k}\right|_{\widehat{X}_{k,k-1}} = H_k,$$

$$y_k = h\left(\widehat{X}_{k,k-1}, k\right) - \left.\frac{\partial h}{\partial X_k}\right|_{\widehat{X}_{k,k-1}} \widehat{X}_{k,k-1}. \tag{10}$$

Then, the equation can be observed as

$$Z_k = H_k X_k + y_k + V_k. \tag{11}$$

The status update method is

$$\widehat{X}_{k,k-1} = f\left(\widehat{X}_{k,k-1}, k-1\right). \tag{12}$$

Observe the update method:

$$K_k = P_{k,k-1} H_k^T \left[H_k P_{k,k-1}\right]^{-1},$$

$$P_{k,k} = \left[I - K_k H_k\right] P_{k,k-1}. \tag{13}$$

In the equation, P represents the variance and $\widehat{X}_{k,k-1}$ represents the filtered mean.

A signal is the carrier of information, a function of time or space that transmits information. In the process of signal detection and transmission, it is inevitable to be disturbed by external environment and internal noise. In order to obtain the desired signal, it is necessary to filter the signal and suppress other signals to obtain the desired signal. Filtering refers to a method or technique of extracting a specific desired signal from an interfering signal. Different filtering methods and means are selected according to the nature of the signal, the criterion of estimation, and the way of observing the information.

4.2. Preparation of Nanoscaffold Materials. The research and development of nanoscaffold materials have been practical for a period of time, and its preparation methods have also begun to diversify. Among them, the typical preparation method of nanoscaffold materials is electrospinning. Electrospinning is a special form of electrostatic atomization of polymer fluids. At this time, the atomized and split substances are not tiny droplets, but tiny jets of polymer, which can travel a considerable distance and eventually solidify into fibers. Electrospinning is a special fiber manufacturing process in which a polymer solution or melt is jet-spun in a strong electric field. Under the action of the electric field, the droplet at the needle will change from spherical to conical (namely "Taylor cone"), and fiber filaments are obtained by extending from the tip of the cone. In this way, polymer filaments with nanometer diameters can be produced. The method is specifically shown in Figure 8.

Electrospinning nanofibrous materials can effectively control the fine structure of fibers. Combining substances with low surface energy, materials with superhydrophobic properties can be obtained. It has high specific surface area and porosity, which can increase the action area between the sensing material and the detected object and can greatly improve the performance of the sensor.

The main process of electrospinning is dispersed and continuous phases that can be prepared separately. In order to
Figure 9: Hip joint cell proliferation.

form the desired solution state, the solution can be configured. The resulting solution is subjected to an electrospinning process under specific conditions, obtaining functional nanofibrous scaffolds.

Cell growth is affected by the surrounding environment and responds differently to different substrate environments. The ultrasmall size of the nanoscaffolds promoted cell adhesion but limited cell infiltration. In this experiment, microfibers were introduced into nanofibers to prepare micronanofiber scaffolds, combining the advantages of microfibers and nanofibers [21].

4.3. Testing through Experiments. In this experiment, 50 patients with hip joint injury from two groups A and B were selected for exercise rehabilitation therapy after surgery. Among them, group A was ordinary exercise rehabilitation therapy, and group B was nanofiber scaffold combined with exercise rehabilitation therapy. Other parameters are as follows: the voltage is 17 kV, the drum speed is 300 r/min, and the selected experimental instruments are shown in Table 3.

4.4. Experimental Analysis and Results. According to the observation of the SEM microscope, the proliferation of hip joint cells in the two groups of patients was obtained, as shown in Figure 9.

As can be seen from Figure 9, the OD value of group A was 0.48 on the first day, the OD value of group B was 0.56, the OD value of group A on the second day was 0.6, and the OD value of group B was 0.8. On the third day, the OD value of group A was 0.62, and the OD value

Table 4: Hip joint function recovery.

Item	A group	B group
Knee range of motion	73.8	93.6
General hip function	85	96.3
Knee complication ratio	16.1%	9.9%

of group B was 1.12. The average growth rate of OD value in group B was 0.112 per day, while that in group A was only 0.028. Therefore, it can be seen that the cell proliferation ability of group B was significantly higher than that of group A.

According to the observation, the hip function recovery of the two groups of patients after 5 months is shown in Table 4.

As can be seen from Table 4, compared with the exercise rehabilitation of the two groups of hip patients after 5 months, the hip mobility score of group A was 73.8. Group B was 93.6, and group B was 19.8 points higher than group A. Group A's overall hip function score was 85, group B was 96.3 points, and group B was 11.3 points higher than group A. The complication probability in group A was 16.1%, while group B was only 9.9%, and group B was 6.2% lower than group A. Therefore, it can be concluded that the therapy of the nanofiber scaffold material combined with exercise rehabilitation can more efficiently help patients with hip joint injury to recover, and the probability of complications is lower compared with the traditional exercise rehabilitation therapy.

5. Discussion

In the experimental process of this study, although many valuable data have been obtained, there are still some problems that need to be further explored. Therefore, we can also explore from the following aspects:

(1) In the process of preparing nanoscaffold materials by electrospinning, we can try to optimize the process parameters to prepare bimodal fiber scaffolds with shell-core structure

(2) In the process of electrospinning, try to mix electrospinning PCL with good mechanical properties and biological macromolecular proteins (such as silk fibroin) and growth factors (such as MGF) with biological functions. One-step methods can then be utilized in order to prepare excellent biomaterials with special functions

(3) In the comparison of the two groups of experiments, the amount of data detection is relatively small, and the frequency of data collection should be increased to make the data more reliable

6. Conclusions

In the abstract, this paper firstly summarizes the overall content of the full text, then introduces the background of exercise rehabilitation therapy in the introduction, introduces the role of nanomaterials, and summarizes the innovations of this paper. In the related work section, some related studies are listed to understand the current situation of the related content studied in this paper. Then, in the theoretical research part, the definition, characteristics, classification, and application fields of nanomaterials are firstly introduced, and then, the related content of sports rehabilitation therapy is introduced, including its concept, specific therapy, training equipment, and evaluation method. Then, the related content of hip joint injury is introduced. Finally, an electrospinning method was proposed to prepare nanoscaffold materials, and the nanoscaffold materials were applied to the exercise rehabilitation process of two groups of hip joint patients, and the data of the patients' rehabilitation were calculated. It is concluded that the therapy of the nanofiber scaffold material combined with exercise rehabilitation can more efficiently help patients with hip joint injury to recover, and the probability of complications is lower compared with the traditional exercise rehabilitation therapy.

Materials have always been a research hotspot in the chemical industry. With the continuous development of technology, the iteration of materials research has become faster and faster. Steel has strong toughness and tensile strength, and it is widely used in construction and other fields. However, one problem that cannot be avoided is the fracture of steel. The purpose of this paper is to analyze the damage and fracture of TWIP steel. In this paper, a microstructure characterization calculation method based on TWIP is proposed, which can effectively analyze the fracture surface, and for the performance of TWIP steel, this paper uses two different TWIP steels for comparative analysis. The results of this paper show that the HDI hardening rate of 22Mn0.6C TWIP steel is higher than that of 22Mn0.6C3Al TWIP steel.

1. Introduction

Twin-induced plasticity steel, also known as TWIP, is a new second-generation high-strength transportation steel developed in China. TWIP steel has attracted extensive attention in the automotive and other industries due to its comprehensive mechanical properties such as high strength, high plasticity, and high strain hardening ability. TWIP steel is usually a relatively stable single-phase austenite structure under the condition of no external load at room temperature. When plastic deformation occurs under the applied load, due to the formation of deformation twins, it will extend without necking, resulting in relatively excellent mechanical properties.

As one of the high-strength steels for automobiles, TWIP steel enjoys high strength, high plasticity, and high strain hardenability, as well as high energy absorption and excellent formability. The good comprehensive mechanical properties of TWIP steel show considerable development potential in the exploration of a new generation of automotive lightweight technology, which has attracted extensive attention in the steel and automotive industries. However, TWIP steel is prone to hydrogen-induced cracking, which is intergranular brittle fracture behavior under low stress.

The occurrence of this dangerous brittle fracture makes the service safety of TWIP steel face an unprecedented challenge, which not only restricts its development but also becomes a bottleneck for its wide application. Therefore, it is necessary to conduct microscopic research on TWIP steel.

The innovations of this paper are as follows: this paper takes 22Mn0.6C and 22Mn0.6C3Al TWIP steels as the research objects; based on the stress distribution relationship, through the loading-unloading-reloading tensile test, the evolution of the stress induced by heterogeneous deformation in the material is quantitatively investigated. The study found that the heterogeneous deformation-induced stress of the two steels increased with the increase of strain, and the contribution of deformation twins to the heterogeneous deformation-induced stress in TWIP steel was limited. Further microstructural analysis also confirmed that deformation twins hinder the geometrically necessary dislocation density more weakly than grain boundaries, so the heterogeneous deformation around the deformation twins is smaller.

2. Related Work

At present, universities and enterprises at home and abroad have developed various TWIP steels with different

compositions and have conducted in-depth research on their processing technology, microstructure, and mechanical properties. The plastic deformation of TWIP steel involves a variety of deformation mechanisms (dislocation slip, deformation twinning, and martensitic transformation), and there are complex coupling effects between different mechanisms, so the source of its excellent mechanical properties has been controversial. Peng et al. believe that stacking fault dynamics is rarely covered by scholars. So they investigated new physical insights into the dynamics of stacking faults in TWIP steels [1]. In order to overcome the relative sheet formability problem of TWIP steel, Kim et al. used TWIP core three-layer construction steel plate to produce a mild steel sheath cladding. In order to optimize the design of layer structure materials, they theoretically and experimentally studied the strain hardening exponent n and strain rate sensitivity m of the laminate [2]. Mohammadzadeh studied the nanocrystals of TWIP steel. He conducted experiments on the structure of microscopic molecules. He believes that the current technology is sufficient to analyze the atomic level, so it is necessary to conduct microscopic steel fracture surface analysis. This is confirmed by the experimental results of TWIP microcrystals with a stress dependence [3]. Hu et al.'s research is more microscopic. They aim to use SEM to analyze the microstructure changes of TWIP steel. Their experimental results prove this, but their experiments lack the necessary data support; there are not many types of steel studied without self-preparation [4]. According to Peng and Zhang's study, by controlling the volume fraction of the TWIP core area, the TWIP core steel sheet covers a wide range of yield and tensile strength and ductility levels required for automotive steel sheets, thus providing a new application for multifunctional automotive steel sheets [5]. Wang et al.'s experiments found that nanotwins were also observed in single-pass and double-pass samples as a result of secondary twinning [6]. Unfortunately, there is still no clear conclusion on the evaluation and method research of hydrogen-induced cracking of TWIP steel and on how to effectively improve the resistance to hydrogen-induced cracking and the fracture mechanism at home and abroad.

3. TWIP Steel and Fracture Nonuniform Deformation

3.1. Deformation Mechanism of TWIP Steel

3.1.1. The Stacking Fault Energy of TWIP Steel. The calculation of stacking fault energy (SFE) is very important for the research of TWIP steel, and it can provide many references for the composition design, alloying element control, and service conditions (such as temperature) of TWIP steel [7, 8]. The calculation of stacking fault energy is mainly based on dislocation theory, and the slip plane and twin plane of austenitic steel with face-centered cubic structure are {1,1,1}. The total dislocation can be decomposed into two incomplete dislocations, the region between the two incomplete dislocations is called stacking fault, and the energy change caused by dislocation is called stacking fault energy.

Stacking faults are formed by the expansion of incomplete dislocations under the action of shear stress, and the stacking fault energy is the work done to overcome the elastic interaction of dislocations. The stacking fault energy is an important factor affecting the deformation mechanism of austenitic steel, but there is no perfect and unified method for the calculation of stacking fault energy. The stacking fault energy results obtained by different methods may vary greatly. There are three commonly used calculation methods for stacking fault energy in TWIP steel alloy systems: based on the method of measuring incomplete dislocation distances by transmission electron microscopy (TEM), the method of measuring stacking fault probability based on X-ray diffraction (XRD), and the calculation of stacking fault energy based on thermodynamic models [9, 10].

Mn is the most important alloying element in TWIP steel. Mn has two functions: (1) Mn expands the austenite phase region and increases the austenite stability. (2) Mn affects the stacking fault energy of alloy elements, but the relationship between Mn content and stacking fault energy is nonlinear, as shown in Table 1. Thermodynamic models also confirmed this nonlinear relationship.

3.2. Interface of Metal Materials. The interface of metal structural materials has a great influence on its performance, and the interface characteristics of materials usually play a dual role. For the improvement of material mechanical properties (such as fine grain strengthening), the interface generally plays a more positive role; however, from the perspective of material failure, the interface often becomes the initiation site of failure damage, but this cannot be generalized. For austenite-based metal materials, there are usually grain boundaries inside the material, and the types of grain boundaries are different. If a phase transformation occurs, there are also phase boundaries. In addition, from the perspective of material failure, the fracture surface (fracture) of the material is also an extremely important interface, which can be used as the direct evidence of failure [11–13].

3.2.1. Fracture Surface (Fracture). The fracture surface, which is often referred to as the fracture, is the matching surface formed after the material breaks during the test or service process and is one of the most important evidences for the failure analysis of engineering materials. The fracture records the irreversible deformation of the material before fracture under the coupling action of the applied load and the service environment and the whole process of crack initiation and propagation until the final fracture. At the same time, the fracture morphology is affected by factors such as stress state, environmental medium, and material properties [14–16]. Usually, the typical hydrogen embrittlement fracture is characterized by the intergranular fracture morphology, and the degree of convexity and concave of the fracture varies greatly with different hydrogen embrittlement susceptibilities. Therefore, to deeply understand the failure and fracture behavior of materials, it is necessary to quantitatively characterize the fracture. Through quantitative characterization, the correlation between the mechanical

Table 1: Effects of different Mn contents on stacking fault energy of austenitic steels.

Component part	Layer fault energy (mJ/m^2)

Fe-25Mn-3Al-3Si	21 ± 3
Fe-28Mn-3Al-3Si	38.8 ± 5

properties of materials and the failure mechanism can be directly established.

3.2.2. Phase Interface. Usually, the interface existing between two solid phases with different crystal structures is called a phase boundary, such as the phase interface in duplex stainless steel. After the phase transformation, the interface between the new phase and the parent phase can also be formed; for example, the ε/γ phase interface is formed after the ε martensitic transformation occurs in TWIP steel. The so-called different structures include materials with different qualities, either in the symmetry of the crystal structure or in the lattice parameters (such as the phase interface between α martensite and ferrite) or in the type of bonding, which will make the phase boundary have very complex structural characteristics [17]. If the two-phase interface is completely ordered and perfectly matched, the interface is called a coherent phase interface. If there are local dislocations at the interface through the relaxation process, the interface with relatively small elastic distortion in the local area is called a semicoherent phase interface. If the interface is completely disordered, it is an incoherent phase boundary.

In general, phase interfaces with very strict coherent relationships are particularly rare. A typical coherent phase boundary is the interface between the face-centered cubic (FCC) phase and the dense hexagonal (HCP) phase after the cobalt phase transition. Since the two phases have the same close-packed properties, but have different stacking orders on both sides of the interface, it is a phase interface with lower energy. In the process of martensitic transformation or in the early stage of precipitation, some phase boundaries can also be regarded as coherent phase interfaces. At this time, the phase boundaries are phase interfaces with a certain orientation relationship, that is, a habitual relationship. Figure 1 shows the geometry of a coherent interface.

A semicoherent phase boundary is a particularly common type of phase boundary. Taking the interface formed by misfit dislocations in epitaxial growth as an example, for example, the two crystal structures have the same lattice, and the slight difference is only manifested in lattice parameters or the angle between lattices (<10%). If a coherent phase interface is to be formed, a large amount of distortion must be generated in the crystal, then by introducing misfit dislocations along the interface, the changes in lattice parameters or included angles can be coordinated, as shown in Figure 2. This concentrates the distortion in the vicinity of the dislocation line, thereby relaxing the coherent elastic distortion of the crystal, which is consistent with the principle of minimum energy.

3.2.3. Grain Boundary. Metal structural materials are usually polycrystalline, and the boundaries between different grains are grain boundaries. Compared with the coherent and incoherent phase interfaces, the lattice distortion of the grain interface is larger, so it has a greater impact on the mechanical behavior (fracture behavior, creep behavior, and corrosion behavior) of the material. Therefore, grain boundaries occupy a high enough position in the study of crystal defects [18, 19]. Generally, grain boundaries can be divided into small-angle grain boundaries and high-angle grain boundaries. The grain boundaries in materials such as TWIP steel are mainly composed of high-angle grain boundaries.

The widely accepted model of high-angle grain boundary structure is the coincident position lattice model. If the two grains separated by the grain boundary are regarded as interpenetrating, some of their lattice points will be coincident, and these coincident lattice points will constitute a new lattice, that is, the coincidence position lattice (CSL). The coincident lattice has nothing to do with the crystal interface, but the orientation relationship of the crystal interface relative to the coincident lattice has a great influence on the interface structure. When the interface is the most densely packed surface of the coincident lattice, the interface has a relatively complete lattice matching degree, the mismatch is small, and the interface energy is also the lowest. Of course, it does not mean that any interface with an orientation relationship has a high density of coincident lattice points. Then if the reciprocal $\sum$ of the coincidence lattice point density is used to represent the coincidence degree, for the face-centered cubic crystal, among the grain boundaries with the [110] direction as the rotation axis, the ones with higher coincidence degree have $\sum 3$, $\sum 9$, and $\sum 11$ grain boundaries. These correspond to rotations of 70.5°, 39°, and 129.5° around the [110] axis, respectively. Figure 3 shows the geometry of the $\sum 3$ grain boundary.

3.3. Microstructure Characterization Calculation Method. The phase content in the annealed samples was measured by XRD (Ultima IV), the target was a copper rake, the wavelength was 1.5406 A, the scanning speed was 20°/min, and the scanning range was 40°~100°. The normal tensile test is carried out at room temperature, and the gauge length of the sample is $20 \times 5 \times 1.3 \, mm^3$. The size of the dynamic hydrogen charging slow strain rate tensile test specimen is the same as that of the normal tensile test specimen, and the tensile rates are $1 \times 10^{-5} \, S^{-1}$, $5 \times 10^{-6} \, S^{-1}$, and $1 \times 10^{-6} \, S^{-1}$, respectively. Using in situ electrochemical hydrogen charging, the hydrogen charging solution is 3%NaCl + 3 g/LNH$_4$SCN, the hydrogen charging current density is 5 A/m^2, and platinum wire is used as the counter electrode for electrochemical hydrogen charging. The test device is shown in Figure 4. All tensile tests were carried out on a microcomputer-controlled stress corrosion slow tensile testing machine model QB/LC-JL-159-2010. After dynamic

hydrogen charging and stretching at a slow strain rate, the fracture morphology of the fractured specimens was observed with a field emission scanning electron microscope (electron microscope model) with a working voltage of 20 kV and a working distance of 12-13 mm. In this work, the loss of elongation is used to characterize the hydrogen embrittlement susceptibility; usually, the hydrogen embrittlement susceptibility (E_{lose}) is calculated by the following formula:

$$E_{lose} = \frac{E_{h(air)} - E_{h(H)}}{E_{h(air)}} \times 100\%. \tag{1}$$

Among them, $E_{h(air)}$ is the uniform elongation of stretching in air, and $E_{h(H)}$ is the uniform elongation of stretching under in-situ hydrogen charging.

The fracture morphology under scanning electron microscope (SEM) usually enjoys a certain degree of undulating fracture surface, with obvious height difference (elevation) at μm scale. Obtaining accurate elevation data is extremely challenging using traditional surveying methods. SEM images are two-dimensional grayscale images, but the differences in different grayscales throughout the image provide an effective indirect method. White indicates the raised area, which represents the highest position (its value is 255). Gray indicates the position between them. Therefore, the gray value can be expressed by the following formula:

$$A(x, y, G) \sim A(x, y, H). \tag{2}$$

Calculate the box counting dimension method and projection covering method, and preprocess and cut each original SEM image. The original SEM image is rectangular (768×1624 pixels), and six areas (upper left, upper middle,

upper right, lower left, lower middle, and lower right) are cropped in such an image. For example, Figure 5 shows the upper right and lower left positions.

Based on the projection coverage algorithm, as shown in Figure 6, it is proposed to calculate the fractal dimension D_s of a single surface area. The rough surface area A_k enclosed by the projected grids $a, b, c,$ and d can be approximately expressed as

$$A_k = S_1 + S_2 = \sqrt{p_1(p_1 - ab)(p_1 - ad)(p_1 - bd)}$$
$$+ \sqrt{p_2(p_2 - bc)(p_2 - cd)(p_2 - bd)},$$

$$p_1 = \frac{(ab + ad + bd)}{2},$$

$$p_2 = \frac{(bc + cd + bd)}{2},$$

$$ad = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (H_1 - H_2)^2},$$

$$A_T(\delta) = \sum_{}^{N(\delta)} A_k(\delta). \tag{3}$$

After the above formula, it can be shown that the grid overlay projection algorithm is effective and can determine the fixed pixel value in the image, where $N(\delta)$ is the total number of boxes. In this paper, the images are distributed in boxes of different sizes, which can be defined as a power law, and the formula is expressed as

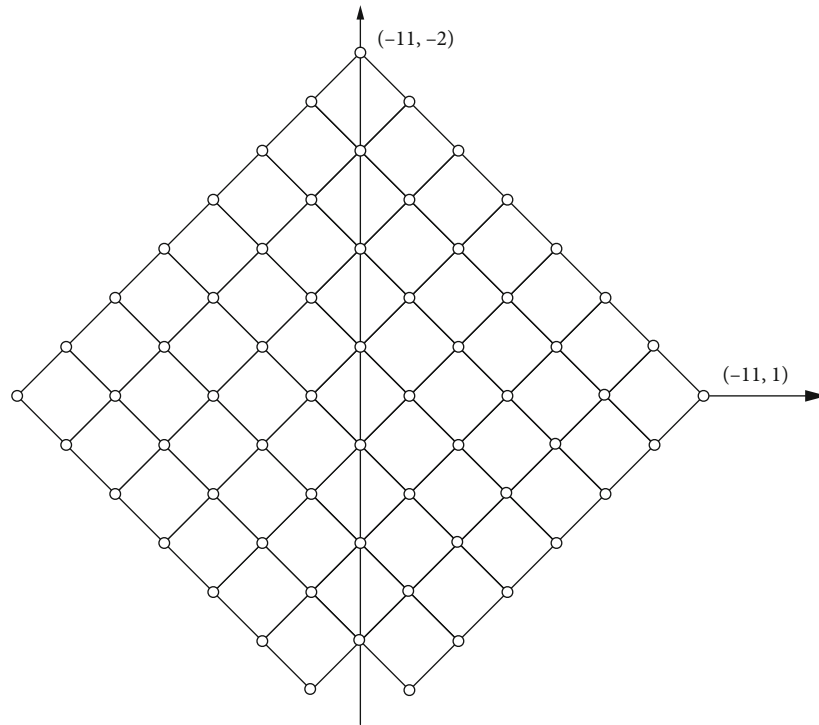
$$A_T(\delta) = \sum_{}^{N(\delta)} A_k(\delta) \sim \delta^{2-D}. \tag{4}$$


FIGURE 3: Geometric structure of the grain boundary of lattice $\sum 3$ at the coincident position.
FIGURE 4: Schematic diagram of the in situ electrochemical hydrogen charging slow strain rate stretching device.

A_T is the total rough area, and when $\delta \longrightarrow 0$, A_T is close to the actual surface area.

Generalized entropy $H_q(\delta)$ and generalized dimension D_q are defined as

$$H_q(\delta) = \frac{\ln \sum_{i=1}^N h_i^q}{1-q},$$

$$D_q = -\lim_{\delta \longrightarrow 0} \frac{H_q(\delta)}{\ln \delta} = \frac{\tau(q)}{q-1} \quad \left(q=1, D_1 = \frac{h_i \ln h_i}{\ln \delta} \right).$$

(5)

After calculation, we can find that there are many definitions that are not perfect, but as shown in Figure 6, the multifractal spectrum can be expressed by the following formulas:

$$f(\alpha) = -\lim_{\delta \longrightarrow 0} \frac{\ln (N(\alpha))}{\ln (\delta)},$$

$$\alpha(q) = \lim_{\delta \longrightarrow 0} \frac{\ln (h_i)}{\ln (\delta)},$$

(6)

where $\alpha(q)$ is the singularity exponent and $f(\alpha)$ is the multifractal spectral function. $N(\alpha)$ represents the α integral value in $[\alpha, \alpha + d\alpha]$. Through the legend transformation, $f(\alpha)$ and $\alpha(q)$ can be given as follows:

$$\alpha(q) = \frac{\partial_\tau(q)}{\partial q},$$

(7)

(a)

(b)

(c)
FIGURE 5: Fracture diagram of digital image recognition technology processing.

$$f(\alpha) = \alpha(q)q - \tau(q). \tag{8}$$

According to the definition of function $\tau(q)$, formulas (7) and (8) can be rewritten as

$$\alpha(q) = \lim_{\delta \longrightarrow 0} \frac{1}{\ln \delta} \sum_i \mu_i \ln (h_i),$$

$$f(\alpha) = \lim_{\delta \longrightarrow 0} \frac{1}{\ln \delta} \sum_i \mu_i(\mu_i). \tag{9}$$

Among them,

$$\mu_i = \frac{h_i^q}{\sum_i h_i^q}. \tag{10}$$

4. Deformation and Microscopic Analysis of TWIP Steel under Damage Fracture

4.1. Thermomechanical Treatment Process. The 22Mn0.6C and 22Mn0.6C3Al TWIP steels used in the experiment were cast into ingots by vacuum smelting, and the weight of the ingots was 75 kg. Subsequently, the ingots were cut with

risers, and samples were taken on the ingots, and the chemical composition of the steel was measured by emission spectroscopy as shown in Table 2.

The chemical compositions of the TWIP steels used in this chapter are shown in Table 2. For convenience, Fe-22Mn-0.6C and Fe-22Mn-0.6C-3Al are abbreviated as 22Mn0.6C and 22Mn0.6C3Al, respectively, in the remainder of this chapter. Figure 7 shows the schematic diagram of the thermodynamic processing of the two TWIP steels: first, the ingots of the two steels were homogenized and heat-treated in an argon atmosphere at 1423 K for 2 h. Subsequently, it is hot rolled to 3 mm thick plate in the temperature range of 1373 K to 1223 K. Then, using a twin-roll mill, the hot-rolled sheet was cold-rolled in multiple passes into a 1.5 mm sheet. Finally, the 22Mn0.6C and 22Mn0.6C3Al steels were recrystallized and annealed at 1123 k and 1173 k for 0.5 h, respectively, and then quickly quenched in water after being taken out to obtain initial materials with uniform equiaxed grains. Tensile specimens were taken from the initial sheet by wire cutting, with the long axis of the specimen parallel to the rolling direction of the sheet.

In this paper, the loading-unloading-reloading method is used to measure HDI stress, and its principle is shown in Figure 8. In the measurement method, first, the hysteresis
FIGURE 6: The schematic diagram of the projection coverage algorithm to calculate the fractal dimension of the fracture.

TABLE 2: Element content (wt.%).

Steel	22Mn0.6C	22Mn0.6C3Al

C	0.55	0.58
Al	0.003	2.86
Si	0.11	0.13
S	0.006	0.005
P	0.008	0.010
Fe	Margin	Margin
FIGURE 7: Schematic diagram of thermodynamic processing of TWIP steel.

loop is obtained through the loading-unloading-reloading process. Then, the unloading yield stress (σ_u) and the reloading yield stress (σ_r) are measured on the unloading and reloading curves, respectively, and finally the HDI stress (σ_{HDI}) is obtained:

$$\sigma_{HDI} = \frac{\sigma_u + \sigma_r}{2}. \tag{11}$$

In addition, the effective stress (σ_{eff}) can also be obtained by subtracting the HDI stress from the total flow stress.

4.2. Initial Microstructure. Figure 9 shows the frequency distribution of grain sizes of two TWIP steels and their log-normal distribution fitting curves. The average grain sizes obtained by statistics are 4.9 μm and 4.3 μm, respectively. The approximately equal grain size helps to elucidate the role of deformation twinning in heterogeneous deformation-induced strengthening.

4.3. Variation of HDI Stress. Figure 10 shows the variation of HDI stress with true strain in both steels. Repeated load-unload-reload tensile tests were performed on two steels at strain levels of 0.01, 0.02, 0.03, 0.04, 0.06, 0.09, 0.11, 0.14, 0.17, 0.19, 0.21, 0.26, 0.31, and 0.34, as shown in Figure 10 (a). Figure 10(b) shows the load-unload-reload curve at 0.14 true strain, and it can be seen that both steels have significant hysteresis loops. Figure 10(c) shows that the HDI stress increases with increasing strain, and the HDI stress of the two steels is approximately equal until 0.11 true strain. Thereafter, as the strain increases, the gap between HDI stresses becomes larger, and at 0.34 true strain, the HDI stress of 22Mn0.6C steel is 104 MPa larger than that of 22Mn0.6C3Al steel. Error bars for HDI stress values were obtained from three replicate experiments. The HDI stress values of the two steels were fitted using the power exponential relationship $\sigma_b = \sigma_{b0} + K\varepsilon^n$, as shown in Figure 10(c). In the fitted curve, σ_{b0}, K, ε, and n represent the intrinsic strength, material strengthening coefficient, true strain, and strain hardening exponent, respectively. It can be seen that the empirical formula can fit the change of HDI stress value well, but its hidden physical meaning still needs to be further explored in the future. In 22Mn0.6C TWIP steel, σ_{b0}, K, and n are 149.8 MPa, 1250.2 MPa, and 0.875, respectively; in 22Mn0.6C3A1 TWIP steel, σ_{b0}, K, and n are 165.7 MPa, 877.0 MPa, and 0.733, respectively.

It can be seen from the stress-strain curve that the plastic loss of the three samples at a strain rate of $1 * 10^{-6} \, S^{-1}$ is greater than that at a strain rate greater than $1 * 10^{-5} \, S^{-1}$. This indicates that the plastic loss increases with decreasing strain rate. At the strain rate of $1 * 10^{-5} \, S^{-1}$, the plastic loss of the three specimens ($T0 \longrightarrow T10 \longrightarrow T30$) gradually increased. However, at the strain rate of $1 * 10^{-6} \, S^{-1}$, the hydrogen embrittlement susceptibility of T0 specimen is greater than that of T10 and T30. The calculated results of

TABLE 3: Brittleness sensitivity (E_{loss}).

Sample	$1*10^{-5}$ S^{-1}	$1*10^{-6}$ S^{-1}
T0	64 ± 1.52	94 ± 0.32
T10	74 ± 0.67	83 ± 0.72
T30	78 ± 0.74	93 ± 1.38

the brittle sensitivity are shown in Table 3. The fitting results show that the HDI hardening rate of 22Mn0.6C TWIP steel is higher than that of 22Mn0.6C3Al TWIP steel.

5. Conclusions

Gradient substructure 22Mn0.6C TWIP steel was prepared by a simple pretorsion method, which combines high yield strength, tensile strength, and plasticity. Gradient substructure samples were found to have greater heterogeneous plastic deformation at the grain scale and at the specimen scale, which resulted in higher heterogeneous deformation-induced strengthening and hardening, compared to the homogeneous coarse-grained structure. More dislocations and deformation twins are formed inside the gradient substructure samples, which hinder the short-range motion of mobile dislocations, resulting in higher effective stress strengthening and hardening. Therefore, the excellent mechanical properties of the graded substructure TWIP steel originate from the synergistic contribution of its higher heterogeneous deformation-induced stress and short-range effective stress. The gradient substructure design strategy is a reasonable method to prepare high strength and high plasticity TWIP steel.

Micro nanotechnology refers to the emerging technology of material production using a single atomic or molecular structure. The structure and size of materials range from one to 100 microns or nanometers. In this paper, micro nanotechnology is used to study the aesthetic practice of sculpture technology and architectural sculpture art. This paper aims to combine traditional art ideas with science and technology to promote common development. This paper first introduces the micro nanoengraving technology and architectural sculpture art, it includes the definition of works, classification of works, and research on artistic commonalities and differences, and then summarizes the characteristics of micro nanoengraving materials. Finally, this paper will carry out aesthetic practice of sculpture works based on micro nanocreation. Finally, this paper compares with the works created by traditional technology. The results show that the recognition and creativity evaluation of sculpture works based on micro nanocreation have reached more than 8 points. It verifies the effectiveness of the technology.

1. Introduction

As an important part of art career, sculpture technology and architectural sculpture art have a development history of thousands of years. For buildings in the traditional sense, it generally refers to the safe and reliable living space built with hard materials, with various styles. Famous traditional buildings include ancient Roman architecture, Gothic architecture, and classical garden architecture. It is not only a work of art but also an important medium for transmitting and preserving culture. However, the architectural sculpture discussed in this paper refers to a kind of microangle. In fact, microcarving art also has a very long history of development. This kind of microcarving cannot be clearly recognized by the naked eye and can be viewed with the help of a microscope. Since the advent of microscope in the mid-20th century, the microcarving technology has made unprecedented progress. It has a strict innovation in size. In the past, most microcarving works were in millimeters.

Now it has entered the micro nanoera, so it is also called micro nanocarving technology and micro nanoarchitectural sculpture art.

With the progress of the times and the innovation of science and technology, micro nanoscience and technology has become one of the focuses of market development. The main forms of its development include micro nanoprocessing, micro nanomanufacturing, micro nanomaterial application, and micro nanoengraving. At present, researchers have developed more new micro nanocarving methods that can perfectly combine the traditional carving art in the process of technological renewal, such as laser method, chemical vapor deposition method, and computer-aided design method. As one of the construction parts of micro nanoscience and technology, micro nanocarving technology and micro nanoarchitectural sculpture art have developed at a higher level in the microworld. Its journey of exploring micro nanocarving technology and the artistic charm of micro nanoarchitectural sculpture is also ongoing.

At present, there is little research on the aesthetic practice of sculpture technology and architectural sculpture art. This paper puts forward a novel art research direction based on micro nanotechnology. It can provide a perfect and improved development suggestion for the engraving industry under micro nanotechnology, and it can also provide new ideas for the research of artistic aesthetics practice.

2. Related Work

In recent years, many scholars have studied micro nanotechnology. Shi J described the nanopore detection mechanism based on translocation. He gave specific examples of nucleic acid analysis and sequencing based on nanopores. This method identifies strategies that can improve the resolution of nanopores. Finally, he discussed the future research direction of promoting nanopore technology to practical application [1]. Tian X has successfully prepared SnO2 micro and nanostructured biscuits by ovalbumin assisted sol-gel method. His experimental results showed that with the increase of calcination temperature, the photoluminescence efficiency of micro and nano will increase [2]. Shah P explored many emerging nanotechnologies. He studied a silver nanocluster nanotechnology based on DNA encapsulation with attractive optical properties [3]. Rohini R believed that the protective characteristics of surge arresters help to reduce the cost of insulation design of electrical systems. He applied this method to micro and nanosamples to verify its effectiveness [4]. Ho C proposed an auxiliary method to overcome the difficulty of drilling sapphire. He studied the effect of adding micro and nanobubbles to the original electrolyte and confirmed that micro and nanobubbles can assist ECDM [5]. Taheri A A considered a two-dimensional transient model with tumor biological tissue. He embedded micro nanosuperparamagnetic materials in the tumor area. The results show that the use of micro nanomaterials will significantly reduce the temperature of healthy tissues around cancer cells, so as to achieve a more favorable therapeutic effect [6]. To sum up, after the exploration in recent years, the application of micro nanotechnology has been deeply studied by many scholars, but there is not much research on the aesthetic practice of architectural sculpture art. Therefore, in order to further promote the development of sculpture art industry, it is urgent to study the aesthetic practice of micro nanosculpture technology and architectural sculpture art.

3. Architectural Sculpture Art and Micro Nanotechnology

3.1. Overview of Micro Nanocarving Technology and Architectural Sculpture Art. Before studying micro nanocarving technology and architectural sculpture art, we need to understand the concept of micro nanoart. In previous studies, many scholars believe that micro nanoart is an art work with micro nanosize characteristics created based on micro nanotechnology [7].

3.1.1. Definition of Micro Nanoengraving Technology and Architectural Sculpture Art. Based on the concept of micro nanoart, we can understand that a work should be called micro nanocarving technology and architectural sculpture art works. It needs to meet two conditions: one is that the work is small in size, and the other is that the work has certain ornamental and artistic value [8].

3.1.2. Classification of Micro Nanocarving Technology and Architectural Sculpture Works of Art. Micro nanocarving technology and architectural sculpture art works can be classified from four levels, as shown in Table 1:

(1) Angle

Based on the different perspectives of micro nanoengraving technology and architectural sculpture art works, we can divide them into two-dimensional works and three-dimensional works. The two-dimensional works are mainly patterns, which are carved on the surface of special materials. This kind of work carves symbolic patterns according to the thoughts and ideas that the creator wants to convey. It can only be viewed through microscopic observation instruments (such as atomic force microscope). The three-dimensional carving works are very three-dimensional, and the length, width, and height of the works are generally in microns or nanometers. It uses electron microscope imaging, and its works using three-dimensional engraving technology are often more lifelike than two-dimensional works. And the carving is more difficult than two-dimensional.

(2) Creative craft

Based on the difference of micro nanoengraving technology and the creation process of architectural sculpture art works, we can be divided into traditional works and processed works [9]. Traditional works generally follow the ancient microcarving technology, as shown in Figure 1. These two works are carved on jade and needles. It is difficult to observe the specific content only with the naked eye. It needs the help of a general microscope, and the processed works have higher eyeballs than traditional works. It is not only unrecognizable by the naked eye but also cannot be clearly viewed by even a general microscope. It needs an electron microscope with high resolution. It also has high requirements for carving tools [10].

(3) Size

Based on the different creation processes of micro nanocarving technology and architectural sculpture works, we can divide the works into different levels, as shown in Table 2:

The traditional carving works that follow the ancient carving technology we mentioned are usually 100 micrometers or 100 nanometers. Although the size of some traditional works exceeds the hundred micro and nanolevel, and even reaches the millimeter level, if the engraving of the nuances of the whole work conforms to the hundred micro and nanolevel, we also call it the hundred micro and

	4	100 nanometer level

nanolevel engraving works. The processing works based on micro and nanotechnology include [11].

(4) Inevitability of creation

Based on the different inevitability of micro nanocarving technology and architectural sculpture art works, we can divide them into intentional works and unintentional works. As the name suggests, intentional works refer to works produced under the guidance of purpose [12]. The creation of many microcarving masters is just the microcarving creation under the premise of purpose, while the unintentional creation refers to the accidental discovery or exploration in research and work. This kind of creation often appears in laboratories that need micro observation. And its creation is in the form of works, as shown in Figure 2. These two pictures are wonderful patterns found on the tested object.

3.1.3. Commonalities between Carving Technology and Architectural Sculpture Art. The emergence and development of carving technology and architectural sculpture art stem from human production activities. And it was directly influenced by religion, philosophy, and other social ideologies in various periods. These two-dimensional and three-dimensional art works are not only the crystallization of the times, thoughts, feelings, and aesthetic concepts but also an important record of the materialization of social development. To understand the relationship between the two, we

must first explore the basis of their symbiotic relationship. We can elaborate from the following four aspects:

(1) Premise of functional requirements

When it comes to architecture or sculpture, we naturally classify them into the category of art and rarely notice that they are directly related to human survival. This starts with the essence of architecture and sculpture. In a narrow sense, the subject considered by architecture is centered on houses or buildings. Greek philosophers called architecture a shelter against wind and rain. French scholars summarized the essence and origin of architecture as the primitive man's search for shelter, and called it the basic house.

In fact, for human beings, architecture and sculpture are more important as necessities than luxury goods [13]. In other words, their emergence is inevitable. The first thing that human beings solve at birth is the problem of survival. When this problem is properly solved, they will care about spiritual things. Therefore, architecture and sculpture should not only meet human physiological needs but also meet human psychological needs [14]. First, we can produce and live as a tool, and then we can care about the beauty of the tool. The requirement from quantitative change to qualitative change is the development process of carving. Similarly, buildings first appeared in order to protect people from the wind and rain and against the dangerous nature. The first thing to solve is whether there are problems. When these basic requirements are met, people will care about the comfort and beauty of buildings, and then start to pursue things at the spiritual level [15]. People began to build spiritual dwellings and public buildings for God. It is a strange phenomenon that residential buildings have not changed much for thousands of years. The greatest contributor to the development of buildings is public buildings. It can be seen that after the basic survival requirements of mankind are met, more attention will be paid to ideology. Therefore, the basic value requirements of architecture and sculpture should be the same.

(2) Aesthetic proposal

The understanding of geometric beauty of architectural form was described as early as the century BC. Later, influenced by the aesthetic thoughts of scholars, architects began to be particularly keen to reveal the mystery of Architectural Formal Beauty from the relationship between geometry and numbers. They use the superposition and change of geometric prototypes such as square, regular triangle, golden section ratio, and circle to shape a beautiful architectural form. The harmonious proportion of the human body is also the focus of the Greeks. Therefore, a large number of sculptures in ancient Greece are based on the beautiful human body to carve (Figure 1) of gods. At the same time, they believe that the human body can be used as the measure of all things. Therefore, in their concept, in order to obtain the beauty of buildings, they must make the buildings have the proportional relationship and harmonious order in line with the beauty of human body.
FIGURE 2: Unintentional micro-engraving works.

(3) Asylum in spiritual places

Through the ages, people's interest in nonpractical aspects and the labor paid for them have greatly exceeded the practical aspects. With the progress of human civilization and the improvement of material acquisition ability, sculpture and architecture show less and less demand for material functions. The expression of ideology, culture, and spiritual consciousness has become an important content. While sculpture and architecture have become the carrier of cultural expression, they have also become the sustenance of spiritual appeal. On the one hand, they show the materialization of human spiritual sustenance; on the other hand, they show the spiritual demand for beauty. As an important medium that leads the material world of architecture to the spiritual world of art, sculpture art with a long history has been changing people's environment. It edifies people's sentiment and stands there for a long time with buildings, witnessing the evolution of human material world and spiritual world.

(4) Subordinate relationship between sculpture and architecture

First, sculptures are attached to buildings. In this case, sculpture can be regarded as a part of architecture, which cannot exist independently. Most of the time, it plays the role of decorative structure. Secondly, sculpture works can enter the architectural space environment. Sculptures in this situation can exist as independent works of art and show their own modeling beauty in the general environment of architecture.

Most of the time, sculpture is the relationship between cooperation and obedience to architecture. From the perspective of practical needs, a large number of sculptures do belong to this category. However, if we only define these two majors as such a subordinate relationship, we underestimate the role of sculpture itself. It ignores the function of carving and weakens the subject consciousness of carving. In fact, the space effect that sculpture can convey is as important as architecture. Sculpture is not only the decoration and appendage of architecture but also the prototype of building space framework together with architecture. The two should have indivisible integrity. Putting aside the limitation of sculpture to talk about an architectural work is not in line with the consciousness of integration in the builder's psychology. Architecture without carving aura is like a body without soul, which is also a kind of blasphemy to the architecture itself.

In the classical period, sculpture was attached to architecture. However, in the modern landscape, it is difficult to say that some structures belong to sculpture or architecture. In the modern environment, the relationship between sculpture and architecture is complementary, interactive, and complementary. They have undoubtedly greatly enriched the form of place space. The combination of sculpture and architecture makes their design no longer isolated, and the integration of design techniques is closer. At the same time, it is of positive significance to the shaping of the whole environment.

3.1.4. Differences between Carving Technology and Architectural Sculpture Art. As two similar disciplines, architecture and sculpture have many similarities in characteristic forms and many differences in essential characteristics. It is these differences that lead to the independence of the two disciplines. In short, architecture is often restricted by function, science, technology, and other factors. Sculpture works can express space more freely. Their differences can be summarized as follows:

(1) Functional differences

Architecture is a high unity of material and spirit, which is in the critical state of pragmatic beauty and artistic beauty. The consideration of function, beauty, and meaning of architecture covers a wide range. In architectural design, the layout of space streamline is very important. The layout of architectural functions has a great impact on the shape of buildings and even the internal space form. Therefore, the design of buildings must first comply with the functions they should have. This consideration is reflected in all stages of the design process. Whether it is the coordination with the base environment, the relationship between space or the organization of streamline, it directly affects the final form of expression of the building. Sculpture seems to be the opposite. The sculptor's pursuit of higher cultural purity and beauty is a kind of sculptural work. It has a strong expressive force, highlighting the artist's self-awareness and emotional expression. It is an effective supplement to the spatial framework on the premise of ensuring that its own has the most basic aesthetic effect. Its attention to beauty greatly exceeds its practicability.

(2) Spatial performance difference

Sculpted space refers to the sculpted shape, while architectural space mainly refers to the internal use space of the

building. It is closely related to the use function of the building. Although the form language of architecture seems more abstract and geometric, it aims to separate or contain the practicability of space. The spatial form of architecture must first meet the functional needs, in addition to meeting people's aesthetic requirements. Engineering structure, technology, and materials will also more or less affect the form of architectural space.

(3) Differences in internal structure

Due to the different sizes of sculptures and buildings, their internal structures are very different. The small scale and no internal space of the sculpture determine its flexibility. Most of the artist's energy is spent on how to mount and carve the outside, and it can build the internal construction of carving at will. As long as it can support the work, it is enough. But buildings are much more complex. Although small-scale building models can also be simulated in the scheme deliberation and creation stage, due to mechanical and engineering factors, we cannot treat real buildings in the way of building models. For example, when building a model, the overhang of a cantilever beam may only depend on the strength of the model material itself, but its equal overhang in a real project needs much more complex calculation and node support.

3.2. Characteristics of Engraving Materials Based on Micro Nanotechnology. Micro nanotechnology has a wide range of applications. At present, it has given full play to its application value in many valuable fields, especially its optical properties have always been paid attention to by the research community. This paper mainly studies the optical properties of engraving materials for nanotechnology according to the principle of optical properties.

Previous studies have shown that there are [16] in a wide range of light intensity:

$$-dI = \alpha I dx. \tag{1}$$

The definitions of parameters in Formula (1) are shown in Table 3:

By integrating with this formula, the light intensity after passing through the medium with thickness is obtained [17]:

$$I = I_0 e^{-ad}. \tag{2}$$

I_0 is the initial light intensity, which is called Lambert's law.

As an electromagnetic wave, the energy flux density of light is expressed by Poynting vector. Light intensity is the time average of energy flow density. For the convenience of calculation, the electric field and magnetic field are expressed as [18]:

$$\begin{aligned}
\vec{E} &= \frac{1}{2}\vec{E}_m e^{-i\omega t} + \frac{1}{2}\vec{E}_m^* e^{i\omega t}, \\
\vec{H} &= \frac{1}{2}\vec{H}_m e^{-i\omega t} + \frac{1}{2}\vec{H}_m^* e^{i\omega t}.
\end{aligned} \tag{3}$$

TABLE 3: Interpretation of each parameter in the formula.

Sequence	Formula parameters	Paraphrase
1	dI	Increment of light intensity
2	dx	Thickness of light passing vertically
3	α	The absorption coefficient of a substance
4	d	Thickness of light passing through

Plane simple harmonic wave [19]:

$$\frac{\left|\vec{H}_m\right|}{\left|\vec{E}_m\right|} = c\varepsilon_0\sqrt{\varepsilon}. \tag{4}$$

If it is taken, then [20]:

$$I = \frac{1}{T}\int_0^T \left(\vec{E} \times \vec{H}\right)dt = \frac{1}{4}c\varepsilon_0\left[\sqrt{\varepsilon^*} - \sqrt{\varepsilon}\right]\left|\vec{E}\right|^2. \tag{5}$$

It can also be expressed as [21]:

$$I = \frac{1}{2}c\varepsilon_0 n\vec{E}_m\vec{E}_m^* = \frac{1}{2}c\varepsilon_0 n\left|\vec{E}_m\right|^2. \tag{6}$$

If the wave vector direction is along the x axis, then [22]:

$$\left|\vec{E}_m\right|^2 = \left|\vec{E}_0\right|^2 e^{-2\omega Kx/c} = \left|\vec{E}_0\right|^2 e^{-\alpha x}. \tag{7}$$

So,

$$I = \frac{1}{2}c\varepsilon_0 n\left|\vec{E}_0\right|^2 e^{-\alpha x} = I_0 e^{-\alpha x}. \tag{8}$$

This is the law of solid light absorption, visible absorption coefficient [23]:

$$\alpha = \frac{2\omega K}{c} = \frac{4\pi K}{\lambda}. \tag{9}$$

Formula (9) shows that the free light coefficient also represents the absorption of light by a solid.

After the semiconductor absorbs photons, it causes the planter excitation and increases the conductivity. The increased conductivity is called photoconductivity. This additional photoconductivity comes from the inter band transition of carriers or the excitation of impurities. The work done by light to photocurrent in unit time and unit volume is called optical power density, which is equal to:

$$W = \left\langle \vec{J} \times \vec{E} \right\rangle. \tag{10}$$

< > means averaging the time. Using the complex forms of and above, we can get [24]:
FIGURE 3: Carbon dioxide crystal structure.
FIGURE 4: Zinc oxide crystal structure.
FIGURE 5: Visible light absorption of doped zinc oxide.

$$W = \frac{1}{2}\varepsilon_0 \omega \varepsilon_i \left| \vec{E}_m \right|^2 = \frac{1}{2}\varepsilon_0 \omega x \left| \vec{E}_m \right|^2. \tag{11}$$

It can be seen here that the imaginary part of the dielectric constant or the imaginary part of the polarizability is related to the free current.

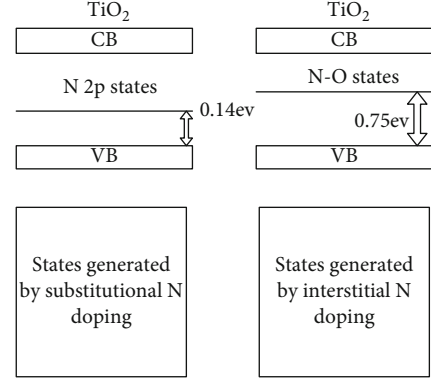
The absorptivity is defined as the ratio of absorbed energy to incident energy. When the light is vertically incident on a solid surface, the incident light intensity (i.e., aver-


FIGURE 6: Visible light absorption of doped titanium dioxide.

age energy flow density) is, and the absorbed energy flow density is equal to the optical power density multiplied by the thickness, then [25]:

$$A = \frac{\varepsilon_0 \omega \varepsilon_i d}{\varepsilon_0 cn} \frac{\left| \vec{E}_m \right|^2}{\left| \vec{E}_0 \right|^2} = \frac{\omega \varepsilon_i d}{cn} e^{-\alpha d}. \tag{12}$$

In air, when the film thickness is very small, ignoring the attenuation of amplitude after light flux, we get:

$$A \approx \frac{\omega \varepsilon_i}{cn} d = \alpha d. \tag{13}$$

The optical power and optical absorptivity can also be expressed as:

$$W = \frac{1}{2}\sigma_r \left| \vec{E}_m \right|^2.$$
$$A \approx \frac{\sigma_r d}{\varepsilon_0 cn}. \tag{14}$$
$$\alpha \approx \frac{\sigma_r}{\varepsilon_0 cn}.$$

When light shines on a solid, according to the conservation of energy, the relationship between absorptivity, reflectivity, and transmittance is:

$$A + R + T = 1. \tag{15}$$

From Michaelis formula:

$$\vec{H} = \frac{\bar{n}\sqrt{\varepsilon_0/\mu_0} \left(\vec{s}_0 \times \vec{E} \right)}{\mu}. \tag{16}$$

$\vec{s}_0$ is the unit vector of the wave vector. It defines the optical admittance of the medium as:

TABLE 4: Artist personal information.

Sequence	Age	Working time
artist 1	21	5 years
artist 2	33	12 years
artist 3	45	21 years
artist 4	38	18 years
artist 5	27	10 years

$$Y = \frac{\vec{H}}{\vec{s}_0 \times \vec{E}} = \bar{n}\sqrt{\frac{\varepsilon_0/\mu_0}{\mu}}. \tag{17}$$

For medium, its optical admittance is:

$$Y = \frac{\vec{H}}{\vec{s}_0 \times \vec{E}} = \bar{n}. \tag{18}$$

The unit of optical admittance in formula (18) adopts free space admittance.

The more common carving materials are zinc oxide and titanium dioxide, which are often used by carving artists because of their unique comprehensive properties, such as good chemical stability, low cost, nontoxic, high quantum efficiency, and redox ability. Titanium dioxide exists in many forms in nature. Its crystal structure is shown in Figure 3:

Zinc oxide also has a variety of morphologies, such as nanocomb, nanorod, nanohelix, nanobelt, nanowire, and nanocrystal. Its crystal structure is shown in Figure 4:

The visible light absorption after doping two materials is shown in Figures 5 and 6:

4. Artistic Aesthetic Practice

This paper uses micro nanotechnology to create a sculpture sample and test its aesthetic practice. The general evaluation of works of art comes from two aspects: the general evaluation of works of art. That is the external evaluation and internal evaluation of the work. External evaluation includes whether the structural proportion of the work is uniform and whether the appearance is aesthetic. This is the most intuitive and basic evaluation index in aesthetic practice. In addition, it also includes the richness and unity of works. The external evaluation of works includes whether the works realize the unity of identification and creativity, practicability, and artistry. As the evaluation of aesthetic practice is affected by many factors, the evaluation method of this paper adopts the subjective evaluation method. Five sculpture artists were invited to evaluate the works of this article. The personal information of the five artists is shown in Table 4. Then, this paper compares the evaluation results with the evaluation results of traditional sculpture works. The evaluation system is bit score system. The full score of each evaluation index is 10. The higher the score, the better

the evaluation of the work. The evaluation results are shown in Figures 7–10.

(1) Proportion and aesthetic evaluation of works

As can be seen from Figure 7, the average overall score of the proportion of sculpture works created based on micro nanotechnology in the evaluation of six artists is about 8.46 points, and the average overall score of aesthetic feeling of works is 8.25 points. The average score of the proportion of works created in traditional crafts in the evaluation of six artists is about 8.20 points, and the average score of the overall aesthetic feeling of works is 8.11 points.

(2) Evaluation of richness and unity of works

It can be seen from Figure 8 that the average overall score of the richness of the sculpture works created based on micro nanotechnology in the evaluation of six artists is about 7.79 points, and the average overall score of the unity of the works is 8.05 points. The average overall score of the richness of works created in traditional crafts in the evaluation of six artists is about 7.87 points, and the average overall score of the unity of works is 8.04 points.

(3) Work identification and creative evaluation

As can be seen from Figure 9, the average overall score of work identification of sculpture works created based on micro nanotechnology in the evaluation of six artists is about 8.44 points, and the average overall score of work creativity is 8.48 points. The average overall score of works created in traditional crafts in the evaluation of six artists is about 8.45 points, and the average overall score of works' creativity is 8.30 points.

(4) Practical and artistic evaluation of works

As can be seen from Figure 10, the sculpture works created based on micro nanotechnology in this paper have an average overall score of about 7.57 points for practicability and 8.25 points for artistry in the evaluation of six artists. The average value of the overall practical score of the works created in the traditional craft in the evaluation of the six artists is about 7.56 points, and the average value of the overall artistic score of the works is 8.17 points.

5. Discussion

By comparing the scores of micro nanosculpture works with traditional craft sculpture works, the following conclusions can be drawn:

(1) In terms of the proportion and aesthetic feeling of works, the overall average score of the proportion of sculpture works created based on micro nanotechnology is 0.26 points higher than that of sculpture works created under traditional technology. The overall average aesthetic score of the works in this paper is 0.14 points higher than that of the sculpture

works created under the traditional technology. It shows that the sculpture works created in this paper are symmetrical in structure, uniform in proportion, and in line with public aesthetics

(2) At the level of richness and unity of works, the overall mean value of the richness score of sculpture works created based on micro nanotechnology is 0.08 points lower than that of sculpture works created under traditional technology. The overall average score of the unity of works in this paper is 0.01 higher than that of sculpture works created under traditional technology. It shows that the richness of the works created in this paper is weaker than the traditional craft works, but it has advantages in the overall unity of the works

(3) At the level of work identification and creativity, the difference between the overall average of the identification score of sculpture works created based on micro nanotechnology and the overall average of the identification score of sculpture works created under traditional technology is 0.01. The overall average score of the creativity of the works in this paper is 0.18 points higher than that of the sculpture works created under the traditional technology, which shows that the works created in this paper are generally recognizable. But it has high creativity

(4) At the level of practicability and artistry, the overall average score of the practicability of sculpture works created based on micro nanotechnology in this paper is 0.01 points higher than that of sculpture works

created under traditional technology. The average score of traditional sculpture works is 0.08. It shows that the works created in this paper have high practicability and artistry

The whole comparative aesthetic practice data show that under the same conditions of other experiments, through the evaluation and test of different projects, the sculpture works created based on micro nanotechnology are superior in terms of proportion, beauty, unity, creativity, practicability, and artistry. And in terms of the richness and identification of the works, there is little gap between them and the works created based on traditional technology. It shows that the carving technology and architectural sculpture art based on micro nanotechnology have good application value and artistic value, which can promote the diversified development of the art market.

6. Conclusion

Since ancient times, sculpture technology and architectural sculpture art have been an indispensable part of art and culture in the process of human history. In order to make it sustainable, it needs to meet the characteristics of the times and innovate. Micro nanocarving technology and architectural sculpture art are the products of traditional art in the development of the times. Micro nanoengraving technology and architectural sculpture art are a composite creation process. It not only involves the subjective art field and art concept but also includes objective scientific theoretical knowledge, although the current stage of micro nanoart is not yet mature, and there are many inherent defects. With the diversified development of the art field and the continuous renewal of science and technology, especially under the background of the improvement and progress of

nanoscience and technology, micro nanocarving technology and architectural sculpture art are bound to usher in a considerable future.

Although this paper uses micro nanotechnology to deeply study the carving technology and the aesthetic practice of architectural sculpture, there are still many deficiencies. In the process of this study, the acquisition of aesthetic practice evaluation data is carried out under absolutely ideal conditions, and the integrity and effectiveness are not enough. It does not take into account some interference factors involved in the evaluation process. The depth and breadth of this research are not enough, the author's academic level research is also limited, and the research on micro and nanotechnology is still in the preliminary stage. In the future work, it will study appropriate research translation methods and means from more angles according to the existing technology and level for the purpose of improving the research quality.

Research Article

Biomimetic Design and Biocompatibility of Biomimetic Calcium Carbonate Nanocomposites for Skeletal Muscle Injury Repair

Yan Han (ID)

College of Physical Education, Xuchang University, Xuchang, 461000 Henan, China

Correspondence should be addressed to Yan Han; 22014015@xcu.edu.cn

As an important part of the human body, skeletal muscle is easily damaged in the process of exercise. The purpose of this study is to investigate the controllable construction and biocompatibility of biomimetic calcium carbonate nanocomposites in exercise skeletal muscle repair. In this study, adult healthy mice were selected as the research objects. First, the mice were anesthetized with 2.5% pentobarbital sodium. Then, the mice were fixed and hit with steel balls on the middle part of the gastrocnemius muscle abdomen to establish a skeletal muscle contusion model. The mice were killed by cervical dislocation under anesthesia. The injured gastrocnemius muscles were quickly removed to prepare the cell suspension. 0.8600 g chitosan was weighed and dissolved in 200 ml deionized water. Then, 0.0660 g of calcium chloride dihydrate was added and stirred to dissolve to prepare chitosan calcium carbonate composite. The calcium carbonate composite material with a length of 8.0 cm is cut into a square sheet of stainless steel. The stainless steel plate was sterilized and then placed in a 12 culture plate to dilute the full cells in the culture bottle. The cells were seeded in 12 well culture plates, and $100\,\mu L$ cells and $600\,\mu L$ medium were added to each well. The samples were cultured in the incubator (there were three control holes in each group for SEM test, three control holes for fluorescence measurement, and six control holes for MTT measurement). The plates were taken out and placed in a new 24 plate. $1000\,\mu L$ medium was added. Then. $100\,\mu L$ MTT solution was added into each well. The biocompatibility test was conducted for 4 h. The GSH PX level in the chitosan calcium carbonate composite group was lower than that in the natural recovery group ($P < 0.01$). The results showed that chitosan calcium carbonate composite could promote the growth of skeletal muscle cells.

1. Introduction

The research on biomimetic materials has long been a hotspot in materials research. In recent years, biomimetic calcium carbonate nanocomposites have attracted more and more attention because of their special structure and good properties. On the basis of optimizing the material structure, the main purpose is to obtain a kind of composite bionic material with strong combination of organic and inorganic energy. On the other hand, through the biomimetic process, the ultimate goal is to make the mechanical properties of the composite materials obtained through formula adjustment controllable. The preparation methods include self-assembly, spin coating, chemical deposition, and compression molding. Bionic film and molding materials were obtained. In recent years, some people have obtained linear long materials with simulated structures using graphene as raw materials. Although the injured skeletal muscle has a strong regenerative capacity, severe trauma, such as loss of muscle tissue, exceeds the natural and complete recovery capacity of skeletal muscle, the clinical treatment has limited effect, and there is no satisfactory bone grafting program at present. Autologous bone is regarded as the "gold standard" of bone defect replacement material because of its excellent osteogenic properties, osteogenic induction, bone electrical conductivity, complete biocompatibility, nontoxicity, and no immune problems. Generally, with a history of trauma or overwork and fatigue, symptoms show localized muscle pain and tenderness.

Many reasons such as trauma and skull tumors can cause skull defects. Skull defects endanger the health of patients, so the repair of the defects is essential. At present,

repair materials include autologous bone, allogeneic bone, and artificial materials. Autogenous bone repair is the best, but its supply is insufficient and its application is limited. Allogeneic bone has severe rejection, which hinders its application. There are many kinds of artificial materials, such as hydroxyapatite and bioceramics, but they have serious side effects and are gradually eliminated. Currently, titanium alloy materials are the most widely used, with good biocompatibility, stable physical and chemical properties, and easy shaping. Carbon fiber has good mechanical properties and biocompatibility, which can improve the mechanical strength of other materials. Bioinert ceramics mainly refer to ceramic materials with stable chemical properties and good biocompatibility, such as alumina, zirconia, and medical carbon materials. The structure of these ceramic materials is relatively stable, the bonding force in the molecule is strong, and they all have high strength, wear resistance, and chemical stability.

Calcium carbonate (CaCO3) nanoparticles have barrier properties and biodegradability effects on polylactic acid (PLA). Aframehr et al. prepare nanocomposite membranes with various CaCO3 nanoparticle contents (0, 3, 5, 10, and 15 wt%) by solution casting method. He uses constant volume and variable pressure equipment to evaluate the permeability of nitrogen (N2), oxygen (O2), and carbon dioxide (CO2) at different pressures and temperatures. In addition, he also observed that the gas permeability of the sample decreased by increasing the feed pressure and increased by increasing the temperature. There are too few experimental data in his research [1]. Acar et al. compared the effect of coffee dyeing on the color of 3 different CAD/CAM restoration materials and nanocomposite resins. He evaluated the color change ($n = 5$) of samples mixed with dental ceramics (VITA Enamic) and nanocomposite resins (Filtek Supreme Ultra Universal) due to thermal cycling. He thermally cycled samples with thicknesses of 0.5 to 0.7 mm and 1 to 1.2 mm for 5000 cycles. The color coordinates obtained from the spectroradiometer are used to calculate the CIEDE2000 color difference ($\Delta E00$) due to thermal cycling in the coffee. Use ANCOVA to analyze the color difference between the thicknesses as covariates between materials. He used the Tukey-Kramer test to analyze the significant difference in average thickness. His research lacks comparative experiments [2]. Nguyen et al. completed the preparation and characterization of modified and unmodified polypropylene- (PP-) wood powder (WP) composites under fixed processing conditions. He used different techniques to study the influence of the size and content of wettable powders and the content of compatibilizers on the properties of composite materials. Scanning electron microscope micrographs show that the distribution of WP in the PP matrix is relatively uniform. His research sample is too small [3]. De France et al. believe that although injectable hydrogels have multiple advantages in biomedical applications, their generally weak mechanical properties often limit their applications. He described that in situ gelling nanocomposite hydrogels based on poly(oligoethylene glycol methyl methacrylate) (POEGMA) and rigid rod-shaped cellulose nanocrystals (CNC) can overcome this challenge. By physically incorporating CNCs into the cross-linked POEGMA hydrogel, he can easily customize the macroscopic properties, including gelation rate, swelling kinetics, mechanical properties, and hydrogel stability. The strong adsorption of the aldehyde and hydrazide modified POEGMA precursor polymer on the surface of CNCs can promote the uniform dispersion of CNCs in the hydrogel and give physical cross-linking in the entire network. His research is not novel enough [4].

In this study, adult healthy mice were selected. First, the mice were anesthetized with 2.5% sodium pentobarbital, and the mice were fixed and then hit the midsections of the bilateral gastrocnemius muscles with steel balls to create skeletal muscle blunt contusion models. The mice were killed by cervical dislocation under anesthesia, and the injured gastrocnemius muscles of both sides were quickly taken to prepare the cell suspension. Weigh 0.8600 g of chitosan and dissolve it in 200 mL of deionized water. Then add 0.0660 g calcium chloride dihydrate, stir to dissolve, and prepare chitosan calcium carbonate composite material. The chitosan-calcium carbonate composite material prepared by using a stainless steel sheet as a base is cut into a square with a side length of 0.8 cm. Sterilize the stainless steel sheet and place it in a 12-well culture plate to dilute the overgrown cells in the culture flask. The cells were seeded in a 12-well culture plate, and 100 μL of cells and 600 μL of culture medium were added to each well. Incubate in an incubator (including three control holes for each group of samples when doing SEM test, three control holes for each group of samples when measuring fluorescence, and six control holes for each group of samples when measuring MTT). Ceramic artificial bone is the use of bioceramics as a repair material for bone tissue defects or deletions and uses it to form a mesh scaffold structure to promote and guide bone tissue.

2. Skeletal Muscle Injury Repair Experiment

2.1. Bionic Materials. Inspired by biological materials, we use the principles of bionics to study the formation mechanism of biological materials and apply them to the synthesis of new materials in the future, to be able to design and synthesize organic materials, inorganic materials, organic-inorganic composite materials, functional, and even smart materials; it is a research hotspot that has developed rapidly in recent years and has developed into a popular research in multiple disciplines and fields such as chemistry, materials, and life sciences [5, 6]. Calcium carbonate material is loaded with rare earth metals or other functional components, which can realize the functions of comprehensive diagnosis, treatment or diagnosis and treatment, and is used for imaging diagnosis and treatment [7, 8]. The minimum energy parameter is expressed as follows:

$$E_{\text{snake}} = \int_0^1 EV(s)ds = \int_0^1 \left\{ E_{\text{int}} V(s) + E_{\text{image}} V(s) + E_{\text{cins}} V(s) \right\} ds. \tag{1}$$

Among them, it can represent the internal energy of a

substance [9, 10]. The constituent materials of natural bio-composites range from organic natural sugars to various proteins and inorganic minerals [11, 12]. The research, design, and synthesis of new materials have brought new methods and routes [13, 14]. Based on the advantages of calcium carbonate material and its wide range of existing applications, its application in the medical field will be more complete, the technology will be more mature, and it will definitely contribute to solving the problems in the human medical field. Reducing the cost of products is the biggest advantage of calcium carbonate, because the price of calcium carbonate is the lowest price among all fillers, and the plastic products compounded with it are of course the lowest price [15, 16].

2.2. Nanomaterials.

With the continuous progress and development of science and technology, nanotechnology is also constantly improving. Nowadays, nanotechnology can be seen everywhere in people's daily life and is applied to all aspects of life. Many nanotherapeutic drugs in clinical and preclinical stages are polymer nanoparticles, which have been widely studied as therapeutic carriers. The design of polymer nanoparticles is based on their biocompatibility and biodegradability [17]. Most of these nanoparticles are formed by the self-assembly process of block copolymers, which are composed of two or more polymer chains with different hydrophilic properties [18, 19]. The resulting structure is very suitable for drug delivery. The hydrophobic core can carry a large number of therapeutic drugs, and the hydrophilic shell provides three-dimensional protection for the nanoparticles [20]. Used to express the compressive resistance of polymer nanomaterials, including

$$\eta(X, \mu) = \frac{1}{2\pi^{n/2}|m|} e^{-1/2(X-\mu)\sum(X+\mu)} + \mu K. \qquad (2)$$

Among them, the larger the molecule, the stronger its cohesion [21, 22]. Other widely studied nanodrug delivery systems include metal nanoparticles. Metal-containing nanoshells are usually composed of inert metals (such as gold or titanium) and are used to control the release of chemotherapeutic drugs. These systems have unique characteristics [23]. Although these metal ions are inert and biocompatible, they will remain in the body in large quantities after administration, and the accumulation of metal particles formed by repeated administration may cause toxicity [24, 25]. For nanomedicine, its therapeutic effect is better, and the toxicity is lower [26]. In fact, the progress of nanomedicine is rapidly applied to clinical practice [27, 28].

2.3. Nanomaterial Preparation Experiment.

PBT is milky white translucent to opaque, semicrystalline thermoplastic polyester, with high heat resistance, toughness, fatigue resistance, self-lubricating, low friction coefficient, not resistant to strong acid and alkali, resistant to organic solvents, flammable, and decomposed at high temperature [29]. Dilute the prepared nano-CaCO3 suspension with deionized water, and observe the particle dispersion in the solution with a transmission electron microscope. Take a part of the nano-

CaCO3 suspension after multiple washing and drying, and then grind to obtain CaCO3 particles, which are combined with the initial nano-CaCO3 particles, and cellulose ether dispersant was analyzed by infrared spectroscopy together. The extruded strip was brittle under liquid nitrogen conditions, and the section was vacuum-plated. The morphology of the section was observed with a scanning electron microscope (SEM), and the accelerating voltage was 20 kV. For PCΠnano2CaCO3 samples with the same thermal history. The pure PC sample is analyzed by gel permeation chromatography, the column PLgel is 5 μm, tetrahydrofuran is selected as the solvent, the test temperature is $T = 35°C$, and PS is used as the standard sample. The sample is injected, the tensile performance is in accordance with the GBΠT104021992 standard, and the bending performance is in accordance with the GBΠT934121988 standard. The impact performance is tested according to the GB/T183421996 standard.

After the resin matrix is filled with nano-CaCO3, the tensile strength and flexural strength have been improved to different degrees. The impact strength of PP composites has increased, and the impact strength of PBT and PC composites has decreased slightly. Combined with the GPC results, it can be considered soft, method does not cause mechanical and thermal degradation of the system matrix when preparing polymer Π nanoparticle composites, and is a new method for preparing nanocomposites of polar and nonpolar polymers. Especially for PP systems, the processing method can only rely on the addition of nanoparticles, which can simultaneously play a role in strengthening and toughening. Scanning electron microscopy photos of nanoporous silicon: a side view and by top view, as shown in Figure 1.

2.4. Main Equipment.

Corotating twin-screw extruder, SHJ220, Nanjing Jiente Mechanical & Electrical Co., Ltd.; Ultrasonic Disperser, VCF21500, Sonic & Materials Inc., USA; Scanning Electron Microscope, JSM25900LV, Japan JEOL Co., Ltd.; Transmission Electron Microscope, HITACHTH2600, Japan Hitachi Co., Ltd.; infrared spectroscopy; Nicolet20SXB Fourier transform infrared spectrometer, American Thermoelectric Nicolas; gel permeation chromatography: Agilent1100Series gel permeation chromatograph, American Agilent company; injection machine, PS40E5ASE type, Nissei Resin Industry Co., Ltd.; Shimadzu universal material testing machine, type AG210TA, Shimadzu Corporation; cantilever beam impact testing machine, type UJ240, material testing machine factory in Chengde City, Hebei Province.

2.5. Selection of Experimental Subjects.

The animals used in this experiment are adult healthy mice, a total of 96 mice, weighing 2.6-3.0 kg, and are half male and female. The food and activities of the experimental animals were good, the skin and mucous membranes were intact, and the epiphyses were closed. The experimental equipment is shown in Table 1.

2.6. Skeletal Muscle Blunt Injury Model.

Skeletal muscle injuries are an important component of trauma in sports
Figure 1: Scanning electron micrograph of nanoporous silicon.

Table 1: Experimental equipment.

Equipment name	Model	Manufacturer
Vacuum multitarget magnetron sputtering instrument	KCCK-III	Shenyang Kecheng
Field emission scanning electron microscope	S-4800	Hitachi

Inverted fluorescence microscope	IX71-Olympus	Olympus

medicine, with injury rates ranging from 10% to 55%. Because treatment failure can delay an athlete's return to play, which can be weeks or months, and lead to recurrence, the management of musculoskeletal injuries requires extreme measures. A simple and reproducible blunt skeletal muscle modelling method is adopted. After the mice were anesthetized by intraperitoneal injection of 2.5% sodium pentobarbital, they were fixed at the knee joint extension at 0° and the ankle joint extension at 90°. A solid stainless steel ball with a mass of 16.8 g and a diameter of 15.9 mm was placed on the top of a transparent tube. (Height 100 cm, inner diameter 16.0 mm) after free fall, it hits the striking device vertically. The bottom of the striking device hits the middle of the abdominal muscles of the mouse bilateral gastrocnemius muscles. The striking position is fixed (the striking area is 20 mm^2), the skin is intact after injury, there is no tibiofibular fracture, and the anatomy confirmed that the damage rate was 100%.

2.7. Animal Selection and Weighing. The genes of mice are very similar to those of humans. The mice are mammals, and their genomes are very similar to those of humans. The effect of using them in genetic experiments is very good, and the cause can be found through experiments on mice, to study the regularity of disease and treatment methods. Strictly according to the time point of the experimental grouping, the mice were killed by cervical dislocation under anesthesia. The injured gastrocnemius on both sides was quickly taken. The gastrocnemius muscle of the same part was taken in the control group, and the material was fixed. The excess connective tissue was carefully removed and

rinsed with 4°C physiological saline. The filter paper was soaked and weighed, and the muscle weight/body weight was used to reflect the relative change of muscle wet weight. Among them, the right gastrocnemius of each group was made into paraffin specimens for histomorphological examination, part of the left gastrocnemius was tested immediately by flow cytometry, and the other was placed in liquid nitrogen for western blotting.

2.8. Flow Cytometric Detection of Skeletal Muscle Tissue. The fresh gastrocnemius tissue ($n = 6$/group) of 1 d and 3 d after blunt skeletal muscle injury was rinsed with PBS and cut into small pieces of about 1-2 mm^3, and 30 times the amount of tissue protease solution (0.1% trypsin mixed with 0.02% EDTA + 0.1 μg/mL collagenase), transfer the pipette to the erlenmeyer flask, place it in a 37°C incubator for 2 h, shake once every 5-10 min, and pass the digestion solution through 300 mesh filter through a strainer, centrifuge at 300 g for 5 minutes, and discard the supernatant. Wash with PBS solution containing 0.1% BSA by centrifugation for 1-2 times; adjust the cell concentration to 1×10/mL with PBS solution containing 0.1% BSA. Add 3 μL CD11b antibody (PE labeled), 10 μL F4/80 antibody (FITC labeled), incubated for 30 minutes at room temperature in the dark, rinse with sterile PBS solution for 1-2 times, add 200 μL 0.5% sterile paraformaldehyde (PFA) solution for fixation, and flow cytometry detects the number of macrophages.

2.9. Preparation of Chitosan Calcium Carbonate Composite. Ethanol is an important organic solvent and is widely used

in medicine, paint, sanitary products, cosmetics, oils, and fats, accounting for about 50% of the total consumption of ethanol. Ethanol is an important basic chemical material. The cut stainless steel sheet was sonicated in absolute ethanol and ultrapure water for 5 minutes to remove oil stains and impurities on the surface and then dried naturally in a nitrogen atmosphere for later use. Weigh 0.8600 g of chitosan and dissolve it in 200 mL of deionized water, adjust the pH to 5.0 with a molar concentration of 2 M HCl solution, and then adjust the pH to 5.0 after stirring for 12 hours. Then take 50 mL of the above solution in a beaker, then add 0.0660 g calcium chloride dihydrate (that is, the final concentration is 9 mM), and stir to make it dissolved. Then add 0.0711 g of ammonium bicarbonate (that is, the final concentration is 18 mM), stir to dissolve. Then use the above solution as the mother solution for electrochemical deposition in a three-electrode system (reference electrode: Ag-AgCl electrode; counter electrode: Pt wire electrode; working electrode: stainless steel sheet). The stainless steel sheet obtained after the electrodeposition process is gently washed in distilled water and air-dried naturally in a clean and dry environment.

2.10. Cell Culture

(1) Cell culture refers to a method that simulates the in vivo environment (sterility, suitable temperature, pH, certain nutrient conditions, etc.) in vitro to make it survive, grow, reproduce, and maintain its main structure and function. Cut the bare stainless steel sheet and the chitosan-calcium carbonate composite material prepared with the stainless steel sheet as a base into a square with a side length of 0.8 cm

(2) Sterilize the front and back sides of the cut film with alcohol and UV, then place it in a 12-well culture plate, digest the overgrown cells in the culture flask, and then dilute. The cells were seeded in a 12-well culture plate, and $100 \mu L$ of cells and $600 \mu L$ of culture medium were added to each well. Incubate in an incubator with a content of 5% CO2 at 37°C (wherein, each group of samples is set with three control holes when doing SEM test, and each group of samples is set with three control holes when measuring fluorescence, and when measuring MTT, each group of samples is set 6 control wells)

2.11. Cytotoxicity Test.

The CCK-8 method was used to study the toxicity of chitosan calcium carbonate composite materials on cells. The skeletal muscle cells in the logarithmic growth phase were seeded in a 96-well plate at a density of 8×10^3/well, grown adherently for 4 h, then added a medium mixture containing different concentrations of chitosan calcium carbonate composite material (final concentration 5, 25, 50, 150, and $300 \mu g$/mL), set a medium without nanoparticles as a control group, and continue to culture for 48 h. After removing the nanoparticle medium and mixing the treatment solution, add $10 \mu L$ CCK-8 solution to each well. A microplate reader (Thermo, USA) was used to detect the absorbance at a wavelength of 450 nm,

and the reference wavelength was 630 nm. Finally, the cell viability (%) was calculated according to the experimental data. Repeat the experiment three times.

2.12. Cell Fluorescence Microscopy Characterization.

First, take out the composite material for cell culture from the culture plate on the first 1, 3, 5, 7, and 9 days, and wash it with 0.1 mol/L PBS buffer three times, each washing for 2 s. Then fixed with 1% paraformaldehyde, and then add $1000 \mu l$ PBS and $50 \mu L$, 0.1 mg/mL DAPI dye to each well for staining. Then continue to incubate in an incubator for 2 hours and rinse with PBS 3 times for a few seconds each time, and finally observe with a fluorescence microscope.

2.13. Biocompatibility Test of Composite Materials.

First, take out the composite material for cell culture from the culture plate on days 1, 3, 5, 7, and 9. Then take out the slides, place them in a new 24-well culture plate, add $1000 \mu L$ of culture medium, then add $100 \mu L$ of MTT solution to each well, continue to incubate for 4 h, wait until the culture solution is aspirated, and then add DMSO solution ($1000 \mu L$/well). Finally, $150 \mu L$ of solution is extracted from each well in the 96-well plate, the wavelength of 490 nm is selected, and the a value of each well is detected on the microplate reader.

2.14. Data Statistics.

Statistical analysis method: in all experimental data, the measured data is represented by $X \pm S$, and the comparison between and within groups is analyzed by single factor variance. Paired comparisons between groups were carried out by LSD test, and there were statistical differences when $P \leq 0.05$.

3. Skeletal Muscle Injury Repair

3.1. Cell Detection and Analysis.

Chemiluminescence method for cell viability test: ATP adenosine triphosphate combines adenine, ribose, and 3 phosphate groups. It releases more energy when hydrolyzed and is the most direct source of energy in the body. The ATP luminescence method analyzes cell activity and proliferation by detecting the content of ATP in the cell. The common ATP luminescence method uses exogenous firefly luciferin/luciferase to oxidize with intracellular ATP to generate photons and monitor the luminosity to detect ATP content to analyze cell activity and proliferation.

The vitality value of the normal control group (A) was 55.5429, and it increased significantly on the 3rd day after injury (B); after the intervention of chitosan, calcium carbonate composite material, on the 5th day after injury, the chitosan calcium carbonate composite material group (C). The level of GSH-Px was significantly lower than that of the natural recovery group (D) ($P < 0.01$); on the 10th day after injury, the GSHPx expression level of the chitosan calcium carbonate composite group (E) was also significantly lower than that of the natural recovery group (E). Group (F) ($P < 0.05$), suggesting that the chitosan calcium carbonate composite material promotes the repair of injury. The cell detection results are shown in Table 2. It can be observed from Table 2 that the GSH-Px of normal rats is at a low level, and it rises rapidly after injury, significantly increases on the

TABLE 2: Cell test results.

Substance time	GSH-Px	MPO
Normal group (A)	55.5429 ± 14.6182	195.1150 ± 34.4581
Day 3 after injury (B)	136.1833 ± 18.9154	360.2419 ± 26.0723
Day 5 after injury (C)	93.9429 ± 22.4785	$265.4867 \pm 15\ 4892$
Day 5 after injury (D)	$11\ 7.9429 \pm 18.7348$	$33\ 18584 \pm 20.1084$
Day 10 after injury (E)	68.5714 ± 20.2318	$21\ 9.4896 \pm 25.9215$
Day 10 after injury (F)	94.4857 ± 15.7812	294.9852 ± 17.0487

3rd day after injury, and then begins to decline, and after the intervention of chitosan, calcium carbonate composite material, after injury on the 5th day, the GSH-Px level of the chitosan calcium carbonate composite group was lower than that of the natural recovery group ($P < 0.01$); during the decline process, the chitosan calcium carbonate composite group decreased faster than the natural recovery group. The difference was statistically significant ($P < 0.01$). The vitality value of the normal control group (A) was 195.1150, and it increased significantly on the 3rd day after injury (B); after the intervention of chitosan, calcium carbonate composite material, on the 5th day after injury, the chitosan calcium carbonate composite material group (C), the expression level of MPO was significantly lower than that of the natural recovery group (D) ($P < 0.01$); on the 10th day after injury, the MPO level of the chitosan calcium carbonate composite group (E) was significantly lower than that of the natural recovery group (F) ($P < 0.01$). The MPO of normal mice was at a low level, and it increased rapidly after injury. It increased significantly on the 3rd day after injury and then began to decrease. After the intervention of chitosan, calcium carbonate composite material, on the 5th day after injury, the chitosan calcium carbonate MPO level of the composite material group was lower than that of the natural recovery group ($P < 0.01$); during the decline process, the chitosan calcium carbonate composite material group decreased faster than the natural recovery group, and the difference was statistically significant ($P < 0.01$). Compared with the normal control group, the chitosan calcium carbonate composite material group and the natural recovery group had significant expression of skeletal muscle cell mRNA ($P < 0.05$); after the intervention of the chitosan calcium carbonate composite material, the skeletal muscle cell mRNA expression level of the natural recovery group (D) was 1.45 times that of the chitosan calcium carbonate composite material group (C), and the difference was significant ($P < 0.01$); on the 10th day after injury, the mRNA expression level of skeletal muscle cells was natural. The recovery group (E) was 1.32 times that of the chitosan calcium carbonate composite material group (F), and the difference was significant ($P < 0.05$).

3.2. MTT Test Analysis of Skeletal Muscle Cells. The density of cells on the surface of the Chi-CaCO3NWs/SS composite material during different culture times is significantly smaller than that of the cells on the surface of the Chi-CaCO3NFs/SS composite material, indicating that ChiCaCO3NFs/SS can provide a good environment for cell growth and spreading, and is also conducive to further proliferation and differentiation of cells. The MTT test analysis result is shown in Figure 1. To further illustrate the good biocompatibility of the ChiCaCO3NFs/SS composite material, we conducted a comparative test of cell culture on a blank stainless steel plate. The density of the cells on the surface of the stainless steel plate is significantly higher than that of the Chi_CaCO3NWs/SS and Chi-CaCO3NFs/SS composite materials. It is much smaller, that is, the growth of cells on the surface of the chitosan-calcium carbonate composite material is clearly more vigorous than that on the blank stainless steel sheet, and this advantage becomes more obvious with the extension of the culture time. It shows that the composite material has a good promotion effect on cell growth. In addition, to further clarify the effect of the composite material on cell growth and understand the growth of MC3T3 cells on the surface of the composite material, we also performed the MTT test to quantitatively observe the difference between the two. The MTT test can indirectly but quantitatively reflect the number of cells.

It can be seen from Figure 2 that the activities of the three groups of cells are increasing with the extension of the culture time, but the Chi-CaCO3NWs/SS composite material and Chi-CaCO3NFs/SS cell activity increase of the chitosan-calcium carbonate nanocomposite is very obvious, indicating that the chitosan-calcium carbonate nanocomposite can promote the growth and proliferation of cells. Among them, the cell growth on the Chi-CaCO3NFs/SS (blue) composite material is the fastest, and it is on the ninth day. The cell activity is close to twice the cell activity on the blank stainless steel plate. It shows that the Chi-CaCO3NFs/SS composite material has a good promotion effect on cell growth.

3.3. Performance Analysis of Composite Materials. To determine the composition of the ChiCaCO3 composite material, we did an XRD test on it. As can be seen, there is a strong peak at $2\theta = 43.8$, which is a characteristic peak inherent in the stainless steel sheet substrate. The strong peaks at $2\theta = 23.2, 29.6, 36.0, 39.6, 47.6,$ and 48.80 coincide with the standard peaks of calcium carbonate on the standard card, corresponding to the 12, 104, 110, 113, 018, and 116 crystal faces of calcite, respectively. The peaks obtained at $2\theta = 24.0, 36.4$ coincided with the peak positions of the standard peaks of chitosan and were identified as the characteristic peaks of chitosan. It shows that the Chi-CaCO3
FIGURE 2: MTT test analysis results.

composite material is composed of chitosan and calcite-type calcium carbonate. At the same time, it can be found that the peak of chitosan is relatively weak, mainly because chitosan is organic, and it is difficult to form stable crystals under this condition. To prove that the CaCO3-ChiNFs/SS composite material has certain mechanical properties, we compared the tensile strength of the smooth stainless steel sheet and the stainless steel sheet as the substrate for electrochemical power deposition to obtain the CaCO3-ChiNFs/SS composite material. From the experimental results, it shows that the tensile strength of the smooth stainless steel sheet cut to a certain shape is $727.1 \pm 14.66MP$, the tensile strength of the CaCO3-ChiNFs/SS composite material under the corresponding conditions has been significantly improved, and its strength reached $1317.2 \pm 3.651MP$. First of all, it shows that the uniform and compact structure of CaCO3-ChiNFs itself has strong integrity, which is the result of the interweaving and close integration of the fiber network that combines the advantages of organic and inorganic materials. This is also similar to the structure of "cement mortar" composed of alternate organic-inorganic shells. At the same time, it also shows that the use of stainless steel sheet as a base not only facilitates the on-demand tailoring of materials but also increases the mechanical properties of the body as a bone tissue material. For biological materials, the properties of the surface of the material can determine part of its biological activity. When the material has proper wettability, it can promote the spread and growth of cells, because the water-soluble surface can provide a humid environment for healthy cell growth. The wettability of the smooth stainless steel sheet, CaCO3-chiNWs/SS, and CaCO3-chiNFs/SS surfaces was tested. The contact angle of the smooth stainless steel sheet is $93 \pm 7.0°$, the contact angle of CaCO3-chiNWs/contact angle of SS is $64.3 \pm 7.0°$, and the minimum contact angle of CaCO3-chiNFs/SS is $32.4 \pm 4.6°$.

This result shows that CaCO3-chiNFs/SS has good water wettability, and its surface state can be cell adhesion and spreading. Provide a good environment, which is more hopeful as a skeletal muscle repair and replacement material
FIGURE 3: Wetting test results.

to provide cells with a more suitable platform for their growth, proliferation, and differentiation, as shown in Figure 3.

3.4. Biocompatibility Analysis of Composite Materials. The skeletal muscle cells were cultured on the surface of ChiCaCO3NFs/SS that had been sterilized beforehand. After the cells had grown for 3 days, they were pretreated, and then the morphology of the cells was characterized by a scanning electron microscope. Skeletal muscle cells are laid flat on the surface of the three-dimensional network fibers. They are larger in size, and the cell bodies and network fibers are firmly combined. And it can be seen that the cells protrude many pseudopods, which have penetrated into the network fibers. It shows that Chi-CaCO3NFs/SS can provide a good environment for cell growth and spread, and it is also conducive to the further proliferation and differentiation of cells. As we all know, the surface properties and nanostructures of
FIGURE 4: Biocompatibility analysis results of composite materials.

biological materials can significantly affect cell growth and viability. Therefore, we did a comparative experiment, cultured skeletal muscle cells on the surface of Chi-CaCO3NWs/SS composite material and under the same experimental conditions, and then performed SEM characterization. The cells appear round and become thicker, that is, the cells are not spread well, but exist in the form of clumps. The results show that the surface of the Chi-CaCO3NWs/SS composite material cannot provide for the spread, growth, and differentiation of the cells. Surface environment very well. The above results show that the three-dimensional network fiber of Chi-CaCO3NFs/SS has good biocompatibility, making it a potential material for repairing damaged bone in tissue engineering.

Hemolysis test was used to evaluate whether Chi-CaCO3NFs/SS has a damaging effect on red blood cells. The red blood cells were exposed to 5 different gradient concentrations of Chi-CaCO3NWs/SS solution, and normal saline and double distilled water were set as negative and positive controls, respectively. After incubating for 1 h, 2 h, and 3 h, they were observed under a microscope. It can be seen that compared with the negative control group, even with the highest concentration (300ug/mL) of nanoparticles incubated for 3 h, the number and morphology of red blood cells did not change significantly. On the contrary, due to the lysis of red blood cells, the double-distilled water treatment group has almost no intact red blood cells remaining under the 1 h microscope. After the red blood cells are lysed, hemoglobin will be released, and the supernatant after centrifugation will show red. Clearly, this phenomenon is more obvious in the double-distilled water treatment group. At the same time, the hemoglobin content in the supernatant is directly proportional to its OD value. The t-test analysis of the OD value of the supernatant in each EP tube found that, compared with the negative control group, the red blood cells incubated with the gradient concentration of Chi-CaCO3NWs/SS solution; there was no statistical difference in the OD value of the serum ($P > 0.05$); on the con-

trary, there was a significant statistical difference compared with the positive control group ($P < 0.01$). The biocompatibility analysis result of the composite material is shown in Figure 4.

3.5. Cytotoxicity Analysis. To confirm the biocompatibility of the Chi-CaCO3NWs/SS composite material, the CCK-8 method was used to detect its effect on cell viability. After the mouse skeletal muscle cells were treated with Chi-CaCO3NWs/SS composite for 48 hours, the cell activity showed a downward trend with the increase of nanoparticle concentration. When the concentration is lower than 50ug/mL, compared with the control group, the activity of the two cells is only slightly reduced, but there is no statistical difference ($P > 0.05$). When the concentration was increased to $50 \mu g/mL$, the difference in toxic effects was statistically significant ($P < 0.05$). The activities of the two cell types were 83.6% and 87.5%, which were still above 80%. The results of the cytotoxicity analysis are shown in Figure 5. Based on the concentration required for cytotoxicity detection and cell imaging of Chi-CaCO3NWs/SS, in other experimental projects, we set the maximum concentration to $50 \mu g/mL$. The blood test results showed that the skeletal muscle toxicity sensitive indicators ALP and ALT had no abnormal changes compared with normal rats, and the HE staining results did not find obvious pathological changes; the nephrotoxicity sensitive indicators urea nitrogen and creatinine levels were also within the normal range. The sections show that the glomerulus and renal tubules are structurally intact; cardiotoxicity is often used as an important indicator of drug toxic side effects. The STAINED picture shows that myocardial cells are tightly arranged and orderly, and the structure of each part is complete; there are no other organ tissue sections. Appears noticeable pathological changes. It can be seen from the cell proliferation experiment that skeletal muscle cells can grow, divide, and proliferate well after inoculation. The cell activity of the experimental group and the negative control group increased significantly with time, and there was no significant
Figure 5: Cytotoxicity analysis results.

difference between the two groups in the statistical analysis. And the RGR of the experimental group and the negative control group was ≥100%, and the cytotoxicity was 0; while the positive control group had RGR < 30%, the cytotoxicity was 4, and the cell growth status was poor. After 24 hours of culture, the growth rate of cell viability of L929 in the experimental group was significantly higher than that in the normal culture group. It can be seen that C2C12 has higher cell activity and proliferation rate than Lg29.

4. Conclusion

The power of exercise comes from skeletal muscle contraction, which is a high energy consumption process. As a result, the body's normal energy balance relationship develops in the direction of imbalance. To prevent the influence of energy imbalance on the body, the mechanisms that reverse this change trend are activated. At present, the research on skeletal muscle injury and repair is no longer limited to muscle satellite cells themselves. The role of immune cells in the repair of skeletal muscle damage is gradually being recognized, and its role and mechanisms are in the preliminary stage of exploration and become a new research focus. Skeletal muscle during strenuous exercise or acute injury can produce a large number of free radicals and neutrophil infiltration in the damaged muscles, followed by a series of inflammatory reactions caused by macrophage invasion. Biomimetic nanomaterials can solve this problem well.

In this study, adult healthy mice were selected. First, the mice were anesthetized with sodium pentobarbital, and the mice were fixed with steel balls to strike the midsections of the bilateral gastrocnemius muscles to create skeletal muscle blunt injury models. The mice were killed by cervical dislocation under anesthesia, and the injured gastrocnemius muscles of both sides were quickly taken to prepare the cell suspension. Weigh and dissolve chitosan in deionized water. Then add calcium chloride dihydrate, stir to dissolve, and prepare chitosan calcium carbonate composite material.

The chitosan-calcium carbonate composite material prepared by using a stainless steel sheet as a base is cut into a square with a side length. Sterilize the stainless steel sheet and place it in a culture plate to dilute the overgrown cells in the culture flask and cultivate them in an incubator.

The skeletal muscle cells were cultured on the surface of ChiCaCO3NFs/SS which had been sterilized beforehand, and then, the cell morphology was characterized by scanning electron microscope. Skeletal muscle cells are laid flat on the surface of the three-dimensional network fibers. They are larger in size, and the cell bodies and network fibers are firmly combined. And it can be seen that the cells protrude many pseudopods, which have penetrated into the network fibers. It shows that Chi-CaCO3NFs/SS can provide a good environment for cell growth and spread, and it is also conducive to the further proliferation and differentiation of cells. In summary, there are many types of calcium carbonate medical materials, which combine the inherent good biocompatibility, osteoconductivity, and good hardness of calcium carbonate materials, as well as the advantages of polymers, collagen, biomolecules, metals, and other materials to make up for the shortcomings of calcium carbonate material are high brittleness. The successful application of calcium carbonate medical composite materials expands the application and development space of calcium carbonate materials in the field of biomedicine. The above results indicate that the material has no inhibitory effect on cell growth and is a qualified noncytotoxic material. It can be seen that the mice can tolerate the experimental concentration of Chi-CaCO3NWs/SS. This new type of nanomedicine carrier will not negatively affect its growth and development, nor will it cause histopathological changes in major organs. Normal skeletal muscle injury often occurs in high-intensity exercise training, more than habitual activities or physical labor. The repair of skeletal muscle injury has always been a basic issue of long-term attention and research in the sports medicine community. Many researchers have carried out research from different angles. Many aspects of research have been carried out, but many mechanistic problems have not been completely solved.

As more and more people love football and participate in more and more football matches, the physical injuries in the confrontation are getting more and more serious. In recent years, bionic photothermal nanomaterials have shown great application potential in disease treatment. Biomimetic photothermal nanomaterials are functional and intelligent materials with special excellent performance that are designed and synthesized by using natural biomimetic principles. Photothermal therapy (PTT) technology is a new treatment technology in recent years. On the one hand, photothermal therapy technology can convert light energy into heat energy through photothermal conversion factor (PTCA). Molecular water-soluble drugs penetrate into the skin to replace the existing injection administration methods with higher risk and low patient compliance and oral administration methods that generally cause first-pass effects, improve the utilization and efficiency of drugs, and can give provide patients with better treatment. The purpose of this article is to explore the application of the photothermal effect of bionic nanomaterials in the treatment of football sports injuries. The method adopted in this paper is to synthesize different bionic photothermal nanomaterials and synthesize bionic photothermal nanomaterials that are fused with cell membranes, thereby promoting the application of photothermal therapy technology in the treatment of sports injuries; further, by synthesizing bionics wrapped by fusion membranes, photothermal nanomaterials introduce collaborative photothermal therapy technology. The experimental results show that the photothermal effect of nanobiomimetic materials is used to treat common injuries caused by football sports. Compared with traditional treatment methods, HA-CuS gel and near-infrared treatment are applied to the skin with the injured tissue of the experimental group. It dropped to 85.7% in 2 h then gradually dropped to 84.2%, and the recovery speed was significantly accelerated.

1. Introduction

Football injuries refer to various physical injuries caused by athletes in football matches. Because football is more intense, and the physical quality and sports skills of athletes are high requirements, and football injuries often occur. In addition to common bruises and contusions, the most common injuries are ankle sprains, muscle tightness, and contusions on the front and back of the thigh, and knee injuries are the second most common [1]. Among them, meniscus inhabitation, knee ligament tears, bone fractures, and osteochondrosis are relatively rare, but once they occur, treatment is more difficult. It needs to rely on some advanced medical technology to treat football sports injuries.

The key to photothermal treatment technology is photothermal conversion factor. At present, there are many types of photothermal conversion nanomaterials that have been studied most. The list is mainly divided into the following categories: high-cost photothermal conversion nanomaterials composed of precious metals and rare metals, new synthetic carbon based on light-to-heat conversion nanomaterials, old-fashioned organic compounds, light-to-heat conversion nanomaterials, and semiconductors composed of light and heat conversion nanomaterials [2, 3]. It has been shown that the abovementioned heat has poor biocompatibility to thermal nanomaterials and cannot escape from the human immune system, and no precise damage has been observed [4, 5].

Years of research and analysis on football sports injuries have shown that the incidence of sports injuries in regular college football teams is 211.9%, among which athletes' injuries are mainly concentrated in the ankle joints of the feet, knee joints, thighs, calf muscles, and feet of the legs. Toes, hip joints, etc. and ankle sports injuries have the highest incidence; the results of sports injuries mainly include contusions, sprains, bruises, residual limbs, residual limbs, etc. The main reason for sports injuries is insufficient mastery of their skills. Even the lack of training level is mostly caused by human factors, including lack of scientific training and other objective factors. At the same time, it puts forward targeted suggestions to promote the improvement of skills and tactics in football team training in mainstream colleges and universities, prevents sports injuries, and provides useful help [6–8]. Studies have shown that football players' injuries are mainly concentrated in the lower limbs, especially in the ankle. The main causes of injuries are improper technical exercises, protection errors, insufficient preparations, and other factors, as well as increased frequency of sports injuries, which should attract people's attention. We propose appropriate preventive measures to further prevent and reduce sports injuries in future training and competitions [9]. In the past ten years, photothermal hyperthermia has become a new treatment technique. It uses the largest external energy to heat cells or tissues, degenerate and necrosis of cells or tissues, and then plays a role in repairing cells [10]. This method is usually a more moderate method, which is less harmful to the human body. The main sources of external energy for heating cells or tissues are radio frequency, microwave oven, focused ultrasound, and laser [11]. The normal cells or tissues of the human body emit heat when the temperature of the human body rises, accelerate blood flow, and expand blood vessels. Therefore, even if the temperature of the normal tissues or cells of the human body rises to 43°C, it will not cause great damage and can self-dissipate [12–14]. In necrosis, the new intercellular blood vessels are malformed and develop abnormally, their shape is abnormal, and the endothelial cells of the internal vascular endothelial cells are very fragile and easy to destroy. Therefore, the cells or tissues cannot dissipate heat normally and rise and cannot be adjusted and repaired. The cells are killed at high temperatures.

This article starts with the meaning of bionic nanomaterials and sports injuries and explores the relationship between the treatment effects of bionic materials based on the degree of injury. By establishing injury models, using biomimetic nanomaterials to observe different changes in cell, tissue and bone activity and conduct comparative studies, we can more accurately grasp the disease process and explore the impact of biomimetic nanomaterials on treatment. This is conducive to the promotion of medical research problems, innovative methods to solve problems, and a good theoretical basis for the treatment of football injuries and other diseases caused by them. By comparing the changes and analyzing the specific experimental results, we can find the basic point of balance between the body's response and drug efficacy, and organically combine the two, provide valuable technical experience for future experiments, draw out the similarities and differences in research directions through comparative advantage analysis, and learn advanced experience at the same time, and make suggestions for improvements in future medical technology advancements, in-depth understanding of the body's pathological conditions, and strengthening of medical expertise. Specialization and accuracy provide theoretical basis for the medical field.

2. Theoretical Basis and Method

2.1. Core Concepts

2.1.1. The Concept of Football Damage. According to foreign records, football is one of the sports with the highest injury rate [15]. Minor injuries are wear and tear, fractures, and dislocations, and ruptures of internal organs can be severe. According to the Guangdong Provincial Sports Commission Medical Bureau (classified by training effect), minor injuries accounted for 47.8%, moderate injuries accounted for 19%, and severe injuries accounted for only 3.2%. Approximately, 86% of injuries are limbs [16, 17]. In addition to common bruises and contusions, the most common injury is an ankle sprain. The muscles of the front and back of the thigh are tight and bruised. Knee injuries ranked second. Among them, meniscus inhabitation, knee ligament tears, bone fractures, and osteochondrosis are relatively rare, but if they occur, it is a bad news for athletes. The treatment methods are currently immature, and the effects of drug treatment are mediocre and difficult to cure, seriously affecting the sports career of football players and cause them great difficulties. For many professional football players, the meniscus or bone has been removed in some medically developed countries. Since goalkeepers often drop the ball and fall, they are vulnerable to wrist (scaphoid fracture) and elbow injuries (bursitis and hematoma). Therefore, the average goalkeeper must wear a sweater, elbow pads, and gloves [18, 19].

2.1.2. Photothermal Treatment. Photothermal therapy is a medical technique for minimally invasive treatment using photoheat developed in recent years. This technology uses photothermal modified materials to directly increase the local temperature by directly irradiating the site with light, thereby killing cells and significantly reducing the body's systemic toxicity. Therefore, photothermal therapy is one of the therapeutic techniques that have the potential to replace surgical therapy. The light-to-heat conversion material can convert the energy of the laser into heat, thereby generating high temperature in the cell area of the human body. The high temperature will heat the cell structure and cause the cell to die quickly. Near-infrared lasers, whose main wavelength range is from 700 to 1100 nm, have a very strong ability to penetrate biological tissues for human or animal tissues and have very little residue in the body after passing through the human body. It can be widely used in the treatment of sports injuries and has become one of the important light sources widely used in the medical field [20, 21]. In order to promote the application of photothermal therapy technology, the development of photothermal

conversion nanomaterials with good biocompatibility and high conversion efficiency is the current focus of photothermal therapy. Nanomaterials with a particle size in the range of 10-200 nm can avoid the body kidney and cam clearly and selectively penetrate into the tissue. The use of nano-photothermal rice materials for photothermal therapy is an effective method [22].

2.2. Light-to-Heat Conversion Nanomaterials

2.2.1. Introduction to Nanomaterials. Currently, the most studied photothermal conversion nanomaterials include noble metal photothermal conversion nanomaterials, carbon-based photothermal conversion nanomaterials, organic compounds photothermal conversion nanomaterials, and semiconductor photothermal conversion nanomaterials. The carbide nanomaterials that convert from heat to heat mainly include gold nanostructures and palladium nanostructures [23]. The photothermal conversion characteristics of precious metals are produced by the plasmon resonance effect of nanoparticles on the surface, which is directly related to the morphology of precious metal nanostructures: gold nanorods, gold nanometer dials, gold nanoparticles, etc. However, as the temperature increases, the photothermal conversion nanomaterials of precious metals will undergo morphological changes, resulting in unstable light and thermal conversion properties, which limits the widespread use of precious metals as photothermal conversion materials in disease treatment [24].

2.2.2. Specific Realization Form. Carbon-based nanomaterials for light and heat conversion mainly include graphene structures and carbon nanotubes. In principle, it does not affect the photothermal conversion characteristics of carbon-based photothermal conversion nanomaterials after long-term laser irradiation, but the preparation and functionalization of carbon-based photothermal conversion nanomaterials are complex, and their light absorption coefficient is relatively low. The photothermal conversion nanomaterials mainly include organic infrared dyes, porphyrin liposomes, and high molecular polymers [25]. Compared with other types of light and heat conversion nanomaterials, this type of tube property conversion nanomaterials can be biodegraded, but they are easily directly degraded by light under long-term laser irradiation. As a research hotspot of nanomedicine, copper sulfide (CuS) nanoparticles in semiconductor photothermal conversion nanomaterials have the advantages of simple preparation process, stable photothermal conversion performance, excellent biocompatibility, and low production cost [26].

2.2.3. Application of Photothermal Nanomaterials. The key points in treatment are issues such as immune system escape and precise targeting to reach the site. Under normal circumstances, our tissues have permeation and retention effects (EPR), and humans use these two effects to design photothermal nanomaterials and guide them to the passive targeting of markers. One of the most important issues is how to extend the residence time of nano-biomimetic materials in organisms. In order to extend the residence time of photothermal materials in organisms, polyethylene glycol is often used to modify the materials, and this method can be used to a certain extent, increase the hydrophilicity of the surface of nanomaterials, reduce the elimination of imitation biomass by the immune system when inside the body, and reduce the interaction between nanomaterials and components in the blood, thereby avoiding attack and elimination by the body's immune system [27, 28]. In order to improve the targeting ability of nanomaterials, active molecules, such as aptamers and penetrating peptides, can be modified on the surface of nanomaterials. Recent studies have shown that there is an antipolyethylene glycol immune response in animals and humans. Polyethylene glycol can cause blood clotting and cell coagulation. To a certain extent, it cannot completely prevent nanomaterials from being processed by the machine. In efficacy, while a single targeted modified nanomaterial is difficult to adapt to the microenvironment in the body, it is difficult to achieve its theoretical targeting effect after entering the body. In recent years, effective methods have used cell membranes to camouflage the upper layer of nanomaterials and modify the nanomaterials to obtain bionic nanomaterials that have the ability to escape the immune system. Biomimetic nanomaterials have good development prospects in drug transportation, imaging, detoxification, vaccine design, and photothermal therapy. The cell membrane wrapped nanomaterial mainly includes two parts: a synthetic nanomaterial core and an outer cell membrane. The core synthesized in the biomimetic nanomaterial can be organic or inorganic nanomaterials with different biological and therapeutic functions. The outer cell membrane used to camouflage the nanomaterial nucleus can be red blood cell membrane, white blood cell membrane, cancer cell membrane, platelet membrane, macrophage membrane, and fusion membrane.

3. Experimental Verification

3.1. Experimental Materials. Through the application, 60 people with sports injuries in the affiliated hospital of the medical university where the author is located were selected, including 30 men and 30 women. In order to create research variables, all patients were randomly divided into 6 groups with 10 people in each group to ensure that the weight of the patients was normal. In the early stage of the experiment, in a well-ventilated environment, ensure that the room temperature is about 22 degrees, the relative humidity is maintained at about 55%, and the light time is maintained at more than 10 hours. Keep adequate food and drinking water. Conventional catering is provided by the medical center, and the MCT required for the establishment of the entire model is selected from sigma. When each group is treated to the appropriate age, the injured tissue should be selected for observation of related indicators. The main reagents include ECL chemiluminescence fluid (Genview company in the United States), and the main instruments include color Doppler ultrasound diagnostic apparatus, optical microscope (Germany LEICA, DM3000).

3.2. Experimental Process. First, complete the preparation of HA-CuS nanoparticles. 150 mg of HA was added to 20 mL of 4 mL CuCb solution, after stirring for 30 min at room temperature, and 1.6 mL of 50 mM Na2S solution and 36 mg of trisodium citrate were added to the system. After stirring quickly, let it stand and heat in a water bath at 80°C for 30 minutes. Centrifuge at 12000 rpm for 30 minutes, discard the supernatant, add deionized water to the sedimentation towel, and resuspend at 12000 rpm for 30 minutes, repeat twice to obtain HA-CuS nanoparticles. The synthesis process of the blank CuS nanoparticles is the same as the above steps, but HA is not added. HA is an acidic mucopolysaccharide. During the synthesis of HA-CuS nanoparticles, it needs to be heated in a water bath at 80°C for 30 minutes. In order to explore whether the treatment will affect the structure of HA, gel permeation chromatography (GPC) is used in this chapter. The molecular weight distribution of HA is tested. Use two detectors: laser light scattering detector and differential detector to detect the HA solution and the unheated HA solution after heating in a water bath at 80°C for 30 min. The HA retention time detected by the two detectors did not change before and after the HA solution was heated. That is, before and after heating, the molecular weight distribution of HA is basically the same. Experimental results show that during the synthesis of HA-CuS nanoparticles,
FIGURE 1: MTT method to detect the cytotoxicity of HA-CuS under near-infrared light irradiation.
FIGURE 2: Variation curves of HA-CuS nanoparticle solutions with different concentrations.

the molecular weight of HA will not be affected by the heating during the synthesis process and remains stable, which provides conditions for the successful synthesis of HA-CuS. The laser light scattering detector detects the molecular weight distribution of HA before and after heating as shown in Table 1. The GPC curve of molecular position distribution before and after HA heating detected by the differential detector is shown in Table 2.

Stain the RBC membrane with DIL staining solution, and stain the B16F10 cell membrane with DIO staining solution. According to the ratio of B16F10 cell membrane to RBC membrane mass ratio of 1 : 1, mix the B16F10 cell membrane with the RBC membrane uniformly and ultrasound at 39°C for 10 minutes to complete the cell membrane fusion. 0.5 mL of 0.3 mg/mL B16F10 membrane solution was added to 0.5 mL of 0.2 mg/mL CuS nanoparticle solution, and the membrane was wrapped by ultrasound for 10 min at room temperature. The reaction system was centrifuged at 10,000 rpm for 5 minutes at 4°C to remove excess membrane. The precipitate is CuS@B16F10 nanoparticles and

Thermal cycle curve of 1000 jg/mL HA-CuS nano-solution

resuspended in FJ deionized water. Similarly, complete the RBC film alone package and B16F10 film alone package. Thus, CuS@RBC nanoparticles and CuS@R16 nanoparticles were obtained.

3.3. Experimental Results. HA is a very promising mucopolysaccharide that mediates transdermal administration and has excellent biocompatibility. The modification of CuS nanoparticles with HA has an important effect on improving its biological toxicity. Before using HA-CuS nanoparticles for biological applications or disease treatment, it is necessary to detect their cytotoxicity. In this chapter, the MTT method is used to detect the cytotoxicity of HA-CuS nanoparticles using NHDF cells. Transfect NHDF cells with a series of sample solutions of different concentrations (200 pg/mL, 100 pg/mL, 50 pg/mL, 25 ig/mL, and 10Hg/mL), and use MTT to detect cell viability even at a high concentration of 200 ng/mL under the condition of sample treatment, the survival rate of cells is also above 90%, indicating that HA-CuS nanoparticles have no direct cytotoxicity.

4. Data Analysis

HA-CuS gel-mediated transdermal drug delivery is realized under the irradiation of near-infrared light. Before the bio-

logical application of HA-CuS gel-mediated transdermal drug delivery in animal experiments, near-infrared light must be performed in stimulated HA-CuS cellularity test. A high-power 980 nm near-infrared laser ($0.58\ \mathrm{W/cm^2}$) was used to irradiate the HA-CuS-intaken NHDF cells and normal NHDF cells for 30 s and 10 min. The results are shown in Figure 1. Normal NHDF cells had a cell survival rate of 91.1% after 10 minutes of near-infrared laser irradiation, while NHDF cells that had taken HA-CuS had a cell# viability rate of 89.1% after 30 s of near-infrared light irradiation, and the time was extended to 10 minutes. The cell survival rate is only 57.6%. The experimental results show that HA-CuS has lower cytotoxicity when the near-infrared light is stimulated for a short time, and when the near-infrared light stimulation time is increased to 10 min, HA-CuS has a higher photothermal conversion property. Therefore, when HA-CuS gel-mediated transdermal administration is performed, the irradiation time of near-infrared light must be controlled.

The concentration of HA-CuS nanoparticle solution is an important factor affecting its photothermal conversion. We have prepared a series of HA-CuS nanoparticle solutions with different concentrations (1000 pg/mL, 500 pg/mL, 100 jg/mL, 50 fig/mL, and 25 ng/mL) to examine its light-to-heat conversion capability. We use a 980 nm near-infrared light source, adjust the intensity to $0.7\ \mathrm{W/cm2}$, irradiate the solution for 600 s, and record the temperature every 2 s, so as to obtain the temperature change curve of HA-CuS nanoparticle solutions with different concentrations as shown in Figure 2.

First, we conducted a temperature increase test on deionized water for damaged tissue cells. Within 600 s, the temperature of deionized water only increased by 13°C, while the h-rise temperature of the HA-CuS nanoparticle solution without concentration was 18.4°C, (25 pg/mL), 26.3°C (500 ng/mL), 32.7°C (100 pg/mL), 39.7°C (500 pg/mL), and 43.4°C400pg/mL). This result shows that HA-CuS nanoparticle solution has strong light-to-heat conversion capability. In addition, with the increase of time, the heating efficiency of the HA-CuS nanoparticle solution continues to weaken. This is because as the temperature increases, the heat loss of the solution increases, and the material can quickly convert the near-infrared light energy

into heat energy, and five is released into the aqueous solution and the surrounding environment, which also shows from the side that HA-CuS nanoparticles have good light-to-heat conversion ability. As the concentration of the HA-CuS nanoparticle solution increased, the material did not undergo coagulation. This is because the HA-CuS nanoparticle played a protective role and made the CuS nanoparticle uniform and stable at a higher concentration. At the same time, we further tested the stability of the photothermal conversion of HA-CuS nanoparticles. We took the highest concentration of HA-CuS nanoparticles solution (1000 pg/mL) in the above series of solutions for 5 times of excitation for 600 s. Cooling hot and cold cycle. The results are shown in Figure 3. The highest peaks of the solution temperature are 69.4°C, 69.3°C, 69.1°C, 69.3°C, and 69.2°C. The slight temperature peak changes indicate that HA-CuS nanoparticles have stable and repeatable light thermal conversion capability.

We use exercise-impaired patients as disease models to study the feasibility of the biological application of HA-CuS gel-mediated transdermal drug delivery. After applying HA-CuS gel on the back of the patients in the experimental group, they were blown dry with a hair dryer, then the gel-treated skin was irradiated with near-infrared light, the gel was wiped off, and the insulin-containing patch was applied to the treated skin with continuous absorption of the drug. The patients in the control group directly attached patches with insulin, directly injected insulin subcutaneously and did not undergo any treatment. Use a blood glucose meter to monitor blood glucose changes every 2 hours until 10 hours. The experimental results of each group are compared as shown in Figure 4. The blood sugar of the control group patients without any treatment and the control group patients who directly applied the patch without skin treatment has been at a high level; the skin is treated with HA-CuS gel and near infrared and then the insulin patch is applied. The blood glucose of the experimental group of patients dropped to 85.7% at the 2nd hour, then gradually dropped to 84.2%, and finally rose to 99.6% at the 10th hour; the blood glucose level of the control group who received direct subcutaneous insulin injection dropped rapidly to 52.7% at the 2nd hour. After that, it rose rapidly, and the blood glucose levels at 6 h, 8 h, and 10 h were 93.1%, 97.1%, and 105.7%. The above experimental results show that the transdermal insulin infusion mediated by HA-CuS gel can stabilize the blood glucose level at a lower level for a longer period of time than the conventional subcutaneous insulin injection, providing a stable and effective treatment for the treatment of sports injuries.

5. Conclusion

The photothermal effect of HA-CuS nanoparticles is used to thermally ablate the skin, mediating a new way of transdermal drug delivery. HA-CuS nanoparticles have good biocompatibility and light-to-heat conversion properties. Under low-intensity near-infrared light irradiation, HA-CuS gel is sufficient to cause damage to the stratum corneum without damaging the deeper skin and can effectively make

BSA penetrate into the skin. Taking type 1 injury as the disease model and insulin as the water-soluble macromolecular drug model, the transdermal drug delivery method mediated by HA-CuS gel can keep the patient's blood sugar at a stable low level for a long time. The transdermal drug delivery method based on the photothermal effect of HA-CuS nanoparticles has great prospects in future clinical applications because of its superior biocompatibility and controllable and stable therapeutic effect.

Use HPDA@[OMV-CC] nanoparticles to perform photothermal therapy and immunotherapy on the injured site. HPDA@[OMV-CC] nanoparticles have good biocompatibility; HPDA@[OMV-CC] nanoparticles have good light-to-heat conversion properties at 1064 nm; HPDA@[OMV-CC] nanoparticles have the same targeting properties. The ability to source damaged tissues can effectively restore damaged cells under near-infrared light; HPDA@[OMV-CC] nanoparticles can increase the amount of dendritic cells entering the lymph nodes and promote the maturation of dendritic cells. In future research, the ability of HPDA@[OMV-CC] nanoparticles' photothermal therapy and immunotherapy for sports injuries can be studied in vivo and further biosafety studies. On the basis of existing research, the ability to increase immunotherapy by fusing bacterial outer membrane vesicles provides a new direction for the application of biomimetic photothermal nanomaterials in the treatment of sports injuries.

With the development of science and the advancement of medicine, there are more and more treatment methods for repairing knee ligament sports injuries. At present, the common method of ligament repair is to implant artificial synthetic materials or natural biological materials into the body to form artificial ligaments to repair and reconstruct damaged ligaments. Existing ligament repair techniques are often accompanied by sequelae, and the implants are not well adapted. The purpose of this article is to compare the degree of repair of damaged ligaments after implantation of artificial ligaments made of different nanomaterials and to study the mechanical properties, biomechanical properties, and immunological properties of artificial ligaments implanted in the body, in order to explore the role of different artificial ligaments on knee ligament repair. According to the different synthetic materials of artificial ligaments, the experimental subjects were divided into three groups: silk fibroin polycaprolactone nanofiber membrane group (SF/PCL), polycaprolactone nanofiber membrane group (PCL), and control group. By comparing the biocompatibility, cell adhesion, cell proliferation rate, and repair ability of collagen fiber formation of the experimental scaffold after implantation in the body, as well as its immunological performance, the results of the study showed that compared with PCL, SF/PCL increased its biocompatibility by 25%, increased its cell proliferation by 57%, increased its somatic cell adhesion by 35%, and increased its collagen fiber formation by 12%, the porosity is about 60%, and the load is as high as $907 \pm 132 \, \mathrm{N}$. The data shows that the silk fibroin polycaprolactone nanofiber membrane scaffold has good biocompatibility, degradability, and mechanical properties.

1. Introduction

Ligament injury is one of the common sports system injuries in clinical practice, which usually leads to a decline in work and sports ability. After ligament injury, there are usually small blood vessels rupture and hemorrhage, local pain, swelling, intraorganism hemorrhage, hematoma, joint swelling, movement disorder, and tenderness. On physical examination, the traction ligaments were found to be significantly painful, and if completely ruptured, the stability of the joint was reduced. With the increase in sports activities and the aging of the population, this number is still rising. Traditional treatment methods include conservative treatment, sutures, autologous and allogeneic transplants, and artificial prostheses. As a result, the tissue structure cannot be restored to its mechanical strength and movement angle before injury. Therefore, exploring methods that can effectively promote lig-

ament regeneration and repair has extremely important clinical significance and application value.

With the development of science and technology, materials science and biomedicine are more and more closely integrated, and nanomaterials have made great achievements in biological applications. The knee ligament is the main static and stable structure for knee flexion and rotation activities, and it plays an extremely important role in maintaining the stability of the knee joint [1]. Knee ligament injury is a high-energy injury, often accompanied by serious injury to other parts [2]. For damaged ligament tissues, we need scaffold materials to promote the regeneration of damaged tissues in the body, the application of surface modification and separation, and culture of cytokines, and seed cells are specific methods for constructing and selecting scaffold materials; a large number of scholars have done a lot of research in this direction [3]. By modifying the surface of

artificial ligaments with biologically active materials, the surface biological properties of the graft are improved, and the formation of the new bone at the interface is promoted. Therefore, in order to achieve compactness, therefore, nanomaterials with surface modification through nanotechnology are widely used. It is very necessary to apply nanomaterials in the repair of artificial ligaments to bring good news to human health.

This article discusses the immunological performance of nanomaterials for repairing knee ligament sports injuries and sets high standards for the selection of tissue engineering scaffolds. The mechanism of the stent in the process of repairing damaged ligaments and the problems discovered and resolved during the research process are also studied. Read et al. first proposed the application of engineered histology in the medical field and proposed a feasible treatment plan for repairing ligaments using nanomaterial scaffolds [4, 5]. Zult et al. first proposed the use of electrospinning technology to fuse silk fibroin and polycaprolactone nanofibers to improve the compatibility of materials and further improve the repair ability of damaged ligaments [6]. Kim et al. used to change the voltage value to explore the relationship between material and fiber diameter and find the best value between voltage and fiber diameter [7]. Evangelopoulos et al. first discovered the effect of SF concentration on fiber diameter during the experiment. When the optimal concentration is reached, the fiber diameter is uniform and neatly arranged, and the compatibility is best at this time [8]. Although their research has introduced various applications of nanomaterials, there is not much research on the repair of artificial ligaments. Therefore, this study is necessary.

This article summarizes and analyzes the research experience and results of many predecessors. In addition, this article has made some innovations in research content and research methods. The specific innovations are as follows: first, this paper constructs the SF/PCL composite nanomaterial for the first time and studies its formation mechanism. The effect of SF content on the repair properties of artificial ligaments in SF/PCL blends is proposed. Secondly, this article uses electrospinning technology to construct a SF and PCL hybrid scaffold for the first time and studied the interaction mechanism of PCL and SF/PCL. Third, this article is the first to use scanning electron microscope observation, infrared spectroscopy, and thermal analysis to study the compatibility of silk fibroin and gelatin in hybrid nanofibers. The combination method is used to analyze statistical data, and the normal analysis of variance and multivariate analysis is used for formal combination verification. The use of electron microscope observation not only effectively increases the observation multiple and improves the clarity of the electron microscope but also can analyze the degree of healing of the artificial ligament.

2. Pathological Study on the Indexes of Off-Pump Transplantation

2.1. The Role of Knee Ligaments and the Impact on the Body after Injury. Ligament injury should be treated early and

fully repaired. If it is not treated in time, the joint will be repeatedly sprained, which will inevitably cause damage to articular cartilage, meniscus, and other important structures, resulting in premature aging of the joint and severe secondary traumatic arthritis. The key to its treatment lies in the repair of damaged ligaments. Partial tears can be directly sutured and repaired, while complete ruptures require surgery to transfer and reconstruct adjacent tendons, fascia, and other tissues. Ligaments are dense connective tissue, mainly composed of collagen fibers. The main ligaments of the knee joint are the anterior cruciate ligament, the posterior cruciate ligament, the medial collateral ligament, and the lateral main ligament. They cross each other and are covered by the synovial membrane, located outside the synovial cavity, and are considered to be the central movement hub of the knee joint [9]. The role of the anterior cruciate ligament is as follows: during the extension and bending of the knee joint, the two bundles cross and twist, thereby increasing the stability of the knee joint. It has the functions of preventing forward displacement of the tibia, over extension of the knee, over bending of the knee, and prevention of knee virus and valgus [10]. The role of the posterior cruciate ligament is as follows: in order to limit the posterior movement of the tibia, ensure the stability of the posterior knee joint and limit the hyperextension of the tibia, and to a certain extent, limit the internal rotation, adduction, and abduction of the tibia tendon [11]. Each bremsstrahlung cooperates with other major belts and organizations to perform certain functions. Each major ligament of the knee joint contributes to the spontaneous tension interlocking inside and outside the joint, which not only becomes a powerful stabilizing device but also completes the function of the knee joint together [12]. Ligament injury has the ability to repair itself, but after the injury, the overall stability of the knee joint will change, and the load stress shared by different structures will also change from the normal situation [13]. After the injury of the posterior cruciate ligament, the function of the posterior cruciate ligament is good in the short and medium-term injuries, but in the later stage, it will lead to poor knee function, joint disease, and advanced osteoarthritis [14]. Anterior cruciate ligament injury can lead to knee osteoarthritis. The degeneration of articular cartilage in the later stage of the posterior cruciate ligament injury is related to the long-term abnormal mechanical environment after the posterior cruciate ligament injury, which makes the anterior cruciate ligament degeneration. Further exacerbated the instability of the knee joint [15, 16]. However, the rupture of the posterior cruciate ligament will also affect the function and structure of the anterior cruciate belt. The mechanical environment is responsible for the development of ligament tissue, and changes in the stress on the tissue will cause changes in the structure and function of tissues and organs. This process is called organizational remodeling [17]. The mechanical properties of the front crossbelt are changed under reduced tensile stress, and the tensile strength is reduced. When the ligament structure is exposed to a reduced stress environment, the longer the time, the greater the damage to the mechanical properties of the ligament and tissue structure. Even for short-term stress relief, it takes a

long time to restore the mechanical properties of the ligament [18]. When the stress on the ligament decreases, we also find that the strength and stiffness of the ligament decrease. Ligament rupture can damage the stability of the knee joint and cause abnormal knee joint mechanics, which may be caused by damage to other tissues inside and outside the joint. Without timely treatment and intervention, knee pain and dysfunction will eventually occur [19]. After the back-crossbelt is injured, cartilage degeneration will occur, leading to osteoarthritis. In general, ligament injuries are accompanied by some complications. The complications of different ligament injuries are not necessarily the same, but all of them will cause inconvenience to the movement of the human body, and even lead to disability in severe cases.

2.2. Mechanism of Repairing Damaged Ligaments by Implanting Artificial Ligaments of Nanomaterials into the Body.

The material of the artificial ligament is a nondegradable fiber with good chemical stability, but its hydrophobicity is strong, and the cell compatibility is poor. In order to improve the hydrophilicity and biocompatibility of materials used for surface treatment and modification, the development of nanotechnology and nanomaterials provides new methods to improve the biocompatibility of materials [20]. The surface area of nanomaterials increases, and the hydrophilicity increases, which can absorb more cells and extracellular matrix proteins. The nanostructures and patterns on the material surface can significantly improve the biocompatibility of orthopedic implants [21]. Researchers believe that the formation of nanopatterns and structures on the surface of the implant can promote the erection and proliferation of osteoblasts in vitro and promote bone formation and bone remodeling on the surface of endophytic bacteria in the body. In the torsion test, the internal fracture of the mineralized bone tissue and the interface between the bone tissue and the implant were intact [22]. Nanocomposites are commonly used as surface modification materials for prosthetic implants, which can greatly improve the affinity between the implant and the surrounding bone tissue. Nanocomposites overcome the shortcomings of common materials in performance. The surface of the artificial ligament implant is coated. Nano and nanocomposite materials have better advantages and excellent functions. Nano enhances the proliferation of osteoblasts and the synthesis of cell proteins and improves alkaline phosphatase (activity and mass deposition), thereby enhancing the tight integration of bones and internal plants and thereby increasing the use rate of prostheses [23]. Like cells adhere and grow better on the nanocomposite coating group, and the cell density will increase over time [24]. The thermal method after spraying is used to apply a nanocrystalline coating on the surface of the implant, which can maintain the structural integrity of the coating, increase the crystallinity, and improve the long-term stability of the implant coating in the body [25]. The nanocoating layer has good cell compatibility, and the nanocoating has excellent biocompatibility and biological activity, increasing the biological activity of the graft and increasing the adhesion of osteoblasts [26]. The composite material is composed of synthetic materials.

In the normal coating group, the experimental group showed higher cell growth and proliferation rates and better effects, thereby improving the hydrophilicity of the implant. In vitro cell tests showed that the coating group greatly promoted the adhesion of osteoblasts and enhanced cell proliferation. Relevant studies have shown that, compared with the uncoated group, the cell expression level was higher, and as the expression amount increased, the expression became more active [27, 28]. Nanocomposite coatings have been successfully used in ligament tissue engineering implant materials. Nanostructure is a new system constructed or constructed according to certain rules on the basis of nanoscale material units. Applying the nanostructured artificial ligament to ligament injury will greatly improve its structural strength.

As the content of nanofibers increases, the microstructure of the formed scaffold changes from a layered structure to a porous structure, indicating that its formability has been significantly improved [3]. More importantly, the content of nanofibers in the silk fibroin solution also affects the mechanical properties and stability of the scaffold in water. Without any posttreatment, a porous scaffold that can maintain the original overall structure and porous microstructure in water can be obtained, and its retention rate in water exceeds 85% [29]. Compared with traditional silk fibroin scaffold materials, the scaffold material has lower crystallinity and faster degradation performance; so, it shows good hydrophilicity and better biocompatibility. The application in the tissue field provides a richer matrix material [1]. The relationship between cell proliferation rate and nanofiber content is shown in formulas (1) and (2).

$$T(s) = \sum_{j=1}^{v} \frac{M_f}{D} * \log 2(d) + J^V, \tag{1}$$

$$V = L * \text{snb} \left[\sum_{i=1}^{nl} (y_i^n - f y_i y_l + y_l^n) + \sum_{im+1}^{n_l+n_R} (y_i^n - f y_i y_R + y_R^n) \right], \tag{2}$$

where V is the cell proliferation rate, and $T(S)$ is the content of nanofibers.

3. Experimental Detection of the Experimental Group and Normal Group

3.1. Experimental Sample Preparation and Experimental Methods.

First weigh the silk fibroin powder of the corresponding mass, add it to the mixed solvent, seal it with plastic wrap, then sonicate it for 1 h until the silk fibroin powder is evenly dispersed in the mixed solvent, and then add 4.0 g PCL. The membrane is sealed and heated in an oil bath at 40°C for 24 h until the PCL is completely dissolved, and the spinning solution is uniform and stable. SF/PCL spinning parameters are different, used for electrospinning: receiving distance 10 cm, bolus speed 2 mL/h, receiving speed 140 r/min, and voltage 15 kV. SF/PCL spinning parameters under the same composition were as follows:

receiving distance 10 cm, bolus injection speed 2 mL/h, receiving speed 140 r/min, and voltage 12-25 kV. The blended fiber membrane obtained by electrospinning is vacuum dried and stored. A certain amount of collagen is dissolved in an acetic acid solution to prepare a collagen solution with a concentration of 10%. After mixing, centrifuge to remove air bubbles, then remove the wire mesh holder, cut it to the width of the hole, and start making. Spread a layer of collagen and freeze at 20 degrees for about half an hour. Spread the thread and stretch it under certain tension. Then, spread a denser layer of collagen and freeze it at 15 degrees. Wrap them in tin foil, freeze them at 10°C for 4 hours, drain them in a vacuum dryer, and cut them into various lengths for in vivo repair. Divide 20 white rabbits into three groups and implant SF/on the PCL of the injury group. The PCL implantation injury group and control group were as follows. Chloral hydrate was injected intraperitoneally, the ear vein was anesthetized with a catheter, fixed in the supine position, the upper and lower legs in front of the left and right knee joints were shaved, and the left or right knee was randomly selected as the experimental group or the control group and disinfected with compound iodine. Put a sterile small hole towel on the skin and make an incision on the inside of the knee joint. The upper end starts from the upper part of the femur, and the lower end reaches the inside of the tibia, approximately the length. Cut the skin and fascia in turn to expose the medial collateral ligament of the knee joint, separate it, and then remove the ligament from it. The knee joint moved several times, and the tension of the reconstructed ligament was satisfactory. The wound was closed layer by layer, and the ear vein was placed with sterile gauze. After the operation, the medial collateral ligament specimen was fixed with formalin for several hours, and the ligament was cut. Embed the fractured tissue and scar in paraffin, slice, stain, and observe the arrangement and density of scar collagen under light. Use a microscope to understand its healing.

3.2. Experimental Results. In the first week after implantation, the number of human-derived cells in the injured area gradually decreased over time. Two weeks after implantation, these genes were detected in the damaged part of the ligament. The secretory ligament matrix promotes ligament repair. SF/PCL scaffold can only help ligament repair and secrete ligament extracellular matrix and can also secrete growth factors to affect ligament regeneration. Most growth factors accelerate cell proliferation, and FS/PCL may also synthesize various factors that can induce musculoskeletal tissue. The expression of chemokines and growth factors is involved in tissue repair and regeneration before and after stent implantation. The cells express chemokines one week after implantation and still express two weeks after implantation, indicating that SF/PCL can secrete chemokines to attract host cells to participate in the formation of new ligaments. The overall observation results four weeks after implantation showed that all the damaged areas of the abdominal cavity window were repaired by connective tissue, and the muscle and spinal cord tissue was significantly proliferated. There was no significant difference between the two groups. There was no significant difference in the muscle health collagen content of each group every week. Thirty days after implantation, a dense tissue was formed, which was mainly composed of spindle-shaped lyocells and collagen fiber bundles. After being implanted in the body, the engineered ligament will undergo a maturation process. Although collagen fibers are still relatively scarce and small and uniform in diameter, collaborative mechanical stimulation can still promote the maturation of collagen fibers. The diameter of collagen fibers increased by about 25%, and the expression of ligament-specific transcription genes and extracellular matrix genes increased during ligament repair. At 12 weeks, the maximum tensile force of the experimental group was significantly higher than that of the control group.

3.3. Material Selection and Physiological Characteristics of Tissue Engineering Scaffold for Knee Ligament Repair. The repair of damaged ligaments is completed by the tissue engineering scaffold implanted in the body; so, the selection of the scaffold is more demanding. The extracellular matrix (ECM) is not only the supporting structure of cells but also functional. It creates a dynamic three-dimensional microenvironment for cells, realizes the signal transmission between the cell nucleus and the extracellular matrix, and promotes cell adhesion, proliferation, migration, and differentiation. Therefore, it is particularly important to imitate the composition and structure of ECM in tissue engineering. It has been found that cell-collagen interaction affects cell growth and differentiation. The biggest advantage of electrospun nanofibers as a tissue engineering scaffold is that it can simulate the composition and structure of the extracellular matrix (ECM). The ideal tissue engineering material should have the following characteristics: nontoxic; that is, the material itself and its degradation products will not produce inflammation and toxic reactions; it has good biocompatibility, biodegradability, and degradation adaptability and will not cause inflammatory and toxic reactions. In short, as a matrix material for different seed cells, the inoculated cells can be positioned, attached, and positioned to grow and proliferate. At the same time, the material can arrange cells orderly in the scaffold space, differentiate with specific functions, and synthesize appropriate extracellular matrix (ECM). In addition, when transplanting functional tissue engineering into the body, the scaffold material should also have mechanical support functions, blood pressure resistance, blood compatibility, thermal stability, and dimensional stability. This material was selected as the primary problem medical treatment for electrospun nanofiber biomaterials. Anterior cruciate ligament (ACL) cells and NIH3T3 cells can adhere, proliferate, and secrete the extracellular matrix on the scaffold material. The scaffold material has excellent biocompatibility and certain mechanical properties, and the maximum tensile force of the experimental group is significantly higher than that of the control group. The grafts coated with SF can greatly induce new bone formation, and the average width of the graft bone interface is significantly lower than the control group. In addition, the surface of the ligament graft also stimulates the high

expression of bone morphogenetic protein and vascular endothelial growth factor at the local interface. SF/PCL infiltrated many megakaryocytes, the inflammatory response was mild, and there were many fibroblasts and new blood vessels around. The absorbable material placed in the anterior cruciate ligament (ACL) reconstruction graft gradually degrades and absorbs with the growth of new tissue after surgery and is finally completely replaced by collagen fibrous tissue. Histological examination confirmed that there was no obvious lymphocyte infiltration, the cells were spindle-shaped, the fibrous tissue was arranged neatly and evenly, and capillary hyperplasia was visible. And the discovery of nonself-tissue alleles indicates that the implanted cells remain viable. The mixed form of nanofibers can promote the proliferation of ACL fibroblasts. Cell morphology analysis shows that the mixed nanofiber material scaffold has better biocompatibility than PCL nanofiber. SF/PCL nanofibers are biomaterials with application potential, suitable for ligament tissue engineering repair. Fibroblasts have been successfully planted on the scaffold material and adhere to and grow well on the material. The results show that the constructed scaffold material has good three-dimensional configuration and biocompatibility, and it is expected to provide a new type of scaffold material for repairing anterior cruciate ligament injury. The data analysis showing the influence of fiber diameter on tensile strength and elongation is shown in Table 1.

It can be seen from the above chart 1 that when the concentration of SF/PCL is 45%, the fiber diameter is the largest, the arrangement is uniform, and the stability is good. Its tensile strength increases by 30%, and the elongation rate increases to 62.5%. Affected by the SF concentration, it increases with the increase of the concentration at the initial stage, and when it is 45% higher, it decreases with the increase of the concentration. The material concentration directly affects the performance of the material.

3.4. Factors Affecting the Repair Performance of Nanomaterial Scaffolds and Immunological Performance. When silk fibroin material is added to PCL, the diameter of the fiber is relatively small, about 290 nanometers, and a bead-shaped fiber is formed. This is because the spinning solution is relatively thin, the surface tension is small, and the electric field force is large to obtain traction. The lower surface tension is not conducive to the complete volatilization of water. Beads appear very easily; after adding silk powder, fine particles will adhere to the PCL fiber. With the addition of silk powder, the composition continues to increase, from 4.8% to 45%. The diameter of the composite fiber also increased from 320 nm to 440 nm. After adding silk fibroin powder, the bead fiber gradually disappeared, and the diameter of the composite fiber increased without being fully extended. When the SF/PCL concentration is 45%, the composite fiber has the largest diameter, and the fiber distribution is more uniform. At this time, the compatibility between silk fibroin powder and polycaprolactone is the best. If the content of silk fibroin powder continues to increase, if the viscosity of the solution is too high, the silk fibroin

TABLE 1: The effect of fiber diameter on tensile strength and elongation.

Group	Fiber diameter	Tensile strength (MP)	Elongation (%)
The first	292	3.55	38.9
Second	438	4.5	62.8
Third	250	4.2	50.4

powder seems to agglomerate obviously, and the diameter of the composite fiber is reduced to 350 nm. The compatibility of silk fibroin powder with polycaprolactone deteriorates, the spinnability of the spinning solution decreases, and the fiber thickness is uneven. The gaps between the fibers are large, and the fibers are bent and deformed. Because the concentration is too large, the electric field force is not enough to overcome the surface tension of the liquid and reduce the relative amount of solvent. The volatilization of the solvent causes the fiber to coagulate and deform the fiber. When the SF/PCL concentration is 45%, the silk fibroin powder in the composite fiber does not appear lumpy, indicating that the concentration at this time is moderate. During the experiment, when the voltage was increased from 15 kV to 25 kV, the fiber diameter increased from 440 nm to 465 nm, and the fiber diameter did not change significantly, but at 20 kV, the fiber diameter was uniform, and the gap between the fibers was large. At 25 kV, the fiber diameter changes again. The size is different, because the applied voltage is too large, the large amount of charge in the solution will make the spinneret spin faster and faster, and the traction will pull out a large amount of solution, resulting in uneven fiber thickness. When the concentration is 45%, the voltage difference affects the uniformity of the fiber diameter. When the voltage is 18 kV and 21 kV, the fiber diameter is 480 nm and 524 nm, the fiber diameter is the same thickness, and the fiber arrangement is uniform and compact. The electric field force overcomes the surface tension of the solution during the stretching process, so that after the fibers are completely solidified, the arrangement is more uniform. The graft has varying degrees of inflammation in the early postoperative period, and there is inflammatory cell infiltration around the artificial ligament. Considering that inflammation affects the regeneration of tissue collagen, leading to the formation of fibrous blisters, controlling inflammation can help improve the transplanted ligament. Hyaluronic acid can be greatly reduced, and hyaluronic acid has been shown to have the ability to inhibit the activity of inflammatory cytokines.

4. Analysis and Discussion of Influencing Factors in Repairing Injured Ligaments with Stents

4.1. Analysis of the Results of Repairing Damaged Ligaments with Nanomaterial Scaffolds. The test results show that the crystallinity of polycaprolactone is not the main factor affecting the difference in mechanical properties, but the

increase in the crystallinity of the stent through heat treatment should further enhance the mechanical properties of the stent. PCL provides space to repair cell adhesion and growth, while SF/PCL provides sufficient mechanical strength. The research results show that, compared with PCL scaffold, SF/PC scaffold has more collagen deposition and rougher collagen production, and its mechanical properties are closer to normal tissues. After adding silk fibroin, the morphology of nanofibers is improved, the diameter of nanofibers is reduced, and the hydrophilicity of the material is increased. The mixed form of nanofibers can promote the proliferation of ACL fibroblasts. Cell morphology analysis shows that the mixed nanofiber material scaffold has better biocompatibility than PCL nanofiber. This proves that SF/PCL nanofibers are biomaterials with application potential and are suitable for ligament tissue engineering repair. At the same time, protein drugs embedded in silk fibroin can maintain its activity for a long time.

The maximum load of SF/PCL artificial ligament is 2.73 times that of human ACL, and it is resistant to repetition. The strength of twisting and bending can prevent damage caused by excessive traction; SF/PCL ligament fibers line up the normal physiological structure of people, and the gap between the fibers is moderate, which is conducive to the normal growth of human tissues, increases the viscoelasticity of ligaments, and avoids wear and tear. Peeling is as follows: LARS ligament has stable performance and is not affected by the human body's biological reaction process; 6 months after surgery, it was found that there are collagen fibers and vascular endothelial cells in the artificial ligament. The patient does not have acute synovitis and feels good; the patient who reconstructed ACL with SF/PCL ligament has no synovial inflammation and serious complications. The biomechanical test data of different experimental groups are shown in Table 2.

The results of the study showed that the biomechanics of the body was changed. Compared with the PCL group, the maximum load of SF/PCL increased by 28%, the stiffness decreased by 10%, and the energy increased by 75%, indicating that the addition of SF material affects the biomechanics and improves the ligament.

The SF/PCL artificial ligament is made of high-strength polyester fiber: its design combines the principles of bionics, the internal structure is similar to normal human ligaments, and the longitudinal fibers in the joints are elastic but not elongated and the external mesh of the joint. The fibrous fibers provide strength without being stretched, and there is no transverse fiber structure inside. The fiber structure promotes the growth of tissue cells and achieves the purpose of repair and reconstruction. It can prevent the friction between the fibers from generating debris particles, thereby avoiding the occurrence of synovitis. In addition, the material has good plasticity and can mimic the movement of normal human ligaments according to the rotation of the ligaments, and the fatigue strength depends on the number of fibers, as shown in Figure 1.

TABLE 2: Experimental group biomechanics test data.

Group	Maximum load	Stiffness	Energy	Displacement
The first	36.1 ± 22.7	21.8 ± 8.5	40.6 ± 35.4	2.3 ± 0.5
Second	47.0 ± 7.4	24.3 ± 3.1	78.1 ± 32.9	3.3 ± 1.0
Three	88.2 ± 18.3	46.21 ± 1.8	171.2 ± 90.5	3.3 ± 1.1
FIGURE 1: The effect of stent implantation time on fiber diameter and tensile strength.

The data analysis results shown in Figure 1 clearly show that the extensibility of bone marrow stromal stem cells increased by 38% after SF treatment, and the ability to adhere to cells was greatly enhanced, which was twice that of the PCL group, and the morphology was significantly better than that of the untreated group. The proliferation rate of artificial ligament cells after SF treatment increased significantly. The quantitative phosphatase activity was 12% higher than that of the untreated group.

The SF/PCL scaffold has similar compressive modulus and mechanical strength to human trabecular bone. By culturing human osteoblasts, it was found that the cells can maintain the phenotype and show higher levels of alkaline phosphatase and mineral deposits. SF and PCL are raw materials, and SF/PCL stents are made by free surface electrospinning. The scaffold can improve the osteogenic differentiation of bone marrow mesenchymal stem cells derived from human cord blood, promote alkaline phosphatase activity and the expression of bone cell-specific transcription factors, osteocalcin, and type I collagen, and is an ideal bone tissue engineering supporting materials, as shown in Figure 2.

From the data in Figure 2, it can be seen that the artificial ligament scaffold increased the cell proliferation rate, the number of cells increased with time, the extracellular genes of the control group decreased, and a large number of cells adhered to the SF/PCL patch, which was higher than the control 67% of the group and was 30% higher than that of the PCL group, inflammation-related genes were 40% lower than the blank group, and adhesion-related genes were 25% higher than the blank group.
FIGURE 2: The relationship between SF concentration and fiber diameter and elongation.

4.2. Analysis of Biological Characteristics of Silk Fibroin Polycaprolactone Nanofibers. In the spinning process, the fiber diameter distribution is uneven, the dispersion is large, the mass fraction is 15%, and the effect on the spinning solution is more obvious. When the mass fraction of the spinning solution is 13%, the obtained nanofibers have a regular morphology, a small diameter, and a relatively uniform diameter distribution. When the mass fraction is 11%, the diameter of the fiber is the smallest, the average diameter is close to 100 nm, the diameter distribution is relatively concentrated, and the dispersion is small. Therefore, the mass fraction of the spinning solution can be 11% and 13%, as shown in Figure 3.

It can be seen from the data in Figure 3 that the voltage also has a certain effect on the engineering tissue scaffold. When the voltage reaches 20 kV, the fiber diameter is uniform, and the gap between the fibers is larger. At this time, the diameter increases by 8%. When the voltage continues to increase, the concentration slowly increases, the fiber diameter varies, and the gap becomes smaller, which affects the infiltration of cells. Such a scaffold will hinder the repair of the damaged ligament.

Polycaprolactone (PCL) and SF are used to manufacture three-dimensional porous scaffolds through electrospinning technology. The addition of sericin enhances the adhesion and proliferation of human skin fibroblasts on the material. The hybrid nanofiber scaffold prepared by this technology is more conducive to the proliferation of ligament keratinocytes and fibroblasts. The scaffold material with SF as the matrix can well promote the growth of fibroblasts and can help wound healing and reconstruct the function of damaged ligaments, as shown in Figure 4.

It can be seen from Figure 4 that the stent implantation time affects the repair of various ligament functions. After one week of implantation, the human source in the injured area is reduced by 30%, and the stromal cells increase by 13% at the second week. After 30 days of implantation, the collagen fiber diameter increases by 25%, 12 weeks, and the maximum pulling force is higher than the control group.
FIGURE 3: The fiber diameter changes with the voltage affect the artificial ligament load.
FIGURE 4: The effect of stent implantation time on adhesion rate.

5. Conclusions

(1) In the process of tissue engineering scaffold repairing damaged ligaments, the concentration of SF increases, the fiber diameter increases, the traction force increases, the tensile strength increases by 30%, the stretching rate increases to 62.5%, and the maximum load ratio of SF/PCL is as follows. The PCL group increased by 28%, stiffness decreased by 10%, and energy increased by 75%. When increased to a certain extent, the fiber diameter is uniform, the pores are large, and the arrangement is neat, which is conducive to cell infiltration, generating new cells, and rebuilding damaged ligaments

(2) The research in this paper shows that the SF/PCL scaffold can make more use of damaged ligaments

to recover, increase biocompatibility by 25%, increase cell proliferation rate by 57%, increase somatic cell adhesion rate by 35%, and increase collagen fiber formation by 12%, the porosity is about 60%, and the load is as high as $907 \pm 132\,N$. However, a large number of cells adhere to the SF/PCL membrane, which is higher than 67% in the control group and 30% higher than in the PCL group. Inflammation-related genes are lower than 40% in the blank group, and adhesion-related genes are 25% higher than those in the blank group. The data shows that the performance of the artificial ligament has been greatly changed by adding SF

(3) The study found that when the mass ratio of nanofibers to ordinary silk fibroin is $1:7$, the mechanical properties of the scaffold are the best. The crystallinity of the scaffold material is reduced by 23%, the degradation performance is increased by 31%, and the hydrophilicity is increased by 60%. The compatibility is improved by 58%. These factors meet the conditions of the ideal scaffold required by tissue engineering and become the first choice for repairing knee ligament injuries. This result has given scientists a new understanding of the selection of scaffolds and laid a new foundation for the development of medicine

With the improvement of people's living standards, the living conditions and environment of residents have changed, and there are also more and more electrical appliances such as air conditioners, air purifiers, and humidifiers. People's living environment and office environment are increasingly closed, which makes it easy for mites to breed and multiply. The changes in the living environment have made many people more and more aware of health and safety issues. Under these conditions, it is mainly used in the field of biomedicine. In the high-tech field, nanomaterials with antimite and antibacterial properties have entered the field of clothing and home textiles. With the advancement and development of science and technology, nanomaterial technology tends to mature and becomes a major player in the field of clothing. However, nanosilver alone has some defects, such as large nanoparticles, poor antimite and antibacterial effect, high cost, easy oxidation, and strong toxicity. Therefore, the preparation of new nanocomposite materials is of great significance for the application of nanotechnology to the field of clothing. In this paper, the antimite and antibacterial properties of different nanomaterials on clothing were explored through deep learning technology combined with experimental methods. According to the experiments in this paper, the $Ag/TiO_2(ATA)$ nanocomposites have obvious antibacterial and acarid effects, and the antibacterial and acarid rates are close to 100% under the conditions of visible light and dark light.

1. Introduction

Bacterial mites are ubiquitous organisms in human life. It has strong vitality, rapid reproduction, and strong ability to adapt to the environment. Some pathogenic microorganisms invade the human body through direct contact or the surrounding environment, which seriously threatens human health and interferes with human normal life. As a necessities of human life, textiles are very easy to breed bacteria and be contaminated with microorganisms such as mites that endanger human health due to their own structural problems. Coupled with the surface temperature, humidity, oil, and sweat of the human body, natural conditions are created for the reproduction of microorganisms. With the development of society and the advancement of science and technology, people's demand for the comfort and functionality of textiles is increasing, so some textiles with special functions are favored by consumers. With the introduction

and rapid development of the concept of deep learning, people use some of its algorithms and features to apply deep learning technology to antibacterial and antimite nanoclothing. Through these algorithms, the antibacterial and antimite properties of nanocomposites are more deeply recognized.

Because nanocomposite materials have the characteristics of antibacterial, antimite, nontoxic, tasteless, and strong stability, clothing fabrics have also begun to use this special material. This has made a significant contribution to the promotion of the textile industry. The use of deep learning, a multilayer neural network learning algorithm, to explore the antibacterial and antimite effect of clothing nanometers better demonstrates the benefits of nanocomposite materials used in clothing fabrics.

The following related researches on deep learning and antibacterial and antimite composite nanomaterials were found through sorting out. Dong Y has summarized recent advances in deep learning-based acoustic models under his

research and investigated the motivations and insights behind the techniques. Models such as recurrent neural networks U+0028 RNNs U+0029 and convolutional neural networks U+0028 CNNs U+0029, which can effectively utilize variable-length contextual information, were discussed, as well as their various combinations with other models. Then, the end-to-end optimized model was described, focusing on feature representations learned jointly with the rest of the system, connectionist temporal classification U+0028 CTC U+0029 standard, and attention-based sequence-to-sequence translation models. Robustness issues in speech recognition systems were further elaborated, and acoustic model adaptation, speech enhancement, and separation, and robustness training strategies were discussed [1]. Oshea T proposed and discussed several new applications of deep learning at the physical layer. A fundamentally new approach was developed by interpreting the communication system as an autoencoder. It shows how to extend this idea to networks of multiple transmitters and receivers and presents the concept of radio transformer networks as a means of incorporating expert domain knowledge into machine learning models. Finally, the application of convolutional neural networks on raw IQ samples for modulation classification is shown. Its accuracy is competitive compared to traditional schemes relying on expert features [2]. Kermany D S has built a deep learning framework-based diagnostic tool for screening patients with common treatable blinding retinal diseases. It used transfer learning to train neural networks with a fraction of the data of traditional methods. This approach can be applied to a data set of optical coherence tomography images, demonstrating comparable performance to human experts in classifying age-related macular degeneration and diabetic macular edema. By highlighting the regions identified by the neural network, a more transparent and interpretable diagnosis can be provided. This further demonstrated the general applicability of the artificial intelligence system in diagnosing pediatric pneumonia using chest X-ray images. This tool may ultimately help to expedite the diagnosis and referral of these treatable diseases, thereby facilitating early treatment and thus improving clinical outcomes [3]. Ravi D provided a comprehensive up-to-date review of research employing deep learning in health informatics. A critical analysis of the technology's relative merits, potential pitfalls, and future prospects is presented. They mainly focused on key applications of deep learning in translational bioinformatics, medical imaging, pervasive sensing, medical informatics, and public health [4]. Wang D L summarized the recent research progress of deep learning-based supervised speech separation. First, the background of speech separation and the concept of supervised separation are introduced. Then, it discusses the three main components of supervised separation: learning machine, training target, and acoustic features. Most of the overview is about separation algorithms and reviewing monophonic approaches, including speech enhancement (speech-nonspeech separation), speaker separation (multispeaker separation), and speech deredundancy, as well as multimicrophone techniques. Generalization problems specific to supervised learning are discussed. They provided a historical perspective on how progress was made [5]. Cheng C showed that functional graphene nanomaterials (FGNs) are

an emerging material. It has extremely unique physical and chemical properties and physiological capabilities to interfere with and/or interact with biological organisms. Therefore, FGN offers multiple possibilities for various biological applications. In addition to their use in drug/gene delivery, phototherapy, and bioimaging, recent studies have shown that FGNs can significantly facilitate interfacial biological interactions, especially with proteins, mammalian cells/stem cells, and microbes. FGNs can adsorb and concentrate nutritional factors including proteins in physiological media. In addition, FGNs can also interact with cocultured cells through physical or chemical stimulation, thereby significantly modulating their cell signaling and biological properties [6]. Shivakumar D T demonstrated that metallization layers of aluminum, gold, or copper can be prevented from interacting with silicon substrates by thin boron layers grown by chemical vapor deposition (CVD) at 450°C. A 3-nm-thick boron layer was investigated in detail. It forms the p-anode region of the PureB diode with zero metallurgical junction depth on the n-type silicon. Metals were deposited by electron beam-assisted physical vapor deposition (EBPVD) at room temperature. It is annealed at temperatures up to 500°C. In all cases, the B layer is an effective material barrier between metal and silicon. The almost unchanged I–V characteristics of the PureB diodes and the microscopy of the deposited layers were examined and verified. In order to obtain this result, it is required that the silicon surface must be cleaned before B deposition. Otherwise, any silicon surface contamination will prevent complete B coverage, resulting in increased current flow, sometimes Schottky-like. For Au, the room temperature interaction with Si is excessive through such pinholes in the B layer after annealing at 500°C [7]. These documents are very detailed for the introduction of deep learning and nanomaterials and have great reference value for the writing of this article.

In this paper, the antibacterial and antimite properties of nanocomposites under different conditions were explored through deep learning methods. And during the experiment, it was found that the ATA nanocomposite is the most suitable for clothing fabrics. Under the same conditions, compared with elemental Ag nanomaterials, ATA has stronger stability and antimite and antibacterial properties, and the cost of using materials is lower.

2. Method of Nanometer Antimite and Antibacterial for Clothing Based on Deep Learning

Research on deep learning has a long history. Deep learning originated from artificial neural networks and is also classified as machine learning. Deep learning conveys image categories and features through a multilayer information network [8–10]. It is mainly used in the field of artificial intelligence and studies multiple interdisciplinary subjects, such as neural networks, image feature modeling, image recognition, and target detection. In 1943, the deep neural network based on deep learning was first proposed, and it was found that the neural network had a strong ability to learn self-features; in 1957, the perceptron model came out to deal

(a)

(b)
FIGURE 1: Unsupervised learning and supervised learning modes.

with the two-class problem; in 1986, the BP neural network based on neural network was proposed; in 2006, the concept of deep learning was first proposed; since 2014, the extensive application of deep learning in deep learning in image recognition has improved the accuracy of image recognition. With the continuous development and maturity of deep learning technology, the application of deep learning is becoming more and more extensive, and this technology is used in more and more fields.

2.1. Autoencoder. Autoencoder is an unsupervised learning algorithm that connects encoder and decoder across layers [11]. The input layer, hidden layer, and output layer constitute the autoencoder. By compressing the input data into another low-dimensional data to output the data set, it is divided into two parts: the encoder and the decoder [12]. In general, determining the expression of input data is mainly to see whether the output data is consistent with the input data. If they are inconsistent, the parameters should be adjusted so that the resulting data has the smallest error and is close to the output data and the input data [13]. The results are shown in Figure 1. The entire encoder contains two convolutional layers and one pooling layer. The convolutional layers work together to extract feature maps. The pooling layer performs downsampling and finally outputs the feature map. The decoder is the final network output. The connection layer between the encoder and the decoder mainly connects the corresponding feature maps and then becomes the data input of the next convolutional layer.

When the decoder activation function is followed by identity, the squared error function is obtained. The identity condition needs to satisfy the normal distribution:

$$Q(t, x) = t - x^2. \tag{1}$$

When the decoder activation function is a sigmoid function, the cross entropy function is obtained:

$$Q(t, x) = -\sum_{o=1}^{n} [t_o \log(x_o) + (1 - t_o) \log(1 - x_o)]. \tag{2}$$

Finally, the overall loss function is obtained:

$$K_{(AF)}(\varepsilon) = \sum_{c \in s} Q(t, g(f(t))). \tag{3}$$

2.2. Restricted Boltzmann Machine. Restricted Boltzmann machine neurons are relatively simple. It consists of two groups of neurons in the input layer and the hidden layer and is a stochastic network model [14]. Here, it is assumed that the input layer is b and the hidden layer is a. As can be seen from Figure 2, each neuron in the input layer and the hidden layer is related to each other. But if the neurons in each network model are independent, the neurons in each layer are not connected to each other [15]. Restricted Boltzmann machine has been applied in dimension reduction, classification, collaborative filtering, feature learning, and topic modeling.

The basic structure of RBM is not limited by orientation. Assuming that the values of neurons in these two layers are between 0 and 1, $k_i \in \{0, 1\}$, $m_x \in \{0, 1\}$, w and e represent the number of neurons in the input layer and hidden layer, respectively. If the specific values of the input neurons have been given, p_i is not equal to 0. The formula that will result in the combined model is

$$E(k, m, \alpha) = -\sum_{i=1}^{w} \sum_{x=1}^{e} g_{ix} k_i m_x - \sum_{i=1}^{w} p_i k_i - \sum_{x=1}^{e} q_x m_x, \tag{4}$$

where g_{ix} represents the weight coefficients of the input layer and the hidden layer; p_i represents the bias term of each neuron in the input layer; q_x represents the bias term of each neuron in the hidden layer; and α represents the grid parameter of the RBM.
FIGURE 2: Restricted Boltzmann machine model.

Using the Boltzmann algorithm to determine the proportional distribution function $Z(\varepsilon)$, the formula can be obtained. Boltzmann machine is used to combine the advantages of multilayer feedforward neural network and discrete Hopfield network in network structure, learning algorithm, and dynamic operation mechanism. It is based on discrete Hopfield network and has learning ability. It can find the optimal solution through a simulated annealing process.

$$f(y, x) = \frac{1}{z(\varepsilon)} \exp\left(-E(y, x; \varepsilon)\right) = \frac{1}{z(\varepsilon)} \prod_{ij} e^{w_r y_i x_j} \prod_i e^{a_i y_i} \prod_j e^{b_j x_j}, \tag{5}$$

$$Z(\varepsilon) = \sum_y \sum_x \exp(-E(y, x; \varepsilon)). \tag{6}$$

A proportional distribution function $Z(\varepsilon)$ of t is input to the data. According to the marginal distribution of the combined probability distribution $f(y, x)$, the problems encountered in real life can be solved, and the following formula can be obtained:

$$f(t) = \frac{1}{Z(\varepsilon)} \sum_x \exp(-E(t, x; \varepsilon)). \tag{7}$$

The grid parameter ε is calculated using the RBM feature extraction method. The subsequent input data is obtained through the calculated grid parameters. It refers to the boundary of grid parameter domain calculated according to the characteristics of 3D grid (while the fixed boundary method is artificially specified). Assuming that the number of samples is W, then, the measurement method of the grid parameters is the likelihood function, and the formula is as follows:

$$\varepsilon = \arg \ \max_\varepsilon \sum_{w=1}^{W} \log\left(p\left(t^{(w)}\right)\right). \tag{8}$$

The optimal parameter ε of the network with the maximum value of the $L(\varepsilon) = \arg \ \max_\varepsilon \sum_{w=1}^{W} \log\left(p(t^{(w)})\right)$ function is measured by the method of stochastic gradient ascent (SGA). The partial derivative value of each network parameter is a $\log\left(p(t^{(w)})\right)$ function, which can be obtained by the following formula:

$$\frac{\chi l}{\chi \varepsilon} = \sum_{w}^{W} \left(\left\langle \frac{\chi\left(-E\left(t^{(q)}, x\right)\right)}{\chi \varepsilon} \right\rangle_{p(\varepsilon)} - \left\langle \frac{\chi\left(-E(t, x)\right)}{\chi \varepsilon} \right\rangle_{p(t, x)} \right). \tag{9}$$

When the partial derivatives of the specific parameters g_{ix}, p_i, and q_i of the likelihood function have only one simple parameter facing the training grid, the following formula can be obtained:

$$\frac{\chi p(t)}{\chi g_{ij}} = \left\langle t_i x_j \right\rangle_{p(x)} - \left\langle t_i x_j \right\rangle_{p(t, x)}, \tag{10}$$

$$\frac{\chi p(t)}{\chi(p_i)} = \left\langle t_i \right\rangle_{p(x)} - \left\langle t_i \right\rangle_{p(t, x)}, \tag{11}$$

$$\frac{\chi p(t)}{\chi(q_i)} = \left\langle t_i \right\rangle_{p(x)} - \left\langle t_i \right\rangle_{p(t, x)}. \tag{12}$$

Assuming that t_0 represents the input layer data, according to the obtained data visualization, the activation value of each hidden layer w_0 is calculated by the method of the sigmoid network activation function, and the following formula is obtained:

$$p(t_0 = 1 | w_o) = 1 / \left(1 + \exp\left(-\sum_i v_i g_{ij} + q_i \right) \right). \tag{13}$$

According to the characteristics of the symmetry of the RBM grid structure, when the hidden layer is in the active state, the activation value of the input layer can be obtained according to the following formula:

$$p(t_i = 1 | t_0) = 1 / \left(1 + \exp\left(-\sum_j t_i w_{ij} + a_j \right) \right). \tag{14}$$

2.3. Deep Belief Network. A deep belief network is a type of machine learning that consists of multiple RBM networks. It is a probabilistic generative model built between data and labels, which can be applied to both unsupervised learning and supervised learning [16–18]. RBM network consists of visible layer and hidden layer. By definition, unsupervised learning is used to deal with the sample set not marked by classification when designing the classifier. Supervised learning refers to the process of using a group of samples of known categories to adjust the parameters of the classifier to achieve the required performance, which is also called supervised training or teacher learning. The difference is that supervised learning means that a set of data is given manually and the attribute value of each data is also given. For each sample in the data set, we want the algorithm to predict and give the correct answer: regression problem and classification problem. In unsupervised learning, data is not labeled or has the same label. Its network structure is shown in Figure 3.

As can be seen from Figure 3, the deep belief network is composed of RBM structures [19]. Deep belief networks
Figure 3: DBN deep learning model.

solve the difficult problem of training multilayer neural networks. It achieves data features by training the weights between each constituent neuron. The deep belief network training process is carried out step by step. In the training process of each layer of neurons, the feature image of the hidden layer is inferred through the data, and the previously obtained hidden layer is used as the data vector of the next layer to progress layer by layer, and so on. Finally, the entire deep belief network is fine-tuned through supervised learning [20]. After the above actions, a basic supervised learning algorithm is completed by concatenating the final results [21].

3. Deep Neural Network

Since the deep neural network is extended from the traditional neural network, the research of the deep neural network has not been effectively developed for a long time, and it has been in the research stage of one or two hidden layers [22]. It does not perform well in forward propagation, back propagation, and gradient descent, and is not even as good as a single hidden layer neural network. In this regard, many scholars have been exploring what causes the deep neural network to have poor ability to deal with problems [23]. At present, the methods of training neural networks are based on the idea of back propagation; that is, according to the error calculated by the loss function, the weight of the depth network is updated and optimized by gradient back propagation.

According to the answers given by most scholars, two main reasons are summarized: First, the value of the initial parameters affects the neural network, which is also the drawback of the gradient descent method. Second, the increase of grid parameters leads to an increase in the number of neural network layers. The neural network is originally a fitter, which aggravates the overfitting of the deep neural network, and the final result is not good [24]. At first, each object is regarded as a cluster, and then, these clusters are merged step by step according to some criteria. The distance between the two clusters can be determined by the similarity of the nearest data points in the two different clusters. The clustering process is repeated until all clusters meet the number of clusters.

It has been proven by practice that the weight matrix can be shifted by training the initial weights of the deep neural network step by step, which makes the in-depth study of the deep neural network go a step further. Some experts proposed to train a DBN in the forward direction based on the RBM network and then expand the DBN in the reverse direction. Finally, the whole network is regarded as a complete AE using the traditional BP algorithm for repeated training [25]. BP network can learn and store a large number of input-output mode mapping relationships without revealing the mathematical equations describing this mapping relationship in advance. In this way, AE actually becomes the first successfully trained deep autoencoder on the intelligent algorithm. The initial training process of the deep neural network is shown in Figure 4.

3.1. Convolutional Neural Network. Convolutional neural network is divided from artificial neural network, which is a multilayer neural network structure with the ability of deep learning [26]. Convolutional neural networks rely on convolutional and downsampling layers to extract data. The weight of some neurons in the same layer is the same, and it is not completely connected with neurons, but each layer has multiple neurons connected to each other [27]. The convolutional neural network is extended into two parts: The first part is the convolutional layer and the pooling layer (downsampling layer). The second part is the fully connected layer and the output layer. The input layer is where the algorithm begins to affect the entire network output value. The convolutional layer mainly plays the function of extracting features and is an important part of the entire neural network. The pooling layer samples the output data and obtains the feature map after the convolutional layer. Each neuron of the fully connected layer is connected to the neurons of the output layer to achieve the function of a classifier.

The concept of weight sharing means that the value of the local receptive field in the convolutional neural network is the same in the process of feature image generation. Neurons have the same features but recognize staggered two-dimensional planes. The weight sharing feature allows the neural elements of the neural network in a two-dimensional plane to be translated but not deformed. It also shows the same feature data during the weight sharing process.

The downsampling operation is a nonlinear dimensionality reduction operation. It can make difficult-to-recognize special images easier to identify through dimensionality reduction methods. It simplifies the entire neural network and reduces the number of neural elements in the neural network, but does not affect the final output. As shown in Figure 5, it is the basic structure of convolutional neural network.

Convolutional neural networks are more widely used in object detection. A new breakthrough has been found for improving the accuracy of target detection through the convolutional neural network method.
Figure 4: Pre-training process of deep neural network.
Figure 5: The structure of the convolutional neural network.

A feature map on a convolutional layer in a convolutional neural network is connected to the corresponding convolution kernel. By introducing an activation function after calculation, and then calculating the feature with the activation function, each input data can be accurately obtained [28]. The data of each output is formed by combining multiple feature maps, and the formula is obtained:

$$v_i^w = f(x_i^w), \tag{15}$$

$$x_i^w = \sum_{k \in M_i} v_i^{w-1} \cdot a_{ki}^w + r_i^w, \tag{16}$$

where v_i^w is the i-th output data of each convolutional layer w in the convolutional network; x_i^w is the activation value of the i-th layer of the w-th convolutional layer of the convolutional network; M_i is the feature data set for calculating the activation value x_i^w; $f(\bullet)$ is the activation function in the convolutional neural network; a_{ki}^w is the convolution kernel vector set in the convolutional network; and r_i^w is the final bias function of the convolutional network.

The activation function set by the pooling layer in each convolutional network is denoted by down($\bullet$). In each pooling layer, the output feature map convolved by each convolutional network can be obtained by the following formula:

$$x_i^w = \int_i^w \text{down}(v_i^{w-1}) + r_i^w. \tag{17}$$

In a convolutional network where each convolutional layer is connected to each other, the input of all connected convolutional layers is the combination of all 2D feature images. All input influence degree coefficients are summed by convolution. Finally, the feature output of each connected convolutional layer can be obtained by using the preset activation function, which can be obtained

$$x_i^w = m_i^w v^{w-1} + r_i^w. \tag{18}$$

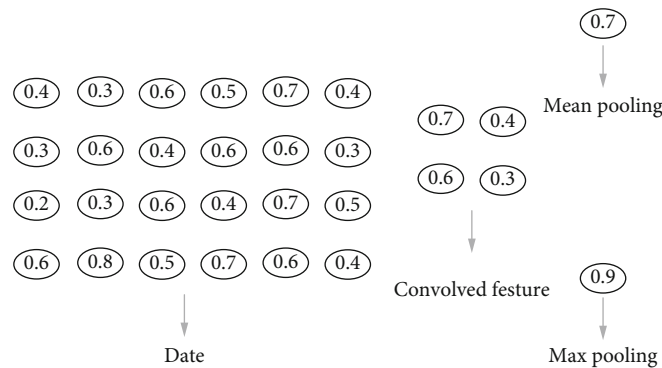
According to each weight, the final output is the convolutional layer sensitivity. The object can be classified, identified, predicted, or decided according to its characteristics. In
Figure 6: Upsampling operation diagram.


Figure 7: Schematic diagram of the operation of convolution and pooling.

this process, the most important step is feature extraction, that is, how to extract the features that can distinguish things to the greatest extent:

$$\phi_x^l = \int_x^{l+1} \left(\lambda' \left(u_x^l \right) \circ \mathrm{up} \left(\phi_x^{l+1} \right) \right). \tag{19}$$

By implementing the convolutional layer using the Kroneckers product, the function can be obtained:

$$\mathrm{up}(z) = z \otimes 1_{n \times n}. \tag{20}$$

According to the maximum pooling used above, put 4 in the model ×4 region is regarded as the set of some characteristics, that is, the set of activation values of a certain layer in the neural network. A large number means that some specific features may be detected. The features in the upper left quadrant may be a vertical edge, an eye, or cap features that people are afraid to encounter. The upsampling operation shown in Figure 6 can be obtained.

After the input image is extracted by the convolution layer image, additional image features are obtained by pooling. Figure 7 is a process diagram of image convolution and pooling.

The fully connected layer inputs a multidimensional vector. Each vector is converted into a bunch of vectors, and the sensitivity can be used to calculate the weight of each neuron. The formula for calculating the sensitivity of the fully connected layer is

$$\phi_x^l = \left(w^{l+1} \right)^R \phi^{l+1} \circ f' \left(v^l \right). \tag{21}$$

The actual training of the convolutional neural network has nothing to do with the previous input variables; it only reacts to the input variables. Because the bacteriostatic rate of ATA composites within 24 hours is constantly changing, in a day, if the time data of a certain hour of the day is randomly selected to analyze the results, the fluctuation of the data of the previous hour or the next hour will be ignored. Therefore, the change data of one day must be sampled.

4. The Research Experiment and Analysis of Nanometer Antimite and Antibacterial of Clothing Based on Deep Learning Technology

The application of nanomaterials in clothing is mainly to integrate nanomaterials into fabric fibers. For the antimite and antibacterial properties of clothing nanometers, the main method is to add substances with antibacterial properties into nanofibers. With the deepening of research, substances with antibacterial properties are mainly divided into the following two categories according to the properties of the substances: (1) Metals and metal oxides. Metal oxide antibacterial materials mainly include ZnO, TiO_2, and Fe_3O_4. (2). The surface chemical structure of house dust mite before and after ATA nanomaterial treatment showed that the structure of lipid, protein, and polysaccharide of

mite body wall changed; TiO2 is a typical photocatalytic antibacterial material, which has the characteristics of low toxicity, low price, acid and alkali resistance, and strong antibacterial ability under UV irradiation; and Ag ion is the most efficient metal ion antibacterial agent known at present. It has the advantages of good antibacterial effect, low antibacterial concentration, killing many kinds of bacteria, and strong drug resistance. Taking Ag, TiO_2, and ATA as research objects, their antibacterial properties were analyzed. Ag ion is a metal ion antibacterial agent that can kill many kinds of bacteria and has strong drug resistance; TiO_2 is a good photocatalyst; ATA has strong stability. The absorbance values of different materials are detected using deep learning techniques. Bacterial growth kinetics were analyzed according to the degree of change in absorbance value. The absorption coefficient is related to the wavelength of the incident light and the material passed by the light. As long as the wavelength of the light is fixed, the absorption coefficient of the same material will remain unchanged. When a beam of light passes through a light absorbing substance (usually a solution), the solute absorbs light energy and the intensity of light decreases. Absorbance is a physical quantity used to measure the degree of light absorption.

4.1. *Preparation of ATA Antibacterial Fabric.* 9 pieces of treated fabrics (20 cm × 20 cm) were immersed in ATA nano-solution at different times. Each corresponds to a different parallel sample. They were taken out at different times, squeezed out excess liquid, and passed through an oven drying process at 125°C for 15 minutes. Then, the change of the fabric before and after loading and the loading of the antibacterial agent of the fabric in different time periods were measured. The longer the load time, the worse the fabric load.

It can be seen from Tables 1 and 2 that in the presence of light, the antibacterial activity of ATA against *Escherichia coli* reaches 99.60% and 100% in two time periods; in the absence of light, the antibacterial activity of ATA against *Escherichia coli* reaches 99.60% and 100%. The bacteriostatic rate of the two cases is basically close to 100%, and the antibacterial effect is excellent.

According to Table 3, the antibacterial performance of *Staphylococcus aureus* is very good in the presence of light
Figure 8: The analysis of the activity of ATA against Gram-negative bacteria.

or in the dark, and the bacteriostatic rate is basically close to 100%.

4.2. ATA against Gram-Negative Bacteria.

The experimental objects were *Acinetobacter baumannii*, *Escherichia coli*, and *Pseudomonas aeruginosa*.

As shown in Figure 8, the minimum inhibitory concentration values of ATA against Gram-negative bacteria are: *Acinetobacter baumannii* was 10 μg/ml. *Escherichia coli* was 16 μg/ml. *Pseudomonas aeruginosa* is 16 μg/ml. Ag concentrations in ATA were 2.11, 3.37, and 3.37 μg/ml. The mini-

mum inhibitory concentrations corresponding to elemental Ag were 4, 8, and 10 μg/ml. And 200 μg/ml still has only weak antibacterial effect. The results of the minimum inhibitory concentration test showed that ATA has strong antibacterial ability against all the tested strains. With the increase of ATA and Ag concentrations, its antibacterial activity was enhanced, and the reproduction and growth rate of all bacteria slowed down rapidly.

4.3. ATA against Gram-Positive Bacteria.

The experimental subjects were *Streptococcus pneumoniae*, *Staphylococcus*
Figure 9: The analysis of ATA against Gram-positive bacteria.

epidermidis, *Streptococcus hemolyticus*, and *Staphylococcus aureus*.

Figure 9 shows that the minimum inhibitory concentrations of ATA against Gram-positive bacteria were 4 μg/ml for *Streptococcus pneumoniae*, 8 μg/ml for *Staphylococcus epidermidis*, 14 μg/ml for *Streptococcus hemolyticus*, and 16 μg/ml for *Staphylococcus aureus*. ml. The Ag concentrations in ATA were 0.84, 1.68, 2.95, and 3.37 μg/ml, respectively; the minimum inhibitory concentrations corresponding to elemental

Ag were 2, 4, 6, and 8 μg/ml. 200 μg/ml TiO$_2$ has only weak antibacterial effect on all the above bacteria. At the minimum inhibitory concentration, the content of Ag in ATA was about 1/2 to 1/3 of that of elemental Ag. That is to say, ATA not only has powerful broad-spectrum antibacterial properties, but also greatly reduces the use of Ag and achieves the purpose of saving precious metal Ag. Even if the concentration of pure TiO$_2$ reaches 200 μg/ml, there is only a weak antibacterial effect. These results imply the occurrence of synergistic antibacterial

TABLE 4: Comparison of minimum inhibitory concentrations of TiO_2, Ag and Ag/TiO_2.

Bacterial species and number	Gram species (negative-; positive +)	TiO_2 minimum inhibitory concentration ($\mu g/ml$)	Ag minimum inhibitory concentration ($\mu g/ml$)	ATA minimum inhibitory concentration ($\mu g/ml$)
A. baumannii	—	More than 200	4	10 (Ag:2.11; TiO2:7.89)
E. coli	—	More than 200	8	16 (Ag:3.37; TiO2:12.63)
P. aeruginosa	—	More than 200	10	16 (Ag:3.37; TiO2:12.63)
S. pneumoniae	+	More than 200	2	4 (Ag:0.84; TiO2:3.16)
S. epidermidis	+	More than 200	4	8 (Ag:.68; TiO2:6.32)
S. hemolyticus	+	More than 200	6	14 (Ag:2.95; TiO2:11.05)
S. aureus	+	More than 200	8	16 (Ag:3.37, TiO2:12.63)

(a)

(b)
FIGURE 10: The relationship between the antihouse dust mite activity and time of the samples at different concentrations.

properties of ATA, possibly because Ag and TiO_2 have different antibacterial action mechanisms. In addition, the minimum inhibitory concentration of ATA was lower than that of other inorganic antibacterial materials. Table 4 is the comparative data of minimum inhibitory concentration of TiO_2, Ag, and Ag/TiO_2.

Through experiments, it was found that adding different amounts of TiO_2 to the nanomaterials can effectively inhibit the activity and survival rate of bacteria. Its main antibacterial mechanism is that TiO_2 kills bacteria by destroying their cell walls. Compared with Ag nanomaterials, ATA nanometers have small particle size and strong stability. Under the same dosage, the Ag concentration in ATA is about 1/2-1/3 of that of elemental Ag, which saves the cost of Ag to a great extent.

4.4. Antimite Activity Analysis of ag/TiO_2. The antimite activity of ATA against house dust mites was evaluated by the method of deep learning technology. It can be seen from Figure 10 that ATA has a strong ability to remove mites. According to the treatment of house dust mites with differ-

ent doses of ATA, the survival rates of house dust mites after 24 hours were 76%, 46%, 33%, 27%, 5%, and 2%, respectively. When the time was extended to seven days (168 h), the survival rate of house dust mites did not change significantly, but only slightly decreased. As can be seen from Figure 10, ATA, Ag, and TiO_2 have obvious antimite effects within 24 hours, and the effect is not so obvious after 24 hours, and ATA has a synergistic antimite effect.

5. Discussion

This paper mainly discusses and studies the antimite and antibacterial effect of clothing nanometers based on deep learning technology. In this paper, the antibacterial and antimite effects of Ag, TiO_2 and Ag/TiO_2 (ATA) nanocomposites were experimentally studied by using deep learning algorithm. It compares the antibacterial and antimite properties of different composite nanomaterials under different conditions. According to the experiments, the nanomaterials with the strongest antibacterial properties and the most suitable for integration into clothing fabrics are obtained. The

experimental results show that the deep learning technology can be used in the research on the antibacterial and antimite of clothing nanometers. And under this technology, the antimite and antibacterial experiments of nanomaterials have obtained satisfactory results.

6. Conclusions

Ag, TiO$_2$, and Ag/TiO$_2$ (ATA) nanocomposites have certain antimite and antibacterial effects and are widely used. However, the Ag/TiO$_2$ (ATA) nanocomposites prepared by Ag and TiO$_2$ have stronger stability and better antibacterial properties. With the advancement of social technology, Ag/TiO$_2$ (ATA) nanocomposites are used more and more widely as a bacteriostatic agent, and the development prospect is getting better and better. The synergistic antimite effect of ATA was obtained by evaluating the antimite activity of ATA against house dust mites by using deep learning technology. Within 24 hours, TA, Ag, and TiO$_2$ had obvious antimite effects during this period.

National sports are traditional sports of ethnic minorities and sports with strong national characteristics. Sports performances generally include weightlifting, boxing or martial arts, gymnastics, skating, high jump, sprint, and hurdles. Such as knee joints that are particularly vulnerable to injury. Therefore, ordinary ethnic sports athletes are particularly vulnerable to injury. Ethnic sports rehabilitation therapy uses some exercises to enable patients to obtain full or partial exercise functions. Training methods for sensory function recovery were used. Ethnic sports rehabilitation therapy is a common rehabilitation therapy for ethnic sports athletes to resume sports training, such as table tennis, tennis, cycling, fishing, climbing, skating, weightlifting, and wrestling. However, with economic development and social progress, the treatment of knee arthritis is closely integrated with nanotubes combined with national sports rehabilitation therapy, and it has been increasingly used in competitive sports and national fitness. From 2003 to 2020, the medical research literature on nanotechnology increased from 20 to more than 20,000. This article presents a way for treating knee arthritis sufferers by combining nanotubes with ethnic sports rehabilitation therapy and discusses the clinical therapeutic effect of nanotubes combined with ethnic sports rehabilitation therapy in the treatment of knee arthritis patients. It provides a certain basis for the treatment of patients with knee arthritis. This article selected 100 knee patients, who, as research subjects, visited our facility for medical treatment between June 2016 and June 2020, and divided 100 patients into two groups, 50 patients in the experimental group and 50 patients in the control group. For patients, the experimental group used nanotubes combined with ethnic sports rehabilitation therapy to treat patients, and the control group used ethnic sports rehabilitation therapy to treat patients. The experimental results show that nanotubes combined with ethnic sports rehabilitation therapy can speed up the treatment process of patients with knee arthritis. When the experiment lasted only 5 days, patients in the control group scored an average of 3 points, and on the last day, they scored an average of 6.9 points. In the experimental group, the average score of patients on the fifth day of the experiment was 5 points, and the average score of patients on the last day was 9.7 points. The knee joint patients in the experimental group have higher walking ability, up-and-down ability, knee flexion, and knee swelling. In the control group, among them, the first to recover from knee arthritis is the ability to walk, and the slowest recovery is the flexion of the knee joint.

1. Introduction

National sports refer to the traditional sports activities of all nationalities in the world, such as Chinese martial arts, qigong health preservation, etc. National sports refer to the sports events and activities of ethnic minorities in a country [1]. As an important part of human sports culture, national sports reflect the horizontal inheritance relationship of national culture from its own characteristics, which can be said to be a means of national education. Along the direction of inheritance and innovation, the national movement has explored the combination of popularization and improvement, the combination of mass and professionalism, the combination of traditional sports and modern sports and has made gratifying progress [2]. Therefore, it can be popularized in the future national sports activities.

Generally speaking, sports rehabilitation refers not only to the rehabilitation after injury but also to actively improve

the ability to prevent sports injury. Preventive rehabilitation is an important part of sports rehabilitation, reasonable exercise training is the basic guarantee of preventing sports injury, and the stability of spine, bone, ligament and muscle plays an important role in prevention and rehabilitation [3]. In the traditional modern rehabilitation system, including physical therapy, speech therapy, psychotherapy, and occupational therapy. Among them, athlete therapy, physical therapy, and stress therapy are the most common [4]. Compression therapy is the application of positive or negative pressure to treat dysfunction. For example, the positive pressure of muscles is used to relieve muscle spasm, and the negative pressure of limbs is used to treat limb vasodilation and improve tissue metabolism. The purpose of exercise rehabilitation is to treat sports injury and chronic diseases. Exercise therapy and physical therapy are two ways of thinking of exercise rehabilitation. Among them, exercise therapy is to slow the patients back to normal through a certain amount of exercise; physical therapy is a widely used treatment concept; it promotes the rehabilitation of patients through sound, light, electromagnetic heat and other means; homework therapy is a kind of treatment concept aimed at helping patients recover normal life function [5]. For example, when a patient exercises, one hand accidentally falls to the ground, resulting in a broken wrist. In the process of rehabilitation, occupational therapists are responsible for the recovery of normal writing and eating of injured limbs, which involves the recovery of some good tactile and proprioception training, which is different from the first two treatments. With the increasing popularity of mass sports, sports injuries, nutrition matching in the process of sports, self-protection, and so on have become the knowledge that the public urgently needs to know. Exercise therapy is to treat through a certain amount of exercise, physical therapy is to promote the recovery of patients by means of sound, light, electromagnetic heat, etc., and pressure therapy is to apply positive or negative pressure therapy [6]. In the past, the major of sports rehabilitation and health was mainly for professional athletes, and there were few talents with systematic knowledge of the combination of medical treatment and sports. Therefore, relevant talents have always been a hot demand for training bases and fitness clubs [7].

Knee arthritis is a chronic arthritis disease, mostly in the middle-aged and the elderly and sports people [8]. Joint diseases are common on these aspects. If knee pain recurred within a month, from mild to severe, accompanied by the sound of joint friction movement, temporary stiffness in the morning, X-ray shows narrowing of joint space, subchondral bone sclerosis or cystic change, osteophyte formation, or joint edge bone hyperplasia, it can be considered osteoarthritis [9]. Early knee pain should pay attention to joint protection measures: appropriate rest, weight loss, prevent excessive joint movement, and weight-bearing, to avoid mechanical injury. Physical therapy is more suitable for chronic knee osteoarthritis and has a good effect on relieving subacute inflammation. A variety of physical therapy forms, including hot compress, electric therapy, magnetic therapy, infrared ray, spa, mineral spring bath, mud therapy, wax therapy, ion and penetration method, to strengthen the functional exercise of the affected limb can be chosen: increase the range of joint activity and strengthen the exercise of muscles. Nanotubes are 10000 times thinner than human hair, 100 times harder than steel, and have good thermal conductivity at 3593°C [10]. Nanotubes can be used not only as metal conductors but also as semiconductors for computer chips and superconduct at very low temperatures. Nanotube technology is mainly reflected in nanotechnology. Nanotechnology is the use of atoms and molecules to manufacture new materials. It is a technology to study the composition of materials with a size range of less than 100 nanometers. At this level, the research and processing of materials and material technology are called nanotechnology. This small space is the size range of atoms and molecules and the space in which they interact. In such a scale space, due to quantum effects, localization, and large surface and interface effects, many properties of matter have undergone qualitative changes. Nanotechnology is the study of nanophenomenon and material control, especially the extension of existing science and technology in nanoresearch.

Traditional knee arthritis patients have to rely on ethnic sports rehabilitation therapy to treat the knee joint, but for some elderly people, the effect of sports rehabilitation therapy is not obvious. Nanotechnology has increasingly infiltrated all facets of our lives as biological information technology continues to advance. Matthew explains how the characteristics of water aid functional recovery following ACLR. Matthew believes that if the major properties of hydrotherapy (density, hydrostatic pressure, buoyancy, and viscosity) are effectively applied to rehabilitation practice, specific protocols and supplemental videos for the use of hydrotherapy following ACLR can be developed to help implementation [11]. The continuous improvement of nanotherapy technology systems, especially the continuous improvement of nanodrug delivery systems, has enabled nanotherapeutics to achieve significant development in the medical field. When nanomedicine enters the human body, it will passively or actively target the nanocarrier, and then, it can be selectively delivered to the injured site. Nanotherapy reduces the harm of drug treatment to the human body to a minimum. On the other hand, the nanocarrier packaged with the therapeutic drug will protect the drug from biodegradation, allow the sustained release of the drug, and prolong the duration of the drug. In general, the targeted nanodrug delivery system has better therapeutic effects and fewer side effects. It is the best choice for knee arthritis treatment. Nanocarriers are widely used in the delivery of anti-knee arthritis drugs, plastids and dendrimers, micelles, nanocapsules, nanomaterials, and many other nanoparticles. These nanodelivery drug systems have achieved remarkable results in the treatment of knee arthritis. Combining nanotubes with traditional ethnic sports rehabilitation therapy to treat patients is the main research focus of this article.

The innovation of this paper is to propose a method combining nanotubes and national sports rehabilitation therapy to treat patients with knee arthritis and to discuss the clinical efficacy of combining nanotubes and national sports rehabilitation therapy for patients with knee arthritis [12].

2. Theoretical Basis and Core Concepts

2.1. Onset Factors of Knee Arthritis. The onset causes of knee arthritis mainly include four aspects: environmental factors, weight factors, age factors, and diet factors. Among them, environmental factors and diet are the main reasons. People who live in humid and cold environment all year round are most likely to suffer from knee arthritis, which is mainly due to low temperature and blood supply disturbance. Secondly, obesity and strong body incidence rate is high, overweight, and knee joint pressure increased. The incidence rate of arthritis is also higher with age. The accumulated strain of joints for many years is an important reason for the knee arthritis in the elderly. Finally, malnutrition is also one of the pathogenic factors of knee arthritis. There is no blood vessel in the articular cartilage, and the nutrition it needs depends on absorbing from the synovial fluid. The repair of cartilage is accomplished by the division and reproduction of outer chondrocytes and the secretion of matrix by chondrocytes. Due to the lack of nutrition and oxygen supply, the proliferation of chondrocytes will be affected, resulting in the reduction of cartilage matrix, insufficient cartilage regeneration, weakening of cartilage, and easy wear of load-bearing area [13]. The repair of cartilage is accomplished by the division and reproduction of the outer chondrocytes and the secretion of matrix by the chondrocytes.

2.2. Clinical Manifestations of Knee Arthritis. Whether suffering from knee arthritis can observe whether the knee joint trauma visible. After the occurrence of knee arthritis, often in the knee joint long bone spur, early bone hyperplasia does not affect the surrounding tissue, with the continuous growth of bone spur; it will gradually affect the surrounding tissue, the formation of inflammatory reaction. The symptoms of knee arthritis mainly include swelling of knee joint, pain of going up and down stairs, pain and discomfort of knee joint when sitting, swelling, tinnitus, and effusion will appear in patients. If not treated in time, it will cause joint deformity and disability, knee synovitis, ligament damage, meniscus injury, knee joint free body, popliteal cyst, chondromalacia of patella, palmar bursitis, knee varus, etc. The diagnosis method of early knee arthritis can be analyzed according to the joint swelling. The joint swelling comes from synovial hyperplasia and intra-articular effusion. In the early stage, it often occurs due to sprain and cold, and it will become persistent swelling later. There is a rubbing sensation or a popping sound when the joint moves.

The main symptoms of knee arthritis are knee swelling and pain, pain when walking up and down stairs, and knee pain when sitting. Patients with swelling, ringing, and effusion, if not treated in time, patients will cause joint deformity and disability. Knee synovitis, ligament injury, meniscus injury, free body of knee joint, popliteal cyst, chondromalacia of patella, goose foot bursitis, knee varus, and other knee diseases often occur [14]. If you stand up when the knee pain discomfort, activity after a period of time symptoms has been reduced, knee arthritis symptoms are obvious, and it should take timely treatment measures to reduce the symptoms of knee arthritis. Oral glucosamine drugs, including glucosamine sulfate and other raw materials to synthesize cartilage, can improve the cartilage state of the knee joint, or lie down, straighten the lower limb, and platform the affected limb to 45 degrees for 3-5 seconds. 20 times, this will increase the strength of the quadriceps muscles to achieve the purpose of protecting the knee joint [15].

2.3. Knee Joint Is Not Aligned with the Lower Limb. The mechanical axis or alignment of the lower limbs is determined by a line from the center of the tibial joint to the center of the femur, which runs from the center of the tibial joint to the center of the femur. The uneven distribution of knee joint load is consistent with the high incidence of medial knee osteoarthritis. Varus deformity and right knee joint deformity are the most common lower limb deformity. Knees aligned with the varus are described as arched legs, while knees aligned with the valgus are described as touching knees. Valgus alignment affects the load distribution on the articular surface and reduces the bearing area. The whole lower limb is a complete exercise chain. Therefore, the arrangement of bones can affect the load pattern at one level and have a profound impact on other levels [16].

2.4. Biomechanical Load and Lower Extremity Osteoarthritis. Some studies have shown that the mechanical mechanism and biomechanical changes of the stressed joint play an important role in promoting the occurrence and development of knee arthritis. The experimental results showed that the total effective rate of nanotubes combined with ethnic exercise rehabilitation therapy in the experimental group was 100%, while the control group believed that only ethnic exercise rehabilitation therapy accounted for 60%. Nanotubes combined with national sports can speed up the treatment of knee arthritis patients and improve the quality of life of knee arthritis patients. A theory that repeated mechanical loading accelerates "wear" of joints has been supported by studies by obese people and professionals who often bend their knees or load. The incidence rate of knee arthritis was monitored for 11 years through a discharge registry in a Swedish hospital. The body mass index (BMI), waist circumference, waist-hip ratio, body weight, and body fat percentage of 1126 men and 16934 women were measured. This study provides strong evidence for the association between obesity and the incidence rate of osteoarthritis in the knee and hip joints. All overweight indicators are associated with the incidence of osteoarthritis of the knee, and BMI is the most dangerous. The incidence rate of hip osteoarthritis is normal, but significant. This study confirms the close association between obesity, mechanical loading and increased risk of knee joint and hip arthritis [17].

The theory of "wear and tear" has been supported by some people engaged in sports related undertakings and related researchers in the industry. The team conducted a longitudinal assessment of the relationship between lacquer joint use and knee arthritis in a multi occupational population. The occupational status and knee osteoarthritis were evaluated by weight-bearing arthrography over 40 years old. The working characteristics of the subjects were their

physiological needs and their relationship with knee flexion. 43.4% : 26.8% of men who engaged in flexion and had at least moderate physiological needs a higher risk of knee osteoarthritis than those who did not participate in both activities. These results suggest that for men, the combination of knee flexion and physiological needs may be the main cause of knee arthritis [18].

2.5. Exercise Rehabilitation for Knee Arthritis.
Exercise therapy to prevent and treat knee arthritis is mainly to increase the muscle training around the knee joint. By exercising the muscle strength of the affected limb joint, it can prevent and control muscle weakness and muscle atrophy. Strengthening muscle strength can increase the stability of the joint, protect the joint, and prevent the development of osteoarthritis. The commonly used muscle strength training methods include isometric and isokinetic training [19]. The main exercise of this paper is hip flexion.

The main methods of exercise rehabilitation in the treatment of knee arthritis are hip four position exercise, clam type exercise, and sitting hip joint flexion exercise. Hip joint four exercises are mainly to exercise the flexors, extensors, adductors, and abductors of the hip joint. Clamshell exercise, the project for the gluteal muscle, thigh lateral muscle, tensor fascia lata, and knee joint muscle exercise. Although hip flexion exercise in sitting position is named after hip flexion and extension, strengthening hip flexor muscle is very important for knee joint strength. When these muscles are strong and work properly, the knees also become strong.

2.6. Nanotube Combined with Exercise Rehabilitation in the Treatment of Knee Arthritis.
Nanotube combined with exercise rehabilitation therapy refers to the treatment of nanodrug at the same time of exercise rehabilitation treatment for knee joint patients. The nanotube drugs selected in this paper are polypeptide nanoselenium and functionalized nanoruthenium drugs. Nano drugs have unique properties, such as active or passive targeting at the injured site, improving the high efficiency of drug loading, intelligent drug release, and long-term kinetics. Secondly, peptide nanoselenium can improve the growth and reproductive performance of animals, improve the metabolic capacity of the body, and has a very good effect on the treatment of knee arthritis. Generally speaking, the greater the surface lipophilicity of nanoparticles, the stronger the binding force with regulatory proteins. Therefore, it is necessary to increase the hydrophilicity of nanoparticles in vivo. This is an important purpose to select the surface modification materials of nanoparticles. At the same time, the physical properties of nanoparticles can be modified to obtain new functions. Exercise rehabilitation therapy has a good effect in the treatment of knee arthritis. The combination of nanodrug therapy and national sports rehabilitation treatment, taking internal and external exercise, will have better treatment effect in patients with knee joint.

2.7. Prevention and Treatment of Knee Arthritis.
Prevention and treatment of knee arthritis should pay attention to keep warm, avoid wearing high-heeled shoes for a long time, pay attention to body posture when walking, and often participate in outdoor activities. When the temperature drops in winter, the knee joint is cold, the blood vessels contract, and the blood circulation is not smooth, which often makes the joint stiff and painful. Therefore, keep warm in cold weather, and if necessary, wear knee protection to prevent the knee from being cold. High heeled shoes change the curve of lower limb strength. In order to reduce the impact on the knee joint and avoid the impact and wear of knee joint cartilage, the elderly should choose thick shoes with soft and elastic soles in their daily activities. Pay attention to your posture when you walk. Do not bend down when you work. Do not bend your legs when you walk. Avoid squatting for a long time. Do not keep an action for a long time. Always change your posture. For example, after a period of practice, you can develop a good habit, for example, after standing every day, stretch your legs, tie horse steps, and develop a good habit of protecting your legs. Finally, we should often participate in outdoor activities. Before doing Yanko dance and Taijiquan, we should make full preparations. We should gently extend the knee to increase the flexibility and flexibility of the lower limbs. After the activity, exercise the knee. When practicing Taijiquan, the range of action should not be too large, and the squatting posture should not be too low, so as to avoid damage to the knee joint caused by weight-bearing.

3. Experimental Analysis and Methods

3.1. Experimental Objects and Standards.
The study time selected in this article is from June 2016 to June 2020. The relevant data of 100 patients with knee arthritis admitted to this hospital during this period were analyzed. All patients were divided into two groups according to the difference in treatment plan: the experimental group and the control group. The patients in the experimental group were treated with nanotubes combined with ethnic sports rehabilitation therapy, and the patients in the control group only received ethnic sports rehabilitation therapy. There is a total of 50 patients in the experimental group and 50 patients in the control group. The experiment lasted for one month. After the experiment, the rehabilitation of knee joint patients was compared according to the results of the experiment.

3.2. Rehabilitation Treatment of National Sports.
Before treatment, X-ray was used to make detailed diagnosis on the pain site of patients and to understand the tissue around the knee joint. The control group was treated with national sports rehabilitation during the period of knee arthritis. The rehabilitation treatment of national sports included three kinds of movements, and the patients in the control group did it twice a day. The three groups of movements include four hip exercises, clamshell exercises, and hip flexion exercises in sitting position. After the three movements, Taijiquan exercise is conducted for 30 minutes every day.

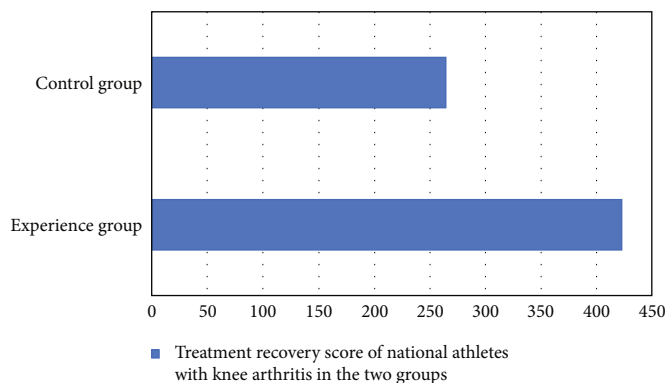
Hip four exercises include abduction, adduction, flexion, and extension. When doing abduction exercise, the upper body should be straight, the right leg should be lifted outward, and then, the left leg should be changed to do 4


FIGURE 1: Treatment recovery score of national athletes with knee arthritis in the two groups.

groups, 8 in each group. In each group, do the right leg extension in 8 directions. When doing the forward bending training, the right leg should be extended forward, and then, the left leg should be changed. There are 4 groups of 8 in each group. When doing the back-extension training, the right leg should be extended backward, and then, the left leg should be changed to do 4 groups with 8 in each group. When doing this exercise, it is required to find a chair as an aid to avoid falling down accidentally; keep the upper body upright during the whole process; do not follow the lower limb to tilt the upper body; the whole process of ankle joint extension as far as possible, that is, bend to the knee joint direction (hook foot) as far as possible.

Clamshell exercise: lie on the ground on one side with the head rest on one arm. The pelvis should always be vertical to the ground. When the legs are opened, the pelvis should not fall back at the same time. During the movement, pay attention to the leg, keep the shoulder, hip, and ankle joints in a straight line. Bend the hip 45 degrees and bend the knee about 90 degrees. Put the left foot directly on the right foot and exert force on the left leg to make the knee slowly away from the body. Then, slowly return to the starting action, once done on both sides; do two groups, you can also use the cello belt to increase the intensity of exercise.

Hip flexion exercise in sitting position: patients are required to sit on a chair and lift their knees vertically. During the exercise, the upper body of the seat is required to keep straight. Each group has 8 legs and 4 groups.

Taijiquan training: two times a day to practice all the movements of Taijiquan, estimated to take 30 minutes.

In the process of exercise, it is appropriate to feel pain. With the improvement of the condition, the angle of flexion of knee joint should be gradually expanded. But do not excessively pursue the angle, causing the secondary damage.

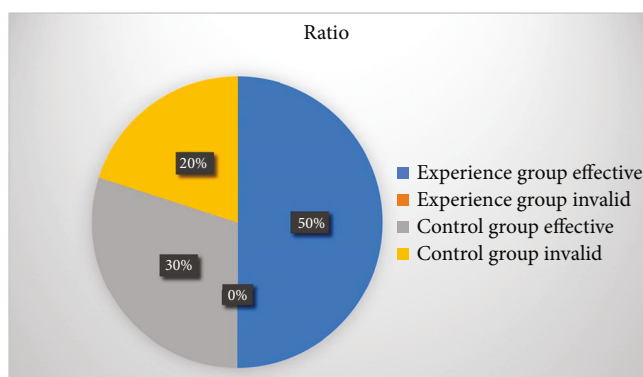
3.3. Nanotube Combined with Sports Rehabilitation Therapy.
The experimental group was treated with nanotubes combined with sports rehabilitation therapy. The method was as follows: Before treatment, X-rays were used to make detailed diagnosis of the painful part of the patient and to understand the tissues around the knee joint of the patient. On the basis of ethnic sports rehabilitation therapy in the control group, the research group took a 30 mm × 40 mm


FIGURE 2: The rate of effective treatment in both groups.

square cloth to make a traditional Chinese medicine package. There are manual methods and automatic machine methods for the production methods of traditional Chinese medicine bags, including weighing and wrapping. The traditional Chinese medicine package contained peptide nanoselenium and functionalized nanoruthenium drugs, Heding, Liangqiu, massage the acupoints of Zusanli, Dubi, Yanglingquan, and Yinlingquan before applying plaster. Polypeptide nanoselenium and functionalized nanoruthenium drugs can deliver drugs to the inflammation of the knee joint. Chinese herbal medicines such as Heding, Liangqiu, and Blood Sea have very good effects on the treatment of knee arthritis. Then, apply the Chinese medicine pack to the knee joint. This step is implemented for three consecutive treatment courses, each treatment course includes 10 days, and this step is once every two days. At the same time, the patient's health exercise was strengthened during the treatment, and the exercise content was the same as the control group.

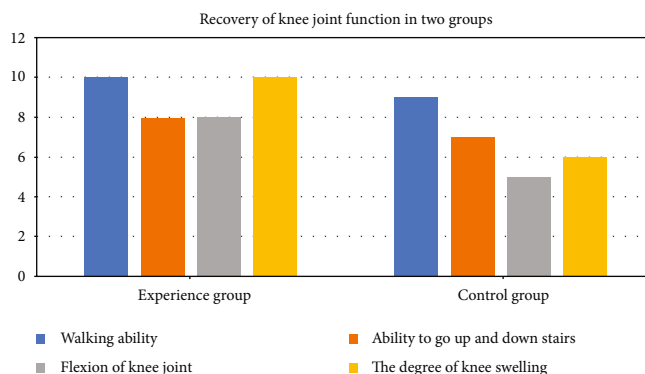
3.4. Observation Indicators for Treatment of Knee Arthritis.
To observe the clinical efficacy of patients suffering from knee arthritis in the experimental group and the control group, the effect of knee arthritis recovery is mainly carried out from the following three aspects. First, the degree of pain: The visual analogue scoring system is used to assess pain severity on a scale of 0-10 points, with 7-10 points indicating no discomfort, 4-6 points indicating mild pain, 1-3 points indicating moderate pain, and 0 indicating severe


Figure 3: Recovery of knee joint function in two groups.

pain. After that, the average score of the two groups was statistically evaluated, and the average score of the effect of knee arthritis recovery of the two patient groups was calculated. Second, the efficacy evaluation criteria are as follows: effective: After treatment, the patient's clinical symptoms have improved; ineffective: after treatment, the patient's clinical symptoms did not improve; and (3) the patient's knee joint function recovery. The knee joint function score scale was used to evaluate the knee joint function of patients. The evaluation items of the score sheet include walking ability, ability to go up and down, knee flexion, knee swelling, etc. The total score for each evaluation is 10 points.

The clinical curative effect is based on the relevant diagnosis and treatment standards for osteoarthritis: knee joint stiffness and pain disappear, no friction sound during joint movement, and the effect is obvious after the movement function returns to normal; knee joint pain is reduced during movement, effectively improving the friction performance.

3.5. Statistical Methods. SPSS22.0 statistical software was used to examine the experimental data. Taking the sum of the scores of the treatment effects of knee arthritis as the standard, calculate the recovery scores of patients suffering from knee arthritis in the experimental group and the control group and the percentage of knee arthritis patients considered to be effective or ineffective in this group, which constitutes. The ratio is expressed as a percentage, and the effect of patient treatment is compared according to the number. The number of patients is counted as n, and the average count is expressed as x.

4. Experimental Results and Analysis

The data for this study comes from 100 individuals with knee arthritis who were examined at our institution between June 2016 and June 2020. Among them, there are 50 patients in each group. First of all, the effect of the recovery of knee arthritis patients. The pain scores and observe the scores of the two groups were compared.

It can be observed from the statistics in Figure 1 that the 50 patients with knee arthritis in the experimental group received a score of 467 in the treatment of nanotube combined with ethnic sports rehabilitation, and the 50 patients in the control group with arthritis The patient's score in

the rehabilitation of ethnic sports is 265 points. Among the 50 people in the experimental group, 50 of them all had a painless range for the treatment of nanotube combined with ethnic sports rehabilitation. Two of them scored 7 points, 9 people scored 8 points, and 9 individuals scored 9 points and 30 people scored 10 points for a total of 467 points. The 50 patients in the control group scored 265 points, of which 8 people scored 2 points, 12 people scored 5 points, 25 people scored 6 points, 3 people scored 7 points, and 2 people scored 9 points. In the control group, 5 people felt no pain, 37 people felt some pain, and 8 people felt severe pain. The data in this section shows that the treatment of nanotubes combined with Chinese medicine packs has a very good effect on the treatment of knee arthritis. This is because nanomedicine can deliver the medicine to the inflamed part of the knee joint, which can more effectively treat knee arthritis.

Figure 2 shows the data from the control group on the left, and the primary sentence from the experimental group on the right. The experimental group, which accounts for 100% of the total number of participants in this group, feels that the combination of nanomedicine and ethnic sports rehabilitation treatment is successful, as shown by the statistics in Figure 2. Thirty respondents in the control group felt ethnic sports therapy was successful, accounting for 60%, and 20 people thought that ethnic sports therapy was ineffective, accounting for 40%.

The total scores of the knee joint patients in the experimental group who received nanomedicine therapy in combination with national sports rehabilitation were better than those in the control group, as shown in Figure 3. In the experimental group, 50 people were judged on walking ability. The average score given is 10 points, the average score given for the ability to go up and down is 8 points, the average score given by 50 people is 8 points for knee flexion, and 50 for knee swelling. The average score given by a person is 10 points. It shows that after a month of treatment, the recovery ability of knee arthritis patients is the best in terms of walking and knee swelling. This also shows that the pressure on the knee joint during walking is relatively small. At the same time, the ability to go up and down and the flexion of the knee joint is not particularly good in most people. The main reason is that the flexion of the up and down, and the knee joint requires higher knee joints. On the contrary, in

FIGURE 4: Scores in both groups during the experiment.

the control group, among the 50 people who only received ethnic sports rehabilitation, the average walking ability score was 9 points, the knee flexion degree was 50, and the average walking ability score was 7 points. People's average score is 5 points. In terms of knee swelling, 50 people's average score is 6 points. The data in the control group also showed that the ability of knee arthritis patients to recover is the ability to walk first, and the most difficult thing to recover is the flexion of the knee joint.

It can be seen from the data in Figure 4 that with the increase of the experimental time, the two schemes are effective, but the patients in the experimental group using nanotubes combined with ethnic sports rehabilitation therapy are significantly better than those in the ethnic sports therapy alone. The patients in the control group gave a higher average score, and the highest score for this stage was ten. When the experiment only lasted for 5 days, the patients in the control group scored an average of 3 points, and on the last day, they scored an average of 6.9 points. In the experimental group, on the fifth day of the experiment, the patients scored an average score of 5 points, and the patients scored an average score of 9.7 points on the last day. This experiment shows that nanotubes combined with national sports can speed up the treatment of patients with knee arthritis and improve the quality of life of patients with knee arthritis.

5. Conclusions

The incidence of knee arthritis in our country has been increasing among middle-aged and elderly people, especially our country is now entering the stage of aging population, so the treatment of knee arthritis is a matter of great importance. Knee arthritis refers to an inflammatory disease that occurs in the knee joint and surrounding tissues. This article mainly uses ethnic sports rehabilitation therapy combined with nanomedicine to have a better therapeutic effect on knee osteoarthritis. The experimental results show that the total effective rate of nanotubes combined with ethnic sports rehabilitation therapy in the experimental group is 100%, and the control group believes that only ethnic sports rehabilitation therapy accounts for 60%. The experimental group is significantly higher than the control group. After treatment, the walking ability, knee flexion score, and knee swell-

ing scores of the experimental group were higher than those of the control group. During the experiment, the scores of the experimental group were also higher than those of the control group, indicating that nanotubes combined with national sports rehabilitation Treatment can speed up the treatment time of patients with knee arthritis and improve the quality of life of patients with knee arthritis. In summary, the combination of nanotubes and ethnic sports rehabilitation therapy has a significant effect on knee osteoarthritis. This method can be used for reference in clinical applications.

Retraction

Retracted: Electrospinning of Nanofiber-Based Materials and Application of the Technology to Lower Extremity Joint Exercise Rehabilitation

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

This study mainly explores the electrospinning of nanofiber-based materials and the application of the technology to lower extremity joint exercise rehabilitation. In response to people's concerns, this study mainly discusses electrospinning technology from the aspects of the safety of nanomaterials prepared by electrospinning technology and the application of nanomaterials prepared by electrospinning technology in lower limb joints. In the safety study of nanomaterials, six groups of experiments were set up to measure the joints of nanomaterials prepared by electrospinning technology under pressures of 500 N, 510 N, 520 N, 530 N, 540 N, and 550 N. For compression resistance, when the pressure is 540 N, the compressive performance of the nanomaterial is preferably 96%. In terms of the application of nanomaterials, 100 patients with lower extremity sprains in the Affiliated Hospital of Sun Yat-sen University were divided into 5 groups and then divided into 6 groups. Patient recovery rate when the device is applied to the patient's lower extremity joint. Patients had the best recovery rate of 92% when the immobilization device was used for 6 days. The use of arthrodesis did not affect the patient's other factors. The experimental results show that when the pressure is 540 N and the fixation device is used for 6 days, the nanofiber material prepared by electrospinning technology has the best rehabilitation effect on lower limb joint movement.

1. Introduction

1.1. Background and Significance. Traditional nanofibrous materials are seriously impractical due to their increasing pressure and corrosion resistance. Whether in the field of biology or construction, people are eager to find a technology to improve nanomaterials, so that the safety performance and corrosion resistance of nanomaterials can be improved to a higher level. With the continuous research of relevant experts, the preparation of nanofiber materials based on electrospinning technology is proposed.

Electrospinning technology is widely used in many fields, and the application of nanomaterials can improve various properties of nanomaterials. Nanomaterials are highly concerned by the medical community as an auxiliary rehabilitation material. The application of electrospinning tech-

nology to the preparation of nanomaterials can not only increase the yield of nanomaterials but also improve various properties of nanomaterials. Improvements in equipment have helped a lot [1].

1.2. Related Work. In Trejo et al.'s research, nylon 6 nm Monburon cloth and silk yarn and stylish fabrics of Eugansa were combined to construct a complete flying object. This work is the first demonstration that laser cutting and ultrasonic technology are used to process electrospun nanofabrics. The morphology and mechanical properties of the composite cloth are analyzed [2]. Although this study did an experimental comparison, it did not divide in terms of detailed parameters. Cianci et al. believe that epoxy resin (LX) A 4 is a metabolite of aladinic acid (arachidonic acid) produced by epoxy kinase. Its therapeutic effect is fully

standardized on various models of cells, preclinical and clinical. Among them, LXA 4 promotes tissue repair of periodontal disease and can also regulate the function of human periodontal ligament stem cells (hPDLSC) [3]. The clinical treatment effect of LXA 4 is obvious, but the study did not discuss it in depth. Jiang et al. believe that nanofibers, as the main component of one-dimensional nanomaterials, have many uses. Electrospinning is a convenient and effective method for constructing nanofibers. However, in the conventional preparation method, since only unoriented nanofibers can be obtained, its applicability is greatly hindered. In recent decades, a lot of effort has been devoted to optimizing preparation methods. By improving the spinning structure, extraction, and separation of nanofibers, successfully aligned nanofibers (ANF) have been successfully obtained. Due to insufficient system evaluation of ANF, their research will outline the application of ANF in electronic spinning-based preparation, tissue engineering regeneration, sensors, reinforcement materials, sensors, and energy machines. ANF's extensive application in tissue engineering regeneration provides a detailed explanation on this point. In the energy sector, ANF will focus on PEM fuel cells. Finally, we summarize the issues and prospects of ANF development [4]. The research only raised many conceptual questions, and specific experiments need to be further explored. Su et al. prepared multilayered TiO2 nanofibers (TiO2-NF) and nanoparticles (TiO2-NP) by template support method and single solvothermal method, respectively. The decomposition of methylene blue (MB) was used as a reaction model to evaluate the photocatalytic properties of these prepared materials. It is important that TiO2-NF prepared by template-assisted solvent heating has a multilayer structure [5]. The study confirmed that TiO2-NF can improve the photocatalytic rate but did not specifically determine the catalytic effect.

1.3. Innovation and Related Content. The main purpose of this study is to discuss the safety of the nanofiber material prepared by electrospinning technology and the application of the nanomaterial prepared by electrospinning technology in the joints of lower extremities. The joint fixation device uses the recovery of the patient's lower extremity joint to evaluate the nanofiber material prepared by electrospinning technology. The main contents are as follows:

(1) Discuss the development of electrospinning technology from the perspective of domestic and foreign research. In-depth analysis of the preparation of nanomaterials by electrospinning technology was used to find out the beneficial inspiration for this research

(2) Conduct an in-depth discussion on electrospinning technology to find out the best method for preparing nanomaterials and related formulas that may be used. The preliminary discussion on the preparation method of nanomaterials is helpful for further research of the experiment

(3) Control the variables related to the experiment when conducting the experiment. The experiment of elec-trospinning technology actually involves the experiment of the solidity of the nanomaterials and deeply grasps the experimental concept to discuss the characteristics and applications of the nanomaterials in the experimental process

(4) The analysis of data after the experiment is based on tables and figures. Through the relevant software, the experiment is processed to draw the best solution and the most practical nanotechnology

2. Electrospinning Technology

2.1. Optimization of Electrospinning Technology. The structure of the mixed nanofiber membrane prepared by electrospinning technology is not outstanding in quality. In water, the reacted nanofiber membrane will partially dissolve and shrink significantly. Moreover, the mechanical properties of the fiber membrane are insufficient and need to be further strengthened, so it is necessary to link the polyvinyl alcohol/chitosan electrospun nanofiber membrane. The fiber membrane is treated with alcohol solution or alcohol vapor. The degree of expansion and shrinkage of the fiber membrane treated with alcohol is reduced, the strength characteristics, quality characteristics, covalent bond expansion, and shrinkage of the nanofiber membrane are improved, and the toughness of the sample is greatly improved, thereby achieving the purpose of cross-linking [6, 7]. At the same time, it is necessary to pay attention to the different conditions of patients in the application of nanomaterials in lower limb joints, so it is necessary to conduct a careful examination of patients before using nanomaterials for rehabilitation treatment [8].

In the field of nanobatteries, due to its excellent conductive properties, it is a widely used carbon material in the research of lithium-sulfur batteries, which can greatly improve the conductivity of battery anode materials. The carbon-silicon composite material can not only improve the conductivity of the active sulfur of the positive electrode but also effectively inhibit the diffusion of polyurethane to the negative electrode through physical adsorption and ease the volume expansion of the positive electrode. It is an electrode material in the working process of the battery. And sometimes, there is research in the field of machinery. This can improve battery performance, but the capacity is small and the decay is fast. Then, sulfur is coated with a carbon material, and the carbon material is used as a conductive skeleton to realize electron transmission. After the porous carbon fiber is prepared by the electrospinning method, the pores of the carbon fiber are filled with sulfur by the liquid-phase deposition method, which is the best preparation method for the battery. When the current density is $6^\circ C$, the initial specific capacity of the battery increases by 800 milliamperes per gram [1, 9, 10]. Liquid-phase deposition belongs to liquid-phase epitaxy technology of the semiconductor growth process.

2.2. Application of Electrospinning Technology in Nanofiber Materials. In the field of nanocatalyst materials, nanometals are an excellent catalyst, combining nanomaterial carriers with

nanocopper and composite catalysts, substitutes for precious metal catalysts such as platinum and gold, many organic reactions have better catalyst characteristics, and high capacitor electrodes. The material and copper oxide have good electrochemical properties. To this end, researchers have been developing nanocomposites with various morphologies, sizes, and characteristics to meet the various applications and needs of today's society. Nanometal is an excellent high-temperature material. The traditional preparation method is mainly based on wet spinning, and the fibers can be obtained in the micron level. At present, there is little research on the preparation of nanometal nanofibers by electrospinning technology. Nanometal can be prepared by electrospinning technology. Nanofibers have good metal tensile properties, so the performance of nanometallic materials can be optimized [11]. By changing the environment of the textile fluid with electric current, the nanoparticles can adapt to the environment in the textile fluid.

The angle of the PAN nanofiber test sample and the droplet formation is one hundred degrees, the material surface has almost no hydrophilic groups, and the hydrophilicity is poor. The average static contact angle of AOPAN nanofibers was reduced to 80 degrees after treatment of PAN nanofibers with amino modification technology. Therefore, a certain number of hydrophilic groups are added to the surface of AOPAN nanofibers modified by amino acids to improve the hydrophilicity. With the further change of ATRP technology of AOPEN nanofibers, the average static contact angle of polymerized nanofibers is reduced to 50 degrees, which can further improve the hydrophilicity of nanofibers. This is because a large number of groups are introduced on the surface of the transplanted nanofibers. In promoting the improvement of hydrophilicity, the carboxyl group plays a very good role, and the hydrophilicity is greatly improved [12]. Electrospinning technology is used to prepare nanometal materials in water, and the manufacturing process of nanometal materials is clearly displayed.

2.3. Research Methods of Nanomaterials by Electrospinning Technology

(1) Polymer research method. During the preparation of the textile solution, the nanomaterials are introduced into the fiber-forming polymer matrix, and then, spinning is performed. This method has a certain influence on the process of electronic spinning; nanoparticles become very easy to aggregate. Therefore, the difficulty of this technology is how to improve the adaptability between nanoparticles and textile liquor. The surface of the nanoparticles can be modified, and the ligand can be rotated in the liquid phase. However, the application of nanosurface modification technology is limited due to its complicated process, and may not be suitable for most nanoparticles and textile solutions [13, 14]. Controlled release of drugs can not only be used in the field of biomedicine, wound repair, biological tissue engineering, and other aspects of the fiber filter material in the gas filtration liquid filtration and personal protection and other fields but also can be applied to the shell of ships, the inner wall of oil pipelines, high-rise glass, automobile glass, and so on [15]

(2) Medical research method. Nanomaterials in medical research, first of all, the comparison of the lower limb pretreatment of sEMG and the wavelet transform-based filtering method in the traditional filtering method, are more effective than the wavelet transform method for noise removal processing of signal filtering. Next, using the three types of time-domain feature value changes, the action at the start of sEMG is determined. Next, the eigenvectors of the lower limb sEMG are studied, and finally, the eigenvalues of the time domain and the frequency domain are extracted. The neural network is trained by using the characteristic values of the time domain and frequency domain features and their joint features as the input of the neural network, where the BP neural network classifier classifies the two operation modes of lower limb bending and design will expand the application range [16, 17]

(3) Carbonization treatment method. During the carbonization process, since the graphite ring structure is formed after dehydrogenation, the PAN will not collapse during the carbonization process. The fiber membrane shrinks during the preoxidation process. Therefore, in order to ensure the specific structure of the fiber, during the preoxidation process, a specific mass object can be used to extend the film in the vertical direction to maintain the fiber state. Clamping the nanofiber bundles at both ends of the jar and placing them in a tubular furnace can produce a fixing material with its own high temperature resistance. In order to prepare the aluminum foil for direct oxidation, the orientation structure of the fiber can be maintained during the preliminary oxidation according to the adsorption force between the fiber film and the aluminum foil. In the preoxidation process, the fiber bundle is covered with glass, and the binding force of glass gravity on the fiber bundle maintains the structure of the fiber bundle [18–20]

(4) Electrostatic treatment method. Generally speaking, it includes the following steps. First, the precursor containing the target material and the organic polymer are mixed, and an organic solvent is added to form a viscous yarn solution. Then, the solution is injected into the high-voltage electrospinning yarn with a specific voltage for spinning and collection. The general electronic spinning system is mainly composed of three parts: high-voltage electrostatic electric field power supply, spinning port discharged from nanofibers, and ground plate. The high-voltage power supply is generally a DC power supply, and the voltage range of the AC power supply is generally sixty volts. The output end is connected to the spinning port, and the other end is grounded. The spinning port is usually a metal needle with a specific

diameter, and the diameter of the spinning port affects the diameter of the nanofiber. The solution is usually discharged directly into the cylinder by gravity, and there is also a peristaltic pump connection for controlling the uniform flow of droplets. The power receiving plate for the metal plate usually uses a ground wire to make the potential of the power receiving plate zero. Therefore, the electrospinning of the output voltage of the high-voltage power supply is the spindle voltage. Another type of device, connecting the attraction device to the receiving board, can not only expand the electric field strength but also reduce the output voltage of the high-voltage power supply [21]

(5) Sprinkler method based on nanomaterials. Three hundred times higher than single nozzle electrospinning efficiency. Multinozzle devices can improve production efficiency but can also cause other problems. For example, during the electrospinning process, since the sprinkler heads are charged, if multiple sprinkler heads are used, an electrostatic repulsive force will be generated between different sprinkler heads, affecting the formation of the jet. Therefore, multiple sprinkler devices of different layouts are designed to reduce mutual repulsion between sprinkler heads. The six needle ring configuration device can not only obtain a stable jet aircraft but also avoid the interference of environmental factors such as air flow. Under the premise of ensuring fiber quality, we improve the production efficiency of fibers and contribute to promoting the mass production and practical application of electric field spinning fibers

2.4. Formulas Used in the Preparation of Nanofiber Materials. In the preparation of nanomaterials by electrospinning technology, it is necessary to conduct a comprehensive study of nanomaterials through performance and actual application. At this time, relevant formulas will be used to explain them.

(1) In the signal recognition of human body, the information transmission function of nanomaterials plays a huge role. The relevant formula is as follows:

$$m_k(t) = \sum_{i=1}^{N} u_k(t) \times \delta(t - \tau_1) \times p_k(t) \times g_{ki}(t) \times M \tag{1}$$

In information transmission, usually the signal transmission requires a certain process, and the transmission time will also be affected by related factors. When using nanomaterials for human body information collection, the time factor and the temperature factor of the nanomaterials need to be considered. The longer the time, the more sensitive the reaction of the nanomaterials, because the nanomaterials

need time to continuously activate during the information transmission.

(2) When processing the collected information with special equipment, the information needs to be processed first. The relevant formula is as follows:

$$u_p(t) = \sum_{k=1}^{M} [u_k(t) \times l_k(t)] = \sum_{k=1}^{M} \left[\sum_{i=1}^{M} \delta(t_k - t_{ki}) \right] (t_k + t_i) \tag{2}$$

The processing of information is carried out in segments, each segment needs to be refined, and then, the image description of the information. The entire process is carried out in a complete processor, which can be directly filtered from the table when data extraction is performed.

(3) In the conduction information of nanomaterials, the conduction distance and the average power of conduction are very important. The relevant formula is as follows:

$$vS_{1(\omega)} = S_y(w)(1 - \cos \omega\Delta) = 4S_y(w) \sin^2\left(\frac{\omega\Delta}{2}\right) \tag{3}$$

When the conducted power is constant, the larger the cosine value of the conduction process, the lower the conduction rate of the nanomaterial. The greater the sinusoidal value during conduction, the greater the rate of conduction. In most medical devices, the rate of change in the rate of nanomaterial conduction will be focused on. For the nanomaterials with larger conduction rate, they will be used first.

(4) The stress performance of nanomaterials reflects the bearing capacity of nanomaterials to a certain extent, and the related formula is expressed as follows:

$$\sigma_m^2 = \frac{1}{2\pi} \int_{-\infty}^{+\infty} S_m(\omega) d_\omega = \frac{1}{2\pi} \int_{-\infty}^{+\infty} |H(\omega)|^2 S_m(\omega) d_\omega \tag{4}$$

$$\sigma_y^2(t) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} S_y(t, \omega) d_\omega = \sigma_m^2 c^2(t) \tag{5}$$

The value of the stress change can directly reflect the quality of the nanomaterial. In general, the stress value of nanomaterials with large specific surface area will also increase; of course, this is to exclude the specific surface area under the environment not affected by temperature. Nanomaterials are highly durable materials, and their corresponding stress coefficients will directly determine the lifetime of nanomaterials.

3. Electrospinning Technology Experiment

3.1. Experimental Equipment. The relevant experimental data needs to be measured before the experiment. The relevant equipment used before the experiment is shown in Table 1. The function of the assembling machine is to systematically assemble the joint fixing device of nanomaterial synthesis during the experiment, which avoids certain errors caused by the experiment in the process of manual assembly. The function of the frequency analyzer is to control the transmission rate and transmission time of the signal during the experiment. The data analyzer is designed to comprehensively collect the data that appears during information processing to prevent the omission of information during the experiment. In addition to controlling the external environment, we also need to control the internal environment reasonably in order to get more accurate results [22]. The data analyzer is controlled by the computer throughout the use. The role of the pressure sensor is equivalent to further data mining of the experiment through the data returned by the pressure sensor when applying pressure to the fixture. The function of the optical instrument is to observe the rehabilitation state of the patient at any time without changing the fixed instrument during the experiment.

3.2. Control of Experiment-Related Factors. We pay attention to controlling related factors during the experiment. When conducting safety experiments, the measurement of the joint fixture must be performed in a safe environment. Each time a measurement is taken, relevant data records are required. The value of pressure is within a reasonable range. During the experiment of the application of the joint fixation device, the joint fixation device needs to be polished to prevent the patient from being scratched during the experiment. During the experiment, the patients had the same degree of sprains, and the patients had the same sprained parts.

3.3. Experimental Process. In the study of the safety of nanomaterials, six groups of experiments were set up to measure the joints of nanomaterials prepared by electrospinning technology under the pressure of 500 N, 510 N, 520 N, 530 N, 540 N, and 550 N and compression resistance.

In terms of application of nanomaterials, 100 patients with sprains of lower extremities who were admitted to the

Group 6	18	25	28	40	38	48

Affiliated Hospital of Sun Yat-sen University were divided into 5 groups, and each group of experimenters was divided into 20 people. A total of 6 groups of days at 1 d, 2 d, 3 d, 4 d, 5 d, and 6 d were used to observe the recovery rate of the patients when the nanomaterial fixation device prepared by electrospinning technology was applied to the patients' lower limb joints.

4. Analysis of Electrospinning Technology

4.1. Summary of Experimental Data. The compressive performance of the nanomaterial joint fixation device when studying different pressures is shown in Table 2.

The performance of nanomaterials is usually determined by the molecular structure of nanomaterials. In general, the
FIGURE 1: Safety performance of lower limb joint fixation device under different pressures.

structural stability of carbon is higher than other similar elements. In the field of nanomaterials, carbon element is the dominant factor. It can be seen from the data in the table that, to a certain extent, the compression performance of the nanomaterial joint fixation device gradually changes with the change of the pressure value. When the pressure value reaches a point, the compression rate of the nanomaterial reaches the highest. Then, it showed a downward trend.

In terms of the application of nanomaterials, the rehabilitation situation of patients with sprained lower extremities at different days is shown in Table 3.

In the process of sports rehabilitation, as the number of days continues to change, the patient's recovery gradually improves, and one of the inevitable factors is the patient's own self-healing. However, because the recovery situation of the patients in the table improved more quickly and was significantly higher than normal, the lower limb joint fixation device played an important role in this. And as time goes by, the recovery rate of patients gradually rises and tends to a stable state.

4.2. Experimental Data Analysis. The safety performance of the lower limb joint fixation device under different pressures is shown in Figure 1. In the figure, when the pressure is 500 N, the safety performance of the 6 sets of data is at the lowest state. The measurement time during the experiment was carried out on the same day to avoid different measurement results caused by different time. Through comparison, it is found that the safety performance also increases when the pressure value gradually increases, but when the pressure value reaches a certain range, it will reach a critical value. As the pressure continues to increase, the entire fixing device is in a state of being easily broken. If this limit is exceeded, the safety performance will be affected. The nanomaterials after applying pressure are no longer suitable for the fixation of the patient's lower limbs.

As the pressure changes, the safety rate of the lower limb joint fixation device is shown in Figure 2. The concept of pressure change is quoted in the figure. The value 1 represents 500 and the value 2 represents 510. When the pressure is 540 N, the compressive performance of the nanomaterials is preferably 96%. When the pressure is 500 N, the maximum value of the measured safety performance is 50%.
FIGURE 2: With changes in pressure, the safety rate of the lower extremity joint fixation device.

The safety performance of the nanomaterial itself has not changed, and the value measured during the experiment represents the actual safety rate under a certain pressure. With the constant change of the pressure value, the highest position is reached when the pressure is 540 N, that is, the safety of the lower limb joint fixing device at this time is the best. Within a certain range, the force sustained by nanomaterials is directly related to safety performance.

With the gradual change of the number of days, the patient's recovery is shown in Figure 3. At a certain number of days, the overall recovery of group 6 is relatively low. Most of the reasons for this situation are due to the different circumstances of the patients, but the overall recovery shows an upward trend with time. Therefore, the specimens collected during the experiment meet the experimental requirements. The recovery effect of the patients in group 4 was lower than that in group 1 on the first day, but after the use of the lower extremity joint fixation device, the patients showed that the recovery situation surpassed that of group 1. It shows that the joint fixation device with nanomaterial as the main power shows a good trend in the use of patients.

The corresponding change of the patient's recovery rate with time is shown in Figure 4. When the fixed device was used for 6 days, the recovery rate of the patient was the best, at 92%. Among them, the fixing device is equivalent to auxiliary treatment to prevent the patient from being injured
FIGURE 3: As the number of days gradually changes, the patient's recovery.
FIGURE 4: Corresponding changes in the recovery rate of patients over time.

again. The recovery rate of the patients in group 1 is generally low, but when the time changes, the recovery rate shows a rising state. The recovery rate of the patients in group 6 is higher at a certain number of days. In this case, it is more suitable for the rehabilitation of patients. The data in the figure also tends to the sixth group. The recovery level of the patients in group 2, group 2, and group 3 is lower than the recovery rate of normal patients, indicating that the patients in these three situations have poor recovery treatment effects.

5. Conclusion

Starting from the background at home and abroad, this research deeply explores the preparation of electrospun nanofiber materials and its application in the rehabilitation of lower extremity joints, and a series of experiments have made breakthroughs, confirming the safety and reliability of nanomaterials. Rehabilitation treatment effect is good. Open up new ideas for further research on nanomaterials.

As a high-strength material with broad development prospects, nanomaterials have made outstanding contributions in the fields of construction, medicine, aviation, and so on. Especially in recent years, the country has paid attention to and supported high-tech and high-information materials, and nanomaterials have become more and more widely used as a landmark application for many polymer materials.

This study explores the strength of nanomaterials from the safety performance of nanomaterials and explores the effect of nanomaterials on the recovery rate of nanomaterials in medicine from the application of nanomaterials. We analyze the practical properties of nanomaterials from different angles. In a certain pressure range and a certain time, the use of nanomaterials is the best. This study has a very important value for the discussion of nanomaterials.

With the rapid development of information science today, the Internet of Things technology is gradually being applied to all walks of life, and the multifunction and intelligentization of instruments have gradually become the focus of people's attention. In recent years, domestic track and field sports have developed to a certain extent, but at the same time, it must also be noted that there are still some difficulties and problems in the development of domestic track and field sports. This article was aimed at studying the application of the rehabilitation training and prevention of athletes' hind thigh muscle group injury based on the intelligent data of the Internet of Things and puts forward the idea of using the intelligent data of the Internet of Things to better use in sports rehabilitation and prevention. This article describes in detail track and field training, athletes' hindquarters muscle injury, and so on. The application experiment of rehabilitation training and prevention of athlete's hind thigh muscle group injury based on the intelligent data of the Internet of Things has been made. The experimental results show that the rehabilitation training and prevention program of athletes' hind thigh muscle injury based on the intelligent data of the Internet of Things can effectively reduce the athlete's muscle injury during training, and it is more than 10% higher than the traditional prevention program. It can effectively improve the bad and wrong movement patterns of athletes, improve their own stability, flexibility, and balance, optimize the transmission of the body's power chain, and improve the athletes' ability to perform competitively.

1. Introduction

Track and field training in physical education institutions is an important part of track and field training in China [1]. Sports school track and field training has provided a large number of excellent talents for the national track and field team, and some athletes have achieved excellent results in the world competition [2]. But for a long time, sports injury has been one of the important factors restricting the health and sustainable development of competitive sports. It not only affects the normal training of athletes but also ends the sports career of athletes prematurely, which is not only a personal regret for athletes but is also a major loss and waste of resources in competitive sports, which is one of the problems to be solved urgently in competitive sports.

The basic skills of athletes should be improved and corrected in time. In addition, the learning and mastering of new technology should be arranged in the period when ath-letes are in good physical and mental state, so as to avoid learning technology under physical and mental fatigue and bad state [3]. Preparatory activities have made full physical and mental preparation for formal training, which must be paid attention to in training. In winter preparation, athletes should also pay attention to clothing and preparation time. Different special events have fixed action patterns and specific muscle groups [4].

The main reasons that affect the prevention and rehabilitation of sports injuries of college athletes are as follows: the increasing number of sports competitions makes athletes do not have enough time for systematic and complete rehabilitation training, and sports injuries are accumulated and repeated. The existing rehabilitation training is difficult to meet the training requirements of athletes, and it is difficult to achieve effective recovery after high-intensity training. [5]. The subject consciousness of athletes refers to their cognition and consciousness of sports injury in training [6].

Track and field athletes are in the process of physical and mental development. In terms of time, sports injury can be divided into early, middle, and late [7]. In the early stage of sports injury, the manifestations of sports injury in this period are local tissue ischemia, obvious pain in the injured part of athletes, a large amount of tissue fluid exudation, and swelling in the injured part [8].

In this paper, the method of experimental research is used to understand the influence of the injury of the posterior femoral muscle group of track and field athletes and to find out the way of sports injury of track and field athletes through theoretical analysis and experimental research; through data recording, sorting, calculation, drawing, and analysis, the data are processed. Through the simulation of the statistical data set of the later rehabilitation training and prevention of the injury of the posterior femoral muscle group of track and field athletes, combined with the data, the role of the posterior femoral muscle group in the track and field sports is empirically analyzed and combined with the effective data. The article further summarizes and sorts out the specific methods of the athlete's posterior thigh muscle injury, the specific requirements of the exercise movements, the advanced movements, and the training load characteristics, enriches and improves the training methods and contents of the sports injury in the physical function training system of college athletes, provides theoretical and practical guidance for coaches, athletes, and other researchers of college long jump training teams and other training teams, and further improves the scientific, systematic, informatization, and rationalization level of the training system of college training teams.

2. Injury of Posterior Femoral Muscles of Track and Field Athletes

2.1. Track and Field Training. The development of track and field athletes needs years of training. Athletes mainly rely on the functions of the ATP-CP system. The absolute speed level of the track and field athlete determines the performance. The speed of the athlete mainly depends on the elongation-contraction ability of the knee and ankle extensor muscles and the ability of the hip joint to contract concentrically. The coordination of speed and explosiveness is the key to determining track and field performance. However, due to the influence of the basic training conditions of track and field and the professional level of coaches, some athletes have different degrees of sports injury, which affects the quality and systematization of the basic training stage. In track and field training, some coaches still rely on experience training, lack of deep understanding of scientific training, and pay too much attention to competition results, which is not conducive to the development of athletes. This situation leads to different degrees and types of sports injuries. The training of high level athletes in track and field is a systematic project. In the system training, the training is carried out in stages. Different training stages complement each other to form a system [9, 10]. If there are more and more serious sports injuries in training, it will not only affect the quality of training but also break the training system. With the increase of modern sports events, the intensity of training is increasing day by day, and even competition is used instead of training. This increases the risk of injury to athletes. With its unique charm, sports attract people to participate in it and enjoy the tension, excitement, excitement, and joy after winning the whole process. It has multiple functions of promoting social development. More and more modern sports training load trend content orientation, load measurement specialization, many years of training process, and training team composition diversification, which means that the complexity of modern sports training organization and implementation and the requirements of comprehensive training are higher, and the requirements of human body in psychology are more and more in-depth, so the actual needs of social activities are higher and higher [11, 12]. Sports have higher requirements and standards for athletes participating in sports competitions. After a long period of practice, sports have become a practical social activity to realize the individual social value of athletes. This is the essential characteristic and internal requirement of sports training. The performance of sports mainly depends on the existing level of athletes [13]. The ultimate goal of competition and training is to achieve excellent results. Psychological ability plays an important role in the ability constitution of track and field athletes. The process of athletes' long-term training until the highest achievement is closely related to individual psychological development [14]. In the early stage of scientific development, people's understanding of sports is relatively low, and they pay attention to the physiological response of body function. Although they have a corresponding understanding of psychology, the research still needs to be strengthened. At the same time, some social factors that are expected by the outside world, lack of psychological coordination and cooperation, often lead to the situation is not ideal, lack of psychological adjustment and maintenance, resulting in their own regret, anger, and other psychological differences. Psychological ability is the key to achieve the level of athletes and achieve ideal sports results. For athletes engaged in sports, the level of motivation to a certain extent affects the performance of individuals or the quality and effect of daily sports training. The realization of social value and self-worth of athletes needs long-term motivation. The quality of incentive determines the realization of incentive demand and the degree of target acquisition. Therefore, athletes have formed professional representatives for a long time. In other words, professional competition and long-term guidance and training are the long-term mechanism of athletes' long-term work. Will quality is the basic guarantee for athletes to overcome the tough training competition [15].

2.2. Posterior Femoral Muscle Damage. "Injury" has a broader and richer meaning and scope than "sports injury," and the meaning and scope of "sports injury" is more specific and detailed, especially referring to various acute and chronic injuries that occur during sports. Therefore, the word "injury" includes "sports injury," and "sports injury" is more professional, scientific, normative, and rational than "injury" in sports application. Patients with severe injuries

need to be hospitalized for a long time and lose their ability to exercise completely, especially the pull injury of posterior femoral muscle group. The main reason of lower extremity injury is the theory of muscle involvement. If the lower extremity hemorrhage cannot be absorbed, it will form fibrous tissue and new bone. For example, too much treading and retreating will make flexor and squat muscles, flexor digitorum, and posterior tibial muscles contract repeatedly, causing a series of pathological changes of periosteum of legs. No matter what the cause of periostitis, if the local load can be in the early stage, timely adjustment of running, jumping, and support can reduce exercise, appropriate treatment can be taken to reduce inflammation and tissue repair process, and adaptive changes will also occur, which will improve the load capacity of bone tissue. Therefore, coaches and athletes should fully consider the mechanism of sports injury and reasonably adjust the training plan when making the training plan. The main reason why the waist and back are easy to be damaged is that the gravity exceeds the endurance of the trunk for a period of time. The proximal end of the rowing bone is relatively narrow and long, and the longitudinal span between the two rows of carpal bones is the most likely to be fractured in the carpal bone. However, due to the track and field without using the wrist, only the wrist closely related to the throwing event and the injured wrist of track and field athletes are relatively low.

Injury of the thigh muscles is common in track and field, football, etc. Although most injuries do not require surgical treatment, athletes need to rest for 2-8 weeks before returning to the level before injury. After athletes resume normal training and competition, repeated posterior femoral muscle strains can lead to longer recovery time, chronic pain, and dysfunction and can even end of their sports careers. Due to the serious consequences of tension, a lot of manpower, material, and financial resources are invested to prevent the tension of the posterior femoral muscles and improve the rehabilitation effect of tension. Strains mainly occur when the muscles are stretched. Strains are related to muscle strains, not to muscle contraction force and speed. Muscle strain is defined as the ratio of muscle relative resting length increment to muscle resting length. In a given human movement, when the muscle length increments are similar, the optimal length of the muscle is shorter, the strain of the muscle is larger, and the risk of injury increases. On the other hand, when the optimal muscle length is similar, the greater the muscle length increment, the greater the muscle strain and the greater the risk of strain. Sprinting is the most important form of movement that leads to the pulling of the posterior femoral muscles. The huge load of the posterior femoral muscles is the cause of the traction. Therefore, we believe that the early stage of the support stage is a high-risk stage of tug-of-war. The tug-of-war for muscles is caused by excessive strain, and huge muscle contraction is not a necessary condition. On the one hand, it affects the size of the muscle strain by affecting the optimal length of the muscle; on the other hand, it may also affect the biomechanical characteristics of the lower limbs during sprinting, thereby affecting the length increase of the posterior femoral muscle group and ultimately affecting the size of the strain

and changing the risk of contingency. Insufficiency of the hamstrings is considered to be the main cause of hamstring injuries. Deficiencies in the hamstrings can result in insufficient hamstrings against the quadriceps during knee extension during the swing phase. Assuming that this is the mechanism of hamstring injury, it is a further inference that the imbalance of muscle strength at the thigh is the cause of hamstring injury.

The hamstring is mainly composed of type II fibers of fast twitch fibers. This muscle group is a typical biarticular muscle, consisting of the biceps femoris located on the back of the thigh, the long and short biceps, and the semitendinosus located on the back of the thigh muscle and semimembranosus muscle. In running movements (especially fast movements), the biceps femoris and semimembranosus are powerful extensors of the hip joint, while semimembranosus is the agonist for knee flexion and calf flexion in addition to coextending the hip. However, the current training methods cannot train this muscle group well, so in high-speed exercise, the injury and recurrence of the posterior femoral muscle group are very common. Severe strain of the proximal part of the posterior femoral muscle group may also affect the lower limb function of the patient. Incomplete recovery after injury will lead to repeated or aggravation of the disease, resulting in difficult recovery, and the second injury is often more serious than the previous one. Repeated injury of the posterior group of extensor muscles may lead to lumbar deformation and reduce the deformation and range of motion of the knee joint, the adhesion of the common peroneal nerve, the reduction of the strength of the quadriceps femoris, and so on. At the same time, it will increase the risk of other parts of the lower limb, such as the anterior cruciate ligament. Serious pull injury of posterior femoral muscle group not only brings great pain to athletes but also brings great economic loss to clubs or sports teams. More than half of the injuries were related to the biceps femoris, and most of them occurred in the long head of biceps femoris. Because the long head and the short head of biceps femoris are controlled by different nerves, this unique dual innervation makes asynchronous nerve stimulation lead to asynchronous contraction of muscles, thus weakening the ability of muscles to produce effective tension control strong load, and at the same time, the relatively short length of muscle fibers also makes pulling. In a given human action, the shorter the optimal muscle length, the greater the muscle tension, and the higher the risk of injury. Serious traction injury of posterior femoral muscle group may be caused by exceeding the physiological limit in a certain exercise process, or it may be the result of long-term microinjury accumulation. It is also possible that the two mechanisms together lead to the final result of the strain. Although jumping, slow overstretching, and so on will cause the strain of the posterior thigh muscles, sprint is still the most important form of exercise.

2.3. *Preventive Measures.* The main problem of the injury mechanism of the posterior femoral muscles during sprinting is the injury time. In addition to the large knee flexion, the hip extension supports the early stage. In order to resist

the acceleration of the forward swing of the leg, the strong contraction of the posterior femoral muscles produces greater knee flexion in the final stage of the swing. The early support period and the later swing period are both high-risk periods of sprained posterior femoral muscles. In daily walking and squatting positions, the knee and hip joints have completed the bending movement, and these two joints have opposite effects on the extension of the thigh muscles. This unique dual innervation causes asynchronous nerve stimulation to cause muscles to contract asynchronously. All three muscles of the posterior femoral muscle come from the ischial tuberosity behind the pelvis. Therefore, when the forward angle of the pelvis increases, the posterior thigh muscles will be in a longer state, which may increase the risk of injury. In certain human activities, the greater the muscle tension, the greater the risk of injury. The optimal length of the posterior femoral muscle group with a history of strain may be shorter, and the risk of restrain may increase. Therefore, the knee flexion angle at the moment of maximum knee flexion can be used to reflect the strain risk of the posterior femoral muscles. Is the change in the optimal length the cause of the previous strain or the result of the previous strain? The ability of tired muscles to resist stretching decreases. In the case of absorbing the same energy, fatigued muscles will stretch longer than nonfatigue muscles, so it is easier to reach a stretched tension state, and the risk of fatigued muscles is higher. Power imbalance is a potential risk factor for posterior femoral muscle stretch injury. The imbalance of strength mainly includes the weakness of the posterior femoral muscle, the imbalance of the strength of the posterior femoral muscles on both sides, and the low strength ratio of the posterior femoral muscle to the quadriceps muscle. The strength of the posterior femoral muscles and quadriceps is relatively weak. In the late stage of the sprint, the eccentric contraction of the posterior femoral muscles is not enough to prevent the swing of the front legs, which may lead to excessive stretching of the posterior femoral muscles, resulting in tension. Because the deformation of the posterior femoral muscle group mainly occurs in the process of strong eccentric contraction, the centripetal muscle force ratio is said to not reflect the actual function of the posterior femoral muscle group. The ratio of centrifugal force to centripetal quadriceps is widely used. During sprinting, the maximum muscle tension of the thigh muscle group is much greater than the maximum muscle tension at the maximum muscle stretching speed, and the maximum muscle stretching speed is much greater than the maximum muscle tension at the maximum muscle tension. Although the occurrence of muscle strain is not directly related to the speed of muscle contraction, once the strain occurs, the speed of muscle stretching may affect the degree of muscle strain and tear. The most important thing in functional recovery is not to force it. We should step up the practice step by step. Pain means overload and delayed recovery.

Functional recovery takes pain as an important indicator, and it is gradually performed in the order of flexibility, muscle strength, speed, coordination ability, and overall endurance, and functional recovery is achieved in the shortest time. Acupuncture, massage, and other treatments called physiotherapy must also be performed under the guidance of a doctor. The purpose of functional recovery is to restore the normal state before the injury. It can perform normal activities as before, with the previous strength and explosive power, restore the active area of the joints, and obtain the maximum muscle strength. If you return to the state before the injury, you can return to the court. The first step of the functional recovery plan is emergency treatment, the second step is to restore the range of motion of the joint, and the third step is to restore strength. The next step is to restore muscle strength. The most difficult part of functional recovery training is the recovery of muscle strength. The recovery of muscle strength is very important, especially for athletes who need muscle strength and explosiveness. Equipment is also essential in the training of muscle function recovery. When an athlete is injured, the countermeasures should be from the initial prevention to the subsequent treatment and rehabilitation. The general prevention method is daily physical exercise and storage, so as to improve their own quality. Before the training, we should also be able to reasonably restore our relaxed nature and work hard in medical work. When there is a treatment problem, it cannot be delayed from on-site first aid to late delivery. After receiving treatment, athletes should be able to maintain their confidence in recovery and recover in time. The excessive damage of the skeletal muscle system is mainly caused by the long-term fatigue effect that exceeds the capacity of the lower limbs to bear the structure. It is related to the overload and repetitive stress of the musculoskeletal system. Although in many structures of the skeletal muscle system, repeated stress may lead to overuse injury, this does not mean that in order to avoid injury, the stress of the skeletal muscle system should be reduced to a very small extent.

Positive adaptation occurs when the applied repeated stress is below the mechanical limit of the structure and there is sufficient time interval between the stresses. On the other hand, negative adaptation is that the applied stress exceeds the mechanical limit at a certain moment. As for the location of the injury, the results are different due to different athletics. Usually, when many athletes have a poor grasp of the landing angle when taking off, or have problems in technical movements, they will make the speed too fast and then make the body fall unreasonably. Normally, strains on large muscle groups are caused by excessive force during take-off. When you land and move the center of gravity downward, your legs are more prone to problems. All joints and ankles are prone to pain and swelling. In ankle joints, severe cases often have varus or valgus, blood stasis on the instep or ankle joint, local tenderness is obvious, and the tenderness is more serious when the ankle joint is active. In the throwing event, the most likely injury is muscle strain. Different sports levels or genders have different injuries due to different bodies. In this way, if the technical action is correct, the problem can be alleviated. In many cases, insufficient preparation and lack of specific strength and flexibility of the elbow joint will exacerbate the problem. Usually, when an athlete is just injured, the body will respond to stress, namely, pain and swelling. When these problems arise, emergency response is the most important.

The usual first aid methods are braking, cold compress, compression, and supine. Braking means stopping motion. When the movement stops, swelling can be further controlled. When bleeding problems occur, they can also be minimized. In case of bleeding, if you cannot get ice in time, you can choose pressure bandaging. Pressure bandages allow blood to enter the tissue and absorb it well. There are many ways to bandage. In order to reduce inflammation, swelling, and pain after injury, the methods used are braking, cold compress, compression, elevation. and fixation. Then, surgery is performed. In order to promote blood circulation, warm treatment should be performed from the site with less pain and more damage, and it is also the beginning of the process of functional recovery.

2.4. IoT Smart Data. The Internet of Things technology is a comprehensive technology that connects objects to the Internet according to a certain communication protocol through communication equipment, sensors, data acquisition and processing systems, positioning systems, and other equipment. Through the Internet of Things, operations such as intelligent monitoring, positioning, and management of objects can be realized. In recent years, due to a large amount of investment in human and material resources, the application system based on the Internet of Things technology has also been continuously developed and improved. However, in the process of continuous improvement of information technology, some unstable factors have also appeared. A large amount of spam has caused great troubles to data collection. Based on this, the research on intelligent data collection systems based on the Internet of Things technology is also particularly important.

Data acquisition is one of the cores of data management system. Data acquisition is the process of using sensors and other measuring devices to collect and input information from outside the system to the inside of the system. Generally, the collected information is converted into electrical signals and transmitted to the system for identification. In the rehabilitation training and prevention of track and field athletes' hindfemoral muscle injury, the role of IoT intelligent data is more prominent. Intelligent data collection based on the Internet of Things technology can accurately record the rehabilitation training performed by track and field athletes after muscle injury in the past, can be stored for a long time, and can be accessed at any time. At the same time, the intelligent technology of the Internet of Things can identify and record some sports actions that may cause muscle damage in track and field sports, which greatly reduces the risk of athletes causing muscle damage in track and field sports. Figure 1 is a deployment diagram of an intelligent data collection server based on the Internet of Things technology.

3. Research Objects and Methods

3.1. Experimental Subjects. In this paper, 60 athletes in Hebei Province were selected randomly, including 30 men and 30 women. Then, a series of training and recovery were carried out. The 60 athletes were observed, and the status quo of the
FIGURE 2: Analysis of the nature of sports injury.

Omnipotent	42.60%	39.50%	57.60%

injury of the posterior thigh muscle group and its prevention and recovery were analyzed. Table 1 is a table of the sports types of 60 athletes.

3.2. Experimental Method

(1) Flexibility training: before the formal training, the subjects complete 5-10 minutes of warm-up by jogging and then complete a series of training after that. The subjects lie on a horizontal pad. The trainer uses one hand to raise the lower limbs of the subjects, while the other hand is placed on the anterior superior iliac spine of the opposite side to prevent pelvis rotation. The trainer shall ensure that the knee joint of the subject is in the straight position during the whole process. When the trainer feels that there is a great resistance or finds that the pelvis of the subject begins to tilt, he shall stop raising the measured leg. At this time, the hip joint bending angle is the maximum hip joint bending angle for flexibility training. Flexibility training intervention to further verify whether the flexibility of the posterior femoral muscle group will affect the risk of strain. As for the 16 week flexibility intervention training of runners, the flexibility training did not significantly reduce the strain rate of the posterior femoral muscle group

(2) Sprint training: the subjects wore tight clothes and trousers, pasted reflective markers on their bodies, and determined the placement of electrodes for biceps femoris, semitendinosus and semimembranosus muscles on both sides according to the anatomical markers on the body surface and the freehand examination. Shave the hair on the skin surface of the preset electrode and wipe it with 75% alcohol. Two recording electrodes were attached to the highest part of the muscle ventral eminence during each muscle contraction to be measured, which was consistent with the direction of the muscle fiber. The distance between the centers of the two electrodes was 2 cm, and a reference electrode, a signal transmitter, was placed close to the recording electrode. The running distance is about 35 meters. The subjects stand at a straight distance of about 20 meters from the force measuring platform to prepare for the starting position. After hearing the command, they run through the training area as fast as possible. It is considered as an effective training for the subjects with normal gait, no step adjustment and training foot on the force measuring platform. The subjects completed three effective exercises on each side of the leg and rested for 60 seconds between each exercise. The three-dimensional coordinates, surface electromyography, and ground reaction force signals of the subject's body surface were collected during each training

(3) Isokinetic strength training: after the sprint training, the subjects keep the original body surface marker points unchanged, first complete the static standing calibration to collect the three-dimensional coordinates of all marker points, because the seat will block the waist points during isokinetic strength training, so remove the waist points after the calibration. The subjects sit on the isokinetic training instrument and keep the hip flexion about 90°. The thigh and calf of the training leg are fixed on the seat and the mechanical arm, respectively, to prevent compensatory action so as to ensure that only the flexion and extension of the knee can be completed. The flexion and extension axis of the knee is aligned with the

rotation axis of the mechanical arm. The range of motion of the arm is 110° and the position of the arm is 0° when the knee is fully extended. The subjects did their best to complete three equal speed knee bending movements with an angular velocity of 10/s for 90 seconds between each time. The three-dimensional coordinates and isokinetic moment data of the body surface mark points were collected during each training

(4) Strength training: during the formal training, the athletes stand on the pedal with their feet fully in contact with the pedal. The knees should not be bent as much as possible. They should stand up straight and back and hold the handrail with both hands, and the legs should be retracted horizontally or vertically. Stretch until the athlete feels the back of the thigh muscles are sore and can retract by himself. According to the focus of strength training, that is, maximum strength, relative strength, strength

endurance, and speed strength, different load intensity is used for training

Literature analysis method: through consulting related books, such as sports therapeutics, sports psychology, sports injury, track and field kinematics, sports science, and sports statistics, to provide a preliminary basis for this study, and then collect relevant literature at home and abroad from CNKI, and analyze the relevant literature. Mathematical analysis: SPSS22.0 statistical software was used to process the relevant data of long jumpers, the results were expressed as mean and variance (M ± SD), two-sided t-test was used, and the P value less than 0.05 indicated statistical significance, providing data support and authoritative basis for the analysis of training methods for sports injury prevention. Logic analysis method: by using the method of judgment and reasoning, this paper analyzes the injury of the posterior femoral muscle group of track and field athletes, explains its causes, provides the corresponding scientific basis for training and competition, summarizes, sorts out, analyzes all the

documents, sorts out and processes all the data, synthesizes the results of logical analysis, and draws relevant conclusions. Field investigation method: This article uses the opportunity of internship in the training team of the academy to observe the process of physical function training of athletes and observes and records the training methods used by athletes to prevent sports injury and the arrangement of training load, which provides a solid foundation for the writing of this article practical basis.

Strength is the power source of human sports, strength training is the key factor to improve the performance of competitive sports, and it is the most concerned problem of modern competitive sports training. A comprehensive and systematic understanding of the theory and methods of sprint strength training, the advantages and disadvantages of various strength training methods, as well as the diagnosis and evaluation methods of strength training effect are the basis of competitive sports training, the guarantee of effectiveness and pertinence of strength training, and the premise of sports training innovation and breakthrough. In the training, the strength of the mobilized posterior thigh muscles is different. In the strength training, the effect of the flexible
FIGURE 5: Preventive analysis.

TABLE 6: Muscle injury data sheet.

	Walking race	Running	Thrown	Jumping class	Omnipotent
Strain	8.2%	5.8%	9.5%	6.5%	8.1%
Sprain	6.8%	8.2%	6.3%	8.9%	9.2%
Periostitis	2.5%	9.2%	5.1%	3.8%	4.6%
Scratch	3.1%	5.0%	2.1%	3.2%	2.9%
Fracture	2.0%	5.4%	3.6%	4.0%	2.9%

strength training device on the posterior thigh muscles is better than the traditional method. The training effect of the comprehensive training device of flexibility and strength on the longitudinal flexibility is more obvious than that of the traditional method. The flexibility training of the posterior thigh muscle group needs persistence, and long-term persistence can get better results. Flexible strength training device has a positive effect on the strength and flexibility of the posterior thigh muscles. It can effectively prevent the injury of the posterior femoral muscle group of athletes in special sports.

4. Discussion and Analysis of Experimental Results

4.1. Analysis of Track and Field Injuries

4.1.1. Analysis of the Nature of Sports Injury. According to statistical analysis of data, as shown in Figure 2 and Table 2, the nature of sports injuries includes acute injuries, chronic injuries, and acute to chronic injuries. Acute injury is caused by one-time violence; chronic injury is caused by long-term local overload, which exceeds the capacity of the tissue. Chronic to acute injury is caused by early acute injury without timely and reasonable treatment. In track and field

sports, walking injury is the main form of injury, accounting for 75.5% of the total injury. The main nature of sports injuries in running events is acute injuries and chronic injuries, accounting for 81.3% and 46.6%, respectively. The sports injuries of throwing events are mainly acute injuries and chronic injuries, accounting for 86.9% and 50.6%, respectively. Long jump sports injuries are mainly acute injuries and chronic injuries, accounting for 78.6% and 67.7%, respectively. Acute, chronic and acute to chronic events accounted for 42.6%, 39.5%, and 57.6%, respectively.

4.1.2. Analysis of Sports Injury Types. According to the statistical analysis of data, as shown in Figure 3 and Table 3, due to the different characteristics, movements, speed, strength, and other performance of different items, the types of sports injuries are also different. Sprains and periostitis were the main sports injuries, accounting for 26.6%, 29.2%, and 32.2% of the total injuries, respectively. Muscle strain is the main injury in running events, accounting for 76.8% of the total. Sprains, periostitis, and abrasions accounted for 28.3%, 22.9%, and 17.9%, respectively. The main sports injuries in throwing events were 31.5% of strain injuries, 35.9% of sprain injuries, and 19.9% of periosteal inflammation injuries. The types of sports injuries in long jump are sprains, contusions, sprains, abrasions, and periostitis, accounting for 46.2%, 38.2%, 45.9%, and 35.9%, respectively.

4.2. Track and Field Prevention Analysis

4.2.1. Analysis of Damaged Parts. According to the statistical analysis of the data, as shown in Figure 4 and Table 4, different sports show obvious characteristics at the location of sports injuries. The main injuries are the waist, knees, calves, and buttocks. The main parts of running injuries are waist, knee, ankle, and thigh. The main parts of sports injuries are waist, knee, and hip, which account for the largest proportion. As there are more all-around sports, there are also more injured parts, especially the waist, ankles, and thighs. Due to the characteristics of different sports forms, speed, duration, and muscle names, the occurrence of sports injuries also has its own characteristics. In the training, the coach should fully consider the muscle strength and weight-bearing parts of different items and arrange the general quality training and special training, training and recovery, and the intersection of different training parts and content. During the training, the coaches of different projects should pay attention to the uncomfortable reactions in the first half of the different projects and actively communicate with the athletes. If there is fatigue, discomfort, and minor injury, it should be adjusted and handled in time to prevent serious sports injuries.

4.2.2. Prevention Analysis. Table 5 shows the athletes' attention to prevention in various aspects to prevent muscle damage during exercise (1-10 points, the higher the score, the higher the attention).

According to the statistical analysis of data, as shown in Figure 5, the first three key points of running sports injury prevention are special training, adjustment recovery, and physical fitness training; the first three points of throwing
FIGURE 6: Diagram of the prevention of muscle injury based on the intelligent data of the Internet of Things.

sports injury prevention are special training, physical training, and psychological training. The first three points of the long jump are special training, physical training, and technical training; the top three all-rounders are physical training, adjustment and recovery, and special training. On the whole, sports training is increasingly valued by coaches. In addition, most track and field coaches attach great importance to recovery after training. To some extent, rehabilitation is the continuation of training. If the recovery work is not done well, it will affect the next training. It is worth noting that modern sports training pays more and more attention to psychological factors and nutritional supplements. In particular, nutritional supplements have special significance for the prevention of sports injuries and should attract the attention of coaches.

4.3. Prevention Analysis of Muscle Injury in Track and Field Sports Based on Intelligent Data of the Internet of Things. In this experiment, an experiment was conducted on the prevention of athletes' muscle injury based on the intelligent data of the Internet of Things, and the athlete's muscle injury was recorded in the experiment. Table 6 is a table of experimental results of preventing muscle damage based on the intelligent data of the Internet of Things.

According to Table 6, a diagram of the prevention of muscle damage based on the intelligent data of the Internet of Things can be drawn, as shown in Figure 6.

According to Figure 6, it can be seen that the program of preventing sports muscle injury based on the intelligent data of the Internet of Things has achieved great results, greatly reducing the probability of athletes causing muscle injury in sports. In this experiment, the highest rate of muscle dam-

age was only 9.2%, which was 18.6% higher than the effective rate of the traditional prevention program. Through the comparison of peak muscle torque on the subject's knee flexor muscle strength and knee extensor muscle strength, it is found that the subject's flexor and extensor muscle strength match is ideal, and the flexion of the left and right knee joints is ideal. The extensor muscle strength is more balanced. However, there is a significant difference in the explosive force level of the knee flexor muscle group compared with the knee extensor muscle group during high-speed exercise through the explosive force parameters (using the rapid strength index and the force rate), which may be one of the factors that affect sports performance and lead to the injury of the posterior femoral muscle group potential factors.

5. Conclusions

(1) In the stance phase, the main torques that control the movement of the lower limbs are the muscle torque and the external torque generated by the ground reaction force; the main torques that control the movement of the lower limbs in the swing phase are the muscle torque and the inertial moment generated by the link movement. The moment of inertia has a significant effect on the motion at the end of support and swing

(2) At the initial stage of support and the end of swing, the stress state of the hamstrings is similar, that is, the external torque pulls the hamstrings in the opposite direction at the same time, making it under huge

stress and strain, so both the initial stage of support and the end of swing are similar high-risk period for hamstring injury

(3) The main parts of running sports injuries are waist, knee, ankle, and thigh. Injury sites also showed diversity, with waist, ankle, and thigh injuries being the most obvious. The main measures to eliminate sports fatigue are jogging and relaxing, sleeping, and massage

(4) Most track and field athletes have experienced torture of posterior femoral muscle damage during training, and the degree of injury is higher. The degree of injury is mostly mild to moderate, but it still seriously affects the training and life of athletes

(5) The degree of occurrence of sports injuries of track and field athletes is as follows: does not affect training, suspends training, and treats sports injuries. The main parts of the walking project are the waist, knees, calves, and hips

(6) The muscle injury prevention program based on the intelligent data of the Internet of Things can greatly reduce the probability of athletes causing muscle injury during exercise, and its effective rate is increased by 18%

It is suggested that the prevention of physical function injury should be promoted and integrated into the daily training of the long jump training team and other training teams, so as to achieve the effect of injury prevention and treatment on the basis of improving the athletes' special performance ability. The concept and method of physical function training has not been introduced for a long time, and its theoretical and practical experience is relatively immature. Therefore, it is necessary to fully study and understand its theoretical knowledge and connotation when applying it and to constantly explore and summarize in specific practice.

Nanomaterial science is a particularly important research field in modern science and technology, which has attracted wide attention and research from all walks of life since its inception and has formed a relatively perfect category of science and technology. The purpose of this paper is to explore the application of carbon nanocomposite sensing and functional magnetic nanomaterial in the sports industry and their biosecurity research. This paper first discusses the research progress of nanocomposite in biosecurity and concludes that chemical modification can reduce the negative biological effects of nanomaterial, then puts forward the research methods on nanocomposite in the sports industry, and then selects nanosilver composites to explore and study the effects of different particle sizes and concentrations on the antibacterial properties of Aspergillus and test and characterize the properties of nanocomposite. The stability of nanocomposite modification electrodes is also explored. The results show that nanosilver has excellent bactericidal effects on both AF293 and Gra04. In particular, 8.08×10^{-5} mol/L and 4.03×10^{-5} mol/L nanosilver has a bacteriological rate of 100%, indicating that the growth of all fungal spores can be completely inhibited, and when the content of 10 wt% is found, the thermal conductivity of PHBE-MWNT pressure-sensitive composite materials is achieved 0.6975 W/(m-K), 1.8 times the MWNT pressure-sensitive glue, higher than the pure pressure-sensitive glue about 255%.

1. Introduction

Microorganisms are beneficial and harmful to human survival. The secondary metabolites of many bacterial species are antibiotics that are very useful for human diseases, and because of the short growth cycle and rapid reproduction of microorganisms, they are used in genetic breeding, which is of great significance. At the same time, microorganisms can also lead to the prevalence of infectious diseases, and 50% of human diseases are caused by viruses. Some microorganisms are spoilage, that is, cause undesirable changes in food odor and tissue structure. The evolutionary history of human society is the history of giving full play to the advan-

tages of favorable bacteria to improve one's own life and to improve the quality of life by solving harmful bacteria. When the size of the material is reduced to a nanoscale, there will be some unique and interesting phenomena that cannot be observed in macromaterials, but these phenomena have not been found in the macrorange. Material scientists have discovered many materials with this phenomenon, such as quantum stimulation limits (quantum dots) for inorganic semiconductor nanomaterial, ultra-submagnetic (SPIONS) for iron oxide nanoparticles and localized surface plasma resonance (LSPR), for precious metal nanoparticles. It is an exciting task to solve practical problems by using the special properties of nanomaterial. The characteristics

of nanomaterials mainly include surface and interface effects, small size effects, quantum size effects, and macroscopic quantum tunneling effects.

To explore all aspects of nanocomposites, because of their smallness, they are not conducive to experimental exploration, but also because of their smallness, so nanocomposites are explored, so that it can provide reliable help not only in microbial research but also for clinical medicine and disease early warning of biomolecule detection methods which provide an important reference.

According to the research progress at home and abroad, different scholars have also made corresponding investigations in the research of carbon nanocomposite material sensing and functionalized magnetic nanomaterial: Zhao et al. conducted laboratory research on the performance of nanocarbon/copolymer SBS/rubber powder composite modified asphalt and chose nanocarbon particles modified by titanate coupling agent as the modifier. The morphology, microstructure, and surface properties of the prepared nanocomposite adsorbent were measured and analyzed by FESEM, TGA, XRD, FT-IR, and zeta potential. Batch experiments on the adsorption of Cr (VI) were carried out to determine the adsorption performance of the composites [1]. Wang et al.'s chemically synthesized conductive nanocomposites consisting of poly (PPy) are compared to components such as Cdots or PPy. It shows higher conductivity. The conductive film of this composite material is used for high sensitivity and selective detection of bitter acids in water and soil. This is the first report on conductivity-based sensing applications for Cdot nanocomposite, as opposed to traditional fluorescence-based sensing methods [2]. Pal et al. studied the composite modified asphalt prepared by Cdots and the high-speed shearing method for nanocarbon/copolymer SBS/rubber powder, used in extended tests, softening point tests, permeability tests, dynamic shear rheometer (DSR) tests, and curved beam rheometer (BBR) tests to evaluate physical performance [3]. Jiang et al. have produced a diamond-like carbon (G/a-C:H) nanocomposite film mixed with graphene by liquid phase electrochemical method. The growth mechanism of the nanocomposite membrane is proposed and discussed. The deposited coating material was measured using scanning electron microscopy (SEM), Raman spectroscopy, spread electron microscopy (TEM), and Fourier transform infrared (FTIR) spectra. The results show that graphene sheets are evenly dispersed in the hydrogenated amorphous carbon (a-C:H) matrix [4]. Xu and Zhang have developed an easy preparation method for nanocomposite consisting of graphene oxide and manganese dioxide nanowires (GO/MnO2NWs). The basic form, structure, and composition of the resulting substance are characterized by a transmission electron microscope, X-ray diffraction, and N2 adsorption and desorption [5]. Hien et al. have successfully developed an effective electrochemical method for the production of poly phenylamine/multiwall carbon nanotube nanocomposite on the fork-finger platinum microelectrics to improve biosensor performance. The shape and properties of nanocomposite were studied through field emission scanning electron microscopes and ultraviolet visible spectra

[6]. Amir et al.'s study discusses the effects of effective functionalization on signal sensitivity observed on 6-TG electrooxidation on CA-Fe3O4 NPs, with the use of bare and niacin (NA) functional Fe3O4 NP modified glass carbon electrode compared. The experimental results provide sufficient evidence to support the importance of favorable functions for achieving higher signal sensitivity of 6-TG electrooxidation [7]. Cao et al. studied the prepared ZnONR sensors, MWCNT sensors, and ZnONR/MWCNT ethanol gas sensitivity of nanocomposite gas sensors. ZnONR/MWCNT nanocomposite sensors exhibit higher response, faster response recovery, and better ethanol selectivity than ZnONR and MWCNT sensors [8]. However, these studies have not combined the application of sports industry and its biological safety to make some progress.

The innovative focus of this paper is mainly reflected in the following: (1) the paper introduces the research on biosecurity of nanocomposite and concludes that chemical modification can reduce the negative biological effects of nanomaterials and puts forward research methods based on nanocomposite in the sports industry. (2) The performance of nanocomposite is analyzed from a biological point of view, and the properties of nanocomposite are tested and characterized, and the stability of nanocomposite modified electrodes is explored.

2. Methods in Biosecurity and Sports for Nanocomposite

2.1. Biosecurity in Nanocomposite. Due to the industrialization of nanotechnology, people's daily life and occupation with nanomaterial contact are increasingly frequent, so the use of nanomaterial on the body and the environment may also cause more attention. Some of the nanoparticles newly created by engineering science may be cancer-causing. Researchers found that fish developed brain cancer after ingesting small amounts of carbon nanomaterials. Laboratory mice developed symptoms of lung disease after inhaling carbon nanotubes, as if they had inhaled asbestos particles. So far, the study of the biological effects of nanomaterial is still in its infancy, and scientists have only made preliminary studies on the biological effects of carbon-based nanomaterial and metals and their oxide nanomaterial [9]. When a biological material exceeds the nanosize (1-100 nm), it has a very good surface area due to its size close to the biological atomic scale, allowing it to interact directly with individual biological atoms [10]. Nanomaterials show the good electronic, optical, magnetic, mechanical, and other properties inherent in nanoscale, making it more sensitive to the surrounding environment and the target molecules in the sample, which is conducive to detection. Nanoelectrochemical sensors made from these nanomaterials have achieved some results in simplifying the detection process, improving sensitivity, reducing detection limits, and reducing costs, as shown in Figure 1.

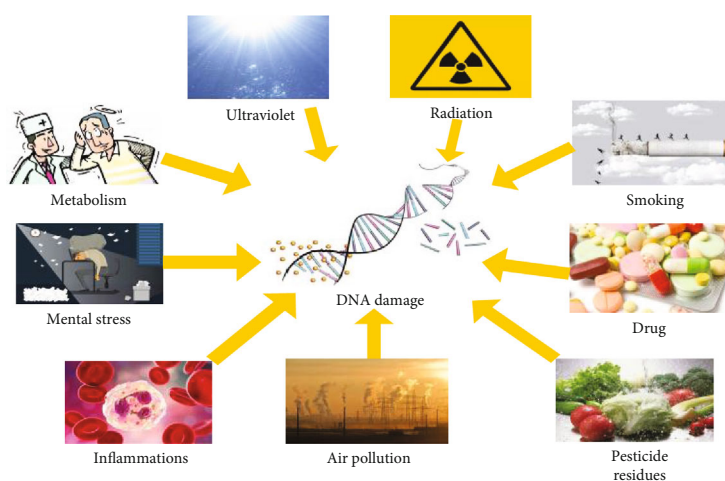
The biological effects of nanomaterial are closely related to their physical and chemical properties, biological cells are at micron scale, and nanomaterials extremely easily enter into biological cells and interact with them, thus affecting
Figure 1: Schematic diagram of electrochemical sensors and biosensors based on nanomaterial and nanostructures.


Figure 2: Factors affecting biological damage.

biological functions [11]. Figure 2 represents the factors that affect biological damage. Because of their small size, these tiny factors are difficult to detect, and they are quietly hidden around us, which will slowly erode our bodies. Scientific studies have confirmed that some micron-scale compounds that appear in the form of stable clusters are nontoxic, but when they are heated into smaller-scale nano- or ultra-microlevel particles, they can also show some toxicity, such as having rats contain 20 nm of PFC (PTEF). Nanoparticles breathe 15 min in the air, and most rats die within the next 4 hours, instead containing 130 nm PTEF. Rats breathing in the air did not see discomfort [12].

The biological effects of nanomaterial are not only influenced by particle size but are also closely related to their structure. With the quantitative change of particle size, the qualitative change of particle properties will be caused under certain conditions. The change in macroscopic physical properties due to particle size reduction is called the small size effect. For ultrafine particles, the size becomes smaller and the specific surface area increases significantly, resulting in a series of novel properties as follows. The study found

that tubular structure carbon nanomaterials (MWCNTs) and onion-like carbon nanomaterial (MWCNO) in the same dose and in the same size range showed different toxic effects and mechanisms on human fibroblasts. MWCNTs cause a strong immune and inflammatory response from fibroblasts in the human skin, while MWCNO is a genetically induced response of fibroblasts to external stimuli [13]. The cytotoxicity of single-walled carbon nanotubes (SWNTS), multiwall carbon nanotubes (MWNT10), and fullerene (C60) to alveolar macrophages was then compared; its cytotoxicity from strong to weak isSWNTS > MWNT10 > C60; for SWNTS concentration of $11.30 \, \mu g/cm^2$ at a concentration of $22.6 \, \mu g/cm^2$, there was significant cytotoxicity, while for C at a concentration of $226 \, \mu g/cm^2$, there is still no significant cytotoxicity [14]. It has also been reported that surface-derived treatment of C60 reduces nanotoxicity to human epidermal cells (HDFs) by 100,000 times, showing that chemical modification can reduce the negative biological effects of nanomaterial.

At present, there is no unified international evaluation criterion on the biological stability of nanomaterial [15].

Nanomaterial can interfere with endogenous metabolism or signal transduction pathways in a very weak way, thus disrupting the biochemical function of cells, and the results are difficult to show in short-term toxicity analysis. Therefore, when evaluating the biological efficacy of nanomaterial using short-term or subchronic experiments, a representative in vivo or in vitro environment should be used, a negative and positive control group should be set up, and the entire experimental process should be calibrated [16].

2.2. Methods on Nanocomposite Materials in the Sports Industry

(1) Factor analysis and spatial effects

Factor analysis is an analytical method that uses the idea of "low dimension" to extract a few representative factors from many original variables [17]. The KMO test statistic is an indicator used to compare simple and partial correlation coefficients between variables. It is mainly used in factor analysis of multivariate statistics, which can also be used to study the similarity between variables in multifactor analysis. The mathematical concept of KMO test statistics is as follows:

$$\text{KMO} = \frac{\sum\sum_{m \neq n} t_{mn}^2}{\sum\sum_{m \neq n} t_{mn}^2 + \sum\sum_{m \neq n} u_{mn}^2}, \quad (1)$$

where t_{mn} is a simple correlation coefficient between a variable a_m and a_n other variables, u_{mn}, and a partial correlation coefficient between a variable and a variable that a_m controls the a_n remaining variables. As can be seen from the formula (1), KMO statistics range from 0 to 1. The closer the KMO value is to 1, the stronger the correlation between the variables, and the more suitable the original variable is for factor analysis [18]. The closer the KMO value is to 0, the weaker the correlation between the original variables, and the less suitable the original variable is for factor analysis [19].

Once the KMO test has passed, factor analysis is possible. The mathematical model of factor analysis is as follows.

With the original g variables, $L_1, L_2, L_3, \cdots, L_g$, and all of which have been standardized, each variable can be $i(i < g)$ represented by a linear combination of $D_1, D_2, D_3, \cdots, D_i$ factors, as follows:

$$\begin{cases} L_1 = k_{11}D_1 + k_{12}D_2 + \cdots + k_{1i}D_i + \omega_1, \\ L_2 = k_{21}D_1 + k_{22}D_2 + \cdots + k_{2i}D_i + \omega_2, \\ \cdots \\ L_g = k_{g1}D_1 + k_{g2}D_2 + \cdots + k_{gi}D_i + \omega_g. \end{cases} \quad (2)$$

Formula (2) can also be expressed as a matrix, $L = KD + \omega$, where D is a common factor; K is a load matrix of factors and is a factor load, $k_{mn}(m = 1, 2, \cdots, g; n = 1, 2, \cdots, i$ representing the first m load of the original variable on the nth common factor; ω is a special factor, which is the part of the

original variable that cannot be interpreted by the public factor, with an average value of 0.

Then, construct the weight function, mainly by using the variance contribution rate of each common, and then, get the comprehensive evaluation function; the formula is as follows:

$$D = \sum_{m=1}^{e} \sigma_m D_m, \quad (3)$$

where $\sigma_m = \varphi_m / \sum_{m=1}^{e} \varphi_s$ indicates the weight of the ith measurement factor.

Spatial relevance is when a region's behavior or phenomenon affects an adjacent region; i.e., features with similar behavior or phenomena are spatially brought together [20]. Therefore, there is a functional relationship d between the observation variable of the ith w_{tm} space observation unit and the observation variable of its adjacent region. Its general expression is

$$w_m = d(w_1, \cdots, w_{m-1}, w_{m+1}, \cdots, w_t) + \omega_m, \quad m = 1, \cdots, t, \quad (4)$$

in the formula, representing ω_m random interference items.

Spatial structure heterogeneity, also known as spatial structure inconsistency and spatial structure differences, is determined by the spatial structure measurement mode of the second main source of spatial structure efficiency [21]. Spatial heterogeneity shows the characteristics of events or phenomena in different regions of the space environment [22]. Spatial heterogeneity can be expressed as

$$q_a = g_a(p_a, \varphi_a, \sigma_a). \quad (5)$$

a represents the space observation unit, $a = 1, \cdots, i$. g_a is the function relationship between q_a-dependent variables and p_a arguments, parameter variables, φ_a and random interference items σ_a.

Typically, a linear relationship is described as follows:

$$q_a = P_a \varphi_a + \sigma_a \quad (6)$$

in formula represents the P_a vector used to interpret the variable, represents the parameter vector that the φ_a explanatory variable has an effect q_a, is the q_a explanatory variable that represents the observation of a region, and is a random σ_a interference term.

Global spatial self-correlation can measure the self-correlation between regions in the overall research space. Common domain-wide spatial self-correlation metrics are Global Moran's I statistics, assuming a vector, described as follows:

$$I = \frac{\sum_{a=1}^{m}\sum_{b=1}^{m} u_{ab}(t_a - \bar{t})(t_b - \bar{t})}{\sum_{a=1}^{m}\sum_{b=1}^{m} u_{ab}\sum_{a=1}^{m}(t_a - \bar{t})^2} = \frac{\sum_{a=1}^{m}\sum_{b=1}^{m} u_{ab}(t_a - \bar{t})(t_b - \bar{t})}{D^2\sum_{a=1}^{m}\sum_{b=1}^{m} u_{ab}}. \quad (7)$$

m is the total number of regions in the study area, the u_{ab} spatial weight; t_a and t_b are the properties of regions a and b,

respectively; $\bar{t} = (1/m)\sum_{a=1}^{m} T_a$ is the average of the property; $D^2 = (1/m)\sum_{a=1}^{m}(t_a - \bar{t})^2$ is the variance of the property.

When the Global Moran I index is measured, it is also tested, usually using the X test the formula as follows:

$$X = \frac{M - F(M)}{\sqrt{U(M)}}. \tag{8}$$

Among them, $F(M)$ is the theoretical mean and $U(M)$ is the theoretical standard deviation.

Essentially, the Local Moran I index is a decomposition of Global Moran's I, a global spatial autocorrelation statistic. For the ith region, it takes the form of

$$I_a = \frac{m^2}{\sum_a \sum_b u_{ab}} \times \frac{(t_a - \bar{t})\sum_b u_{ab}(t_b - \bar{t})}{\sum_b (t_b - \bar{t})^2}. \tag{9}$$

The Local Moran I index is tested similar to the global index.

(2) Linear regression model in sport

In practice, there are often many factors that influence a phenomenon, so multiple regression analysis methods are often used to study the interaction between a variable and many variables [23]. In practical problems, the establishment of a multiple regression model can analyze complex problems in a diversified manner, making them easier to understand, so as to solve the problem. A multilinear regression model can be formed when there is a linear association between the resolved variable and the resolved variable. The usual form of a multilinear regression model is

$$y = \varphi_0 + \varphi_1 x_1 + \varphi_2 x_2 + \cdots + \varphi_n x_n + \delta, \tag{10}$$

where it is called a dependent variable and is called an $x_1, x_2, \cdots, x_n$ argument; $\varphi_1, \varphi_2, \cdots, \varphi_n$ is n plus 1 argument to be evaluated, is a constant, is φ_0 a regression parameter, and is a random $\varphi_1, \varphi_2, \cdots, \varphi_n \delta$ error.

The GWR model can be represented as

$$f_a = \partial_0(s_a, t_b) + \sum_{b=1}^{h} \partial_b(s_a, t_b)x_{ab} + \varphi_a, \quad a = 1, 2, \cdots, m. \tag{11}$$

(s_a, t_b) is the spatial coordinate of the first sample point, $\partial_b(s_a, t_b)$, and the bth regression factor of the a sample point is a random error φ_a term. For ease of expression, you can shorthand the above as

$$f_a = \partial_0 + \sum_{b=1}^{j} \partial_{ab} x_{ab} + \varphi_a, \quad a = 1, 2, \cdots, m. \tag{12}$$

If $\partial_{1b} = \partial_{2b} = \cdots = \partial_{mb}$, the GWR model then becomes a normal linear regression model.

Further, based on "data that is farther away from the observation data closer to position i has a greater impact on the estimate," the GWR model parameters can be estimated using weighted least squares:

$$\widehat{\partial}(s_a, t_b) = \left(C^E U(s_a, t_b) C \right)^{-1} C^E U(s_a, t_b) F, \tag{13}$$

where $\widehat{\partial}$ is the estimate of ∂, m is the number of spatial sample points, b is the number of arguments, U_{am}, and the position; a depiction model is given to the data point, the weight of m, which is the corresponding spatial $U(s_a, t_b)$ weight matrix.

How to select the appropriate threshold L is the key to the distance threshold method. The distance between data point b and regression point a is recorded as l_{ab} comparing the l_{ab} value to L; if l_{ab} is greater than L, the weight is 0, otherwise 1; the formula is as follows:

$$U_{ab} = \begin{cases} 1 & l_{ab} \le L, \\ 0 & l_{ab} > L, \end{cases} \tag{14}$$

where spatial relationships are measured by distance:

$$U_{ab} = \frac{1}{l_{ab}^{\alpha}}. \tag{15}$$

In the upper class, α is the appropriate constant, generally with a value of 1 or 2, which corresponds to the square of the distance countdown and the distance countdown, respectively.

The continuous monotony decreasing function is used to reveal the correlation between distance and weight, in which Gauss function method is a more common function; the specific formula is as follows:

$$U_{ab} = \exp\left(-\left(\frac{l_{ab}^{\alpha}}{k} \right)^2 \right). \tag{16}$$

k is a nonnegative attenuation parameter that illustrates the correlation between weights and distance coefficients and is also called bandwidth. It can be found by the formula sub (16); the larger the broadband k, the lower the rate of weight decay with the increase of distance. If the broadband k is smaller, the rate of weight decay increases as the distance increases, as does Figure 3 for the Gauss spatial right function.

In practice, data points that have little effect on regression parameters are usually cut off and do not participate in the calculation [24]. In this case, the Gauss function is replaced by a finite Gaussian function, which is the most commonly used method.

$$U_{ab} = \begin{cases} \left[1 - \left(\frac{l_{ab}}{k} \right)^2 \right]^2 & l_{ab} \le k, \\ 0 & l_{ab} > k. \end{cases} \tag{17}$$
Figure 3: Gauss space weight function.

Akaike also made improvements to the parameter estimation method of the greatly similar principle, and on this basis, a more general mode l selection criterion, namely, Akaike information criteria, is given. The AIC guidelines are defined as

$$AIC = -2lnH\left(\widehat{\delta}_H, x\right) + 2r. \tag{18}$$

Among them, $\widehat{\delta}_H$ is for a very similar estimate and r is the number of unknown parameters.

AIC guidelines are widely used in practice. In the early days, the AIC criterion was applied to nonparametric regression analysis to select smooth parameters, the formula being

$$AICc = 2mln\left(\widehat{\theta}\right) + mln(2\pi) + m\frac{m + tr(T)}{m - tr(T)}. \tag{19}$$

Here, AICc represents the "modified" AIC estimate and m is the size of the sample point, represents the standard distance between the random error term and the estimate, represents the trace of the GWRT matrix, and is a function of bandwidth. The value of the AIC can also be used to judge whether GWR modeling is better than OLS modeling.

To find out how to choose the best bandwidth method, cross-validation is recommended, which is based on local regression analysis, the formula of which is represented as follows:

$$CV = \sum_{a=1}^{m}\left[f_a - \widehat{f}_{\neq a}(m)\right]^2, \tag{20}$$

where $\widehat{f}_{\neq a}(b)$ is the sum value of f_a; i.e., the observation of point a itself is deleted when fitting. This way, when bandwidth m becomes very small, the model only fits near regression point a, included in bandwidth m. Sample points in the range do not include a itself [25]. The smaller the CV value, the better the model fits. In the actual calculation, in order to select the optimal bandwidth m and its CV value, you can select multiple bandwidths b at the calculation and measure their CVs separately value to find the best result. The application of carbon nanocomposite sensing and functional

magnetic nanomaterial in the sports industry is studied in Figure 4 [26–28].

3. Experimental Results of Carbon Nanocomposite Sensing and Functional Magnetic Nanomaterial in Biosecurity Research

3.1. Exploration of Nanosilver Composites of Different Particle Sizes and Concentrations in the Biological Field. In order to analyze the performance of nanocomposites from a biological point of view, this paper selects nanosilver composites to explore and study the effects of their different particle sizes and concentrations on the antibacterial properties of aspergillosis [29].

(1) Effects of different particle sizes on the antibacterial properties of Aspergillus AF289

Table 1 shows the results of the experiment showing the same concentration (12.12×10^{-5} mol/L) of nanosilver solution; at 10 nm to 40 nm, the antibacterial effect in the particle size range is very significant, especially 10 to 25 nm. Nanosilver antibacterial rate reached 80%, so the antibacterial effect on fungal spores under this particle size is most obvious.

(2) Effects of different particle sizes on the resistance of the drug-resistant bacteria Gra04 to aspergillation

In Table 2, experimental results show the same concentration (12.12×10^{-5} mol/L) of nanosilver solution; at 10 nm to 40 nm, the antibacterial effect in the particle size range is very significant, especially the nanosilver antibacterial rate of 10 to 25 nm that reached 80%, so the antibacterial effect on fungal spores is most obvious under this particle size.

(3) Effects of different concentrations on the antibacterial properties of aspergillosis AF293

As can be seen from Table 3, different concentrations of nanosilver have different antibacterial activities against AF293 of pentomycin. In experiments with the same particle size, nanosilver series dilution concentration, in the range of 2.02×10^{-5} mol/L to 16.16×10^{-5} mol/L nano-silver has a significant antibacterial effect, especially 8.08×10^{-5} mol/L and 4.03×10^{-5} mol/L. The bacteriostatic rate reached 100%, indicating that the growth of all fungal spores could be completely inhibited [30].

(4) Effects of different concentrations on the resistance of Gra04, a drug-resistant bacteria of aspergillation

In Table 4, the experimental results show that different concentrations of nanosilver have different antibacterial activities against the drug-resistant bacteria Gra04 of penicillin. In experiments with the same particle size nanosilver series dilution concentration, in the range of 2.02×10^{-5} mol/L to 16.16×10^{-5} mol/L, nanosilver has a significant

antibacterial effect, especially 8.08×10^{-5} mol/L and 4.03×10^{-5} mol/L. The bacteriostatic rate reached 100%, indicating that the growth of all fungal spores could be completely inhibited.

3.2. Performance Testing and Characterization of Nanocomposites. The tensile strength and thermal conductivity of PSA, MWNT/PSA, and DABP-MWNT/PSA composites are tested with electronic pullers and thermal coefficients, as shown in Figure 5.

As can be seen from Figure 5, the stretch strength of the decompression carbon nanotubes of DABP liquid crystal is more significant than that of the undefined carbon nanotubes. The maximum tensile strength of pure pressure-sensitive adhesive is 0.5048 MPa, and the pressure-sensitive adhesive nanocomposite is produced with MWNT and DAP-MWNT technology, respectively, and the maximum tensile strength of pressure-sensitive adhesive composites will be significantly increased due to the increase of nanoparticle concentration, and for DABP-MWNTs/under different nanoparticle contents, the tensile strength of the pressure-sensitive composite is greater than that of the MWNT/pressure-sensitive composite. When the MWNT content is 2 wt%, the DABP-MWNT/pressure-sensitive composites have a tensile strength of 14.19 MPa, which is greater than MWNTs. The 1.914 MPa of pressure-sensitive composites is approximately 641% higher than pure pressure-sensitive composites, approximately 27 times higher than pure pressure-sensitive adhesives. In the description of carbon nanotubes due to defects such as easy reunion and poor compatibility with pressure-sensitive adhesives, its excellent mechanics have been unachievable,

and the effect of improving the properties of pressure-sensitive adhesives is not obvious, and the carbon nanotubes have been functionalized by DABP liquid crystals because DABP and MWNTs combine to π-π interactions, the reunion of carbon nanotubes inhibited the dispersion, and compatibility of carbon nanotubes in pressure-sensitive adhesives is improved, which makes the dynamics of pressure-sensitive adhesive composites significantly improved [26]. In addition, if the concentration of nanoparticles is further increased, the pressure-sensitive adhesive complex required in the mold will not be formed, so the maximum concentration of nanoparticles in the pressure-sensitive adhesive complex that detects the dynamic properties is 2.0 wt%.

It can be found from the figure that the thermal conductivity of pure pressure-sensitive adhesives is only 0.1965 W/(m-K), which has been modified by MWNTs and DABP-MWNTs, and due to the increase in the concentration of nanoparticles, the thermal conductivity of pressure-sensitive adhesive complexes is further improved. Compared with carbon nanotubes that have not been functionalized by liquid crystals, DABP-MWNTs have a particularly strong effect on the thermal conductivity of pressure-sensitive adhesives. At various nanoparticle concentrations, the thermal conductivity of DABP-MWNT/pressure-sensitive adhesive composites is larger than that of MWNT/pressure-sensitive adhesive composites. This is due to defects such as the ease of reuniting of the carbon nanotubes themselves and poor compatibility with pressure-sensitive adhesives, which make their excellent thermal conductivity impossible, thus improving the thermal conductivity of pressure-sensitive adhesives without significant effect, but through
FIGURE 5: The influence of nanocomposite tensile strength and thermal conductivity.

FIGURE 7: The relationship between mechanical properties and filler content.

FIGURE 8: Chronoamperometry graph.

FIGURE 9: Differential pulse voltammograms.

tent of MWCNTs increases; as a result, the energy storage capacity of PDLA/PHA/MWCNT nanocomposites increases as well. When a platform appears in the low-frequency area of the energy storage module G' curve, it usually indicates the formation of a overseepage network. The energy storage modulus G' of PDLA/PHA mixture increases monotonically as the frequency of scanning increases, showing the end flow behavior of the viscous polymer melt. When the MWCNT content in PDLA/PHA/MWCNT nanocomposites is 0.6 wt%, the material appears in the low-frequency zone with energy storage modulus platform which indicates that the critical content of MWCNTs forming a network structure is 0.6 wt%. PDLA/PHA/MWCNT-g-PLLA nanocomposites show similar patterns of change. However, its rheological percolation content is lower, 0.4 wt%. The above results indicate that the rheological percolation network structure is the conductive percolation network structure.

Composite PHA in the material improves the brittleness of the PDLA while significantly reducing the tensile strength of the PDLA. It can be seen from Figure 7 that the tensile strength of PDLA/PHA blends increases with the increase of MWCNT content. When the content of MWCNTs increased from 0 wt% to 1.2 wt%, the tensile strength of PDLA/PHA/MWCNT and PDLA/PHA/MWCNT-g-PLLA nanocomposites increased from 32.1 MPa to 45.1 MPa and 50.2 MPa, respectively. However, there was no significant change in the fracture elongation of the two composites. It is worth noting that PDLA/PHA/MWCNT-g-PLLA nanocomposites are always more tensile than PDLA/PHA/MWCNT nanocomposites at the same filler content. This is because MWCNTs-g-PLLA is selectively dispersed in the substrate PDLA and has a large adhesion to the substrate's interface (building composites). The enhancement effect on the substrate is more significant. Based on the above discussion, the formation of MWCNT and MWCNT-g-PLLA networks can significantly enhance PDLA/PHA mixes, resulting in weak to strong transitions. In addition, this transition can be achieved by adding a small amount of MWCNTs-g-PLLA compared to MWCNTs. Once the nanofiller network is formed, the strength of the two nanocomposites will stabilize with the increase of nanofillers.

3.3. Stability of the Nanocomposite Modified Electrode.

The stability of nanocomposites as electrodes is one of the important parameters to measure the quality of sensors. Timing current method is a kind of electrochemical method related to the function between the measurement of voltage response and current duration. When time tends to be infinite, the voltage will also be closer to zero as the content of surface active substances in the high-voltage electrode decreases gradually with electrolytic time. In this paper, the stability of modified electrodes is studied by the timing current method, as shown in Figure 8.

In this paper, the stability of modified electrodes is studied by timing current in different concentrations of TNP solutions. As the concentration of the TNP solution increases, the response current page for the modified electrode increases, and the current gradually stabilizes after approximately 50 seconds of timing, indicating that the

DABP, the carbon nanotubes after the functionalization of liquid crystal have better dispersion and compatibility in the pressure-sensitive glue, which makes the thermal conductivity of the pressure-sensitive adhesive composite material improve greatly. When the content is 10 wt%, the thermal conductivity of the DABP-MWNT/pressure-sensitive composites reaches 0.4208 W/(m-K), which is MWNTs/1.1 times the pressure-sensitive glue, which is about 114% higher than the pure pressure-sensitive glue.

Rheological parameters such as storage modulus (G') are very useful in detecting the dispersion state of fillers, especially when forming the percolation network structure of anisotropic fillers. For PDLA/PHA/MWCNT and PDLA/PHA/MWCNT-g-PLLA nanocomposites at 180 degrees C in energy storage module G' and filler content, the graph of scan frequencies is shown in Figure 6. As can be seen from the figure, in the low-frequency region, MWCNTs tend to form a network structure in the PDLA substrate as the con-

FIGURE 10: Hydrogen evolution catalytic performance graph.

prepared nanocomposite modified electrode pair TNP has good stability and electrocatalytic activity.

In addition, we use DPV as shown in Figure 9.

We immersed NQS/GO GCE in a 1.0 mM potassium iron cyanide solution and then added creatine to the solution continuously and examined the electrochemical behavior of different concentrations of creatinine on the electrodes. It can be seen from the figure that with the increase of creatinine concentration in the solution, the peak current decreases gradually. This is mainly due to the ability of creatinine to react with NQS on the electrode surface, causing the electrode surface to change, resulting in a gradual decrease in peak current.

The electrodeposition parameters, especially the sedimentary current density, have a significant effect on the hydrogenic catalytic properties of Co/CoP-NF catalysts. The catalysts produced were named Co/CoP-NF-2, Co/CoP-NF-5, and Co/CoP-NF-8. Figure 10 describes the hydrogenic catalytic properties of Co/CoP-NF-2, Co/CoP-NF-5, and Co/CoP-NF-8 catalysts. Obviously, the Co/CoP-NF-5 catalyst showed the highest hydrogenic catalytic activity, the hydrogen-based catalysis of Co/CoP-NF-8 was moderate, and the hydrogen-analysis catalysis of Co/CoP-NF-2 was the worst. The values of switching current density and hydrogen analysis performance are shown in Table 5, from which the Co/CoP-NF-5 catalyst has the highest exchange current density, further demonstrating that it has the highest hydrolytic catalytic activity.

4. Discussion

It is well known that nanosilver has a good killing property, against bacteria, fungi, mold, and other pathogens. Therefore, we have studied the nanosilver experiment to kill smoke and mold. Experimental results show that at concentrations of 4.04×10^{-5} mol/L, nanosilver-to-smoke mold with a particle size of 10 to 15 nm (drug-resistant and wild strains) is better killed. Therefore, nanosilver has a great prospect in the killing treatment of drug-resistant strains. In addition, nanosilver sterilization is likely caused by nano-

TABLE 5: Co/CoP-NF catalyst HER performance parameters under different deposition current densities.

Deposition current	n_{10} (mV)	n_{100} (mV)	b (mV)	j_0 (mV)
0.3	81	209	101	1.69
0.6	38	129	69	2.99
0.9	39	171	102	2.79

silver damage to the integrity of the cell wall and cell membrane, resulting in the outflow of material from the cell. However, the most critical issue for nanosilver particles is biosecurity. It is now known that nanosilver is indeed toxic, so it is urgent to find the right dose and concentration of sterilization that are harmless to humans. At the same time, based on the mechanism of a pronuclear replacement reaction between organic matter NQS and creatine, a new method of creatine coloric testing based on NQS/GO nanocomposites is established. The sensing mechanism is proved by UV-vis and electrochemical techniques. Experimental results show that NQS can be combined with GO through π-π and can effectively improve the effectiveness of color detection. The absorbance of solvents and the added creatinine content has a good linear relationship within the specified content range. Direct visual sensing methods are simple, fast, sensitive, economical, and selective, so we do not need some sophisticated analytical instruments to achieve rapid detection. It provides an important reference for the detection of biomolecules in clinical medicine and disease early warning and a new method for exploring the principle of visual sensors.

5. Conclusions

Using the thermal conductivity factor instrument, the thermal conductivity of PSA, MWNT/PSA, and PHBE-MWNT/PSA composites was detected, and the results showed that after the transformation of MWNTs and PHBE-MWNTs, the thermal conductivity was increased,

and the thermal conductivity of pressure-sensitive adhesive composites was significantly improved due to the increase of nanoparticle concentration. Compared with nanotubes that have not been functionalized by liquid crystals, PHBE-MWNTs have improved their thermal conductivity in pressure-sensitive adhesives. This is due to the fact that PHBE and MWNTs can be combined with π-π interactions, inhibiting the unification of carbon nanotubes and improving their dispersion and compatibility in pressure-sensitive glues, which makes the thermal conductivity of pressure-sensitive composite materials significantly improved. When the content is 10 wt%, the thermal conductivity of the PHBE-MWNT pressure-sensitive composite material is 0.6975 W/(m·K), which is MWNTs 1.8 times the pressure-sensitive glue, which is about 255% higher than the pure pressure-sensitive glue. At the same time, the effects and antibacterial mechanisms of nanosilver on the antibacterial effects of the drug-resistant bacteria Gra04 of aspergillosis AF293 and aspergillosis were studied. The nanosilver produced in this paper has excellent sterilization effects on both AF293 and Gra04. In particular, 8.08×10^{-5} mol/L and 4.03×10^{-5} mol/L nanosilver has a 100% bacteriological rate of both, indicating that the growth of all fungal spores can be completely inhibited. Through DIC microscope observation, nanosilver causes protein denaturation by destroying the proteins in spores, further causing the rupture of cell walls and cell membranes.

The catalytic effect of nano-HZSM-5 zeolite on co-pyrolysis of cotton shell (CS) and municipal plastic wastes (MPW) was studied. The influence of reaction temperature during individual pyrolysis, blending ratio, and catalytic effects was studied by applying constant heating rate. The experiments were conducted in a fixed bed batch type reactor. The hindering effect during catalytic decomposition of MPW was carried out and its positive synergistic effect on liquid oil yield was analysed. The reaction temperature for all the experiments are fixed based on the decomposition rate obtained from thermogravimetric study. The experimental outcomes revealed that during co-pyrolysis, the formation of char was reduced to 7.2 wt% with increased liquid oil yield of 66.5 wt%. Furthermore, adding catalyst for co-pyrolysis process improved the reaction by decreasing char formation. During catalytic process, the maximum liquid oil output was 69.3 wt% at 500°C temperature, CS/MPW ratio of 1 : 2. When compared to co-pyrolysis process, the catalytic co-pyrolysis showed 4.21 wt% higher liquid oil yield. The physical analysis of the oil shows maximum hating value of 34.6 MJ/kg. The FTIR study on catalytic co-pyrolysis oil shows the presence of aliphatic and aromatic hydrocarbons.

1. Introduction

The increased energy demand and rapid industrialisation due to the population and modern lifestyle force researchers to find alternative sources for conventional fuels. According to the survey conducted in the middle of 2020, the need for global energy is expected to increase by 30% over the next two decades in order to sustain rapid urbanisation [1]. Every

living being requires a healthy atmosphere in order to thrive and develop. One of the biggest issues is the degradation of ecosystems caused by the discharge of inorganic and organic pollutants from various industries and automotive engines [2, 3]. There has been considerable demand around the world to investigate the production and use of biofuels for heat and power applications [4]. Fossil fuels have played a major part in satisfying current energy demands, but their

widespread usage has aggravated serious environmental challenges, including global warming. Utilising biofuels for power production has increased nowadays due to flexible conversion methods and increased fuel properties. It is an alternative energy source that can replace fossil fuels by up to 30% to 40% in the near future [5]. The augmented solid waste output by the growing population provides carbon-rich energy resources and gives a widespread option for the production of energy. This could also help with the waste disposal problems.

Biomass is generally classified as virgin biomass, waste biomass, or agricultural residues. It can be converted into energy-rich fuels through various conversion processes. Lignocellulosic biomass obtained from agricultural wastes is a carbon-free renewable energy source and is an excellent resource for biofuels and chemicals [6]. The basic elements of biomass are categorised as cellulose, hemicelluloses, and lignin (20–30%). Cellulose comprises the major part of the total components (about 40 to 45%). Apart from this, some amounts of extractives, hydrocarbons, and inorganic components are also present. Matured agricultural wastes, commonly called as agro-wastes, are the end product of any agricultural process. The safe disposal of these residues is a challengeable one without affecting environmental sustainability. Due to agricultural activities, the quality of land waster and water bodies is being affected much. Pesticides used to meet global agricultural demand are the primary source of water and soil pollution [7]. These pesticides contaminate water through rain and irrigation systems [8]. In order to remove these contaminants from the body of water, Wabaidur et al. [9] and Alothman et al. [10] utilised absorption techniques through multiwalled nanocomposite and biosorbents. These wastes are typically burned in the open field after harvesting, and this practice is becoming more common, resulting in increased air pollution [11, 12]. The burning of agro-residues on farms is currently a substantial contributor to global warming [13]. As a result, policymakers are now tasked with identifying the best solution to address the aforementioned issues by effectively utilising agricultural wastes to generate clean energy. Converting solid waste into value-added products is a step towards a sustainable world [14]. Pyrolysis has become a popular technology due to its faster reaction time, low energy consumption, and generation of solid carbon-rich fuel as well as value-added liquid products. Khan et al. [15] developed a hydrochar by utilising sesame oil cake through hydrothermal carbonisation conducted at a temperature of 150–250°C. The produced hydrochar was utilised for the adsorption of metal ions from water. Alqadami et al. [16] developed citric anhydride anchored mesoporous metal organic framework to absorb nonessential lead (Pb) trace elements from water. Cotton shell (*Gossypium arboretum*) often known as tree cotton. It is one of the most important crops that plays a significant role in India's economic development. It is cultivated on a wide range of soils, such as black clayey, red soil, and black and mixed black soil. Cotton seeds are extracted and used to make high-viscous oil. The pressed oil is used for burning and biofuel production. Nabi et al. [17] produced cotton seed oil methyl ester and utilised for

IC engine operation. This study showed lower exhaust gas emissions, except for NOx.

Plastics are the materials produced from fossil fuels that have become an integral element of modern life. They are more durable, weigh less, and have a lower cost. Many plastics are made from polyethylene (PE), polypropylene (PP), polystyrene (PS), polyvinyl chloride (PVC), and polyethylene-terephthalate (PET) [18]. They are nonbiodegradable and can endure for more than a hundred years. The global rate of waste plastics has been increasing rapidly for the past two decades. In India, over 3.4 million tonnes of plastic waste were generated in the financial year 2020, an increase of more than 1.0 million tonnes compared to 2018. In Tamil Nadu, plastic waste generation is around 0.43 million tonnes per annum, of which 0.4 million tonnes are collected and segregated by the local urban bodies. Used plastics are generally recycled to produce new and useful products. When recycling is done properly, it can reduce the dependence on landfills and conserve resources. But at present, only 15–20% of total plastic waste can be recycled using traditional sorting and grinding [19]. The process of energy recovery from used plastics is an alternative way and is gaining more attention nowadays. There are many innovative and promising methods available today that can convert waste plastics into fuels and other valuable resources.

Incineration and pyrolysis are the two main processes that are being utilised for energy recovery from plastics in many studies [20, 21]. Incineration is a simple energy recovery process that converts hydrocarbons to combustion products. Incinerating plastic waste creates environmental pollution. Burning in an open field or in a controlled environment emits poisonous gases which is very dangerous to all living organisms [22]. Pyrolysis is an effective technique that converts plastic waste into energy-rich liquid oil. It is a thermal decomposition method that is performed without supplying air. Pyrolysis is a temperature-dependent process that is generally performed at a low, medium, or high temperature to break the structure [23]. Co-pyrolysis is another technique that produces synthetic liquid fuel with improved properties. It is also a very effective method of utilising two or more dissimilar feedstocks. Many reports have reported the maximum liquid oil yield through the co-pyrolysis process. Co-pyrolysis of plastics with agricultural waste is directed towards synergistic effects that possibly improve the favourable properties of the products [24]. Burra and Gupta [25] conducted a co-pyrolysis experiment utilising pinewood and mixed plastic wastes under different mass fractions. The study showed positive synergistic effects compared with individual components. The study carried out by Johansson et al. [26] showed the maximum production of hydrocarbons during co-pyrolysis. In this study, the addition of plastic waste to woody biomass significantly affected the product composition. Jin et al. [27] examined the synergetic effect during co-pyrolysis of wheat straw and plastic waste. The study also showed a positive synergistic effect on char yield. Oyedun et al. [28] demonstrated the quantity and properties of char and oil with respect to the amount of plastic during the co-pyrolysis process. Dewangan et al. [29] conducted co-pyrolysis studies on combined LDPE and

sugarcane bagasse. The study produced maximum liquid oil with 40 MJ/kg heating value.

In order to improve the quality of liquid oil, a large variety of nanobased catalysts are utilised. Many studies have reported catalytic pyrolysis processes with various catalysts, for instance ZSM-5 [30], HZSM-5 [31], zeolite [32], Cu-Al$_2$O$_3$ [33], and Fe$_2$O$_3$ [34]. These catalysts lower the energy inputs and increase the condensable liquid oil. Zhang et al. [35] conducted pyrolysis experiments on Douglas fir sawdust and HDPE in the presence of ZSM-5 catalysts. From the experimental results, it was understood that adding the HZSM-5 catalyst could decrease the activation energy. Copyrolysis of macroalgae and HDPE was done by Xu et al. [36] to analyse the synergistic effect towards enhanced biofuel production. This process showed that the catalytic process lowered the oxygen, nitrogen, and acid levels in the derived bio-oil. Furthermore, adding HZSM-5 with the feedstocks increased the reaction pathways and biofuel production as well as lowered the activation energy.

The goal of this work is to investigate the synergistic effects of agricultural residues and plastic during the co-pyrolysis process in the presence of HZSM-5 nanocatalysts. The synergistic effect on liquid oil yield was analysed using a batch type fixed bed reactor. The liquid oil yield and its compositions during thermal, co-pyrolysis, and catalytic co-pyrolysis were analysed based on synergistic effects.

2. Materials and Methods

2.1. Materials. CS and MPW were used for this study to analyse probable synergistic effects during their co-pyrolysis. The cotton shell used for this study is a typical lignocellulosic biomass and was collected from the local fields in and around Coimbatore. The city is generally called the cotton city of the state. The city has more than 100 spinning mills and produces a variety of cotton fabrics. The feedstocks for these industries are supplied by nearby agricultural farms. The climate in and around the city is more suitable for the cultivation of cotton. After eliminating cotton from the shells, they were thrown away and fired into the field itself. The open burning of these shells causes a severe effect on the environment. In order to avoid this and to find a suitable recycling method, this study focused on the utilisation of CS for the pyrolysis process. The municipal plastic wastes contains majority of PE, HDPE, and PET materials. Both the materials were completely screened and dried in the open sunlight for more than 15 days. They are converted into small particles with an average diameter of 0.5 mm to 1.0 mm. The elemental analysis of both the materials was analysed to find its suitability for the pyrolysis process. The proximate analysis was done to measure the volatile matters within it. All the analysis was performed by following ASTM protocols. Table 1 shows the proximate and ultimate analysis of the feedstock materials.

2.2. Thermogravimetric Analysis. Thermogravimetric analysis of the selected feedstock was performed to find thermal degradation properties using the TGA701 (LECO Corporation, St. Joe, Michigan, US) thermogravimetric analyser.

TABLE 1: Feedstock characteristics.

Parameters	CS	MPW
Proximate analysis (wt%)		
Volatile matter	61.60	89.40
Fixed carbon	26.06	0.42
Moisture content	9.52	0.35
Ash	2.81	9.83
Ultimate analysis (wt%) (ash free basis)		
Carbon	46.02	82.20
Hydrogen	4.91	15.65
Nitrogen	0.60	2.40
Oxygen[#]	48.46	0.30
Sulfur	0.01	1.45

[#]By difference.

The test was carried out in a nitrogen environment and its volume flow rate was maintained at 3.5 l/min. The dehydration and devolatilisation were done at the heating rate of 20°C/min. Before heating, the feedstocks were dried at 100°C. The analysis was done by heating the sample from atmospheric conditions to 600°C. For the analysis, 10 mg sample is loaded into the crucibles.

2.3. Material Characterisation. The collected feedstock material was subjected to proximate and elemental analysis. The 2400 CHNS Organic Elemental Analyzer (N2410650, Perkin Elmer Ltd, US) is employed to find the elements present in the samples. The same instrumentation is also used for liquid oil analysis. The FTIR analysis of the obtained liquid oil through catalytic co-pyrolysis was done with the aid of a FTIR (BRUKER Optik GmbH, TENSOR 27 Bruker Corporation) spectrophotometer with the support of OPUS version 6.5 in transmission mode. The analysis was done by collecting the spectrum between 400 and 4000 cm^{-1} with 4 cm^{-1} resolution. After the sample was disseminated over zinc selenide crystal, the spectrum was obtained in reflectance mode. The physical analyses of the liquid samples were investigated to determine their applicability for various uses. The physical properties of the oil were done in accordance with ASTM standards. Many physical characteristics such as density, kinematic viscosity, flash point, heating value, and pH value were considered for this analysis. The individual and catalytic pyrolysis oils used for physical analysis were collected under experimental conditions that yielded higher liquid oils.

2.4. Reactor Facility. Individual and co-pyrolysis experiments were performed using a batch type laboratory scale fixed bed reactor. The internal diameter and height of the reactor are 50 mm and 150 mm, respectively. The set-up consists mainly a reactor with an electrical heater, a condenser, and a liquid collection unit. The reactor is perfectly insulated with Mineral-Chromel and Alumel to avoid energy loss during pyrolysis. The temperature of the reactor is controlled by the PID controller and auto transformer. The temperature inside the reactor was measured by using K type
Figure 1: TGA analysis of CS and MPW.

thermocouples fixed at two locations inside the reactor. Once the reactor reached the desired temperature, it was maintained stable by auto cut-off unit. The outlet of the reactor pipe is connected to the series of two condensers. The ice water supplied to the condenser is kept at 5°C. The condensed liquid obtained from the condenser was collected in conical flasks and stored separately for further analysis. At the end of each experiment, the char was collected from the bottom of the reactor and weighed using an electronic weighing machine. The liquid oil obtained from the reaction was also collected and weighed. The weight percentage of uncondensable gas fractions was found by the remaining material balance.

2.5. Experimental Procedure. The effect of thermal, co-pyrolysis, and catalytic co-pyrolysis on liquid oil yields was investigated by four different phases. In the first phase, the thermal pyrolysis of CS was examined by changing process temperature from 350°C to 550°C. In the second phase, the thermal pyrolysis of MPW was also conducted by changing the temperature from 350°C to 550°C. The aim of the second phase is to find the optimum temperature for maximum liquid oil yield and the impact of process temperature on biofuel yield. The next phase of experiments was conducted on co-pyrolysis by changing the biomass and plastic blend ratios to 1:0, 2:1, 1:1, 1:2, and 0:1 at 500°C. The fourth phase of the experiments was carried out on catalytic co-pyrolysis at 1:2 blending ratio (biomass to plastic) by utilising HSZM-5 nanocatalysts supplied by Sri Aathi Vinayaga Industries, Tamil Nadu, India, to find the synergistic effect on liquid oil production.

3. Results and Discussions

3.1. Thermogravimetric Analysis. Figures 1 and 2 show the TGA and differential thermogram (DTG) of a CS and MPW. In the case of CS, there were no volatiles released

until it reached 200°C. According to d'Almeida et al. [37], the biomass is stable till it reaches 200°C, with negligible weight losses. This stage represents the drying and removal of extractives. The rapid pyrolysis occurred between 290°C and 450°C. The weight loss below 290°C represents the desertion of water molecules from CS. The first and second peaks developed in the experiment due to hemicellulose and cellulose breakdown [38]. Generally, decomposition of hemicelluloses into acetic acid, furfural, and furan occurs at temperatures between 200 and 260°C. The slow degradation rate after 420°C represents the breakdown of lignin. It is the main reason for the formation of phenolic compounds in the pyrolysis products [39]. The differences in thermal behaviour between CS and MPW in TGA analysis occur due to molecular arrangement and degradation rate. The degradation MPW occurs in single step between 340°C and 540°C. Comparing with biomass, the degradation of plastics takes place at elevated temperatures. MPW begins to degrade structurally at around 260°C. The single peak noticed in both the curves represents the weight loss owing to the temperature increase. At 350 to 500°C, the maximum degradation occurred (81.5%). Girija et al. [40] also represented the single stage degradation of PET material. It is also very difficult to explain the thermal disintegration mechanism of plastics due to their aromatic nature.

3.2. Thermal Pyrolysis of Cotton Shell. Figure 3 depicts the product distributions of the thermal pyrolysis of CS samples under different operating temperatures. The results reveal that when the pyrolysis temperature is increased, the char yield is reduced. This is owing to increased primary breakdown at higher temperatures [41]. The abrupt increase in gas fractions and the reduction in liquid oil products have been noticed as the temperature increased above 450°C. This could be due to secondary reactions of the pyrolysis liquid into noncondensable gases at elevated temperatures [42]. The results are also in good agreement with the previous
FIGURE 2: DTG analysis of CS and MPW.
FIGURE 3: Product distributions during pyrolysis of CS.

literature conducted on different biomass materials such as rapeseed and soybean cake [43, 44]. The yield of liquid oil is lowered at lower temperatures and increased with increasing temperatures. The increased decreased pattern of the liquid oil yield with increased temperature is due to the higher decomposition of condensable volatiles at 450°C. The liquid oil production reached maximum at 450°C (36.6 wt%). With increasing temperatures, the yield of gas fractions also increases. At 350°C, the gas yield is 33.2 wt% and at 550°C, it reaches the maximum value up to 44.9 wt%. In most cases, the lower pyrolysis temperature favours a higher char yield and the higher temperature promotes gas yields. The same trend is also observed in the flash pyrolysis of CS [45].

3.3. Thermal Pyrolysis of Municipal Plastic Wastes.
Figure 4 demonstrates product distributions during the thermal pyrolysis of MPW at various temperatures. In this study, the yield of char products decreased with increased temperature. At 550°C, the char production is only 3.3 wt%. The reduction in char yield is attributed to secondary repolymerisation reactions [46]. When the temperature is changed from 350°C to 550°C, the yield of liquid oil changes from 62.4 wt% to 69.4 wt% and the maximum yield is recorded as 70.6 wt% at 500°C. The higher temperature of the reactor increases the gas yield and reduces the char production. When compared to biomass, the pyrolysis of plastics yields more liquid oil due to its structure. In plastic pyrolysis process, the stability of the benzylic radical favoured unzip
FIGURE 4: Product distributions during pyrolysis of MPW.
FIGURE 5: Product yield at different blend ratio.

reaction and restricted further cracking process. As a result, the main product of plastic pyrolysis was liquid oil.

3.4. Co-pyrolysis at Different Blend Ratio.

Figure 5 demonstrates product distributions during co-pyrolysis of CS and MPW under different blend ratios. The figure shows increased liquid oil production with respect to the increased amount of plastics in the feedstock. The aim of the experiments in this phase is to produce high-quality and large-quantity liquid oil. The liquid oil yield is increased to 66.5 wt% at 1 : 2 ratio. The increased yield at higher percentage of plastics in the feedstock is attributed to the presence of higher levels of hydrogen in the feedstock [47, 48]. During the co-pyrolysis process, polyolefin polymers in the plastics

can act as perfect hydrogen donors, resulting in higher oil production [49]. While biomass is reacting with plastics, a number of reaction radicals can be created. These radicals interact and favour the production of liquid oil without phase separation. A considerable increase in pyrolysis liquid output has been reported by many researchers, indicating synergistic impact [50, 51]. Furthermore, the reduction of char was found as the plastic ratio increased, indicating a higher degree of conversion.

3.5. Catalytic Co-Pyrolysis Process.

For the catalytic process, 30 grams of blended feedstock (1 : 2-CS:MPW) was mixed thoroughly with the catalyst (10% wt%/wt% of feedstock) and kept in the reactor. The temperature throughout this
Figure 6: Comparison between catalytic and noncatalytic co-pyrolysis process.

Table 2: Physical characterisation of liquid oils.

Type of oil	Density in kg/m^3	Viscosity in cSt	Flash point in °C	pH	HHV in MJ/kg
CS pyrolysis oil	1005	7.7	160	3.4	17.65
MPW pyrolysis oil	935	2.6	95	6.2	41.6
Co-pyrolysis oil	980	5.7	110	4.8	34.1
Catalytic co-pyrolysis oil	980	5.6	105	4.6	34.6

phase of experiments is kept at 500°C. Figure 6 evaluates the yield of liquid oil, char, and gas obtained from co-pyrolysis and catalytic co-pyrolysis processes. From the figure, it can be understood that the catalytic co-pyrolysis process yields more liquid products than the co-pyrolysis process. At co-pyrolysis, the maximum liquid oil production was 66.5 w%. But through catalytic co-pyrolysis, the production of liquid was enhanced to 69.3 wt%. The catalytic process increased the yield by up to 4.21%. The increase in liquid oil production and the reduction in char residue showed a beneficial synergy between CS and MPW. The reaction between the catalyst and feed materials is quite complicated due to the complex structure of the materials [52]. But the main reason for the positive synergy effect on liquid yields is the relationship between biomass and plastic-derived olefins [53]. In the presence of the catalysts, it was found that the oxygenated components could react with olefins. Furthermore, it has also been shown that plastic-derived hydrocarbons can perform as hydrogen donors for biomass-derived oxygenates, reducing the formation of char in catalytic conversions [54].

3.6. Characterisation Study

3.6.1. Physical Analysis of Liquid Oils. Table 2 represents the physical characterisation of liquid oils obtained from this study. The table shows some of the basic fuel properties.

Table 3: Comparison of heating value of the liquid oils.

Source	Value in MJ/kg	Reference
MPW	41.6	This study
CS and MPW	34.6	This study
Napier grass	19.79	[55]
Pine seed	20.00	[56]
Ficus religiosa	18.30	[57]
Spirulina platensis	25.70	[59]
Hard wood	18.63	[60]
Palmyra fruit bunch	13.92	[61]

When compared with CS pyrolysis oil, the co-pyrolysis oil offers a higher heating value. The density of MPW pyrolysis oil was found to be lower than other pyrolysis oils. The heating value of the individual MPW oil is higher than other oils due to the absence of oxygenated elements. The comparison of MPW pyrolysis oil, co-pyrolysis oil, and bio-oil obtained from other samples is provided in Table 3. From the table, it can be understood that the MPW pyrolysis oil has a higher HHV than co-pyrolysis oil. The presence of lower oxygen molecules in the bio-oil is the main reason for the increased heating value. The addition of wood-based lignocellulosic material with plastic waste reduced the heating value to 34.6 MJ/kg. Furthermore, individual biomass pyrolysis oils
FIGURE 7: FTIR spectra of catalytic co-pyrolysis oil.

showed lower heating values than co-pyrolysis oils due to a higher fraction of oxygenated elements in the feedstock materiel. The pH value of the co-pyrolysis and catalytic pyrolysis oils is moderate in the range of 4.6-4.8. It is a representation of the corrosiveness of the oil. The value of pH indicates that the bio-oil has less corrosive properties than other bio-oils produced from other biomass materials [55–57]. Acids in the pyrolysis oils are mostly caused by the breakdown of hemicellulose present in the biomass material. The pyrolysis oil typically has a pH value of between 3 and 6 [58]. The lower pH value is naturally corrosive to steel, aluminum, and nickel-based materials.

3.6.2. FTIR Spectra. The FTIR spectrum of liquid oil obtained from the catalytic process derived at maximum yield conditions is shown in Figure 7. From the obtained spectra, it can be confirmed that the liquid oil is a combination of water, phenolic compounds, aromatic compounds, acids, alkenes, and nitrogenated elements. The existence of water and phenolic compounds in the oil is identified by O-H stretching vibration at 3200-3600 cm^{-1}. The same compounds were discovered and reported in the literature [62, 63]. The existence of aliphatic hydrocarbons is specified by C-H stretching and bending vibrations at 2900-3000 cm^{-1} and 1300-1450 cm^{-1}. The existence of alkenes is identified by the peak obtained at 675-900 cm^{-1}.

4. Conclusion

In this work, the synergistic effect of catalytic co-pyrolysis of cotton shell and municipal plastic wastes on liquid oil yield was analysed. The four-phase experimental study showed higher liquid oil yield during the catalytic co-pyrolysis process. During catalytic pyrolysis, a positive synergistic effect on liquid oil production was identified with reduced char

production. During the co-pyrolysis process, polyolefin polymers in the MPW act as perfect hydrogen donors, resulting in higher liquid oil products than biomass pyrolysis oil. On the other hand, the catalytic co-pyrolysis process increased the yield by up to 4.21% more than the co-pyrolysis process because of its positive synergistic effect. The relationships between biomass-derived oxygenated compounds and plastic-derived olefins were the main reason for the positive synergy effect. By the catalytic co-pyrolysis process, the maximum liquid oil yield of 69.3 wt% was acquired at 500°C with a CS/MPW ratio of 1 : 2. The physical analysis of the oil obtained at the maximum yield condition shows 34.6 MJ/kg. The obtained liquid oil can be tested as an alternative fuel for boilers and IC engines. Further research is also possible on kinetic studies of noncatalytic and catalytic pyrolysis reactions.

Retraction

Retracted: Athletes' Ankle Injury Features and Rehabilitation Methods Based on Internet Big Data

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

In addition, our investigation has also shown that one or more of the following human-subject reporting requirements has not been met in this article: ethical approval by an Institutional Review Board (IRB) committee or equivalent, patient/participant consent to participate, and/or agreement to publish patient/participant details (where relevant).

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

With the development of science and technology and the improvement of living standards, people are paying more and more attention to sports and health. However, the foot joints are very important joints in the human body and are one of the most vulnerable parts in sports. Foot joint sprain is a common clinical disease in orthopedics, accounting for the first place of joint ligament sprain. If the treatment is not timely or appropriate, it often leaves pain and joint instability, followed by osteoarthritis. The rate of repeated injuries after the first injury is very high. Due to the rapid development of visual sensing technology, computer technology, and image processing technology, Internet big data has been widely used in food, medical treatment, construction, chemical industry, electronics, packaging, automobile, and other fields. This article mainly studies the characteristics and rehabilitation methods of athletes' ankle injuries based on Internet big data. Based on Internet big data, this paper studies the function and structural stability of the foot joints and analyzes the causes of gymnast foot joint injuries. On this basis, this paper puts forward the treatment method of ankle joint injury. In this paper, 20 male competitive bodybuilders with ankle joint injury on one side were randomly divided into experimental group and control group. The experimental group received proprioception recovery training, and the control group received normal functional recovery training. Experimental results show that the proprioception training of foot joint can improve the dynamic balance ability of gymnasts and effectively prevent the occurrence of foot joint injury. In this paper, the stability of the anterior and posterior foot joints was measured by comparing the control group with the experimental group. After 6 weeks of proprioception training, there was no significant difference between the static balance ability of one foot and the healthy part of the injured side foot joints ($P > 0.05$).

1. Introduction

With the advent of the cloud era, big data has also attracted more and more attention. Big data, also known as massive data, refers to the collection of massive data, which can be retrieved, managed, processed, and sorted out in a reasonable time to help enterprises make business decisions. The analyst team believes that big data is usually used to describe a large amount of unstructured data and semistructured data created by a company. These data will spend too much time and money when downloaded to a relational database for analysis [1–3].

Foot joint injury is one of the most common sports injuries, accounting for 10 to 30 percent of the total sports injuries. The ankle joint is the flexion and garrison joint with the largest load on the human body. When standing, the whole body weight falls on the ankle joint, and the load value when walking is 5 times of the body weight. Therefore, ankle sprain is the most prone trauma in daily life. The most important technique in aerobics is jumping. The movement of a series of calisthenics basically depends on the ankle, and the knee, of wide bone flex stretch cushion, reduces the impact that moves to joint and reduces the harm to human body. Therefore, this study clarified the effects of aerobic training on the muscle strength, muscle strength perception, and joint motion perception of the participants' foot joints, providing a reference basis for improving the stability of foot joints and preventing and reducing foot joint injuries.

In terms of theoretical research, experts and scholars at home and abroad have done relevant research on the causes and treatment and rehabilitation methods of sports injury. Hunt et al.'s team believes that injury to the distal ligaments of the tibia and fibula heralds long-term ankle dysfunction. Mild and moderate maxillary joint injuries are difficult to stratify, and the impact of joint mandibular injuries on the size and distribution of ankle strength during physical activity is unclear. Significant changes in ankle kinematics and contact mechanics may explain why moderate comorbidities injuries take longer to heal and are more likely to develop long-term dysfunction and may lead to ankle arthritis [4]. Janssen et al.'s team describes the relationship between the potential predictor variables related to participants and the cumulative compliance of interventions to prevent sprained ankles. They randomized controlled trials (RCT) of the secondary analysis of compliance data and compared measures to prevent ankle ligament injury. They found that participation in high-risk sports was significantly associated with lower compliance of each group receiving NM training [5]. De Castro et al.'s team believes that current-limit strength training or KAATSU training has been proven to be as effective as traditional strength training, which can promote muscle strength and hypertrophy. Metabolic stress plays an important physiological role and may affect the training adaptability in question. In addition, the hypoxia generated by this technique may change the pattern of nerve recruitment. The implementation of this method will lead to an increase in the concentration of growth hormone (GH), which may lead to an increase in the plasma, or even muscle insulin-like growth factor 1 (IGF-1) [6].

Based on the theoretical basis of the treatment of ankle injury, this article randomly selected 20 male competitive aerobic athletes with lateral ankle injury as the research object and randomly divided them into training group and control group. The two groups were trained in rehabilitation for six weeks. The experimental group received ankle proprioceptive rehabilitation training, while the control group received general functional rehabilitation training. Experimental results show that ankle proprioceptive training can improve the dynamic and static balance of gymnasts and can effectively prevent the occurrence of ankle joint injuries.

2. Proposed Method

2.1. Ankle

2.1.1. Physiological and Anatomical Characteristics of Ankle. The ankle is a saddle joint with a wide front and narrow back of the talus. When the foot is in the flexion position of the sole, there is a large number of varus gap, which is easy to cause varus and damage the lateral collateral ligament during exercise. In aerobics, the ankle is mostly used, and excessive fatigue is the external factor leading to the injury [7, 8]. In the ankle joint, the foot is at right angles to the normal position of the lower leg. The increase in the angle between the lower leg and the back of the foot during exercise is called toe flexion, and vice versa. In the normal position,

the ankle joint is not easy to move laterally through the reinforcement of the surrounding ligaments, but easy to bend and extend. Ankle joint is often sprained in training, most of which are foot flexion, which suddenly turns inward, resulting in strong traction and injury of lateral ankle ligament [9, 10]. Valgus causes damage to the medial collateral ligament, also known as the deltoid ligament. The medial ligament of the ankle is very strong. When the medial collateral ligament is damaged, it is easy to be combined with avulsion fracture. But when the occurrence of medial injury, it is easy to combine the fracture, the formation of compound injury. Figure 1 shows the CT image of the ankle joint.

2.1.2. Structural Stability of the Ankle. In order to understand the proprioception and muscular strength characteristics of the foot joints, it is necessary to first understand the components of the foot joints. Ankle joint is one of the most important joints in human body, and it is the basis to guarantee the normal life of human body [11]. Anatomically, the ankle joint is the joint from the bone to the thigh, also known as the gauntlet joint. The fossa consists of the inferior tibial articular surface, the medial side of the fibula leg joint, the lateral side of the fibula foot joint, and the distal articular head. The foot joint package can be relaxed back and forth, retractable, with ligaments on both sides. These ligaments are the medial deltoid ligaments, which fan down from the medial malleolus and rest on the shoulder bone, the distance bone, and the heel bone. There are three lateral ligaments: anterior ligament of the calf, medial ligament of the ankle, and posterior ligament of the calf. All three ligaments begin laterally and stop at the anterior, inferior, and posterior ends of the distance bone and the heel bone. In the ankle ligament injury, the most common is the lateral injury, especially fibula ligament injury. The major muscles of the foot joint are the triceps, tibialis posterior, long neck, and long neck muscles. Fibula has long tendons and short tendons on the outside of the lower leg: the tibial tendon of the foreleg, extensor tendon of the sole of the foot, extensor tendon, and the third peroneal muscle [12, 13]. In fixing these muscles, the foot joints act as fulcrum for movement. In the distal fixation, the thigh is moved with the foot joint as the fulcrum. The ligaments around the foot joint participate in the movement of the foot joint. Before the foot touches the ground, the relaxation of the ligaments around the foot joint is conducive to the integration of the bones of the foot joint. After the foot touches the ground, it can induce the stabilization of the foot joint and the movement of the distance from the bone.

Therefore, the physiological anatomic structure of the ankle is the basis of ankle function and stability. The strength of ankle joint is directly related to the stability of supporting the whole body when completing the action. In aerobics, there are many jumps, and athletes need to control the height, distance, speed, and ankle force of the jump, which requires the athlete's vision, body, and balance to work together. On the other hand, the instability of ankle function sex can make athletic result drops.
Figure 1: CT image of ankle joint.

2.1.3. Functional Stability of the Ankle. The mechanical function of the ankle joint is mainly the stabilization function of the ligaments around the foot joint and the joint package. The motor function mainly includes foot sole bending and dorsiflexion movement and varus valgus movement, and the neutral position of the internal and external rotation of the ankle refers to the angle perpendicular to the finger. The coordinated movement of the ankle, that is, the correctness of the so-called ankle posture, is mainly reflected in maintaining the stability of the foot below the center of gravity through the force in the opposite direction and eversion. Around the front axis of the foot joint, the foot is flexed and stretched (foot flexion or sole flexion; upward extension or dorsiflexion). The foot joint is basically a one-way joint, and the distance from the bone is mainly along the horizontal axis to represent the sagittal plane movement, which deviates from the coronal plane and promotes dorsolateral and sole flexion. The foot joint and the distance bone joint complement each other, forming a functional complex like the universal joint. The function of the foot joint is mainly in the sagittal plane, and the function of the subosseous joint is mainly in the coronal plane. In dorsiflexion of foot joint with external roll and plantar flexion with internal rotation, the subtalar joint may be combined with dorsiflexion, valgus, and varus. Plantar flexion incorporates internal and external rotation. When walking, the foot joint movement is almost always accompanied by the movement of the subosseous joint. On the contrary, the subosseous joint and the subosseous joint complement each other and move continuously.

2.2. Causes and Preventive Measures of Ankle Injury. The basic steps of calisthenics are alternating system, step system, ground system, foot lifting system, and leg system. Most of these technical movements are mainly based on the spring technique and carried out through the flexion and extension of the foot joints [14, 15]. Body sensation and strength play an important role in everything from body balance to ankle control. When the body and strength feel poor, the ankle is relatively unstable, and the possibility of sports injury increases, which directly affects the training and sports performance. The ankle joint technique of competitive calisthenics runs through the whole movement, and the difficulty of gymnastic movement and jumping rotation increases gradually.

2.2.1. More Difficult Movements. The calisthenic movement is a very difficult item and needs the superb technique for the performance, many difficult moves consist of support, jumps, and turns. These difficult movements will inevitably add to the load on the ankle, especially if the ankle is suddenly thrown into an explosive jump, and the ankle will bear two to four times the weight of the body. When athletes do not have good basic physical quality but are force to learn more difficult and complex technical movements, artificially, they will lack the necessary foundation and cannot complete the difficult technical movements. Therefore, these difficult movements will inevitably increase the possibility of ankle injury.

2.2.2. Too Long Training Time. Calisthenics training time is also the cause of ankle injuries. Because of the long training, the ankle is always under strain. Long-term training and the pressure on the ankle joint is too great, so that the ankle joint is constantly subjected to friction and compression, resulting in excessive fatigue of the ankle joint and resulting in ankle joint injury.

2.2.3. Weak Local Forces. Weak ankle and leg strength is another cause of ankle injuries. In aerobics, there are many jumping movements. Athletes need to fall from heights for a long time, such as kneeling and jumping and splitting in the air. At that time, the strength of the ankle joint was relatively weak, and the buffering effect could not be well controlled when landing, resulting in a short extension, flexion, and valgus of the ankle joint during landing and resulting in ankle joint injury. On the other hand, due to the weak force, some technical movements will be due to their own quality errors, resulting in irregular movements and deformation and resulting in ankle joint injury. It requires that the ankle joint must be strengthened in training or practice to meet the requirements of high-intensity sports.

2.2.4. Insufficient Preparatory Activities. In normal teaching and training, teachers generally pay more attention to the learning of teaching content and technical action. They do not pay enough attention to the lesson preparation activities, resulting in too short lesson preparation time, leading to students in the lesson preparation activities perfunctory. Ankle injuries are caused by intense training, especially aerobic exercise, because of their own characteristics, is more prone

to injury. Winter is the season for ankle injuries. As a result of this period of time, the temperature is lower, the human body capillary contracts, the muscle elasticity decreases, and the viscosity increases; therefore, the leg can cause ankle joint pain and sprain because of insufficient preparation for the movement. Preparatory activities mainly play the following three roles: first, improve muscle temperature and increase the elasticity and extension of muscles and ligaments, second is to improve the skill level of physical participation in sports internal organs, and third is to regulate the psychological function.

2.3. Treatment of Ankle Injury

2.3.1. Routine Treatment. Following, an ankle injury is the "price" principle of the usual treatment in the acute phase, which is the initial braking rest to avoid load, to eliminate swelling, and to allow the tissue to repair itself. Within 48 hours, ice compress was performed on the ankle joint to reduce bleeding and pain then wrapped with a small amount of tape, and finally, the injured ankle was raised higher than the heart to achieve analgesia, cooling, and hemostasis. In severe cases, the stent should be fixed. After receiving basic protection, go to the hospital to take X-ray photos as soon as possible to rule out the possibility of fracture. The basic pain symptoms in the acute phase are relieved, and traditional Chinese medicine is usually used. Athletes' injured ankles are treated with massage, acupuncture, electrotherapy, and rehabilitative practitioners. In the course of treatment, it is necessary to ensure the range of motion of the ankle joint to prevent joint adhesion and the decrease of the range of motion of the ankle joint of the new fibrous tissue. Usually the treatment of ankle injury site is mainly to prevent the injury of the patient to prevent adverse effects to play a certain amount of protection. But the main use of human physiology knowledge of this method of hemostasis and cooling, the lack of clinical effect of rehabilitation, the need to relieve pain and other normal function of the ankle muscle strength training, make their ankle joint get sufficient exercise.

2.3.2. Muscle Strength Training. An injury is accompanied by pain, swelling, effusion, and other symptoms. Braking and physical therapy are carried out in the pretreatment, and muscle strength training is carried out before the joint movement area is recovered and the pain is reduced or disappeared. The purpose of muscle strength training after foot joint injury is to recover the muscle dysfunction caused by motion brake reduction, such as incapacitated tendon atrophy, and to recover the articular tendon weakness caused by foot joint injury. Muscle training to increase muscle strength of the associated muscles around the foot joint is considered an important means to improve joint stability and prevent reinjury. However, the report showed that the negative effects of ligament damage were more significant than the functional changes in muscle strength in motor disorders such as closed soft tissue injuries and joint sprains. Although the muscle tissue around the foot joint was not damaged and muscle strength did not decline, the function of the foot joint was limited. Although the muscle strength of the ankle's associated tendons is strengthened, the ankle can also facilitate recovery and prevent repeated injuries. Some of the findings suggest that the increased muscle strength around the ankle, ankle safety, and ankle stability no longer reduce the risk of injury.

How important muscle strength training is to the rehabilitation treatment of ankle injury, the physiological system of the effect of muscle strength training on ankle rehabilitation still needs further research, and maybe because of the muscle machine, the muscle strength training that leads to the increase of muscle function has the effect of promoting the rehabilitation of ankle. Therefore, in the current research results, muscle strength training is considered to be the first treatment method to consider in the early rehabilitation training of foot joint injury.

2.3.3. Neuromuscular Control. Proprioception training is not a specific training method, but through different training methods, the body's main body fully elicits the sensory acceptor and proprioception to judge the body's shape, and after the perception of the movement process, the unit seeks the comprehensive adjustment of nerve and muscle activity activation. In rehabilitation training after a sprained ankle, as a balance of choice, many therapists restore the function of the ankle to train the nerves; muscle control function is one of the important methods. According to research, there is a certain signal after an ankle sprain, but the relevant empirical research is not very clear. In training, in order to maintain the stability of the ankle joint, its rehabilitation balance function plays a great role. It is usually necessary to train the patient to balance on the uneven plane, such as rotating plate, foam material, special ankle movement balance training machine, standing on the adjustable imbalance plane, by the ankle receptor around the agent to participate in the exercise of the adjustment, which helps improve the stability of the ankle. This balance training has been studied in different sports to improve joint proprioception and reduce the risk of reinjury. The training does to some extent increase the stability of the foot joint and reduce the risk of recurrent sprain, but it is necessary to investigate whether there is a potential association with the physiological mechanism and the enhanced neural control function of the surrogate receptors around the foot joint.

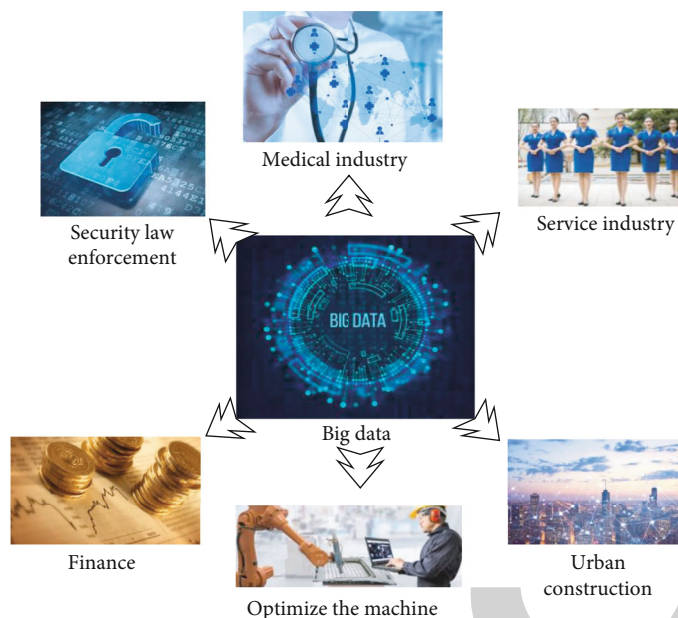
2.4. Big Data. Big data, or huge amount of data, refers to the amount of data involved is so large that it is impossible to capture, manage, process, and organize within a reasonable time through the current mainstream software tools to help enterprises make business decisions more positively. Big data has the characteristics of large scale, fast flow speed, and rich forms. Big data has been widely used and developed in aviation, e-commerce, and other fields, making up for the previous data acquisition methods and expanding the breadth and depth of data utilization. Figure 2 shows the application areas of big data.


FIGURE 2: Application areas of big data.

3. Experiments

3.1. Data Collection. In this paper, 20 male competitive calisthenics players with ankle joint injury of only one foot were randomly selected as the research object: experienced unilateral ankle joint sprain within half a year, no ankle joint sprain in the last month, no history of lower limb fracture or operation, and the other side of the foot joint was not injured. The pretensile test and range bone tilt test were negative. According to the basic conditions of the research subjects' age, height, weight, etc., this article randomly divided 10 subjects into the experimental group and the control group in order to compare the damage of knee and ankle muscle strength and function of injured athletes and the degree of recovery after training. The age distribution is shown in Table 1. There was no significant difference between the two groups ($P > 0.05$), which could be compared. All subjects fully understood the purpose and process of the experiment and spontaneously participated in the experiment. The specific conditions of the two groups are shown in Table 2.

3.2. Experimental Method. In this paper, all the experimental intervention and data mining processes were completely completed in a professional sports rehabilitation training hall, and the whole process of the experimental process was monitored, so as to achieve timely adjustment and authenticity of the experimental data. The experimental group received proprioception recovery training, and the control group received normal functional recovery training. The experimental group and the normal training group were given 6 weeks, 3 times a week, of about 40 minutes of exercises on foot joint function. The experimental intervention was performed once a day for 1 test subject, and the same training could not be performed more than twice a day. Intervention sessions are held Monday through Friday from

TABLE 1: Age distribution table of the two groups.

Age	20	21	22	23	24
Test	2	1	4	1	2
Control	1	1	5	2	1

TABLE 2: Details of the two groups.

Group	Height	Weight	Diseased side Right	Left	Age
Test	173	68	4	6	22
Control	174	68	5	5	22

9 a.m. to 12 a.m. and from 2 p.m. to 5 p.m. Experimental interventional rehabilitation training was carried out on 6 persons in the experimental group and the normal training group each day. During the experiment, this study tried to create an atmosphere consistent with the usual training, so as to ensure that each subject's lifestyle did not need to change, and they would not receive any other rehabilitation training and physical sensory training. At the same time, there was no uncomfortable stimulation.

3.3. Test Index

3.3.1. Ankle Stability Test. Overall static parameters reflect the ability of the ankle joint to balance and stabilize. Front and rear axial static parameters reflect the ability of the ankle joint to balance and stabilize in the front and back directions. Left and right axial static parameters reflect the ability of the ankle joint to balance and stabilize in the left and right directions.

3.3.2. Ankle Proprioception Test. The overall stability index (SI) reflects the overall average swing angle or swing of the subject when standing. The anterior-posterior stability index

	Test group		Control group	
	Before	After	Before	After
Overall static parameters	3.7	2.7	3.7	2.8
Front and rear axial static parameters	2.5	2.1	2.5	2.3
Left and right axial static parameters	3.4	2.6	3.4	2.4
FIGURE 3: Test result of the static balance ability of the affected ankle.

(A/PSI) reflects the average swing angle or swing of the subject on the sagittal plane when standing. The left-right stability index (M/LSI) reflects the average swing angle or swing of the subject on the frontal plane when standing. The lower the above value, the smaller the degree of body shaking, indicating that the balance ability is stronger.

3.4. Statistics. This article uses Excel2010 to process the data before and after the experiment. All parameters are expressed in the form of mean ± standard deviation. SPSS18.0 software is used for mathematical statistical analysis. The test method is multivariate analysis of variance and paired sample T test. The significance level is 0.05.

4. Discussion

4.1. Test Results and Analysis of Injured Ankle Balance Function

4.1.1. The Static Balance Ability of the Affected Ankle Joint. Before and after the experiment, the experimental group and the control group were tested on the balance of the ankle. In this article, we tested each study object using the one-legged static balance test feature of the pro-kin system. Each subject was tested according to standard procedures, using the same test instrument. After the completion of the test, the test results of 20 subjects were collected and counted. Then, the three important indexes of stability of ankle joint in one-foot static balance function test system were analyzed. Then, the three indexes are calculated as the mean and standard deviation. The results of one-foot static balance test of the affected ankle joint are shown in Table 3 and Figure 3.

As we can see from Table 2 and Figure 1, intervention before the experiment, according to the control group and experimental group of ankle joint parts of a single static balance test results, can be seen, and after an ankle injury, ankle joint parts of the overall static parameters than health intactness of the overall static significantly increased ($P < 0.05$), especially front axle static parameters are significantly different ($P < 0.05$), and the difference of front axle static parameter is not obvious ($P > 0.05$). That is to say, the stability of the foot joint changes after the injury, especially the static parameters of the left and right axis direction are significantly different, and the potential risk of unstable reinjury of the foot joint is significantly increased. After 6 weeks of ankle function recovery training, the two groups of affected ankle joints were tested on the static balance function of one foot. There was a significant difference between the experimental group and the experimental group ($P < 0.05$). There were significant differences in the foot joints of the training group compared with those before the experiment ($P < 0.05$). This suggests that six weeks of training in the ankle function recovery system can effectively improve the stability of the damaged ankle joint.

4.1.2. Healthy Ankle Joint Static Balance Ability of One Foot. The main foot joint is the foundation and key to complete the new gymnastic balance movement. The balance pose requires not only the strength of the flexor muscles but also the strength of the muscles to be extended by combining with the ankle to achieve the balance. The quality of the balance movement is mainly determined by the development balance of the conventional ankle joint force and the joint

TABLE 4: One-leg static balance ability of the healthy ankle.

	Test group		Control group	
	Before	After	Before	After
Overall static parameters	2.9	2.8	2.7	2.7
Front and rear axial static parameters	2	2.1	2.1	2.1
Left and right axial static parameters	2.4	2.5	2.2	2.3
FIGURE 4: One-leg static balance ability of the healthy ankle.

Left and right axial static parameters	0.104	0.069	0.133	0.127

improvement of flexion and extension. Low-level athletes spontaneously teach the foot joint force imbalance, and the stability of the balance movement is poor. Therefore, in the balance movement of the new gymnastics to the strength of the ankle joint, the main demand is the strength of the flexion and extension group of the coordination of balanced development and common improvement. The results of static balance ability test of healthy ankle joint are shown in Table 4 and Figure 4.

As shown in Table 3 and Figure 2, according to the results of measuring the static balance ability of one foot in the experimental group and the normal training group before the experimental intervention, the overall static parameters of the healthy foot joints in the experimental group were not significantly different from those in the control group ($P > 0.05$). After 6 weeks of training on the recovery of foot joint function, the static balance function of one foot in two groups of healthy joints was tested again. After the experiment, there was no significant difference in the static balance ability of one foot in the affected side foot joint compared with that before the experiment ($P > 0.05$), and there was no significant difference between the affected side foot joint in the comparison group and before the experi-

FIGURE 5: Test results of dynamic balance ability with eyes open and standing on both feet.

ment ($P > 0.05$). The comparative analysis of relevant data between the experimental group and the comparison group showed no significant difference, indicating that the

Table 6: Test results of standing dynamic balance ability with closed eyes and feet.

	Before (test)	After (test)	Before (control)	After (control)
Overall static parameters	0.224	0.331	0.097	0.241

Left and right axial static parameters	0.113	0.142	0.020	0.167

magnitude of foot joint load did not affect the functional training of injured foot joint balance.

4.2. Test Results and Analysis of Ankle Joint Function with Standing Feet

4.2.1. Dynamic Balance Ability when Standing with Eyes and Feet Open. In general, the lower the balance index, the less the body shakes and the higher the balance. In this paper, the results of proprioception test of ankle joint when standing with eyes and feet open were analyzed by multifactor dispersion analysis: gender: male and female; combination: experimental group and control group; test cycle: six weeks. It had a significant impact on the overall stability index (SI) and the left and right stability index (M/LSI) of open eyes before and after the test and had a significant difference in the SI and M/LSI values after 6 weeks of training ($P < 0.05$). The stability index (A/PSI) was lower after training than before, but there was no significant difference ($P > 0.05$). The results of the dynamic balance test when standing with both eyes and feet are shown in Table 5 and Figure 5.

We can see from Figure 3 that the different value of the overall stability index before and after the experiment is more significant than that of the control group. In this paper, professional sample T test was used for data analysis, and the analysis index was the anteropositive stable index (a/psi) and the left and right stable index (m/lsi). In this paper, it was found that when standing with the eyes open, the change of the stability index was greater than that of the left and right stability index, and the difference was significant ($P < 0.05$).

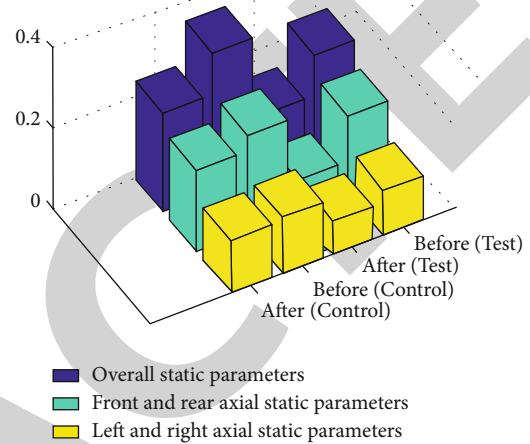
4.2.2. Dynamic Balance Ability when Standing with Eyes Closed and Feet Closed. In this paper, the dynamic balance ability of the experimental group and the control group was measured before and after the experiment. There was no significant difference in the dynamic balance ability of the two groups before the experiment, and the left and right stability index (M/LSI) of the experimental group was obvious after the experiment, that is, the left and right stability index of the experimental group was significantly smaller than that of the control group after the experimental training. There was a significant difference in the left and right eye closure stability index (M/LSI) before and after training, and the index test value decreased significantly after the training. In terms of overall stability index and before and after stability index, compared with before training, the value after training tends to decrease, but there is no significant difference. Table 6 and Figure 6 show the test results of standing dynamic balance ability with closed eyes and feet.


Figure 6: Test results of dynamic balance ability with eyes closed and standing on both feet.

As can be seen from Figure 4, for the left-right stability index when standing with eyes closed and feet closed, the posttest index value of the experimental group and the comparison group was smaller than the pretest value. The left and right eye closing stability index and right and right foot stability index of the experimental group with proprioception training were significantly reduced compared with the control group with normal rehabilitation training, which also indicated that the balance stability of proprioception training was better. After the anteroposterior stability index and the left and right stability index were analyzed by the corresponding sample T test, the anteroposterior stability index was significantly larger than the left and right stability index under the two-vertical condition of eye closure ($P < 0.05$).

5. Conclusions

(1) The experiment in this study shows that after the foot joints are damaged, the proprioception of the foot joints of competitive aerobic players will be affected and their ability will be reduced. Normal functional recovery training for damaged foot joints can help restore proprioception. Under the reduced condition, the proprioceptive function of the foot joint did not change, although the load was reduced. Therefore, weight loss training can be applied in the early stage of foot joint injury to help competitive bodybuilders recover the function of damaged foot joint

As an important energy material, mineral resources have an important role in the rapid growth of the national economy. In recent years, with the enhancement of mining strength and the improvement of mechanized production level, the depth of mining has also increased year by year. Therefore, the number of heat hazards in deep mine mining has increased year by year, and the problem of heat loss in deep mines has become increasingly prominent, which has seriously affected the safe and efficient production of mines. In this paper, the application of nanoporous super insulation materials in the prevention of thermal damage in deep mining of metal mines is studied, and the related theories of nanoporous super insulation materials and the prevention of thermal damage in deep mining of metal mines are understood on the basis of literature data. Nanoporous thermal insulation materials refer to thermal insulation materials with pore diameters in the nanometer range. This material can effectively prevent the collision of gas molecules and prevent the heat conduction of the gas. Then, the application experiment of nanoporous super thermal insulation materials in the prevention and control of heat damage in deep mining of metal mines is carried out. Through experiments, it is concluded that the room temperature thermal conductivity of the experimental material decreases with the increase of the addition of SiO_2 aerogel, and the downward trend is linear, and when the heat source temperature is 200°C, the coating surface temperature of the thermal insulation material (excluding aerogel) is 100°C, and the thermal insulation temperature difference is 100°C, while when the coating surface temperature of the aerogel thermal insulation coating is only 60°C, the thermal insulation temperature difference is 140°C. From these data, it can be seen that the thermal insulation performance of nanoporous super thermal insulation materials is better, which verifies the feasibility of its application in the prevention of heat damage in metal mine mining.

1. Inductions

Mineral resources, as one of the main energy consumed by the current social development, have played a vital role in the progress of social development. The mines in the central and eastern mining areas have introduced deep mining before, and the current mining depth of deep mines is still expanding [1, 2]. However, due to the expansion of mining depth, the temperature of deep mine shafts continues to rise, which seriously affects normal safe production [3, 4]. Thermal damage

in deep mine development is an objective reality, and creating a cool working environment is also an issue that needs to be improved in China's domestic mine development [5, 6]. Since China is the world's largest mineral resources producer, 95% of its mineral resources come from wells. In-depth study of mine utilization methods in order to obtain more mineral resources to support national construction and many mines in China have been developed at depths of more than 900-1300 meters, so high temperature heat loss in mines is an urgent need to solve the problem [7, 8].

In order to meet the high demand for mineral resources in the rapid development of society, it is necessary to increase the exploitation of mineral resources in the deep part of the earth. Solving the problems of ventilation difficulties and high temperature heat damage encountered in the process of deep well mining will greatly reduce the difficulty of mining mineral resources deep in the earth, improve the availability of underground energy, and promote the rapid development of society [9].

Regarding the investigation of thermal damage in mines, some scientific researchers pointed out that ventilation and refrigeration is the most common nonfreezing cooling method at present, which can be used to cool, dehumidify, and increase air concentration on the surface of hot mines. Mine ventilation can bring enough air to underground workers, and it can also reduce the content of harmful gases, thereby reducing the high temperature in the basement, but by increasing the ventilation, the pressure increases linearly, and the output of the fan is increased by three times, so mine ventilation alone cannot effectively alleviate the thermal hazards of high temperature mines. Therefore, the conventional coal mine ventilation principle cannot completely alleviate the thermal damage of high temperature coal mines [10]. Relevant researchers believe that the temperature of the original rock rises with the expansion of the mining depth, and the heat release of the original rock is also one of the main heat sources in the deep mine. In the tunnel under the hot mine, because the temperature of the cold air rises, the cold air inevitably conducts countercurrent heat exchange with the hot tunnel wall. If heat insulation materials are used to isolate the heated road wall from the cooling flowing air, the high temperature of the hot mine can be significantly reduced, similar to the thermal insulation of the building facade, which can prevent the facade from interacting with each other in summer and winter. The air between the inner walls performs countercurrent heat exchange, which has a cooling effect in summer, and a heat preservation effect in winter [11]. In the research of nanoporous insulating materials, some scholars have pointed out that SiO_2 and its composite aerogel have the characteristics of extremely low density, large specific surface area, and high porosity. They are suitable for many fields, and many unknown fields have great applications. Especially in the field of private thermal insulation, with the progress of economic growth, the world pays more and more attention to energy issues, and daily energy saving is particularly important. Due to the special pore structure characteristics of aerogel, it has an excellent thermal insulation effect. Compared with other insulation materials such as cotton insulation and polyurethane insulation, it has the advantage of better insulation performance and makes up for the disadvantage of poor thermal stability, so it has good potential application value [12]. To sum up, the research on the prevention and control of heat damage in mines has attracted much attention, but most of the studies have focused on artificial cooling measures, and few scholars have studied the use of heat insulation materials to control the generation of heat sources.

The innovations of this paper are as follows: (1) The application of nanoporous super insulation materials in the prevention and control of heat damage in deep mining of metal mines is studied. (2) The thermal damage in deep mining of metal mines and the thermal insulation principle of nanoporous super insulation materials are analyzed. (3) The feasibility of applying nanoporous super insulating materials in the prevention and control of heat damage in deep mining of metal mines is analyzed. (4) The application test of nanoporous super insulating material in the prevention and control of heat damage in deep mining of metal mines was carried out, and the feasibility of the method was verified by experiments.

2. The Prevention and Control of Thermal Damage in Deep Mines in Metal Mines and Nanoporous Super Thermal Insulation Materials

2.1. Analysis of Thermal Hazards in Deep Mine Mining in Metal Mines. The mining depth is more than 800 m, which is a deep well mining. Rocks with type II deformation characteristics at this depth will experience frequent rockbursts, which will affect the safety of the operation. The factors that cause thermal damage to deep wells include geothermal heat (mainly hot water produced by surrounding rocks and wells) and air compression heat entering the well (mainly air intake wells, inclined wells, etc.), ore oxidation, and thermal diffusion of underground electromechanical equipment, heat dissipation, explosive heat, and underground heat [13]. The mining methods of deep well mines are basically the same as those of shallow well mining, including three categories: open field method, filling method, and caving method. However, its structural parameters, mining sequence, and mining process should be adjusted according to the characteristics of deep mines, and due to the particularity of deep mines, the backfill mining method will become the mainstream mining method. Among them, the problems faced in deep well mining include deep well heat damage, ventilation and cooling problems, high ground pressure, and deep well water inflow. As the mining depth and lifting height increase, the weight of the lifting wire rope increases, and the ineffective energy consumption caused by the dead weight of the wire rope in the lifting operation becomes more and more prominent.

The heat of blasting is released instantaneously and plays a major role in the instantaneous rise of the temperature in the well, but the heat in the mine does not rise because of the short duration. Especially the underground DC ventilation can effectively prevent the accumulation of shock waves and quickly dissipate heat. Generally speaking, iron ore requires staff to clean up the site before organizing ore mining and blasting. After blasting, ventilation is required for a period of time before personnel can enter. Therefore, it is not necessary to consider the super position of blast heat as a cooling system to improve the working environment of underground workers [14]. Among them, deep well mining has the following main characteristics: high ground pressure, high ground temperature, and large mine gas.

2.1.1. Geothermal (Wall Stone). For deep iron ore, the initial rock temperature is very high, which is usually the main

reason for the high temperature of the mine. The heat transfer between hot wall rock and airflow is a complex and unstable heat transfer process. The airflow is very active in the mine. The walls and roads of the mine are convex. The thermal energy on its surface releases heat to the wind flow, thereby transferring the heat from the original rock to the cold mine wall and driveway. At the same time, the deep rocks are also cooled to form a cooling zone, and the temperature rises after heating. With the extension of the aeration time (generally one year later), the expansion of the cooling zone begins to weaken after the surrounding rock and the airflow have fully heat exchanged [15].

2.1.2. Thermal Oxidation.
Sulfur and iron in iron ore may undergo an exothermic oxidation reaction when they encounter oxygen in the air, leading to an increase in soil temperature. The heat released by oxidation is generated by the ore exposed to wind currents. After the connecting strips of the iron ore vein road, all the walls of the road surface are fixed with concrete mortar, so the oxidation heat release is mainly carried out in the vein tunnel and mining [16].

2.1.3. Heat Dissipation of Electromechanical Equipment.
With the increase in the degree of mechanization of production links such as underground mining, tunnel boring, and iron ore transportation, the installed capacity of electromechanical equipment has grown rapidly. The installed power of tunnel surface is above 1000 kW. The electrical energy consumed by underground electromechanical equipment is either used to increase the kinetic energy of materials or liquids (the kinetic energy changes very little, usually negligible), or it is converted into heat energy, and almost all of the heat energy generated is diffused into the air [17].

2.1.4. The Surface Atmosphere Brings Heat.
Air flows from the surface to the wellhead, and the temperature and humidity of the surface atmosphere inevitably affect the temperature and humidity of the air in the well. The moisture content of the surface atmosphere changes very little every day, showing a pattern of high at noon and low at night. Although the daily temperature fluctuates greatly, when it flows into the well, due to the heat exchange with the rocks in the surrounding tunnel, the fluctuation of the air temperature in the well gradually becomes smaller, and this change is basically not felt in operation. The main influence of downhole air temperature by climate is the seasonal variation of surface temperature, especially water content. This is because the latent heat of water vaporization is much greater than the specific heat of air. In summer, the surface temperature and humidity are relatively high, which is one of the factors that affect the increase in temperature and humidity of downhole air flow [18].

2.2. Thermal Insulation Principle of Nanopore Super Thermal Insulation Material

2.2.1. Principle of Heat Conduction.
The essence of heat conduction is the process of transferring energy from the high temperature part of the object to the low temperature part, or from the high temperature object to the low temperature object, by the collision of a large number of molecular thermal motions in the material. A porous material is a material with a network structure composed of interconnected or closed pores [19]. For porous materials, the gas thermal conductivity measured experimentally is often greater than the sum of the gas thermal conductivity and the gas thermal conductivity. The gas-solid combined thermal conductivity is the increase in thermal conductivity caused by the gas-solid interaction. In the process of transferring heat to the porous material, some gas molecules are placed in the small holes, which can be used as a shortcut for heat transfer to create new heat transfer channels. Compared with continuous medium materials, porous materials generally have the advantages of low relative density, high specific strength, high specific surface area, light weight, sound insulation, heat insulation, and good permeability. If the material contains many channels, it can conduct gaseous heat, which will make the gaseous heat have a more obvious effect (as shown in Figure 1). This heat transfer process is carried out with gas molecules as the carrier, so it is related to the number of gas molecules (gas pressure). The greater the difference between the thermal conductivity of solid and the thermal conductivity of gas, the more obvious the bonding effect, and the greater the thermal conductivity of gas-solid bonding. If the pore size is very small, the gas molecules transfer heat in a manner similar to the lattice vibration, which can produce a very obvious gas-solid bonding thermal conductivity [20]. In the industry, there are many heat transfer processes dominated by heat conduction, such as heating and vulcanization of rubber products and heat treatment of steel forgings. The law of heat conduction plays an important role in the design and calculation of kilns, heat transfer equipment, and thermal insulation and in the analysis of temperature distribution of catalyst particles [21].

2.2.2. Characteristics of Nanoporous Thermal Insulation Materials.
Nanoporous thermal insulation materials refer to thermal insulation with pore diameters in the nanometer range. This material can effectively prevent the collision of gas molecules and prevent the heat conduction of the gas. The thermal conductivity of the nanoporous thermal insulation material under normal temperature and pressure can be lower than that of static air. Therefore, nanoporous thermal insulation materials and vacuum thermal insulation materials are also called super thermal insulation materials. At present, nanoporous insulating materials are mainly composed of aerosol and nanopowder insulating composite materials. Table 1 shows the density and thermal conductivity of many nanoporous insulating materials. It can be seen that the thermal conductivity of nanoporous insulating materials is relatively low. Nano-microporous thermal insulation materials mainly include thermal insulation materials such as nanoinsulation boards and nanoaerogel felts, and Jinshi nano-microporous thermal insulation materials. According to the particularity of thermal motion, it uses the unique thermal conductivity of nanoporous materials and the heat reflection function given by functional
FIGURE 1: Schematic diagram of gas-solid combined thermal conductivity.

materials and is suitable for binders and various inorganic elements. A low thermal conductivity thermal insulation material is produced by a synthetic process, which is actually smaller than the thermal conductivity of still air.

2.2.3. Reasons for Heat Insulation

(1) The pore size of the nanoaerogel is below 100 nm, which effectively increases the reflective interface. If the particle size of the material is in the same order of magnitude as the incident wavelength, the incident electromagnetic wave will be affected by the scattering effect, and the transmittance of the incident electromagnetic wave will decrease. The ability of the material to absorb heat radiation significantly achieves the purpose of heat insulation

(2) Since the air is mainly composed of nitrogen and oxygen, its mean free path of thermal motion is about seventy nanometers. The pore size of nanoinsulating materials is basically no more than fifty nanometers, which is much lower than the mean free path of thermal motion between molecules in the air, so it is in a condition similar to that of a vacuum. Gas molecules cannot enter the nanopores at will. When the gas adheres to the pore wall, the pores no longer conduct heat energy, thereby effectively reducing the thermal conductivity of the material. There are many performance indicators of insulating materials, and the characteristics of various insulating materials are also different. The main performance indicators of commonly used insulating materials include breakdown strength, heat resistance, insulation resistance, and mechanical strength

(3) Due to the low bulk density of nanogels and a large amount of air inside, the thermal conductivity of air at room temperature is the lowest, which effectively improves the thermal insulation performance of the material

Nanoaerogel thermal insulation coating is a kind of composite thermal insulation coating, which combines the characteristics of thermal insulation coating and radiation thermal insulation coating. The thermal insulation principle of the two works together [22].

2.3. The Application of Nanoporous Super Thermal Insulation Materials in the Prevention and Control of Thermal Hazards in Deep Mining of Metal Mines

2.3.1. Preventive and Management Measures against High Temperature Hazards. Nonartificial cooling measures mainly include optimizing the development system and road layout during mine development and development, optimizing extraction and filling methods, strengthening ventilation, adopting controllable circulation, and taking personal protective measures by workers [23].

(1) The development system and road layout are optimized. The mining development system should consider separate development methods as much as possible, and try to use a hybrid or lateral ventilation system with a short air inlet path to reduce heat absorption

(2) Optimize the fixing method and filling method, and adopt the post-fixing sequence. Under the same conditions, the air volume and wind speed of the work surface is higher than that of the front support, which helps to reduce the temperature, which can improve the air circulation and heat dissipation conditions of the mine. Compared with the cavitation method, the filling method increases the effective air volume of the mine and solves the basic problems of hot water leakage, residual combustible ore and surrounding rock in the hole, roof heat, and floor heat diffusion. Lower filling materials will also absorb a lot of heat

2.3.2. Application of Nanoporous Thermal Insulation Materials. According to the above analysis, the nanoporous super insulating material has excellent thermal insulation performance, so this feature can be used to control the heat dissipation of the deep well heat source. The following are the nanoporous thermal insulation measures.

(1) Laminated Insulation. The method of laminated insulation is relatively simple. Insulating laminate materials are usually filled with materials with low thermal conductivity and rolled onto the surface where insulation is required. There are three types of laminated insulation: foam type, powder type, and fiber type [24]. In addition to the average temperature of the insulation layer, the thermal conductivity of the foam insulation material also depends on the material and density of the foam gas. Therefore, the insulation laminate should be made of as dense material as possible, because the low density will reduce the heat in the solid. The main disadvantage of dust and fiber insulation is the penetration of water vapor and air through the insulating layer to the cold surface. This problem can be solved by installing a moisture-proof layer. In order to prevent the condensation and solidification of the gas in the insulation material space and ensure good insulation performance, it is necessary to fill and accumulate gas with low thermal conductivity, and the condensation temperature of this gas should be lower than that of the cold surface. Generally, cold

TABLE 1: Density and thermal conductivity of nanoporous insulating materials.

Materials	Composition	Density (g/cm^3)	Thermal conductivity (W/(m:k))	Maximum service temperature (°C)
	Cellulose	0.056-0.098	0.031-0.034	-270
	Polyimide	0.11	0.031	350
Aerogel	Phenolic aldehyde	0.19	0.011	-250
	SiO$_2$	0.16	0.01 3	800
	Carbon	0.052-0.183	0.020-0.037	≥2000

surface temperatures above 77 K are filled with nitrogen, and cold surface temperatures below 77 K are filled with argon.

(2) Vacuum (or Fiber) Heat Insulation. Vacuum heat preservation is to fill the insulating intermediate layer with porous insulating material and at the same time evacuate the space of the insulating intermediate layer to a specific vacuum. The heat conduction of gas is the main way of heat transfer between porous media. Filling the vacuum interlayer with dust can reduce the distance between the radiation surfaces and reduce the thermal conductivity of the gas. Dust particles can reflect and scatter radiation and reduce the heat transfer of radiation. At the same time, the contact area between the dust particles is small, the thermal resistance is high, and the thermal conductivity of the solid is low.

2.4. Preparation of Nanoporous Super Insulation Material. The silicon aerogel manufacturing process includes three basic steps: sol-gel process, aging process, and drying process. The possible uses of silica aerogels depend to a large extent on the microstructural properties of the 3D framework and the nanostructured surfactant group. These special surface structures can generally be obtained by adjusting the sol-gel process parameters and modified silica aerogels, and the process parameters can be used to obtain bubbles with different characteristics. Therefore, it is very important to select a suitable composition and processing method to prepare silica aerogel to meet the performance required by bubbles in various applications. Figure 2 summarizes the existing aerogel manufacturing process and some synthesis parameters. These parameters affect the formation of the gel network, which in turn affects the performance and application of aerogels. Almost all aerogels can be prepared by liquid chemistry (sol-gel method). During the preparation process, changes in several parameters such as the type and quantity and type and concentration of precursors will affect the evolution of the microstructure of the aerogel network. The chemical reaction process of the aerogel composition used to prepare the aerogel material, such as the type of solvent, reaction temperature, and pH value, should be designed according to the desired yield.

In the process of silicon aerogel forming colloidal gel with lattice structure, the alkoxide-forming aerogel can ionize the precursor through hydrolysis or acid-catalyzed reaction and then alkali-catalyzed dehydration and condensation. In the reaction, the two -OH remove a H$_2$O molecule to form a siloxane bond. During the aerogel preparation process, the condensation polymerization reaction and hydrolysis reaction of the silane precursor and the alkoxide

solvent proceed simultaneously, continue to exist in the entire colloidal gel process, and eventually lead to gel after the reaction.

The sol-gel reaction process has many parameters that affect its structure. The three-dimensional structure of the gel can be adjusted by adjusting the basic parameters of the reaction, and ultimately determine the nanostructure of the network and the properties of the final material, which is controlled. These parameters usually include precursor concentration, relative precursor and solvent concentration, solvent type, relative water and precursor concentration, temperature, and pH. In addition, organic molecular groups or nanoscale organic groups can be added during the sol-gel reaction process to give the gel network a specific function. Generally speaking, suitable alkoxide derivatives containing organic functional groups can be added by chemical reactions, or additives can be used in the porous network by natural methods. For example, it can be used in liquid gels to obtain hydrophobic aerogels, and the surface of the network structure is introduced by chemical reaction to introduce methyl functional groups to obtain a hydrophobic structure. It can also increase the mechanical strength of polymer mixtures and gels. In addition, catalysts, nanoparticles, magnetic, or titanium oxide nanoparticles can be added to the gel network structure to obtain new aerogel properties such as catalytic properties, optical properties, mechanical strength, and magnetic properties.

3. Application Experiment of Nanoporous Super Thermal Insulation Materials in the Prevention and Control of Heat Damage in Deep Mining of Metal Mines

3.1. Preparation of Experimental Materials

3.1.1. Experimental Materials. The materials used in the experiment are 45% concentration silica solution, solidified magnesium oxide, Portland P. C 32.5R initial strength silicate composite cement, White Soot 2000 mesh, foaming agent, pore former, and other additives.

3.1.2. Additives. The additives used were pore-forming agent and foaming agent obtained from Chengdu Kelong Chemical Reagent Factory.

3.1.3. Reinforced Materials. Glass fiber was obtained from Chengdu Kelong Chemical Reagent Factory. The chemical composition is shown in Table 2.
FIGURE 2: Aerogel manufacturing process.

TABLE 2: Chemical composition of glass fiber.

	SiO$_2$	Al$_2$O$_3$	MgO	Li$_2$O	Fe$_2$O$_3$	B$_2$O$_3$	CeO$_2$
%	51-59	24.5-26.5	11-20	0-0.9	0.6-1.5	1-4	0.6-0.8

3.1.4. Formation Mechanism of Stomata Structure. Weigh cement-based materials, fillers, pore formers, etc. According to a certain mixing ratio, pour into a container and mix into a liquid slurry. After the blowing agent is injected, gas is generated and formed during the continuous expansion of the gas-wet interface. When gas passes through the liquid, the surface of the liquid shrinks automatically due to the action of surface tension, and the gas is wrapped by a layer of liquid film to form bubbles. At the same time, the added surfactant contains a large number of anionic groups, these anion groups are compressed into a gas absorption layer, and some of the remaining groups diffuse around the colloid or silicone beam particles, thereby producing surface micelles. The gas acts as a "coating" that sticks the bubbles to the system. The solid particles adhere to the vicinity of the bubble under the action of the initiator, thereby effectively preventing the precipitation of solid particles, and a uniform and stable three-phase power source "solid-liquid-gas" coexistence system is established near the bubble. When the solid phase is condensed, the liquid phase separates, and the solid phase closely surrounds the bubbles, thereby producing a porous silica-based porous insulator with closed pores.

3.1.5. Process Flow. Figure 3 shows the manufacturing process flow of a porous insulating material based on silicon dioxide. Cement-based materials, fillers, air trapping agents, surfactants, and fibers are weighed in a certain proportion, mixed with the cement-based materials, and then the fillers, fibers, and surfactants are added to the container and stirred for about 40 seconds to form a uniform slurry. Then, add the air-entraining agent and stir evenly, and then quickly pour the slurry into the mold. The porous material is formed by on-site self-assembly technology and dried under natural conditions, and then, the experimental sample is cast.

3.2. Experimental Method

3.2.1. Thermal Conductivity Test. There are different thermal conductivity methods for measuring thermal conductivity according to measuring different types of materials, working temperature, and thermal conductivity materials. The method of measuring thermal conductivity can be classified according to the mechanism of thermal conductivity, the shape of the sample, and the direction of heat flow. According to the macroscopic mechanism of thermal conductivity, it is divided into steady method and unsteady method. According to the shape of the sample, it is divided into plane method, rod method, cylindrical method, and ball method. According to the direction of heat flow, it can be divided into longitudinal heat flux method and radial heat flux method. Usually laser method, hot cable method, heat flow method, protective hot plate method, etc. are used.

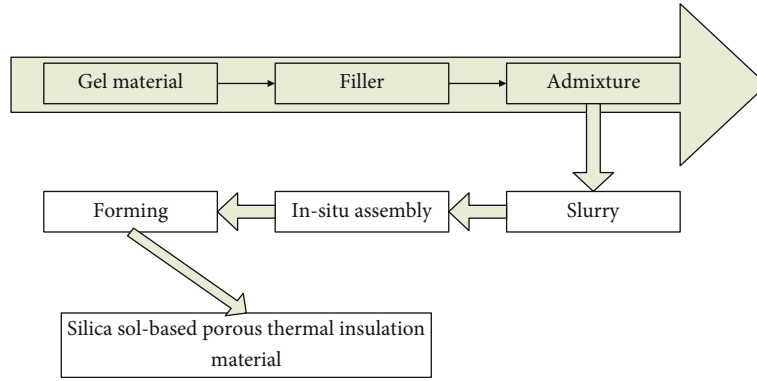
In this paper, the thermal conductivity of the insulating protective layer is measured by the protective plate method. The protective plate method is measured according to the basic principle of the steady-state differential equation of thermal conductivity. By installing the same two samples between the two cooling plates and the concentrated heating plate of the thermal conductivity meter, a laminated structure of cooling plate, sample, hot plate, sample, and intercooling plate can be produced. In order to ensure the same direction of heat flow through the two specimens, the structure is equipped with a heat preservation structure around the specimen and the heating plate to avoid radial heat transfer and conform to the characteristics of axial one-dimensional heat conduction. After waiting for the temperature distribution of the test sample to balance, a constant temperature δT ($\Delta T = T2 - T1$) is formed on the top and bottom of the sample. By measuring the direction of the temperature flow of the sample and the temperature step


FIGURE 3: Manufacturing process flow of porous insulating material of silicon dioxide.

along it, the direction of the temperature flow and the thermal conductivity of the sample can be obtained using the following heat equation. The test principle of the protection board method is simple and the measurement accuracy is high.

$$\Delta T(\tau) = \left[\frac{p_0}{\pi^{3/2} kr}\right] f(\tau). \tag{1}$$

In the formula, p is the output power of the catheter, the unit is W, r is the radius of the catheter, the unit is m, and $f(\tau)$ is a dimensionless transient function. Here,

$$\tau = \sqrt{\frac{\alpha t}{r^2}}. \tag{2}$$

In the formula, τ is the test time, the unit is s; a is thermal diffusivity.

In this experiment, the Swedish thermal constant analyzer HotDisk TPS250 was used to determine the thermal conductivity of the coating. The sensor placed between the two materials acts as the heat source and temperature sensor of the device and generates specific output energy by introducing current pulses. Since the temperature rise of the catheter is proportional to the voltage, the thermal conductivity of the material can be calculated from the temperature data that changes over time, and the average value of each sample group is measured 3 times.

3.2.2. High Temperature Insulation Performance Test.
Dry the $15\,\text{cm} \times 15\,\text{m} \times 3\,\text{cm}$ sample to be tested, and then place it on a constant temperature hot stage with ceramic digital display to ensure that a stable and uniform air flow can be formed on the heated surface of the sample. Due to the temperature change on the back and the heat-resistant ceramic fiber insulation blanket around the thermocouple, the temperature error caused by the air flow moving on the back of the sample is reduced. Through the three detection points on the front and back of the sample, the temperature evaluation test is carried out within 30 minutes of data. For samples with good high temperature insulation, the lower the front and back temperature, the better the effect of the high temperature insulation system of the sample.

3.3. Establishment of Thermal Conductivity Model.
According to Fourier's law, the thermal conductivity of randomly distributed nanowires is

$$k_{eff} = -\frac{Q_z}{A_z VT}. \tag{3}$$

In the equation, Q_z is the heat flow through the cross section, and VT is the temperature difference in the direction of the heat flow. This is because the pores of the fibrous porous material are very small, and the filling stage is air. Therefore, in the model, the contribution of air to the thermal conductivity of the fibrous porous material is negligible. Therefore, Q_z is the sum of the heat flux of each nanowire passing through the cross section, which can be written as

$$Q_z = \sum_{\alpha=1}^{n_s A_z} Q_\alpha. \tag{4}$$

In the formula, Q_α is the average heat flow through a single nanofiber, the negative sign indicates that the direction of the heat flow is opposite to the z-axis direction, and Q_α is the areal density of the nanowire. Assuming that the contact points of all nanofibers have the same contact thermal resistance, and when the heat passes through the contact points, half of the heat flow flows into or out of a single nanofiber, so we get the heat flow of a single fiber as

$$Q_\alpha = k_0 A_0 \frac{N_c}{2} Bi \frac{\Delta T_{\alpha\beta}}{L}. \tag{5}$$

In the formula, k_0 represents the thermal conductivity of a single nanofiber, $\Delta T_{\alpha\beta}$ represents the temperature difference between contacting nanofibers, and Bi represents the biological number. The formula is

$$Bi = \frac{HL}{k_0 A_0}. \tag{6}$$

In the equation, H is the thermal conductivity of the

nanowire contact, which is the reciprocal of the contact thermal resistance.

Therefore, for randomly distributed nanowires, according to geometric parameters such as the volume fraction, size, and orientation distribution of the nanofibers, the effective thermal conductivity of the porous fiber material can be expressed as follows.

$$k_{eff} = \phi \frac{Bi}{o(4.55 + Bi_T)} k_0. \tag{7}$$

In the formula, φ is the filling rate of fibers in the fibrous porous material, and k_{eff} and k_{eff} respectively, represent the effective thermal conductivity of the fibrous porous material and the thermal conductivity of the fibrous material.

4. Experimental Results

4.1. Thermal Conductivity Test Results. The thermal insulation coatings with different addition amounts of SiO_2 aerogel (as shown in Table 3) were prepared into $15 \, cm \times 15 \, m \times 3 \, cm$ samples, and the thermal conductivity of the coatings at room temperature was tested after drying. The results are shown in Figure 4.

It can be seen from Figure 4 that the room temperature thermal conductivity of the experimental material decreases with the increase of the SiO_2 aerogel addition, and the downward trend is linear.

4.2. High Temperature Insulation Performance Test. In order to investigate the influence of aerogel on the thermal insulation temperature difference, the test results of the thermal insulation temperature difference between the aerogel-free experimental material and the aerogel thermal insulation material were compared, and the results are shown in Figure 5.

It can be seen from Figure 5 that the surface temperature of the aerogel insulation material is generally lower than the surface temperature of the non-silica-based insulation material. This shows that SiO_2 aerogel can effectively enhance the thermal insulation effect of thermal insulation coatings. When the heat source temperature is 200°C, the surface temperature of the material of the thermal insulation layer (without aerogel) is 100°C, and the thermal insulation temperature difference is 100°C, but when the surface temperature of the aerosol thermal insulation material is 60°C, the insulation temperature difference is 140°C. Compared with the nonaerogel thermal insulation material, the temperature of the silica-based thermal insulation material is reduced by 42.3%, and the thermal insulation temperature difference is increased by 42.9%. In contrast, silica-based thermal insulation materials have excellent thermal insulation effects.

Figure 6 is a graph showing the temperature change with time of a silica-based insulation material and a silica-based insulation material-free material.

TABLE 3: Addition of SiO_2 aerogel.

Sample no.	The volume fraction of aerogel in the mixture (%)	The volume fraction of closed pores in the mixture (%)
QY-1	49	4
QY-2	44	4
QY-3	41	4
QY-4	39	4
QY-5	34	4
FIGURE 4: Thermal conductivity of paint at room temperature.

It can be seen from Figure 6 that as time goes by, the temperature of the backside of the silica-based insulating material gradually increases. The heating rate is very fast in the first 20 minutes, and the temperature on the back of the sample rises linearly, rising by 7-8°C every minute. After 20 minutes, the growth rate began to slow down. This is mainly due to the fact that as the silica aerogel starts to function and decomposes at high temperatures, the reaction begins to absorb part of the heat. The addition of aerogel powder increases the porosity of the material, resulting in most pores with a diameter of less than 50 nm, which actually eliminates the transfer of heat in the material.

4.3. Fire Performance Analysis. In this part of the experiment, closed pores and air-entraining agents introduced by aerogel powder were used to form a complex insulation system. The aerosol content puts different volume fractions of closed pore gas into the slurry while maintaining its raw material ratio unchanged. Finally, it is possible to produce high-fire performance composite materials with closed porous aerogel material powders with different bulk densities. At the same time, considering the bursting of the foam during the adding or mixing process, the amount of foam added can be adjusted by adjusting the volume density of the mixture. The closed pores refer to the air bubbles sucked by chemicals from the air, except for cement concrete, excess water and other pores produced by cement hydration. In the test, a reference sample with the same composition and no insulation component is usually used as the reference
Figure 5: Insulation temperature difference test result.
Figure 6: Temperature vs. time curve.
Figure 7: Sample thermal conductivity, fire resistance, and adhesive strength test results.

Table 4: Composition ratio of closed-cell aerogel powder composite coating.

Sample no.	The volume fraction of aerogel in the mixture (%)	The volume fraction of closed pores in the mixture (%)
QY-1	53	0
QY-2	53	4
QY-3	53	7
QY-4	53	10
QY-5	53	13

material, and the relative density between the insulation component sample and the control sample is used to express the porosity. Table 4 shows the composition ratio of the closed-cell aerogel material and the powder composite coating. In the course of the experiment, the corresponding error is allowed according to the adjustment of the bulk density of the mixture.

The samples QY-1 to QY-5 that reached the 28th curing period were tested for thermal conductivity, fire resistance, and adhesive strength. The test result is shown in Figure 7.

It can be seen from Figure 7 that both the thermal conductivity of the composite coating and the thermal conductivity of the aerogel coating gradually decrease with the decrease of the volume density of the closed-cell gas.

5. Conclusions

This article focuses on the application of nanoporous super insulation materials in the prevention of heat damage in deep mining of metal mines. After understanding the relevant theories, the application experiments of nanoporous super insulation materials in the prevention of heat damage in deep mining of metal mines are carried out. According to the experimental results, in the heat insulation test experiment, the temperature of the back surface of the experimental material gradually increases with the increase of time. The temperature rises quickly in the first 20 minutes, and the temperature on the back of the sample rises linearly, rising by 7-8°C every minute. After 20 minutes, the growth rate begins to slow down. This is mainly due to the addition of aerogel powder and the increase in the porosity of the coating, which reduces the pore size inside the coating, most of which is less than 50 nanometers, which effectively eliminates the increase in heat transfer inside the coating. However, due to the limitation of time and technology, we have not carried out in-depth research on it, so we will further explore other aspects of nanoporous insulating materials in the follow-up.

With the continuous development of information science and technology, micro- and nano-fiber optic sensing technology has been widely used in the fields of medicine, communication engineering, and environmental monitoring, and fiber optic devices are widely available in the market because of their advantages such as anti-magnetic interference, corrosion resistance, light weight, high sensitivity, and transmission bandwidth. The purpose of this paper is to investigate the intrinsic correlation between micro- and nano-optical fiber devices and electronic information, introduce the fabrication process of micro- and nano-optical fiber, numerical simulations, and corresponding magnetic field experiments, explore the effects of polarization dispersion and polarization-related dissipation on the system, and enhance the sensing characteristics of micro- and nano-optical fiber through experimental design to maximize its functionality. The experimental results show that the refractive index and magnetic field exhibit a linear relationship with correlation coefficients of 0.995 and 0.994, respectively, when the external magnetic field is between 70 Oe and 300 Oe.

1. Introduction

1.1. Background. Fiber optic technology began in the 1950s, the essence of the medium optical waveguide, while optical fiber is the study of the transmission and exchange of light, the emergence of low-loss optical fiber in the 1970s to promote the development of fiber optic technology [1, 2]. With the continuous progress of science and technology, the convenience of the use of tools has become the mainstream trend, but also continue to become the direction of the scientific community continue to research, the use of tools more and more integrated to meet the needs of the times, micro-fiber optic technology has become the subjects of research, in this context, micro- and nano-fiber optic technology into the field of vision, due to the continuous in-depth research found that micro- and nano-fiber optic technology can form different functions of micro- and nano-photonics devices. It has different degrees of impact on many modern industries, and from this perspective, there is a real need for the development of micro- and nano-fiber optic technology.

1.2. Significance. With the continuous development of micro- and nano-fiber technology, researchers have found that micro- and nano-fibers have many interesting properties [3, 4]. When the diameter of the fiber reaches the micro-nano-scale, the outer diameter of the optical fiber is generally 125-140 μm, and the core diameter is generally 3-100 μm and when the diameter is kept within a certain range, the binding of the optical field is stronger than that of an ordinary fiber, which can enhance the interaction between light and the medium and produce nonlinear effects at lower input power; it can transfer the energy force of the optical field to propagate outside the fiber, and this energy can be used as a sensitive sensor material for light coupling in certain cases.

1.3. Related Work. Micro- and nano-fiber optic technology is relevant in real life, but because of its late appearance, many functions are still being explored and have led to numerous studies. XIA presents different micro- and nano-structured fiber optic probes for biosensing, imaging, and stimulation applications and argues that modifications to the fiber can

extend the design freedom from waveguide optimization to functional material integration, and that fiber optic probes with optimized waveguide structure or integrated functional materials of fiber optic probes can achieve enhanced optical mode interaction with biological samples, leading to ultra-sensitive biosensors with significantly low detection limits [5]. Jiang J proposed an optical detection method based on micro- and nano-fiber (MNF) technology through a simple single-mode fiber. Theoretically, the evaporation field generated by MNF is calculated and its relationship with refractive index and water in oil is established, after which a MNF probe with a diameter of $800 - 125 \mu$m is fabricated and prepared by means of a home-made melt-tapered platform. The experimental results showed that the MNF-based optical sensor could achieve real-time measurement of moisture in transformer oil with a sensitivity of 1.8 ppm when the MNF diameter was 800 nm [6]. May-Arrioja D. A. presented experimental results of an optical fiber pressure sensor based on multimode interference effects (MMIs). The key component is a small multimode fiber (MMF) part without cladding, which is placed in direct contact with a polydimethylsiloxane polymer layer previously attached to a pressure-sensitive membrane. As the applied pressure increases, both the polymer contact area and the induced stress on the MMF increase in proportion to the applied pressure. The response of the sensor is highly linear over the pressure range of 0-960 kPa with a sensitivity of -0.145×10-3 mW/kPa. The main features of the MMI pressure sensor are its low cost and high repeatability [7]. Liu presented recent research advances in key devices and technologies for fiber optic sensor networks (FOSN). As the most important devices for FOSN, a variety of light sources have been developed, including broadband multi-wavelength fiber lasers operating in C-band, switchable tunable 2-μm multi-wavelength fiber lasers, ultrafast mode-locked fiber lasers, and optical broadband chaotic sources with very promising applications in FOSN [8]. Krehlik P. provided an overview of an electronically stabilized (ELSTAB) fiber time and frequency (T& F) distribution system, which is based on the idea of using variable electronic delay lines as compensation elements, describes various extensions of the basic system that allow the creation of a long-range multi-user network, discusses the fundamental limitations of the approach caused by fiber dispersion and system dynamics, and outlines the main hardware challenge of the system, which is the design of a pair of low-noise, precisely matched delay lines. Finally, experimental results of T&F distribution over a 615 km long fiber are presented, demonstrating an average frequency stability of 105 s and a time calibration well below 50 ps accuracy in the range of $1-7 \times 10$-17 [9]. Pimentel R presents a cost-effective bridge crane (B-WIM) system for identifying train loads using fiber optic technology. The system is capable of estimating the speed, geometry, and static axle loads of trains using an algorithm proposed by Moses. The algorithm involves solving a reverse identification problem where the measured structural response is known and the load scenario is unknown. The method relies on the concept of the influence line (IL), which is estimated from the passage of a calibrated vehicle with known characteristics

[10]. An innovative reversible data hiding (RDH) scheme is proposed which uses Lagrangian interpolation polynomials, secret sharing, and bit permutation to achieve electronic medical security. The covered medical images are subsampled into four shares, and cloud computing with Internet proves to be an important tool for providing better healthcare services. However, the maintenance, privacy, confidentiality, and security of electronic health information (EHI) pose a huge challenge for telemedicine. The scheme is used to expand subsamples to hide EHI, and secret information is processed using Lagrangian interpolation polynomials before being embedded in various cover images [11]. Wang presented the principle of holographic lithography and described its application in fabricating various micro- and nano-photonic structures such as 3D face-centered cubes, wooden piles, diamond-like photonic crystals, and quasi-crystalline structures, chiral metamaterials, and periodic defect mode structures, and holographic lithography is a low-cost, time-saving, and efficient microfabrication method with promising applications in making metamaterials and photonic crystal templates [12]. Micro- and nano-photonic structures are booming with a series of results in structural characterization, theory, and fabrication, but most of the high-quality photonic structures are artificial, and there are still some challenges in fabricating artificial large-area high-quality photonic materials.

1.4. Innovation Points. In this paper, we analyze the refractive index sensing characteristics of different types of single-mode fiber modes, think about the relationship between them in different cases, and verify the sensitivity of the refractive index through the experiment of interferometric instrumentation of different fibers; we propose a diameter-based fiber regulator to destroy the fiber by external force to change its original mode field distribution, and analyze its sensitivity in different cases through experiment. From this, the reasons for the change in transmission are explored.

2. Theoretical Modeling of Composite Micro- and Nano-Fiber Devices and Research Methods for Electronic Information Applications

2.1. Overview of Micro- and Nano-Optical Fibers. In the late 1870s, micro- and nano-fiber optic technology began to develop and was widely used in several fields, especially in the field of information applications [13]. Micro-nano-photonics mainly studies the law of interaction between light and matter at the micro-nano-scale and its applications in light generation, transmission, regulation, detection, and sensing. Micro-nano-photonics subwavelength devices can effectively improve the photonic integration, and it is expected to integrate photonic devices into a small single optical chip like electronic chips. Fiber optic technology is essentially a sensing technology, and the first controlled recordings appeared in the early 1990s, when some researchers proposed the use of glass fibers for medical
FIGURE 1: Micro-nano-area under optical microscope.

examinations, which led to the further development of micro- and nano-fiber optic technology in medicine. The difficulty of using light propagation is how to reduce transmission down loss and achieve optical communication. It was not until the continued maturation of fiber optic materials and wire drawing technology in 1972 that the low consumption of optical fibers was substantially advanced and successfully used to create a successful fiber optic communication system line, which laid the foundation for the practicalization of fiber optic communication [14].

Because fiber optic technology has many advantages such as high temperature and corrosion resistance and is widely used in real life, the survey data show that the global consumption of micro- and nano-fiber optic sensor market will grow at a rate of 20%, and the output value of about 5 billion U.S. dollars, in the Asia-Pacific region, China is the largest consumer and production market [15]. Photonic devices with many structures have been successfully made using micro- and nano-fiber technology, which have shown important research value in different fields such as communication and sensing, and more micro- and nano-fibers are designed and widely used. Microstructured fibers have been widely used in cutting-edge research in many fields such as optical communication, fiber sensing, and optical metrology, such as the generation of supercontinuum, high-power pulse transmission, ultra-low-power nonlinear effects, and tomography and remarkable results have been achieved in this research direction. Figure 1 shows the micro- and nano-regions under optical microscope.

2.2. Micro- and Nano-Fiber Mode Field Distribution. Micro- and nano-fibers are those whose diameters are infinitely converging to the micron or nanometer scale and whose refractive indices are relatively large. To explore the mode field distribution of micro- and nano-fibers, we first need to understand Maxwell's set of equations [16]. Figure 2 shows a schematic diagram of a micro- and nano-fiber.

First, we need to construct an ideal model of a micro- and nano-fiber, assuming that it can satisfy the following conditions.

(1) A diameter greater than 10 nm, which can respond to the optical field

(2) The micro-nano-fiber is relatively long, enough to establish a suitable mode field distribution

(3) The micro-nano-fiber indicates that it cannot be too coarse, but acceptable only to the extent that scattering of light is negligible

(4) The diameter of the micro-nano-fiber is uniformly distributed

Based on the above ideal state of the micro-nano-fiber, we can set the micro-nano-fiber as a cylinder, at which time the refractive index of the micro-nano-fiber can be segmented to represent.

$$t(a) = t_1, 0 < a < q, \tag{1}$$

$$t(a) = t_2, q < a < \infty. \tag{2}$$

In the above equation, q, t_1, and t_2 are the radius, core refractive index, and external ambient refractive index of the micro-nano-fiber, respectively. Fiber index of refraction generally refers to graded-index fiber. Graded-index fiber is also called self-focusing fiber. The center of refractive index of the fiber is the highest and decreases along the radial direction. The light beam propagates in the fiber and can be automatically focused without dispersion.

In general, neglecting their depletion, we express Maxwell's equations in the micro- and nano-fibers as follows: Maxwell's equations are a set of partial differential equations established by British physicist James Clark Maxwell in the 19th century to describe the relationship between electric and magnetic fields, charge density, and current density.

$$\left(\nabla^2 a^2 t^2 - \rho^2\right) \vec{b} = 0, \tag{3}$$

$$\left(\nabla^2 a^2 t^2 - \rho^2\right) \vec{k} = 0. \tag{4}$$

In the above expression, a is the refractive index of the point, $t = 2\pi\tau$, where τ is the wavelength and ρ is the wavelength propagation constant.
FIGURE 2: Schematic diagram of micro- and nano-fiber.

The eigenequation of the vector mode sum is expressed as:

$$
\begin{bmatrix} J'_Q(U)_+ k'_Q(W) \\ UJ'_Q(U)WK_Q(K) \end{bmatrix} \begin{bmatrix} J'_Q(U)_+ m^2{}_2 k'_Q(W) \\ UJ'_Q(U)m^2{}_1 WK_Q(K) \end{bmatrix} \\ = \left(\frac{v\alpha}{km_1} \right)^2 \left(\frac{V}{UK} \right)^4 . \tag{5}
$$

For PE$_{0M}$ mode, there exists:

$$
\frac{m_1{}^2 J_1(U)_+ m_2{}^2 T_1(W)}{UJ_0(U)WK_0(W)} = 0. \tag{6}
$$

For PN$_{0M}$ mode, there exists:

$$
\frac{J_1(U)_+ T_1(W)}{UJ_0(U)WK_0(W)} = 0. \tag{7}
$$

In the above equation, it denotes the Cybel function, $V = P_0 t(m_1^2 - m_2^2)/2$, $U = t(k_0^2 m_1^2 - \alpha^2)/2$, $W = t(\alpha^2 - k_0^2 m_2^2)/2$ where $t = 2b$.

Theoretically, optical fibers have many propagation modes, but only the transmission conditions and republican transmission modes can be propagated using optical fibers at the same time, and from this perspective, the propagation modes are not infinite. According to the number of transmission modes in the fiber, the fiber can be divided into multimode fiber and single-mode fiber. At a certain operating wavelength, multimode fiber is a dielectric waveguide that can transmit many modes, while single-mode fiber only transmits the fundamental mode. In micro- and nano-optics, the accommodation mode depends on the radius and refractive index of the micro- and nano-optics [17]. The expression for the refractive index of micro- and nano-optics medium is as follows:

$$
\Delta m = m_1 - m_2. \tag{8}
$$

The expression of the fundamental mode energy condition of the micro- and nano-fiber is:

$$
W = \pi \frac{f_{AZ}}{\mu_0} \left(m_1^2 - m_2^2 \right) \approx 2.40, \tag{9}
$$

where $f_{AZ} = 2b$ denotes the critical diameter of the micro- and nano-fiber.

The expressions for each component of the electric field transmitted in a micro- and nano-fiber can be expressed as:

$$
e_t = -\frac{c_1 J_0(UR) + c_2 J_2(UR)}{J_1(U)} f_1(u), \tag{10}
$$

$$
e_u = -\frac{c_1 J_0(UR) - c_2 J_2(UR)}{J_1(U)} g_1(u), \tag{11}
$$

$$
e_p = -i \frac{U J_1(UR)}{\mu \sigma J_1(U)} f_1(u), \tag{12}
$$

where $0 \leq c < q$;

$$
e_t = -\frac{U c_1 K_0(WR) - c_2 k_2(WR)}{W K_1(W)} f_1(u), \tag{13}
$$

$$
e_u = -\frac{U c_1 k_0(WR) + c_2 k_2(WR)}{W k_1(W)} g_1(u), \tag{14}
$$

$$
e_p = -i \frac{U k_1(WR)}{\tau \sigma k_1(W)} f_1(u). \tag{15}
$$

For a micro-nano-fiber with uniform diameter and no significant folding, the expression can be expressed as:

$$
T_{c1} = \frac{1}{2} \left(\frac{\gamma_0}{\pi_0} \right)^{0.5} \frac{l m_1^2}{\alpha J_1^2(R)} * \left[c_1 c_3 J_0^2(RF) + c_2 c_4 J_2^2(RF) \right. \\ \left. + \frac{1 - A_1 A_2}{2} J_0(RF) J_2(RF) \cos (2\theta) \right]. \tag{16}
$$
Figure 3: Machining tools and materials.

At this point, $0 \le c < q$.

$$T_{c2} = \frac{1}{2} \left(\frac{\gamma_0}{\pi_0} \right)^{0.5} \frac{l m_1^2 U^2}{\alpha L_1^2(W) W^2} * \left[c_1 c_5 l_0^2(WF) + c_2 c_6 l_2^2(WF) \right.$$
$$\left. + \frac{1 - 2\Delta - A_1 A_2^2}{2} L_0(WF) L_2(WF) \cos 2\theta \right].$$
(17)

At this point, $q \le c < \infty$.

2.3. Electronic Information. "Electronic information" is an informatics vocabulary, and its appearance is closely related to the rapid development of computer technology, communication technology, and high-density storage technology and its wide application in various fields. Electronic information engineering is a discipline that applies computer and other modern technologies for electronic information control and information processing. It mainly studies the acquisition and processing of information, and the design, development, application, and integration of electronic equipment and information systems.

2.4. Preparation Methods of Micro- and Nano-Optical Fibers. Micro- and nano-optical fibers are circular optical waveguides with diameters in the micron range. Since the introduction of micro- and nano-fiber technology, researchers have explored a variety of methods for fabricating micro- and nano-fibers. In terms of specific practice, there are only two methods to fabricate micro-nano-constructions: top-to-bottom and bottom-to-bottom. The process of making optical fiber by chemical growth method is a bottom-to-top process, and the micro-nano-fiber drawn from bulk glass is a top-to-bottom process. It is customary for us to refer to the process of fabricating micro- and nano-fibers using chemical techniques as bottom-up. Other technologies manufacture processes called top-to-bottom processes whose

main raw materials include, but are not limited to, block glass and single-mode fibers [18, 19].

2.4.1. Single-Mode Fiber Fabrication. The fabrication of micro- and nano-optical fibers using flame heating hair was first proposed in 2003. This method mainly uses an alcohol lamp for heating; first, a small section of fiber is heated until it melts, and then tension is applied to both ends of the fiber until the desired diameter of the micro-nano-fiber is obtained. If we want to make it very light, the heating and melting operation in the natural environment is very easy to be affected by the external environment; secondly, when applying tension to the micro-nano-fiber, we need to keep the tension constant, then there is a great limitation of this method when we need to make a finer diameter, and the micro-nano-fiber is easy to break if we are not careful, so this method is only applicable to the ideal state, and it is very difficult to do in practice [20, 21]. When heating the single-mode fiber, a certain stretching force is applied to both ends of the single-mode fiber, and the pulling force can be kept constant by controlling the stretching speed. Figure 3 shows the processing tools and materials:

2.4.2. Block Glass Fabrication. In addition to single-mode fiber fabrication, researchers have proposed that bulk glass can be used as a material for micro-nano-fiber preparation, and this method has a wide selection of materials, including sulfide glass, fluoride glass, and tellurite glass, among others, and the desired substances, such as ions, can be added to these materials, so that the fabricated micro-nano-fiber can be more complete during the fabrication process [22]. The steps are as follows.

(1) First, the micro-nano-fiber is heated, noting that the melting point at this point must be greater than that of the chosen glass material

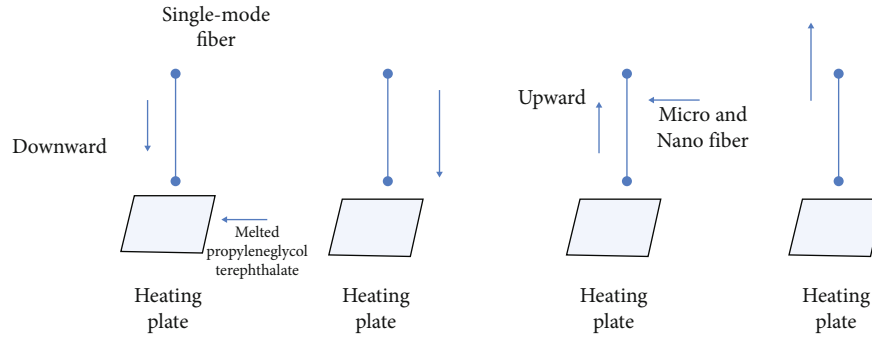
(2) Contacting the bulk glass with the heated fiber while continuing to maintain the high temperature of the micro-nano-fiber


Figure 4: . Operation schematic.

(3) Take away the lump glass when the mutual contact appears to be melted, but it must be confirmed that there is a small portion of melted glass material on the micro-nano-fiber at this time

(4) Pacing the new micro-nano-fiber in contact with the heated micro-nano-fiber

(5) Lowering the heating temperature to cool down the glass between the two micro-nano-fibers

(6) The application of a certain rate of pulling from unheated micro-nano-fibers results in new micro-nano-fibers. Using this method of fabrication, micro-nano-fibers with different characteristics can be produced depending on the materials chosen

2.4.3. Polymer Fabrication. In addition to the above-mentioned raw materials, researchers have found that polymers can also be used to fabricate micro- and nano-fibers. In the early days, micro- and nano-optical fibers have been successfully fabricated using polypropylene terephthalate polymers. The low melting point, good flexibility, and fast crystallization rate of poly (propylene terephthalate) make it possess the requirements for fiber formation, and the refractive index of poly (propylene terephthalate) is only 1.638 when it is in the amorphous state, which possesses good optical confinement [23, 24]. The manufacturing steps are as follows.

(1) Firstly, poly (propylene terephthalate) is heated to a softened state in which the temperature is kept stable

(2) Contacting the melted poly (propylene terephthalate) with a single-mode optical fiber, at which point the single-mode fiber will have some residue of the poly material

(3) Lifting the single-mode fiber at this time at a certain speed

After lifting the single-mode fiber, an intuitively very fine micro-nano-fiber will appear, and it will rapidly cool down into an amorphous poly (propylene terephthalate) micro-nano-fiber. Figure 4 shows a schematic diagram of the operation:

2.4.4. Laser Preparation. Since the use of gas for heating is susceptible to interference from the external environment and can easily cause errors during preparation, researchers have worked to find fabrication methods that are free from interference from the external environment, and in 2006 successfully fabricated micro-nano-fibers using a carbon dioxide laser as a heating instrument, which uses a carbon dioxide laser to scan and heat a single-mode fiber [25]. The main principle is to adjust the output of the carbon dioxide laser with a total controller, and use a tool to focus the laser on a single-mode fiber, and the spot diameter matches the micro-nano fiber used. By controlling the angle of the tool, the entire light spot in the single-mode fiber can move axially, and the heating of the single-mode fiber needs to change the structure; the longer the micro-nano-fiber needed, then the higher the power output of the CO2 laser needs to be, but this method is not infinitely long, and the diameter of the pulled micro-nano-fiber is still said to be relatively large compared to other methods [27].

2.4.5. Electrode Heating Preparation. To understand the problem of interference from the external environment, in addition to using a CO2 laser, researchers have proposed to protest the use of electrodes for heating; the main steps of which are as follows.

(1) First fixing the single-mode fiber with one end placed in a heater

(2) Using a heater bar to press the single-mode fiber into the container, the heater bar needs to be connected to the electrode with a standard voltage of 250 V. The temperature of the heated container needs to reach 1600°C

(3) The other end of the micro-nano-fiber is fixed on the rotating platform, and the rotating platform is driven to rotate after reaching a certain temperature, and the heated single-mode fiber can be drawn out of the micro-nano-fiber during the rotation process

The micro-nano-fiber prepared using this heating method can reach 900 nm in diameter and several hundred mm in length, and the heating of the single-mode fiber using electrodes can provide a large heating area and make the

TABLE 2: Relative humidity values of salt solutions.

Solution		Magnesium chloride	Lithium chloride	Potassium carbonate	Sodium chloride
Relative humidity (%)	26°C	32.3	11.1	43.5	75.1
	29°C	32.1	11.2	43.5	75.2
	30°C	32	11.2	43.5	75.2

single-mode fiber uniformly heated; in this process, the user can change the voltage as well as the rotating platform to change the length and diameter of the micro-nano-fiber [28]. Table 1 shows the comparison of various micro- and nano-fiber drawing methods:

3. Experiments on Theoretical Modeling of Composite Micro- and Nano-Fiber Devices and Electronic Information Applications

3.1. Experimental Environment. The micro-nano-fiber sensor is put into different humidity devices, and the data acquisition connector is connected to the broadband light source and the spectrum analyzer through a 3 dB coupler, and the humidity environment in the experiment uses a supersaturated solution, and we select different supersaturated solutions such as sodium chloride, potassium carbonate, magnesium chloride, and lithium chloride for the experiment, keeping the experimental temperature between 26°C and 29°C [29]. If the temperature of the chemical solution is too low or too high, a chemical reaction will occur, resulting in the deterioration of the solution, and deviations will occur in the experiment. The experimental setup is shown in Figure 5.

3.2. Experimental Data Acquisition. Table 2 shows supersaturated solutions with different humidity levels, and in our experiments, we passed sensors with different specifications through these supersaturated solutions in sequence, labeled separately, at different temperatures, and the wavelength of the micro-nano-fiber changed as the humidity of the solution varied [30]. The wavelength of magnesium chloride solution will shorten as the temperature increases, and other solutions will remain unchanged or elongated.

According to the data in Table 3, it can be seen that the wavelengths of the micro-nano-fibers were significantly shifted by adding them to different supersaturated solutions while keeping the experimental temperature constant, but they basically drifted toward the long wave direction. In addition, with the increase of ambient humidity, the center wavelength of the reflection spectrum of the humidity sensor shifts to the long wavelength direction.

According to the data in Table 4, it can be seen that different micro-nano-optical fibers change in different supersaturated solutions while keeping the experimental temperature constant, and overall, when the temperature is constant, the greater the relative humidity of the solution, then the greater the amount of drift to come, and according to the experiment, it can be seen that the larger drift occurs

TABLE 3: Wavelengths of saturated solutions with different humidity.

Solution	Magnesium chloride	Lithium chloride	Potassium carbonate	Sodium chloride
Temperature (°C)	25	25	25	25

TABLE 4: Wavelength drift.

Solution	Magnesium chloride	Lithium chloride	Potassium carbonate	Sodium chloride
Temperature (°C)	25	25	25	25
Wet relative humidity (%)	10	30	50	70
Wavelength drift amount (nm)	0	0.2	0.7	1.3

TABLE 5: Sensor corresponding parameters.

Sensors	Micro- and nano-fiber diameter (μm)	Sensitivity (pm/%)	Linearity (%)
Magnesium chloride	115	23.12	99.61
Lithium chloride	23	31.75	99.59
Potassium carbonate	17	32.18	99.29
Sodium chloride	14	35.46	99.73

in magnesium chloride, followed by sodium chloride solution, and the smallest drift occurs in lithium chloride solution [31].

According to the data in Table 5, it can be seen that the sensitivity of the sensors used in the experiments is above 99%, and most of the humidity sensors are higher than the sensitivity of ordinary optical fiber humidity sensors, so it can be concluded that the sensor sensitivity of micro-nano-fiber humidity sensitivity has been improved to a great extent compared with ordinary micro-nano-fiber. Combined with the above mentioned that within a certain humidity, the wavelength drift amount and humidity have a good linear relationship, so we believe that the humidity sensor has good detection effect in a certain acidic solution environment [32].

4. Theoretical Modeling and Electronic Information Application Research Analysis of Composite Micro- and Nano-Fiber Devices

4.1. Micro- and Nano-Optical Fiber Stability Characteristics. In the above experiments, we introduced that wavelength and refractive index are length dependent. If the length is simply changed, then the wavelength also changes, and in order to explore the relationship, we utilized an interferometer axial strain characteristic measurement instrument for detection (Figure 6 shows the interferometer axial strain system) each time the position is shifted and its length is changed, and the following data are obtained.

According to Figure 7, we can see that we have carried out the projection profiles during the changes of 80 μm,
FIGURE 6: Interferometer axial strain system.

160 μm, 240 μm, and 320 μm, respectively, and from the data, we can see that the difference in the values of the spectral interference valley drift is relatively small in different length displacement changes, and overall it is still relatively stable and basically does not change much according to the valley comparison, so that it can be used as a strainer [33].

According to the data variation in Figure 8, we can find that analyzing the ratio of the length of the axial change to the length of the fiber can be derived from the microstrain of the fiber axially, and according to the recorded changes corresponding to the wavelengths shown in the figure, we can see that the reasonable sensitivity of the interferometer is around 0.55, while the sensitivity of the interferometer we obtained is around 0.6 and 0.61, so we can confirm that the sensitivity is reasonable at this time.
FIGURE 7: Microstrain measurement.
FIGURE 8: Relationship between wavelength and strain variation.

4.2. The Magnetic Field of Micro- and Nano-Fibers. As mentioned in the previous section, the magnetic field of micro-nano-fiber is closely related to the fiber diameter and core refractive index. According to the analysis in the study, chemical means can be used to change the diameter of the micro-nano-fiber as a way to change the whole magnetic field distribution, and in order to verify this conjecture, we conducted an experimental analysis and found that the diameter size of the micro-nano-fiber does have a large influence on the whole magnetic field [34].

According to Figure 9, when the corrosive solution is contacted with the micro-nano-fiber, it is found that it has a large impact on the diameter of the micro-nano-fiber, resulting in a higher loss of the micro-nano-fiber, so it can be seen that the difference between the wave and valley in the figure is large, and once the external interference is performed, it will lead to a large change in its magnetic field; when the corroded micro-nano-fiber is added to the magnetic fluid solution when there is no external magnetic influ-

ence, its refractive index size remains at 1.4. When we add the magnetic fluid, it is obvious that the wavelength of the micro-nano-fiber has changed and the frequency has shifted.

4.3. Relationship between Magnetic Field Strength and Transmittance of Micro- and Nano-Fibers. In the above, we mentioned that the size of external magnetic field will cause the micro-nano-fiber to change to different degrees, and by adding different properties of magnetic fluid can make the refractive index of the micro-nano-fiber change, and when the refractive index changes, its transmittance will also change, and the main changes are as follows:

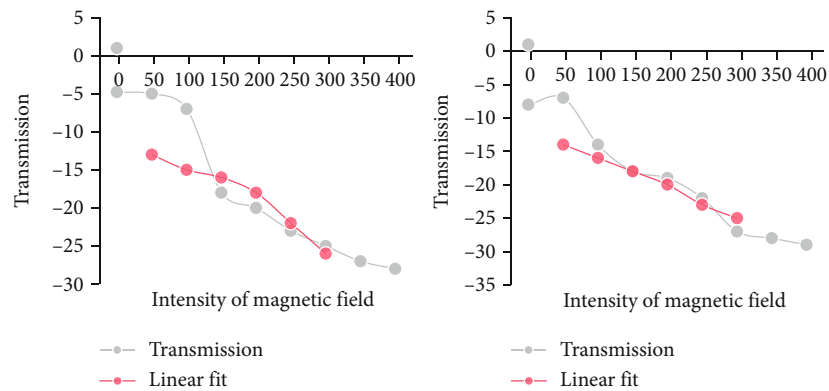
From Figure 10, it can be seen that the influence of the magnetic field size on the transmittance, but according to the obtained data, we find that the transmittance presents a nonlinear relationship; when the external magnetic field is less than a certain data, the transmittance will remain unchanged, and when the external magnetic field reaches the degree of saturation, its transmittance does not change
Figure 9: Comparison chart of corroded fiber.


Figure 10: Comparison of magnetic field strength and transmittance.

significantly, but when the external magnetic field is between 70 Oe and 300 Oe. However, when the external magnetic field is between 70 Oe and 300 Oe, they show a certain linear relationship with correlation coefficients of 0.995 and 0.994, respectively. This data indicates that the relationship of the optical magnetic field can be adjusted by using different degrees of external magnetic field and can be applied in the communication magnetic field.

5. Conclusions

With the continuous development of micro- and nano-fiber technology, fiber optic devices are gradually adding to the convenience of miniaturization, and in the process of continuous miniaturization, micro- and nano-fiber technology is also developing, and micro- and nano-fibers of different structures, diameters, and lengths are being manufactured continuously, and at present, the academic exploration of the characteristics of micro- and nano-fibers with differences in fabrication and the application of devices in different fields has become the current fiber optic science and technology and scientific. In this paper, we will focus on the fabrication of micro- and nano-fibers. In this thesis, we have (1) investigated the fabrication methods of micro-

and nano-fibers in different transmission modes, and analyzed their physical significance, advantages, and disadvantages in the practical process, and their practical value; (2) explored the transmission characteristics of fine core micro- and nano-fibers with different diameters and their distribution characteristics, and simulated the transmission modes of different sizes of micro- and nano-fibers; (3) investigated the connection between the magnetic field of micro- and nano-fibers and fiber diameter, core refractive index, and found the connection between the magnetic field of micro- and nano-fibers. The larger the diameter of the micro-nano-fiber, the larger the wavelength shift, and the corresponding change in refractive index, thus changing the magnetic field; (4) to explore the correlation between the magnetic field and transmittance, it is found that when the external magnetic field is less than a certain data, the transmittance will remain unchanged, and when the external magnetic field reaches saturation, the transmittance does not change significantly, but when the external magnetic field is between 70 Oe and 300 Oe, the transmittance does not change significantly. However, when the external magnetic field is between 70 Oe and 300 Oe, they show a certain linear relationship. Although this paper has explored certain contents, there are still many shortcomings: (1) the operation

steps of the micro-nano-fiber research in this paper are all in the ideal experimental environment, the encapsulation technology of micro-nano-fiber needs a constant temperature environment, and due to this necessary condition, it cannot be utilized in a commercial environment on a large scale; (2) when using chemical technology for corrosion, it is easy to make mistakes, and the corrosion solution. We still need to find other relatively safe methods to fabricate micro-nano-fibers; (3) the techniques adopted in this paper are considered to be operational, which makes it difficult to ensure that the fabricated micro-nano-fibers are identical, which makes it more difficult to mass produce micro-nano-fibers.

This research paper deals with a system-on-chip (SoC) architecture design where multiple processors are inbuilt with other blocks of memory and control logic developed by nanomaterials. The multiprocessing-based SoC architecture is commonly used in the latest electronic devices such as smartphones, tablets, and smart wristwatches with large memory sizes. The data handing in these highly memory-dense devices is a critical task, and it needs special attention for the smooth operation of the device. This research proposed a smart controller to exchange data between various processors and input-output devices to tackle this challenge. A proposed controller block controls the data flow between memory and different SoC components and processors. A memory access controller (MAC) is presented in this research study to manage and accelerate data transmission speed and reduce the processors' activity for SoC-based devices. The proposed MAC will integrate into the SoC with multiprocessing units, including gaming processors, at minimum hardware overhead and low power consumption. It improves the memory accessing efficiency and reduces the processors' activity of a system. As a result, the system's performance and power consumption improve at an acceptable level compared with the other conventional methods. This research is aimed at enhancing the performance of any SoC-based device where multiprocessing engines are inbuilt and flexible enough to serve various SoCs.

1. Introduction

In response to the rising demands of IoT devices, the 4G mobile phone devices cannot provide complete imminent services, which is required for the next-generation IoT-based system and other SoC-based systems [1, 2]. There is ample research conducted in this context of next-generation 5G mobile services [3, 4].

The traffic growth exponentially increases mobile phone networks from the generation of the cellular system 1G to 5G [5]. As per the survey of the CISCO Corporation, the data traffic on the mobile web becomes doubled from 2010 to 2011. They also stated that mobile traffic would increase by 1000x and above by 2021 compared to 2010 [6]. Due to this increased level of mobile traffic, the energy consumption of the mobile handset user increases with immense power. Therefore, it directly affects the expenditure. It is necessary to rethink the design to control these attributes and manage the network to reduce spending in a next-generation mobile

phone system called the 5G generation. There is a future prediction of a fully connected society where everybody and everything is interconnected, on a common platform of the Internet of Things (IoT)—where many devices serve a single person. Therefore, the forthcoming 5G cellular infrastructure for massive data support will enable smart cities. There will be a need for an intelligent SoC design to support these 5G features in next-generation mobile phone devices and other SoC-based devices. The SoC of these devices should compromise with a high-end processing unit with an intelligent memory controller inbuilt feature.

In this context, a low-power, high-performance SoC development approach is accessible [7] that deals with the power management in the SoC for IoT-based devices. This SoC approach was developed on 65 nm technology and occupied an area of $1.0 \times 1.7 \, \text{mm}^2$. Similarly, a method dealt with an adaptive power management (APM) design module that extensively supports learning techniques [8] and reduces power consumption in the IoT-SoC.

We are aware that the SoC is a single-chip integrated system and each block of it remains the intellectual property (IPs). The IPs are part of SoC, are available as processor core (one or more) peripheral devices, and are sometimes called macros. They are incorporated as per the requisition or demand of the SoC design. The SoC of these intelligent devices consists of some hardware and some software IPs. The hardware IPs are the processor, random access memory (RAM), and universal serial bus (USB) devices. The software IPs are the device drivers, the processor running algorithms, etc. IPs communicate together via specific channels called the on-chip bus, and it links all the IPs that belong to it [9]. This SoC bus works on a precise communication protocol containing various bus strategies. For instance, the IP begins communication to any other IP only when the bus is idle (not accessible by any further IPs). In this case, the IP with control over the bus is called the master, and other IPs responding to it are called slaves [10].

In case the master is accessing the SoC bus to convey their messages to other IPs at a particular instance, known as the active master. This SoC bus will remain idle during the absence of the active master. In recent times, multiprocessor systems have been drastically used to improve power performance compared to single processor systems in desktop segments. It caused the extensive application of multiple processor SoC cores, known as multiprocessor SoCs (MPSoCs) [11, 12]. These MPSoC cores are commonly available in the latest smartphone and other gaming devices. Therefore, some processors need to be offloaded to handle essential tasks and deal with such a high configurable multiprocessor-based SoC.

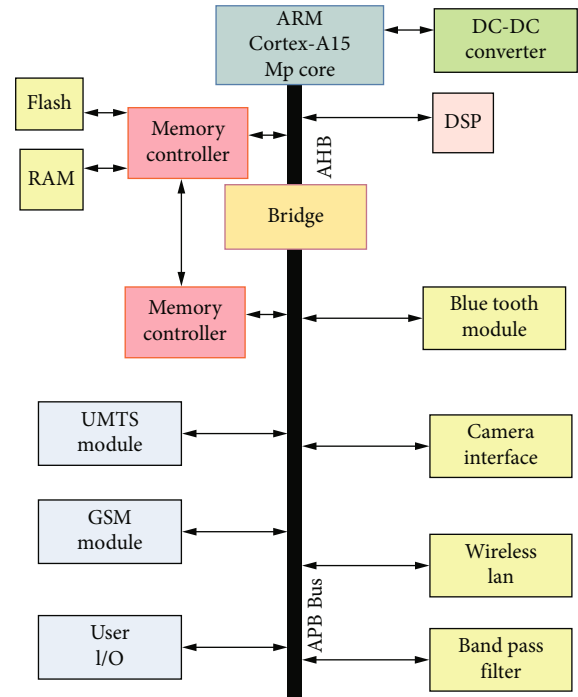
This paper is motivated by the future requirements of the SoC architecture of multiprocessor-based smart devices to fulfill consumers' demands. We cannot ignore the snapdragon SoC as it explicitly concerns multiprocessor-based devices [13]. The majority of the market for android-based devices uses Snapdragon SoC in their devices. The single snapdragon SoC contains many processing units based on the ARM instruction set. In this research study, we proposed a MAC unit to perform tasks in parallel with the processor to enhance the speed and performance of the processing engines. Memories generally occupy the majority area of SoC, and it motivates this research to choose the MAC unit as a research topic to improve the processor performance. SoC architectures of the majority of digital systems mainly consist of nanomaterial-based memories. For example, the SoC of mobile phone devices, smart wristwatches, and mobile tablets comprises large memory sizes. The International Technological Roadmap for Semiconductor (ITRS) report is available for reference [14, 33] to convey that the memories occupy most of the SoC area. The MAC unit is small in hardware and occupies a tiny space overhead when integrating with SoC design when manufacturing the nano-technological chip. Compared with the processor area (here, we consider a Snapdragon SoC), it holds a very thin area overhead of 0.0003% with low power consumption and a fast data transfer rate. Thus, the area overhead is negligible compared to a SoC area.


Figure 1: SoC architecture with multiprocessing units.
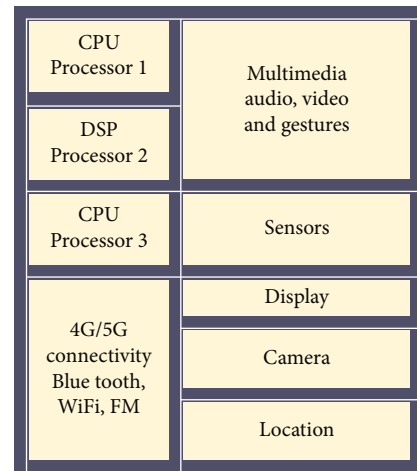

Figure 2: The Snapdragon multiprocessing is SoC.
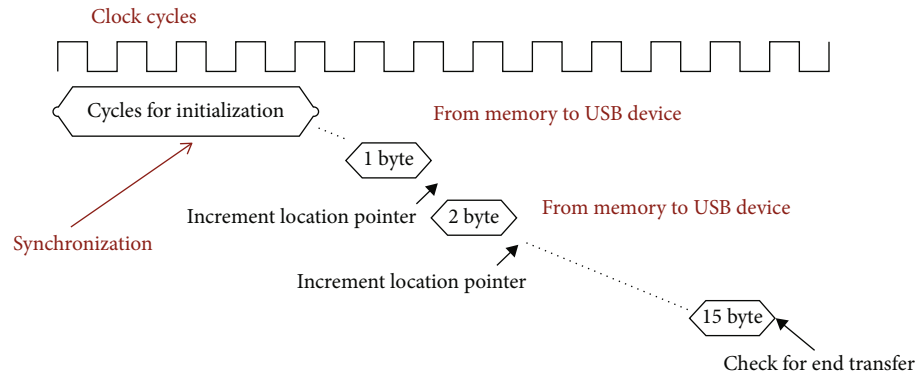
Figure 3: MAC data exchange principle.


Figure 4: MAC transfer of data between peripheral and memory.

The authors' contributions to the article is noted as follows:

(i) Proposing a novel MAC unit architecture to perform memory accessing tasks while integrated with SoC at a fast transfer rate

(ii) Evaluate area overhead and power consumption and analyze the processor's performance with and without integrating the MAC unit into the SoC of the smart device

(iii) Reduces the processor's activity, and hence, it saves system power and temperature by integrating MAC unit into SoC

The paper is organized as follows: Section 2 outlines the SoC architecture of the mobile phone for previously available devices in terms of the services provided. Section 3 proposes the MAC architecture for mobile SoC. Simulation and ASIC Synthesis results are presented in Section 4. In this section, we have compared the area overhead of SoC by taking the example of Qualcomm's processor Snapdragon SoC. Finally, we conclude the paper in Section 5.

2. SoC Architecture with Multiprocessing Units

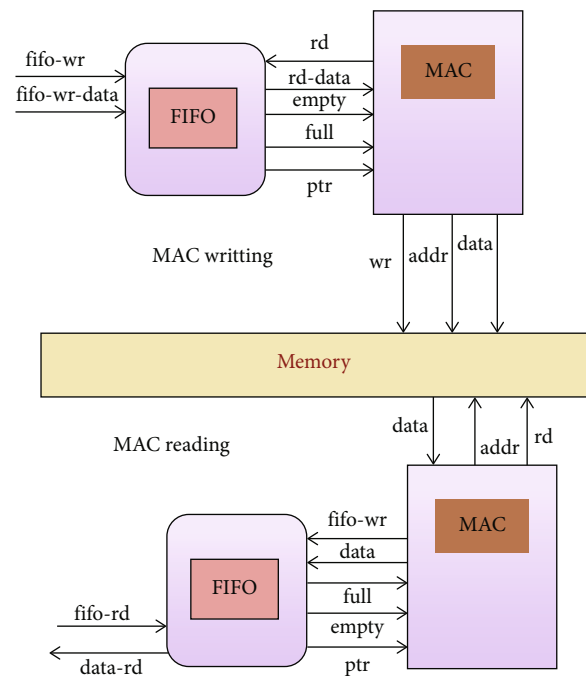
A generic SoC architecture with multiprocessing units with various IP blocks is depicted in Figure 1. This SoC architecture uses the ARM Cortex-A15 multicore processor with advanced microcontroller bus architecture (AMBA) [15]. There are two different processing cores included in this SoC, namely, ARM Cortex A15, also known as a general purpose multiprocessor (GPMCP), and digital signal processing (DSP) processor [12]. These GPMCP and DSP processors are coupled with the memory controller core, enabling them to collaborate with other external flash memory, and system memory with the help of a high-performance AMBA advanced high-performance bus (AHB). In addition to these IPs, there is additional peripheral IP in the system, which supports UTMS (universal mobile telecommunications system) and GSM (global system for mobile communication). The external IPs are connected with the system through the high-performance bus known as AMBA advanced peripheral bus (APB). Since every mobile phone SoC consists of these two


Figure 5: Proposed memory controller for multiprocessor-based SoC.

high-performance buses, AMBA-AHB and AMBA-APB [16], the system will work [17]. These two buses are responsible for data exchange between peripherals and processors. A bridge is used as an interface between the AMBA-AHB bus and the AMBA-APB bus to share information. A system architecture that uses AXI bus architecture is also available in recent research [18] for the FPGA-based dynamic partial reconfigurable security system for low area and power.

In SoC technology, trivial functions are conceived through the reusability of IPs. The reusability of IPs results in the rapidity of constructing a computer system based on a single-chip application. It is the root cause of the ever-growing fame of SoCs [19]. The constructional block diagram of a SoC is built up by reusing different modules. These reusable prevailing modules comprise an ARM processor core, peripherals modules like GSM and UMTS, memory controllers, etc. The precompiled libraries for the system-

TABLE 1: Signal description of memory controller for mobile SoC.

Pin	Description
rd	This signal enables the read operation when MAC wants to read data from FIFO.
rd_data	The data bus, which holds data, is read from FIFO to write into the memory through the state machine.
full	This input indicates to the MAC state machine about FIFO-full status.
empty	This input indicates that FIFO is empty to the MAC state machine, with no further data available to read.
ptr	There are two FIFO pointers to indicate reading and writing location and decide between empty and full status.
wr	wr is a write-enabled signal to memory, indicating writing operation.
addr	Addr signal indicates the exact location of memory to write/read data from or into it.
Data	It is a data bus that carries data to write into and read from memory.
rd	Read enable to indicate read operations from memory.
fifo_wr	Enable signal from MAC state machine to write into the FIFO.
fifo-rd	Request from the peripheral to read data from FIFO.
Data-rd	Data bus carrying the data read from FIFO for any external device.

level programmer are also available in the form of software drivers. The multiprocessor SoC system is flexible to extend by adding new IPs.

The IP configuration in SoCs always describes the formal models. The multiprocessor SoC incorporates many IPs like different peripherals, processors, and memory cores. These IPs perform various functions at various speeds and work at different data exchange behaviors. Due to their unusual behavior, their interconnections have to be comprehensive enough to handle the individual IP smoothly. Also, they must provide a standard approach to connect with all such IPs.

Usually, in the typical SoC architecture, all the IPs are connected with a common bus called a SoC bus. This SoC bus is linked with all the IPs of that particular SoC. Therefore, it has to set up a single platform for every IP connected to it, and the design is consequently called the platform-based design. This platform builds by integrating generic hardware (buses, processors, memory, etc.) and software (microcontroller code), and it can be remodeled to obtain differentiated products. Presently the typical SoC buses include Altera Avalon [20], IBM Core Connect, IDT IP Bus [21], Open Core Protocol [22], and Wishbone. This research work analyzes the AMBA [15] in detail, as it is the industry standard for creating SoCs. For example, AMBA is being used by many corporations like NVidia, Qualcomm, and Actel [23, 24] in their products.

The standard AMBA is rendered by ARM, which elucidates as a generalized set of useful buses and is used in system-based integrated circuits (ICs). These system-based ICs are known as SoCs, traditional microcontrollers, and application-specific integrated circuits (ASICs). In 1996, the first time the ARM-based processors used this standard (AMBA) in their SoCs. Internally, AMBA consists of two types of buses: high-performance system buses to connect core IPs and a flexible peripheral bus to join many input outputs devices and the components. The AMBA-AHB connects various IPs, for example, a processor, a DSP, and advanced memory controllers as shown in the SoC architecture.

Similarly, the AMBA-APB (advanced peripheral bus) connects various peripheral IPs dedicated to that system.

Additionally, AMBA provides the flexibility of upgrading the SoC. The SoC upgradation is possible by replacing some IPs with advanced versions (like the Bluetooth IP module) and adding IPs to enhance the functionality of the existing design (for example, adding an FM receiver, etc.). There is a bridge between the AHB and APB buses which is also shown in the multiprocessor SoC. This bridge is a standard bus-to-bus interface that provides communication between the IPs connected to different buses in a standardized way.

In this research, we are focused on specialized processing and integration. We know that the building of multiprocessor SoC requires many particular processing engines, which are custom designed to provide the user with the lowest power and higher performance [25]. A notable example is the Qualcomm Snapdragon (Snapdragon) [26, 27]. The SoC of Snapdragon processing is shown in Figure 2. The SoC consists of typical processing engines that integrate into a single piece of silicon [28]. There is a trend towards integrating more and more onto the SoC. The integration capabilities depend on the silicon traders' IP technology and design abilities.

The benefits of integration result includes being cost-effective, low area, lower power, and low temperature. The SoC architect will make the appropriate design decisions and trade-offs among the many dependencies throughout the system. This insight gives the right system view and the ability to propagate features, accurately simulate use cases, and quickly respond to market demands. This research takes a step to enhance the system performance and speed of the devices using multiprocessing units to accept the consumers' challenges and needs. The proposed MAC unit is an independent entity. It can easily integrate with the SoC with a reasonable transfer rate to get these features at low power consumption and a lite area overhead.

3. Implementation of Proposed MAC for SoC

The processor does intelligent operations like arithmetic and managerial processes. The real-time mobile systems incorporated today are built up with multiprocessors. These processors performed various functions by interacting with any

other processor in the same SoC. By doing this on one side, adding many processors to share the load on the other side. The processors waste their time by transferring data between themselves. Therefore, this research introduces the MAC to avoid this labor work of data transmission performed by any specialized processing engine in SoC-based devices. The MAC is a separate entity, and it integrates into SoC to perform such tasks. The research presents a real-time embedded system with fast data accessing support. It is known for its processor multitask support to achieve better yield and less power consumption while supporting future expansions. The system is called intelligent when it integrates the memory access controller for accessing the data between IP devices and memory, including cache. Hence, it can increase processing speed and reduce processing activity to save power. The active processor, among other processors in a specific SoC, excessively uses the memory while in use. Therefore, the MAC unit plays a significant role while the processor offloads memory accessing tasks in any specific SoC-based device.
FIGURE 8: MAC responds to an external agent's request to access the memory.

Today, high-end smart processors are used in sophisticated real-time systems such as automotive, avionics, and some medical equipped devices where this MAC unit can be used for integration. The use of MAC in the systems provides CPU usage and high system throughput. Before the MAC application was narrow to computers, servers, etc., but now it has become an integrated system entity in a new generation system. The MAC unit can transfer data between the entities as follows:

(i) Between two memories

(ii) Between memory and IPs

(iii) Between two IPs

(iv) Between two processing systems

The MAC handles all data transfer tasks, freeing the processor to manage other essential functions for any selected embedded systems [28].

How data exchange between peripherals (together with memory blocks) and processors by using these buses in SoC as indicated in Figure 3. There are two masters over the bus, the CPU and MAC. Once the data is accessed from memory by either of these two masters, the appropriate memory address information is updated. It works in two modes. The first mode CPU is the master, and the second mode MAC will be the master over the bus. The CPU sends the request to the bus for access in the first mode. A bus will grant access to the CPU in response to this request. The CPU will operate on data accessing by updating data into an appropriate memory location after getting a permit on a bus. On another side, when MAC is master over a bus, it can access any peripheral and memory connected to the bus in the second mode.

3.1. Case when MAC in SoC. There is an example of a case when MAC is in the SoC.

Example 1. For example, when MAC transfers the data between UART and memory. It reads the UART registers

and appropriate memory locations through the bus and released the bus grant once the operation finished. If the processor alone performs this operation, it requires more instruction cycles. This way, it needed more time to transfer the data between a memory and an external peripheral connected. Instead, the MAC engine handles this transfer operation by offloading the processor for sharing of data. An arbitration mechanism is used to grant access between the processor and MAC. The data transfer procedure is represented in Figure 4 by the MAC unit between peripherals and memory, data copied from memory and transferred to the USB by MAC itself. The data length of 15 bytes is considered.

Benefits of being MAC in multiprocessor-based devices:

(i) The power consumption reduces to a great extent. If the CPU runs for longer, it consumes more power, which the presence of the MAC will overcome by offloading the CPU
FIGURE 9: Processor utilization comparison with and without MAC.

(ii) MAC is an individual entity, and it performs data transfer operations individually in parallel to CPU operation. Thereby, it may be used in the simulation of a multiprocessing environment and helps in improving the processor's bandwidth

(iii) It makes the CPU idle for more time and frees up the processor to perform a more advanced task in future product improvement

3.2. Proposed MAC Architecture. The proposed memory access controller for multiprocessor-based SoC is shown in Figure 5. The MAC engine with first-in-first-out (FIFO) handles the extra load of the multiprocessing units to free the individual processor to perform another essential task in parallel. This offloading of the processing units in smartphone devices takes place by MAC's proposed design method. The architecture consists of MAC in the writing mode and MAC in the reading mode, and a FIFO block on both sides is used for synchronization. In the first part, the MAC performs reading operations for any IP (peripheral) from FIFO. Similarly, the MAC performed writing operations into the FIFO for any external IP (peripheral) in the second part.

Once the writing or reading operation is complete, the data will be available for any external device or IP to read or write from FIFO. The external device then accesses the data from FIFO.

Two memory controllers are implemented in Verilog hardware description language for accessing the data. The buffer memories (FIFO) on both sides are used to store the data temporarily to avoid data loss and mismatches. Hence, it synchronizes the speed of the peripheral and controller. The MAC signals and the description are summarized in Table 1. The external IP will write the data into the FIFO in writing mode. This data is then read by MAC and stored in the memory. The status of available data in FIFO will be updated by the pointer signal 'ptr.' Therefore, the MAC engine will read the appropriate data from FIFO and write it into the memory. Thus, the memory contains the data by writing any external IP into it.

TABLE 3: ASIC area report for proposed MAC.

Design	Cell	Cell area (nm^2)	Net area (nm^2)	Total area (nm^2)
Proposed MAC unit	2201	31272	16220	67497

TABLE 4: Area comparison between the proposed MAC and the other existing approaches.

Design	Cell	Cell area (nm^2)	Net area (nm^2)	Total area (nm^2)
Proposed MAC	2201	31272	16220	67497
DMA [30]	3901	56179	21237	99417
DMA [31]	3637	48312	25177	93289
DMA [32]	4637	62749	30256	101389
DMA [33]	4213	56274	28096	10017

Writing of memory is carried out as follows:

(i) The experiment results are taken by considering 8 K of memory

(ii) Memory size (Mem-array) = 8 K

(iii) Each location of memory contains 64-bit data = 8 bytes

(iv) Total location required for 8 K data (max-add) = 210

(v) Address location will vary from zero '0' to the 2^{10}

The data is written into the memory for all 1000 address locations, and each address location contains 8 k of data. If 64-bit is the data line, it requires 2^{10} address locations. Max-add is indicating as 2^{10}. The writing operation can be performed and expressed in equation (1).

$$MEMORY[Add] < Data\_wr. \qquad (1)$$
Figure 10: Area comparison graph.

The data is already available in the memory on the other side of the MAC reading operation. The MAC engine will read it from memory and write it into the FIFO for any connected external IP. Once the data is available in FIFO, the external IP will come and read it. The MAC reads the status of FIFO by pointer 'ptr' signal. The reading operation can be performed and expressed in equation (2).

$$Data\_rd <\ = Memory\ [Address]. \tag{2}$$

The IP request for accessing the memory decides that MAC has to work in writing or reading mode. If the request is for writing to the memory, the MAC first checks for the data request is for how many bytes (length), and then it grants writing into the FIFO to the requested IP. The MAC continuously checks the full-empty status of FIFO and depends on the availability of data in FIFO. MAC will write the data into the memory on the availability of data in FIFO. Whereas if the request is to read the data from memory, the MAC first checks the IP request, calculates the bytes, and allows the IP to read the data from FIFO. The data in the FIFO is available by the MAC after reading it from memory. The flow of reading and writing data for any requested IP is shown in Figure 6. Multiple requests and reading writing operations can perform in parallel by the proposed MAC unit in any SoC-based system.

4. Results

Verilog HDL is used to design the MAC unit. The simulation and synthesis are performed on the EDA tool. The top-level Verilog module includes two-part transmitting (writing) and receiving (reading) parts, and each part uses a MAC unit with a FIFO block. The simulation is performed on the Xilinx simulator. A case where an external device is writing data into the memory is shown in Figure 7. In this case, the external IP wants to write into the memory by sending a write request. It writes data into the FIFO on the approval of its request by a grant signal. Once the data is

Table 5: Data transfer rate for the proposed MAC and other existing methods.

Design	Max frequency (MHz)	Mega cycles per sec	Transfer rate (Mbytes/sec)
Proposed DMA	350	350	1400
DMA [30]	320	320	1200
DMA [31]	320	320	1200
DMAC [32]	250	250	1000
DMA [33]	250	250	1000

available in FIFO, the MAC will read it and write it into the memory. The MAC unit continuously reads the FIFO pointer to act during this process. On the other side, when external IP wants to read data from memory, the MAC unit will read data from memory and write it into the FIFO for any requested external IP. The read-write request handled by the MAC unit itself to offload the processor is shown in the graph in Figure 8 and Table 2.

FIFO pointer in each operation increments and appropriate information about data availability is communicated with the MAC. Depending on the pointer location, MAC will perform operations. We consider 64 as the FIFO depth for both the reading and writing sides. In this research, we implement a controller that can allow multiple IPs to access the memory without any involvement of the processors. As a result, processor performance and speed will increase drastically, and it can only concentrate on its operations other than memory access.

The developed MAC unit can integrate into mobile phone SoC to perform enhanced features data accessing memory to offload the processor. Hence, it increases the processing speed and power optimization of any processor. It can merely be understood by considering an example of wave generation. In a wave generation process for SoC, the MAC will perform a data exchange operation instead of a

FIGURE 11: Data transfer rate comparison.

processor. As a result, processor utilization will reduce drastically, directly affecting processor speed and power consumption. The purpose of a wave generator is to generate waves continuously [29]. The continuous stream will create without interruption by continually accessing the data from the look-up-table (LUT) to the digital-to-analog converter (DAC) data register. If there is a MAC unit available in the SoC architecture, the updating of data from LUT to the DAC register will take place by the MAC unit, and hence processor activity reduces significantly.

Large processor bandwidth and power are required when the wave's frequency and the number of samples increase. In case of the absence of the MAC unit in mobile device SoC, it forces the processor to perform this hectic task of data updating into the DAC register. Therefore, in this way, the processor consumes many instruction cycles to copy the data from LUT to the DAC register, affecting its performance significantly.

Instead, the MAC unit can easily do this task of data accessing from memory to the DAC register at the required time interval. Additionally, the MAC is not interrupt-driven like a processor. In this case, the processor does not need to do anything as long as the wave generates. As a result, a large amount of power will save because, generally, the processor consumes more energy than the MAC unit. The processor acts in power-down mode if it is not in use for data transfer operation, and hence, there will be a reasonable saving of static and dynamic power consumed. Thus, the MAC helps optimize the system's power consumption where a significant portion of work is to transfer data. The comparison graph between processor utilization with and without MAC is plotted and shown in Figure 9, and it is not scaled. We can see from the chart how speed and power performance affect any mobile phone SoC when the MAC unit is integrated.

The synthesis process of the MAC unit is performed on the ASIC platform. The ASIC synthesis results are received on the synopsis tool design compiler with $32 \, nm^2$ technology. The MAC unit is implemented on ASIC to calculate the area overhead and to integrate with Qualcomm's Snapdragon SoC. The design of MAC uses only 2201 cells with a cell area of $31272 \, nm^2$, a net area of $16220 \, nm^2$, and a total

TABLE 6: Power consumption of proposed and other methods.

Design	Leakage power (μW)	Dynamic power (μW)	Total power (μW)
Proposed DMA	1.67	194	196
DMA [30]	2.09	246	248
DMA [31]	2.90	233	236
DMAC [32]	2.07	252	356
DMA [33]	2.72	230	333

area of $67497 \, nm^2$. The synthesis result for area calculation is tabulated in Table 3. The design frequency, the power consumption, and the data transfer rate of the MAC block are computed. The existing approaches of the MAC are also implemented, and the obtained results are compared with the proposed MAC unit. The area comparison is tabulated in Table 4 and indicated in the graph in Figure 10.

The design frequency and the data transfer rate of the proposed MAC unit and the other available conventional methods of memory access controller are tabulated in Table 5. The comparison graph is shown in Figure 11.

The power consumption comparison for the proposed and other approaches are listed in Table 6 and the graph in Figure 12.

The commercially available SoC having the transistor count, including only the processing units, is 32 billion MOSFETs by 2019. For example, Qualcomm's Snapdragon processor gate count is more than 3 billion transistors [34, 35]. If we consider one cell having four gates or 16 transistors (4-transistors per logic gate), three billion transistors have 187 million cells.

The proposed design in this research used only 2201 cells with $32 \, nm^2$ technology. Therefore, integrating this controller with the Snapdragon SoC results in negligible area overhead with enhanced power optimization and speed features. The processor activity reduces to a great extent, and hence, it optimizes the system's power consumption. The result of the
Figure 12: Power consumption comparison.

Table 7: Comparison of area overhead.

Design	Cell	Overhead
Proposed MAC unit	2201	0.0011%
Snapdragon SoC	187 million	—

SoC area = 187 million cells, MAC area = 2201 cells, and area overhead = 0.0011%.

comparison of area overhead is tabularized in Table 7. The results show that integrating a MAC unit with SoC increases the area to just 0.0011%. Some SoC-based systems are available in the research study [36–40] for our notice.

5. Conclusion

A memory access controller for the multiprocessor-based SoC devices is proposed in the presented research. The architecture of a memory controller is proposed to fulfill the consumer's demands for IoT devices. The SoC consists of a multiprocessing unit, and MAC integration decreases the processing activity and power consumption by offloading processors from the memory-accessing task. As a result, it increases the speed of the processors to perform more essential tasks. The processor performance comparison is noticed with and without integrating a memory controller into the SoC while developing this nanomaterial-based product. It has been seen that the memory controller's presence will drastically affect processing speed and the power consumption of the processing units. The MAC unit is minimal, and it takes a low area overhead at low power consumption and fast data rate transfer. The hardware overhead is only a limitation. The MAC unit is a separate entity, and therefore, it may use for any future enhancement of SoC design with a lite area overhead.

Data Availability

The simulation screen results and excel file graphs data used to support the findings of this study are included within the article.

Research Article

Nanomaterials and Research on the Repair of Basketball Sports Ligament Injury

Zhongyou Xing [ID]

College of Physical Education, Xuchang University, Henan 461000, China

Correspondence should be addressed to Zhongyou Xing; 11992005@xcu.edu.cn

Sports ligament injury refers to muscle or joint injury caused by excessive use of limbs or long-term use of wrong training methods. This is a very common sports disease, and the body's ability to heal itself is poor. At present, the clinical methods to treat this disease mainly include autologous structure transplantation, allogeneic structure transplantation, and artificial ligament reconstruction. Nanomaterials refer to materials made of them as basic units. Transplantation of homologous and allogeneic structures may cause immune rejection in the human body. Therefore, the use of nanomaterials to reconstruct artificial ligaments is the current research hotspot of sports injury repair. This article mainly studies the repair effect of nanomaterials on basketball sports ligament injuries. In this paper, by implanting nanofiber scaffolds in sports-injured rabbits, observing and comparing the healing, growth, and proliferation of damaged cells after implantation, and the compatibility of nanofibers with cell tissues, so as to determine that nanomaterials have an impact of lion sports injury repair and the interaction between nanomaterials and cells. According to the experimental results, the implantation of nanofiber scaffolds can greatly accelerate cell proliferation and differentiation and promote the healing of sports-damaged tissues; nanofiber scaffolds have good histocompatibility, so the use of nanomaterials can promote the repair of sports ligament injury in basketball sports.

1. Introduction

Partial ligament injury without dislocation of the joint is called transition ligament itself complete fracture, it can also be attached to the bone avulsion, so as to form a potential joint dislocation subluxation or even complete dislocation. The main types of ligament injury are lacerations or ruptures. This is a very common sports disease, and the human body has very poor self-healing ability to this disease. The current clinical methods to treat this disease mainly include autologous structure transplantation, allogeneic structure transplantation, and artificial ligament reconstruction. Artificial ligaments have a long history of repairing sports ligament injuries. As early as the 1970s, artificial ligaments have been used in clinical research. These artificial materials have carbon fiber and other synthetic materials that are well described with human cells. For fibers, the treatment effect is not very good because these materials generally produce great friction with the tissue cells of the body, and even produce some debris, which has a great impact on the body's

movement function. Today, with the development of nano-technology, nanomaterials such as inorganic nanomaterials, polymer organic nanomaterials, nanocomposites, and bionic nanomaterials have been continuously developed, which have been used in the field of biomedicine. In 2007, Qin Ruiyun and others developed nanobone, which has a great effect on repairing damaged tissue cells. The porous structure of the nanomaterial is conducive to cell metabolism, because the effect of nanomaterials on cell structure and function determines the cytotoxicity and application value of nanomaterials, but it will not cause immune rejection in the body, so it has high compatibility with cells [1].

At present, homologous structural transplantation and allogeneic structural transplantation that can repair the ligament injury caused by dragon dance and lion dance may cause immune rejection in the body. Therefore, the use of nanomaterials for artificial ligament reconstruction is the current research hotspot of sports injury repair. This article is studying the effect of nanomaterials on the repair of ligament injury caused by dragon dance and lion dance.

Nanomaterials have many excellent structural characteristics, like nanomaterials that can be applied to infrared sensor materials because of their high optical absorption. The size of this material is on the order of nanometers. Due to the reduction of its particle size, nanomaterials have a large proportion of surface atoms and strong adsorption capacity, so they have high chemical reaction activity. This feature can regulate cell adhesion, proliferation, and differentiation. In addition, there are interactions and connections between nanometer units of nanomaterials. Many artificial synthetic materials used to treat sports ligament injuries have many shortcomings, such as low compatibility, which causes tissue inflammation, and too long use-time that may cause breakage. These problems will cause poor treatment effects. With the development and progress of nanotechnology, nanomaterials have gradually overcome these shortcomings, so nanomaterials will be widely used in the field of biomedicine, especially in the treatment of sports ligament injuries in recent years. This article uses experiments to explore the impact of nanofiber scaffold implantation on the repair of sports ligament injury [2, 3].

In this paper, by implanting nanofiber scaffolds into rabbits with sports injuries, the author observed and compared the healing, growth, and proliferation of damaged cells after implantation, and the compatibility of nanofibers with cell tissues, so as to judge the sports injury caused by nanomaterials. The effect of repair and the interaction between nanomaterials and cells. In the experiment, 20 healthy rabbits were selected; all artificially created sports ligament injuries and epidermal wounds. Then, 10 of them were implanted with nanofiber scaffolds as the experimental group, and the remaining 10 were left untreated as the control group. In the following three days, seven days, and ten days, the wound healing of the rabbits was observed, and samples were collected for H&E staining, flow cytometry, and scanning electron microscopy, and corresponding charts were made based on the test results. Implanting nanofiber scaffolds in the body is a very effective method for judging the compatibility of materials and cell tissues. This method can directly observe the body's response to nanomaterials, and this experiment further studies nanomaterials and nanomaterials through slicing and the relationship between tissue cells. In the experiment, we will also observe the rabbit's mental state, eating, and wound changes to judge the effect of nanomaterials on wounds and the effect on cell tissue. HE staining in this experiment can clearly observe the state and number of cells, and flow cytometry can count the proliferation and differentiation of cells [4].

Sports ligament injuries are often caused by strenuous exercise or external forces, which are mainly divided into lacerations or ruptures. The human body has a poor self-healing ability for this disease. The current clinical treatment of this disease mainly has its own structure. Transplantation, allogeneic structure transplantation, and artificial ligament reconstruction; the first two treatments may cause immune rejection in the human body. Therefore, this article is studying the role of nanomaterials on the repair of ligament damage caused by dragon dance and lion dance. In this paper, by implanting nanofiber scaffolds into rabbits with sports inju-

ries, the author observed and compared the healing, growth, and proliferation of damaged cells after implantation and the compatibility of nanofibers with cell tissues, so as to judge the sports injury caused by nanomaterials. The effect of repair and the interaction between nanomaterials and cells. The experimental results in this paper show that the porous structure of nanomaterials can promote the metabolism of cell tissues. Since the material has no biological activity, it will not cause immune rejection in the body. The implantation of nanofiber scaffolds has a certain promotion effect on wound healing and improves the healing rate of wounds. According to H&E staining tests, nanomaterials can promote cell proliferation and differentiation, and it can be intuitively observed that nanomaterials such as tissue cells have good compatibility which reduces the inflammation caused by the dragon dance and lion dance motor ligament injury, so the use of nanomaterials can promote the repair of the dragon dance and lion ligament injury [5, 6].

2. Preparation and Performance of Nanofiber Scaffold

2.1. Preparation Method of Nanofiber Scaffold

2.1.1. Weaving. The three-dimensional nanofiber scaffold is a kind of collector that uses a high-speed rotating shaft to prepare a unidirectionally arranged nanofiber mat. The first single-circle-oriented nanofiber scaffold used a high-speed rotating mandrel as a collector, and then cut into thin strips along the direction of fiber arrangement. And then using lasso technology, a relatively good structure nanofiber scaffold can be prepared. Using this principle in the same way, weaving and other textile techniques can be used in the preparation process to prepare PLA, PCL, and other nanomaterials into various specific structures [7].

2.1.2. Gas Foaming. The chemical foaming method uses a chemical method to generate gas to make the plastic foam; heat the chemical foaming agent added to the plastic to decompose it to release the gas and foam. In addition, it can also use the chemical interaction between the plastic components, reacting with the released gas and foam. The gas foaming method can maintain the shape of nanomaterials during the preparation of nanofiber scaffolds. Xie et al. developed another more advanced gas foaming method, which requires the generation of bubbles in aBH4 aqueous solution and then rapid freeze drying. The NaBH4 aqueous solution will quickly penetrate into the nanofiber membrane. In addition, the customized mold combination can optimize the gas foaming method. Based on the predesigned glass cover, the thickness of the expanded nanofiber scaffold can be adjusted [8].

2.1.3. 3D Printing. 3D printing is a technology that uses adhesive materials such as powdered metal or plastic to construct objects layer by layer on the basis of digital model files. 3D printing is a kind of rapid prototyping technology, also known as additive manufacturing. It is a technology that uses powdered metal or plastic and other bondable materials

to construct objects based on digital model files by printing layer by layer. 3D printing technology is realized through a printer, so the computer can precisely control the shape and structure of the nanofiber scaffold. Due to the high precision of this technology, it is very suitable as a new way to prepare the nanofiber scaffold. The nanofiber scaffold prepared by 3D printing has a porous structure and the internal network is built by nanofibers. At present, many nanofiber scaffolds at home and abroad are prepared by using 3D printing technology. It is believed that with the further development of this technology, its role in preparing nanofiber scaffolds will become more and more important [9].

2.1.4. Self-Assembly.

Self-assembly is a phenomenon in which the constituent elements of the system gather and organize themselves into a regular structure without the intervention of human external forces. For example, the crystallization of molecules is a self-assembly phenomenon. Self-assembly generally exists in nature. For example, the cells of organisms are self-assembled by various biological molecules; and the self-assembly of various molecules is also a very important method to construct nanomaterials. This so-called bottom-up method is currently widely used to prepare nanomaterials with optical, electrical, magnetic, sensing, and catalytic functions. According to the current research status at home and abroad, molecular self-assembly is a new way to prepare nanomaterials. Generally, the structural units of molecular self-assembled nanomaterials are macromolecular substances such as polypeptides and proteins. Molecular self-assembly is currently widely used in spacecraft at home and abroad. Nanofiber scaffolds prepared by this method have very good performance and are widely popular in domestic and foreign research fields. Therefore, this method has become a research hotspot [10, 11].

2.1.5. Freeze-Drying.

Freezing prevents further agglomeration, and vacuum-dried particles tend to agglomerate and grow larger. Freeze-drying uses the principle of sublimation of ice crystals. In a high vacuum environment, the moisture of frozen food materials is directly sublimated from ice solids to steam without melting of ice. Generally, the moisture in vacuum-dried materials is converted in liquid form. The food is dried in the vapor state, so freeze-drying is also called freeze sublimation drying. Freeze-drying technology can not only dry the material quickly but also not destroy the original material structure of the material. This dehydration method is very convenient, efficient, and safe. Therefore, it is often used in two fields of food and materials. It has a wide range of applications, welcomed by everyone. Three-dimensional porous nanofiber refers to the preparation of the scaffold which requires this method. Ding et al. first studied the use of a high-speed homogenizer to break the electrospun nanofiber membrane, and then freeze-dry the material to obtain a nanofiber scaffold. The nanofiber scaffold prepared in this way has a wide range of applications and can be applied to a variety of different tissues, because it is a nanofiber scaffold with a specific shape and function that can be 3D printed using a computer [12].

2.2. Performance of Nanofiber Scaffold.

Nanofiber scaffolds with good performance need to be able to simulate the natural extracellular matrix environment and need to have the following advantages: high compatibility, certain mechanical strength, biodegradability, hydrophilicity, large specific surface area, and highly penetrating porous structure. The characteristics of nanofiber scaffolds need to enable cell adhesion, migration, differentiation, and proliferation, as well as the transmission of nutrients and metabolism. Therefore, most of the materials of nanofiber scaffolds are three-dimensional nanofiber porous structures, because this nanomaterial has good compatibility with cell tissues, and its structure not only meets the requirements, but also promotes cell proliferation and differentiation. At present, the preparation process of nanofiber scaffolds at home and abroad includes weaving, gas foaming, 3D printing, self-assembly, freeze-drying and other steps. After being made, they are mostly used to lead the way in biomedicine. This article is about nanofiber scaffolds for dragon dance and lion dance sexual injury. Of course, there are many other preparation methods. Compared with other methods, this method is cheaper and easier to operate and is suitable for large-scale production. At present, nanofiber scaffolds such as PLLA, PCL, and PLAG have been prepared by this method at home and abroad [13].

The crystallinity and hydrophobicity of PCL are stronger than those of PLLA. PLLA and PCL are two kinds of nanomaterials that are widely used. They have good compatibility and are biodegradable. However, if PLLA is not easy to be implanted in the body, it may break due to too long usetime. On the contrary, a good PCL can make up for the shortcomings of PLLA. The material has good toughness and strong plasticity but insufficient mechanical strength. Therefore, mixing the two materials can improve each other's shortcomings. The performance of the new mixed material is very outstanding, and it overcomes the insufficient toughness of PLLA and the insufficient strength of PCL. The mixed material is very popular in clinical medical research [14]. About 72 hours after injury, platelet and multi potential mesenchymal cells began to appear in the wound. At this time, macrophages devoured necrotic tissue and released growth factors including FGF, TGF, and PDGF, which stimulated the proliferation of fibroblasts and the synthesis of collagen I, III, and V and noncollagen egg white, and induced vascularization and granulation tissue formation, which we call the proliferation period. In the proliferation stage, fibroblasts produce compact and porous connective tissue with collagen characteristics and are combined in the ligament fracture area, which we call scar tissue. The scar tissue was irregular in shape at the beginning of formation, rich in collagen of type 3 and type 5, and began to form a small diameter collagen fiber bundle, followed by the remodeling and maturity of the tissue, and finally the ligament healing was realized. During the process of regeneration ligament maturation, the porosity of tissue gradually decreases and extracellular matrix gradually enriches and grows along the axial direction. The new tissue begins to have a stable directionality, which lasts for at least one year.

If ionomer treatment is performed on the fiber scaffold, the surface of the nanofiber scaffold can be changed for a long time, and the water contact angle of the nanofiber scaffold can be reduced, thereby improving the hydrophilicity of the nanofiber scaffold, and this operation can also improve the nanofiber scaffold biocompatibility, so the performance of the nanofiber scaffold can be improved through this treatment. The hydrophilicity of the nanofiber scaffold increases with the increase of plasma treatment time, and the function of the nanofiber scaffold to promote cell proliferation after plasma treatment is also improved. However, plasma treatment can also damage the fiber structure of the nanofiber scaffold, and the longer the time, the more serious the structure damage, which leads to the destruction of the performance of the nanofiber scaffold. Therefore, when performing plasma treatment on the nanofiber scaffold, it is necessary to strictly follow the steps to control the time within the effective time range that can improve the performance of the nanofiber scaffold without damaging the structure of the nanofiber scaffold. In the preparation of nanofiber scaffolds, it is necessary to change the force applied to the fibers to change the performance of the nanofiber scaffolds [15].

2.3. Prospect of Nanomaterials in the Ligament Injury of Basketball Sports. Research on the use of nanofibers in tissue engineering started late and is still in its infancy, especially in the field of biomedicine. There are fewer studies on fusion of nanomaterials. Many domestic and foreign studies have not entered the stage of clinical experimental research, so nanomaterials are used in dragon dance and lion dance. There is little experience in sexual ligament injury, and the related safety and reliability performance still need a lot of experiments to further improve. At present, nanomaterials are still facing many problems when used for sports ligament injuries, such as how to construct the cell-nanomaterial interface, how to reduce the body's immune rejection caused by nanofiber scaffolds, and how to improve the compatibility of nanomaterials. With the advancement of tissue engineering technology, the second generation of biomaterials began to develop into the third generation of activated bionic materials. Therefore, it is necessary to develop a nanobionic material with repair function in sexual ligament injury and reduce complications such as inflammation caused by immune rejection reaction [16].

With the further development of nanotechnology, nanobiology, nanomaterials, nanomedicine, and other disciplines have also developed and progressed. Especially in recent years, these disciplines have gradually begun to merge and penetrate, and there has also been an in-depth integration between the biological field and nano materials. Research has brought new treatment methods and ideas, and the application of nanomaterials in medicine has opened up many new research directions. At present, new nanomaterials will be developed for ligament injuries [17].

With the further development of nanotechnology, nanomaterials have begun to merge with the biological. This trend has also provided new ways and methods for the treatment of ligament injury caused by dragon dance and lion dance. Over the years, nanomaterials have made great achievements in the treatment of ligament injuries. Big research results and applications have gradually increased and become research hotspots. However, the application of nanomaterials in various aspects is still insufficient, especially in the biological field. There are fewer studies on fusion of nanomaterials. Many domestic and foreign studies have not entered the stage of clinical experimental research. If nanomaterials are required to be integrated and used more widely in the biological field, it will take a long time to strengthen the research and cooperation of personnel in related fields to develop more useful bionanomaterials and integrate nanomaterials into medical treatment more deeply. We believe that with the further development of nanotechnology and the development of more nanomaterials, there will be progress in disease diagnosis and drug treatment. This material will be used to treat more diseases and bring new hope to more patients [18].

3. Experimental Steps

3.1. Experimental Materials and Instruments. The materials and instruments used were 20 healthy male and female rabbits, PCL nanofiber scaffold, physiological saline, test tube, surgical instrument, pipette, 75% ethanol solution, 30% supersaturated sodium sulfide solution, flow cytometer, microscope, and centrifugal precipitator.

3.2. Experiment Method

3.2.1. Experimental Grouping. In the experiment, 20 healthy rabbits were selected, all artificially created sports ligament injuries and epidermal wounds. Then, 10 of them were implanted with nanofiber scaffolds as the experimental group, and the remaining 10 were left untreated as the control group. In the following three days, seven days, and ten days, the wound healing of the rabbits was observed, and samples were collected for H&E staining, flow cytometry, and scanning electron microscopy, and corresponding charts were made based on the test results.

3.2.2. Preparation of Animal Models and Wound Treatment. Shave the hair beside the spine of the healthy rabbit, then gently wipe the rabbit's back with a 30% supersaturated sodium sulfide solution, and clean it after a few minutes. Subsequently, the rabbit was injected with 3% pentobarbital solution, and then the rabbit's skin was cut and separated to the deep fascia. Then, 10 rabbits were randomly selected to be implanted with nanofiber scaffolds as the experimental group, and the remaining 10 rabbits were dipped in gauze and wrapped in saline to wrap their wounds as the control group.

3.2.3. Collection of Animal Model Specimens. In three days, seven days, and ten days after the sports ligament injury, the specimens were collected according to the steps. Collect specimens at each observation time node, then fix the specimens with formalin for 48 hours, then dehydrate with ethanol and embed the sections with paraffin, so that the sections are ready.

3.2.4. TUNEL Test. According to the established observation time node, collect the required specimens, follow the detection steps of TUNEL detection, complete the detection step by step, and then carefully observe the number of apoptotic cartilage cells and the spatial distribution characteristics and distribution range under the microscope. Under the microscope, it can be observed that the nucleus of the apoptotic cartilage cells is brown, and their morphology and size are different. Compared with normal cells, the nuclear phase is more compact, and even some cytoplasms may be positive and stained. The apoptotic cells in the late stage will be further broken up, and there are apoptosis cells with different nuclear fragments. Some apoptotic chondrocytes were positive, but the color was very light. The nuclei of normal cargo cells are stained blue, and the nuclei are similar in shape and size. The nucleus is larger than the apoptotic nucleus.

3.2.5. Observation by Transmission Electron Microscope. Take 2 days, 7 days, and 10 days after the injury of the motor ligament, and 2 samples from the control group, then soak the samples in glutaraldehyde phosphate solution, and then put the samples in the refrigerator for two days. After the specimen is processed, it is trimmed into a neat long strip, and then placed in osmic acid and fixed for 2 hours. Then, follow the conventional steps of making slices, process the collected specimens step by step, and finally observe the cell status carefully under the microscope to observe the number of apoptotic cells and the characteristics and range of their distribution locations.

4. Results Analysis

4.1. H&E Staining. After H&E staining, it can be seen that there are a few scattered apoptotic and necrotic cells around the ligament injury area and articular cartilage. The color of the nucleus is very prominent after staining, and it can also be seen that the cell membrane is not broken. Two days after ligament injury, more apoptotic ligament cells can be observed. On the fourth day after injury, the number of apoptotic ligament cells that can be observed reaches a peak and is distributed everywhere. Compared with the control group, after the nanofiber scaffold was implanted in the treatment group, the number of apoptotic ligament cells was much less than that in the control group on the second day, and the rate of cell apoptosis was also greatly delayed.

As shown in Figure 1, within ten days after the ligament injury, the ligament injury gradually healed over time. Three days after ligament injury, the healing rate of the control group without any treatment was very low, only 25%. On the contrary, the wound healing rate of the experimental group implanted with nanofiber scaffolds was nearly twice as that of the control group, as high as 40%. Seven days after the ligament injury, the wound healing rate of the experimental group soared to 70%. Although the control group also increased slightly, it was still much less than the experimental group, only 57%. Ten days later, the wound healing rate of both groups increased, but because the wounds were basically close to healing, the increase in the experimental group was only 20%, while the increase in the control group

was as high as 30%. It can be seen that implanting nanomicroscopic scaffolds in the body can help promote wound healing.

In Figure 2, the number of normal ligament cell apoptosis is generally very small, while the number of ligament apoptotic cells after ligament injury increases significantly. Two days after the ligament injury, the number of ligament injury cells in the experimental group was 23, while the control group had 62 cells under the microscope. Four days after the ligament injury, the number of apoptotic cells in the ligament reached its peak. There were 117 in the control group, while the experimental group had 78 in comparison. Then, until the fourth week, the apoptotic cells in the ligament began to decline gradually, and the decline in the experimental group was more rapid than the decline in the control group. On the tenth day, the experimental group dropped to 42, while the control group had a little more, down to 59. And then in the fourth week, the two groups' costs fell to the same level. It can be seen that implanting nanofiber scaffolds in the body can reduce the apoptosis of ligament cells and promote the healing of ligament injuries.

According to the analysis of this experiment, it can be concluded that implanting nanofiber scaffolds in rabbits can promote cell metabolism, accelerate wound healing, and reduce the apoptosis of ligament damaged cells. According to the experimental results, no complications such as inflammation and immune rejection occurred, indicating that the nanofiber scaffold has good compatibility with the cells in the body, and promoting wound healing indicates that nanomaterials can increase cell metabolism and accelerate cell proliferation and differentiation.

4.2. Flow Cytometry Detection. After implanting the nanofiber scaffold in the experimental group, after the ligament cells reacted with type II collagenase at each observation time node, the collected samples were made into cell suspension, and then tested by flow cytometry. The test results show that compared with the control group and normal ligaments, the apoptosis rate of ligament cells and the number of ligament cells in the treatment group are greatly reduced at each time node. This is for future research on nanomaterials. The relationship with cells plays an important role.

The results of flow cytometry can see the proliferation of ligament cells. Figure 3 shows the proliferation of ligament cells after ligament injury. It can be seen from the figure that the number of ligament proliferating cells that can be observed under the microscope under normal circumstances is certain. After ligament injury, ligament cells begin to proliferate in large numbers. In the four days after ligament injury, the ligament cells of the experimental group and the control group increased significantly, and the experimental group increased by 10 more than the control group. After the fourth day, the proliferation rate of ligament cells increased. By the seventh day, the number of ligament cells increased, reaching 55 in the control group and 68 in the experimental group. In the next few days, the number of ligament cell proliferation in the experimental group and the control group began to decline, while the control group declined even faster, and it dropped to 20 on the 14th day,
FIGURE 1: Comparison of wound healing rate.
FIGURE 2: Comparison of changes in apoptosis of ligament injury.

while the experimental group dropped to 28. Four weeks later, the number of ligament cell proliferation in the experimental group and the control group was basically the same as the normal group. Figure 3 illustrates that implanting nanofiber scaffolds in rabbits can promote the proliferation and differentiation of ligament cells after ligament injury, so as to promote the healing of ligament injury.

In this experiment, the state of the cells can be observed under a microscope, and it can be judged that after ligament injury, there will be ligament cell apoptosis. According to Figure 4, in the control group, the apoptotic rate of ligament cells continued to rise within four days after injury, reaching

a peak on the fourth day, and then the apoptotic rate decreased. It can be seen that when the ligament is damaged, the ligament cells will continue to undergo apoptosis and necrosis. Within a short time after the ligament is injured, a small amount of apoptosis appears in the surface layer of the ligament. In the following two days, this kind of apoptosis begins to move to the middle layer. After days, apoptotic cells are more widely distributed and the damage is more serious. After 14 days, the damage was reduced and the wound began to recover. Four weeks later, the damage was basically healed, and the cells no longer continued to apoptosis. After the experimental group was implanted with
FIGURE 3: Ligament cell proliferation.
FIGURE 4: Comparison of changes in apoptosis rate of ligament cells.

the nanofiber scaffold, although the trend was similar to that of the control group, the cell apoptosis rate was much smaller in comparison. On the second day after ligament injury, the apoptosis rate of ligament cells in the experimental group was 5% lower than that of the control group. On the fourth day of the peak apoptosis rate, the experimental group was 50% lower than that of the control group. After 14 days, the experimental group was 50% lower than that of the control group. The control group was 15% lower than that of the control group on the fourth day, and the rate of difference between the two groups began to drop. Figure 4 shows that implanting nanofiber scaffolds in rabbits can inhibit ligament cell apoptosis and reduce the rate of ligament cell apoptosis.

The above two figures show that the implantation of nanofiber scaffolds in rabbits can promote the division of ligament cells and inhibit the apoptosis of ligament cells. Promoting cell division can prove that the porous structure of nanofibers can promote cell metabolism, and the relatively large surface area is conducive to cell adhesion, which can promote the proliferation of ligament cells. In addition, nanomaterials can also inhibit cell apoptosis, indicating that nanomaterials have good compatibility with ligament cells, which can avoid immune rejection and reduce complications such as inflammation.

5. Conclusions

The degree of differentiation of ligament cells is high; the proliferation is slow in vivo, and it is difficult to self-heal for sports ligament injuries. Therefore, the use of nanomaterials in the treatment of sports ligament injuries has become

a current research focus. In this paper, nanofiber scaffolds are implanted in rabbits with sports injuries. By observing the results of H&E staining, flow cytometry, and e-sports scanning, the healing and cell organization of damaged wounds before and after nanofiber scaffolds can be compared. The healing rate of serotonin, as well as the cell growth and proliferation after sports ligament injury and the compatibility of nanofibers with cell tissues can be judged, so as to determine the effect of nanomaterials on sports injury repair and the mutual influence between nanomaterials and cells. The experimental results in this paper show that the porous structure of nanomaterials can promote the metabolism of cell tissues. Since the material has no biological activity, it will not cause immune rejection in the body. The implantation of nanofiber scaffolds has a certain promotional effect on wound healing and improves the healing rate of wounds. According to H&E staining tests, nanomaterials can promote cell proliferation and differentiation, and it can be intuitively observed that nanomaterials such as tissue cells have good compatibility and reduces inflammation caused by motor ligament injury. With the development of nanotechnology, nanoelectronics, nanobiology, nanomaterials science, nanomedicine, and other subdisciplines have been established and developed. What is particularly important is that these disciplines are merging and penetrating into each other. The combination of materials science and biomedicine is more and more close, and various materials with specific functions will be more and more applied to biomedicine. In the next few years, nanoceramics in biomaterials will play a leading role in artificial bones. Inorganic and organic composite nanomaterials with various characteristics will also play an important role in the interventional repair of ligament injury. By pretreating OA chondrocytes with mgf-c24e in vitro, the therapeutic effect of mgf-c24e on the complications of ligament injury was studied. It was found that mgf-c24e could inhibit the spontaneous apoptosis of OA chondrocytes and promote the proliferation, migration, mechanical properties recovery, and extracellular matrix synthesis of OA chondrocytes. It was found that mgf-c24e regulated endoplasmic reticulum stress through endoplasmic reticulum membrane protein perk and inhibited cartilage degradation in the pathogenesis of OA.

The rapid development of society promotes the rapid improvement of science and technology. On this basis, the development of nanotechnology has also made great achievements and has been applied to all walks of life. Among them, nanotitanium oxide provides favorable conditions for the medical treatment of various joint injuries. And sports rehabilitation training also plays an irreplaceable role in the treatment of joint injury, promoting the rapid recovery of joint injury. Boxing is a sport in which boxing gloves are worn for fighting. It has both amateur and professional competitions. The purpose of this paper is to study the therapeutic effect of nanotitanium oxide combined with sports rehabilitation training on the wrist joint injury of boxers. According to the therapeutic effect of the research, it can provide useful treatment basis for clinical treatment and help boxers recover wrist joint injury, so as to carry out boxing training later. The method adopted in this paper is as follows: first, the subjects were randomly divided into nanotitanium oxide combined with sports rehabilitation training group, nanotitanium oxide treatment group, sports rehabilitation training treatment group, and control group. Then, the subjects were tested with the score table, and the score data were recorded. Finally, chi-square test was used to test the experimental results. In conclusion, through the research and comparison, it is found that nanotitanium oxide combined with sports rehabilitation training can reduce the pain of boxers' wrist joint injury; after the treatment of wrist joint injury of boxers by nanotitanium oxide combined with sports rehabilitation training, the pain score decreased, and the daily function was improved; the PT score before the experiment was 15%, and the peak torque score after the experiment was 26%. The Pt/BW score was 22% before the experiment and 37% after the experiment. This reflects the strength of wrist muscle contraction, judging that the stability of wrist joint is enhanced after the experiment; nanotitanium oxide combined with exercise rehabilitation training can increase the sensitivity of wrist joint after the treatment of boxer wrist joint injury.

1. Introduction

Boxing [1] is a competitive sport with strong antagonism. Boxing was introduced into China in the 19th century. However, due to various reasons, boxing was not carried out in China until 1986 and gradually embarked on the road of standardization. It is a contest between two athletes in terms of physical fitness, skills, psychology, and agility. It is also a sport to test the comprehensive ability of athletes. It can improve and cultivate people's agile, calm, brave, and indomitable spirit. Boxing in China is gradually developing. The goal of boxing is to win more points than the other

party to win or knock the other party down. At the same time, the competitor should try to avoid the attack of the other party. Although China's boxing has made a breakthrough, there is still a considerable gap between the overall level and the high-level countries. Compared with boxing developed countries, China does not have its own boxing culture, and China's professional boxing has no echelon construction. One of the most important reasons is sports injury. To improve boxing level, not only from the boxing training process, but also from the recovery of the body after training, is a very important aspect. Through stretching training, the recovery after exercise and the causes of boxing

injury are comprehensively and systematically studied in order to reduce sports injury [2] and promote the vigorous development of boxing in China. Boxing started late in China, and from the development trend in recent years, the state pays attention to training methods and means and attaches importance to the physical training of athletes. How to maximize the performance of athletes has become the primary task, but the research on muscle recovery and injury prediction after training is not enough. Injury is an important factor that affects boxing performance. Body pulling training can improve the flexibility of the body, relieve the pain of skeletal muscle, increase the elasticity of skeletal muscle, reduce the hardness of foot, and prevent sports injury. The reason why rehabilitation training is necessary in training is that after high-intensity training, the energy reserve in the body will inevitably be consumed, leading to fatigue and functional decline. According to the principle of recovery and over recovery, it is necessary to recover and over recover the energy and material of the body after the exercise, so as to improve the functional level of the body and create material conditions for the improvement of sports performance.

Nanoparticle is a kind of nanomaterial [3], also known as ultrafine particle, which refers to the size of 1-100 nm particles. Nanoparticles are located in the transition zone between atomic clusters and macroobjects and between microsystems and macrosystems. They are a group composed of a small number of atoms or molecules. Therefore, they are both atypical microsystems and atypical macrosystems. It has small size effect, surface effect, quantum size effect, and macroquantum tunneling effect, which makes it present the characteristics of magnetic, optical, and electrical sensitivity that traditional materials do not have. Therefore, it has different toxicological characteristics from micron and conventional particles. In the field of drug therapy and molecular imaging, nanoparticles have become potential new drug carriers due to their special chemical structure, surface properties, and small particle size [4], which provides new prospects for drug delivery and targeted therapy at specific sites. Among the nanomaterials, nanotitanium dioxide (TiO_2) [5] is the most widely used. Because of its small particle size, it has been industrialized and widely used in coatings, pigments, ceramics, sunscreen cosmetics, antiaging, air purification, sewage treatment, antibacterial detoxification, food packaging, antistatic, and other fields. Adding nano-TiO_2 powder to cosmetics in a certain proportion can effectively shield ultraviolet rays. At the same time, nanotitanium oxide has a certain role in promoting the treatment of boxer wrist joint injury [6].

In the process of human activities, the original components and energy materials of human tissues and cells need to be continuously decomposed to release energy to meet the needs of human activities. In the process of decomposition of energy materials, the synthesis of energy materials was also carried out. According to the principles of recovery and over recovery, restorative training can realize the recovery and storage of basic energy materials and create material conditions for improving the physical level of the body. After high load training, athletes will have the feeling of

muscle "compression" and often feel heavy leg, even pain. If massage, bath, application of some drugs or jogging, and other means of recovery will speed up the blood circulation in the muscle, the muscle will return into a relaxed state as soon as possible. After high load training and competition, the nervous system remains normal in activity. Rehabilitation training [7] can affect this complex functional system, fixing the control path between the central nervous system and the surrounding organs dominated by random control. Long-term and systematic rehabilitation training can not only improve the interaction between vegetative organs and motor organs but also improve the interaction between organs around the central nervous system and central organs [8]. Rehabilitation training can adjust the long-term tension of the striated muscle to moderate relaxation, thus forming a strong connection and making the muscle work actively in the next step; it can also change the cross-section and tension of blood vessels, capillaries, arterioles, and venules. In relaxation training, the tension and contraction of blood vessels can be relaxed and the tension can be relieved. As a result, dilated blood vessels can contract and become normal medium tension. The human body's response to movement, especially the training of tissues and organs caused by the changes of morphological structure and function, is conducive to maintaining the relative stability of the internal environment, so as to achieve the purpose and function of protecting the human body from injury, and further expanding the production capacity, that is to say, human adaptability. When the body adapts to a certain level after training, the body is in a relatively stable state and needs to provide new stimulation, that is, a higher level of training. Break the original stable state and make the body adapt to the new training load.

An excellent athlete often works out a reasonable recovery method after training or before training, which can lay the foundation for athletes to maintain good competitive state for a long time and obtain the best sports results. Through literature retrieval and analysis, it is found that in China, the research on wrist joint injury of boxers [9] mainly focuses on the proportion of wrist joint injury, injury site, simple factors of injury, and some simple prevention and treatment measures. This paper mainly studies the therapeutic effect of nanotitanium oxide combined with sports rehabilitation training on boxer wrist joint injury. In this study, the subjects were randomly divided into nanotitanium oxide combined with sports rehabilitation training group, nanotitanium oxide treatment group, sports rehabilitation training treatment group, and control group. Then, the subjects were tested with the score table, and the data obtained from the score were recorded. Finally, the experimental results were tested by chi-square method. The innovation of this paper is to compare the treatment scores of nanotitanium oxide combined with sports rehabilitation training group, nanotitanium oxide treatment group, sports rehabilitation training treatment group, and control group without treatment. The experiment proves that nanotitanium oxide combined with sports rehabilitation training has a positive effect on the treatment effect of boxing athletes' wrist joint injury, which provides some useful for clinical treatment basis.

2. Nanotitanium Oxide and Wrist Joint Injury of Boxers

2.1. Nanotitanium Oxide.
A nanometer is a unit of length, one billionth of a meter. When the size of the material reaches the nanometer level, the material will have many different characteristics, thus showing its unique effect and function. Nanomaterials refer to materials with one or more components and at least one dimension in the range of 1-100 nanometers, including nanoparticles, nanofibers, nanotubes, and nanosynthetic materials. Nanoparticle is a kind of nanomaterial, which means that the single particle size is less than 100 nm. The physical properties of nanomaterials [10] mainly depend on the size, composition, and surface properties of nanomaterials, while the biological effects of nanomaterials are closely related to the physical and chemical properties of nanomaterials. Due to their unique small size effect, surface effect, quantum size effect, and macroscopic quantum tunneling effect, nanomaterials have electrical, optical, mechanical, and magnetic properties different from ordinary materials [11, 12].

Nanotitanium oxide (TiO_2) is a new inorganic chemical material. In recent years, due to its special performance, wide application, and broad market prospect, it has become a research hotspot. Nano-TiO_2 has large specific surface area and surface atomic number; the surface energy and surface tension increase rapidly with the decrease of particle size; the thermal, magnetic, optical, and sensitive properties and surface stability of nanoparticles are different from those of traditional particles due to small size effect, surface effect, quantum size effect, and macroscopic quantum tunneling effect. As a new photocatalyst [13], UV-resistant agent, and photoelectric effect agent, it is widely used in coatings, pigments, ceramics, sunscreen cosmetics, antiaging, air purification, sewage treatment, antibacterial detoxification, food packaging, antistatic, and other fields. Different orders of nano-TiO_2 enter some specific parts of the human body in different ways and produce inherent toxic effects. At present, the research of nano-TiO_2 is mainly focused on animal experiments, such as tissue effect, cytotoxicity [14], effect on the molecular structure and expression of genetic material DNA, and the influence on other biological macromolecules.

2.2. Boxing.
Boxing is a highly confrontational sport, which belongs to the skill type combat project. The project is characterized by technology led. Physical fitness and tactics play a decisive role in this project. The characteristic of boxing match is that under the same rules, both players wear protective gloves and hit each other's effective scoring position with their fists. The confrontation between the two sides is the external performance of the project, and obtaining effective scores is the ultimate goal. The two players in the designated area competition hit each other but also need to be prepared for defense and counterattack this high-intensity confrontation; the athletes' physical requirements are very high but also determine the core role of health in this project. There are four rounds in each round of women's boxing, and each round is 2 minutes, with an interval of 60 seconds. The uniqueness of boxing lies in people's different views on box-

ing. Boxing is a person-to-person competitive event. Therefore, the beating and being beaten in the competition, as well as the injury consequences, especially the scene of being knocked down and unable to stand up in professional boxing, have great objections in many people's thoughts.

2.3. Wrist Joint Injury.
Wrist joint, also known as radial wrist joint, is an important part of hand joint. The wrist is the connection between the hand and the forearm. It is an important part of the upper limb and bears a large load in the support and thrust of the upper limb. In addition to the distal radius [15] and ulna, there are eight carpal bones of different shapes. Due to the complex structure of wrist joint, more joints, and ligaments, it has higher flexibility. The anatomical features of the wrist allow it to move in two planes: radial ulnar deviation in the frontal plane (abduction adduction) and sagittal flexion and extension (palmar flexion and dorsiflexion). As far as wrist joint is concerned, it should include radial and ulnar joints. Intercarpal joint consists of adjacent carpal bones. The bone and bone are intertwined, and they are connected by complex ligaments and tendons in varying degrees of motion.

Wrist injury has great influence on fine motion of hand and upper limb. It is necessary to define the types of wrist joint disorders and take effective rehabilitation guidance in time. Wrist rehabilitation medicine involves many aspects; rehabilitation evaluation and rehabilitation treatment are the core. Correct rehabilitation assessment is the premise of effective rehabilitation treatment, and the functional recovery under ideal state depends on effective rehabilitation treatment [16].

For wrist rehabilitation assessment, the clinical is mainly evaluated by the pain, motion dysfunction and other subjective assessment indicators of the wrist [17]. ROM, also known as ROM, refers to the maximum motion curve of the joint, that is, the normal range of motion from the beginning to the end of the joint, usually expressed in degrees. It is one of the important indexes to evaluate the range and degree of joint motor function injury. First of all, it is the preferred evaluation method for physical dysfunction diseases with limited joint activity such as fracture and arthritis. It is suitable for joint movement disorders caused by various reasons, such as joint fixation, trauma, and surgery. The range of motion can be divided into active range and passive range. Active range of motion (AROM) refers to the arc of joint movement when muscles contract actively; passive range of motion (PROM) refers to the arc movement of joints without muscle contraction under the action of external force. It can be seen that the range of motion of the joint is the activity behavior of patients, which can be used to evaluate the influence of muscle contraction force on joint range of motion. The range of passive joint motion refers to the passive behavior under the action of external force, which can evaluate the limited degree of joint activity of examiners. Due to the different anatomical structure and physiological mechanics of each joint, the active and passive range of motion of the same joint is also different. The range of motion of the joint is also affected by race, gender, age, and examination position. Taking the normal range of

ROM in rehabilitation medicine as reference value, the differences of rehabilitation goals were analyzed and compared.

3. Exercise Rehabilitation Training

3.1. Rehabilitation. The World Health Organization defines rehabilitation as through various measures to reduce the impact of disability and to reintegrate the disabled into society. These include the use of training to promote the adaptation of persons with disabilities to their surroundings and the adjustment of their surroundings and social conditions to facilitate their social integration. Therefore, rehabilitation refers to the comprehensive and coordinated use of various measures to reduce the mental, social, and physical barriers of the disabled, so as to make them play their full potential and return to society.

Rehabilitation medicine [18] is a medical application subject with independent theoretical basis and functional evaluation method, with large application scale and high treatment technology. Its purpose is to speed up the rehabilitation process of human injury, prevent and reduce the degree of disability, and help the disabled return to society. Rehabilitation treatment is a variety of measures taken by people to reduce the disability of the disabled, train the disabled to acquire knowledge and skills, and improve their ability of self-care and social participation. Rehabilitation treatment can be generally divided into the following categories: (1) physical therapy (PT); (2) occupational therapy (0t); (3) speech therapy; (4) psychotherapy; (5) recreational therapy; and (6) traditional Chinese medicine. Physical therapy includes exercise therapy and physical factor therapy: physical factor therapy, also known as "physical therapy," is a method to prevent and treat diseases by using physical factors such as electricity, light, sound, magnetism, water, cold, and heat; occupational therapy is a process of applying purposeful and selected occupational activities to evaluate, treat, and train patients who have lost their ability to take care of themselves and work in varying degrees due to physical, mental, and developmental dysfunction or disability. It is a rehabilitation treatment method. Exercise therapy refers to active or passive movement of patients with bare hands or with the aid of instruments and improves functions and promotes rehabilitation through the effect of force, which is a widely used treatment. Entertainment therapy is a psychotherapy method to cultivate temperament and improve physical and mental health through various entertainment activities (such as listening to music, learning singing, watching movies, watching TV, watching drama performances, dancing, games, playing chess, and visiting the garden).

3.2. Exercise Rehabilitation Training. In the rehabilitation of wrist injury, early and correct exercise is very important. For professional athletes, once the injury occurs, it will directly affect the play of skills and tactics and sports life in the competition. Therefore, it is very important to protect the wrist. Through muscle movement, promote blood circulation, accelerate metabolism, prevent muscle atrophy, and enhance muscle strength. It is necessary to make short-term functional rehabilitation plan and long-term ADL rehabilitation plan according to the course of disease and the severity of the disease.

Common rehabilitation methods are as follows: physical therapy such as external application (external application of drugs can promote good blood circulation and prevent inflammation), acupuncture, and moxibustion (which can improve local pain valve and gradually improve mechanical balance of muscles), by promoting blood circulation, improving the nutrition of local tissues, improving the vitality of cell tissues, accelerating the absorption or elimination of pathology and metabolites, promoting wound healing and eliminating inflammation, and injection therapy (which can promote local blood circulation and prevent joint adhesion). Exercise therapy, also known as therapeutic exercise [19, 20], is one of the basic treatment methods of rehabilitation medicine, according to the characteristics of patients' life to improve the function of patients.

The general principles of wrist rehabilitation training are as follows:

(1) Early principle: the structure of wrist joint is complex; the recovery time is long after injury. When wrist ligament injury or fracture occurs, early medical treatment can seize the best treatment opportunity to prevent cartilage wear and tear, ligament aging and joint pain, joint relaxation, and instability caused by improper movement during the injury; when wrist joint dysfunction caused by stroke, timely and effective treatment can avoid the occurrence of joint deformity, so as to ensure the normal range of motion of the joint. At the same time, by stimulating the activity of brain cells, it can promote the occurrence of compensatory function of brain tissue in corresponding regions, so as to reduce the degree and rate of disability

(2) Moderate principle: although increasing the number and frequency of rehabilitation training is helpful to the recovery of motor function, blind pursuit of progress may lead to secondary injury of injured joints. If the swelling and pain of the affected joint is aggravated, it should be stopped immediately, and the treatment should be evaluated after the tissue pain disappears

(3) Sufficiency principle: on the premise of following the moderate principle, the range of motion of each joint should reach or be as close as possible to the normal range of motion of each joint

(4) Progressive principle: in rehabilitation training, it should be carried out step by step, and the training form and exercise amount should be adjusted according to the special pathological conditions of joints in each rehabilitation stage

(5) Gentle principle: in passive exercise training, we should pay attention to observe the expression changes and reactions of patients and try to avoid the pain of patients and the soft tissue injury of affected limbs and joints

TABLE 1: Pain scale sheet.

Pain grading	No pain									The most painful
At rest	1	2	3	4	5	6	7	8	9	10
Repetitive wrist movement	1	2	3	4	5	6	7	8	9	10
When lifting weights	1	2	3	4	5	6	7	8	9	10
Frequency of pain	1	2	3	4	5	6	7	8	9	10
The most painful time		2	3	4	5	6	7	8	9	10

TABLE 2: Functional difficulty scale.

Pain grading	No pain									The most painful
Daily life	1	2	3	4	5	6	7	8	9	10
Housework	1	2	3	4	5	6	7	8	9	10
Work	1	2	3	4	5	6	7	8	9	10
Recreational activities	1	2	3	4	5	6	7	8	9	10

(6) Self-help principle: many patients cannot fully recover after discharge, and most patients need long-term rehabilitation training after discharge. Therefore, it is necessary to have a kind of portable and convenient rehabilitation training assistant device anytime and anywhere

(7) Rehabilitation training needs the principle of individual treatment. According to different age, condition and functional state, exercise means, preparation posture, and amount of exercise are selected to develop and improve muscle function (strength, speed, and endurance) and joint activity

4. Therapeutic Effect of Nanotitanium Oxide Combined with Exercise Rehabilitation Training on Wrist Joint Injury of Boxers

4.1. Experimental Materials. The total number of patients in this study was 80, aged 16-47 years, with an average of 25.6. They were randomly divided into four groups: nanotitanium oxide treatment group, rehabilitation exercise training treatment group, nanotitanium oxide combined with rehabilitation exercise training treatment group as the experimental group, and wrist joint injury natural healing as the control group, with 20 cases in each group, 11 males and 9 females. The injury treatment study lasted from 1 to 30 days. All patients were provided by the department of orthopedics and traumatology, the first hospital of D province.

4.2. Experimental Methods. Random grouping method: random number method was used in this experiment. Nanotitanium oxide treatment group, rehabilitation exercise training group, and nanotitanium oxide combined with rehabilitation exercise training group were the experimental group, and the wrist joint injury natural healing was the control group

Case shedding and treatment: automatic use of other methods during the treatment process or accidental death (except for complication death) cases decreased. Treatment: follow-up, registration, and analysis

Case exclusion criteria: the clinical data records were found to be wrong, incomplete, or completely missing before statistical analysis, which affected the statistical analysis

Efficacy criteria: pain and function: the pain and function during the 5-week treatment were scored by PRWE score standard, and the score results were recorded

Safety assessment criteria: level 1: safety, no adverse reactions. Level 2: relatively safe. If adverse reactions occur and no treatment is needed, the trial can continue. Grade 3: safety problems, moderate adverse reactions, can continue to test after treatment. Grade 4: the test was stopped due to adverse reactions

4.3. Data Processing. Observation time and index record: the observation records were made before and after treatment at three time points (the first day, the seventh day, and the 35th day).

Chi-square test was used for counting data, and t test was used for measurement data. Take $p > 0.05$ as no statistical significance, no difference; take $0.01 < p < 0.05$ as the difference has statistical significance; $p < 0.01$ as the significant statistical significance, the difference is significant.

4.4. Scoring Table. Pain score table:

As shown in Table 1, please evaluate your average wrist pain in the past week on a 0-10 scale. 0 means that there is no pain at all, (0-10) indicates that the pain is increased once, and 10 means that the pain has never stopped, or dare not move because of the pain.

Function score table:

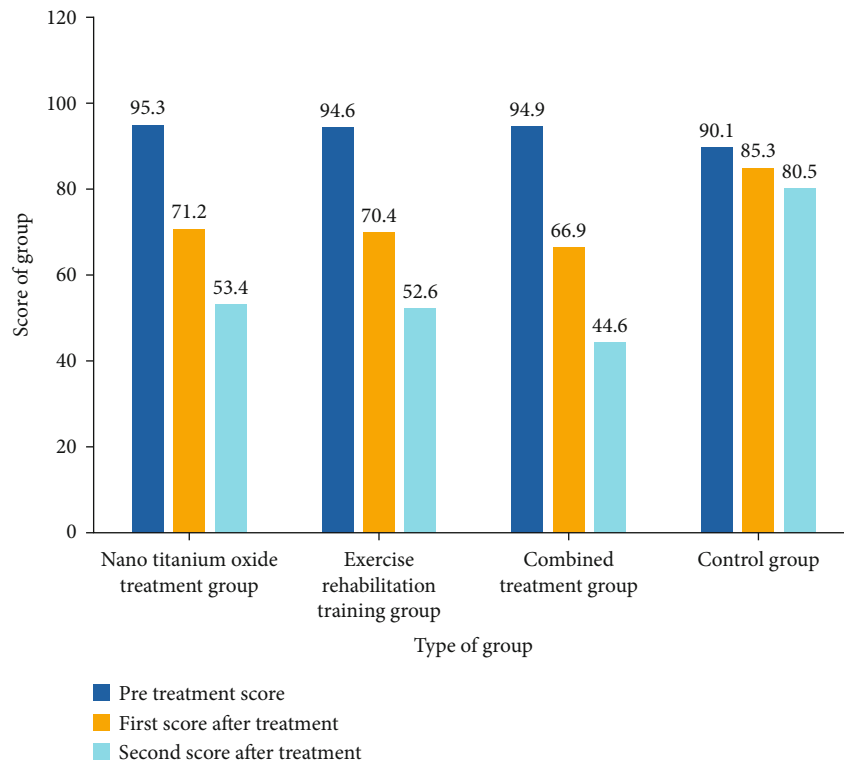
As shown in Table 2, please circle the most difficult movements in the past week on a scale of 0-10. 0 means there is no difficulty, (0-10) indicates that the activity difficulty increases in turn, and 10 means that the activity is very difficult and cannot do these daily activities.
Figure 1: Comparison of pain between the four groups.


Figure 2: Functional comparison between the four groups.

5. Results and Discussion

5.1. Comparative Analysis of Pain. As shown in Figure 1, before treatment, the scores of nanotitanium oxide treatment group, rehabilitation exercise training treatment group,

nanotitanium oxide combined with rehabilitation exercise training treatment group, and control group were 40.1, 40.3, 40.6, and 40.3, respectively. Pain comparison was made for the first time after treatment in nanotitanium oxide treatment group, rehabilitation exercise training treatment group,

Measurement of wrist internal rotation velocity
Figure 3: Measurement of wrist internal rotation velocity.
Figure 4: Treatment effect of three groups of treatment on boxer wrist joint.

nanotitanium oxide combined with rehabilitation exercise training treatment group, and control group. The scores were 27.9, 27.1, 22.6, and 35.7, respectively; the scores of nanotitanium oxide treatment group, rehabilitation training group, nanotitanium oxide combined with rehabilitation exercise training group, and control group were 15.6, 15.1, 10.1, and 22.1, respectively, after the second treatment; through comparison, it was found that nanotitanium oxide combined with rehabilitation exercise training could reduce the pain of wrist joint injury of boxers.

5.2. Function Comparison Analysis. As shown in Figure 2, before treatment, the functional scores of nanotitanium oxide treatment group, rehabilitation exercise training treatment group, nanotitanium oxide combined with rehabilitation exercise training treatment group, and control group

were 95.3, 94.6, 94.9, and 90.1, respectively. The first functional scores of nanotitanium oxide group, rehabilitation training group, nanotitanium oxide combined with rehabilitation exercise training group, and control group were 53.4, 52.6, 44.6, and 80.5, respectively. Before treatment, there was no significant difference among the groups. After treatment, the score of nanotitanium oxide combined with exercise rehabilitation training decreased significantly. Through comparison, it was found that after the treatment of wrist joint injury by nanotitanium oxide combined with sports rehabilitation training, the functional score decreased, and the daily function was improved.

5.3. Analysis of Peak Torque Comparison. As shown in Figure 3, the peak torque (PT) reflects the maximum muscle strength produced by muscle contraction. The maximum

torque output produced by muscle contraction, namely, peak torque to body weight ratio (Pt/BW), refers to the peak torque value per unit weight. The relative muscle strength reflecting muscle contraction can be used for the peak torque ratio between active muscle and antagonistic muscle of individuals or people of different weights. It can reflect the balance of muscle strength and judge the stability of joints in a certain sense. In Figure 3, the PT score before and after the experiment was 15%, 26%, 22%, and 37%, respectively. Therefore, nanotitanium oxide combined with sports rehabilitation training has a great role in promoting the treatment of boxing wrist joint injury.

5.4. Sensitivity Comparison Analysis. As shown in Figure 4, the sensitivity score of nanotitanium oxide treatment group before treatment was 5.59 and after treatment was 3.22; the sensitivity score of exercise rehabilitation training treatment group before treatment was 5.61 and after treatment was 3.21; the sensitivity score of nanotitanium oxide combined with exercise rehabilitation training before treatment was 5.63 and after treatment was 2.19; the sensitivity score of control group before treatment was 4.91 and after treatment was 4.65. It can be seen that there is no significant difference between the two groups. The scores of nanotitanium oxide treatment group and exercise rehabilitation training treatment group were significantly reduced by 2.37 and 2.40, respectively, but the effect of nanotitanium oxide combined with exercise rehabilitation training treatment group was more obvious. It shows that nanotitanium oxide combined with exercise rehabilitation training has a great role in promoting the sensitivity of wrist joint injury treatment of boxers.

6. Conclusion

China's boxing is gradually developing. Compared with developed countries, there is a big gap between China and developed countries. One of the most important reasons is sports injury. Wrist injury is a very common kind in life; especially when exercising, it is easy to cause wrist injury. To improve boxing level, not only from the boxing training process, but also from the recovery of the body after training, is a very important aspect. This paper mainly studies the therapeutic effect of nanotitanium oxide combined with exercise rehabilitation training on wrist joint injury in boxing, which provides some beneficial basis for clinical treatment. By studying the therapeutic effect of nanotitanium oxide combined with sports rehabilitation training on Boxers' wrist joint injury, it is found that nanotitanium oxide combined with sports rehabilitation training can reduce the pain of boxers' wrist joint injury; after the treatment of wrist joint injury of boxers by nanotitanium oxide combined with exercise rehabilitation training, the pain score decreased and daily work decreased. The Pt/BW score before and after the experiment was 15% and 26% and 22% and 37%, respectively. The relative muscle strength reflecting muscle contraction can be used for the peak torque ratio between active muscle and antagonistic muscle of individuals with different weights. It can reflect the balance of mus-

cle strength in a certain sense and judge the stability of wrist joint after nanotitanium oxide combined with exercise rehabilitation training.

New energy composite is an advanced material that can replace the traditional single metal material, especially the newly developed or developed material with superior performance. At present, the material is widely used in automobile manufacturing and other fields, but there is a lack of development and application of the material in the field of sports. To solve these problems, this paper puts forward the application of new energy composites in sports facilities and fitness equipment. In this paper, the testing methods of new energy materials, including thermoelectric testing method and energy absorption testing method, can quantitatively evaluate the properties of a kind of new energy composites and point out the direction for the development of materials with high thermoelectric properties and high-energy absorption and consumption properties. Then, through the preparation experiment of new energy materials, this paper studies the preparation process and self-shrinkage test of carbon nanomaterials. Finally, it is proposed to use carbon nanomaterials in the sensor design of health monitoring data acquisition system. The experimental results show that when the water ash ratio is low, the self-shrinkage value of carbon nanomaterial slurry is 74.68% lower than that under the original conditions. In the experimental study of omnidirectional monitoring characteristics, through the repeated tensile tests of rectangular sensor and omnidirectional sensor at different temperatures, it is found that the sensitivity coefficient of the sensor made of carbon nanomaterial is between 55.8 and 60.4, and the maximum fluctuation is only 5. This fully proves that the carbon nanotube omnidirectional sensor has omnidirectional detection ability.

1. Introduction

1.1. Background. Since the birth of human civilization, material has been closely related to human life. There are generally three forms of matter in nature, namely, solid, liquid, and gas. With the development and progress of science and technology, materials not only penetrate into people's daily life, but also are widely used in aerospace, marine engineering, biomedical engineering, optoelectronics, and other fields. This article observes that new energy materials may also be applicable to the field of sports. New materials refer to some newly developed or under research and development materials with excellent performance, mainly including superconducting materials, solar cell materials, hydrogen storage materials, solid oxide cell materials, intelligent materials, magnetic materials, nanomaterials, high-temperature structural ceramics, amorphous materials, and high-density energy storage materials. Composite material refers to the new material composed of material components of different properties by using advanced material preparation technology.

1.2. Significance. Under the background of global fossil energy shortages and environmental pollution, the development of high-performance thermoelectric materials and efficient new energy technologies has attracted extensive attention in the industry. The composite material not only

maintains the advantages of the material properties of each component, but also obtains the comprehensive performance that cannot be achieved by a single component material through the complementarity and correlation of the properties of each component. Human beings also need to systematically study the durability of carbon nanomaterials and other cement-based composites. The unique one-dimensional structure of carbon nanotubes and nanofibers and the two-dimensional structure of graphene, as well as the advantages of compact structure, large specific surface area, and high strength of carbon nanomaterials, can effectively transport water in cement through the landfill matrix and holes in the matrix, improve the compactness of cement materials, and further improve the durability such as impermeability and corrosion resistance. On the basis of improving the self-shrinkage properties of carbon nanomaterial and cement-based composites, other durability properties of carbon nanomaterial and cement-based composites can be systematically studied to improve their safety and service life, which is of great engineering significance and value. With the popularization of high-performance concrete with low ratio of water and binder, the crack phenomenon caused by early automatic shrinkage of concrete is becoming increasingly obvious. Adding carbon nanomaterials into cement materials can not only effectively fill the pores of the cement matrix, but also increase the content of hydration products, to improve the density of matrix.

1.3. Related Work. The role of new energy and composite material, materials, and sports equipment in human life is becoming increasingly obvious, and many scholars have carried out research on these two topics. Wang Q believes that, under the background of establishing emerging engineering education, the content of organic chemistry of material engineering needs innovation. He strives to improve the application effect of organic chemistry from the aspects of material preparation and material application, selection, process, method reform, improvement of evaluation system, and optimization of organic chemistry experiments. His research focuses on the application expansion of materials, but ignores the detailed manufacturing innovation of materials [1]. Martinho F pointed out that the monolithic series integration of third-generation solar materials on silicon has broad prospects in the fields of photoelectrochemistry and photovoltaics. However, this may be challenging when involving the high-temperature reaction process, which may damage the bottom cell of photovoltaic equipment. They have proved that the protection of the bottom cell of photovoltaic equipment largely depends on the barrier layer engineering at the device level, but their research has not produced several single-chip series solar cells, which is limited to the application of new energy materials [2]. Mansurov Z A studied the effect of activated carbon with multilayer graphene (three layers and more sheets) on the thermal decomposition of substances based on hydroxyammonium nitrate and carboxymethyl cellulose. His results showed that the addition of activated carbon with multilayer graphene could increase the combustion rate of hydroxyammonium nitrate by up to four times; however, in the exper-

iment, the addition of activated carbon in the thermal decomposition stage reduced the temperature and time of chemical reaction, resulting in some deviations in the experimental results [3]. Paben J believes that the flexible packaging material will not disappear soon, and the upcoming pilot project aims to ensure that it will not enter the landfill. He proposed a material recycling facility, which will install additional sorting equipment. The transformation will enable the facility to start producing postconsumer flexible packaging bags, which are defined as single-layer or multilayer material films, expanding the source mode of new energy materials. However, he did not explain the defects of materials made from recycled raw materials [4]. Tao Kunwei studied the compact materials project, which will provide a high-energy, high-throughput neutron source for material irradiation research, which is essential for advanced nuclear energy projects driven by China's long-term accelerators. He introduced a numerical study of a particle beryllium targets using inclined particle flow as the target and heat carrier. To study the heat treatment capacity of the target as a sports facility, the heat deposition and transfer in the target were numerically simulated. However, his research damaged the back plate of the experimental material in terms of heat dissipation and radiation [5]. Lee J Y evaluated the function of a dual water supply system operating in sports facilities based on technical, quantitative, and financial data, including the collection and use of rainwater for nonpotable purposes. Analysis was conducted to determine the water-saving efficiency and cost reduction of the facility within 3 years. The results show that rainwater can be managed for the benefit of the environment, and economic benefits can be obtained by saving the water cost of municipal water supply and sewage treatment. However, the results of this study are not encouraged because of the overexploitation of groundwater [6]. Sukiri's research aims to determine customer satisfaction with the services and fitness equipment of the academic gymnasium of the School of Sports Science, Jakarta State University. He made a questionnaire and published it using Google forms. His research used survey and descriptive analysis. According to the data returned by the interviewees, the average interviewee was satisfied with the facility, but did not pay attention to the interviewee's satisfaction with the facility [7]. Thakur T S believes that cycling and other sports activities are a healthy, interesting, and low impact way of exercise, which is suitable for people of all ages. His research paper covers the evolution of sports facilities from ancient times to modern times. Through this study, he has tried to study the transformation of sports facilities through a wide range of technical applications to improve and enhance their functions, but his research focuses on the improvement of bicycles and does not extend the research results to other fitness equipment [8]. The deficiency of these studies is that the research methods and perspectives are still not novel and comprehensive enough.

1.4. Innovation Points. This paper boldly puts forward the application of new energy materials in the field of sports and expands the application scope of new energy materials. The most representative carbon nanomaterials in new

energy materials are used to prepare motion monitoring sensors, which expands the new idea of sensor design.

2. Performance Test Methods of New Energy Materials

2.1. Thermoelectric Test Method for New Energy Composites. New energy composites are made by combining two or more fibers in a matrix. New energy composites have the characteristics of high strength, elastic modulus, and excellent mechanical properties. Mechanical characteristics are also relatively good, which can fully meet the requirements and make them a popular choice for light weight and high-performance applications. Because the cost of carbon fiber is too high, the combination of glass fiber and carbon fiber is needed to obtain reliable mechanical properties [9]. The new energy composites with mixed carbon fiber and glass fiber have a good balance in mechanical properties; that is, the disadvantages of one fiber can be offset by the advantages of another fiber [10]. In addition to the mixed structure, the strength, damage resistance, and service life of new energy composites can be improved by changing the microstructure of materials. However, the mixing and aggregation of fibers have a significant impact on the elastic properties of the composites. On the one hand, it is the microstructure characteristics of fibers, namely, the aggregation of fibers and the distribution of fibers in the aggregation area, a small amount of bonding between the foundation and fibers, bending effect, and unevenly distributed fibers, that will weaken the mechanical properties of composites [11]. On the other hand, it is generally believed that the experimental mechanical properties of new energy composites are far from the theoretical prediction results. Therefore, it is of great significance to determine the influence of these defects on the effective properties of new energy composites.

The content of the experimental method is the thermoelectric test of materials. Firstly, the key technical indexes of thermoelectric performance test are analyzed. All relevant metrics were analyzed in detail. According to the thermoelectric performance test principle, the signal acquisition circuit required for corresponding parameter measurement is designed, and the thermoelectric performance test platform is built to realize the automatic measurement of thermoelectric performance parameters of new energy materials [12].

Seebeck coefficient is the ratio of voltage to temperature difference generated by Seebeck effect, which represents the ionization impurity scattering coefficient [13]. Assuming that only the electric field and temperature gradient of the material are in a stable state, and the material is a nondegenerate semiconductor, the relaxation time is approximately obtained according to the Boltzmann equation. Then, the Seebeck coefficient of the material is shown in

$$A = \pm \frac{k_B}{e} \left[b - \left(s + \frac{5}{2} \right) \right], \qquad (1)$$

where s is the scattering coefficient and B is the reduced Fermi level. Therefore, if semiconductor thermoelectric

materials are doped, the ionized impurity concentration increases, and the ionized impurity scattering coefficient increases [14]. If the large ionized impurities are scattered (high concentration of ionization impurities), the Seebeck coefficient corresponding to the specified carrier concentration is greatly improved, and the thermoelectric performance is improved. If the material is a single band nondegenerate semiconductor, the Seebeck coefficient of the material can be expressed by

$$A = \pm \frac{k_B}{e} \left[b - \left(s + \ln \frac{N}{n} \right) \right] \qquad (2)$$

Therefore, the Seebeck coefficient of materials is related to carrier concentration, state density, Fermi energy level, scattering coefficient, and other physical quantities. In formula (2), n is the state density, and N is the carrier concentration.

When calculating the conductivity of materials, the expression of conductivity q is Q = neu. In the formula, n is the carrier concentration, and u is the error rate.

$$n = \frac{2(2\pi m^* k_B T)^{1.5}}{h^{1.5}} F_{s+0.5}(b), u = \frac{4e}{3\pi^{1/2}} (s + 1.5)(k_B T)^s \frac{t_0}{m^*}, \qquad (3)$$

where $m*$ is the effective mass of the carrier, h is the Planck constant, and t0 is the relaxation time. Formula (3) shows that the conductivity is affected by the scattering coefficient, effective mass, Fermi level, and other factors, and the carrier concentration and mobility do not necessarily increase at the same time. When the effective mass of the material increases, the carrier concentration increases, and the mobility decreases [15]. If the mobility decreases, the conductivity and thermal conductivity decrease at the same time.

From the microscopic point of view, the transmission process of heat energy is mainly realized by carrier motion and lattice vibration. In the case of semiconductor materials in the intrinsic state and semiconductor materials in the exogenous excitation region, only the contribution of carrier and lattice phonons to the thermal conductivity must be considered [16]. In other words, $k = k_{ph} + k_c$, where k_{ph} is the phonon thermal conductivity and k_c is the thermal conductivity of the carrier. General thermoelectric materials are applicable in the exogenous excitation stage. Therefore, only the contribution of carrier thermal conductivity and phonon thermal conductivity to thermal conductivity must be considered [17]. At the beginning of the twentieth century, Altengilsch of Germany put forward the analysis of three important parameters affecting thermoelectric properties and put forward the thermoelectric performance index Z to measure the thermoelectric properties of materials.

$$Z = \frac{A^2 Q}{k}, E = A^2 Q, \qquad (4)$$

where a is the Seebeck coefficient, K is the thermal conductivity, q is the conductivity, and E is the power factor. This formula can be used to reflect the comprehensive

thermoelectric properties of materials. The larger the Z value, the higher the thermoelectric properties of the material. Therefore, for materials with good thermoelectric characteristics, the Seebeck coefficient is large; that is, the obvious thermoelectric effect requires the conductivity Q to be as large as possible, and the thermal conductivity must be K small with less Joule heat. Materials with high thermoelectric properties point out the direction for the production of new energy composites [18].

2.2. Test Method for Energy Absorption of Materials.
Sports facilities and fitness equipment have high mechanical requirements for materials, and the manufacturing materials must have strong energy absorption capacity in order to meet the sports facilities and fitness equipment for the material strength requirements. This paper has mentioned that the new energy material absorber achieves impedance matching conditions by adjusting the electromagnetic parameters, to reduce reflection and achieve high absorption, because the reflection is actually caused by the impedance mismatch with the material surface. However, the use of impedance matching theory means that new energy materials need to be regarded as a whole; that is, their optical properties can be described by macroscopic optical parameters impedance Z and refractive index n [19]. According to the equivalent media theory (theory of composite properties), the structural unit of new energy materials is a subwavelength size smaller than its working wavelength, so they can be regarded as a whole. Moreover, their electromagnetic characteristics can be expressed by the equivalent permeability Ueff and equivalent dielectric constant Eeff [20].

In free space, the impedance Z, refractive index n, dielectric constant e, permeability u, and reflectivity R are assumed. If a uniform plate with thickness D, when the electromagnetic wave with angular frequency w is vertically incident on one side of the material plate, its transmission performance can be expressed by the reflection coefficient F and transmission coefficient T [21]. The expression is as follows:

$$\frac{f}{t} = -\frac{i}{2}\left(Z - \frac{1}{Z}\right)\sin nkd, \tag{5}$$

$$t^{-1} = \left[\sin(nkd) - \frac{i}{2}\left(Z - \frac{1}{Z}\right)\cos(nkd)\right]e^{ikd}. \tag{6}$$

The principle of magnetic wave vertical incidence is shown in Figure 1.

Under the condition of impedance matching, it can be seen that the reflection coefficient r tends to 0, while the transmission coefficient T can be reduced to the exponential form:

$$t^{-1} = e^{-i(n_1-1)kd} * e^{n_2kd}. \tag{7}$$

At this time, there are two limit cases for the transmittance of the material $t = |t|2$. In the first case, when the transmittance T and reflectivity R are both 0, the absorbance A is 1, and the electromagnetic wave is completely absorbed. The second case is that the reflectivity R and absorptivity a are 0 and the transmittance t is 1. At this time, the material neither

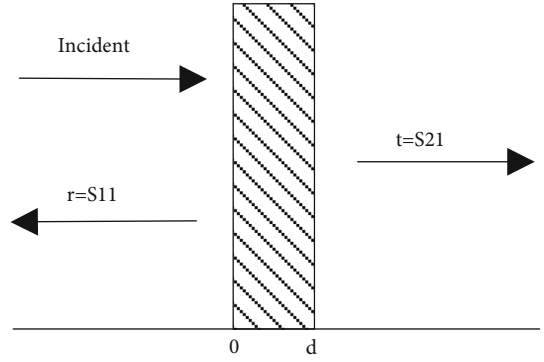

Figure 1: Schematic diagram of scattering parameters of electromagnetic new energy materials.

reflects nor absorbs electromagnetic waves, realizing perfect stealth [22]. For energy absorption by new energy materials, only the first case is considered in this paper. At this time, there are

$$\lim_{n2\to\infty} T = |t|^2 = \lim_{n2\to\infty} e^{-2n_2kd} = 0. \tag{8}$$

Since t only tends to 0 in the actual structure, $N2$ usually shows a large peak. It can be seen that the design of new energy materials to absorb energy is actually to design a structure with appropriate dielectric constant Eeff and permeability Ueff to meet the impedance matching conditions, reduce the reflectivity r to 0, reduce the transmittance t as much as possible, and consume the energy of electromagnetic wave inside the structure as much as possible, to obtain high absorption [23].

3. Preparation, Experiment, and Application of New Energy Materials

3.1. Preparation of Carbon Nanomaterials.
In this paper, the representative carbon nanomaterials in new energy materials are selected to study their preparation and application process. The preparation and application of carbon nanomaterials are beneficial to improve the material quality of exercise equipment. In this paper, the effects of different carbon nanomaterial content, water-cement ratio, and test age on the self-shrinkage properties of cement paste samples were studied: (1) three water-cement ratios of 0.25, 0.30, and 0.35 were selected to study the changes of self-shrinkage properties of carbon nanomaterial cement paste with water-cement ratio. (2) Six contents of 0.05 wt%, 0.075 wt%, 0.1 wt%, 0.12 wt%, and 0.15 wt% were selected to study the effects of different carbon nanomaterial contents on the self-shrinkage properties of cement paste composites. Choosing different doses of nanomaterials for research allows for a full understanding of carbon nanomaterials properties. (3) The self-shrinkage values of three kinds of carbon nanomaterial and cement-based composites were measured every 1 min by self-shrinkage tester to study the self-shrinkage characteristics of carbon nanomaterial and cement paste composites. To ensure the good workability of the specimens with low water-cement ratio, a certain

amount of polycarboxylic acid water reducer was added in the preparation process.

The dispersant of multilayer carbon nanotubes is gum Arabic, and the mass ratio of multilayer carbon nanotubes to gum Arabic is 1 : 6. In addition, a certain amount of defoamer needs to be added to the prepared multiwall carbon nanotube suspension [24]. Through experimental exploration, it is determined that the addition of 0.13 wt% tributyl phosphate defoamer can eliminate the bubbles generated in the ultrasonic process of multiwall carbon nanotube suspension. The mix proportion design of high-performance multiwall carbon nanotube cement-based composites is shown in Table 1.

The dispersant of carbon nanofibers is methylcellulose, and the two mass ratios are 1 : 2. Moreover, a certain amount of defoamer must be added to the prepared carbon nanofiber suspension. The experimental investigation results show that if 0.15 wt% tributyl phosphate defoamer is added, the bubbles generated by the carbon nanofiber suspension can be removed in the ultrasonic process [25].Table 2 shows the ratio of basic composites to high-performance carbon nanofiber products.

The dispersant of graphene (GNP) is polyethylene vinyl phenyl ether (co 890), and the mass ratio of GNP to co 890 is 1 : 5. In addition, a certain amount of defoamer must be added to the prepared graphene suspension. The experimental investigation shows that the addition of 0.20 wt% three-phosphate butyl defoamers can eliminate the foam [26] formed by the suspension of graphene in an ultrasonic process.

3.2. Self-Shrinkage Test Results of Carbon Nanomaterials. The effects of multiwalled carbon nanotube content, water-cement ratio, age, and surfactant Arabic gum on the self-shrinkage of cement paste that were studied here are some results from the above tests.

(1) Under the same water-cement ratio, the self-shrinkage of multiwalled carbon nanotube cement paste changes with age.

Under the condition of the same water-cement ratio, the change of self-shrinkage performance of multiwall carbon nanotube cement paste with age is shown in Figure 2.

It can be seen from these four figures that when the water-cement ratio is 0.30 and 0.35, the automatic shrinkage value of multilayer carbon nanotube cement paste test piece first decreases and then increases with the increase of age. When the water-cement ratio is 0.25, the autogenous shrinkage value of the specimen increases with age, especially from the initial setting time to the first day of the test time. When the test age increases to 7 days (w/C =0.35 and 0.30) or 14 days (w/C =0.25), the growth rate of self-shrinkage value of MWCNT cement paste is very small, the growth rate of self-shrinkage value is slow, and the self-shrinkage curve tends to be stable. Because the reaction between cement and water is heating, the temperature of the sample increases, resulting in thermal expansion. The early heating reaction of cement is intense, and the hydration reaction will release a lot of heat, causing the thermal expansion of the

cement, to offset part of the self-shrinkage. The self-shrinkage value at this time is actually the combined result of thermal expansion and self-shrinkage. When the water-cement ratio is 0.3 and 0.35, respectively, on the first day of measurement, the expansion value caused by thermal expansion is greater than the self-shrinkage value, resulting in the decline of the self-shrinkage curve, and the self-shrinkage value is negative [27]. Then, with the increase of age, the hydration reaction of cement slows down gradually, which weakens the thermal expansion phenomenon, and the self-shrinkage value is gradually greater than the expansion value, which makes the self-shrinkage curve rise and the

(a) W/C = 0.35

(b) W/C = 0.30

(c) W/C = 0.25

(d) W/C = 0.25 (influence of GA)

FIGURE 2: Self-shrinkage changes of new energy materials with different nano and lime ratios.

self-shrinkage value presents a positive value. However, when the water-cement ratio is 0.25, even on the first day of measurement, the self-shrinkage value of the specimen is much greater than the thermal expansion value, so the self-shrinkage value of the specimen increases with the increase of age.

(2) Under the same water-cement ratio, the self-shrinkage of multiwalled carbon nanotube cement paste changes with the change of carbon nanotube content.

It can be seen from these four figures that, under the condition of a certain water-cement ratio, with the increase of the content of multiwalled carbon nanotubes, the self-shrinkage value of multiwalled carbon nanotube cement paste first decreases and then increases. When the water-cement ratio is 0.35 and the test age is 7 days, the self-shrinkage value of cement paste containing 0.05 wt% MWCNTs is the smallest, which is 46.74% lower than that of the blank sample. In addition, when the water-cement

ratio is 0.30 and the measurement age is 7 days, the optimum content of multiwalled carbon nanotube cement paste is 0.075 wt%, and the reduction rate of self-shrinkage value is 45.37% compared with the blank specimen under the same conditions. When the water-cement ratio is 0.25 and the measurement age is 7 days and 14 days, respectively, the optimum content of multiwalled carbon nanotube cement paste sample is 0.075 weight, and the self-shrinkage value is reduced by 9.32% and 11.54%, respectively, compared with the blank sample. It can also be observed from the figure that when the doping amount of multiwall carbon nanotubes reaches 0.12 wt%, the self-shrinkage value of the cement paste specimen containing multiwall carbon nanotubes is greater than that of the reference sample. It can be inferred that the high content of multiwalled carbon nanotubes limits the dispersion of multiwalled carbon nanotubes in the cement matrix, resulting in poor dispersion and aggregation of multiwalled carbon nanotubes in the cement matrix. This not only fails to give full play to the advantages of multiwalled carbon nanotubes, but also causes interface

(a) W/C = 0.35 (7 d)

(b) W/C = 0.30 (7 d)

(c) W/C = 0.25 (7 d)

(d) W/C = 0.30 (14 d)

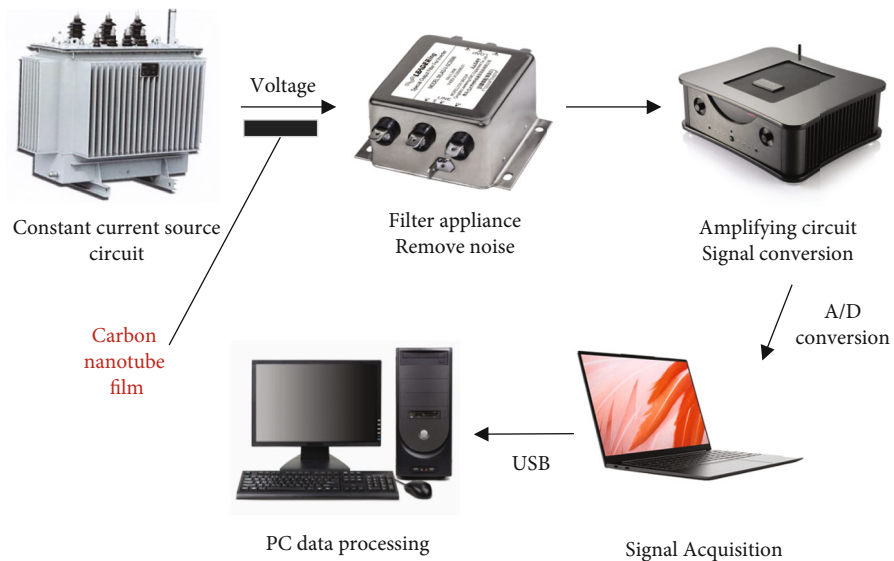
FIGURE 3: Variation of self-shrinkage value of nanomaterials under different water-cement ratio.


FIGURE 4: Hardware circuit design block diagram.

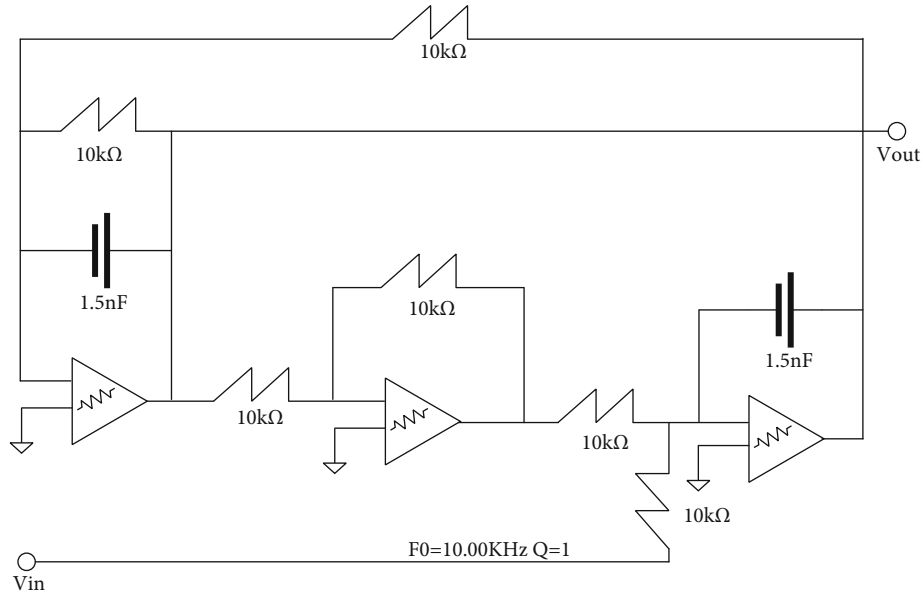
defects between multiwalled carbon nanotubes and cement matrix, which brings harm to cement-based materials and increases the self-shrinkage value of specimens [28]. Under a certain water-cement ratio, the auto-shrinkage performance of the multiwalled carbon nanotube cement slurry varies with its content, as shown in Figure 3.

The experimental results of self-shrinkage of carbon nanomaterials are as follows. When the ratio of water to cement is 0.3 and 0.35, the self-shrinkage value of carbon nanomaterial cement paste first decreases and then increases with the increase of age. When the ratio of water to cement is 0.25, the self-shrinkage value of the test piece increases with the increase of age, especially from the initial setting time to the second day of the test age. When the test age increases to 7 d (w/C =0.35 and 0.30) or 14 d (w/C =0.25), the growth rate of autogenous shrinkage value of carbon

FIGURE 5: Simulation diagram of third-order Butterworth filter.


nanomaterial cement paste will decrease, but the growth rate of autogenous shrinkage value is slow. Under the same water-cement ratio, with the increase of carbon nanomaterial content, the self-shrinkage value of carbon nanomaterial cement paste first decreases and then increases [29]. When the water-cement ratio is 0.35 and the test age is 7 days, the self-shrinkage value of cement paste containing 0.05 wt% carbon nanomaterial is the smallest, which is 46.74% lower than that of the blank sample. When the content of carbon nanomaterial reaches 0.12 wt%, the self-shrinkage value of carbon nanomaterial cement paste sample is greater than that of the blank sample. The greater the content of carbon nanomaterial, the greater the self-shrinkage value of cement paste.

3.3. Application of Carbon Nanomaterials. This part mainly studies the hardware circuit design of polymer-based composite health monitoring data acquisition system based on carbon nanotube thin film sensor. The system is mainly composed of power supply circuit, constant current source circuit, filter circuit, amplification circuit, data acquisition circuit, and main computer. The communication circuit is composed of real-time online detection of basic parameters such as resistance value, film temperature, and film distortion state of the film sensor during composite deformation [30]. The block diagram of hardware design is shown in Figure 4.

Compared with other filters, the amplitude characteristic curve in the passband of Butterworth filter is almost parallel, there is no obvious fluctuation, and the useful signal can pass through almost without attenuation. For the clutter signal above this frequency, the amplitude curve shows a strict downward trend, the interference with the signal is stronger and stronger, and the filtering accuracy is higher and higher. However, the transition band is long, and the clutter signal processing effect near the cut-off frequency is not obvious. After filter simulation, the circuit design scheme and spec-
FIGURE 6: Amplitude frequency diagram of third-order Butterworth filter.

trum diagram of the curve are obtained, as shown in Figure 5 and Figure 6.

It can be seen from the amplitude-frequency diagram of Butterworth filter that the curve is strictly monotonically decreasing. When the amplitude is -3 dB, the passband gain is 0.7, and the corresponding cut-off frequency is 9.982 khz, which is a little different from the ideal value of 10 kHz. However, the transition band is relatively flat, and the filter gain corresponding to 12.5 k frequency is as high as 0.5, which has no obvious effect on the clutter near the cut-off frequency.

Generally, the damage mode of large structural members has the following two characteristics: the uncertainty of damage location and the randomness of damage direction, which poses a great challenge to the current real-time

FIGURE 7: Multiangle tensile comparison test of rectangular sensor and omnidirectional sensor.

FIGURE 8: Tensile test results of rectangular sensor at 0° and 90°.

condition monitoring method of large structural members. In view of this situation, this paper puts forward the following design scheme. Traditional rectangular sensors are distributed in matrix composites in an array manner to detect different areas of the structure online and in real time. The scheme is shown in Figure 7.

For the first scheme, when the composite substrate is locally bent and deformed, four rectangular sensors with different orientations will produce different strain characteristics, resulting in some differences in the fluctuation value of the resistance change rate. By comparing the data fluctuation, the position of bending deformation can be preliminarily determined. However, because the sensor pasting method of the traditional rectangular sensor is synchronized with the fiber direction of the tested polymer matrix composite, the rectangular sensor can collect the change value of resistivity

in the fiber direction in real time. However, when the fission direction of the composite substrate is in the vertical direction or any angle of the optical fiber, there is a certain measurement error in the distribution mode of the rectangular sensor array. The measured resistance value is only the vertical component of the optical fiber direction, which cannot well reflect the strain state of the material. Therefore, in the comparative test of this paper, this paper will further verify whether the rectangular sensor has omnidirectional characteristics and test whether the rectangular sensor has omnidirectional monitoring capability of composite materials.

The experimental results of data processing are shown in Figure 8. Because the four sensors are symmetrically distributed in the array, their deformation states are completely consistent. This paper takes the sensor in the upper left corner as a representative for real-time data analysis. It is found

that there is always a strict linear relationship between the resistance change rate of the film sensor and the tensile stress whether the film detection direction is along the horizontal or vertical direction. In the range of 0-6000ue, with the increase of tensile stress, $\triangle$ R/R0 increases linearly. Carbon nanotube films are very sensitive to small strains. During the loading process, the change rate of resistance is positively correlated with the increase of tensile strain. Through the linear fitting of the least square method, the tensile strain sensing equation of the rectangular thin film sensor is $\triangle R/R0 = 70e - 0.5$ along the optical fiber direction and $\triangle R/R0 = 40e - 0.1$ along the vertical direction of the optical fiber. The sensitivity coefficients of the two directions are quite different, and the feedback damage information of the same material in different directions is different, so there is a certain measurement error.

4. Discussion

With the diversification of application fields, materials are often affected by complex mechanical loads, multiphysical field coupling, and even corrosive environment. The research of carbon nanomaterials, carbon nanofibers, and graphene-based composites is still in the exploratory stage, and further research is needed in many aspects. This paper needs to further study the total shrinkage of carbon nanomaterial and cement-based composites. The shrinkage of cement materials also includes drying shrinkage, plastic shrinkage, carbonization shrinkage caused by carbonization, chemical shrinkage, and cold shrinkage caused by temperature reduction. The conditions can further test the total shrinkage value of carbon nanomaterials and cement-based composites and study the effects of carbon nanomaterials, carbon nanofibers, and graphene on the total shrinkage properties of cement-based materials.

5. Conclusions

With the increase of water-cement ratio, the self-shrinkage of cement paste specimen decreases clearly. When the water-cement ratio is 0.25, the self-shrinkage value of 0.05% carbon nanomaterial cement paste is 74.68% lower than that when the water-cement ratio is 0.30. In the experimental study of omnidirectional monitoring characteristics, through the repeated tensile tests of rectangular sensor and omnidirectional sensor at 0℃, 30℃, 60℃, and 90℃, it is found that the sensitivity coefficient of rectangular sensor is quite different from the short side, but the sensitivity coefficient of omnidirectional sensor fluctuates slightly in different directions, ranging from 55.8 to 60.4, and the maximum fluctuation is only 5. This fully proves that the carbon nanotube omnidirectional sensor has omnidirectional detection ability.

Graphene, as an emerging two-dimensional carbon nanomaterial, has attracted widespread attention and in-depth research by domestic and foreign researchers. With its excellent mechanical properties, graphene is used as a reinforcing material in polymers, ceramics and rubber, and other matrices, which can significantly improve the toughness of the matrix. However, under the action of natural factors such as continuous rainfall or heavy rain, the accumulation layer landslide is often in an unsaturated state, which is very easy to induce disasters. Based on this background, we use micronumerical simulation methods and graphene composite materials to study the mechanical properties of unsaturated soil-rock mixtures to understand the mechanical properties of unsaturated soil-rock mixtures and evaluate and predict its stability. This paper takes the soil of a landslide zone in a certain city as the numerical test object. Through the automatic generation technology of the mesostructure model of the soil-rock mixture, a series of numerical experiments were carried out on the random mesostructure model of the soil-rock mixture, and the gravel content was analyzed in depth. Experiments show that the model can reasonably describe the volume expansion of the soil-rock mixture under low confining pressure, the volume compression under high confining pressure, and the phenomenon that the peak strength of the soil-rock mixture increases with the increase of confining pressure, which verifies that the model is simulating soil and rock. This shows that the stress-strain relationship curves of different soil-rock interface parameters, rock content, saturation, and the number of wet and dry cycles all show obvious nonlinear characteristics and strain hardening. This shows that graphene composites can be used in the study of the mechanics of unsaturated soil-rock mixtures, which is of great significance for improving the landslide environment and enhancing its mechanical properties.

1. Introduction

With the development of the national economy, in engineering practice, foundation resistance problems exist in UHV transmission line foundations, underground space foundations, high-rise building foundations, and marine construction foundations. Therefore, geotechnical scholars have more research on the resistance of foundations. More and more, it has gradually become a popular direction. In many engineering constructions, there are very high requirements

on the mechanical properties of soil-rock mixtures. Most of the natural shallow soils exist in unsaturated forms, with less overall water content, and have good shear resistance [1–3]. The increase of water content will weaken its performance, so the change of water content will have a greater impact on the mechanical characteristics of natural unsaturated soil. Of course, it is not the only influence. Therefore, the mechanical research on the properties of this kind of media, as well as the stability analysis, deformation and instability prediction, and prevention of the common accumulation

layer slopes and other slopes containing soil-rock mixed media in engineering construction in my country. It has good application value.

The rapid development of nanotechnology is continuously expanding the application of traditional materials such as soil and rock, bringing new opportunities and hopes to the development and transformation of mixed soil composite materials [4]. Nanomaterials are ultrafine materials with a particle size on the order of nanometers. Combining them with mixed soil can successfully enhance the mechanical strength of the mixed soil. Graphene, as a 2D layered inorganic nanomaterial with a periodic structure, is currently the strongest material known in the world [5, 6]. Due to its excellent mechanical properties, it can act in a polymer matrix like other nanomaterials, to nanoenhancement. At the same time, due to the physical properties of graphene itself, it can also be widely used in composite materials.

In the past ten years, scholars at home and abroad have conducted a large number of pioneering and fruitful researches on soil-rock mixtures and have accumulated rich research results and research experience. Qin et al. studied the preparation and mechanical properties of graphene and multiwalled carbon nanotube reinforced composite ceramic coatings. Use infrared spectroscopy (FTIR analysis) to identify the structure of functionalized and hybrid functionalized carbon nanotubes. The coating is brushed on the substrate and then cured at a temperature below 250°C. The morphological and cross-sectional features were studied by scanning electron microscopy (SEM). The experimental results show that the composite coating has a compact structure, and the graphene and the mixed-treated carbon nanotubes are well dispersed. The addition of 0.2 wt% graphene and 0.2 wt% hybrid functionalized carbon nanotubes resulted in a significant increase in hardness and fracture toughness. At the same time, due to the high tensile strength of graphene and carbon nanotubes, the bonding strength between the composite coating and the metal substrate is improved. Compared with pure alumina coating, the friction coefficient, wear depth, and wear width of composite coating are much lower. However, the experimental conclusions are not suitable for application to unsaturated soil-rock mixtures [7]. Lei et al. studied the characteristics of the shear strength parameters of the rock and soil aggregates in the embankment slope of the reservoir, gave the law of the shear strength of the rock and soil aggregates, and proposed the characteristics of the rock and soil aggregates considering the influence of suction and saturation. The unsaturated shear strength formula studies the physical mechanism of sliding or failure of such slopes under rainfall infiltration conditions. Based on the analysis of the slope rainfall infiltration process, a 3D unsaturated saturated-unsaturated seepage field and its finite element solution model were established. Studies have shown that the minimum safety factor of accumulated rock and soil aggregates is not reached when the rainfall stops, but occurs several hours after the rainfall stops. This phenomenon is consistent with the destruction process of the actual slope engineering, but its overall research lacks data support, and more data is needed to support its conclusions [8]. In order to obtain the mechanical properties of the weathered soil-rock mixture at the edge of a highway landslide in western China, Jin needed to perform large and medium-sized triaxial shearing on the three weathered rock-soil mixtures on site due to the reduction of sample size and particle size test. The effects of particle size and sample size were analyzed. The results show that it has a strong scale effect: mechanical properties are closely related to particle size, sample size, and sample classification. As the particle size increases, the internal friction angle increases first and then decreases. At the same time, the reasons for these differences are analyzed. The experimental results lack more data to support the trend of internal friction angle changes [8].

This paper uses the FORTRAN language program to realize the method of establishing the soil-rock mixture numerical model by the indoor test gradation, and with the help of the mesonumerical simulation method and the implicit integration algorithm, the finite element program is used to surround the seepage mechanics response of the soil-rock mixture of the accumulation layer landslide. And the mechanism of deformation and failure carries out a series of biaxial tests of unsaturated soil-rock mixed media under different soil-rock interface parameters, rock content, and saturation, and different numbers of dry and wet cycles, using soil mechanics, rock mechanics, seepage mechanics, and elastoplastic mechanics obtain the influence law of soil-rock interface parameters, rock content, saturation, number of dry-wet cycles, and other factors on the deformation and strength characteristics of soil-rock mixture to reveal its seepage mechanism and deformation and failure characteristics.

2. Mechanical Properties of Unsaturated Soil-Rock Mixture and Graphene Composite Materials

2.1. The Structure and Properties of Graphene. Since Professor N and Professor G successfully prepared single-layer graphene, graphene has attracted more and more attention and research from all walks of life. Graphene is the basic unit of other carbon materials in various dimensions. Currently, members of the carbon family include the following: zero-dimensional fullerenes, one-dimensional carbon nanotubes, and two-dimensional graphene to three-dimensional diamond and graphite. Graphene has a six-membered ring arranged in a periodic honeycomb structure, in which C atoms are connected to adjacent C atoms by sp^2 hybrid orbitals, the bond angle of the C-C bond is 120°, and the bond length is 0.142 nm. This stable structure gives graphene ultrahigh strength, with Young's modulus of 1.1 TPa and a breaking strength of 125 GPa. Each C atom of graphene has 4 valence electrons. When 3 electrons form an sp^2 bond, there will be an unbonded electron forming a large π bond above and below the plane of the graphene. At this time, the π bond is half-filled. The state allows electrons to move freely in it, and the large π bonds between layers form π orbitals perpendicular to the graphene plane. These π orbitals are effective channels for free electrons to shuttle

through the two-dimensional structure of graphene. Give graphene excellent electrical and thermal conductivity. The electron migration rate of graphene in a single atomic layer reaches $10000\,cm^2/v$, and the thermal conductivity is 3000-$5000\,wm^{-1}/k$. Theoretically, the specific surface area of a single-layer graphene can reach $2630\,cm^{-2}/g$, which not only further increases the electrical and thermal conductivity of graphene but also provides a larger contact area for its surface functionalization. In addition, the unique energy band structure of graphene also enables it to possess electromagnetic properties such as quantum Hall effect, quantum tunneling effect, and quantum Hall ferromagnetism. With its excellent properties in terms of force, light, electricity, and magnetism, graphene is widely used to enhance and improve the mechanical, electrical and electromagnetic shielding properties of composite materials.

Strictly speaking, there is thermodynamic instability in the two-dimensional crystal structure, and there is no long-range ordered two-dimensional crystal in nature. That is to say, if in a free state, the graphene sheet will curl into carbon nanotubes or stacked into graphite, which also makes graphene easy to agglomerate in a macroscopic state, and it is difficult to exist as a single layer.

Professor A added the original graphene and the functionalized graphene treated with nitric acid to the cement-based material to test its mechanical properties and explored the influence of the incorporation of graphene on calcium silicate hydrate. Atomic force microscope observations found that in cement-based materials mixed with graphene, graphene is present in the generated calcium silicate hydrate, and the content of high-density calcium silicate hydrate increases, and the overall mechanical properties of the composite material are enhanced. Molecular dynamics shows that the addition of functionalized graphene improves the interface strength and the integrity of cement-based composites. In addition, phase analysis shows that the incorporation of graphene and functionalized graphene can affect the phase composition and surface toughness of the product, which is the reason why the overall toughness and plasticity of graphene cement-based composites are improved.

2.2. Simulation Method of Soil-Rock Interface.
In a soil-rock mixture, the existence of soil-rock interface has an important influence on its mechanical properties and deformation and failure characteristics [9, 10]. The contact of the soil-rock interface is a typical nonlinear problem. In the numerical calculation, the contact surface element is generally introduced to simulate the contact problem. When there are many contact surfaces, the calculation is often not easy to converge [11, 12]. Therefore, for materials with a large number of discontinuous surfaces on the mesoscale, such as soil-rock mixture, the use of conventional contact surface elements to simulate the soil-rock interface has obvious limitations.

2.2.1. Master-Slave Interface Model.
The master control plane can invade the slave plane between the nodes of the slave plane, as shown in Figure 1(a) [13]. This regulation can well realize the simulation of the mechanical behavior of the soil-rock interface, because in the soil-rock mixture, the stiffness and strength of the rock are generally much greater than those of the soil, and the rotation and translation of the rock under the external load will affect it. The surrounding soil produces contact force, and the sharp corners of the rock passing through the soil will cause the deformation and failure of the soil, which is consistent with the mechanical mechanism of the interaction between soil and rock [14, 15].

In order to obtain the best simulation results, when simulating the soil-rock interface, the pair of surfaces in contact between the rock and the soil is defined as the contact pair in the calculation model. The soil surface is the subordinate contact surface, and the rock surface is the dominant contact surface shown in Figure 1(b) [16].

2.2.2. Friction Model.
When simulating the contact characteristics of soil and boulders, the Coulomb friction model should be used as the soil-rock interface contact model, and the friction factor is used to characterize the friction behavior between two surfaces. The relationship between stress and shear displacement on the contact surface is shown in Figure 2.

The solid line in the figure is the ideal friction behavior. The default friction factor is 0 (the contact surface is completely smooth). Before the stress at the contact surface reaches the maximum stress τ_{max}, the tangential slip is 0 until the stress between the contact surfaces is equal to the relative sliding of the contact surface which will occur only when the ultimate stress μp is [17, 18], namely,

$$\tau_{max} = \mu p. \tag{1}$$

In the formula, μ is the friction factor, and p is the normal contact force between the two contact surfaces.

2.3. Unsaturated Soil Seepage and Strength

2.3.1. Unsaturated Seepage.
The flow of liquid pores into unsaturated soils follows Darcy's law or Forchheimer's law, and the expressions are as follows:

$$V = -K\,grad H = KJ, \tag{2}$$

$$snV_f\left(1 + \beta\sqrt{V_f \cdot V_f}\right) = -K\frac{\partial H}{\partial X} = -K\,grad H, \tag{3}$$

where V is the seepage velocity, J is the hydraulic gradient, H is the piezometric head, snV_f is the seepage velocity through the unit area in a certain direction, and K is the permeability coefficient [19, 20].

According to Darcy's law, there are

$$k = \frac{v}{gK}. \tag{4}$$

According to Forchheimer's law, there are

$$k = \frac{v}{g + g\beta\sqrt{V_f \cdot V_f}}K. \tag{5}$$

(a) The Master can Invade the Slave   (b) Soil Block Contact Surface
Figure 1: Simulation method of soil-rock interface.

Figure 2: Schematic diagram of Coulomb friction model.

In the formula, v is the dynamic viscosity coefficient. For unsaturated soil, since liquid and gas coexist, the degree of saturation directly affects the permeability resistance, so at this time, k or K is a function of the degree of saturation S, so it is uniformly written as

$$k = k_s(S)K. \qquad (6)$$

In the formula, $k_s(S)$ is the saturation correlation coefficient, and for isotropic materials, K is a scalar.

2.3.2. Unsaturated Soil Strength. An important factor in the instability of the soil-rock mixture slope caused by rainfall is that the rainfall causes the reduction of the matrix suction in the shallow unsaturated soil-rock mixture, resulting in loss [21, 22]. The influence of unsaturated characteristics on soil-rock mixture is mainly reflected in the influence of matrix suction on its shear strength, namely,

$$\tau_f = c' + (\sigma - u_a) \tan \phi' + (u_a - u_w) \tan \phi^b. \qquad (7)$$

In the formula, τ_f is the shear strength of unsaturated soil, σ is the normal stress, and $\sigma - u_a$ is the net normal stress.

2.4. Automatic Generation Technology of Soil-Rock Mixture. With the rapid development of digital graphics processing technology, remarkable results have also been achieved in the mesostructure of soil-rock mixtures. However, digital image processing technology largely relies on the acquired cross-sectional images of all the soil-rock mixtures in the study area, so this method has certain limitations [23–26]. The main function of the preprocessing program of the soil-rock mixture numerical model is to generate a certain amount of rock in a specific research area, so that the parti-

cle size distribution of the rock system itself conforms to a specific gradation curve. Furthermore, it is possible to make the generated discrete stone system have statistical self-similarity properties, that is, fractal [27].

2.4.1. Random Number. The stochastic simulation method is used to simulate the size, orientation and spatial distribution of the blocks in the soil-rock mixture, namely,

$$R_i = \text{mod} \, (2053 R_{i-1} + 13849, m), \qquad (8)$$

$$\text{RND}_i = \frac{R_i}{m}. \qquad (9)$$

Among them, R_{i-1} is the seed number that triggers the random number generator input from the outside.

2.4.2. The Shape of the Block Stone in the Soil-Rock Mixture. In order to simulate boulders objectively, arbitrary random polygons are used in the program to simulate boulders. The maximum and minimum number of sides of the boulders is put from the outside [28]; then,

$$L(x, \lambda) = f(x) - \lambda^T c(x). \qquad (10)$$

Among them,

$$c((x)) = (c_1(x), \cdots, c_p(x))^T, \qquad (11)$$

$$\varphi(x, u) \equiv f(x) + \frac{1}{\mu} \|c(x)\|_1. \qquad (12)$$

Among them, μ is called the penalty factor, and $\|c(x)\|_1$ is the l_1 norm of the vector function $c(x) = (c_1(x), \cdots, c_p(x))^T$. In the specific simulation process, as needed, the concave polygon is not needed for artificial control [29, 30].

2.4.3. Determination of the Spatial Position and Orientation of Block Stones in Soil-Rock Mixture. First, create the center of the rock, and then multiply the random number by the width of the sample to get the coordinate value of the center of the rock in the sample [31, 32]. Before determining the vertex coordinates of the polygon, a random number must first be created as the angle of deflection of the side of the polygon. After determining the deflection angle, since the number of sides of the polygon has been determined, the deflection angle required to generate a polygon radius can

be calculated as

$$\beta = a + (i - 1) \cdot \frac{2\pi}{n}. \tag{13}$$

Then, generate a random number and combine the boundary diameter of the polygon with the maximum and minimum radius to determine the radius of the polygon at this time. After the polygon radius is determined, since the angle between the polygon side and the x-axis is known, multiply the angle by the angle. The cosine and sine values of can get the vertex coordinates of the polygon [33, 34].

2.4.4. Determination of the Area of Block Stone in Soil-Rock Mixture. This type of polygon is decomposed into multiple triangles, and the area of the polygon is calculated by calculating the area of the triangle separately. The formula used is as follows:

$$\text{Area} = \frac{1}{2} \sum_{i=1}^{n} \begin{vmatrix} x_0 & x(i) & x(i+1) \\ y_0 & y(i) & y(i+1) \\ 1 & 1 & 1 \end{vmatrix}. \tag{14}$$

Among them, (x_0, y_0) is the coordinate of the center of the polygon; $(x(i), y(i))$ is the coordinate of the vertices of the polygon.

2.4.5. Determination of rock content in the model. In the established two-dimensional model, the size of the stone content is defined as the ratio of the area occupied by the boulders in the model to the total area of the model. The specific formula is as follows:

$$e = \frac{\sum A_i}{A}. \tag{15}$$

In the formula, e is the stone content rate, A_i is the area of a single stone, and A is the total area of the model.

2.5. Mechanical Safety of Unsaturated Soil-Rock Mixture. Since the mechanical properties of the unsaturated soil-rock mixture effectively inherit the advantages of steel and concrete, it has good plasticity and adjustability and can form a beautiful structure. It has high strength and rigidity and can be built into a larger span structure. Good integrity, good ductility, and the structure can better resist external disasters, such as earthquakes and hurricanes; good durability and fire resistance can be applied to many characteristics such as harsh environments and widely used in construction and other civil engineering.

3. Experimental Design of Mechanical Properties of Unsaturated Soil-Rock Mixture

3.1. Test Subject. Taking the landslide zone soil in a landslide area of this city as the object of numerical experiment, through the automatic generation technology of the mesostructure model of the soil-rock mixture, a series of numerical experiments were carried out on the random mesostructure

model of the soil-rock mixture, and the gravel content, the soil-rock contact characteristics, saturation, dry-wet cycle, and many other factors affect the macromechanical properties and deformation failure of unsaturated soil-rock mixtures. The material composition of the landslide accumulation body and the sampling point diagram of the accumulation body are shown in Figure 3.

3.2. Content of Numerical Experiment

3.2.1. Mechanical Properties of Unsaturated Soil-Rock Mixture under Different Rock Contents. The unsaturated soil-rock mixture consists of soil and crushed stone. The different content of crushed stone will change the internal structure of the soil-rock mixture, which will inevitably affect its mechanical deformation properties. Based on the landslide zone test ground gradient in a landslide-prone area of this city, the random soil-rock mixture intermediate generation system is used to create numerical experimental geometric models with different rock contents and the corresponding unsaturated soil-rock mixture. They are determined in the ABAQUS test model, perform a biaxial compression test, and study the effect of the content of crushed rocks on the stress-stress ratio and volume-axial stress curve of the unsaturated soil-rock mixture.

3.2.2. Mechanical Properties of Unsaturated Soil-Rock Mixtures under Different Saturations. As a typical heterogeneous bulk material, unsaturated soil-rock mixture has a large internal porosity and is affected by saturation. This paper uses the ABAQUS program as a platform to combine mechanical calculations and seepage calculations to conduct biaxial tests of unsaturated soil-rock mixture samples under different saturation conditions. Study the mechanical properties and failure mechanism of soil-rock mixture samples under different saturations.

3.3. Numerical Test Model Establishment. The numerical test refers to the indoor triaxial shear test of a sliding body in a landslide area in this city for sample preparation. The indoor test is scaled according to the original gradation of the sliding body at the landslide site. The particle size of the sample is above 60 mm, accounting for 5.22%. The particle size of 20 mm or more accounts for 25.52%, and the content of fine particles smaller than 5 mm is 35.84%. Therefore, the equivalent replacement method is used to scale the ultraparticle size part, and the ultraparticle size part ($d_{\max} = 60$ mm) is 60-5 mm. Perform equivalent substitutions, and the gradation composition is shown in Table 1.

3.3.1. Determination of Minimum Particle Size. This frequency value test adopts a 30 cm ∗ 60 cm biaxial test. The minimum particle size of the numerical biaxial test is determined by the soil-rock threshold combined with the original gradation of the landslide body to be 1 cm.

3.3.2. Model Establishment. This paper simulates the five sets of gradation curves of the indoor triaxial test. Within the range of 30 cm ∗ 60 cm, the self-developed random stone generation system is used to automatically generate crushed

stones and soil, and then, the corresponding nonstandards are established in ABAQUS.

3.3.3. Crushed Stone Content.
According to the grading curve, the rock content is 32%, 38%, 47%, 56%, and 65%, and then, the geometric model of the soil-rock mixture is generated according to the random generation system of the block stone, and the corresponding geometric model is established in ABAQUS. Divide the grid, as shown in Figure 4, and set the initial conditions and boundary conditions of the soil-rock contact characteristics of the unsaturated soil-rock mixture to prepare for the next biaxial numerical test.

3.4. Statistical Processing.
Statistical analysis was performed with SPSS 13.0 statistical software. The significance test of the difference was performed by one-way analysis of variance, the difference between the two groups was tested by LSD-t, and the statistical results of the mechanical properties of the unsaturated soil-rock mixture were performed by the group t-test. $P < 0.05$ is considered to be statistically significant.

4. Mechanical Properties of Unsaturated Soil-Rock Mixture

4.1. Verification of Numerical Model Test.
Take the indoor triaxial test of gravel soil with 47% gravel content as an example to verify the rationality of the random soil-rock mixture model. The parameters of the biaxial numerical model are shown in Table 2.

The size of the model is 30 cm ∗ 60 cm from the previous three-axis test. The vertical displacement of the bottom boundary is constrained, the surrounding stress boundary conditions are used, and the top of the model is servo controlled to apply axial load. Confining pressures of 0.4 MPa, 0.8 MPa, 1.2 MPa, and 1.6 MPa were, respectively, applied in the calculation of the biaxial test. The calculation results of the biaxial test mainly analyze the relationship between deviatoric stress and axial strain and the relationship between volume and axial strain. At the same time, it is compared with the indoor test results, as shown in Figures 5 and 6.

Figures 5 and 6 show that the normality of the calculated value of the model and the measured value of the test are the same whether it is the voltage-voltage ratio curve or the

Stone content 32%   Stone content 38%   Stone content 47%   Stone content 56%   Stone content 65%

Block stone	2800	17500	0.20	41	12000

volume-axis voltage ratio curve, which shows the adaptability of the model to different pressure situations. It shows that the model can reasonably describe the volume expansion of the soil-soil mixture at low constraint pressure, the compression of the volume under high constraint pressure, and the increase of the maximum strength of the soil-rock mixture with the increase of the constraint pressure, which confirms that the model simulates a soil-rock mixture.

4.2. Deformation Characteristics of Unsaturated Soil-Rock Mixture under Different Soil-Rock Interface Parameters. Using the unsaturated numerical test model, the biaxial consolidation drainage test was carried out under the confining pressure of 0.4 MPa, 0.8 MPa, 1.2 MPa, and 1.6 MPa, respectively. During the loading process, the confining pressure is kept stable by the strain servo control, and the speed of the upper loading plate is controlled to apply the axial force to obtain the stress-strain relationship curve and the volume-axis strain relationship curve of the corresponding confining pressure under different soil-rock interface contact parameters, such as shown in Figures 7 and 8.

It can be seen from Figures 7 and 8 that the stress-strain relationship curves of the unsaturated soil-rock mixture with the same rock content show obvious nonlinear characteristics. The initial linear segments coincide, and the peak principal stress difference increases with the increase of confining pressure. The five types of samples with rock content all show the characteristics of strain hardening, and with the increase of confining pressure, the phenomenon of strain hardening becomes more significant. From the volumetric strain-axial strain relationship curve, it can be seen that at low confining pressure, the specimens have undergone a deformation process from shear shrinkage to dilatancy. As the confining pressure increases, the dilatancy

deformation of the specimen gradually weakens at high confining pressure. During compression, the specimen basically exhibits shear deformation, and with the increase of strain, the growth rate of shear deformation tends to decrease. Under the same confining pressure, the larger the rock content of the unsaturated soil-rock mixture, the higher the peak strength value. The smaller the axial strain when the peak strength is reached, the more rock content and the greater the initial elastic modulus of the sample, which will enter the plasticity. After the deformation stage, the strain hardening characteristics are more pronounced.

4.3. Failure Mechanism of Unsaturated Soil-Rock Mixture under Different Soil-Rock Interface Parameters. Under various soil-rock interface parameters, the mesoscopic failure morphology of each sample during each axial strain process under confining pressure is shown in Figure 9.

It can be seen from Figure 9 that when the friction coefficient of the soil-rock interface is small, the unsaturated soil-rock mixture appears as a loose failure mode, with obvious open cracks, and when the friction coefficient is large, it appears as an overall failure. This is due to the broken stones and the soil. During the loading process, the gravel inside the soil-rock mixture moves and rotates. When there is no friction between the soil and the boulder or the friction is small, the movement of the boulder cannot drive the surrounding soil. The coordinated deformation of the body will leave a large gap behind it. When the soil behind it reaches a plastic state, the crushed stones can not play a restraint, making the shear failure zone of the soil-rock mixture extremely irregular and appearing to be circumscribed. When the interface friction coefficient is very large, the greater the occlusion between the rock and the surrounding soil, the more coordinated the deformation of the rock and the surrounding soil; the friction required for basic rotation and translation of the rock is very large, so only translation and dislocation occur. So the shear failure zone basically passes through the sharp corners of the rubble and seldom branches and bypasses the previous rubble.

4.4. Mesopermeability Test Analysis. In order to study the influence of the rock content of the soil-rock mixture on the macroscopic permeability, the test selects the rock content of 32%, 38%, 47%, 56%, and 65% and five conditions, respectively. When the crushed stone is in close contact with

TABLE 3: Relationship curve between permeability coefficient and rock content of unsaturated soil-rock.

Osmotic pressure (MPa)	0	20	40	60	80
0.1	0.095	0.082	0.078	0.074	0.069
0.2	0.098	0.087	0.085	0.083	0.080
0.3	0.101	0.095	0.098	0.101	0.103
0.4	0.105	0.107	0.118	0.129	0.139

the soil and the permeability of the stone is not considered, the mesoseepage field distribution of each sample obtained through the numerical permeability test is shown in Figure 10.

According to the results of numerical experiment analysis, the relationship between the macropermeability coefficient of the soil-rock mixture and the rock content of the soil-rock mixture is drawn as the ordinate. The results are shown in Table 3.

It can be seen from Table 3 that the macroscopic permeability coefficient of soil-rock mixture changes with rock content obtained from the prediction of each mesostructure model and numerical experiment. It can be seen that when the rock is in close contact with the soil, when the pore water passes through the broken rock in the narrow soil between the rocks, the seepage rate is relatively large, and the pore water pressure contours are densely distributed. The pore water pressure of these parts on the surface drops faster. The narrower the channel, the denser the value, and the faster the pore water pressure drops. The permeability before and after the block rock is very small. Under the same seep-

age pressure, the macroscopic permeability coefficient of the unsaturated soil-rock mixture decreases with the increase of the rock content. This is mainly because the pore water flows through the pores in the unsaturated soil between the crushed stones. The increase in the rock content of the soil and the narrowing of the spacing between the crushed stones makes the soil more discontinuous, and the flow of pore water is more difficult.

5. Conclusions

In this paper, the purity, crystallinity, chemical structure, and micromorphology of graphene are characterized and analyzed at multiple levels through comprehensive testing methods such as microscopy, providing a reliable basis and basic guarantee for subsequent testing. Based on the random rock generation system, the corresponding unsaturated soil-rock mixture ABAQUS finite element program was compiled. Using the master-slave contact algorithm, the characteristics of the soil-rock interface, rock content, saturation, and dry humidity were proposed. After fusing the graphene composite material into the unsaturated soil-rock mixture, starting from the difference in circulation, the biaxial numerical test method is used to deeply analyze the influence of various factors such as soil-rock interface parameters, rock content, saturation, and dry and wet cycles. Study its mechanical properties and the microscopic damage mechanism and macroscopic mechanical behavior of unsaturated soil-rock mixtures. From the shape of the stress-strain relationship curve, the stress-strain relationship curves of different soil-rock interface parameters, rock

content, saturation, and the number of wet and dry cycles all show obvious nonlinear characteristics and strain hardening. As the confining pressure increases, the hardening becomes more obvious. The shear strength parameters of unsaturated soil-rock mixtures increase with the increase of soil-rock interface parameters. Finally, there is a comprehensive use of various microtesting methods to study the microscopic mechanism of graphene in the soil-rock mixture. When the soil-rock interface is completely smooth, the unsaturated soil-rock mixture sample is broken in bulk, with obvious open cracks and obvious dilatancy. When the interface parameter increases to a certain extent, the unsaturated soil-rock mixture is destroyed as a whole, and the dilatancy phenomenon is not very obvious. Both the constitutive model and the yield criterion of the numerical experiment in this paper adopt the Mohr Coulomb model, which has a certain gap with the results of the indoor experiment. Therefore, it is necessary to strengthen the theoretical research.

Using sulfide ore and oxide ore tailings of a tin mine in Yunnan as raw materials, 17 groups of flocculation settling tests were designed by Box-Behnken in Design-Expert software, and the settling velocity and underflow concentration of mixed tailings with sulfur/oxygen ratio of 5 : 5 were studied. The effects of volume concentration, flocculant unit consumption, and flocculant concentration on settling velocity and underflow concentration were explored, and the optimal parameters of settling velocity and underflow concentration were obtained. *Results*. The best mixing parameters of mixed tailings are volume concentration of 17.66%, flocculant unit consumption of 39.589 g/t, and flocculant concentration of 0.195%. At this time, the settling speed is 2.231 mm/s and the underflow concentration is 65.289%. The flocculation settling velocity under this parameter condition was tested, and the experimental results were consistent with the predicted results of the model. This surface method can be used to design the flocculation and settlement test of mine tailings, which has certain guiding significance for the selection of parameters in actual production of mines.

1. Introduction

With the continuous development of social economy, people's demand for mineral resources is higher and higher. The deepening of resources and the large-scale stacking of solid waste have become the difficult problems facing the development of mining industry. Filling method is widely used as a clean and efficient mining method, which can solve the stacking of surface tailing waste [1–3].

The filling method needs to make tailings and other solid wastes into slurry and transport them to the goaf. The thickening and dehydration of tailings is the premise of the filling pulping process. The traditional tailing dewatering method is natural sedimentation, which can improve the sedimentation efficiency by increasing the sedimentation area. However, with the progress of beneficiation technology, the particle size of tailings becomes smaller and smaller, and the tailings become finer and finer. There are some problems in the use of natural sedimentation, such as serious fine particle overflow and slow sedimentation speed [4]. Adding flocculant to the tailing slurry can improve the settling velocity of tailings and reduce

the overflow concentration [5]. Therefore, many scholars have carried out a lot of research work on the process of flocculation sedimentation. By studying the settling velocity of muddy liquid surface, based on the settling time, unit consumption of flocculant, and settling velocity of muddy liquid surface, the action mechanism of unit consumption of flocculant in different settling stages was obtained [6]. The law of multifactor flocculation and sedimentation is studied, and the important factors affecting flocculation and sedimentation are selected by the Design-Expert software, and the parameters are optimized [7]. Through the static flocculation sedimentation test of total tailings, the solid flux model of total tailing flocculation sedimentation is established, and the influence law of different feeding speed on sedimentation in the process of dynamic flocculation sedimentation is explored [8]. The support vector machine (SVM) regression prediction model is established, and the model parameters are optimized by genetic algorithm to predict the settlement velocity [9]. A simple regression model of sedimentation rate was obtained by fitting the static flocculation sedimentation test according to the feed concentration and unit consumption of flocculant [10].

It can be seen from the above reference that a series of tests are needed to determine the parameters of flocculation and sedimentation. Summarize the rules from the experiment, and finally determine the addition range of parameters. The surface response method has some advantages in this process. The test scheme can be designed by determining the variation range of independent variables, and the overall test can be simplified, and at the same time, the optimization scheme within the variation range of independent variables can be obtained.

In this paper, aiming at the two kinds of tailings of sulfide ore and oxide ore of a tin mine, the indoor static flocculation sedimentation test of sulfide ore tailings, oxide ore tailings, and three mixed tailings with different sulfur oxygen ratio are carried out to study the influence of different particle size composition of tailings on the sedimentation rate. For the mixed tailings with sulfur oxygen ratio of 5 : 5, the response surface method is used to design the test, explore the influence law of various parameters on flocculation sedimentation effect, and optimize the feeding parameters.

2. Experimental Materials

2.1. Basic Physical Parameters of Total Tailings. There are mainly two kinds of tailings of a tin mine in Yunnan: oxidized ore tailings and sulfide ore tailings. Specific parameters are shown in Table 1.

As shown in Table 1, the apparent density of sulfide tailings is 3042 kg/m^3. The apparent density of oxidized tailings is 2861 kg/m^3. The density of sulfide tailings is higher. The loose density of sulfide tailings is 1365 kg/m^3. The loose density of oxidized tailings is 1245 kg/m^3. The stacking compactness of sulfide tailings is 0.449, and the porosity is 0.551. The stacking compactness of oxidized tailings is 0.435, and the porosity is 0.565. In terms of loose density, packing compactness, and porosity, they are relatively close.

From Table 2, showing the mineral composition analysis, it can be seen that the main components of the tailings are calcite and mica, accounting for 40–50% and 23–35%, respectively. The chemical properties of the tailings are relatively stable, and there is no chemical reaction with water.

2.2. Tailing Grading. The two kinds of tailings are obviously different in appearance, gradation, and basic physical parameters. The grading analysis of two kinds of tailings is carried out. The detailed results of tailings grading are shown in Figure 1.

It can be seen from the figure that the tailings of sulfide ore are mainly distributed below -500 mesh, accounting for 40.87%. The average particle size of sulfide tailings is 84 μm. The median particle size was 40 μm. The particle size of 60% tailings is 53 μm. Oxidized tailings are mainly distributed below -500 mesh, accounting for 46.11%, and the median particle size is 31 μm. 60% of oxidized ores is below 40 μm. The average particle size and median particle size of oxidized ore tailings are smaller than sulfide ore tailings, which shows that in morphology, oxidized ore tailings are finer than sulfide ore tailings. Both kinds of tailings are distributed below -500 mesh. Generally speaking, the particle size of the two filling

TABLE 1: Basic physical parameters of sulfide ores.

Type	Apparent density/ (kg/m^3)	Loose density/ (kg/m^3)	Packing compactness	Porosity
Sulfide ores	3042	1365	0.449	0.551
Oxidized ores	2861	1245	0.435	0.565

TABLE 2: Analysis results of mineral composition of tailings.

Mineral name	Mineral content of sulfide ores (%)	Mineral content of oxidized ores (%)
Calcite	40–50	35–40
Mica	25–35	25–40
Fluorite	5–10	5–10
Dolomite	5–10	5–15
Amphibole	1–5	5-10

tailings is too fine [11, 12]. If natural settlement is adopted, it will cause problems such as too slow speed, insufficient underflow concentration, and high overflow concentration. Therefore, it is necessary to adopt flocculation settlement method to improve the settlement effect of tailings and realize stable sand discharge of sand bin.

3. Flocculation Sedimentation Mechanism

The polymer flocculant aggregates the particles through "bridging action" to form flocculation groups [13, 14]. The action mechanism is that some active groups in the molecules are adsorbed on the surface of the particles, the rest extend into the solution to form unstable molecules, and the particles with vacancies on other surfaces contact these extended parts to form aggregates, so as to complete the "bridging" between the particles. If the flocculant is excessive and the polymer active group completely wraps the particles, there is no other vacancy on the particle surface for the extended active group to contact, and the bridging action will not be completed. Therefore, the addition amount of flocculant has a reasonable range, and the larger the flocculant is, the better the flocculation effect is. Different flocculant types will produce different effects. Polymer flocculants can be generally divided into anionic, cationic, and nonionic types. Because different types of flocculants have different molecular composition and flocculation structure, and their action forms and effects are significantly different in solution environments with different pH values and different charges, the polymer flocculant rt301 with polyacrylamide model is selected for flocculation sedimentation test in this test.

4. Flocculation Sedimentation Test of Mixed Tailings

4.1. Experimental Design. In order to study the interaction between flocculant and tailing slurry sedimentation velocity and underflow concentration, a tailing flocculation sedimentation test was designed. Considering that in the actual
FIGURE 1: Grain size composition of full tailings.

production and application of the mine, sulfide tailings and oxidized tailings will be mixed and discharged in the proportion of 5 : 5 in most cases. The volume concentration range of the mixed slurry discharged by the concentrator is 15%-21%. Most research results believe that the main influencing factors of flocculation sedimentation are slurry volume concentration, flocculant unit consumption, and flocculant solution concentration. Therefore, based on the above conditions, the volume concentration of test slurry is designed to be 15%~21%, the unit consumption of flocculant is 20~60 g/T, and the flocculant concentration is 0.1~0.3%.

Response surface method [15, 16] can intuitively optimize the feeding parameters and predict and analyze the objectives. It can not only conduct single-factor analysis but also consider the impact of parameter interaction on the objectives. The volume concentration X_1 of tailing slurry, unit consumption X_2 of flocculant, and flocculant concentration X_3 were selected as independent variables, and the sedimentation velocity Y_1 and underflow concentration Y_2 were selected as response values. Box-Behnken in the Design-Expert software is used to design the test scheme of three factors and three levels and analyze the influence law of the interaction of various variables on sedimentation velocity and underflow concentration. The levels of various factors are shown in Table 3.

4.2. Test Result.
In the settlement test, the settlement velocity of solid particles in the slurry is mainly determined by observing the position of the solid-liquid interface, as shown in the figure. The settling velocity and underflow concentration of solid particles are calculated by recording the height and time of solid-liquid interface.

Figure 2 shows the settlement process of tailings with the passage of time. With the passage of time, the height of settlement interface is getting lower and lower. The settlement

Volume concentration $(X_1)/(\%)$	15	18	21
Unit consumption of flocculant $(X_2)/(g/t)$	20	40	60
Flocculant solution concentration $(X_3)/(\%)$	0.1	0.2	0.3

speed of tailings can be calculated by reading the height of settlement interface.

The specific test scheme and results are shown in Table 4. The multiple regression equations of response value, sedimentation velocity (Y_1), and underflow concentration (Y_2) are obtained by multiple fitting of the test results with design expert:

$$Y_1 = -0.63 + 0.35X_1 + 0.02X_2 + 1.94X_3 - 1.25 \\ \times 10^{-4}X_1X_2 - 0.067X_1X_3 - 7.5 \times 10^{-3}X_2X_3 \quad (1) \\ - 0.012X_1^2 - 2.19 \times 10^{-4}X_2^2 - 1.525X_3^2,$$

$$Y_2 = 7.197 + 4.07X_1 + 0.48X_2 + 47.42X_3 - 1.125 \\ \times 10^{-3}X_1X_2 + 1.09X_1X_3 - 0.18X_2X_3 - 0.096X_1^2 \quad (2) \\ - 5.34 \times 10^{-3}X_2^2 - 149.9X_3^2.$$

During the experiment, the experimental concentration, flocculant unit consumption and flocculant concentration can be determined. However, the granularity of tailings in each experiment has a small amount of uncertainty. Therefore, under the same experimental conditions, there will be some differences in the experimental results, but these

differences are very small, and there will be no serious deviation from the correctness of the experimental results.

4.3. Reliability Test of Regression Model Based on Response Surface Method. The model reliability of multiple regression equations of sedimentation velocity (Y_1) and underflow concentration (Y_2) is tested. Figure 3 shows the comparison between the predicted values of the sedimentation velocity and underflow concentration model and the test values. It can be seen from Figure 3 that the test values are evenly distributed on the fitting line and both sides. It can be seen that

the error between the two is small, which proves that the sedimentation velocity and underflow concentration model are reliable.

Goodness of fit (R^2) represents the difference between the measured value and the regression value, and the value is between 0 and 1. The closer R^2 is to 1, the higher the reliability of the model is. The R^2 values of sedimentation velocity and underflow concentration are 0.998 and 0.99, respectively, which are close to 1, which means that the model is very reliable. The p value of the model represents the significance of each factor, and the p value less than 0.05 represents the significance of the model. The p values of the regression models of sedimentation velocity and underflow concentration are less than 0.0001, and the residuals of the two regression models are not significant, which represent that the model is very significant.

5. Influence of Response Surface Parameters on Flocculation Sedimentation

5.1. Effect of Single Factor of Response Surface Parameters on Flocculation Settlement of Mixed Tailings. It can be seen from Figure 4 that the influence law of various factors on flocculation sedimentation is as follows:

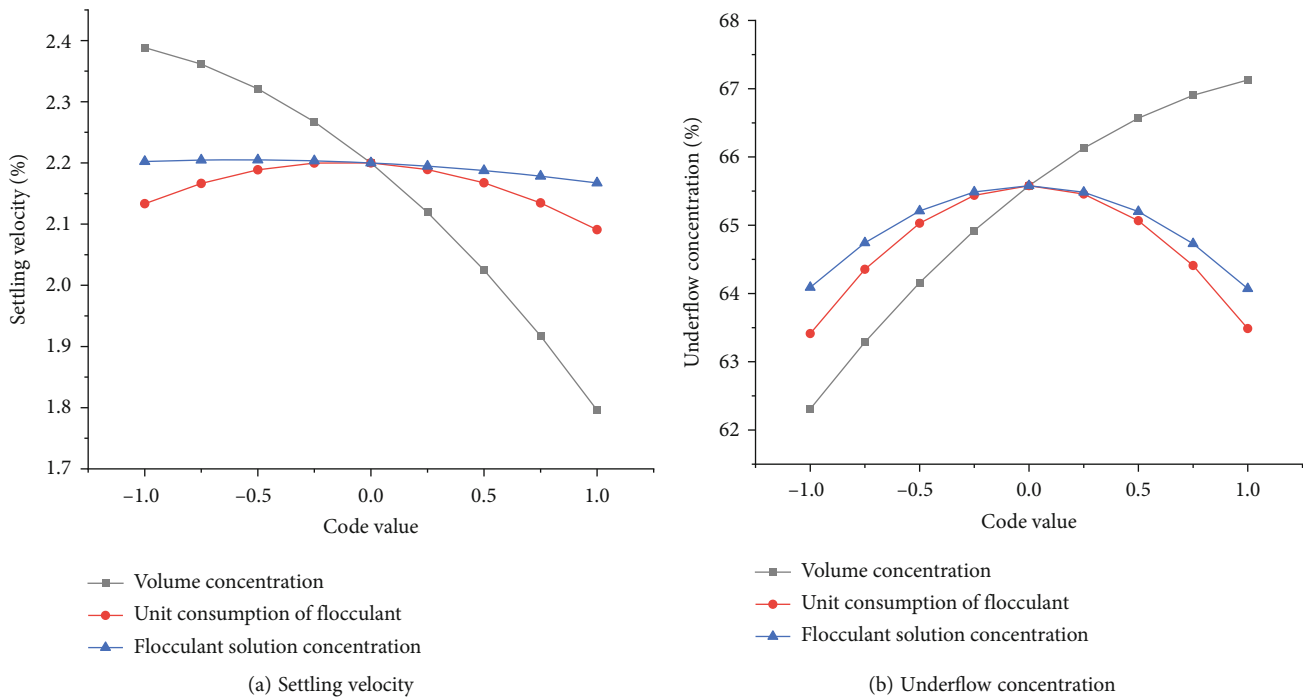
(1) Keeping the unit consumption of flocculant and flocculant concentration unchanged, with the increase of volume concentration, the sedimentation rate gradually decreases and the impact is more intense. The underflow concentration first gradually increases and then tends to be flat, which indicates that the impact of the continuous increase of the initial feed volume concentration on the underflow concentration is decreasing

(2) Keep the volume concentration and flocculant concentration unchanged. With the increase of

(a) Settling velocity

(b) Underflow concentration

FIGURE 3: Comparison between experimental value and predicted value.

(a) Settling velocity


(b) Underflow concentration

FIGURE 4: Single-factor analysis of response surface.

flocculant unit consumption, the sedimentation velocity and underflow concentration increase first and then decrease and reach the maximum in the range of 37-41 g/T. This shows that if the unit consumption of flocculant exceeds the optimal action range, the sedimentation effect will become worse. This is because the fine tailings adsorb a large number of flocculating molecules to produce too much floc water, which will worsen the driving effect of coarse particles on fine particles. The steric effect of a large number of polymer adsorption membranes makes the tailing particles

repel each other; the siltation layer occupying the bottom space hinders the downward sedimentation of particles and worsens the compaction and dehydration process in the later stage, and too much flocculation structure reduces the underflow concentration

(3) Keep the volume concentration and unit consumption of flocculant unchanged. With the increase of flocculant concentration, the sedimentation velocity changes little, and the underflow concentration increases first and then decreases, reaching the maximum at about 0.2%.

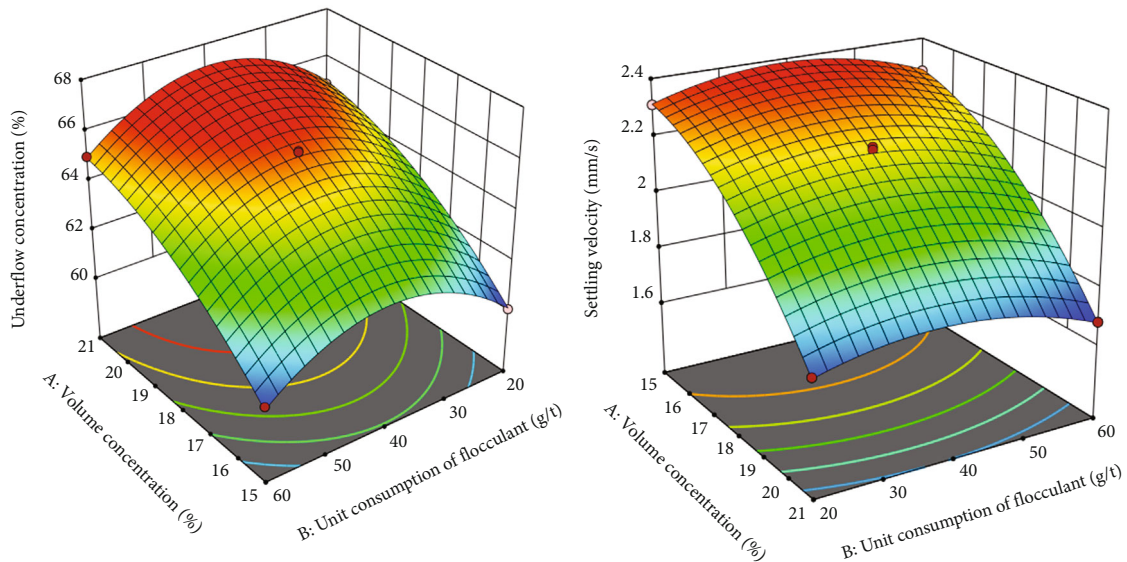

FIGURE 5: Interaction analysis of response surface factors.

5.2. Effect of Interaction of Response Surface Parameters on Flocculation and Sedimentation of Mixed Tailings. From the variance analysis of sedimentation rate and underflow concentration (as shown in Tables 5 and 6), it can be seen that the *F* value of volume concentration and flocculant unit consumption AB is the largest, which means that the interaction between them has the most significant impact on the flocculation and sedimentation of mixed tailings. Keep the flocculant concentration unchanged at 0.2%. Analyze the impact of volume concentration and flocculant unit consumption on sedimentation rate and underflow concentration, as shown in Figure 5. It can be seen from the figure that the sedimentation rate and underflow concentration are affected by the unit consumption of flocculant, and both increase first and then decrease. The best unit consumption of flocculant is in the range of 37-41 g/T. The increase of volume concentration makes the sedimentation velocity gradually smaller. The volume concentration increases from 15% to 18%, the velocity decrease range is about 7.9%, the volume concentration increases from 18% to 21%, and the velocity decrease range is about 18.36%, which indicates that the influence on the sedimentation velocity becomes more and more intense with the continuous increase of volume concentration. The underflow concentration increases with the increase of volume concentration, the volume concentration increases from 15% to 18%, the increase range of underflow concentration is about 5.2%, while the volume concentration increases from 18% to 21%, and the increase range of underflow concentration is about 1.8%, which indicates that the influence on underflow concentration decreases with the increase of volume concentration. With the increase of volume concentration, the influence of unit consumption of flocculant on sedimentation velocity and underflow concentration is decreasing, which proves that the influence of volume concentration on sedimentation effect is greater than that of unit consumption of flocculant.

5.3. Parameter Optimization. The Design-Expert software is used to optimize the results of flocculation sedimentation test. The underflow concentration and sedimentation velocity are the largest. The best parameters calculated by the model are feed volume concentration 17.66%, flocculant unit consumption 39.589 g/t, and flocculant concentration 0.195%. The sedimentation velocity is 2.231 mm/s, and underflow concentration is 65.289%. Taking the volume concentration of 17.7%, the unit consumption of flocculant 39 g/T, and the flocculant concentration of 0.2% as the actual test parameters, a flocculation and sedimentation test was designed.

The settling velocity is 2.247 mm/s, and the underflow concentration is 65.77%, which is basically consistent with the optimization results. The test results prove the correctness of the optimization model.

6. Conclusion

In this paper, the slurry flocculation sedimentation tests under different slurry volume concentration, flocculant unit consumption, and flocculant solution concentration are designed, and the test results are analyzed and studied by response surface method. The following conclusions are drawn:

(1) The effect of flocculation and sedimentation is not only affected by single factors, but also by the interaction between factors, especially the interaction of volume concentration and unit consumption of flocculant

(2) Based on the research results of response surface method, the optimal mixing parameters of mixed ore tail mortar with sulfur oxygen ratio of 5 : 5 are predicted. The volume concentration is 17.66%, the unit consumption of flocculant is 39.589 g/t, the flocculant concentration is 0.195%, the settlement velocity is 2.231 mm/s, and the underflow concentration is 65.289%

With the continuous development of society and the continuous development of technology, people's living standards have gradually improved, and the development of new things has gradually entered a new agenda. Alcoholism has gradually taken over most people's lives. Excessive drinking can lead to excessive alcohol content in the body, which is harmful to the liver. The stomach and other organs are affected, and the formation of high blood pressure is directly related to excessive drinking. And hypertensive patients are prone to have some adverse reactions and cause other more serious diseases. Hypertensive ocular fundus disease is one of its complications. Hypertensive ophthalmopathy is caused by abnormal changes in the retina, which can be very harmful. Patients with low rates and blindness can cause vision loss. Such diseases must be treated in time to allow patients to get rid of the troubles of the disease as soon as possible and restore their quality of life. In the treatment of hypertensive fundus disease, low-intensity laser radiation combined with nanomicelle ocular drug delivery carrier treatment has achieved a relatively ideal treatment effect. This article adopts the comparative treatment method and selects 120 patients with hypertensive ocular fundus disease admitted to X Hospital from 2018 to 2020 and evenly distributes them into the experimental group and the control group for comparative treatment experiments. Conclusions are obtained based on the analysis of treatment data. Related factors analyzed include age, gender, whether retinal laser photocoagulation has been performed before, and whether anti-VEGF treatment has been performed before surgery. The experimental results proved that there was no difference in the overall quality of life between the two groups before the treatment and at the end of the first course of treatment ($P > 0.05$), and the overall quality of life of the experimental group was higher than that of the control group until the end of the second course of treatment ($P < 0.05$). Hypertensive fundus disease is very harmful. If it is not treated in time, it will cause blindness in patients. In the treatment of hypertensive fundus disease, the use of low-intensity laser irradiation combined with MPEG-PCL nanomicelle therapy is beneficial to the recovery of vision and blood flow. The change index can guarantee the safety of treatment at the same time, which is worthy of clinical promotion.

1. Introduction

Ophthalmic diseases have more complex causes, more different diseases, and more variable conditions and belong to clinical ophthalmic diseases. It will seriously affect the vision of the patient and may even cause blindness. Therefore, in order to effectively improve the vision of patients, the above-mentioned various consequences must be effectively prevented. Effective treatment of patients with bottom disease is very important. The traditional method of administration can make the drug concentration in the retina reach a higher level, but the half-life of the drug in the vitreous is shorter. Therefore, chronic uveitis requires repeated injections and patient compliance is poor. In order to solve the above problems, nanomaterials have emerged as different carriers for drugs. Compared with traditional drug delivery methods, the use of nanomaterials to distribute drugs to treat eye diseases has great advantages. Drug nanoformulations can target drug delivery, extend the time of drug action, improve drug bioavailability, and reduce drug dosage and side effects.

Researchers at home and abroad have conducted a lot of research on the problem of blood vessel retrieval in retinal images, and new methods are constantly emerging. Foreign scholars are interested in classifier methods [1, 2]. The classifier method is mainly applied in two stages. First, perform spatial connection region segmentation through a basic algorithm, and then use peripheral features to divide the selected region into blood vessels and nonvessels. The classifier design only uses the gray matter information of blood vessels, and the influence of external conditions on the segmentation results cannot be excluded. The proportion information of the segmented object can only be obtained after the segmentation is completed, and must be used in combination with other methods, and cannot be directly used in the application field of the basic segmentation algorithm. Fengping and Weixing cited the filter operator used in air road detection and designed a classifier for blood vessel segmentation [3]. GeethaRamani and Balasubramanian use teaching samples to perform machine learning to segment samples and unknown objects [4]. Rodrigues and Marengoni divided 12 groups by calculating the average value and change of the gray pixel value under the line segment with an interval of $\pi/12$ and divided into the final blood vessel segmentation method by the support vector machine method [5].

With the rapid development of the Internet of Things technology in China, various hospitals have also accelerated the construction of medical intelligence and built a hospital information system under the new situation to realize the sharing of medical information and resources, and at the same time carry out the reasonable allocation of medical resources in hospitals and communities [6–9]. The image of the retinal fundus is often affected by external conditions, resulting in problems such as uneven light, uneven contrast, and weak contrast between blood vessels and the collected image, making it difficult to remove retinal blood vessels. Haythornthwaite combines the connectivity of the blood vessel network to monitor the top line of the blood vessel to execute the structure of the blood vessel network [10],

Zhang et al. proposed a segmentation threshold exploration method based on local and global features, which combines window matching and dynamics Monitoring technology is used to extract blood vessels, and iterative rules are designed, and the adaptive threshold method is further used to segment the blood vessel region. This method has achieved a good export effect [11]. Takahashi et al. monitor blood vessels by detecting the connection points and connection points of blood vessels, so as to realize network extraction [12].

The existing extraction methods are mainly aimed at normal retinal images, which are not universal. Under ideal conditions, such as uniform light distribution, less noise interference, and no disease, they can basically extract the structure of blood vessel contours correctly when diseases appear in the image, especially in large damaged areas and vascular area. This article focuses on the method of extracting blood vessels from retinal images. The purpose is to eliminate noise interference and diseases and to obtain a complete retinal blood vessel network structure. This article deeply studies the retinal blood vessels under the disease. A new technique for suppressing lesions based on a filtering method is proposed, combined with the technique of restoring the binary image of the vascular network structure, to complete the segmentation of the retinal vessel structure, thereby extracting the structure of the vessel.

2. Application of Nanomaterial Drug Delivery System in the Treatment of Hypertensive Fundus Disease

2.1. Research Content and Methods. This article first uses the literature survey method to query a large amount of data, gives a brief introduction to the preparation and characterization of nanomicelles, explains and elaborates the application of nanomaterials in medicine, and analyzes the nanomaterial drug delivery vehicle in ophthalmology treatment, the application of nanomaterials in the treatment of glaucoma, and the application of nanomaterials loaded with drugs in uveitis. After that, the method of comparative treatment was adopted, and the experimental group and the control group were compared with two different treatment methods. Here, we use the method of limiting single-factor analysis and regression analysis to analyze the influence of each factor on this experiment. Finally, based on the regression results, the construction of MPEG-PCL nanomicelle ocular drug delivery vector and its application in the treatment of hypertensive fundus disease is put forward corresponding suggestions. The article structure is shown in Figure 1.

2.2. Nanomaterials

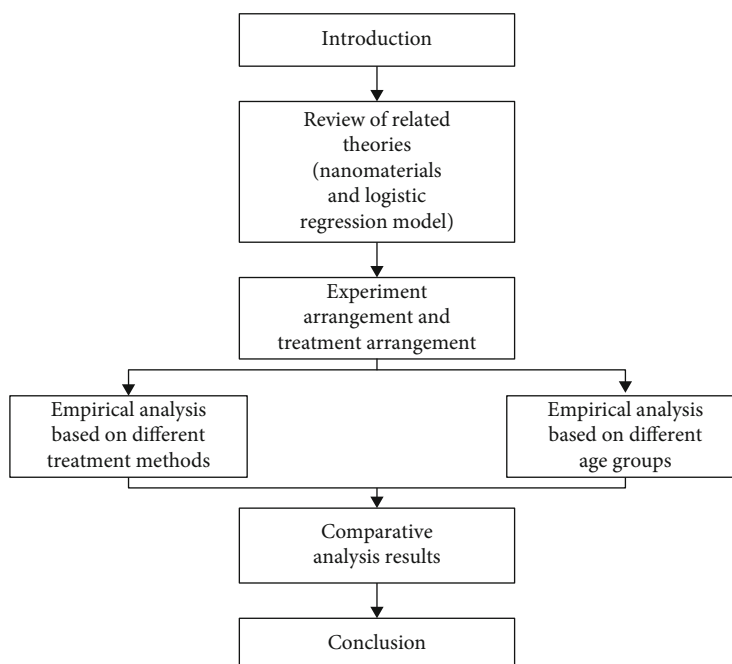
2.2.1. Characteristics of Nanomaterials. Nanomaterials are generally very small in size, large in specific surface area, and high in surface energy. The number of surface atoms accounts for a high proportion of the total number of atoms. When the particle size is less than 10 nm, the percentage of surface atoms increases sharply, and these surface atoms


FIGURE 1: Research flow chart.

are in a very empty state. They have extremely high activity and are very unstable [13, 14]. Once you encounter other atoms and combine them to stabilize themselves, this effect is called surface effect.

In nanomaterials, when the particle size reaches a certain physical characteristic size, the energy levels of electrons adjacent to the metal Fermi plane change from an almost continuous state to a discrete state, while the nanoparticles have discontinuous, higher-occupancy molecules. The orbital and lower molecular orbital are asymmetry, and the energy gap is the quantum size phenomenon of nanomaterials [15].

The ability of tiny particles to pass through the dam is called the tunnel effect. When a dielectric layer with a small dielectric constant is modified on the surface of a nanomaterial, it is related to the rest of the medium surrounding the unmodified nanomaterial [16, 17]. Compared with bare nanomaterials, this will cause greater changes in its optical properties. This phenomenon is called the dielectric confinement phenomenon.

(1) Application of Nanomaterials. Throughout the scientific frontier literature and books on nanoelectrocatalysts, the most mentioned word is energy. Energy is no longer a problem of a certain country but has become a problem of global concern. When a crisis occurs, there is no one. The country can take care of itself. The vast number of scientific researchers is working against clean energy. Nanoelectrocatalysts, as a very important role in clean energy, are attracting widespread attention. Regardless of whether the heat increases or decreases, nanoelectrocatalysts will become a solution. The key to the energy problem, nanomaterials have attracted great attention since their birth [18, 19]. With the continuous advancement of science and technology, the research on nanoelectrocatalysis by scientific researchers has become more

and more in-depth, and it has played its own application value in many aspects, such as hydrogen and oxygen evolution electrocatalyst, electrocatalytic carbon dioxide reduction catalyst, and microbial fuel cell electrocatalyst.

2.3. Logistic Regression Model. Regression accounting model is a two-type model, as long as the vector $x = (x_1, x_2 \cdots x_n)$ has n independent variables and the ratio coefficient is p $(y = 1|x) = p$, it can be represented by the conditional probability distribution $p(y = 1|x) = p$ of partial logistic distribution [14]. Show the observed value of $p(y = 1|x) = p$ probability. Therefore, the logistic regression model can be expressed as

$$p(y = 1 \mid x) = \pi(x) = \frac{1}{1 + e^{-g(x)}}. \tag{1}$$

Usually $f(x) = 1/1 + e^{-g(x)}$ is called the logistic function and

$$g(x) = w_0 + w_1 x_1 + \cdots + w_n x_n. \tag{2}$$

The probability that y; does not occur under the condition of x is

$$p(y = 0 \mid x) = 1 - p(y = 1 \mid x) = 1 - \frac{1}{1 + e^{-g(x)}} = \frac{1}{1 + e^{g(x)}}. \tag{3}$$

Therefore, the ratio of the probability of y occurring to not occurring is

$$\frac{p(y=1 \mid x)}{p(y=0 \mid x)} = \frac{p}{1-p} = e^{g(x)}. \quad (4)$$

This ratio is called the occurrence ratio of the event and is recorded as odds. Take the logarithm of odds to get

$$\ln\left(\frac{p}{1-p}\right) = g(x) = w_0 + w_1 x_1 + \cdots + w_n x_n. \quad (5)$$

Usually use maximum likelihood estimation to find the parameters of the classification model:

$$L(w) = \prod_1^n (\pi(x_i))^{y_i} (1 - \pi(x_i))^{1-y_i}. \quad (6)$$

The maximum likelihood estimation is to find the parameter $w_0, w_1, \cdots, w_n$ so that $L(w)$ takes the maximum value [20].

In the same way, the basic idea of the logistic regression model is applied to personal credit risk assessment: Given the sample data $(X_{i1}, X_{i2}, \cdots, X_{in} : Y_i)(i = 1, 2, \cdots, k), X_i \in R^p$ of n groups of loan application customers is an indicator variable, $y_i \in [0, 1]$ is a 0-1 variable, where $y_i = 0$ indicates that the credit category of the i customer is a bad customer, $y_i = 1$ indicates that the credit category of the i customer is a good customer [21]. The relationship between Y_i and X_{i1}, $X_{i2} \cdots X_{in}$ is as follows:

$$E(Y_i) = P_i = f(\beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \cdots + \beta_n X_{in}). \quad (7)$$

Among them, $f(X)$ is a monotonically increasing function in [0,1].

$$P_i = f(X) = \frac{e^x}{1 + e^x}. \quad (8)$$

Y_i is the 0-1 distribution of the mean $P_i = f(\beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \cdots + \beta_n X_{in})$, the probability function:

$$\begin{aligned} P(Y_i = 1) &= P_i \\ P(Y_i = 0) &= 1 - P_i \end{aligned} \quad (9)$$

Then, the logistic regression equation is

$$P_i = \frac{\exp(\beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \cdots + \beta_n X_{in})}{1 - \exp(\beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \cdots + \beta_n X_{in})}. \quad (10)$$

The above equation can be linearly transformed, so

$$\ln\left(\frac{P_i}{1-P_i}\right) = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \cdots + \beta_n X_{in}, i = 1, 2, \cdots, n. \quad (11)$$

$Y_1, Y_2, \cdots, Y_n$ is an independent binary variable, $f_i(Y_i)$ represents the probability of Yi = 1 or 0. And the likelihood function is

$$L(\beta) = f(Y_1, Y_2, \cdots, Y_n) = \prod_1^n f_i(Y_i) = \prod_1^n P_i^{Y_i} (1 - P_i)^{1-Y_i}. \quad (12)$$

Both sides of Formula (12) take the natural logarithm and the log-likelihood function:

$$\ln f(Y_1, Y_2, \cdots, Y_n) = \sum_1^n \left[Y_i \ln\left(\frac{P_i}{1-P_i}\right) \right] + \sum_1^n [\ln(1 - P_i)]. \quad (13)$$

Bringing Formula (10) into Formula (13) is

$$\begin{aligned} \ln f(Y_1, Y_2, \cdots, Y_n) &= \sum_1^n Y_i(\beta_0 + \beta_1 X_{i1} + \cdots + \beta_n X_{in}) \\ &- \sum_1^n \ln\left[1 + e^{(\beta_0 + \beta_1 X_{i1} + \cdots + \beta_n X_{in})}\right], i = 1, 2, \cdots, n. \end{aligned} \quad (14)$$

2.4. Application of Nanomaterial Drug Delivery Carrier in the Treatment of Ophthalmopathy

2.4.1. Application of Nanomaterial Drug Delivery Carrier in the Treatment of Glaucoma. Surgical filtration is a common method of clinical treatment. The main reason is the increase in intraocular pressure caused by conjunctival fibrosis and drainage tract contraction [22, 23]. The advantages are high drug loading and good biocompatibility. Targeted liposome-polypeptide-siRNA nanoparticles as an effective and safe nonviral gene delivery system can be used to prevent conjunctival fibrosis after glaucoma infiltration surgery and other fibroblast-induced ophthalmology.

2.4.2. Application of Drug-Loaded Nanomaterials in Uveitis. Uveitis is a general term for inflammation of the iris, ciliary body, and choroid tissue and is also a chronic inflammation. At present, glucocorticoids, nonsteroidal, anti-inflammatory drugs and immunosuppressive agents can effectively treat uveitis, but these drugs have difficulty reaching the retina to achieve a complete therapeutic effect [24, 25]. Therefore, treating uveitis remains a challenge. Recent studies have shown that nanocells can improve the solubility of drugs and increase the permeability of conjunctival epithelial cells through good hydrophilicity and high drug encapsulation potential.

(1) Application of Drug-Loaded Nanomaterials in Retinal Diseases. By activating specific promoters to reduce the loss of photoreceptor cells, reduce the cavity between the plexus layer and bipolar cells, increase the thickness of the outer nuclear layer of the retina [26, 27], and promote the growth of the retina. And improve the structure of the retina. Therefore, solid lipid nanoparticles gene replacement therapy can restore the retinal structure of mice with retinal protein deficiency.

(2) Application of Nanomaterial Drug Delivery Carrier in the Treatment of Hypertensive Fundus Disease. Through the mutual transformation of the primary and secondary structure of the polypeptide and the self-assembly behavior, among them, polypeptide hydrogel is a self-assembled nanomaterial with nanofiber structure. The hydrogel polypeptide has good biocompatibility and controlled degradation. As a controlled drug delivery system, it has the advantages of high drug loading and smart drug release [28, 29]. Therefore, the gel based on nanofiber polypeptide can prevent the occurrence of hypertensive bottom disease by affecting the proliferation and differentiation of LEC, so as to achieve a better therapeutic effect.

2.5. Drug Delivery Vehicle

2.5.1. Drug Delivery Nanocarrier. With the development of new drug delivery systems, it has become a research hotspot to keep the therapeutic activity of drugs to the maximum while reducing the side effects of drugs. In recent decades, amphiphilic block copolymer drug carriers that can form nanomicelle structures through self-assembly in the water phase have received extensive attention. The amphiphilic block polymer as a drug carrier can physically encapsulate hydrophobic drugs in the core of the micelle, increasing the water solubility of poorly soluble drugs, and the hydrophilic layer formed by the hydrophilic segment of the amphiphilic polymer material can protect the drug carrier from passing through. Pass the biological barrier to enter the diseased site and achieve drug delivery [30, 31]. The chemical composition, molecular weight, and hydrophilic-hydrophobic block ratio of the amphiphilic polymer can be flexibly changed according to the required micelle particle size and morphology. As a drug carrier, nanomicelles can not only extend the time of drug circulation in the body and improve the shortcomings of poor solubility and low stability of the drug but also enrich the drug in the diseased site through the EPR effect and increase the uptake of the drug by cells and tissues.

2.5.2. Characterization of Polymer Materials

(1) NMR Ammonia Spectroscopy. The polymer material was vacuum dried in advance and then analyzed by H-NMR. Weigh 5-10 mg of the sample to be tested and transfer it to a clean NMR tube, add $500\,\mu\mathrm{L}$ of deuterated chloroform or deuterated DMSO to fully dissolve it, use tetramethylsilane as the internal standard, and detect the displacement of ammonia protons in each sample by a nuclear magnetic resonance spectrometer. Analyze the chemical structure of the sample to be tested [32].

(1) Fourier transform infrared spectroscopy

The polymer material is vacuum dried in advance. Take about 200 mg of potassium bromide (KBr) and use a grinding rod to fully grind into ultrafine powder, weigh 2 mg of the sample to be tested and potassium bromide to fully grind

and mix, and then make it into potassium bromide tablets for detection by infrared spectroscopy [33–36].

2.5.3. Preparation and Characterization of Micelles

(1) Preparation of Polymer Micelles. The polymer material is prepared by solvent evaporation method to make micelles. The method is briefly described as follows: weigh 10 mg polymer powder and dissolve it in 5 ml tetrahydrofuran, ultrasonically make it fully dissolved, and then add the solution dropwise to 10 ml deionized water at a rate of 1 second/drop through the 21-gauge needle of a glass syringe. During the process, keep the stirring speed at 500 r/min. After the addition is completed, continue to stir until the tetrahydrofuran is fully volatilized to obtain the polymer micelle solution. Before the particle size and morphology of the micelle solution are tested, use a 450 micron filter to filter out impurities and collect it in a container store in a refrigerator at 4°C.

2.5.4. Characterization of the Particle Size and Morphology of Micelles. The dynamic light scattering method is used to detect the average particle size and polydispersity index of the prepared nanomicelles. The abovementioned micelle preparation method is used to prepare a polymer micelle solution with a concentration of 1 mg/ml, and it is detected by a dynamic laser scattering nanoparticle sizer. The test temperature is 25°C. A transmission electron microscope was used to observe the morphology of the prepared nanomicelles. Use the abovementioned micelle preparation method to prepare a nanomicelle solution with a concentration of 1 mg/ml, drop a drop of the micelle solution to be tested on the surface of the carbon film copper mesh, keep it for 90s, absorb the remaining liquid with filter paper, and add a drop of phosphonic acid. (2.5 wt%) aqueous solution for negative dyeing. After dyeing for 60 seconds, the residual dye is absorbed and the surface of the copper mesh is fully evaporated before observation by transmission electron microscope.

3. Experimental Study on the Application of Nanomaterial Drug Delivery System in the Treatment of Hypertensive Fundus Disease

3.1. Test Subject. The main data source of this study is the 120 patients with hypertensive fundus disease who visited the hospital from 2018 to 2020 in X Hospital. These 120 patients with hypertensive fundus disease are the subjects of our study. We obtained the patient's willingness to participate in this study anonymously. The 120 volunteers were divided into groups by random grouping, 60 people in each group. In the experimental group, there were 35 males and 25 females, aged between 37 and 65, with an average age of 44.5 years and a course of 1 year to 3.5 years, with an average of 2.2 years; the control group, 37 males and 23 females, were between 38 and 62 years old, with an average age of about 45.2 years, and the course of disease was 1 to 3 years, with an average of 2 years. The 120 volunteers suffered from hypertensive ocular fundus disease after examination, and

there was no interference from other diseases, and there were no symptoms of drug allergy, and the kidneys and other organs were functioning normally. The three doctors with rich work experience in this hospital are comprehensively judged for judging the degree of treatment. If there is a dispute, the result can be selected through discussion.

3.2. Efficacy Judgment and Index Observation Analysis. The BCVA levels of the patients before treatment, 1 month after treatment, 2 months after treatment, and 3 months after treatment were detected by the eye chart. The BCVA levels of the two groups of patients were compared and statistically recorded. Comparison of the clinical treatment effects of the two groups of patients. According to the degree of recovery of clinical symptoms such as eye pain, swelling, congestion, and the degree of improvement in vision, the level of treatment effect is judged.

3.3. Experimental Method

3.3.1. Preparation Before Treatment. Before treatment, the two groups of patients were tested for vision, and the blood pressure and hemorheology indexes of the two groups of patients were measured at the same time. Provide psychological care to patients, mediate their psychological pressure, and reduce their psychological burden. Try to meet the needs of patients, avoid patients from being left out, and keep patients warm. Introduce the possible reactions of such symptoms to the patient and the cases that have been successfully treated, improve the patient's self-confidence, and help improve the treatment effect.

3.3.2. Treatment. The control group was given low-intensity laser irradiation treatment, using a low-intensity laser with a power of 300 mW to irradiate the eyes of the patient, 2 times/d, 30 min/time, a week as a course of treatment, lasting for two courses; after each irradiation, the patient's eyes were protected by dripping levofloxacin hydrochloride gel. The experimental group was combined with nanotherapy on the basis of the control group. One week was a course of treatment and lasted for two courses. After treatment, the patient's vision, blood pressure, and blood rheology were tested again.

3.4. Gather Data. In order to obtain accurate data to compare and analyze the feasibility and effectiveness of this experiment, this paper uses the Cora dataset and the IMB dataset. The statistical data used in this article has a different unit dimension for each index data. After calculating the data in the previous steps, we can get the similarity between users and select several users closest to the interests and preferences of user u_a to form set N_a. Then, calculate the score of user u_a on j according to the score of the user in the set N_a on the unrated item j, the prediction formula is shown in Formula (15):

$$p_{a,i} = \frac{\sum_{b \in N_a} sim_{u_a,u_b} r_{b,i}}{\sum_{b \in Na} | sim_{u_a,u_b} |}, \tag{15}$$

where $p_{a,i}$ is the predicted score of user a on the unrated item i. In the recommendation system, user scoring preferences are

sometimes different. For example, some users are accustomed to giving higher ratings to items, while some are accustomed to giving lower ratings. In order to reduce the difference between users scoring preferences and improve the accuracy of rating prediction, the method of Formula (16) introduces the users average rating $\bar{r}$, and the specific form is shown in Formula (16):

$$p_{a,i} = \overline{r_a} + \frac{\sum_{b \in N_a} sim_{u_a,u_b} (r_{b,i} - \overline{r_b})}{\sum_{b \in N_a} | sim_{u_a,u_b} |}. \tag{16}$$

There are many data standard processing methods, but different data standardization methods will have a certain impact on the evaluation results of the system. For the positive indicator standardization method:

$$y_{ij} = \frac{x_{ij} - \min \{x_{ij}\}}{\max \{x_{ij}\} - \min \{x_{ij}\}}. \tag{17}$$

For negative index standardization methods:

$$y_{ij} = \frac{\max \{x_{ij}\} - x_{ij}}{\max \{x_{ij}\} - \min \{x_{ij}\}}. \tag{18}$$

After standardizing the data, using the principal component analysis of nonlinear logarithmic centering, the processing steps of logarithmic transformation and row vector centering are

$$z_{ij} = \ln y_{ij} - \sum_{i=1}^{m} \ln y_{ij}/m. \tag{19}$$

3.5. Statistical Methods. SPSS23.0 software was used for data processing, and the count data was expressed as a percentage (%), k is the number of data in this experiment, σ^2 is the variance of all survey results, and $P < 0.05$ indicates that the difference is statistically significant. The formula for calculating reliability is shown in equation (20).

$$a = \frac{k}{k-1} \left(1 - \frac{\sum \sigma_i^2}{\sigma^2}\right). \tag{20}$$

4. Experimental Analysis of the Application of Nanomaterial Drug Delivery System in the Treatment of Hypertensive Fundus Disease

4.1. Evaluation Index System Based on Index Reliability Testing. Reliability refers to the stability and reliability of the questionnaire. This article adopts the α coefficient method created by L.J. Cronbach. The α coefficient can be obtained by Reliability Analysis in SPSS software. It is generally believed that the α coefficient above 0.8 indicates that the effect of the index setting is very good, and above 0.7 is also acceptable. Here, we analyze the reliability of each type of object, and the reliability index we choose for each type of object is slightly different. The results are shown in Table 1.

TABLE 1: Summary Table of Reliability Test Results.

Group	Index combination	Alpha coefficient (α)
Control group	The effect is obvious Partial relief Stable Invalid Deterioration	0.7932
Experimental group	The effect is obvious Partial relief Stable Invalid Deterioration	0.8226

TABLE 2: Quality of life data analysis table.

	Control group	Test group	Time (t)	Significant difference (P)
0 day	7.832	7.742	0	1
1-2 days	7.952	7.952	0.85	1.202
3-4 days	8.189	8.256	2.132	1.503
5-6 days	8.426	8.628	5.292	2.232
7-8 days	8.827	9.125	8.513	3.273
9-10 days	8.869	9.256	9.952	1.469
11-12 days	8.912	9.389	11.692	0.662
13-14 days	8.982	9.537	13.5	0.001
FIGURE 2: Comparison of the overall quality of life between the two groups of patients before and after intervention.

It can be seen from Table 1 that the influence of the data obtained by the control group and the study group on this experiment is acceptable ($\alpha > 0.7$), and the influence caused by the environment and living habits is within the acceptable range, satisfying the experiment prerequisites to start.

4.2. Based on the Quality of Life and Complications of the Two Groups of Patients during Treatment

4.2.1. Comparative Analysis of the Quality of Life of the Two Groups of Patients. We first compare and analyze the quality of life of the two groups of patients. We choose to conduct surveys and process data for analysis every two days before

TABLE 3: Anxiety data analysis table.

	Control group	Test group	Time (t)	Significant difference (P)
0 day	17.000	17.000	0.074	0.984
1-2 days	15.521	15.387	0.241	0.821
3-4 days	14.127	13.124	1.121	0.234
5-6 days	12.682	11.486	2.012	0.112
7-8 days	11.020	9.264	2.982	0.004
9-10 days	8.869	7.132	3.125	0.003
11-12 days	6.852	4.162	3.632	0.002
13-14 days	3.326	1.521	4.437	0.001

treatment. When we conduct data collection and analysis, we ask three doctors with extensive work experience to participate in this experiment, the overall quality of life of the patients was comprehensively scored to calculate the significant difference, and the results are shown in Table 2. We make a scatter plot based on this result, as shown in Figure 2.

It can be seen from Figure 2 that there was no difference in the overall quality of life of the two groups before the treatment and at the end of the first course of treatment ($P > 0.05$), until the end of the second course of treatment, the overall quality of life of the experimental group was higher than that of the control group ($P < 0.05$). That is to say, when the treatment is completed, the overall life treatment of the experimental group is higher than that of the control group. This conclusion is reliable and there is no significant difference.

4.2.2. Comparative Analysis of Anxiety Degree between Two Groups. We compare and analyze the anxiety of the two groups of patients. We choose to conduct surveys and process data for analysis every two days before treatment. When we conduct data collection and analysis, we asked three doctors with extensive work experience participating in this experiment, the patients' anxiety level was comprehensively scored to calculate the significant difference, and the results are shown in Table 3. We make a bar graph based on this result, as shown in Figure 3.

It can be seen from Figure 3 that there was no difference in anxiety between the two groups of patients before the first use of targeted drugs ($P > 0.05$). The two groups of patients were compared at the end of the first course of treatment and at the end of the second course of treatment. The score of the experimental group was low. Compared with the control group ($P < 0.05$), that is to say, the anxiety level of the experimental group is lower than that of the control group during half of the treatment. This conclusion is reliable and there is no significant difference.

4.2.3. Comparative Analysis of Depression Degree of Two Groups of Patients. We made a comparative analysis of the depression levels of the two groups of patients. We chose to conduct surveys and process data for analysis every two days before treatment. When we collected and analyzed data, we asked the three doctors who participated in this experiment with extensive work experience, the degree of

depression of the patients was comprehensively scored to calculate the significant difference, and the results are shown in Table 4. We make a line chart based on this result, as shown in Figure 4.

It can be seen from Table 4 that there was no difference in the degree of depression between the two groups of patients before the first use of targeted drugs and at the end of the first course of treatment ($P > 0.05$), and until the end of the second course of treatment, the degree of depression in the experimental group was higher than that in the control group ($P < 0.05$). That is to say, the degree of depression in the experimental group is higher than that in the control group when the treatment is completed. This conclusion is reliable and there is no significant difference.

4.3. Based on Single-Factor Comparison. First, through univariate analysis, all the above possible factors are studied to initially screen out the relevant factors. Among them, the chi-square test is used for categorical factors, and the independent sample T test is used for data factors. The results are shown in Table 5.

(1) Analyze the treatment effects of different genders

We analyzed the treatment effect of patients according to different gender groups at the same time and judged the treatment effect level according to the degree of recovery of clinical symptoms such as eye pain, swelling, congestion, and the degree of improvement in vision. Let the three doctors with extensive work experience participating in this experiment calculate the significant difference by comprehensively scoring the patient's overall quality of life, as shown in Figure 5.

It can be seen from Figure 5 that the cure rate for men is 93.05%, and the cure rate for women is 89.58%. At the same time, whether it is completely cured or completely ineffective, there is no correlation between gender and ERD ($P > 0.05$). That is to say, the probability of suffering from hypertensive fundus disease is not related to gender. This conclusion is reliable and there is no significant difference.

4.3.1. Analyze According to whether Cataract Surgery Has Been Done. We divided patients into groups according to whether they had undergone cataract surgery and analyzed their treatment effects. We judged the level of treatment effect according to the degree of recovery of clinical symptoms such as eye pain, swelling, and congestion, and the degree of improvement in vision. Let the three doctors with extensive work experience participating in this experiment calculate the significant difference by comprehensively scoring the patient's overall quality of life, as shown in Figure 6.

It can be seen from Figure 6 that the cure rate of patients who have undergone cataract surgery is 83.33%, and the cure rate of patients who have not undergone cataract surgery is 91.22%. At the same time, whether it is completely cured or completely ineffective, gender is related to the occurrence of ERD. Sex ($P < 0.05$). That is to say, the probability of suffering from hypertensive fundus disease is related to whether

FIGURE 3: Comparison of anxiety between the two groups of patients before and after intervention.

TABLE 4: Depression data analysis table.

|	Control group	Test group	Time (t)	Significant difference (P)
0 day	7.00	6.98	0.044	0.984
1-2 days	6.33	6.40	0.489	0.922
3-4 days	5.35	5.12	1.121	0.552
5-6 days	3.98	3.87	1.428	0.213
7-8 days	3.42	2.39	1.818	0.073
9-10 days	2.55	2.10	1.321	0.182
11-12 days	2.09	1.82	0.992	0.289
13-14 days	1.66	1.41	0.776	0.44

FIGURE 4: Comparison of depression between two groups of patients before and after intervention.

or not cataract surgery has been done. This conclusion is reliable and there are significant differences.

4.3.2. Analyze According to whether PRP Surgery Has Been Done. We grouped patients according to whether they had undergone PRP surgery and analyzed their treatment effects at the same time. According to the degree of recovery of clinical symptoms such as eye pain, swelling, congestion, and the degree of improvement in vision, the level of treatment

TABLE 5: Categorical independent variable and dependent variable assignment table.

Assignment variable		Category	Number	Proportion
Dependent variable	Result	ERD	10	8.3%
		NO ERD	110	91.7%
Independent variable	Gender	Male	72	60%
		Female	48	40%
	History of cataract surgery	Yes	6	5%
		No	114	95%
	PRP treatment history	Yes	22	18.3%
		No	98	81.7%
	History of anti-VEGF treatment before surgery	Yes	30	25%
		No	90	75%
FIGURE 5: Analyze the treatment effect of different genders.
FIGURE 6: Analysis diagram of environmental pollution caused by three kinds of cars driving the same distance.

FIGURE 7: Analysis chart according to whether PRP surgery has been done.

FIGURE 8: According to whether there is a history of anti-VEGF treatment before surgery.

effect was evaluated. Let the three doctors with extensive work experience participating in this experiment calculate the significant difference by comprehensively scoring the patient's overall quality of life, as shown in Figure 7.

It can be seen from Figure 7 that the cure rate of patients who have undergone PRP surgery is 86.36%, and the cure rate of patients who have not undergone cataract surgery is 92.85%. At the same time, whether it is completely cured or completely ineffective, there is no correlation between gender and ERD. Sex ($P > 0.05$). That is to say, the probability of suffering from hypertensive fundus disease has noth-

ing to do with whether or not PRP has been performed. This conclusion is reliable and there is no significant difference. Because it is impossible to count the number of treatment points of patients undergoing PRP before surgery in this study, this may have a certain impact on this result.

4.3.3. Analyze According to whether There Is a History of Anti-VEGF Treatment before Surgery. We grouped patients according to whether they had a history of anti-VEGF treatment before surgery and analyzed their treatment effects. We judged the treatment effect according to the degree of recovery of clinical symptoms such as eye pain, swelling, and congestion, and the degree of visual improvement. Let the three doctors with extensive work experience participating in this experiment calculate the significant difference by comprehensively scoring the patient's overall quality of life, as shown in Figure 8.

It can be seen from Figure 8 whether the cure rate of patients with a history of preoperative anti-VEGF therapy is 90%, and the cure rate of patients who have not undergone cataract surgery is 92.22%. At the same time, whether it is completely cured or completely ineffective, it is all gender and ERD. There is a correlation ($P < 0.05$). That is to say, the probability of suffering from hypertensive fundus disease is related to whether there is a history of anti-VEGF treatment before operation. This conclusion is reliable and there are significant differences. In this study, due to the fact that there are many new blood vessels in the fundus of some patients, in order to smooth the operation and achieve better results after the operation and reduce the occurrence of rebleeding, anti-VEGF treatment is used within 3-7 days before the operation, and the drug is selected according to the patient's own wishes. All patients in this group who received anti-VEGF treatment before surgery did not develop ERD.

5. Conclusion

The use of nanocarriers for drug delivery can significantly improve the bioavailability of the drug, reduce the dosage and frequency of administration, increase the residence time of the drug in the local tissue, and reduce the side effects of the drug, overcoming many of its shortcomings. Traditional methods of administration can improve ocular tissue disease. At present, the ophthalmic drug delivery system is still in the process of continuous improvement. Therefore, it is a huge challenge to develop a drug delivery system for the back of the eye that results in a sustained and controlled release, is noninvasive, and can be self-administered by the patient. Advances in nanodrug delivery systems and drug delivery technologies have greatly promoted the development of ophthalmic drug delivery and provided broad prospects for the treatment of ophthalmic diseases. However, there are few reports on the quality control and safety assessment of the drug distribution system, so further research and exploration are needed. It is believed that with the continuous deepening of related research, nanodrug delivery systems will be more used in clinical treatment during the administration of ophthalmic drugs, which will bring good news to patients with ophthalmological diseases.

At present, most retinal blood vessel extraction methods are mainly used for normal retinal images. Therefore, when applied to a large range of lesion images, it is difficult to accurately extract blood vessels due to the interference of lesions and other nonvascular structures, and a large number of nonvascular structures cannot be filtered. In addition, this article focuses on vascular bone extraction and vascular structure segmentation methods suitable for retinal imaging. At the same time, in order to further eliminate the residual nonvascular pixels, a multiple hysteresis threshold method based on dilution of the standard hysteresis threshold is proposed. On this basis, a method suitable for fundus was proposed. The method of extracting the vascular skeleton of the nonvascular structure of the diseased image is suppressed. This method filters the nonvascular structures in the patient image to a large extent and can keep the blood vessel skeleton relatively complete.

This study investigated the effect of the combination of low-intensity laser radiation and traditional Chinese medicine treatment on hematological indicators of patients with hypertension. It can be seen from the results that at different times after treatment, the BCVA of the study group was significantly higher than that of the control group. Recovering vision can obviously help. In the treatment process, the combined treatment of the two methods did not increase the incidence of side effects but reduced the incidence of side effects. At the same time, the results of the two bleeding groups showed that the bleeding index of the study group was better than that of the control group. The treatment effect is ideal. In addition, doctors must continue to strengthen research to provide patients with more effective treatment methods and drugs to accelerate the recovery of vision.

Although the use of MPEG-PCL nanomicelle ocular drug delivery carrier has carried out in-depth research on the treatment of hypertensive fundus diseases, there are still many shortcomings. The depth and breadth of this research are not enough. In the process of this research, the experimental data, the selection and acquisition of the test were carried out under absolutely ideal conditions, and the completeness and effectiveness were not enough. Some interfering factors involved in the experiment were not taken into account, and the patient's condition tracking was also restricted by many factors. The research on the academic level is also limited, and the treatment of hypertensive fundus diseases is still in the preliminary stage. In the future work, appropriate treatment methods and means will be studied from more perspectives based on the existing technology and level, and the quality of medical treatment will be continuously improved.

Retracted: Garment Digital Design Method Oriented to the Production Process of Graphene-Modified Nylon Knitted Fabric

Journal of Nanomaterials

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope

(2) Discrepancies in the description of the research reported

(3) Discrepancies between the availability of data and the research described

(4) Inappropriate citations

(5) Incoherent, meaningless and/or irrelevant content included in the article

(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Graphene is a single-atom-thick layer of carbon atoms, the thinnest material ever discovered. The special single atomic layer structure of graphene makes it have many unique physical and chemical properties, and these excellent properties make graphene have a bright application prospect in the field of composite materials. The use of modern digital production technology to coordinate the management of various production departments of an enterprise can greatly reduce the input of human resources and improve the utilization of materials and equipment resources. In the process of caprolactam monomer polymerization, adding filler is a common method to strengthen and toughen nylon. The main fillers are powder fillers and fibrous materials. In order to make the fillers denatured, the fillers are usually pretreated with a silane coupling agent before modification. This research mainly discusses the digital clothing design method oriented to the production process of graphene-modified nylon knitted fabric. The color of graphene-modified cotton fiber is gray and black. With the increase of graphene content, the color becomes darker. Graphene has become a hotspot in materials science due to its unique two-dimensional crystal structure and excellent mechanical, thermal, and electrical properties. In this paper, the preparation and organic modification of graphene oxide and its application in cast nylon are mainly studied. Therefore, when designing graphene-modified cotton fiber jacquard graphene knitted fabric, the color matching has certain restrictions. The shrinking is to reduce the friction between the fibers through the appropriate concentration of the shrinking agent and improve the stretching and shrinking ability of the wool fiber. The fabric feels plump after shrinking, forming fluff, and improving the warmth retention performance. Due to the different design of the veil material, ground yarn material, and organizational structure of the fabric sample, the basic parameters of the fabric are directly different. Therefore, first perform the width, density, areal density, thickness, and raw material content ratio of the blank sample of the fabric. And wait for testing. In order to realize the digitization of styles, this research has developed a drawing system, which provides a large number of drawing tools to enable designers to draw clothing styles more accurately. The system for digital realization consists of six parts, including desktop environment, drawing tools, linear settings, curve drawing, data storage, and user interface. There are a variety of curves to choose from in computer graphics. The B3 spline curve has become the first choice due to its smoothness, no Runge phenomenon, and few saved data. When the mass fraction of graphene-modified nylon was reduced to 18%, the inhibitory rate of *Staphylococcus aureus* and *Escherichia coli* was still greater than 80%. Nylon/modified graphene oxide nanocomposites with different filler contents were prepared by in situ polymerization with modified graphite oxide as modified filler. The effects of modified graphene oxide on the mechanical properties, wear resistance, and thermal properties of the composites were investigated. This research will promote the development of a customized platform for apparel collaborative management.

1. Introduction

Nylon has the advantages of high strength and good wear resistance and has a wide range of applications in clothing and industrial fields. At present, through the differentiation, higher performance, and multifunctionalization of nylon, it is the trend of nylon development to consolidate and deepen the application of nylon in high-end fields. Graphene is a simple substance formed by the ordered arrangement of carbon on a two-dimensional plane. This unique layered structure

enables graphene to have many excellent properties, enabling graphene to be used in various fields. With the continuous development of thermal clothing, the use of new thermal fiber to improve the thermal performance of clothing has become a main development direction. The new graphene-modified fabric is prepared by mixing the graphene and polymer slices to cut the mother particles and then adding the polymer melt spinning fluid. The thermal function of graphene-modified cotton fiber has become a concern.

As the most common material on earth, carbon material is even more wonderful in itself. It is the fundamental material that constitutes the hardest diamond and the softest graphite. Since the appearance of fullerenes and carbon nanotubes, researchers from all over the world have shown great interest in the study of carbon materials. The electrical properties of graphene-modified cotton fiber can reduce the harm of static electricity of woolen products to the human body, while the antibacterial performance is more healthy and hygienic. Relatively speaking, graphene-modified cotton fiber makes the development of multifunctional light knitting fabric have a new exploration direction. In this study, graphene knitted fabrics are more useful by combining with graphene-modified cotton fibers.

These unique properties of graphene make it have a broad application prospect in the fields of field effect devices, sensors, transparent electrodes, photodetectors, solar cells, energy storage devices, polymer composites, nanocomposites, etc. Graphene has a wide range of uses. Bo reported on the design and implementation of multimode optical fiber sensing technology for displacement sensing. Multimode fiber speckle pattern sensor with different core fiber structure is used for sensing spatial information content. The sensor is highly sensitive to the geometry change of the sensing part by using the inner product of the speckle field of multimode fiber. The sensitivity and dynamic range of displacement sensor of heterocore fiber speckle pattern sensor and straight multimode fiber speckle pattern sensor are studied. It is found that the sensitivity of the FSS is as high as $0.1\,\mu$m, and the dynamic range is about $3\,\mu$m, which is better than the FSS of the straight structure multimode fiber. The dynamic response of noncore FSS displacement was also studied [1]. Liu believes graphene has become a hot topic in the material world. Many applications of graphene have already been produced, including gas sensors, photovoltaics, and field effect transistors. He demonstrated that graphene sheets can be used as an ideal inorganic ingredient to build hybrid polymer hydrogels via supramolecular pathways, which have not yet gained the same popularity as other applications. GO nanosheets were first modified by grafting β-cyclodextrin to chemically transformed graphene (CCG) and then noncovalently functionalized by inclusion complexation of block copolymer Azo-PDMA-B-PNIPam [2]. Modern techniques for using monocrystalline silicon are based on growing high-quality ingots of monocrystalline silicon up to 12 inches in diameter or more. For many applications of graphene, large areas of high-quality (preferably single crystal) materials will be possible. Since it was first grown on copper foil a decade ago, inch-sized single crystal graphene has been achieved. Here, he showed graphene

films grown in 20 minutes (5×50) cm^2 size, with >99% ultrahigh oriented grains. This growth is achieved by synthesizing a single crystal Cu(11 11) foil of the size of a meter as the substrate. Graphene islands were epitaxial grown on Cu(11 11) surface. The graphene islands merge seamlessly into graphene films with high single crystallinity and ultrafast growth of graphene films. These achievements were achieved through temperature gradient-driven annealing techniques for the production of single crystal Cu from industrial polycrystalline copper foils and the wonderful effect of continuous oxygen supply from adjacent oxides [3]. Khan presents a novel method for the formation and deposition of copper nanocube-decorated reduced graphene oxide (RGO-CUNCs) nanosheets on indium tin oxide (ITO) electrodes using a very simple method. Cubic copper nanocrystals have been successfully prepared on RGO by chemical reduction at low temperature. He characterized the morphology of the synthesized materials by UV-vis spectroscopy, scanning electron microscopy (SEM), Fourier transform infrared spectroscopy (FTIR), and atomic force microscopy (AFM). He found that the CuNCs formed were uniformly and evenly decorated on the RGO nanosheets. This novel ITO/RGO-CUNCs represents a promising platform for future device manufacturing and electrocatalytic applications [4]. Cao believes that van der Waals heterostructures are an emerging class of metamaterials, consisting of vertically stacked two-dimensional building blocks, which provide a huge tool set to design their properties on top of the already rich tunability of two-dimensional materials [5]. Chen studied the binary language multiattribute group decision-making problem for evaluating the design effect of clothing and accessories with incomplete weight information and introduced some basic concepts and operation rules of binary language variables. He established a model based on entropy weight method to determine attribute weight. According to the traditional idea of gray relation analysis (GRA), he determines the optimal alternative by calculating the linguistic degree of each alternative and the gray relation between the positive and negative ideal solutions of binary language. Finally, he gives an illustrative example for evaluating the design effect of clothing and accessories to validate the developed method [6]. According to the current market and research status, there are two types of new fiber: active and passive thermal insulation. The passive thermal fibers are mainly hollow thermal fibers. Many research teams load graphene on textiles through dip rolling, coating, UV curing, and other methods to obtain textiles with far-infrared and antistatic properties, but the durability of the textiles prepared is poor. The graphene surface has no functional groups, so it has limited dispersibility in organic solvents, which severely limits the application prospects of graphene in the preparation of functional materials. Graphene oxide has abundant oxygen-containing functional groups and also has the excellent performance characteristics of graphene.

The exfoliation of graphite oxide in the polymer matrix is a prerequisite for the preparation of nanocomposites with well-dispersed graphite oxide fillers. Therefore, exfoliation treatment of graphite oxide is crucial. At present, solvent-based exfoliation and thermal exfoliation have become the

main methods to obtain single-layer graphite oxide. The color of graphene-modified cotton fiber is gray and black. With the increase of graphene content, the color becomes darker. Therefore, when designing graphene-modified cotton fiber jacquard graphene knitted fabric, the color matching has certain restrictions. The shrinking is to reduce the friction between the fibers through the appropriate concentration of the shrinking agent and improve the stretching and shrinking ability of the wool fiber. The fabric feels plump after shrinking, forming fluff, and improving the warmth retention performance. Due to the different design of the veil material, ground yarn material, and organizational structure of the fabric sample, the basic parameters of the fabric are directly different. Therefore, first perform the width, density, areal density, thickness, and raw material content ratio of the blank sample of the fabric. In recent years, seamless knitted fabrics have become the trend of fashion underwear because of their comfort, body sculpting, beauty, fashion, and changing characteristics and are more and more favored by consumers. However, the current seamless knitted fabrics on the market generally use some common materials, and the use of functional fibers is less, so it is difficult to meet people's requirements for healthy and functional clothing fabrics. Graphene composite fiber is a new type of functional fiber, which not only has the conventional characteristics of general fibers but also has far-infrared, antistatic, antiultraviolet, and other properties.

2. Research Methods

2.1. Graphene-Modified Cotton Fiber Jacquard Knitted Fabric Design

2.1.1. Product Weaving Process.
The graphene composite fiber is applied to the field of seamless knitting, and the seamless knitted product obtained can not only reflect its inherent comfort and beauty but also endow it with far-infrared, antistatic, antiultraviolet, and other characteristics. The color of graphene-modified cotton fiber is gray and black. With the increase of graphene content, the color becomes darker. Therefore, when designing graphene-modified cotton fiber jacquard graphene knitted fabric, the color matching has certain restrictions. In addition to the white, gray, and black combination of the above-mentioned plain products, in order to have a certain breakthrough in color, a combination of gray and pink is used, and black tops are used to wrap the pattern. The gray yarn is a graphene-based top, and the pink yarn is a conventional top. The graphene-based top is a graphene-based polyester top, and the conventional top uses a mixed top of 60% wool and 40% acrylic. The jacquard pattern and jacquard machine are shown in Figure 1. The main pattern color of the jacquard knitted fabric is red, the edging is black, and the background is gray. The jacquard pattern is shown in Figure 1(a). As a textile tool, the jacquard machine is an important invention in ancient China. Ordinary looms can only weave plain weave fabrics, and fabrics with complex patterns can only be woven by jacquard looms.

The equipment used is a computer jacquard antiair blower artificial fur machine, as shown in Figure 1(b). This machine is a stepper motor controlled top feeding circular knitting machine. It can be used for jacquard and plain color. The pattern capacity is more than 8 million pixels. When designing jacquard fabrics, it can be used for fixed-point jacquard according to various parts of the human body. The artificial fur machine has 18 routes, the machine number is E6, the needle diameter is 27 inches, the total number of needles is 1184, the rated speed is 35 r/min, and the number of knitting colors is 2-8, which is the top of the machine. The number of carding devices, the large cylinder carding head can card the fiber length range of 38~200 mm, the small cylinder carding head can card the fiber length range of 26~127 mm. The positive blowing device is installed on the sinker triangle seat platform, and its main function is to blow the top fiber straight and smooth through the high-pressure fan to weave a plush fabric. On this basis, an antiblowing device is added, which is installed on the edge of the suction hood, and its main function is to blow the top fiber into the knitting needles and knit to form a flat graphene knitted fabric.

The calculated weights form a set of weighted numbers:

$$\beta = \frac{1}{n-1}\sum_{i=1}^{n}(x - x_1)^2 + \frac{1}{n+1}\sum_{i=1}^{n}(y - y_1)^2, \tag{1}$$

$$\overline{\phi} = \sqrt{\phi}. \tag{2}$$

For numerical attributes, the similarity calculation method is

$$\mathrm{sim}(f_1, f_2) = 1 - \frac{|f_1 - f_2|}{1 + |f_1 - f_2|}. \tag{3}$$

Further give the following similarity calculation formula:

$$\mathrm{sim}(f_1, f_2) = \frac{1}{1 + |f_1 - f_2|}. \tag{4}$$

The similarity is as follows:

$$\mathrm{sim}(X_0, X_1) = \frac{\mathrm{count}(x_0, x_1)}{\mathrm{count}(x_0) + \mathrm{count}(x_1)}. \tag{5}$$
Among them, $\mathrm{count}(x_0)$ is the number of fabric elements [7].

Obtain the preferential membership degree matrix r [8, 9]:

$$r_{i,j} = \frac{(x_{i,j} - x_{\min})}{(x_{i,j} - x_{\max})}. \tag{6}$$

The similarity of fabric nodes can be calculated using the following formula [10]:

$$\mathrm{sim}(f_1, f_2) = \frac{\sum_{k=1}^{l} s(f_1, f_2)}{z}. \tag{7}$$

(a) Jacquard pattern

(b) Computer jacquard antihair faux fur machine

FIGURE 1: Jacquard type and jacquard machine.

Multiply the weight of the attribute w_i by the above formula [11]:

$$\text{sim}(f_1, f_2) = \frac{\sum_{k=1}^{l} sw_i(f_1, f_2)}{zw_i}. \tag{8}$$

From the definition of cubic spline function, the i-th segment spline function can be expressed as [12, 13]

$$y(x) = \left[(x_1 - x_t)^2, (x_1 - x_t)^3, 1\right] \begin{bmatrix} \dfrac{2}{h} & \dfrac{2}{h^2} & \dfrac{1}{h^3} \\ \dfrac{2}{h} & 0 & \dfrac{2}{h} \\ \dfrac{1}{h^3} & \dfrac{2}{h^2} & 0 \end{bmatrix}. \tag{9}$$

You can use the condition that the second derivative of the front and back two curve segments is continuous at the type value point to list an equation [14]:

$$\beta m + 2m + \chi m = C. \tag{10}$$

Among them, $\beta = 1/h$.

Need to construct three interpolated cubic splines on the parameter U [15]:

$$\begin{aligned} x &= x(U), \\ y &= y(U), \\ z &= z(U). \end{aligned} \tag{11}$$

The cumulative chord length corresponding to the given value point P is [16]

$$S = \sum_{j=1}^{k} |P_j - P_i| = \sum_{j=1}^{k} \sqrt{(x - x_i)^2 + (y - y_i)^2}, \tag{12}$$

$$Q(m, n) = Q(m, n) + K(m, n)N(m, n). \tag{13}$$

Take the scale factor at the above feature size as [17]

$$S(m, n) = N(m, n)r * t(m, n). \tag{14}$$

N is the number and S is the area.

Import the pattern into the Design Star artificial fur design system, and set the corresponding flower width and height. This pattern has a flower width of 1184 and a flower height of 210. After the import is successful, carefully check the details of the pattern, such as different colors and misalignment. The colors are arranged in the order of feeding, which are gray tops, pink tops, and black tops. During the feeding process, the gray bottom is fed with graphene-based polyester gray tops, the red part is fed with pink wool and acrylic blended tops, and the black part is fed with black wool and acrylic blended tops. At this time, the system will automatically calculate the ratio of excellent yarns, which is gray, respectively, tops : pink tops : black tops are 43.8% : 27.8% : 28.4%.

After processing the pattern diagram, export the pattern diagram (BMP format), the wool feeding program (WM format), and the needle selection program (XZ format) from the system and import them to the U disk. Copy the three files and transfer them to the control panel. Set the rotation speed to 25 r/min. When the number of cycles (the number of cycles is the total number of yarns plus 1) is 4, the total number of revolutions Z is set to 11318 [18, 19].

$$Z = \left(\frac{x_m}{0.0254}\right) \times \frac{Z_m}{x_L}. \tag{15}$$

Among them, x_m is the number of meters under the cloth. x_L is the number of loops. Z_m is longitudinal density [20].

Calculation of elastic elongation [21]:

$$S = \frac{D_2 - D_1}{D_1} \times 100\%. \tag{16}$$

Air permeability T calculation [22]:

$$T = \frac{Q}{A} \times 167. \tag{17}$$

Q represents the average airflow, and A represents the study area [23].

Moisture permeability calculation [24]:

$$WV = \frac{\Delta m}{A \cdot t}. \tag{18}$$

2.1.2. Product Finishing Process. The general finishing process after the forward and reverse blowing graphene knitted fabric off the machine is gray cloth $\longrightarrow$ shrinking $\longrightarrow$ washing $\longrightarrow$ dehydration $\longrightarrow$ opening $\longrightarrow$ shaping $\longrightarrow$ shearing $\longrightarrow$ steaming $\longrightarrow$ finished product.

Shrinking is to reduce the friction between the fibers through the appropriate concentration of the shrinking agent and improve the stretching and shrinking ability of the wool fiber. The fabric feels plump after shrinking, forming fluff, and improving the warmth retention performance. This product uses a weakly acidic surfactant with a pH between 5.5 and 6.0 and calcium chloride with a concentration of 5%. Calcium chloride improves the separation of wool fibers and prevents excessive felting of wool fibers, thereby obtaining better shrinkage. With acid shrinking, the shrinking effect is better when the temperature is higher, so the temperature is set to 42°C.

The setting equipment is a hot air setting machine with a setting speed of 13 m/min, a steam pressure of 4 kg/cm^2, a cloth drop speed of 12.2 m/min, and a post-overfeeding speed and a cold water roll speed of 12.4 m/min.

Shearing adopts the method of moving cloth forward and round knife forward rotation, and the rotation speed of the round knife is set to 1000 rpm/min. Shearing makes the surface of the fabric more uniform and has a better gloss.

The steaming equipment is XHL-1900 continuous steaming machine, the steaming temperature is set to 130°C, and the speed is 20 m/min.

2.2. Finishing Process of Graphene-Modified Cotton Fiber Knitted Fabric

2.2.1. Experimental Fabric Design. Design a thin graphene knitted fabric with wool, polyester, and nylon in raw materials. The two sides of the fabric formed by the double-sided structure can show different properties and styles through different materials, and the fabric is richer and has a certain fluffy feeling. Four ways are 55dtex nylon filaments, 5 ways are blended yarns of 20% wool and 80% polyester, and 6 ways are 55ditex graphene-modified nylon filaments. The knitting result of the thin knitted fabric is shown in Figure 2. The equipment is E 40 double-sided circular knitting machine.

2.2.2. Finishing Process Design. Boiling it can make the thin woolen cloth smooth and dense, stiff, smooth, and elastic. The setting is to stabilize the performance of polyester and nylon filaments, thereby improving the dimensional stability of thin wool. The effect of steaming on the structure and style of thin woolen cloth is similar to the cooking process, which makes the woolen cloth smoother and the body bones more elastic. Therefore, the postfinishing process of formulating thin knitted fabrics is gray cloth $\longrightarrow$ cooking $\longrightarrow$ dehydration $\longrightarrow$ opening $\longrightarrow$ wet inspection $\longrightarrow$ shaping $\longrightarrow$ shearing $\longrightarrow$ steaming $\longrightarrow$ finished product.

(1) Cook It. In order to make the fabric smooth and compact and obtain a crisp feel, it is necessary to carry out the cooking process. The cooking process parameters are set to a temperature of 90 degrees Celsius and a time of 50 minutes, and softener is added when the temperature is slowly cooled to below 40 degrees Celsius by adding cold water.

(2) Finalize. In order to make the surface of the fabric smooth and prevent the fabric from wrinkling, it is necessary to shape and finish the sample. The shaping process parameters are temperature 160 degrees Celsius, speed 30 m/min, and width 160 cm.

(3) Steaming. Steaming is to improve the stability and flatness of the cloth surface, while improving the gloss and feel of the cloth surface. Because the fabric is light and dense, in order to improve the feel of the fabric as much as possible, the feeding speed should be reduced. The setting parameters of the steaming process are temperature 170 degrees Celsius, speed 5 m/min, and tension 80 N.

2.3. Basic Parameter Test of Rough Sample. The structural parameters of the fabric have a certain influence on the wearability of the fabric. Due to the different design of the veil material, ground yarn material, and organizational structure of the fabric sample, the basic parameters of the fabric are directly different. Therefore, first perform the width, density, areal density, thickness, and raw material content ratio of the blank sample of the fabric. Then, wait for testing. The basic parameters of the blank sample are shown in Table 1.

(1) Fabric density test: place the sample flat on the table without stretching or widening. The Y51IB fabric density mirror was used to measure the longitudinal density and lateral density of different samples from the warp and weft directions of the sample. The unit is circle/cm

(2) Fabric thickness test: the YG(B)141D digital fabric thickness meter with an accuracy of 0.01 mm is used, and the standard used is GB/T 3820-1997 "Determination of Thickness of Textiles and Textile Products"

(3) Fabric surface density test: a FA1004 electronic balance with an accuracy of 0.0001 g is used to weigh the mass of the sample. The experimental procedure is in accordance with FZ/T 70010-2006 "Determination of the Dry Weight of Knitted Fabrics in Square Meters"

(4) Spandex content test: the veil, ground yarn, and spandex are detached from the fabric manually and

#7	277.57	2.252	5.82	0.228
#8	282.52	2.472	5.92	0.220
#9	225.26	0.864	6.22	0.225

then dried and cooled before being weighed. Finally, calculate the spandex content Q:

$$Q = \frac{P}{M + N + P} \times 100\%. \tag{19}$$

M is the veil, N is the ground yarn, and P is the spandex.

If the total time used to produce a suit jacket is T_1, the total time used for each machine position is

$$T = \frac{T_1}{N}. \tag{20}$$

2.4. Digitization of Clothing Styles. There are many commonly used drawing software, such as Photoshop, Adobe-image, and AutoCAD. In order to realize the digitization of styles, this research has developed a drawing system, which provides a large number of drawing tools so that designers can more accurately complete the drawing of clothing styles. After the styles are drawn, they will be stored in the library for recall. This can not only improve the efficiency of designing clothing but also save the designed clothing according to the parts, so as to provide nonprofessional designers for selection, splicing, modification, and other recreation. The digital processing plan of clothing is shown in Figure 3.

2.4.1. Basic System Environment. Hardware environment is Pentium 4 PC, color laser printer.

Software environment is Win2000 Server operating platform, Microsoft SQL Server 2000 database management system.

Development tools are Microsoft Visual c++6.0, Access 2000, Adobe Photoshop, CorelDRAW.

For users and fashion designers, there are mainly the following requirements:

(1) Each clothing style is uniformly divided into collars, pieces, sleeves, pants, or skirts. Designers must strictly follow this order when drawing styles

(2) The software should provide designers with enough drawing tools so that they can input clothing styles more accurately, including the elimination tool and the tool to get the mirror image of the drawing about the axis of symmetry of the screen

(3) After the designer finishes drawing a garment part, he must save it before he can continue drawing the next part. After saving a part, the part will be displayed in gray, indicating that the part has not been placed

(4) When inputting detailed points and lines, the software provides the designer with abbreviated display of each detail for his selection

2.4.2. Curve and Its Storage Method. There are a variety of curves to choose from in computer graphics, and B3 spline is preferred due to its smoothness everywhere, no lattice phenomenon, and less data.

In the course of the work, the junction of the curve is uncertain, so the chain table is used to store the curve.

2.4.3. Digital Realization. The system for digital realization consists of six parts, including desktop environment, drawing tools, linear settings, curve drawing, data storage, and user interface.

Among them, the desktop environment module contains two classes: COMyBitmap and CWorkEnviroment. The former is a simple encapsulation of the functions of the CBit map class. It can display a bitmap with a transparent background. In the graphics input system, the ClyBit map class is used to display the entry and other details of the clothing as a template for drawing clothing. The latter saves all the
FIGURE 3: Clothing digital processing scheme.

environment parameters of the desktop, including the color of the current brush, the display ratio, and the height and width of the desktop.

The database has established three tables for each part, which are used to store the information of the points on the curve, the information of the curve, and the information of the parts.

When saving clothing parts, select the point selection tool, click the node or line with the right mouse button to display its number, and, at the same time, you can save the details of the selected point and line. This is an important step in the digitization of clothing styles. The correct and detailed definition of key points or lines is the basis for intelligent transformation of clothing. Figure 4 shows the digital intelligent design of clothing.

3. Results

Without instructions, the customer will study the details according to his selected style or sample style. The production process sheet is a guiding document for the workshop workers to process and make garments. Therefore, these contents need to be recorded in the customer-specific RFID tags. Clothing customization needs to redesign the process according to the customer's requirements. In order to reduce the operation time of the personnel, the basic craft sheet can be made in advance. After the system reads the customer style information, it will automatically jump out modification of the craft list which can form a customer's personalized craft list. This method of making documents greatly reduces the time to remake the craft sheet, and the technicians only need to click to select or input a few sentences to complete the production. The content of the subpage of the "production" link of the digital production process sheet is shown in Figure 5.

Click to enter the production sheet section, the production sheet that has been made will display "modify," and the customer column that has not been made will display the "make" link. The homepages of production sections such as production notices, production process sheets, production

processes, and RFID tags are all in tabular form, as shown in Table 2.

Set up a buffer zone for the stock of flour and accessories, and set a red line for the stock volume to ensure the stability of the buffer stock. When the inventory is below the red line, the management staff immediately contact the supplier to supplement the materials, instead of waiting until the surface accessories have been consumed. The traditional inventory only needs to keep the noodles and accessories. When the production department needs the materials, the outbound management is done. The material management under the digital collaborative management requires the management personnel to prepare in advance based on the daily fabric sales data and the inventory balance. This mechanism can ensure that as long as the fabric is displayed at the front end of the sales, the production department can provide enough processing materials, and the overall production process will not be affected by the lack of stock. At the same time, we can arrange customized production sequence and adjust production technology according to the availability of surface accessories. In the material management module, it is possible to know the inventory situation at any time and, according to the sales situation of last week, combined with the inventory red line, determine whether to request replenishment. Material management is shown in Table 3.

According to 50% calculation, the lowest market price and garment price are shown in Table 4. The cost of the vest is lower, and the use of yarn replacement to keep warm can also reduce a certain cost. The thicker the fabric weave, the greater the cost. Because the factory's products need to maintain a 15% profit, agents and shopping malls also have a certain profit, so the sales price is generally more than 50% of the cost. The retail price of the clothing is 198 yuan, and the actual purchase price is 89 yuan. Therefore, the clothing designed in this study is moderately priced in the market and has a certain market potential.

The fabric comparison of different samples is shown in Table 5. It can be seen from Table 5 that the ground yarns of the fabrics of the 9 samples are all nylon, so the antipilling performance is the same for the inside of the fabric. The veil
FIGURE 4: Digital and intelligent design of clothing.

FIGURE 5: Subpage content of the digital production process list.

TABLE 2: Home table form.

Customer serial number	Order number	Notice/process/ process/RFID
1	2222356	Make
2	2222357	Make
3	2222358	Make
4	2222359	Make
5	2222360	Revise
6	2222362	Revise
7	2222362	Revise

of the fabric is different, and the antipilling performance is different. The veil is nylon, which has a high resistance to pilling, and there is almost no pilling after rubbing for 7000. The antipilling performance of the fabric using viscose is relatively low. After 2000, serious pilling has been produced on the surface of the fabric. Experiments show that the fuzzing and pilling resistance of the veil made of nylon is better than that of the veil made of viscose. Nylon is not easy to fuzz and pill, which has little effect on the appearance of the fabric.

After the fabric was irradiated with a full-spectrum UVB metal halide solar lamp for 10 minutes, samples 1-6 rose to the highest temperature, and samples 2 and 5 were higher than other fabrics. Turn off the metal halide solar lamp, and each sample undergoes a 10-minute cooling process.

Table 3: Material management.

Type code	Style description	Last week's sales	Inventory balance	Inventory red line
#1	6% cotton, 94% polyester	11 meters	345	300 m
#3	Oxford fabric	23 meters	128	150 m
#4	2% chemical fiber, stripes	168 meters	456	400 m
#2	Pure cotton red	123 meters	785	200 m

Table 4: The minimum market price and ready-to-wear price are calculated at 50%.

Clothing style	$X1$	$X2$	$X3$	$Y1$	$Y2$
Cost price (yuan)	22	22	41	42	30
Lowest market price (yuan)	34	67	62	63	45

Table 5: Fabric comparison for different samples.

Clothing style	#1	#2	#3	#4	#5	#6	#7	#8
125	4.7	4	4.7	3.7	4	4.7	7	4
500	4	3	3	3.7	7	3	3.7	3
1000	7	3	3	3	3.7	3	3.7	3
2000	7	1.7	3.7	1	1	1	7	1
5000	7	1.1	3	1	3	1.7	7	1
7000	4.7	1	3.7	1.7	3.7	1.7	7	1.7

The final temperature of sample 2 is close to sample 1 and higher than sample 3, and the temperature of sample 5 is close to sample 4 and higher than sample 6. It can be seen that when graphene-modified nylon is on the surface of the fabric, the fabric has better heat storage performance. Graphene-modified nylon heat storage performance is shown in Figure 6.

The test results of the fabric's thermal insulation performance are shown in Figure 7. The veil of sample 2 uses graphene-modified nylon, and the heat preservation rate is higher than that of other fabrics. Judging from this, when the coverage of the graphene-modified nylon on the surface of the fabric increases, the warmth retention of the fabric is improved. The main reason is that the surface of the graphene-modified nylon has particulate matter, which increases its specific surface area and has more voids in the composition. The formation of still air is relatively more.

The mass fraction of graphene-modified nylon of sample 1 is 40%, and the corresponding *Staphylococcus aureus* and *Escherichia coli* have the highest antibacterial rate. When the mass fraction of graphene-modified nylon is reduced to 18%, *Staphylococcus aureus* has antibacterial rate of bacilli which is still greater than 80%. Graphene-modified nylon makes knitted fabrics have longer-lasting antibacterial properties, and when the mass fraction of graphene-modified nylon reaches 18%, the antibacterial properties of knitted fabrics can meet the standard. The antibacterial effect is shown in Figure 8.

Orthogonal experiment to explore the relationship between temperature, time, and expansion rate is shown in Figure 9. As the temperature increases, the expansion rate increases and then decreases. The longer the time, the greater the expansion rate, which will decrease after 30 s.

Fourier transform infrared spectroscopy is used to study the chemical structure of fibers. It can be seen that fiber 1 and fiber 2 have weak amide characteristic peaks around 1720 cm (respectively, -CO-NH- stretching vibration and bending vibration), while the modified graphene fiber does not show corresponding characteristics. Peak, which shows that during the formation of fiber 1 and fiber 2, the carboxyl groups on the modified graphene sheet are ionized and form noncovalent ionic bridges with the coupling agent. During the fiber drying process, in the process, with the volatilization of the solvent between the sheets, the distance between the modified graphene sheets decreases so that the ion bridge can be further reacted into a covalent bond form. The transition from ionic bridges to covalent bonds can enhance the mechanical properties of the fibers. Among them, such a transformation is more significant in fiber 2. Fourier transform means that a function that satisfies certain conditions can be expressed as a trigonometric function (sine and/or cosine function) or a linear combination of their integrals. In different research fields, Fourier transform has many different variants, such as continuous Fourier transform and discrete Fourier transform.

The mechanical properties of the fiber can be characterized by a tensile machine. In the characterization, the original size of the fiber is 1 cm, and the stretching rate is 10%/min. The final value obtained is the average value obtained by testing at least 10 samples of each fiber. Dried fiber 1 and fiber 2 prepared by this method have good mechanical strength. The mechanical strength of fiber 2, fiber 1, and modified graphene fibers can reach 356 MPa, 296 MPa, and 148 MPa, respectively, and their mechanical strength is comparable to modified graphene fibers and CNTs obtained by other wet spinning methods. At the same time, the fiber is also flexible and can be bent into different shapes or spun into a textile structure. High bulk density and large ion accessible surface area are two prerequisites for supercapacitor electrodes to achieve high volume capacity. The infrared spectra and tensile properties of fiber 1, fiber 2, and modified graphene fibers are shown in Figure 10.

4. Discussion

At present, the main types of thermal underwear on the market include pure cotton underwear, cashmere thermal underwear, and wool thermal underwear. The advantages of pure cotton underwear are breathable, moisture-permeable, soft, and comfortable, but its disadvantages are easy
Figure 6: Thermal storage properties of graphene-modified nylon.

Figure 7: Test results of the insulation performance of the fabric.

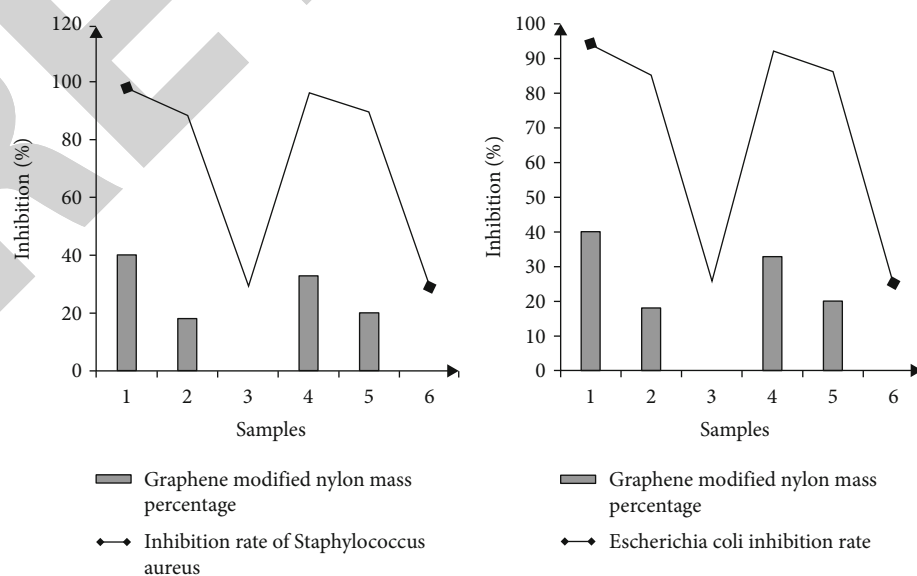

Figure 8: Antibacterial effect.

Figure 9: The relation between the time and the amplification rate.

Figure 10: Infrared map and tensile properties of fiber 1, fiber 2, and modified graphene fibers.

to shrink, easy to deform, and not close to the body; cashmere thermal underwear has the advantages of soft, slippery, comfortable, and dry. There is a high content of still air inside the fabric, and the curled fluff on the surface of the fabric also enhances the fabric's elasticity, warmth retention, and bulkiness, making the underwear more elastic. Cashmere fabric can also quickly discharge sweat and quickly adjust the temperature to make people feel comfortable according to the external environment. However, the output of cashmere is relatively rare, and its price is relatively high; most of the wool used in wool thermal underwear is merino wool. Merino wool has delicate fabrics and has the advantages of being comfortable to wear next to the body, without any irritation. In addition to its good heat retention and moisture absorption, it also has a more comfortable stretch tension. In China, in the 1950s, a method of adding warmth to people with warm colors was adopted. Long ago, thermal underwear used was mostly cotton wool, which is comfortable and warm, and by increasing its thickness to reduce heat loss, thereby improving the thermal effect of underwear.

However, the thickness of the clothing is not linearly related to the warmth retention effect, and the warmth retention effect will decrease when it is thicker to a certain stage. In addition, the continuous increase in the thickness of underwear also seriously affects people's free movement and beauty. In order to make thermal underwear not only have good thermal insulation properties but also reduce the thickness of clothing, people have introduced various thermal underwear [25, 26].

The preservation of key lines and key points of components is the more cumbersome part of the digital preservation process, but it is also the basis for the intelligent realization of the software, because only the definition of each key line and each key point can be used to make these inputs The lines are no longer ordinary drawing lines, but smart lines that can be changed according to the requirements of the designer and can be combined and transformed in place according to instructions. The digital realization of clothing styles is the basic part of the entire clothing design software, and the purpose is to serve the display and changes

of subsequent clothing styles. Since the display of clothing styles requires a large number of fully defined original clothing styles as a basis, professional designers need to draw the required styles into the library. This drawing and storage of the digital clothing design system research process is the digital process of styles [27, 28]. How to enable professional designers to input styles accurately and as easily as possible has become the most important problem in the design process of this research [29].

With the development of industrialization, in order to reduce the cutting and stitching process in the traditional knitting process, seamless knitting technology has begun to be developed. Seamless garments can be woven not only on circular knitting machines but also on flat knitting machines. Seamless flat knitting machines can weave multiple tubular fabrics at the same time and connect them directly in the production process. The intelligence of a computer is given by people. When the designer enters the style into the computer, the computer does not know that the input line is the neckline, which is the neckline, or the combination of these lines is a collar, it just records the entire line in a picture format just the picture. Therefore, simply using the brush to draw how many styles on the computer can not realize the future intelligent call, so assigning values to the drawn lines and points has become a prerequisite for achieving intelligence [30, 31].

5. Conclusion

This research mainly discusses the digital clothing design method oriented to the production process of graphene-modified nylon knitted fabric. The color of graphene-modified cotton fiber is gray and black. With the increase of graphene content, the color becomes darker. Therefore, when designing graphene-modified cotton fiber jacquard graphene knitted fabric, the color matching has certain restrictions. The fabric feels plump after shrinking, forming fluff, and improving the warmth retention performance. Due to the different design of the veil material, ground yarn material, and organizational structure of the fabric sample, the basic parameters of the fabric are directly different. Therefore, first perform the width, density, areal density, thickness, and raw material content ratio of the blank sample of the fabric. The customization system platform was developed in research and changed the custom model of customers in the store to try on clothes in the past. Consumers can choose suitable products according to the clothing categories, styles, fabrics, etc. provided on the corporate website and can discuss the details of clothing with the designer. Designs such as embroidery and logo, while saving customers' time, meet customer's personalized clothing design. The follow-up work can further optimize the production process sheet and production notice. In the later stage of the article, different fabrics can be studied, combined with ergonomics, to design and develop a set of graphene composite fiber seamless underwear.

This study was undertaken to report the swift, facile and convenient synthesis of novel hydrazones obtained by condensation reaction between 2-Amino-3-formylchromone and hydrazine derivatives. Various characterization techniques such as MALDI Mass, FTIR, ^{1}HNMR and ^{13}CNMR spectrum analysis was done to determine the chemical structure of these novel six hydrazones. Furthermore, UV-Vis and fluorescence spectra was studied to calculate λ_{max} and ε_{max}. These hydrazones are quite useful for their facile synthesis and chemical structure. Such hydrazones require separate clinical research to find their applications in biomedical fields.

1. Introduction

Hydrazones are special organic compounds derived from the Schiff-base family and comprising of $\diagup_{C}{=}_{N}{-}_{N}{=}_{C}\diagdown$ bonds with additional donor sites. The donor sites make hydrazones more flexible and versatile for their structural and functional properties [1]. For instance, hydrazones are very significant reactants in different reactions such as hydrazone iodination, Shapiro and Bamford-Stevens reaction. On the other hand, hydrazones act as intermediates in Wolff-Kishner reaction. The C and H atoms in hydrazones tend to react with organometallic nucleophiles. Due to its highly acidic nature, the alpha-hydrogen atom of hydrazones is comparatively more nucleophilic than that of ketones [2]. Different studies have reported the biological importance of trigonal hybridized nitrogen atom in azomethine group of hydrazones which is remarkable for having one pair of electrons in its either π or sp^2 orbitals [3, 4]. Their hetero atomic nature and specific electronic properties make them very important structural compounds [5]. One of the most promising organic hole transporting materials are aromatic hydrazones. Recently, some researchers have reported the synthesis of polymeric hydrazones with remarkable properties such as high glass transition temperatures, good film-formation and moderate charge transport [6].

The ligation of hydrazones with surface immobilized hydrazines and aldehydes-modified antibodies can be used to anchor captured proteins on oxide coated biosensor substrates [7]. Hydrazones are also being used as inhibitors such as strong poly (ADP-ribose) glycohydrolase (PARG) [8].

Aroyl hydrazones have been reported to use in clinical theranostic applications due to their ferric ion scavenging activities [9]. The role of N, O and S in metal coordination at the active sites of numerous metallobiomolecules is also well known for various industrial, antimicrobial, anticancer and herbicidal applications [10, 11]. The chelating ligands get coordinated with metal ions by N, O or S as donor atoms. They have been found to show a wide variety of biological applications and are becoming a hotspot of research [12, 13]. The coordination of metal ions with the biologically active compounds can enhance their potential [14]. The polymeric hydrazones and their coordination in polymer drug conjugates is involved in hydrolysis. The rate of hydrolysis is significantly faster at acidic pH as compared to those of carbamates [15]. Hydrazone linkers are stable only in physiological conditions (pH 7.4) but they are prone to get cleaved under acidic conditions such as the intracellular conditions of endosomes and lysosomes protects them by forming micelle around. The hydrophobic drugs are hence gets protected from the host defense system in the body [16]. For instance, the anticancer drug DOX is released at higher rate under acidic conditions due to the nature of linkage between the DOX and micelles [17]. Chromone derivatives have received great attention of researchers for their applications. These compounds show wide spectrum of biological activities such as antimicrobial, antitumor, anti-allergic, antiviral, anti-inflammatory and anticancer activities [18].

Due to the aforementioned applications of hydrazones, herein we have reported the quick, facile, and convenient synthesis of six novel hydrazones containing N, O, or S atoms derived from Chromone. Hopefully, the combination of the chromone moiety with hydrazides may provide more biologically active resulting compounds. The typical synthesis of hydrazones can be described as follows:

$$2 - \text{Amino-3-formylchromone} + \text{Hyadrazide} \xrightarrow[\text{Reflux}]{\text{Acetic Acid}} \text{Hydrazone}$$

(1)

2. Materials and Methods

2-Amino-3-formylchromone, 2-hydroxybenzhydrazide, 3-hydroxy-2-napthoic acid hydrazide, isonicotinic acid hydrazide, 2-picolinyl hydrazide, thiophene-2-carboxylic hydrazide, and 2-furoic acid hydrazide were purchased from TCI (Japan) or J&K (China) with purity higher than 98% and used without further purification. UV-Vis spectra were recorded by using a UV-1000 spectrophotometer of Techcomp (China). Fluorescence spectra were recorded on F-7 Fluorescence spectrophotometer (Hitachi, Japan). MALDI mass spectra were obtained on time-of-flight Ultrflex II mass spectrometer (Bruker Daltonics). ^{1}H and ^{13}CNMR spectra of hydrazones in DMSO-d6 solutions were recorded on a 300 MHz Bruker AV 300 spectrometer and chemical shifts are indicated in ppm.

The equimolar mixture of 2-amino-3-formylchromone and hydrazine derivative (i.e., 2-hydroxybenzhydrazide, 3-hydroxy-2-napthoic acid hydrazide, isonicotinic acid hydrazide, 2-picolinyl hydrazide, thiophene-2-carboxylic hydra-

zide, or 2-furoic acid hydrazide) in acetic acid was refluxed for a certain time (Table 1). After reflux, the solution was cooled to room temperature, poured into ice-water and stirred. When the precipitates started to appear, the reaction mixtures were allowed to stand for an hour to afford maximum precipitates. Detail reflux times, colors of the precipitates, and yields of the hydrazones are shown in Table 1. MALDI mass, Fluorescence, FTIR, and ^{1}HNMR data of the 6 hydrazones are shown in Tables 2–5. UV-Vis and fluorescence spectra of the 6 hydrazones are shown in Figures 1 and 2, respectively.

3. Results

In this study, different hydrazides were used such as 2-hydroxybezhydrazide (CBH), 3-hydroxy-2-napthoic acid hydrazide (CNH), isonicotinic acid hydrazide (CISH), 2-picolinyl hydrazide (CPH), thiophene-2-carbhydrazide (CTPH), and 2-fouric acid hydrazide (CFH) for synthesis of hydrzones. The results of the study have revealed that it took only 9 min for CBH to obtain maximum white precipitates of the reaction mixture. On the other hand, the

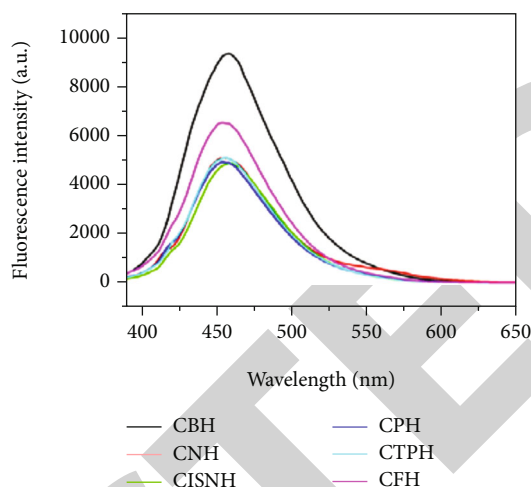
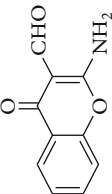
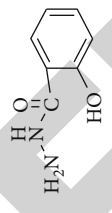
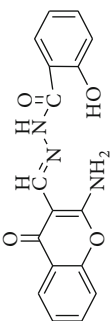
hydrazones through CNH was appeared with greenish precipitates in the reaction flask within one minute. The stirring of reaction mixture on heat was done to obtain maximum precipitates for few minutes. But it was not happened during the synthesis of hydrazones of CISNH, CPH, CTPH, and CFH. The precipitates were not appeared during reflux. In these reactions, a clear solution was observed for 25 min.

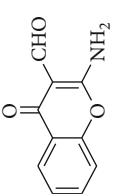
After reflux, the solutions were cooled at room temperature, poured into ice-water, and stirred. When the precipitates started to appear, the reaction mixtures were allowed to stand for an hour to afford maximum precipitates. The precipitates were then filtered, dried, and characterized. Structures of the precursors and synthesized hydrazones are listed in Table 6.

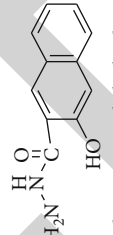


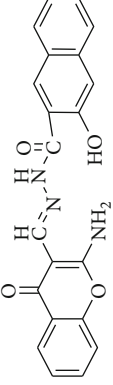


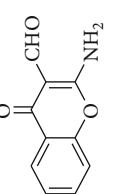


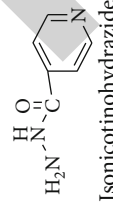


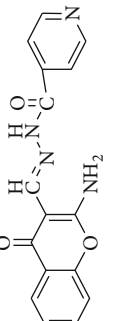


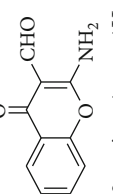


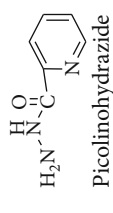


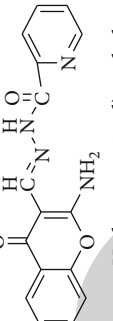


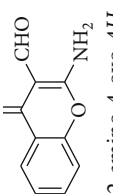












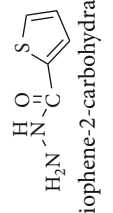


FIGURE 2: Fluorescence spectra of the 6 hydrazones in DMSO. The concentration of CBH and CFH is 100 μM, while the concentration of other 4 hydrazones is 10 μM.

The results obtained through MALDI mass are well consistent with the molecular weights of these six hydrazones, as shown in Table 2. The λ_{max} and ε_{max} values of these six hydrazones were calculated according to their UV-Vis spectra. Fluorescent properties of the hydrazones were also studied and their excitation and emission wavelengths are mentioned in Table 2. Furthermore, FTIR, ^{1}H and ^{13}CNMR spectral data of the hydrazones confirmed the proposed structures of hydrazones.

4. Discussion

Detailed principle peaks on the FTIR and ^{1}HNMR spectra are listed in Tables 4 & 5, respectively. The signal at chemical shifts (δ, ppm) of 11.93-12.34 in ^{1}HNMR spectra are assigned to the –NH group, concomitant with the observation of rapid loss of these signals. Same is the case with -NH$_2$ groups whose peaks of both protons signals at chemical shifts of 9.28-9.88. The signals at δ of 11.98 ppm and 11.50 ppm are assigned to the aromatic –OH protons of CBH and CNH, respectively. The resonance peaks between 8.91 ppm to 9.08 ppm in the spectra are assigned to the azomethine (-CH=N-) of these hydrazones. Signals at δ 6.70-8.79 are assigned to the aromatic protons. In 13CNMR spectra of these hydrazones, four key resonance signals were observed. These are δ 153.0-153.4 for azomethine (-CH=N-), carbonyl carbon of chromone ring roughly at δ 162.9-165.0, carbon of chromone ring attached to carbon of azomethine at δ 92.6-92.8, and δ 173.3-173.7 for the carbon (–C-NH2) on the chromone ring in all hydrazones. The signals of carbonyl carbons from hydrazine motifs were observed roughly at δ 162.9, 160.7, 150.4, 160.1, 157.3, and 145.7 from CBH, CNH, CISNH, CPH, CTPH, and CFH, respectively. The detail of other carbons in all hydrazones is described as following: Six carbons on the benzene ring of chromone of CBH are shown at δ 145.6, 133.9, 128.1, 125.3, 121.8, and 117.6. Three carbons on chromone ring are δ 173.7, 165.0, and 92.6. Six carbons on the benzene ring having –

2-amino-4-oxo-4H-chromene-3-carbaldehyde	Isonicotinohydrazide	(E)-N′-((2-amino-4-oxo-4H-chromen-3-yl)methylene)isonicotinohydrazide
2-amino-4-oxo-4H-chromene-3-carbaldehyde	Picolinohydrazide	(E)-N′-((2-amino-4-oxo-4H-chromen-3-yl)methylene)picolinohydrazide
2-amino-4-oxo-4H-chromene-3-carbaldehyde	Thiophene-2-carbohydrazide	(E)-N′-((2-amino-4-oxo-4H-chromen-3-yl)methylene)thiophene-2-carbohydrazide
2-amino-4-oxo-4H-chromene-3-carbaldehyde	Furan-2-carbohydrazide	(E)-N′-((2-amino-4-oxo-4H-chromen-3-yl)methylene)furan-2-carbohydrazide

OH were shown at δ 160.1, 133.9, 125.3, 119.0, 116.9 and 115.2. Six carbons on the benzene ring of chromone of CNH are shown at δ 150.4, 133.4, 129.0, 121.1, 121.1, and 117.1. Three carbons on chromone ring are at δ 173.5, 163.9, and 92.6. Ten carbons on the naphthyl ring are shown at δ 145.7, 129.0, 127.1, 125.9, 125.2, 125.2, 125.2, 125.2, 124.1, and 110.9. Six carbons on the benzene ring of chromone of CISNH are shown at δ145.7, 128.7, 126.9, 125.0, and 116.8. Three carbons on the chromone ring are at δ 173.5, 163.0, and 92.6. Five carbons on the isonicotinic ring are shown at δ133.6, 125.0, 125.0, 121.5, and 121.5. Six carbons on the benzene ring of chromone of CPH are shown at 150.0, 135.2, 127.1, 125.0, 122.2, and 117.1. Three carbons on chromone ring are at δ 173.4, 163.1, and 92.8. Five carbons on the pyridine ring are shown at δ 148.9, 146.1, 134.9, 125.0, and 122.2. Six carbons on the benzene ring of chromone of CTPH are shown at δ 144.2, 128.5, 125.3, 125.3, 121.8, and 117.1. Three carbons on the chromone ring are at 173.4, 162.9, and 92.8. Four carbons on the thiophene ring are shown at δ 138.1, 133.5, 131.6, and 128.5. Six carbons on the benzene ring of chromone of CFH are shown at δ 133.4, 125.2, 125.2, 125.2, 121.7, and 116.8. Three carbons on the chromone ring are at δ 173.3, 163.0, and 92.8. Four carbons on the furan ring are shown at δ145.7, 145.7, 114.5, and 112.2. These spectroscopic data confirmed the successful syntheses of the 6 hydrazones mentioned above. The λ_{max} (nm) and εmax values of these six hydrazones were calculated according to their UV-Vis spectra, the λ_{max}, are in the range of 344 to 351 nm and ε_{max} was from 1.50 x 10^4 to 3.26 x 10^4 cm^{-1} M^{-1}.

5. Conclusions

This study highlighted the synthesis and spectroscopic characterization of 6 novel hydrazones. The hydrazones were quickly synthesized through convenient and facile approach. This study reported the synthesis of CBH in 9 min. On the other hand, CNH was synthesized in 1 min only. After the reflux of 25 min, other 4 hydrazones were synthesized. The importance of these hydrazones can be realized in live cell imaging for detection of metal ions. These compounds are quite beneficial for their role as chemo sensors. As a future perspective of this study, these hydrazones containing oxygen, sulfur, and nitrogen atoms may lead biologists for its applications in biomedical fields.

Nanomaterials Combined with Sports Rehabilitation Therapy in the Treatment of Shoulder Arthritis of Volleyball Players

Jie Cui ⬤

Department of Sports and Arts, Bengbu Medical College, Bengbu, 233030 Anhui, China

Correspondence should be addressed to Jie Cui; 0200047@bbmc.edu.cn

Shoulder arthritis is one of the most common injuries of professional volleyball players. It needs shoulder force to buckle, block, and bounce, which leads to frequent shoulder injuries. In addition, the late rehabilitation treatment is not in place, which will seriously affect the performance of volleyball players' skills. Periarthritis of the shoulder is referred to as frozen shoulder, commonly known as congealed shoulder and fifty shoulder. The shoulder pain gradually develops, worse at night, and gradually increases, and the shoulder joint movement function is limited and increasingly aggravated. After reaching a certain level, it gradually relieves and finally fully recovers as the main manifestations of the shoulder joint capsule and its surrounding ligaments and tendons. Shoulder periarthritis is a common condition in which shoulder pain and inconvenience are the main symptoms. This paper studies the application of nanomaterials combined with sports rehabilitation therapy in the treatment of shoulder arthritis of volleyball players. We selected 50 volleyball players with shoulder arthritis injuries, randomly assigned nanomaterials combined with sports rehabilitation therapy as the experimental group and traditional sports rehabilitation therapy as the control group, 25 cases in each group. The experimental group was treated with nanomaterials combined with sports rehabilitation, while the control group was treated with traditional sports recovery methods for 5 weeks. Nanomaterials have a certain uniqueness. When the scale of matter is small to a certain extent, quantum mechanics must be used instead of traditional mechanics to describe its behavior. When the particle size of the powder is reduced from 10 microns to 10 nanometers, its particle size is 1000 times, and when converted into volume, it will be 10 times the 9th power, so there will be obvious differences in the behavior of the two. The physical examination of the two groups of volleyball players' shoulder joint visual analogue scale (VAS) pain score and shoulder joint isokinetic detection (including shoulder joint extension and adduction, shoulder joint flexion and extension, and shoulder joint movement to 90° shape) is compared. The results showed that the VAS score of the experimental group was significantly lower than that of the control group ($P < 0.05$), and the isokinetic test of the experimental group was better than that of the control group ($P < 0.05$). After exercise rehabilitation training for shoulder joint dysfunction, the average strength and activation of 10 muscles were improved, among which the lower trapezius, the middle trapezius, and the serratus anterior were significantly improved. It can be seen that as an effective treatment of shoulder arthritis, nanomaterials combined with sports rehabilitation therapy can not only accelerate the rapid recovery of volleyball players after injury but also effectively prevent the occurrence of arthritis symptoms, so that volleyball players can give full play to their skills on the court.

1. Introduction

Under coach Lang Ping's leadership, the Chinese women's volleyball team won the World Cup in 2015 and the Rio Olympics in 2016. In 2018, China once again dominated Asia and became the champion of the Jakarta Asian Games. It stands at the top of the world again, and Chinese volleyball has entered a new stage of development. Volleyball is a kind

of competitive sport which is dominated by technology [1]. It usually takes a long time and repeated training to improve skills. Long-term, high-load training is easy to make athletes' muscles and joints suffer from chronic injury or strain. If we do not pay attention to it, the condition will appear repeatedly or even worsen, and it will not be easy to cure completely. Sports training, competition practice, and sports injury are inseparable. Training can improve the athletes'

sports level. Competition is one of the standards to test athletes' sports ability. But at the same time, unreasonable, overload training or incorrect technical movements will also cause sports injury, affecting the normal training and the improvement of competition results. Therefore, it is one of the necessary conditions for volleyball players to know the common sports injuries, preventive measures, and rehabilitation means. Shoulder arthritis is very common in sports, especially in badminton, volleyball, swimming, baseball, and other items; because of the retrograde movement of athletes' upper limbs, it is easy to produce the symptoms of shoulder joint pain. In 2016, the National Training Bureau also carried out statistics on athletes' rehabilitation injuries. The main injuries of shoulder joint were subacromial impact syndrome, rotator cuff injury, and Meng lip injury.

Shoulder joint injury [2] is one of the most common injuries of volleyball players, which is an important reason to affect the training and competition performance of volleyball players. In volleyball, shoulder joint is used in defense, block, spike, and serve. Therefore, volleyball technique depends on the function of shoulder. In the process of spiking, the strength is transferred from the body, shoulder, elbow, and wrist to the end of the upper limb. When it is transferred to the end of the upper limb, it needs to reach a higher speed to catch a high-quality ball. When you swing your arm, you need to overcome a lot of resistance and a lot of spiking. Shoulder joint, as an important part of the upper limb and body power transmission, needs to bear high exercise load. Therefore, if the athletes continue to carry out high-load training under the condition of insufficient preparation or irregular technical movements, they may damage the shoulder joint. Shoulder joint is the largest and most flexible joint of the upper limb. The articular surface is large, the glenoid is shallow and small, the joint capsule is loose, and the ligament is weak. These physiological characteristics determine that the shoulder joint has good flexibility and poor stability. In the volleyball injury technique, the shoulder joint injury caused by impact is the most likely. The common cause of shoulder pain caused by shoulder joint injury is subacromial impact syndrome, and the nature of the injury is mainly chronic injury. In daily training and competition, due to the need for multiple swing arm strokes, high-intensity, long-term exercise on the shoulder is easy to make the impact of the coracoacromial arch, leading to subpeak mucositis, and more serious will lead to shoulder sleeve tissue degeneration or tear, leading to shoulder pain and obstacles. The method of adding vibration stimulation to conventional strength training can more effectively improve the effect of volleyball players' shoulder joint strength training.

When spiking the ball, the abduction angle of the upper arm is less than 120°, and the flexion of the arm to hit the ball forward and downward at a high speed is the most important factor leading to shoulder injury of the players. Secondly, because these young players started the college entrance examination for sports from the second and third year of high school, and the training time was tight, so the exercise load and amount of exercise were not reasonable enough. In recent years, semiconductor polymer nanoparti-

cles with strong near-infrared absorption and good biocompatibility have attracted people's interest in biosensors, fluorescence imaging, photoacoustic imaging, and photothermal therapy. There are three commonly used methods for preparing conjugated polymer nanoparticles: nanoprecipitation, microemulsion, and self-assembly. However, these conjugated polymer nanoparticles with hydrophobic surfaces are not stable in themselves, and their surfaces do not further couple the functional groups of biomolecules. In general, amphiphilic polymers or phospholipids can be coated on the surface of conjugated polymer nanoparticles to improve their biocompatibility and provide further modified functional groups. Therefore, most of the existing conjugated polymer nanoparticles have the problems of easy dissociation and poor structural stability, which hinder their application in biomedicine. In recent years, it has been reported that hydrophilic polyethylene glycol (PEG) [3] is grafted onto the main chain of semiconductor polymer to prepare nanoparticles with stable structure. However, the synthesis of amphiphilic semiconductor oligomers requires a time-consuming and laborious process. Each modification is specially designed for each different semiconductor-conjugated polymer. Therefore, it is necessary to prepare semiconductor polymer nanoparticles with stable structure, surface functional groups, excellent imaging, and therapeutic properties [4]. This paper studies the treatment of volleyball players' shoulder arthritis with nanomaterials combined with exercise rehabilitation therapy [5, 6]. Badminton is an indoor sport that uses a long-handled mesh racket to hit a small ball made of feathers and cork across the net. The badminton game is played on a rectangular field with a net in the middle of the field. The two sides use various techniques and tactics such as serving, hitting, and moving the ball to hit the ball back and forth on the net so that the ball does not fall within the effective area of its own side or make the opponent miss the ball to win.

In volleyball, serving and spiking are the two most lethal techniques in volleyball, and they are also the basic techniques that are mainly controlled by the shoulder joint, using the most and deepest techniques of the shoulder joint. The joints have certain physiological and anatomical weaknesses, and if they are not well adjusted in the teaching and training, sports injuries will be caused. Shoulder injury will not only disrupt the daily training rhythm of volleyball players but also reduce their competitive level and performance and even end their career in advance. On this basis, this study compared the characteristics of athletes with or without shoulder arthritis in the school of education, Nanjing University of Physical Education, and the observation of shoulder pain, the impact of stability and flexibility syndrome peak, and the peak of power sequence and arm swing to complete the mobilization and recruitment of dynamic chain muscle strength are different from the normal shoulder joint function of athletes. On the one hand, through the timely evaluation and detection of the shoulder function of volleyball players, functional training is carried out for the weak points of the shoulder to prevent injuries. On the other hand, after the occurrence of mild injury, timely targeted training should be carried out to find and correct wrong

movements, strengthen weak muscle strength, reduce the chance of injury recurrence, and improve sports performance and competitive ability. Through the application of nanomaterials combined with sports rehabilitation therapy in the experimental group and the traditional treatment in the control group for 5 weeks, respectively, the physical examination of the two groups of volleyball players' visual analogue scale (VAS) pain score and shoulder joint isokinetic test (including shoulder joint extension and adduction, shoulder joint extension and adduction, and shoulder joint isokinetic test) was carried out. The results show that the viewpoint put forward in this paper is conducive to the recovery of shoulder arthritis [7]. The results can provide a reference for the scientific training and rehabilitation of volleyball players and provide suggestions for the treatment and prevention of shoulder arthritis of volleyball players. Visual analogue scale (VAS) is a simple method for measuring pain intensity in clinical practice. The basic method is to use a walking scale about 10 cm long, with 10 scales on one side, and two ends, respectively. Among them, the "0" score indicates no pain, and the "10" score indicates the most severe pain, which is unbearable. In clinical use, turn the scale side away from the patient and let the patient stand on the ruler; the corresponding position that can represent the degree of pain is marked on the top, and the doctor assigns the score according to the position marked by the patient. In daily training and competition, volleyball players with subacromial impact syndrome will have pain in their shoulder when they repeatedly serve and spike for a long time, which will negatively affect their shoulder function, competitive ability, and psychological state.

2. Preparation of Conjugated Polymer Nanomaterials

The conjugated polymer system [8] of the molecular main chain contains large delocalized π bond. The most important characteristics of them are that they have three unsaturated carbon bonds, double space carbon bonds, or single structure bonds intersecting with aromatic rings. This property is conducive to the delocalization of free electrons and carriers in the polymer. The delocalization and delocalization polarization of the internal structure of the conjugated polymer directly affect the luminescence of the conjugated polymer. Because of the long-range shift and large π bond, the gap between the molecular energy level becomes smaller and smaller, and the free electron can move freely along the main chain of the main chain-conjugated polymer, that is, the so-called "molecular line" effect. Conjugated polymers have excellent electrical signal conductivity, excellent energy transfer rate can achieve the effect of signal amplification, and fluorescence resonance energy transfer (FRET) [9] can achieve significant enhancement of fluorescence signal. Nanomaterials refer to materials that have at least one dimension in the three-dimensional space at the nanometer size (1-100 nm) or are composed of basic units, which are approximately equivalent to the scale of 10 to 1000 atoms tightly packed together.

2.1. Synthesis Methods of Common Conjugated Polymer Nanomaterials

2.1.1. Suzuki Coupling Reaction. The early Suzuki coupling reaction [10], sometimes called Suzuki Miyagi coupling reaction, was named after scientists Suzuki Chang and Miyagi. Suzuki's reaction mechanism consists of three steps in the catalysis and circulation, which has been widely used at present.

The first step is oxidation addition reaction. As a catalyst, LNPD and electrophilic RX have oxidative addition, and the product is a transition compound. The first step is the most important. PEG is a series of products that are nontoxic, nonirritating, and slightly bitter in taste, have good water solubility, and have good compatibility with many organic components. They have excellent lubricity, moisture retention, dispersibility, adhesive, antistatic agent and softener, etc. and are widely used in cosmetics, pharmaceuticals, chemical fibers, rubber, plastics, paper, paint, electroplating, pesticides, metal processing, and food processing. There are a wide range of applications in the industry.

The second step is transfer metallization. Under the action of alkaloids, organic borides are first transformed into negatively charged substances and then metallized with the products.

The third step is reduction and elimination of reaction. Product R is formed by transfer metallization and elimination process $R_1 - R_2$. The FLIR E40 touchscreen user interface is designed to be intuitive, taking full advantage of the full 3.5-inch display and providing easy access to all analytical tools. The 3 movable detection points can accurately and perfectly analyze three-phase electrical problems. By viewing the automatically calculated temperature difference, you can instantly grasp the crux of the problem. The temperature range and image can be fine-tuned. Various suitable color palettes are available to enhance detection. Thermal images are superimposed with visible light images for easy and clear positioning.

2.1.2. Heck Reaction [11]. Palladium is used as catalyst to catalyze the cross-coupling reaction of halogenated aromatics, haloalkenes, and vinyl compounds, which is called Heck reaction. It is worth mentioning that β-hydrogen, a free halogenated hydrocarbon, can also trigger the ghost alkylation reaction.

First of all, halogenated products have oxidation and replenishment; the matrix is coordination and transfer, carbon bond rotation, palladium and β hydrogen removal sequence, and catalyst deoxidation and elimination cycle.

2.1.3. Sonogashira Cross-Coupling Reaction. The synthesis of aryl halides and alkenyl halides with palladium or copper as catalyst under the catalysis of terminal alkynes is called the Sonogashira cross-coupling reaction. Transition metal catalysis is one of the most commonly used methods for the synthesis of carbon triple bonds. The Sonogashira reaction is widely used in material synthesis, natural material purification, active intermediate catalysis, and other fields. Due to the high price of palladium, copper catalyst is usually used.

The Sonogashira coupling reaction has been developed and improved by a large number of chemical researchers. On the one hand, the cost of the reaction process is low and the conditions for chemical synthesis are mild. On the other hand, a large number of novel green reaction conditions are used in the Sonogashira cross-coupling reaction, which has far-reaching significance in the field of chemistry and great potential in the development and application of real life. At present, the main problem is that the activity of copper salt as catalyst is not enough, and no efficient and cheap copper salt ligand has been found.

2.1.4. Glaser Polymerization. The oxidative stress polymer reaction with copper as catalyst is called the Glaser polymer reaction. The Glaser coupling reaction is also an important reaction to construct C-C single bond, which plays a key role in the synthesis of natural compounds, drugs, and optoelectronic information materials. In recent years, there are many reports about catalytic coupling reactions, mainly focusing on the search for new catalysts, new ligands, and new catalytic systems.

In recent years, the coupling reaction between polyethylene glycol and ionic liquid has been widely used in chemical industry. At present, polyethylene glycol and ionic liquid are the green media studied by many researchers. Compared with the Glaser reaction method using traditional organic solvent, the first two methods have simple conditions and high yield. On the other hand, reactants can be recycled and reused, thus greatly improving the utilization of atoms from the point of view of atoms in the chemical synthesis process. In addition, the odor of traditional basic organic amines can be rejected in the reaction process. In the process of chemical synthesis of Glaser in the medium of PEG, the effects of different molecular weight of PEG, different catalysts, different copper ligands, and different temperatures on Glaser reaction were studied. The best reaction conditions were selected, and the catalytic coupling of terminal alkynes with different properties was realized under the best reaction conditions. RX reacts with a non-transition metal-organic compound RM under the catalysis of transition metal complexes to form carbon-carbon bonds. The cross-coupling reaction has high efficiency, good selectivity, and mild reaction conditions and is an effective means of modern organic synthesis.

2.2. Preparation of Instruments. The distribution of nanomaterials in the cells and the production of ROS were studied by fluorescence imaging of Olympus IX81 laser scanning confocal microscope [12]. The cytotoxicity test and analysis were carried out by Casey cell count, enzyme-linked immunosorbent assay, and Sch RFE system. The temperature change of photothermal test was monitored by FLIR E40 thermal infrared imager; PerkinElmer used the new K-series III small animal internal imager to image the human shoulder.

2.3. Preparation Method of Polymer Nanoparticles. At present, the three methods most widely used in the field of conjugated polymer nanoparticles are nanoprecipitation, microemulsion, and self-assembly.

2.3.1. Nanoprecipitation Method. Nanoprecipitation is also called reprecipitation. The main step is to inject the hydrophobic conjugated polymer organic solution into the weak solvent represented by ultrapure water under the condition of ultrasound with certain power intensity. Under the hydrophobic action, the solubility of conjugated polymer in two solvents is very different. Once the conjugated polymer molecules extend in organic solvent, they will gradually agglomerate in ultrapure water and finally form spherical nanoparticles. In addition to the coupling polymer itself, the size of nanoparticles is also affected by their high concentration in the initial organic solution. Then, the organic solvent and excess water were removed by rotary evaporation apparatus, and finally, the conjugated polymer nanoparticles with good stable distribution were obtained.

2.3.2. Microemulsion Method. Compared with the nanoprecipitation method, the biggest difference between the microemulsion method is that the solvent phase is composed of acetone, dichloromethane, tetrahydrofuran, and other organic solvents and is insoluble in water. The most important thing is to add surfactants as stabilizers in the process of microemulsion preparation. The main function of surfactants is to prevent the aggregation of conjugated polymers. Firstly, the organic semiconductor polymer is dissolved in the organic phase and then injected into the super pure water mixed system containing surfactant. In the high-power water bath ultrasonic state, the organic phase in the conjugated polymer is dispersed slowly in the aqueous phase, and finally, the emulsion is formed. Finally, we can turn on the rotary evaporator, evaporate the excess organic solvent and ultrapure water, and finally form the nanosolution we need. In this process, the emulsion forms four conjugated polymer nanoparticles through nucleation, coalescence, agglomeration, and heat treatment. Microemulsions typically consist of surfactant, cosurfactant, solvent, and water (or aqueous solution). In this system, two immiscible continuous media are divided into tiny spaces by surfactant amphiphilic molecules to form a microreactor, the size of which can be controlled in the nanometer range, and the reactants react in the system to form solid phase particles. Because microemulsion can precisely control the particle size and stability of nanomaterials, it limits the nucleation, growth, agglomeration, and other processes of nanoparticles. The resulting nanoparticles are coated with a layer of surfactant and have a certain amount of condensed matter structure.

2.3.3. Self-Assembly Method. Compared with the former two methods, the self-assembly method is relatively simple. Its main step is to suspend or completely dissolve the conjugated polymer and coassembly materials with positive and negative charges in ultrapure water. They vibrate violently in a certain proportion, and then, we can directly get the nanoparticles we need through the centrifugal process at a certain speed.

3. Research on the Combination of Nanomaterials and Rehabilitation Therapy of Shoulder Joint Injury

3.1. Causes of Shoulder Joint Injury. The shoulder joint injuries of 75 volleyball majors in the Nanjing Institute of Physical Education were investigated by questionnaire and observation. It is found that the key to shoulder joint injury in volleyball is serve and spike. The main reason for the injury is that the athlete's technical mastery is not comprehensive and the standard and warm-up are not enough. Excessive shoulder abduction angle is the key to shoulder injury. The average abduction angle of attacker with shoulder joint injury was 146.51° and that without injury was 117.23°. The results show that the optimum temperature range is between 105° and 130°. In addition, the reason of shoulder injury is that the swing sequence of the upper limb is not the swing time and the front limb is too long. When smashing, the abduction angle of the upper arm is less than 120°. At the same time, the arm bends to hit the ball forward and down at high speed, which is the most important factor leading to the shoulder injury of small players. Because of the structural attribute of shoulder joint and the high requirement of hitting speed due to the action range and explosive force in volleyball match, students are easy to cause shoulder joint injury under the premise of nonstandard and uncoordinated volleying. The second important reason is the shoulder injury caused by the difference of preparation and physical fitness. In addition to the weakness of the anatomical results of the shoulder joint itself, the technical links leading to the shoulder joint injury include the following: due to the rigidity of the limbs, unable to understand the flogging action, directly press the upper arm down to hit the ball; the force sequence is wrong, and the elbow joint is dominant; the shoulder is not relaxed enough, and the arm is in the leading stage; the whole body lacks the process of coordination force, and the coordination force is just the local force of the shoulder; the jump time is not correct, and the ball is not buckled or missed.

To sum up, the causes of shoulder injury of volleyball players can be started from internal and external factors. The internal reason is that the shoulder joint is composed of humeral head and scapula, which is a typical ball and socket joint. The joint capsule is thin and loose, the joint basin is shallow, and the shoulder joint is flexible but unstable. Its stability mainly depends on the dynamic balance of shoulder joint muscle strength. If the amplitude and speed of the upper limb movement are too large and too fast, the imbalance of muscle strength between the protomyo and the antagonistic muscles is easy to cause damage. The external reason is in all volleyball techniques, serve and spike are the two techniques with the highest score. If the team wants to win, they will do these two exercises over and over in their daily training. Jumping and spiking refers to that when the human body is in the air, the strength of the trunk is transferred to the shoulder to drive the arm to swing and hit the ball. The damage caused in this process can be divided into two situations: one is that there is a mistake in the take-off process, and then, the ball is hit into the air; the other is that

the technical action at the moment of hitting is not standardized, which is easy to cause shoulder damage.

3.2. Sports Rehabilitation Therapy for Shoulder Joint Injury. It has been reported that Bobath handshake weightlifting training is mainly used for active and passive sports, lasting for 10-20 minutes, 4-6 times a day; the second is the centripetal winding method, 3-4 times a day. The research adopts a group of dumbbell strength training methods, which consist of eight movements, including shoulder bending 90 degrees and 180 degrees, 90 degrees abduction, push up, rotation, neck rear arm flexion and extension, and neck rear arm flexion and extension+rotation of the forearm internal and external rotation, easy to pull, basically including most of the shoulder joint function training mode; each group of dumbbell maintains 10 weeks through weekly incremental training. Rehabilitation training program is designed for patients with rotator cuff injury 3 weeks after surgery, with a total of four stages: in the first stage, shoulder joint fixation, elbow bending and expansion function, hand grip strength, wrist, rowing, and other exercises. The intensity of training develops gradually according to the patient's bearing range. The shoulder muscles perform long contraction movement, and the shoulder joints perform passive movement. In the second stage, the movement pain should be avoided as much as possible. The shoulder joint should carry out active and passive activities, just as it is assisted by pulley, shoulder ladder, and other equipment. The range of motion is controlled under the scapula to ensure no pain; while performing isometric contraction exercise, the muscles at different angles start to exercise the hand resistance function scapula movement, 20 times/time, 2 times/day. In the third stage, the glenohumeral joint and scapula are trained, and the stability of tendon sleeve training is ensured. According to the adaptation, the shoulder abduction activity plan is made by me. Gradually, return to the normal range of activity and continue to carry out posture correction training; muscle strength increased. Attach a low weight sandbag to the arm to enhance the stability of the joint, 40 times/time, 3 times/day. In the fourth stage, the resistance training should continue to recover the upper limb movement function, increase the strength training of the rotator cuff muscles as much as possible, then expand the rotation muscle tension, and enhance the muscle strength, proprioception, and flexible coordination training, which can improve the throwing, skills, and other training methods, 40 minutes/time, 3 times/day.

Some scholars have designed similar rehabilitation training programs: the first stage lasts for one week, mainly using grip strength training, elbow flexion and extension training, joint capsule tension training, neck extension training, and vertical swing training; the second stage lasts for five weeks, mainly using shoulder bending movement, external and internal rotation movement, and cuff muscle tissue, 10 times/group of exercise load. In the third stage, horizontal bending, large external rotation, shoulder bending forward, back pulling towel, and straight arm lifting were used. The results show that the rehabilitation training program can accelerate the relief of pain, shoulder joint movement

limitation, and other symptoms, reduce the dependence of anti-inflammatory analgesic drugs and local block drugs, and significantly improve the shoulder joint movement function.

There are also scholars who have studied a rehabilitation training program for excellent high-level volleyball players with shoulder arthritis. Rehabilitation training emphasizes the accuracy of the movement, based on the principle of small intensity and multiple times. Exercises include the following: (1) strengthening the stability of shoulder muscle group, upper limb stability exercise, and ball holding stability exercise of locking power chain, which are 30-40 seconds/ group and 3 groups/day, respectively. (2) The weight was small (3 kg), 20 times/group, 3 groups/day for the whole pot exercise, straight elbow rowing exercise, bird bending exercise, dumbbell shoulder turning exercise, shrug exercise, and dumbbell resistance exercise. (3) Elastic belt strength exercise includes abduction pull-up, forward pull-up, back pull, chest extension, front pull, forearm internal rotation, and forearm external rotation, 20-30 times/group, 3 groups/day. (4) The elastic rope mimics the forehand and backhand movements. The results showed that after 4 weeks of rehabilitation training, the angle expansion increased significantly, the pain of expansion and kidnapping disappeared, the strength of rotating muscle increased, the strength and stability of shoulder increased significantly, there was no pain, no soft feeling, fear disappeared, and no need for muscle paste protection.

3.3. Nanomaterials and Rehabilitation Therapy for Shoulder Joint Injury. Phototherapy with conjugated polymer nanomaterials is mild and will not cause obvious damage to normal tissue cells. Because the light source is absorbed by the photosensitizer gathered around the shoulder cells by the external light source, the external light source should have strong tissue penetration ability, and the near-infrared light is generally selected as the external light source [13]. At present, photodynamic therapy mainly includes PDT [14] and PTT [15]. Photodynamic therapy uses photosensitizers to capture light sources and then act on oxygen to produce monooxygen or reactive oxygen radicals. It uses the strong oxidation of singlet oxygen or reactive oxygen radicals to cause irreversible damage to biological cells and kill the pathogenic cells. Photodynamic therapy is a kind of treatment method that photosensitizers absorb near-infrared light to penetrate biological tissues, convert light energy into heat energy, and make the inflammatory cells of local shoulder joint reach high temperature and then kill the inflammatory cells.

(1) Photodynamic therapy (PDT) [16] is a kind of treatment method that uses photosensitizers to absorb light, produce single oxygen or reactive oxygen free radicals, kill inflammatory cells of shoulder joint, and treat shoulder injury. The basic reaction process is that when the photosensitive substance in biological tissue is illuminated, it absorbs photon energy and changes from ground state (S0) to excited state (S1). The excited photosensitive material is very

unstable, and it will emit energy back to the ground state (S0) by emitting fluorescence or system crossing into the three states (T1). Generally speaking, most photodynamic reactions involve the triplet state of photosensitizer. Triplet photosensitizers transfer the light of oxygen molecules under the condition of energy and produce singlet oxygen (type II). Photodynamic therapy (PDT) is a method that uses photosensitizer molecules to gather in the inflammatory cells of shoulder joint and then irradiates the inflammatory cells of shoulder joint with external light source to produce singlet oxygen or active oxygen free radicals, killing the inflammatory cells of shoulder joint. Photodynamic therapy has been widely used in the treatment of skin diseases and superficial tissue diseases because of its mild conditions and no damage to normal tissue cells

(2) Photothermal therapy [17] is a therapeutic method to kill inflammatory cells of shoulder joint by using heat generated by photothermal converter. The main working principle of photothermal therapy is as follows: under the action of photothermal conversion agent, the near-infrared light which has good penetrability to biological tissue is used as the excitation light source to improve the local temperature, so as to achieve the treatment method of killing inflammatory cells of shoulder joint. This kind of local treatment is simple and effective without obvious side effects. In recent years, photothermal therapy has been greatly developed, because light source and photosensitizer only need two basic conditions. However, because these photosensitizers need to penetrate tissues, they also need to have good ability to absorb near-infrared light. In addition, PTT can be used for deep treatment of shoulder inflammation because of its strong tissue-penetrating ability

Conjugated polymer nanomaterials combined with sports rehabilitation therapy can effectively cure the athlete's shoulder arthritis, relieve the athlete's pain, and quickly treat and prevent the recurrence of inflammation. In the case of conjugated polymer nanomaterials, photodynamic therapy or photothermal therapy can reduce the pain of patients with shoulder joint inflammation.

4. Results and Discussion

4.1. Comparison of Gender, Age, and VAS Score before Treatment between the Two Groups. Shown as Table 1, there were 50 volleyball players with shoulder arthritis. During the follow-up, 4 cases were excluded and 2 cases were dropped. Finally, 23 cases in the experimental group and 21 cases in the control group were followed up. There were 13 males and 10 females in the experimental group and 9 males and 12 females in the control group. There was no significant difference in gender between the two groups ($P > 0.05$).

Shown as Table 2, there was no significant difference in age between the two groups ($P > 0.05$).

Table 1: Comparison of gender differences between the two groups.

	Total/case	Male/case	Female/case
Experience group	23	13	10
Control group	21	9	12
X^2		0.004	
P		0.963	

Table 2: Comparison of age distribution between two groups ($\bar{x} \pm s$, year).

	Number/case	Age
Experience group	23	59.36 ± 4.35
Control group	21	62.27 ± 5.84
t		1.237
P		0.238

Table 3: VAS score before treatment in two groups ($\bar{x} \pm s$, min).

	Number/case	Age
Experience group	23	5.35 ± 0.35
Control group	21	6.34 ± 1.34
t		0.446
P		0.563

Table 4: Comparison of VAS scores of two groups at different time points after operation ($\bar{x} \pm s$).

	12 h	24 h	48 h
Experience group	3.02 ± 1.27	2.23 ± 0.65	2.79 ± 0.54
Control group	4.53 ± 0.84	3.61 ± 0.26	3.02 ± 0.82
t	-1.271	-1.029	-0.472
P	0.324	0.023	0.628

Shown as Table 3, there was no significant difference in VAS score between the two groups before treatment ($P > 0.05$).

4.2. Comparison of VAS Scores of Two Groups in Different Time Periods. Shown as Table 4, there was no interaction between time and group in repeated measurement of variance statistical analysis; VAS scores of the two groups at different time points had time effect; VAS scores of the two groups at different time points had group effect. It can be seen from Table 4 that the pain score of the experimental group is better than that of the control group at 12 h, 24 h, and 48 h, but the difference is not statistically significant ($P > 0.05$).

Shown as Figure 1, VAS scores of the two groups had grouping effect at different time points. As shown in Figure 1, there may not be any change at the beginning,

but after the method of the experimental group, the VAS score began to produce a qualitative change. The pain score of the experimental group was better than that of the control group at 3 weeks, 6 weeks, and 12 weeks, and the difference of VAS score from 4 days to 3 weeks was statistically significant ($P < 0.05$).

Shown as Figure 2, the number of compressions between the test group and the control group was 0-12 h, 12-48 h, 48-96 h, and 96-156 h, and the average number of compressions in the four time periods in the experimental group was smaller than that in the control group, with statistical difference ($P < 0.05$).

4.3. Adverse Effects of Analgesia in the Experimental Group within Two Days. Shown as Figure 3, the incidence of adverse reactions in the experimental group was 23.0%, among which nausea accounted for 30% and dizziness and headache accounted for 30%. The incidence of adverse reactions in the control group was 36.4%, including 4 cases of nausea, 2 cases of vomiting, and 5 cases of dizziness and headache. The incidence of adverse reactions in the experimental group was significantly lower than that in the control group ($P < 0.05$).

4.4. Shoulder Isokinetic Test. Shown as Figure 4, there was no interaction between the two groups through repeated measurement of variance statistical analysis; there was time effect in the constant Murley score of the two groups; there was grouping effect in the constant Murley score of the two groups. There was no significant difference in pronation and abduction scores between the two groups, but there was significant difference in the scores of 1 week and 3 weeks ($P < 0.05$). At 6 weeks, the scores of entropion and abduction in the experimental group were slightly higher than those in the control group, but the difference was not statistically significant ($P > 0.05$).

5. Conclusion

The stability and flexibility of the shoulder joint and the muscle control ability of the shoulder joint are decreased in patients with shoulder joint dysfunction. It is easy to cause injury; the activation sequence of shoulder muscles for those with shoulder joint dysfunction is inconsistent with the requirements of the volleyball spiking action, which is easy to cause injury and affect the spiking effect. The biological structure of human shoulder joint is complex. It consists of muscle group, skeleton, ligament, tendon, surrounding soft tissue, and skin. There are nerves and blood vessels in the muscle structure of the shoulder joint, which provide power for the movement of the shoulder joint. Volleyball players need to spike, serve, and release the ball in training and competition engineering, which is easy to cause shoulder injury and inflammation. In order to catch the ball with quality and strength, it is necessary to overcome the huge resistance when swinging the arm. If the shoulder causes sports injury, it will seriously affect the play of skills on the field, resulting in the decline of competition results. In order to avoid the occurrence of such events, this paper proposes the
Figure 1: VAS score trend chart of two groups at different time points after operation.

Figure 2: Comparison of compression times of analgesia pump between the two groups in different time periods within two days after operation ($\bar{x} \pm s$).

Figure 3: Comparison of analgesic adverse reactions between the two groups within two days after surgery.

application of nanomaterials combined with sports rehabilitation therapy in the treatment of volleyball players' shoulder arthritis. Firstly, the preparation of conjugated polymer nanomaterials is studied, which can be used in photodynamic therapy or photothermal therapy to treat the shoulder inflammation of volleyball players. Therefore, the experimental group and the control group are divided into different treatment methods. The results show that the experimental group is better than the control group in VAS pain analysis, and the pain score is significantly lower than the control group. The number of times of the experimental group and the control group are the same as the control group in the comparison of the number of times of pressing. The adverse reaction rate of the control group is 36.4% in the test of adverse reactions of analgesia; the score of varus and abduction in the experimental group was slightly higher than that in the control group. It can be seen that the nanomaterials combined with sports rehabilitation therapy proposed in this paper have a very good effect on
FIGURE 4: Perioperative abduction scores were obtained before and after surgery at 3, 6, and 12 weeks ($\bar{x} \pm s$).

the shoulder arthritis of volleyball players, and there is a great market space in the future. Exercises to improve shoulder mobility are suggested to be added to the preparatory activities for daily training. During the intensive spike training week, more attention should be paid to activating weak small muscle groups and improving their strength, so as to keep the strength of the shoulder muscles balanced, so as to prevent shoulder joint injuries and improve sports performance.

Construction and Research of Amorphous Alloys and Ferroelectric Materials in the Digital Logistics Platform

Zhi Chen and Ying Wang (ID)

College of Economics and Management, The Open University of Guangdong, Guangzhou, 510091 Guangdong, China

Correspondence should be addressed to Ying Wang; ywang@gdrtvu.edu.cn

People have higher and higher requirements for the size, sensitivity, measurement range, repeatability error, and power consumption cost of sensors and memories in the field of electronic information technology. "Logistics" as another new industry in the modern social division of labor is showing its infinite vitality, and the rise of digital logistics is the use of network technology to meet the development of this era. Based on the application of amorphous alloys and ferroelectric materials to the construction of logistics digital platform, this paper is aimed at demonstrating the function of nonstatic alloys and ferroelectric materials to promote the data storage of logistics digital platform and other aspects from multiple perspectives. This article is mainly divided into two general directions. The first is to study the physical and chemical properties of amorphous alloys and ferroelectric materials separately. The content of the article is more complete by referring to relevant research literature or obtaining relevant targeted information; the basic structure of the digital logistics platform is modeled, and the application of amorphous alloys and ferroelectric materials is mainly applied to the two parts of the data service composition and the data layer. This arrangement is based on the sensor as the key to data processing. Location is of great significance to the entire platform system. The experimental results show that the digital logistics platform constructed in this paper can reach a score of 7.75 in terms of data security and 7.39 in terms of flexibility. It also increases the efficiency of the entire operation process.

1. Introduction

With the rapid development and rapid popularization of computer network application technology, electronic trading platforms have gradually increased. After development, a comprehensive trading system with a complete logistics system, financial services, and platform technology has been gradually formed [1, 2]. E-commerce is in a stage of rapid growth with strong growth, and many companies are approaching the direction of e-commerce, and modern logistics systems must rely on efficient modern logistics information platforms [3, 4]. In the traditional transaction mode, it is difficult for the demand side to know all the conditions of the materials, which is not conducive to the sale of the supplier, and it is not conducive to the purchase of the demand side. Because the concept of logistics is highly valued in the rise of e-commerce and the development of modern logistics relies greatly on the construction of information, information technology in logistics is another important application industry in

the future information industry. Utilizing the accuracy, speed and openness brought by information technology greatly facilitate both supply and demand, better adapt to the needs of social and economic development, and promote the transformation of material transactions from traditional models to electronic transaction models [5].

In the customer-centric era, time and information efficiency are of the utmost importance. The efficiency of logistics management directly determines the efficiency of the entire supply chain [6]. With the application of the sharing economy, human logistics has become an emerging industry, and only logistics-based management platforms can show its efficiency and flexibility. Through the standardization of company logistics and warehousing, further improve the management process of warehousing logistics, so that the company has the ability to provide logistics public services. With the help of the R&D platform, the synchronization area of the business center is developed to reduce the loss of income caused by internal use and to increase

the integration of the sources of all parties and strengthen the source [7].

Due to the wide practicability of amorphous alloys and ferroelectric materials, researchers at home and abroad have paid a lot of attention. Lee et al. at home and abroad have prepared a Zr-based amorphous alloy-based composite material reinforced by continuous fibers of tungsten (W) or tantalum (Ta) by liquid pressing technology. The relationship between their tensile strength properties, microstructure, and mechanical deformation was studied using the Hopkinson split tie rods. The dynamic tensile test results show that the maximum strength of W fiber-reinforced composites (757 MPa) is much lower than the quasistatic measured strength, while the maximum strength of Ta fiber-reinforced composites (2129 MPa) is very high, but it is not yet widely used [8]. Lesz and Dercz have prepared binary Ni-Nb amorphous alloy ribbons by melt spinning technology. Melt spinning, a forming method using polymer melt as raw material, is spun using a melt spinning machine. Any heating can melt or turn into a viscous flow state without significant degradation of the polymer and can be spun using melt spinning method. Differential scanning calorimetry was used to study the glass transition and crystallization phenomena of the alloy, and the thermal properties of the binary Ni-Nb tape during heating and cooling were analyzed by DTA. The structure and fracture morphology of the belt were examined by X-ray diffraction and scanning electron microscopy [9]. Kulikova et al. studied the crystallization process and determined the structure and thermal properties of the Al86Ni8Ho6 amorphous alloy in a wide temperature range. It found the three-stage nature of the crystallization process when heated to 700 K. According to the high temperature X-ray diffraction analysis data, the three-stage kinetic model of the crystallization process has a reaction sequence based on the calculation of multiple nonlinear regressions [10]. In Rajaei et al.'s research, Ni-Mo and Ni-Mo-P alloy coatings were electrodeposited on AISI304 stainless steel samples as metal bipolar plates to improve the corrosion resistance, hydrophobicity, and conductivity of the samples. Scanning electron microscope (SEM) micrographs show that the prepared coating is uniform and dense. Potentiodynamic and potentiostatic polarization tests carried out in a simulated PEMFC cathode environment show that the corrosion resistance of the coated sample is significantly improved compared with that of the bare sample [11]. Barrett et al. reviewed the application of light emission electron microscopy (PEEM) and low energy electron microscopy (LEEM) in the study of the electronic and chemical structure of ferroelectric materials. Both PEEM and LEEM can be used for direct and reciprocal space imaging. Together, they provide access to surface charge, work function, topography, chemical mapping, surface crystallinity, and band structure. The application examples of ferroelectric thin film and single crystal research are introduced [12]. Fedeli et al. use the (vector) phase-field model description of ferroelectric domain evolution coupled with electroelastic equations to establish a simulation framework for electromechanical active materials. Several numerical experiments were performed to test the behavior of the adopted simulation framework. They proposed equal geometric collocation as a cheap but very accurate alternative to standard finite element discretization, which is also suitable for complex coupling problems [13]. Gorodetsky et al. proposed the conceptual model of the digital platform for cyber-physical management of manufacturing enterprises in the industry 5.0, proposed the types of basic platform services, listed the minimum service set of each type, and described their functions. It confirmed the leading role of multiagent system as the basic software architecture and technology, developing digital ecosystem applications. Examples of digital platforms and smart service ecosystems are provided to manage the cargo transportation of Russian railways in accordance with the principle of "Uberization." Ubiquitization means transforming existing work and services into tasks that are independent of each other and assigning them when needed [14]. Obviously, these studies are aimed at any aspect of amorphous alloys, ferroelectric materials, and logistics digital platforms. However, there is a relative lack of research that combines the two of them or even studies based on these three subjects. In terms of methods, these studies are relatively singular, so that the experimental results have certain limitations.

The main innovations in the construction of amorphous alloys and ferroelectric materials in the digital logistics platform studied in this paper are as follows: (1) By studying the interaction between defects and microstructures in ferroelectric materials, in-depth exploration of the failure mechanism of ferroelectric materials has better theoretical guiding significance for the reliability design of smart components. (2) By studying the interaction between electrical inclusions and microstructures, the hysteresis loops of different electrical inclusion models are given, so that the dielectric constant of electrical inclusions can be controlled to improve material properties or prevent material performance degradation. (3) The phase field method is used to study the stress field and microstructure evolution process of the electrode tip in MFA under different applied electromechanical loads and different temperature environments. The main consideration is the effect of temperature changes on the stress concentration area. (4) The temperature change of a substance is often closely related to the change of the microstructure and macroscopic properties. Through thermal analysis, accurate thermodynamic data related to the chemical reaction or physical process of the substance can be directly obtained.

2. Theoretical Analysis of Amorphous Alloys and Ferroelectric Materials

2.1. Ferroelectric Materials. In the past few decades, low-dimensional ferroelectric materials such as ferroelectric thin films, ferroelectric nanowires, and ferroelectric nanopillars have been widely used in the development of micronano devices due to their various excellent physical properties [15]. The preparation technology of ferroelectric materials is also more and more developed. Ferroelectric materials developed by the combination of thin ferroelectric thin films and microelectronics technology have become the most

active field of ferroelectric research in the world. Ferroelectric materials have a thermoelectric effect [16]. Ferroelectrics belong to pyroelectric crystals, but the crystal structure is more special. With its inherent characteristics of low energy consumption and fast response, it is widely used in the preparation of microfunctional components and has become a hot research object. Density functional theory does not care about the specific configuration of electrons. Its central goal is to find the space distribution of charges corresponding to the ground state of the system and to describe the physical state and chemical properties of particles, materials and solids through corresponding particle density functions. Multiferroic materials with ferromagnetic and ferroelectric properties are mainly concentrated in transition metal (rare-earth element) oxides, mainly due to their complex electronic structures and competing interactions. The mechanism of electric polarization is very complicated, and the corresponding multi-iron mechanism is also different. Ferroelectric materials can be applied to data storage [17]. Under the action of the stronger alternating electric field, the polarization intensity P of the ferroelectric body varies nonlinearly with the external electric field, and in a certain temperature range, P behaves as a double-valued function of the electric field E, showing a hysteresis phenomenon, and this P-E return line is the electric hysteresis return line. The hysteresis line is able to visually reflect the magnitude of the maximum polarization strength, residual polarization strength, coercivity field, etc., and the energy storage density of the material can be calculated from the hysteresis line integral. Due to the hysteresis loop of ferroelectric materials and the polarization reversal properties produced in the hysteresis loop, ferroelectric materials are widely used in ferroelectric memory (FRAM). Integrated ferroelectric materials are used in storage, infrared detection and imaging devices, ultrasonic and surface wave devices, and optoelectronic devices. In fact, under the action of external mechanical-electric load, the electric field near the crack is strengthened, which causes the electrical domain structure near the crack to reverse, that is, domain change [18, 19]. Since the accumulation of charge in the crack indicates that the electric field is concentrated in the crack, the formation of high-energy electric inclusions is formed. The crack tip produces high tensile stress concentration, which eventually leads to device failure. The digital oscilloscope completes the work of the acquisition card and does not require a voltage automatic attenuation module and a frequency measurement circuit, which greatly reduces the complexity of the circuit, while the operation is simple, and the integration and safety of the system are also improved [20].

2.2. Amorphous Alloy.

The amorphous alloy is solidified by ultrarapid cold solidification, the alloy solidifies when the atoms are too late to orderly arrangement of crystallization, the solid alloy obtained is a long-range disordered structure, the molecules (or atoms, ions) that make up its material are not spatially regular periodic, there is no grain, and grain boundaries of crystalline alloys exist. The best properties of amorphous materials are directly related to their unique atomic properties. Therefore, studying the atomic system

of amorphous materials is of great significance for understanding the properties of amorphous materials [21, 22]. A large number of scientists gradually discovered the insignificant value of these materials and supported their enthusiasm for the research of amorphous materials. The continuous grid accident model is used to describe the structure of metal-like amorphous alloys. The structural units of these amorphous alloys are random, and they are randomized in the form of copoint, collinear, and coplanar in a three-dimensional space. The connection forms a long-range disordered amorphous alloy. The structure of the amorphous alloy is isotropic, there are no line and surface crystal defects, and the metal bonding characteristics between atoms are maintained [23]. Compared with crystalline materials, amorphous alloy materials have a similar collision process. Considering the microstructure of amorphous alloys, the vacancies, interstitial atoms, and atom-depleted regions formed by it can exist instantaneously, but over time, these defects are impossible to stably exist in the amorphous alloy body. Related experimental studies have found that adding a certain number of large-scale atoms to the amorphous alloy will change its close packing mode, thereby reducing the corresponding diffusion coefficient and affecting its structural changes [24]. Many atoms show a certain state of coordination unsaturation, which makes the free energy of the system higher, which makes it have better mechanical properties and unique physical and chemical properties than traditional crystal alloys [25, 26]. The choice of opposing interaction forces in the system has a significant impact on the accuracy of molecular energy simulation results. Under low temperature or high pressure conditions, the tensile strength between the atomic plane of the amorphous alloy and the surrounding atoms is very strong, which is likely to cause a large amount of local plastic damage. However, large local atoms will not undergo plastic deformation due to local fatigue at high temperature or low pressure but will flow in a diffusion configuration [27]. The plastic deformation state of amorphous alloy is shown in Figure 1.

The energy saving and economic advantages of amorphous alloys are expected to be a reasonable and efficient evaluation method [28]. Amorphous alloys are widely used in distribution transformers, high power switching power supplies, pulse transformers, magnetic amplifiers, medium frequency transformers, and inverter cores, suitable for frequencies below $10\,\mathrm{kHz}$. Amorphous alloys are prepared by the powder solidification and direct solidification methods. At present, the structure determination technology of amorphous materials also shows certain application limitations in this aspect, and it is unable to accurately detect the atomic arrangement. Study the internal molecular dynamics of amorphous alloys, and use formulas to derive this process:

$$
R_\alpha = \sum_l Q_l(\delta_{l,k}(a)) + \frac{1}{2}\sum_{li}\varphi_{li}(a_{li}) - \sum_{i\neq l}\delta_i^x(a_{il}),
$$

$$
\varphi(a) = \left\|1 + \chi\left(\frac{a}{a_h}\right)\right\| \exp\left[-\varphi\left(\frac{a}{a_h - 1}\right)\right]. \tag{1}
$$

Among them, Q_l is the energy required for atomic

Compression   Ball punching

Push into   Bending

FIGURE 1: Plastic deformation state of amorphous alloy.

movement, $\delta_{l,k}$ is the electron density, and the distance between adjacent atoms is represented by a_{il}. According to the mechanical properties of the material, the multibody potential φ_{il} is simulated [29], and the density of the boundary structure can be calculated as

$$\delta(a) = \delta_o f(a-1) = \frac{1}{m-1} \left(\sum_{il} \chi(a - a_{il}) \right) \lim_{l \longrightarrow \nabla}(a),$$

$$[a_l(s+s_i) - a_l(s_0)]^2 = \lim_{l \longrightarrow \nabla} \frac{\|\bar{a}(s) - \bar{a}(s)\|}{s-1}. \qquad (2)$$

$\lim_{l \longrightarrow \nabla}$ represents the diffusion coefficient, s is the square of the average displacement, $\bar{a}$ is the position of the atom, m is the free volume, and the surrounding volume is represented by $f(a-1)$. After measuring the macroscopic hardness of the material with a Vickers hardness tester, it is found that the general hardness of the material has not changed. This is caused by the combined effect of hardness and elasticity, that is,

$$\iint s = \frac{R}{(3\pi)^{1.2r}} * \frac{1}{(Li)^{1.2}} \exp\left(-\frac{l^2}{3Li}\right),$$

$$\eta_{il} = \eta_{i0} = \frac{1}{3}\eta_{l1} = -\frac{\delta \forall r}{2(1-a)^2}. \qquad (3)$$

Since there is not enough time to make a specific dynamic system $\iint s$, the flow of the amorphous alloy is accompanied by an increase in its internal free volume content $\forall r$, to identify the enriched area and the sparse area, expressed by the following formula:

$$Q = \left(\frac{h_1}{\kappa}\right) \exp\left[-\frac{ya^3\alpha}{G(\nabla G)^2}\right]. \qquad (4)$$

The collision will change the trajectory of the particle. The particle moves along a broken line κ inside the material, constantly changing the direction of travel, and there is a complex cascade rotation outside [30, 31]. After the particle leaves, an empty space ∇G surrounded by a large number of oxides is formed.

3. Practical Application Data and Experiments of Materials in the Digital Logistics Platform

3.1. Properties of Amorphous Alloys. The storage system has become the bottleneck of data system performance improvement. In essence, intensive data computing poses unprecedented problems for the speed of storage systems. However, most storage systems, especially those that require high-speed data processing, are also built on custom magnetic hard drives. Because flash hard disks are completely built on semiconductor chips and do not have mechanical transmission functions, this different feature makes flash hard disks an efficient storage medium, which can improve the storage efficiency of mass systems [32, 33]. In the storage system, it is necessary to find a suitable location for the flash drive to achieve the proper balance between performance and cost. The existing method considers the difference of storage media, but does not consider the difference between the four functions. At this stage, magnetic hard drives are still very important in storage systems. Therefore, for most storage systems, flash drives should not be as easy to plan as replacing existing magnetic hard drives but should be a way to improve storage system performance. Many amorphous alloy materials have excellent corrosion resistance, which greatly promotes their practical applications in various technical fields. Because no matter what kind of product, its corrosion resistance is an important index to measure its quality; especially for sensor technology, this is even more important. The basic structure of the sensor provides the material basis for its work. But the sensor's sensitive components usually need energy while realizing its sensitive functions. And energy is basically provided by the appropriate form of circuit. In some important areas, it performs search operations better than other applications. The physical properties of amorphous alloys are shown in Table 1.

The breakthrough in the preparation process has enabled more and more millimeter-level bulk amorphous alloys and centimeter-level bulk amorphous alloys to be successfully prepared. Through some chemical theories, we have known that the activation point of chemical reaction is the defect in the material structure, and the reason for the formation of the galvanic cell in the electrochemical corrosion process is the fluctuation of the composition. Through industrial technology, we can deliberately introduce defects into the material to realize this material and analyze the mechanism and original elements of several

commonly used amorphous alloy materials preparation methods, as shown in Figure 2.

Amorphous alloys have a very unique microstructure. The magnetostriction of amorphous alloy materials has become an important reason that affects its magnetic properties because there is no obvious macroscopic magnetic anisotropy in amorphous alloys. It is the existence of this excellent characteristic that makes amorphous alloy materials become excellent high-resistance materials and precision resistance materials. To this end, research is carried out on the correlation between physical characteristics and performance, as shown in Figure 3.

Due to the existence of alloy composition, preparation process, heat treatment, and other methods when preparing amorphous alloys, amorphous alloys can also exhibit unique dynamic characteristics according to different production methods. The paper value of similar amorphous materials has little effect on the statistical results; but the effect of specific heat on the statistical results is more significant. Measuring pressure not only is a very important issue in various fields of production and scientific research but also has a very important meaning in people's daily life. By picking up the signal in the induction coil and processing the signal data, the changed voltage and frequency signals are finally obtained, and the relationship between the output voltage and the vibration frequency is explored, as shown in Figure 4.

The above figure is a data analysis of the correlation between the expansion voltage and the output voltage and the vibration frequency in different regions of different turns. On the whole, the output voltage expands with the continuous expansion of the voltage, respectively, when the voltage is 1.1 and 2.25 reaching the maximum value; and the relationship between vibration frequency and voltage is generally negative. When the temperature is constant, it decreases with the increase of the compressive stress, and when the compressive stress is constant, it increases linearly with the vibration frequency. Whenever a new type of functional material appears, people will try their best to apply this material to sensor technology and try to explore the advantages of these functional materials to serve the development of sensor technology. The output voltage increases monotonously with the increase of distance and pressure, and the oscillation frequency decreases monotonously with the increase of distance and pressure. It can effectively hinder the rapid expansion of the shear band, overcome the shortcomings of catastrophic fracture and no macroscopic plasticity of metallic glass materials during tensile deformation, and make the composite material on the basis of maintaining the high elasticity and high strength of the amorphous alloy. It has large compressive plasticity and hardness.

3.2. Ferroelectric Materials. Ferroelectric materials are indispensable electrodes and have been extensively studied. It has a variety of polarization conditions. At different frequencies, multiple polarization conditions will produce different effects, so the dielectric appearance of different materials is very different. And the higher the polarization strength and electrical distribution of the dielectric material is, the greater the possibility that the material size will be uniform. The ferroelectric crystal maintains the ferroelectric phase below the Curie temperature and has ferroelectricity. When the temperature exceeds the Curie temperature, the ferroelectric crystal undergoes a phase change from a tetragonal crystal level to a rectangular energy level and transforms into a paraelectric body, which causes the spontaneous polarization of the ferroelectric material. The refrigeration mechanism of the ferroelectric card is shown in Figure 5.

The microstructure of ferroelectric materials determines the macroscopic properties of ferroelectric materials to a certain extent, and the simulation of the microstructure is very important in material design. It is difficult for ferroelectric bulk materials to control the crystal orientation, but the crystal orientation also has a negligible effect on the physical properties of the bulk material. If a compact block is used as an active amplifier, the response speed of the composite block is low and the oscillator is high. As regards frequency characteristics, design curve is impossible. We know that under the excitation of the alternating electric field of the probe, the surface of the sample is deformed due to the inverse piezoelectric effect, specific to the local area of the sample surface touched by the probe which may produce a slope. The records of the data statistics of the electric card effect under different electric inclusion situations are shown in Table 2.

Most ferroelectric applications have a phase transition temperature from a high paraelectric temperature to a low ferroelectric temperature. The ferroelectric vibration theory proposed on the basis of the elastic state theory considers the participation of the electric field, which can fully explain the purpose of spontaneous polarization. The increase of the external electric field within a certain range can make the temperature environment generated by the giant electric card effect more biased towards room temperature and thus form a more friendly experimental temperature. As the temperature increases, the ferroelectricity of the ferroelectric single crystal becomes smaller and smaller, but the high electric energy generated by the concentration of the electric field at the electrode tip keeps the domain structure active.

3.3. Construction of Digital Logistics Platform. Digital logistics is a system provider, optimizer, and combiner. We combine all aspects of logistics chain information operations for customers, provide customers with operational solutions, collect real-time information, provide a platform for
Figure 2: The impact of different methods on different elements.

Figure 3: The correlation between physical characteristics and performance.

operational operations, promote the realization of logistics standardization, and constitute a multi-interface, multiuser, cross-regional, time-free macrologistics service platform. Nowadays, distribution and multitasking and manufacturing activities put forward requirements for the construction of

store systems and logistics platforms required by logistics companies, requiring logistics companies' applications and materials used in logistics to be more integrated, modern, and diversified. The logistics cost advantage is the core competitiveness of every logistics company. The logistics

Water	240	6.26	0.216

information platform of logistics enterprises can use this series of feedback data to carry out effective analysis and improvement, and at the same time, it can also strengthen the communication and cooperation between logistics enterprises and goods suppliers and subordinate agent distributors. Because of the impressive use of a large number of inactive resources in society, the economic distribution system has taken root in all walks of life, and the concept of distribution is deeply ingrained. The current network platform includes the field of live broadcast services. Digital logistics has no time and space constraints and can complete logistics tasks with high quality within the specified time. The platform architecture is shown in Figure 6. For suppliers or digital logistics platforms with multiple distribution centers, when selecting a distribution center, they often agree on the service scope of the distribution center.

Use these controls repeatedly on multiple pages. Compared with user controls, custom controls are another step forward. Collect multisource data through the data augmentation system. Firstly, it is integrated, sorted, and saved to the data system level and then transmitted through the data call bar. Filter out the appropriate data information according to the corresponding database table, and then return to the front-end interface for display. It provides a robust functional system and is very suitable for large-scale applications that require reasonable unit testing, such as a digital logistics information platform that can carry multiple systems. The first appearance of the system is the database operation interface. Users can click on the table to be modified in the navigation bar on the left side of the interface. When the database model changes, just change the mapping object of the model. Due to information asymmetry and information barriers, it will lead to waste of resources on both sides of the supply and demand. In the process of loss, the profits of each party cannot be maximized, and some even cause serious economic losses, which seriously disrupt the normal order of social and economic activities. Therefore, it is necessary for us to digitize logistics management. Part of the logistics and distribution data of a certain company is selected, as shown in Table 3.

System functional requirement analysis is to describe all the functional submodules of the system from the user's point of view, and it needs to reflect the function and operation process of each module. Analyze the characteristics of digital logistics, as shown in Figure 7.

The data in the above figure shows that the digital logistics platform constructed in this article can reach a score of 7.75 in terms of data security and up to 7.39 in terms of flexibility. The logistics information management platform uses the power of the Internet to develop a network system based on logistics information and improve information exchange. Part of the multihoming phenomenon caused by platform differentiation is normal behavior. The multilayer system structure can provide more complete components for the logistics information platform, which not only improves the stability of the system performance, power consumption, and reusability but also saves a lot of system development costs; the currently widely used electronic authentication technology has passed. The identification of the user's identity and effectively prevent illegal users from entering is an effective method for scientific management and control of the system. In this system, the number of people used is relatively large, and the data involved is also a lot, which has higher requirements for the accuracy and completeness of the data.

In the case of low cost of multihoming behavior of bilateral users of logistics platforms, logistics platforms need to face the problem of the scale of bilateral users in the market. The logistics platform's product differentiation product service strategy determines the transfer barrier of the logistics platform. Platforms with differentiated services can often lock users more stably in market competition. Logistics platform companies use advanced GIS geographic information system navigation and GPS transportation and vehicle tracking systems to provide optimized route services for cargo transportation on the platform and vehicle safety supervision during driving. Perform data evaluation on the four aspects of basic management, business management, supervision management, and decision-making management of three different logistics management modes: visual logistics, bilateral logistics, and traditional logistics, as shown in Figure 8.

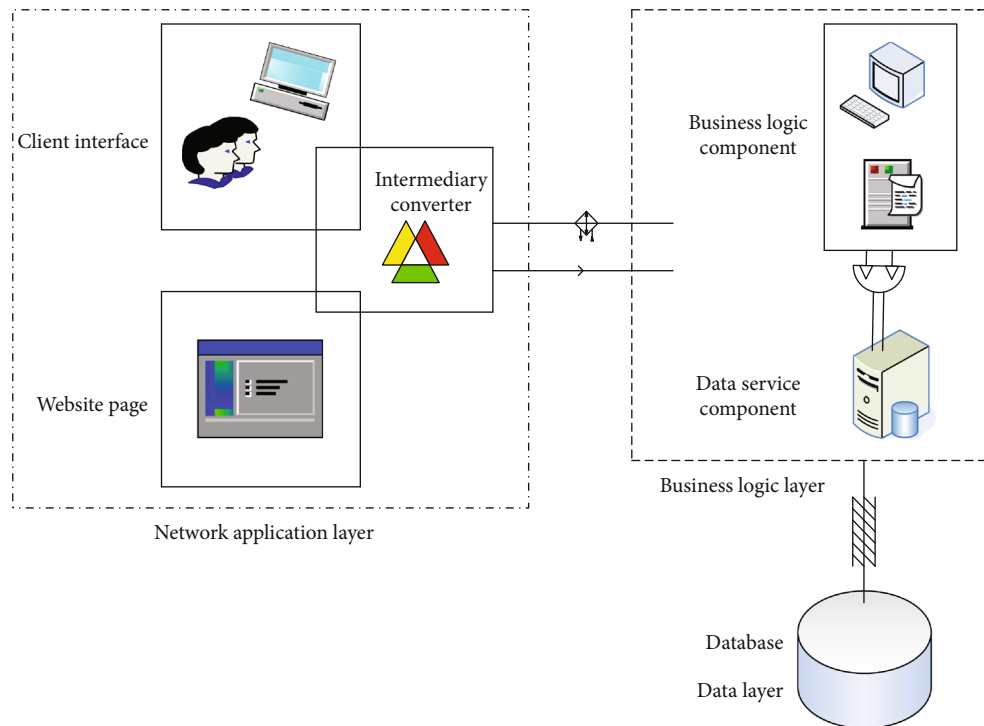
Compared with the traditional logistics management system, the digital logistics platform based on virtual simulation technology of logistics services can enhance the intuitiveness of river basin information expression and improve the system's display and processing ability of multi-dimensional and massive logistics data. The test of the system is not only a test for the function of the system, but also the operating environment of the system must be tested. Data owners need a set of effective data management and maintenance methods, and data users also need to understand the data and discover the data. In the process of data access, high efficiency, availability, and stability meet the development requirements. The scale of the data is conducive to the use


FIGURE 6: Platform architecture.

128	117.771	33.589

of users and ensures the security and stability of the data. Digital logistics can help Chinese transport enterprises to improve the efficiency of transport operations and the quality of logistics services. It is an indisputable fact in the industry that the operation of logistics needs to be networked.

4. Discussion

With the rise of the global Internet of Things technology boom in recent years, sensors, as the core component of the Internet of Things technology, have received unprecedented attention. The sensitive function of amorphous alloy material means that when this alloy is used as a sensor's sensitive material, it can convert the detected nonelectricity into a signal that is easier to pick up and process according to a certain rule. In some special occasions, it can also exert

unimaginable positive and effective effects. Therefore, when studying the use of amorphous alloy materials, the mechanical functions should be used properly and flexibly. So far, bulk amorphous alloys have significant tensile strength and value as advanced materials. The polarization time of amorphous materials is slower than that of thin film materials. Therefore, the result cannot indicate the exact location. In the whole process, the shape of the amorphous alloy material does not change. The magnetic properties of the amorphous alloy material are mainly used, and it is difficult to measure the pressure. Comprehensive utilization of various properties of amorphous alloy materials is for achieving the purpose of pressure measurement.

There are abundant material expectations for ferroelectric applications, especially in small sensors and transducers. Nowadays, more and more experts and scholars are beginning to use ferroelectric testing devices in a multiphysics coupling environment to explore the richer information of ferroelectric materials in a multiphysics coupling environment. Due to its own characteristics, in actual service, ferroelectric materials are affected not only by the electric field but also by the interaction and influence of the stress field and the temperature field. Ferroelectric materials often exhibit richer physical properties in a multi-physics coupling environment, thus expanding their application fields. The ferroelectricity of ferroelectric crystals is the result of the movement of electric domains on the microscopic level, and the hysteresis loop and electrostriction of ferroelectric materials are the result of the movement of electric domains. This research content is relatively small in this article, and follow-up work will conduct more detailed research on this.

5. Conclusion

Logistics distribution is an important part of modern logistics management, especially suitable for objects with a large number of workplaces, such as companies with thousands of customers. Many logistics companies have begun to explore the logistics platform model, hoping to achieve cost reduction and efficiency enhancement, transformation, and improvement through the construction of logistics platform, and significantly enhance their competitiveness. Warehousing is one of the most important links in the supply chain. The efficiency and cost of the warehousing system also directly affect the efficiency and cost of all logistics. In the available logistics and collection process, the incompetence of the distribution chain supply chain is often caused by the inaccuracy or poor visibility of information in the logistics process. The integration of internal logistics sources, the planning and optimization of supply logistics, production logistics, and sales logistics systems through centralized management and innovative services are in full swing, and some results have been achieved. The lack of data measurement and exchange methods has a significant impact on all aspects of storage, such as storage and messaging, and there is also a lack of supporting information to identify macro and micro decision-making. Track the location through the specific positioning of the logistics location, to realize the storage of commodity data and the process of emergency adjustment of orders when it is out of storage and real-time monitoring of the path of the outgoing process to realize visualization. These links have extremely high requirements for data processing technology.

Today, with the gradual improvement of material living standards, basketball is becoming more and more popular, and the pursuit of sports protection and shoes performance is also getting higher and higher. A good pair of basketball shoe soles can help athletes solve these problems. This article is aimed at studying the preparation of basketball shoe soles made of high resilience and nonslip composite materials. Under this research topic, this paper proposes a method for the design of shoe sole antislip pattern and the measurement method of composite material's resilience performance and a 3D printing method based on FDM technology to print the shoe sole. At the same time, an experiment was designed to explore the high resilience and antislip performance of the sole. And the stability of printing technology is analyzed to ensure the quality of sneaker printing. The experimental results in this article show that the antislip performance of the sole printed by the above method design has been improved by 31%, and the rebound capacity has been improved by 44%. At the same time, the rebound time is significantly shorter than that of several common basketball shoes on the market.

1. Introduction

The correct selection of sports shoes with appropriate functions is an important link that sports enthusiasts should not ignore. The structural design and material function of sports shoes play a very important role in protecting the human body and improving sports performance. The basketball population in China is increasing day by day, and there is a great demand for basketball shoes. Various manufacturers compete with each other for the research and development of basketball shoes. The functionality and professionalism of basketball shoes are the main considerations for fans. In a fierce basketball game, if a person's foot touches the ground, it will receive an impact from the ground to the human body. The impact of the impact can cause various damages to all parts of the human body. For example, if you twist your feet hard, your ankle will be sprained, your feet will be swollen, and pain will occur. At the same time, in basketball, excessive footsteps will move laterally, putting a burden on muscles and bones, and eventually, joint skills will decline, and tendons may become stiff. Basketball players will exercise their knees after a lot of sports. Injuries, ankle and middle finger injuries, are very common. At the same time, the antiskid of basketball shoes is also extremely important, which can effectively prevent athletes from slipping and causing ankle injuries.

However, there are two problems with the slip resistance and high elasticity of current basketball shoes. First of all, companies have exaggerated the antislip and elastic functions of basketball shoes, causing people to misunderstand the understanding and consumption of basketball shoes; second, as the basic performance of basketball shoes, the antislip and rebound ability has not received full attention from basketball shoe manufacturers. Most basketball shoes are designed with nonslip mode, and the structure is more beautiful than the actual function. The problem of ankle sprain caused by basketball foot slip cannot be solved at all. With this in mind, we believe that the study of the sole pattern and resilience of basketball shoe soles has important value and importance.

The sole design of basketball shoes is the focal point of the entire sports shoe. Basketball shoes are a prerequisite

for excellent performance. Basketball shoes provide excellent protection and elasticity, and most of these basketball shoes have excellent bottom design. With the increasing influence of basketball, more and more people have begun to devote themselves to the design of high resilience and nonslip performance of the soles of basketball shoes. Liang et al. proposed a feasible method to select the material of the beam collector in the HPM device. First, he compared the elasticity of several metals to strong relativistic electron beam (IREB) bombardment. This resilience is mainly determined by the density and melting point of the material. Compared with stainless steel, copper, molybdenum, and tungsten, titanium shows good resilience. Therefore, the theoretical results indicate that titanium is a promising material that can be used in HPM equipment [1]. However, this research is only an analysis based on theoretical research, and no experiment is used to verify the conclusion. Kakunuri et al. use the controlled pyrolysis of electrospun SU-8 photoresist nanofibers to fabricate a binder-free carbon nanofiber mesh on a stainless steel wafer collector. The electrochemical performance of the prepared carbon nanofiber mesh was studied by conducting charge and discharge experiments under different current densities. This excellent electrochemical performance can be attributed to the smaller lithium-ion diffusion length and the elasticity in the entangled carbon nanofibers to adapt to the volume changes during charging and discharging [2]. However, under different current densities, the charging and discharging experiments did not compare the performance under low current and high current, and there are still some deficiencies. Han et al. proposed that in order to make the structural noise of ship-borne equipment reach the prescribed standards, the excitation force of the equipment should be limited, and antivibration devices such as elastic supports and bellows should be added. Since structural noise depends on the design of the equipment base, it is important to achieve a low-vibration base design. In his research, the typical pump base was optimized using design of experiment (DOE) and computer-aided engineering (CAE) techniques to minimize the vibration transmitted from the equipment base to the ground [3]. However, there is still no clear statement on how to achieve a certain degree of antivibration through the structure of the material. Ju et al. conducted a parametric study on field data of more than 100 locations measured under two heavy object impact sources. The results show that the size of the room and the dynamic stiffness of the elastic floor mat material are the main factors affecting the impact noise of the floor. According to the analysis results, a simple regression equation of the impact noise of the heavy hammer is proposed. These formulas are expected to guide engineers to consider floor impact noise levels in the early design stage before construction [4]. Among them, the elasticity of the elastic floor mat material can be well used in our design. Xiao et al. tested the 4% cement stabilized base mixture in different system laboratories, including unconfined compressive strength and splitting strength of curing time, 90 d compression and splitting elastic modulus, erosion resistance, freeze-thaw resistance, dry shrinkage, and temperature shrinkage. And he conducted a comparative analysis of the test results [5].

We can use its experimental experience on elastic modulus for reference in our material elasticity experiment. Kim et al. believe that recycled synthetic resin materials produced from waste vinyl and waste plastics contain many foreign substances. Such plastic products made of recycled resin materials containing foreign matter are of poor quality, and their strength and rigidity are reduced. Foreign objects include heavy metals, cement, foil, dyed paper, and dust. After installing the manufactured equipment, recycled resin is produced, and its heavy metal content is evaluated. Recycled synthetic resin materials are also used in plastic products, and their strength is evaluated. In addition, changes in production are also evaluated [6]. For the preparation of PVC synthetic resin, we can use it in the preparation of shoe soles. Sun et al. modified the surface of iron-rich sludge with silane coupling agent KH550 to prepare modified iron-rich sludge, which was then filled into polyvinyl chloride to prepare PVC/KH550-FeS composite materials [7]. By modifying FeS, its heat resistance, stretchability, and other related properties can be improved very well, and the same can be done in the preparation of sneaker sole material PVC. By blending or adding various additives (such as antioxidants, etc.) to improve to enhance functional performance, Shen et al. classify polymer-based building materials into three categories: substrates, coatings, and adhesives according to their uses. And he carefully demonstrated the latest progress in their preparation and application [8]. Most of the appeal literature is about the consideration of elasticity, and the experimental analysis of the specific parameters of elasticity has not been explored in detail. The experimental part is also researched on the basis of theory, and the external environment factors in the actual use process are not taken into consideration. The innovation of this article lies in the theoretical support of the pattern design and antiskid design of basketball shoes. This article designs its antiskid pattern and resilience ability and designs experiments to analyze and compare its antiskid ability and resilience ability. At the same time, 3D printing technology is used as technical support to print the soles of sneakers in batches. The quality problems of sneakers that may be caused by parameter problems in the 3D printing process are also analyzed, and the influence of irrelevant factors is excluded, which can ensure the performance of sneakers while ensuring the output.

2. Sole Performance Design Method

2.1. Shoe Sole Antislip Pattern Design. The characteristics of the outer layer of the venue, such as material, reinforced hardness, and microhardness, will greatly affect the performance of antislip and wear resistance. In the link where the field and the pattern maintain continuous friction, due to the action of force and heat, the outer layer of contact has obvious changes (the antiskid pattern of the sole is worn, the sole is deformed, etc.), and such changes also affect the performance of friction loss. The outer morphology and microscopic contact of the field and the pattern continue to change during the friction process [9]. In addition, the microscopic components of the friction outer layer will also

appear to be cracked and transferred and then act on the shape of the contact outer layer, so that the antislip and abrasion performance of the outsole pattern will be significantly changed. Therefore, the status of the venue will be directly related to the functional attributes of the outsole pattern (floor humidity, antiskid ability, and floor material of the arena, etc.). When there are differences in venues, different outsole patterns should be designed (square, dotted, and divergent). The study of different sole patterns plays a vital role in the antislip performance of the soles. A good and suitable sole pattern can greatly improve the antislip properties of the soles [10].

The shoe soles with square pattern and small dot pattern have the best slip resistance on asphalt pavement and the second place on cement pavement. This is because both cement roads and asphalt roads are rough surfaces, and the soles are in surface contact when they are in contact with them. The contact area between the small dot pattern soles and the cement roads and asphalt roads is obviously smaller than that of the square pattern soles. Therefore, the test results of cement pavement and asphalt pavement are consistent. In other words, the sliding resistance of the sole of the square pattern is greater than the sliding resistance of the sole of the small dot pattern. The type of friction surface is an external factor and cannot be controlled. DuShaxun [11] of Shaanxi University of Science and Technology and others used two continuous, four continuous, and sliding block samples to study the antiskid properties of wood, cement, and marble on three different pavements. The double-sided continuous mode is composed of one or more decorative elements, and a specific curve is used as the skeleton to form a unit mode, which is arranged continuously according to a specific space, distance, and direction to form a regular pattern. The square continuous pattern is a pattern that uses one or more decorative elements to form a basic unit. It is repeatedly configured in a specific space according to a specific bone structure, and it can be expanded and continued indefinitely (it stretches through infinite stacking and cascading). In the experiment, the marble surface is the smoothest, the pattern that touches the ground is the largest, the adsorption between molecules is the strongest, so the friction between the ground and the sole of the shoe is the largest, and the sliding performance is the highest. However, due to the different places where various types of shoes are used (concrete road, indoor court, outdoor plastic court, etc.), that is, the road conditions are different, the pattern design is not single (zoomair, get, regular pattern, and chevron), it needs to be designed according to the external environment and different uses of the sole. The analysis of the foundation state of the basketball court mainly focuses on its surface shape. The characteristics of the foundation shape have a great influence on the movement function of the sole and the pattern design of the sole. The contact surface between the pattern of the shoe sole and the ground is composed of tiny raised peaks and valleys of various shapes. The shape of the thick peak of the contact surface between the outer Tor and the field is usually an ellipsoid. Since the contact size of the ellipsoid is much smaller than its own radius of curvature, it can almost be regarded as a sphere. The contact of two planes can be regarded as the contact of uneven spheres, which simulates the contact of rough surfaces in the ideal state [12].

2.1.1. Basketball Shoes. In the main distribution map of plantar pressure under different walking postures, the main force area and sliding trend of the stressed foot pressure are analyzed by measuring the plantar pressure of different adults' bare feet under different walking postures (duck gait, scissor gait, rooster gait, jumping gait, etc.). This coincides with the design of the circular pattern on the inner side of the forefoot of the basketball shoe. According to Figure 1 (measured gait is scissor gait), the analysis of the sliding trend of the stressed foot under different walking postures can also be used to design soles with different pattern directions for shoes of different purposes [13].

The circular outsole pattern is mostly used in basketball shoes (as shown in Figure 2). The outer sole pattern is usually the center of the circle on the inner side of the front sole. Because when a basketball player turns around while holding the ball, with one foot as the axis, the center of gravity of the body will fall on the inner side of the forefoot (resulting in larger hands on the forefoot of the sole, increased wear and tear, and easy to cause pattern wear). Designing a pattern with a heart shape here can make it easier for basketball players to do this technical action, turning more sensitive and saving effort. This pattern is especially suitable for big players.

2.2. Determination of Elastic Properties of Shoe Sole Composite Materials

2.2.1. Determination of Poisson's Ratio. Poisson's ratio is used to express the elastic properties of materials. (Poisson's ratio refers to the ratio of the absolute value of the transverse normal strain to the axial normal strain when the material is in unidirectional tension or compression, also known as the transverse deformation coefficient, which is an elastic constant that reflects the transverse deformation of the material). Poisson's ratio is defined as the absolute value of the ratio of the transverse strain A caused by the uniformly distributed longitudinal stress to the corresponding longitudinal strain B within the proportional limit of the material, namely,

$$\mu = \frac{-\varepsilon_x}{\varepsilon_y}. \tag{1}$$

At the same time, Poisson's ratio can be described by material performance parameters such as elastic modulus E, bulk modulus K, and shear modulus G [14]. For linear materials, the following relationships exist:

$$\mu = \frac{1}{2}\frac{(3K - 2G)}{(3K + 2G)},$$

$$\mu = \frac{E}{2G - 1},$$

$$\mu = \frac{1 - E/3K}{2}. \tag{2}$$

Figure 1: Analysis of the sliding trend of the stressed foot in different walking postures.

Figure 2: Basketball shoes with nonslip patterns.

When two of the three quantities of the material's elastic modulus E, shear modulus G, and bulk modulus K are known, the Poisson's ratio can be calculated.

For the Poisson's ratio of isotropic linear elastic materials, expression (1) is fully applicable. In the case of viscoelastic materials, Poisson's ratio is a parameter related to both temperature and load time. According to the nature of the load, it can be divided into static viscoelastic Poisson's ratio and dynamic viscoelastic Poisson's ratio [15, 16]. The former represents the transverse strain response to longitudinal strain under static load conditions, and the latter represents the transverse strain response to longitudinal strain.

Under dynamic load conditions, it represents the response to longitudinal strain. According to the viscoelastic properties of the material, the distortion has hysteresis. Therefore, we have sufficient reasons to believe that the Poisson's ratio of viscoelastic materials is more complicated.

Starting from the definition of Poisson's ratio, this article uses a static strain gauge to determine the Poisson's ratio of the resin matrix according to the full-bridge connection method, as shown in Figure 3. R1, R2, R3, and R4 are resistance strain gauges, R1 and R3 measure longitudinal strain, R2 and R4 measure lateral strain, and RL is a temperature compensation sheet. The full bridge approach we use can

efficiently utilize the concept of double differential. Therefore, the output voltage can reach as much as 4 times of the single-arm output voltage, which can greatly improve our measurement sensitivity in the actual measurement [17].

The measurement of Poisson's ratio is carried out under relaxed conditions, that is, the strain of pure resin material is compressed by 2%, and the change process of Poisson's ratio with time in 100 minutes is measured. Among them, the proportion of the test piece is 1 : 1 according to the volume ratio of resin to curing agent, and the plasticizer is 5% volume fraction of dibutyl phthalate and xylene agent, pouring the test piece in a 50 ml syringe and cutting it according to a certain size. The measurement result is shown as the solid line in Figure 4.

It can be found from Figure 4 that the Poisson's ratio of pure resin material also has relaxation characteristics, gradually decreasing until it stabilizes. The Poisson's ratio under relaxation conditions of viscoelastic materials is similar to the relaxation modulus, and the expression of attenuation series can also be used to approach the experimental data [18–20]. Using the origin curve fitting function, the result of Poisson's ratio can be fitted to the dashed line in the figure above, and the fitting curve expression is:

$$\mu(x) = 0.419 + 0.059e^{-1008x} - 0.054e^{-0.031x} + 0.062e^{-0.022x}.$$
$$(3)$$

2.2.2. Calculation of the Relaxation Modulus of the Combined Unit.
For a completely elastic material, there is such a relationship between the shear modulus and the elastic modulus and Poisson's ratio:

$$G = \frac{E}{2(1 + \mu)}.$$
$$(4)$$

But for linear viscoelastic materials, the relationship between shear modulus and elastic modulus and Poisson's ratio is related to time, and there is such an implicit relationship:

$$\int_0^t G(x - \tau) \frac{\partial \mu(\tau)}{\partial x} = \frac{E(x)}{2 - G(x)} [1 + \mu(0)].$$
$$(5)$$

Differentiate both sides of formula (5) to get:

$$G(0) \frac{\partial \mu(x)}{\partial x} = \frac{\partial E(x)}{\partial x} - \frac{\partial G(x)}{\partial x} [1 + \mu(0)],$$
$$(6)$$

where:

$$G(0) = \frac{E(0)}{2(1 + \mu(0))}.$$
$$(7)$$

$E(0)$ and $\mu(0)$ are directly determined from the experiment:

Solutions have to:

$$\frac{\partial G(x)}{\partial x} = \frac{((\partial E(x)/\partial x) - G(0)(\partial \mu(0)/\partial x))}{[1 + \mu(0)]}.$$
$$(8)$$

2.3. 3D Printing Process Based on FDM Technology.
According to the different printing methods of each layer in the molding process, the mainstream methods of 3D printing currently include fused deposition modeling (FDM), SLS, LOM, and SLA. However, the layered printing methods and materials used in the above technologies are quite different, and they all have their own advantages and disadvantages, and the fields of use are also different. In this paper, here's the advantage: additive manufacturing industry advances FDM 3D printers are feature-rich and can manufacture durable parts from your computer-aided design documents (CAD files). The parts are so robust that they can be used as high-level concept models, functional prototypes, manufacturing tools, and production parts. Engineers can produce a variety of products simply by loading different files and materials, which no other traditional machining process can do. FDM technology is used to 3D print the soles of sneakers to prepare the high-resilient nonslip sneakers we need [21].

2.3.1. Fused Deposition Modeling (FDM).
In fused deposition modeling (FDM), the thermoplastic material is melted by a heated nozzle, and the molten material is extruded from the nozzle by extrusion and friction, and it is coated on the worktable according to the slice model, and the parts are layer by layer [22].

The principle of FDM is shown in Figure 5, which shows a dual-nozzle printer. The filamentous prototype material (typically 1.75 mm or 3 mm in diameter) and the support material are printed by different nozzles. Usually, the support material will be made of characteristic materials (such as water-soluble materials), so that it can be removed by the corresponding method after printing. The coiled wire-like prototype material and supporting material pass through the wire feeding structure, and the wire is sent to the nozzle to be heated to a molten state. Then, according to the distribution data of the slice model on this layer, the corresponding prototype or supporting material is squeezed at the corresponding position, and it is coated on the workbench to gradually complete an entire layer. When a layer is completed, the nozzle rises a layer height distance. Then, the next layer is melted, and the newly coated layer is bonded to the previous layer, and so on, until the entire preliminary solid shape is completed. After the overall modeling is completed, the supporting materials are removed, the rough burrs on the solid surface are trimmed and then painted, polished, and colored as needed. Single-jet printing means that the prototype and supporting materials use the same material and the same nozzle [23].

The principle of fused deposition molding is easy to understand, simple in structure, and convenient to operate. PLA (polylactic acid) and various ABS plastics are often used. The materials are mostly in rolls and filaments, which are easy to carry and replace. At the same time, the overall
Figure 3: Full bridge circuit connection.

Figure 4: Poisson's ratio measurement results.

price of equipment and materials is relatively cheap (FDM, SLA, 3DP, SLS, LOM, and PCM). It is the most commonly used and popular 3D printing method in the current market. It has impressive performance in desktop and industrial printing. The disadvantage is that supporting materials are required, and the printing speed of the mechanical nozzle is slow, and the accuracy is slightly insufficient when making high-precision parts.

3. Experiment

3.1. The Antiskid Performance of the Sole of Basketball Shoes. According to the test data information given by "Underwriters Laboratories (UL)" and other institutions, when the friction coefficient does not exceed 0.4, it corresponds to a very dangerous interval, that is, it is extremely easy to slip. The friction coefficient is in the range of 0.5 to 0.6, which is the basic safety range. The friction coefficient $p > 0.6$, which is in a very safe range. This experiment is to use this standard as the antiskid performance standard of sneakers to conduct experimental investigations. The objects of investigation are 6 common antiskid basketball shoes on the market and experimental shoes printed by FDM technology combined with 3D printing technology (30 pairs of shoes of each brand were sampled for experimental investigation). The relevant parameters of the experimental objects are shown in Table 1.

As shown in Table 2, there are seven groups of test subjects. Let them move on the relatively dry-pressed ceramic floor, keeping the moving direction to slide forward horizontally. The antiskid friction coefficient of ordinary sports shoes is 0.73~1.25 (the average value is 0.98). Sliding the heel forward on the dry-pressed ceramic floor tiles, the antiskid friction coefficient of ordinary sports shoes is 0.67~0.98 (average value is 0.80). It can be seen that under dry conditions, the friction coefficients of ordinary sports shoes sliding forward horizontally and the heel sliding forward are both

greater than 0.6. It is in a very safe range, and the sole has excellent antislip properties.

As shown in Table 3, we moved seven groups of test subjects on the pressed ceramic floor filled with distilled water, keeping the direction of movement as horizontal and sliding forward. The antiskid friction coefficient of ordinary sports shoes is 0.59~0.75 (average value is 0.65), which is between the basic safe range and the very safe range. Sliding forward on the heel of pressed ceramic floor tiles with distilled water, the anti-skid friction coefficient of ordinary sports shoes is 0.37~0.58 (average value is 0.47). The average value of friction coefficient is in the range of 0.5 to 0.6, which is in the basic safe range. Only sample no. 2 has a sole friction coefficient of 0.37, which is in a very dangerous range.

From this, we can get the size of the forward horizontal sliding friction coefficient, which depends on the friction between the entire sole and the tile surface. The contact friction part between the heel and the tile surface is also another key factor that affects the friction coefficient of the forward horizontal sliding.

3.2. Resilience Performance Test of Composite Materials for Preparing Shoe Soles

3.2.1. Experimental Method. The tensile performance test of the composite material for preparing shoe soles is carried out in accordance with GB/T14337-2008.

Table 1: Related parameters of experimental sneakers.

Group	Brand	Price	Antislip parameters
1	Nike	1299	0.71
2	Adidas	2499	0.74
3	Anta	599	0.68
4	Li Ning	899	0.64
5	Jordan	800	0.66
6	Peak	500	0.65
7	FDM	—	—

Table 2: Sliding condition of shoe soles on dry-pressed ceramic floor tiles.

Sliding direction	Slide forward	Swipe back
1	1.1	0.98
2	0.8	0.7
3	0.73	0.67
4	0.8	0.72
5	0.86	0.76
6	1.13	0.89
7	1.05	0.85

Table 3: Sliding condition of shoe soles on pressed ceramic floor tiles with distilled water.

Sliding direction	Slide forward	Swipe back
1	0.66	0.4
2	0.61	0.37
3	0.59	0.58
4	0.6	0.41
5	0.61	0.54
6	0.7	0.53
7	0.71	0.5

Table 4: Elastic performance test results of different brands of sole composite materials.

Group	Breaking strength	Elastic modulus
1	5.34	1002
2	5.11	854
3	4.79	762
4	4.36	694
5	4.23	652
6	4.02	669
7	5.97	1283

First, equilibrating the prepared shoe sole composite material sample in a test environment with a temperature of $20 \pm 3°C$ and a humidity of $65 \pm 5\%$ for 24 hours.

Table 5: Test results of resilience performance of different brands of sole composite materials.

Group	Height before pressing	Height after pressing	Rebound time
1	2.3	2.28	8.6 s
2	2.5	2.47	7.8 s
3	2.8	2.75	9.1 s
4	2.3	2.29	8.8 s
5	2.5	2.5	7.9 s
6	2.2	2.19	8.2 s
7	2.4	2.39	7.1 s

Adjusting the electronic multifunction strength machine to the normal state, setting the pretension to 0.5 cN, the pull-up force value of 1 cN, the clamping distance of 20 mm, and the stretching speed of 10 mm/min. Tensile tests were carried out on the composite materials of the soles of seven groups of different brands from 1 to 7, respectively, and the number of experiments was 50 times in total.

3.2.2. Experimental Results. Table 4 shows the average experimental results of the composite materials of seven groups of different brands of shoe soles.

From the data in Table 4, we can see that the elastic parameters of several common brands on the market have reached a relatively excellent range, and the elastic modulus of the sole prepared in this experiment is 1283, and the breaking strength is 5.97. In that respect, they are significantly better than the shoes on the market. But at the same time, the resilience performance of sneakers is also more important. Now, we will explore its resilience performance and reflect the strength of its resilience performance through the resilience time. The specific data is shown in Table 5.

From the data in Table 5, it is not difficult to see that the resilience performance of several common brands of basketball shoes on the market is still good. The modulus of resilience of the soles prepared in this experiment differed by 0.1, which is considered to be an excellent price comparison. The rebound time is also far ahead of other brands of basketball sneakers. The time is only 7.1 s, which is 0.7 s faster than the second-placed 7.8 s.

4. The Influence of Sole Printing Parameters on Sole Performance

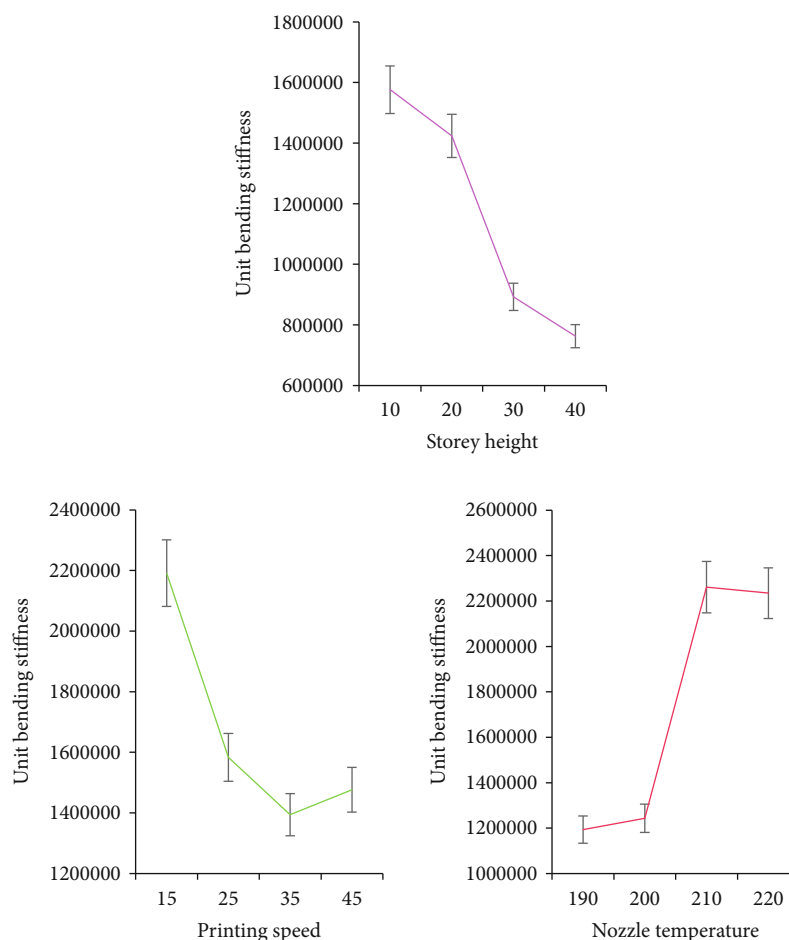
4.1. 3D Printing Impact Analysis. This section mainly selects 4 factors of layer height, thickness, printing speed, and nozzle temperature as independent variables. The single factor of KES style and stiffness are tested and orthogonally tested, respectively. This paper analyzes the relationship between 3D printing parameters and the surface, compression, and tensile properties measured in KES, as well as the influence of printing parameters on the stiffness of the printed sample, and obtains the best combination of process parameters for the corresponding performance. After measuring the bending length and the mass per unit area, the relationship between the printing parameters of the single factor


FIGURE 6: The relationship between each single-factor printing parameter and the bending stiffness per unit width.

experiment and the bending stiffness per unit width is shown in Figure 6.

From the Figure 6, we can see that in the range of 0.1 mm to 0.4 mm, the flexural rigidity per unit width decreases as the layer height increases. That is, the bending deformation ability of the printed sample increases with the increase of the layer height. In the thickness range of 0.5 mm to 1.0 mm, as the thickness increases, the bending stiffness per unit width increases. That is, the bending deformation ability of the printed sample decreases as the thickness of the printed sample increases. In the printing speed range of 15 mm/s to 45 mm/s, as the printing speed increases, the bending stiffness per unit width decreases first, and the trend tends to be flat around 35 mm/s. The overall trend is that the bending stiffness per unit width decreases with the increase of printing speed. That is, the bending deformation ability of the printed sample increases as the printing speed increases. In the nozzle temperature range of 190°C to 220°C, as the nozzle temperature increases, the bending stiffness per unit width increases, and the trend gradually becomes gentle. That is, the bending deformation ability of the printed sample decreases with the increase of the temperature of the nozzle. Overall, it has little effect on the antiskid and high resilience performance of sneakers.

5. Conclusions

This article mainly studies the preparation of sneaker soles made of high-resilient nonslip composite materials. First, this article analyzes the formula for high resilience. Through formula calculation, by comparing the suitable high resilience interval of the shoe sole, in terms of antislip performance, the pattern of the shoe sole is also analyzed, and the pattern with the best antislip ability is obtained by comparing several patterns. This article mainly studies the preparation of sneaker soles made of high-resilient nonslip composite materials. First, this article analyzes the formula for high resilience. Due to their unique characteristics, natural fiber reinforced polymer composites have recently been increasingly utilised to replace traditional materials. Fire retardant resins can increase flammability, and they have a deleterious influence on the mechanical properties of the material (Fan et al., 2020). As a result, this experiment examined the flammability of woven jute fiber reinforced with fly ash. The specimens were created by hand layup using a L9 orthogonal array and varying ratios of jute fiber, fly ash, and time for chemical fiber treatment. Vertical and horizontal flammability tests are conducted in accordance with ASTM D635 and ASTM D3801, respectively. According to the test results, the inclusion of fly ash significantly reduces flammability. In this work, 5 wt% inclusion of the jute fiber, 15 wt% addition of the fly ash, and with 10 hours, NaOH treatment produces a composite with minimum burning rates of 10.2 mm/min in horizontal UL-94 tests. To determine the link between input and output characteristics, various regression models from machine learning are used. Multilayer perception produced a stronger association in both horizontal and vertical testing, according to the models.

1. Introduction

Numerous plants and animals are naturally exploited to obtain fibers. Apart from this, numerous synthetic fibers are manufactured and reinforced. The shelf life and degree of biodegradability of fibers are determined by their physical and chemical structure. Synthetic fibers have superior mechanical properties over natural fibers since they are manufactured specifically for their intended use. Due of their unique characteristics and abundant availability, natural fibers are frequently used as reinforcement in polymer composites. Salem et al. examined the fundamental features of jute fiber reinforced composites and discovered that by increasing the interfacial bonding between the fiber and matrix, and the thermomechanical properties can be enhanced [1]. Ashraf et al. conducted a critical analysis and addressed recent advances in jute-based composites. Additionally, they illustrated the various issues associated with the excessive use of synthetic composites [2]. Saravanan et al. and Dinesh et al. discussed the challenges associated with developing composites reinforced with jute fiber using a variety of manufacturing techniques and reported on their mechanical properties. They discussed the mechanism through which the material degrades using scanning electron microscopy [3, 4]. Roya et al. investigated the fire resistance of jute cloth treated with flame retardants and

discovered that the treated specimens developed char and contained minimal volatiles [5]. Zaman et al. examined the challenges associated with developing natural fiber-reinforced composites with superior mechanical characteristics and chemical and flame resistance. They used a variety of treatments on natural jute fibers to strengthen the interfaces with resins [6]. Wang et al. conducted a characterisation study on silane-treated jute fabric and evaluated its thermal and surface properties, concluding that the treated fibers demonstrated increased stability in hot conditions due to the structures, as well as improved tensile characteristics [7]. Khalili et al. developed biodegradable composites by using flax fibers with hydroxyapatite nanoparticles. They discovered that the addition of flax fiber enhances the flexural and tensile modulus, whereas the presence of nano-HA reduces the strength and increases the water intake [8]. Sonnier et al. investigated the differences in fire retardancy between natural, glass, and carbon fiber reinforced composites and discovered that, when compared to natural fibers, carbon and glass fibers exhibit greater resistance to flame [9]. Shah et al. evaluated the flame resistance capabilities of numerous natural fiber composites and concluded that the inclusion of appropriate additives increases the natural fibers' flame resistance. He demonstrated that silicon-based additives perform better [10]. Oktem et al. enhanced the fire resistance and mechanical capabilities of hybrid jute/flax composite buildings while maintaining their attractive appearance. They enhanced these properties by a variety of chemical treatments [11]. Rashid et al. investigated the flame resistance of green composites and discovered that the synergistic technique significantly reduces the peak temperature rate while silane treatment enhances the decomposition temperature [12]. Mathubala and Nandhini synthesised jute fiber composites and investigated their heat and fire resistance properties, concluding that fiber adherence and bonding to the matrix improve the composites' fire resistance properties [13]. Latif et al. concentrated on the production of nanocomposites utilising vinyl ester as the matrix and jute cloth as the reinforcement. Additionally, they concentrated on organo-modified montmorillonite (OMMT), which has a high aspect ratio and a low surface charge density [14]. Shahinur et al. investigated the thermal properties of composites reinforced with jute fiber and discovered that fiber that had been chemically treated absorbed less heat than untreated samples [15]. Salimov et al. investigated the flammability and fire resistance of certain natural fiber and textiles in order to safeguard them from fire. Additionally, they provided the findings of their investigation [16]. Ribeiro et al. investigated the flame resistance of jute fiber reinforced epoxy composites intended for tile applications and discovered that the incorporation of jute fiber had no effect on the fire resistance [17].

Sakthi Balan et al. incorporated waste plastics and eggshells into composites along with jute and bahunia racemose fiber reinforcement and evaluated the composites' moisture absorption. They concluded that the addition of particulates and fillers reduces the composites' water absorption more than fiber do. Fibers promote moisture absorption because they are hydrophilic [18, 19]. Sakthi Balan et al and Nava-neethakrishnan et al. improved the composite's mechanical properties to make it more resistant to environmental influences. They examined critical parameters such as tensile strength, hardness, and resistance to moisture absorption and optimised the data to determine which factor had the most influence on mechanical properties [20, 21]. Nava-neethakrishnan et al. created an epoxy-based composite reinforced with MWCNTs/g-C3N4 and investigated the composite's water absorption and wear properties [22]. The properties that can be altered in the polymer composites make them versatile for applications in various fields, such as constructions, microelectronics, and biomedical fields. Devastations due to building fire stress the importance of flame-retardant polymer composites, since they are directly related to human life conservation and safety [23]. The flammability of a composite formed by reinforcing woven jute fiber with waste fly ash is investigated in this work. The data are optimised in order to determine the most significant element affecting flammability. The low-flammability specimen is recommended for usage in roofing materials as well as vehicle and airplane structures.

2. Materials and Methods

A composite is composed of a matrix as a base and a reinforcement to enhance the strength and some physical and mechanical properties. The physical and other composite characteristics can also be improved by choosing proper chemical treatment. On the whole, the strength of the polymer composite can be improved by proper chemical treatment of the fibers and by producing defect-free composites. Defects are mostly produced during the manufacturing of the composites, and proper measures have to be taken to minimize or avoid the common defects. In this work, natural fiber jute is chosen for reinforcement, a filler of fly ash is used, and its flammability studies are carried out as per the standards. Normally, fibers are used in many forms such as short fibers, long fibers, and woven fabric. When using the short and long fibers, orientation of the fibers and fiber density plays a major role. During the usage of natural fibers, the fibers have to be treated chemically to improve the bonding between the matrix and the fibers. In this work, the woven jute fabric is used which is chemically treated before usage. NaOH treatment is well suited for jute fibers.

Fly ash is used as filler material which is obtained from the thermal power plant which burns lignite-type coal. Generally, fillers are used to improve the surface and hardness properties of the composite. In this composite, the main purpose of using the filler is to reduce the pore formation during the production of the composite and to suppress the flame propagation during the flammability test. Normally, jute fiber is flammable, but if it is reinforced into a polymer matrix along with nonflammable filler powders, the flammability property of the material changes. Three factors are chosen as important and varied during the manufacturing of the composite as per Taguchi's experimental design. Percentage of fiber addition, percentage of filler addition, and the chemical treatment are chosen as the input factors, and the composites are manufactured. After curing, the

TABLE 1: Orthogonal array experimental design with burning rate UL-94 results.

Percentage of jute fiber	Percentage of fly ash	NaOH chemical treatment time in hours	Burning rate (mm/min)		Cotton ignition	Classification
			Horizontal UL-94 test	Vertical UL-94 test		
5	5	0	13.4	14.5	No	v0
5	10	5	10.8	12.3	No	v0
5	15	10	10.2	11.2	No	v0
10	5	5	17.1	19.4	No	v1
10	10	10	13.9	15.3	No	v1
10	15	0	11.8	13.1	No	v0
15	5	10	22.5	24.3	No	v1
15	10	0	19.9	21.2	No	v1
15	15	5	18.7	20.5	No	v1

composites are tested for their flammability by following the standard procedure as per ASTM standards. The jute fibers are chemically treated with NaOH with fixed concentrations. One set of fibers is used as untreated, and another set is treated for 5 hours and another set for 10 hours. After chemical treatment, the fibers are flushed with ordinary water and dried in an oven. Then, the filler powder fly ash is collected from the thermal power plant is sieved to remove the foreign particles and particles of varying sizes. The fly ash filler must be of the same size and as it is collected from the cyclonic separator and water scrubber, and the fly ash is also dried in the oven and then used. As the fiber and fillers are added in weight percentages, both are weighed before adding to the composite.

The composites are manufactured by compaction process using mild steel mold. The traditional hand layup process is used for making the composite. The epoxy is mixed in an equal ratio with the hardener, and the filler powder is also mixed along with resin and layered on the surface of the mold. Then, the woven jute fabric fiber which is chemically treated is stacked over the resin-filler mixture and then again a layer of resin and filler is layered. The process is repeated until the required thickness is obtained and then the composite is closed with a top cover and tightened using bolts and nuts. The whole setup is kept in the compression molding machine and given pressure so that the excess resin can be removed, and this compression removes the air trapped inside the composite stacking. Then, the setup is left undisturbed for 12 hours for curing, and then the composite is removed from the mold. The mold is then cleaned and used for stacking the next set of composite with different input factors.

3. Flammability Studies

Flammability tests on polymer composite materials are conducted according to the ASTM D635 protocol for horizontal UL–94 testing and ASTM D3801 process for vertical UL–94 testing. A specimen size of 1251333 mm is required to complete a flammability test. The test is carried out by fixing the specimen in horizontal and vertical directions with the help of a stand. Below the specimen, the base must be filled with a layer of cotton to check the dripping from the specimen. A

Bunsen burner is used to fire the specimen. The fire is introduced at the open end of the specimen for 10 seconds and then removed and allowed to propagate along the length of the specimen. A stopwatch has to be used for calculating the time taken for the specimen to burn from 25 mm to 100 mm. This process is repeated for all nine specimens, and the burning rate of the material is calculated using the following equation.

$$\text{Rate of Burning (mm/min)} = 60 \times \frac{\text{Length of the sample burnt (mm)}}{\text{Sample burning time (Seconds)}}. \tag{1}$$

Based on the time taken for the specimen to burn, the specimens are classified under v0, v1, and v2 classes. If the burning time is less than 10 seconds and without igniting the cotton, then, the specimen is classified under v0 category which has high flame resistance. If the specimen burns for less than 30 seconds and could not ignite the cotton at the bottom, then, it comes under v1 category. If the specimen burns less than 50 seconds and if the cotton underneath the specimen got ignited, then, it falls under v2 category which has less flame retardant. Some specimen burns completely and that falls under NC (no classification). The specimen without any dripping and has less burning time can be identified as a specimen with high flammable resistance.

4. Results and Discussion

Flammability tests were executed as per the standard procedure, and the cotton ignition was also checked for the dripping nature of the composite materials. The tested composites are categorized under three categories as v0, v1, and v2 based on the burning time of the composites. In Table 1, the parameters that are varied for the manufacturing of the composites and their different levels are listed along with the flammability test results. The results of the test were fed into MINITAB software for regression analysis and ANOVA table formation [24, 25]. Various plots are plotted during optimization to study the behavioral pattern of the results.
FIGURE 1: Burning rate—horizontal UL 94 vs. vertical UL 94 test results.

TABLE 2: Difference in values between horizontal and vertical UL-94 tests.

| Specimen number | Burning rate (mm/min) | | Difference in values |
	Horizontal UL-94 test	Vertical UL-94 test	
1	13.4	14.5	1.1
2	10.8	12.3	1.5
3	10.2	11.2	1
4	17.1	19.4	2.3
5	13.9	15.3	1.4
6	11.8	13.1	1.3
7	22.5	24.3	1.8
8	19.9	21.2	1.3
9	18.7	20.5	1.8

In Figure 1, the burning rate data for the nine specimens are presented alongside the results of the horizontal and vertical flame tests. The plot reveals that the test results are fairly similar and that the difference between them is very small. Table 2 indicates the difference in values between the horizontal and vertical UL-94 tests.

4.1. ANOVA for Horizontal Test. In Table 3, variance results for the flat test were mentioned, and the Fischer value suggests that the addition of jute fibers affects the firing ability of the material, and fly ash addition also suppresses the propagation of the fire. From the main effect plotting, as shown in Figure 2, the influence of the input parameters can be proved once again.

$$
\begin{aligned}
\text{Regression Equation for Horizontal UL} - 94 \text{ test} \\
= 10.32 + 0.8900 \text{ Composition of Jute fibers} \\
- 0.4100 \text{ Composition of Fly ash} \\
+ 0.0500 \text{ NaOH treatment.}
\end{aligned}
\tag{2}
$$

In Figures 3 and 4, the interaction between the input fac-

tors and the relation between the two most influencing factors were mentioned, respectively, through interaction and contour plots. From the contour plot observation, for minimum flammability, the inclusion of jute fiber must be 5 wt% and fly ash inclusion must be 15 wt%. From Figure 5, the contribution of factors can be understood. The equation for regression analysis of both the horizontal and vertical flammability tests was designated in equations (2) and (3).

4.2. ANOVA for Vertical Test. In Table 4, ANOVA results were tabulated, and the summary of the model is also tabulated.

$$
\begin{aligned}
\text{Regression equation for Vertical UL} - 94 \text{ test} \\
= 11.67 + 0.933 \text{ Composition of Jute fibers} \\

To know the significance of the model, the regression square value is verified. R-squared measures the strength of the relation between a model and the dependent variable on a convenient scale. After fitting a linear regression model, it determined how well the model fits the data. Based on the experimental results, the R squared value changes; in this work, we got the R-square value is 95.50% for vertical test and 95.10% for horizontal test, which indicates the significance of the model. Fischer's value from Table 4 indicates the influence of each input factor on the results. From the F value, the composition of the fibers was found to be the most influential factor and the addition of the fly ash to the composite also has some influence on the flammability property of the composite. The main effect plot shown in Figure 6 is plotted for signal-to-noise ratio with a smaller is better principle. The plot indicates the jute fiber addition influences the results more as that plot shows more deviation. As per the smaller is a better concept, the addition of the jute fiber must be minimum, the addition of the fly ash must be maximum, and the chemical treatment has a very negligible amount of contribution in deciding the flammability property.

The interaction plot in Figure 7 shows the interlinkage between the input factors. In Figure 8, the contour plot

indicates the best optimum level to obtain minimum burning rates. From the contour plot, for getting lower burning rates, the inclusion of fiber should be minimized, and the addition of the fly ash must be increased. As the fiber used in this composite is a natural fiber, the tendency to catch fire is more and so if the percentage addition of the fiber is more, the burning rates are also found to be increased which is not advisable. The fly ash addition seems to lower the burning rates as it is already obtained from burning the coal. The ash will diminish the fire and tends to form char, which will stop the propagation of the fire throughout the material. As the fly ash was added in powder form, it reduces the defects formed during the production of the composite. The major defect formed in a polymer composite during the production is the formation of blowholes and surface cracking. The fly ash fills the holes formed in the core and surface of the composites and also improves the surface properties and reduces

the microcracks formed during curing. The NaOH chemical treatment has no contribution in determining the burning properties of the composite. Maybe it can influence the strength and other properties of the composite. The addition of the jute fiber increases the burning rate by 81%, and the fly ash addition minimizes it by 19% which can be understood by the contribution plot shown in Figure 9.

4.3. Regression from Machine Learning. Regression analysis is performed to forecast the value of yield values from the set of independent variables. In addition, it is used to find the effect of input data on the dependent variable. Recently, many researchers are using machine learning models that are capable of analyzing complex data with more accurate results. Navaneethakrishnan et al. [22] used linear regression, MLP, and SVR in addition to ANOVA to find the best regression model to predict the output parameters. Hence, in this work also, various regression models from machine learning are applied. To apply these algorithms, WEKA open source software is used. Tables 3 and 4 show the regression models for both horizontal and vertical tests. Figure 10 shows the difference between various output parameters.

In Table 5, output data of the machine learning analysis were tabulated, the difference between the actual value and linear regression, MLP, and SVR was plotted, and the error bars indicate the levels of variation between the regression values and actual burning rate values of the horizontal test. Table 6 shows the error values between the actual value and the three regression analysis values. Error value 1 shows the difference between actual value and linear regression values, error value 2 shows the difference between actual

9	18.7	17.7645	0.9355	18.6747	0.0253	18.6993	0.0007

SVR:

$$\text{Burning rate} : 0.2516 + 0.6748\,(\text{jute fiber}) - 0.3267\,\text{x}\,(\text{fly ash}) + 0.0733\,\text{x}\,(\text{NaOH}). \tag{9}$$

From Tables 3 and 4, it is evident that all the regression models have a correlation coefficient of more than 0.97, and its mean square value is less than 0.07. This shows a strong association among parameters of both input and output. From the equations, it is also understood that jute fiber has a positive correlation, and fly ash has a negative correlation. It shows that by addition of fly ash reduces the burning rate and the effect of NaOH is very less. These results were confirmed with the ANOVA test.

5. Conclusion

Flammability tests are done especially for the composites manufactured with natural fiber reinforcement, as by nature natural fibers have high burning properties when compared to manmade fibers. The test carried out for flammability of polymers and plastic materials used in electronic devices is expressed as UL-94. The test results were rated as V0, V1, and V2 based on the extinguishing of the flames after removing the burner.

Thus, the natural fiber-reinforced composite with jute fiber reinforcement and fly ash filler addition was manufactured and tested for its flammability. From the results obtained from the testing and optimization, the addition of the jute fiber influences more and increases the flammability property of the composite, and the inclusion of the fly ash

reduces the burning rates of the composites. The results were verified by referring to various plots and graphs. The optimum levels obtained from the plot are with 5 wt% inclusion of the jute fiber, 15 wt% addition of the fly ash, and with 10 hours chemical treatment; minimum burning rates can be obtained. In horizontal UL-94 tests, 10.2 mm/min burning rate, and in vertical UL-94 tests, 11.2 mm/min burning rate was obtained. Validation tests were also carried out with these levels, and the results obtained show minimum deviation from the predicted values which are acceptable. To analyze the process parameters' effects on flammability, ANOVA, LR, MLP, and SVR were used.

The regression models also indicate that jute fiber induces the burning rate due to positive correlation and whereas fly ash reduces the burning rate due to negative correlation. The effect of NaOH is very less on the burning rate. In the future, fly ash could be added as a reinforcement agent to reduce the flammability for other natural fibers and greatly reduce the flammability affecting electronic parts. As it is self-extinguishable, it can be used in places where the material needs to be requiring more resistance to flames.

Biomass is a renewable and sustainable green energy material. It is made up of lignin, cellulose, and hemicellulose with considerable amount of water, extractives, and inorganic chemical compounds. The use of biomass materials and other biogenic wastes for energy recovery represents an eco-friendly way. Biomass material selection is one of the most significant aspects for any energy conversion process, and it is a common outsourcing problem that includes material preparation, reactor performance, economic assessment, and calorific value of the products. Fuzzy systems can be quite useful in high-performance computing during the selection of biomass materials. In each engineering process, material selection is a crucial step since each material is having its own set of characteristics. This study presents the application of type-1 fuzzy set for the selection of suitable biomass material for yielding maximum bio-oil. This study focuses on seven locally available materials such as rice straw (M-1), sunflower shell (M-2), hardwood (M-3), wheat straw (M-4), sugarcane bagasse (M-5), corn cop (M-6), and palm shell (M-7). The study evaluated seven important properties of the materials such as lignin (P-1), cellulose (P-2), hemicellulose (P-3), volatile matter (P-4), fixed carbon (P-5), moisture content (P-6), and ash content (P-7). The findings demonstrated that sugarcane bagasse (M-5) is the best option for maximum bio-oil yield. Furthermore, the potential of nanoscale catalysts in improving the yield of bio-oil through real-time experiments was studied. The findings of this work add to our understanding of the application of fuzzy-based systems for energy applications.

1. Introduction

In recent years, the use of biomass materials for the production of valuable chemicals and biofuels has gained popularity as a way to minimise emissions of greenhouse gases emitted by the combustion of fossil diesel fuels [1]. It is an organic substance with a lot of chemical energy. It has traditionally been used for energy purposes through direct burning. The annual global biomass production is expected to be 146 billion metric tonnes. The current biomass availability in India is estimated as 500 million metric tonnes per year. According to the report received from ministry, biomass availability is expected to be between 120 and 150 million metric tonnes per year. Biomass presently accounts for 32% of the country's overall primary energy consumption. It is a renewable resource that appears to offer clear environmental benefits and lower greenhouse gas emissions. Wood chips and agricultural wastes are the examples for low-value biomass feedstocks. It comprises a wide range of chemical components. Alcohols [2], organic acids [3], formic acid, and furfurals [4] are among the compounds addressed. These chemicals are then transformed into a variety of derivatives that are employed in the chemical and pharmaceutical sectors. Many researchers have published data on chemicals extracted from a wide range of biomass feedstocks, as well as specific feedstocks including carbohydrates, triglycerides, cellulose, hemicellulose, lignin [5], and furfural [6]. Machine learning algorithms are designed to extract knowledge from data using classic approaches such as clustering, classification, and relationships. To create more flexible outcomes, fuzzy sets are used in combination with these approaches. In the construction of machine learning algorithms and models, fuzzy-based knowledge representation and reasoning are widely used. They gave a new-fangled life to the scientific truth of machine learning which have been in a hidden stage for a long period. Fuzzy sets are used throughout the data processing stage because it may simulate partial and inaccurate data representations. In the mapping of data representation, the fuzzy extension principle was used.

The effective handling of erroneous data and uncertainty is a critical phenomenon in any decision-making process. According to Lee et al. [7], if the imprecision of humanity's decision-making process is mishandled, the results could be perplexing. Fuzzy set theory is a wonderful tool for expressing human knowledge [8]. It is a formalised technique for scientifically conveying ambiguity and vagueness [9]. Zadeh proposed fuzzy sets theory in 1965 as an expansion of the classical notion of set [10]. Salii defined an L-relation, a more broad type of structure that he examined in an abstract algebraic framework [11]. Fuzzy relations are a type of fuzzy relation that is currently widely used in fuzzy mathematics and has applications in linguistics, decision-making, and clustering. Fuzzy set theory has been used by several researchers to deal with uncertainty in a range of decision-making problems [12]. Many literatures used fuzzy-based techniques for energy management system. Previously, Chehri and Mouftah [13] proposed this system for hybrid grid solar power energy management system. Samuel [14] proposed a home energy management system based on a multioutput adaptive neurofuzzy inference system. For a photovoltaic solar home, Chekired et al. [15] proposed a fuzzy logic energy management system. The main idea behind this study is to evaluate the biomass materials in order to get higher quantity and rich biofuel by evaluating the yield parameters. This can be attained with the aid of fuzzy logic and fuzzy inference systems, which have been shown to be useful tools. This system can identify, predict, and control the complex, nonlinear, and imprecise systems. This is very attractive technology that can solve any problems without any accurate mathematical models [16]. Typically, a fuzzy system is formed by collecting knowledge from subject experts and converting their tacit knowledge of the underlying process into linguistic variables and fuzzy rules. Previously, this approach was used for various decision-making processes such as identification of suitable distributor location [17], medicine [18], assessment of power transformer [19], employee performance [20], and hospital performance [21].

Pyrolysis is the method of thermochemical decomposition of organic compounds for the production of energy-rich biofuel in the absence of air at elevated temperatures. There are three different types of pyrolysis reactions differentiated based on the process temperature and reaction time. They are conventional slow pyrolysis, fast pyrolysis, and flash pyrolysis. In fast and flash pyrolysis, the biomass is heated rapidly up to the temperature of 500°C to 650°C. Among other thermochemical conversion processes, pyrolysis offers an innovative solution to problems with heat transmission, product quantity, and quality. In the point of environment considerations particularly emission and waste management, pyrolysis technologies for biomass conversion to energy generation have attracted more attention in recent years and are increasingly attaining advances [22]. Furthermore, for the pyrolysis reactors for biomass conversion into bio-oil, char gas offers various advantages, including improved product quality, reduced operating costs, higher liquid product yield, enhanced reaction speeds, and lower heat requirements. Catalytic pyrolysis is a potential technology for improving biomass-based materials into liquid fuel and other value-added products [23]. Use of nano-based catalysts enhances the pyrolysis process with lower activation energy by lowering the lowering pyrolysis temperature [24]. In catalytic process, the catalyst and feedstock materials are mixed together and kept inside the reactor for catalytic reforming and cracking. Various types of catalysts including nickel-based, metal-based, alkali-based, zeolite catalysts, and carbon-supported catalysts are used in various processes for the production of higher amount of volatiles [25]. For the catalytic pyrolysis conversion of wood-based biomass materials, ZSM-5 zeolite is the most commonly utilized catalysts. Because of the medium pore size and two-dimensional channel-like pore structure, these catalysts are widely used for increasing maximum fuel yield from biomass [26]. The ambient environment had a substantial impact on the catalytic pyrolysis effects particularly which could boost hydrogenation by increasing catalyst accessibility. The identification of suitable material for the yielding maximum biofuels and chemicals has not been

examined using analytical hierarchy process (AHP) and other multicriteria decision-making (MCDM) approaches.

This research focused on the use of fuzzy AHP to select suitable biomass materials for thermochemical conversion processes, specifically pyrolysis. Pyrolysis is a hopeful option for thermochemical conversion of lignocellulosic material. It is a method for converting organic molecules into energy-rich products. This method can produce carbon as a byproduct, which is referred to as carbonization. Pyrolysis, unlike other high-temperature processes such as hydrolysis and combustion, does not require the use of water, oxygen, or other reagents. It is a simple, inexpensive technology that can be used for variety of feedstocks. This process produces high-quality liquid oil and chemicals when compared to other conversion techniques. The qualities and requirements for selecting the best biomass material are examined using expert critiques and literature before selecting numerous materials for this study. The selected materials are available plenty and have no value. After the cultivation, these materials are burnt in open atmosphere in the field itself because of its low density. Open burning of these materials causes severe impact on the environment. So appropriate recycling of these materials is essential. In this context, this study selected seven alternatives out of available plenty in nature to produce maximum liquid oil through thermal and nano-catalytic pyrolysis by investigating its lignocellulosic and its components identified through proximate analysis. The developed fuzzy logic model predicted the yield for a given set of inputs. Finally, the prediction is validated with experimental study conducted by using specified set of input through thermal as well as catalytic pyrolysis.

2. Materials and Methodology

2.1. Materials. The raw biomass materials used for this study are collected from local agricultural field in Coimbatore, India. The raw wood is finely processed into particles having average diameter of less than 0.5 mm. For this form, the biomass materials are initially processed with ball mill and shieved using shieve shaker. To promote pyrolysis reaction and feedstock characterization, the particle size of the biomass materials is very important to prevent heat and mass transmission constraints. So the feedstock has been ground to below 0.5 mm. Before evaluating proper characteristic study, the biomass materials are dried in open sunlight for a week and further dried in an oven for 1 hr maintained at ±100°C. This process can considerably remove the moisture content in the biomass samples which affect the process as well as yield quantity.

2.2. Methods

2.2.1. Material Evaluation. Economic and environmental variables are the two most important elements that can influence biomass material choices. They are listed as follows. Various studies explain some parameters to consider in biomass selection. However, no study effectively specifies this information. Figure 1 shows the property evaluation of the biomass materials.
FIGURE 1: Biomass material property evaluation.

(vii) *Sustainable Energy.* Replacing fossil fuel

2.2.2. Type-1 Fuzzy Approach. Fuzzy sets were brought out by Zadeh in 1965 as the expansion of the conventional notion of set [10]. Here, each constituent has depicted with the help of membership function valued in the actual unit interval [0, 1]. Because of their ability to handle vagueness in preference values, fuzzy set theory has steadily gained favour in the selection of appropriate materials. This approach is frequently utilized in a variety of fields when data is partial or inaccurate [27]. The type-1 fuzzy set $\tilde{a}$ in X is a set of well-organized pair where $\tilde{a}$ is represented as $\tilde{a} = \{(x, \mu_{\tilde{a}}(x)) \mid x \in X\}$ where x represents the constituents of the set X and $\mu_{\tilde{a}}(x)$ is called the membership function or the degree of membership of x.

Suppose $\tilde{a}$ is a triangular fuzzy number (TFN) (a_l, a_m, a_u), where a_l, a_m, and a_u are the promising values of membership function shown in Figure 2.

Then the membership function is defined as

$$\mu_{\tilde{a}}(x) = \begin{cases} 1 - \dfrac{a_m - x}{a_m - a_l}, a_l \leq x \leq a_m, \\[2mm] 1 - \dfrac{x - a_m}{a_u - a_m}, a_m \leq x \leq a_u, \\[2mm] 0, \text{otherwise.} \end{cases} \tag{1}$$
Figure 2: Illustration of triangular fuzzy set.

Suppose $\tilde{a} = (a_l, a_m, a_u)$ and $\tilde{b} = (b_l, b_m, b_u)$ are two triangular fuzzy numbers so the mathematics operations between two type-1 fuzzy sets are as follows:

$$
\begin{aligned}
\tilde{a} \oplus \tilde{b} &= (a_l + b_l, a_m + b_m, a_u + b_u), \\
\tilde{a} \ominus \tilde{b} &= (a_l - b_l, a_m - b_m, a_u - b_u), \\
\tilde{a} \otimes \tilde{b} &= (a_l \times b_l, a_m \times b_m, a_u \times b_u), \\
\frac{\tilde{a}}{\tilde{b}} &= \left(\frac{a_l}{b_u}, \frac{a_m}{b_m}, \frac{a_u}{b_l}\right), \\
\frac{1}{\tilde{b}} &= \left(\frac{1}{b_u}, \frac{1}{b_m}, \frac{1}{b_l}\right), \\
k \times \tilde{b} &= (k \times b_l, k \times b_m, k \times b_u),
\end{aligned}
\tag{2}
$$

where k is a crisp number.

The choice of material for thermochemical conversion to produce biofuels and chemicals is a strategic and critical decision for researchers. The evaluation of many parameters is part of this selecting procedure. This approach involves evaluating a number of factors to select the best biomass source. Some studies may consider higher profits and better outcomes; however, the evaluation should be focused on social and environmental issues. The majority of researchers are only interested in the biological composition of biomass. For 2nd-era ethanol, Kahr et al. [28] evaluated the lignocellulosic ethanol potential of wheat straw, rice straw, oat straw, and maize stover among other potential agricultural wastes. Ciancolini et al. [29] used agglomerative hierarchical cluster analysis to assess the biomass and polyphenol production of eight cardoon genotypes. Nine capacities are tested in this study in order to find significant differences. Vaezi et al. [30] developed a numerical set of rules for biomass material selection in the gasification process. Figure 3 shows the methodology adopted for this study.

2.2.3. Validation by Catalytic Pyrolysis Experiment

(1) Reactor Setup. The pyrolysis reactor is the heart of the pyrolysis process. In this study, the top two ranked biomass material suggested by fuzzy technique is utilized for fixed-bed pyrolysis in order to verify the reliability of the assessment. For this purpose, the reactor made up of stainless steel with inner diameter 100 mm and length 150 mm is utilized. The system consists of heating system, condenser unit, and liquid collection system. The reactor is heated with a 2 kW electrical resistance heater attached with ammeter and volt-

meter setup. A separate autotransformer is attached with the reactor to control the rate of heat input. For proper collection of bio-oil, the evolved gas generated from the reactor is allowed through the condenser, in which the ice water maintained at 0°C is supplied for the condensation process. The condensed liquid oil is then collected into the glass beaker and stored for further study. The char generated during the pyrolysis process was collected from the bed directly at the end of each run. The uncondensable gases produced from the reactor are collected by using gas balloon system.

(2) Reaction Process. ZSM-5 is selected for this study due to its higher activity and stability, as well as its good selectivity, metal tolerance, and flexibility, especially when used as an additional catalyst [31]. Zeolites can be shape-selective catalysts through transition state selectivity or molecular diameter-based exclusion of competing reactants. These catalysts can be utilized for oxidation. The processes can take place within the pores of the zeolite. Desilication of ZSM-5 with NaOH solution produced HZSM-5 for the catalytic process. For this, 25 grams of zeolite is combined with a 250 mL of 0.3 M NaOH and maintained at 75°C. After that, the mixture is filtered and dried in an oven by keeping the temperature not less than 100°C. The dried sample was changed to hydronium form with a 0.2 M NH_4NO_3 solution at 80°C for 24 hours and then again dried at 100°C and calcined at 500°C for almost 6 hours, yielding 0.3 HZSM-5 as the final product. On the reactor, 100 grams of powdered biomass was combined with catalyst and reaction was carried out at by keeping the bed temperature of 500°C. The evolved gases coming out from the reactor are allowed to condenser unit, and the condensed vapour is collected in the form of bio-oil. The weight of the bio-oil is measured directly with the help of weighing machine. Each experiment is conducted till no volatile matter is released from the reactor. For that purpose, minimum of 45 min is maintained for each run. In catalytic pyrolysis process, two types of reactions are taken place inside the reactor. First is the formation of phenolic contents due to deoxygenation or the loss of one or two oxygen atoms. This stage is also the responsible for the formation of cyclopentadiene, fulvenone, and fulvene components. The process of deoxygenation is basically driven by the stability of the separation groups such as water, carbon monoxide, and carbon dioxide. Second is the formation of final products and transmethylation. This stage is responsible for the production of cresols and methyl components [32]. The yield of the desired product is found by the following formula.

$$
\text{Yield (wt\%)} = \frac{\text{Yield of oil/char/gas}}{\text{Biomass feed}}.
\tag{3}
$$

3. Results and Discussion

3.1. Material Selection.
Biomass material selection is mainly concerned with the biomass to biofuel conversion techniques in order to yield the maximum biofuels such as crude bio-oil, char, and gas to fulfil the future energy needs. In the world, there are plenty of materials available as a resource
FIGURE 3: Methodology.

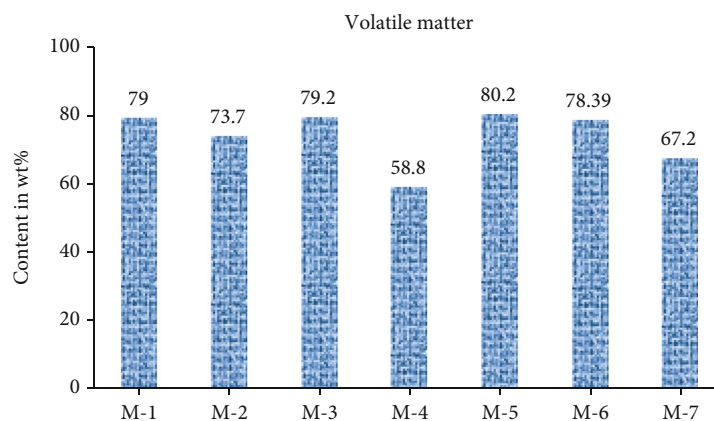
for various applications. Each material has its own unique characteristics, applications, advantages, and limitations. Earlier than the beginning of petro oil era, renewable feedstock materials were a major segment for total energy and chemical supplies. Biomass is a natural material supply chemicals and energy up to date. Among the other types of renewable materials, lignocellulosic biomass are available abundant, low-value materials utilized for fuels, chemicals, and energy to replace fossil resources [33]. They are composite material which has cellulose, hemicellulose, and lignin approximately at 50 wt%, 25 wt%, and 25 wt%, respectively [34]. The components are connected mutually to provide structural stability. It also contains reasonable amount of water, extractives with inorganic elements. Cellulose is a linear long-chain polymer that encircles mostly crystalline structures with tiny amorphous regions. They are structured in fibrils and then grouped together to form cellulose fibres, which are aware of the fibrous character of biomass cell walls. Hemicelluloses are also the amorphous polymers having shorter structure of five to six carbon sugars. It serves as a link between the cellulose and the lignin [35]. Lignin is a three-dimensional polymer made up of phenylpropane units linked together in a number of ways. The most prevalent outsourcing difficulty is material selection, which is the most important aspects of any biomass conversion process. Since different materials have some unique properties and value, the procedure for biomass material selection has a main role related to the conversion efficiency as well as the heating value of the biofuel [36]. This process of selection is identified to be the imperative decision-making process for biofuel conversion techniques which includes biomass preparation, performance of the reactor, economic evaluation, and heating value of the biofuel products.

3.2. Evaluation of the Material Properties. Different biomass materials have some unique characteristics. Analysis of material properties shown in Figures 4–10 is very important for the selection of best biomass material for pyrolysis. Chemical analysis biomass material is one of the most essential parts during the evaluation of reaction characteristics. In biomass, cellulose and lignin are often considered as the most important components [37]. The lignocellulosic content of materials is measured using the conventional wet chemistry technique. It is suggested as the best approach for analysis of lignocellulosic contents [38]. This method is a powerful and accurate method, whereas 0.50 grams of samples is analysed for each entry. Figure 4 shows the lignin content, and Figure 5 shows the cellulose content present in the materials 1 to 7. According to the data, the lignin content of the materials is varied from 13.4 wt% to 44 wt%. It can be clearly shown that M-5 has lower lignin content but M-7 has higher lignin concentrations. Generally, higher lignin contents of the material slower the pyrolysis reaction yielding maximum char. The presence of cellulose in the material enhances the thermochemical conversion yielding maximum liquid products [39]. The values of cellulose in the selected materials vary from 27.7 wt% to 52.5 wt%. The material M-6 contains the highest amount of cellulose content of all the samples, and M-7 has the lowest. With reference to lignin and cellulose contents, M-6 may be suggested as a suitable material, but the hemicellulose content of the material M-6 is lower than the M-2 and M-5.
Figure 4: Lignin contents of the selected materials.

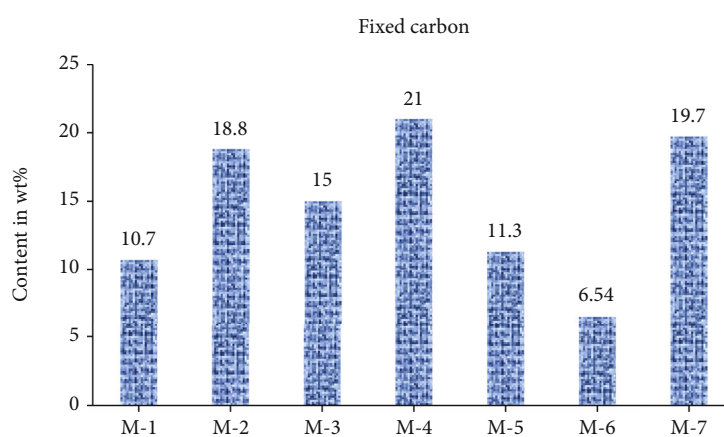
Figure 5: Cellulose contents of the selected materials.

Figure 6: Hemicellulose contents of the selected material.

The presence of hemicellulose content of the material also enhances the conversion of material to biofuel during pyrolysis. The total content of the cellulose and hemicellulose is termed as holocellulose favour for the yield of biofuel. Based on the above said three properties, the favourable material for yielding maximum biofuel cannot be suggested without deep investigation. Material with more volatile contents produces more bio-oil and biogas, while material with higher fixed carbon yields more char particles. The selected sample is having more amount of volatile contents (58.8 wt% to

80.2 wt%). Based on volatile contents, M-5 can be suggested as the best one for maximum energy conversion. The presence of fixed carbon in the material is ranging from 6.54 wt% (M-6) to 21.0 wt% (M-4). The material's moisture content has an impact on the heat transfer phenomena during energy conversion [40]. The moisture content present in the feedstock might obviously reduce the reaction temperature. During conversion process, the initial heat applied to the process is used to evaporate the moisture content of the feedstock material. It also affects the heating value of


Volatile matter

FIGURE 7: Volatile matters of the selected materials.


Fixed carbon

FIGURE 8: Fixed carbons of the selected materials.
Moisture content

FIGURE 9: Moisture contents of the selected materials.

the reaction products. Previously, many studies have recommended the feed particles should have lower moisture content in order to favour for quality bio-oil yield [41, 42]. The material with lower moisture content always yields the fuel with higher energy content [43]. According to Figure 9, the moisture content of the materials is varied from 3.5 wt% to 16.1 wt%. From the figure, it can be shown that M-2 has lower moisture content whereas M-4 has more. The analysis was carried out in accordance with ASTM pro-

cedures to determine the proximate analysis (VM-ASTM D3175, FC-By difference, MC-ASTM D3173, and AC-ASTM D3174). The increased moisture content in the material significantly affects the oil quality. The influence of ash content during pyrolysis has been studied extensively. The amount of ash in the biomass sample has a direct impact on the yield and composition of the pyrolysis products. It also has an impact on the efficiency of the conversion process. As a result, one of the factors for selecting the best
FIGURE 10: Ash contents of the selected materials.

biomass is the lower level of the samples. During pyrolysis, ash particles usually extinguish the vapour conversion. So for this process, the biomass with reduced ash content is often preferred. As a result, the best material for pyrolysis should have most of volatile matter, fixed carbon, and lowest moisture and ash contents. Based on the above characteristic study, the properties such as cellulose, hemicellulose, volatile matter, and fixed carbon are considered as beneficial (high are better) and lignin, moisture, and ash contents are considered as nonbeneficial (low are better).

3.3. Ranking of the Material. The fuzzy pairwise comparison matrix for weight calculation using type-1 fuzzy AHP is shown in Table 1. The weights are derived using geometric mean method [44]. The type-1 fuzzy weights are defuzzified to obtain the crisp numeric weights, which are further normalised to obtain the final weights of criteria. These values are reproduced by multiplication with the evaluation matrix to get preference score. Table 2 displays the weighted normalised evaluation matrix. The graphical representations of the ranks are also shown in Figure 11. It can be seen that sugarcane bagasse is the best alternative having rank 1. The

next best material is hardwood which is ranked 2. The ranks are obtained based on the preference score shown in Table 3, and Table 4 shows the ranks of the selected biomass materials based on the preference score. The lignin percentage of sugarcane bagasse is so low compared to other materials, and the lower lignin level of 13.4% and greater hemicellulosic content of 47.6% forecast the best option for optimum bio-oil production. The moisture level of the sugarcane bagasse is also quite low, at only 5.4 wt%. As a result, sugarcane bagasse provides greater quality and has a higher

Hardwood	2	44.6	46.8	2

3.4. Experimental Validation. The yield of bio-oil with respect to biomass pyrolysis and catalytic pyrolysis is shown in Table 5. For thermal pyrolysis, the yield of bio-oil is 48.3 wt% for sugarcane bagasse and 44.6 wt% for hardwood material. At a catalyst loading of 2 wt%, the bio-oil yield is increased to 50.4 wt% and 46.8 wt% for sugarcane pyrolysis and hardwood, respectively. The yield of bio-oil from top-ranked sugarcane bagasse via thermal pyrolysis and catalytic pyrolysis is more when compared to second-ranked hardwood. When the experimental and theoretical findings were compared, they were virtually identical, indicating a strong correlation between them.

4. Conclusion

In this study, type-1 fuzzy set approach was used to design a mechanism for selecting optimal biomass material for the pyrolysis process for maximum bio-oil yield. The type-1 fuzzy set was suggested which helps in the process of selecting suitable biomass materials among a large number of available alternatives. By considering seven evaluation criteria, this study gives the ranking order of the materials based on the performance score, and the order was sugarcane bagasse>hardwood>sunflower shell>corn cop>rice straw>palm shell>wheat straw. For a particular biomass material selection problem, this method considers biomass material selection qualities and their interrelationships. This method yields significant results and also establishes a link between previous studies for appropriate material selection for optimal bio-oil yield. The results of this method are in good accord with those of experiments. Under the same experimental circumstances, the top-ranked material yielded 3.7 wt% and 3.6 wt% more liquid oil than the second-ranked

heating value. The quality of the oil is generally affected by the water content of the biomass feedstock [45]. Various researches have also confirmed this. One of the reasons for the superior quality of the bio-oil is the lower ash level of the sugarcane bagasse [46]. Wheat straw has higher moisture content than other biomass materials, as well as a lower cellulose content, which means it has a lesser chance of producing maximum bio-oil yield [47]. As a result, it was placed seventh among the other selected materials. During thermochemical conversion processes, there is a strong relation among the degradation of volatile contents and the rise in product yield [48]. The production of biofuels results in a 90% loss of their volatile constituents [49]. Even if rice straw and sugarcane bagasse have the same quantity of volatile matter, higher level of hemicellulose and lower ash content in sugarcane bagasse may be the key reason for its ranking among other biomass materials and for the prediction of acceptable biomass.

material during thermal and catalytic pyrolysis, respectively. The results provide confidence, and this approach can be applied for other thermochemical conversion processes in order to identify the best biomass material.

Data Availability

The data used to support the findings of this study are included in the article.

Supercapacitors are a revolutionary type of energy storage device. They must be able to charge and discharge quickly while maintaining a high energy density. A storage material's cyclic stability is a desirable feature. The type of electrode materials employed for the specific study design affects supercapacitor performance. Manganese dioxide has long been regarded as one of the best and most abundant materials in nature, having a potentially high specific capacitance. They also offer a wider potential range, more electroactivity, and are more environmentally friendly. However, because of its decreased volume expansion and low conductivity, it is difficult to use as a capacitor material. As a result, carbon-based porous films and supports can be employed to produce critical composites to overcome the current shortcoming. These nanoparticle-based materials will have improved electrical conductivity and a large surface area. Graphene oxide (GO) has a high surface area, thermal stability, and porosity. As an electrode material, many types of MnO2/carbon-based materials have been widely used in supercapacitors. Their overall performance is influenced by their construction processes, metal ratios, electrolyte medium, and voltage factors. Microwave technology was chosen as a cost-efficient and effective alternative to expensive and laborious techniques for fabricating MnO2/GO composites. The production procedure of a supercapacitor has been explored in this study using MnO2-GO composite materials. Using the electrochemical deposition process, the nanocomposite materials of MnO2-GO are significantly deposited on the stainless steel (SS) substrate material. Galvanostatic charge-discharge techniques and cyclic voltammetry (CV) analytical methods were used to investigate the storage and cycle ability of supercapacitors. The composite MnO2-GO supercapacitor has a higher electrochemical capacitance based on these findings.

1. Introduction

There is a great demand for both energy (conventional and nonconventional) resources due to the increase in living standards. For that reason, the electrochemical energy storages are obtained to be the substitute for this problem [1, 2]. A supercapacitor (SC), formerly electric double layer capacitor (EDLC), is the generic term for the electrochemical capacitor (ECs) family. A conventional solid dielectric is not present in SCs. Two storage principles determine the capacitance value of an EC, which both indivisibly contribute to the total capacitance [1, 3]. In this day and age, consumption of energy in the form of fossil fuels like oil, coal, and natural gas has drastically increased. This adversely affects the world and the environment in ways like global warming, ecological destruction, and endangering life forms. Utilization of renewable energy is the need of the hour as it is ecofriendly. Countries have allotted funds and manpower exclusively to develop ways to use and create energy. Solar, tidal, hydrothermal, geothermal, and wind energy have played their share in alleviating major problems related to energy and environmental conservation all around the world [3, 4]. However, clean energy is very limited and cannot be directly applied to many applications. This is due to the natural conditions and the shortfall of resources; it greatly depends on the types of sources used and causes poor stability as well as tunability with regard to electricity generation. Hence, trustworthy electrochemical systems are encouraged to address efficient conversion, utilization, and storage of above sources [4]. Supercapacitors also known as electrochemical capacitors are the next-generation storage devices. They are popular for their green and clean nature of fabrication and implementation [5]. They also have a greater capacitance potential with higher power output and shelf life when compared to lithium-ion batteries [6]. Along with simple structure, they possess faster charging and pollution free effects while manufacturing. They can be easily applied to portable electronics, hybrid electric locomotives, data backup, etc. [7].

Due to their compact structures, high surface area, unique chemical, physical, and mechanical capabilities, nanomaterials have gotten a lot of interest in recent years. The ability to produce and process NMs is the first milestone in nanotechnology for exploring novel physical features and understanding possible uses of NMs. The NMs are also epic in structure and have features that can be adjusted. As a result of this development, NM has been useful in real-world applications [2, 8].

Manganese oxide (MnO_2) offers the benefit of relatively cost-effective, high theoretical capacitance (~1300 F g^{-1}), and environmentally compatible [9]. MnO_2 is used for catalysts, sensors, lithium batteries, and alkaline MnO_2/Zn cell applications. The advancements required in generating active materials mainly concern with overall stability, high reversible capacitance, structural flexibility, improved cation diffusion rate under high charge-discharge condition, and environmental friendliness. The composition of MnO_2 materially changes the morphology of the surface and leads to an increase in the pseudocapacitive performance of MnO_2 as an increase in porosity [2]. The proposed theoret-

ical reasons for MnO_2 being a better alternative for electrode materials is its high theoretical capacity in reference to an individual electron-based redox potential reactions of each atom was observed in a wider potential window, electroactive in neutral electrolytes, etc. [10]. These lead to lower corrosion of the collector, and other benefits were incorporated in Figure 1. Improving the performance of electrode materials for the production of high-energy supercapacitors.

The availability of the material is also found to be in excess naturally, which decreases its price value. The crystal structure of the metal also forms crystallinity hence supporting charge storage and dissipation. It has been reported that tunnel or chain structure of alpha, beta, and gamma MnO_2 facilitates easier transfer of electrons with higher capacitance. Nanoranged MnO_2 has a larger reaction area for feasible and enhanced cation intercalation and deintercalation when compared to its amorphous form [11, 12].

In recent years, graphene attained huge interest especially in the fields of electric devices, energy storage applications, and sensors due to their unique property of physiochemical characteristics, such as high surface area, excellent conductivity, and mechanical stability. Structurally, graphene oxide (GO) has been visualized as a graphene sheet with its basal plane and edges filled with oxygen groups. Graphene hybridization with functional NMs enhances the component functional properties and even produces new properties through cooperative interaction.

GO has been an appropriate support material for MnO_2 loadings in electroactive materials for supercapacitors [13]. GO not only affords high surface area for MnO_2 nanosheets deposition but also provides to those nanostructures good adhesion. GO had a significant impression on the property of electrochemical in the GO-MnO_2 nanocomposites. Scheme of MnO_2 nanocomposites shown in Figure 2 mentioned with the application of supercapacitors made out of MnO_2 with optimizing parameters which helps in improving the capacitance, stability, and storage etc.

MnO_2 nanoparticles can be deposited uniformly on GO with high density. The high loading efficiency of MnO_2 and high surface area of MnO_2-GO increase the specific capacitance of MnO_2-GO [14].

This work is aimed at fabricating the composite of MnO_2-GO and achieving good conductivity in the charge storage process. The MnO_2 and MnO_2-GO composites were synthesized by the electrodeposition method. After electrodeposition, the galvanostatic charge-discharge analysis was performed to characterize the charge storage ability of the film from which we can find the ability of the composite as an electrode of a supercapacitor.

2. Materials and Method

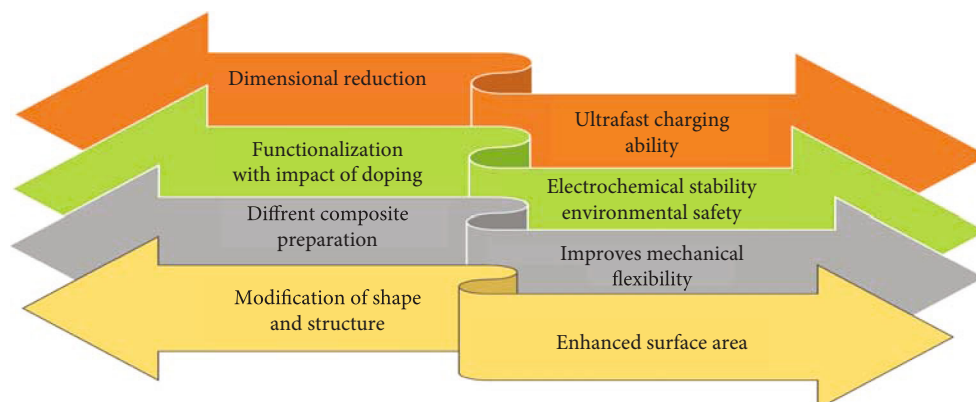
2.1. Fabrication of MnO_2-GO Nanocomposite Supercapacitor. MnO_2 was synthesized using standard protocol reported previously in 2015 [15]. Graphene oxide was synthesized by modified Hummers method [16]. MnO_2 and MnO_2-GO NMs were coated on electricity collector substrates by constant potentiostat mode in the electrodeposition method. The SS substrate was cut and polished into


FIGURE 1: Performance enhancement of electrode materials for high-energy supercapacitors.

FIGURE 2: Scheme of MnO$_2$ nanocomposites for the application of supercapacitors.

1×1 cm size and then washed for 15 min in deionized water by a bath sonicator.

The electrochemical deposition was performed for 30 min at 0.8 V using the as prepared SS substrate as the working electrode. Different concentrations of GO (10 mg, 15 mg, and 20 mg) with 25 ml DI water were dispersed by ultrasonication, and then 0.1 M of MnSO$_4$ solution was added to prepare the electrolyte solution. The pH of the electrolyte solution was maintained at 10 by adding 1 M NaOH. Ag/AgCl and Pt electrodes were used as reference and counter electrodes, respectively [17]. The resulting thin films were dried at room temperature after the process of rinsing in DI water. The overall process of synthesis was displayed in the scheme of Figure 3.

2.2. Electrochemical Analysis

2.2.1. Analyzing Setup.
For the electrochemical analyses 0.1 M of Na$_2$SO$_4$ dissolved in 50 ml of double-distilled water used as an electrolyte solution, Ag/AgCl was fixed as the reference electrode, whereas prepared MnO$_2$ electrodes made with thin films are considered as working electrodes, and electrodes made out of platinum wire are considered as a counter electrode. These three electrodes were immersed in the electrolyte solution the setup was connected to the BIO-

LOGIC Science SP-50 model Electrochemical Workstation for the analyses.

2.2.2. Cyclic Voltammetry.
The electrochemical characteristics of specified composites are typically measured using cyclic voltammetry, a standard technique. The potential scan starts at a point where there is no electrochemical reaction. The scan proceeds to the switching potential at a predetermined constant rate, then reverses direction and returns to the electrode as oxidation or reduction, accordingly. The formula below was used to compute the active material's specific capacitance.

$$\text{Specific capacitance} = C = \frac{I}{(mv(V_a - V_c))} \left(\frac{F}{g}\right). \quad (1)$$

I considered as applied current (A), where $(V_a - V_c)$ are considered as the potential of sweep window (V), m is known as mass of the active material (g), and v is the scan rate (V s^{-1}).

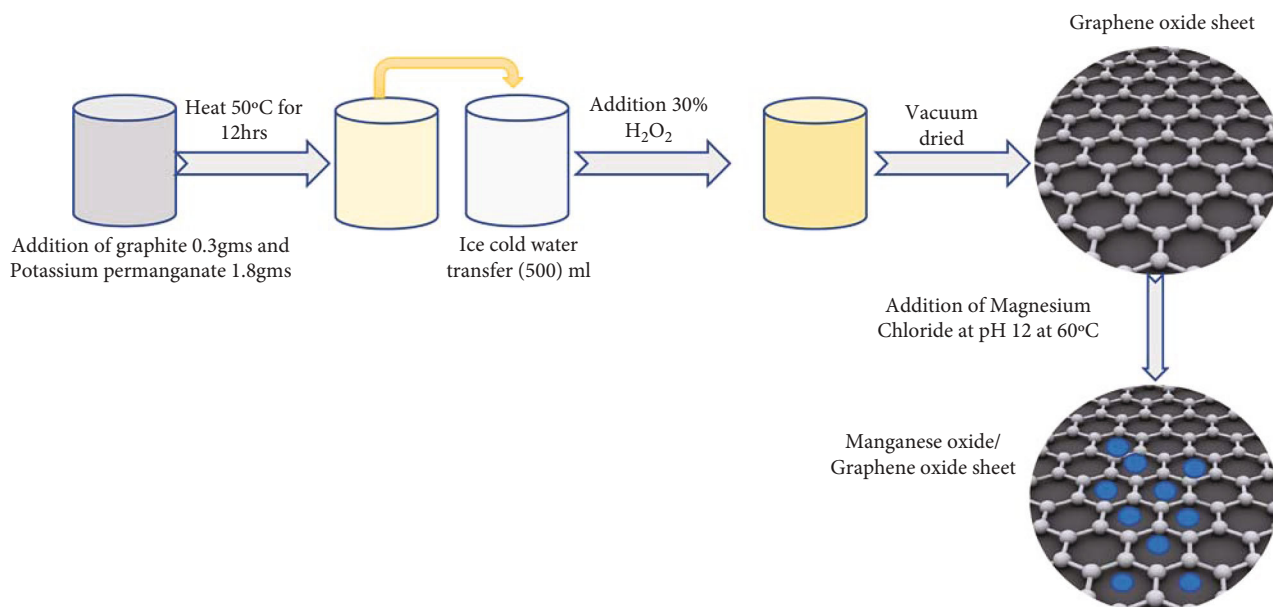
2.2.3. Galvanostatic Charge–Discharge.
The charge-discharge potential and cycle ability of prepared MnO$_2$-GO nanocomposite was measured using galvanostatic charge–discharge


FIGURE 3: Schematic of GO sheets and formation of MnO2/GO nanocomposites.

(GCD) technique. It is necessary to conduct the charge and discharge at a constant current until a predetermined voltage is obtained. A cycle is a loop of charging and discharging that repeats over and over again. The time required to reach the set potentials for the applied current was plotted. In the charging process, the constant rate of increment in the potential and the discharge process the constant rate of decrement in the potential with time is the perfect behavior for the charge storage device.

Using the charge-discharge curve the capacitance and cycling behavior of the electrode material has been monitored, and also the charge density, energy density, and capacitance of the material were calculated from the following equations.

Specific Capacitance of the active material is $C = \dfrac{(IX\Delta t/\Delta VXm)F}{g}$.

(2)

3. Results and Discussions

3.1. Cyclic Voltammetry Studies. Cyclic voltammetry was performed using prepared MnO_2 and MnO_2-GO thin films. Here, prepared thin films were fixed as working electrodes whereas the platinum wire was considered as a counter electrode, and Ag/AgCl was a reference electrode, respectively, an aqueous solution of 0.1 M Na_2SO_4 as the electrolyte for different scan rates.

Figure 4 shows a cyclic voltammogram of MnO_2 and MnO_2-GO thin films by applying a scan rate of $5\,mV\,s^{-1}$ between the potential of 0 and 0.8 V. It shows the current density vs. potential curve of MnO_2: GO (different concentration) composites and pure MnO_2. From that, we found that MnO_2 has a low current density 10 mg MnO_2 added for GO composite which has high current density compared
FIGURE 4: CV current density of MnO_2 and MnO_2-GO.

to pure MnO_2. Also, 15 mg MnO_2-GO composite has a high current density compared to 10 mg composite, and 20 mg MnO_2-GO composite has a low current density compared to 15 mg composite because further increment in GO tends to decrease the amount of MnO_2 on the surface of the electrode. Ding reported successful electrodeposition of manganese dioxide nanoparticles onto an indium tin oxide glass substrate using the cyclic voltammetry (CV) method, which was used to create an indium tin oxide glass substrate from an aqueous solution of 0.1 M Na_2SO_4 containing 5×10^{-3} M $MnSO_4$, and they achieved 294 Fg^{-1} [9].

3.2. Galvanostatic Charge-Discharge Technique. Galvanostatic charge/discharge experiments were performed to evaluate
FIGURE 5: Charge and discharge times in MnO_2 and MnO_2-GO.

the specific capacitance and cycle ability of the developed MnO_2 and MnO_2-GO electrode materials. Further, the insight into the relationship between the specific capacitance of the different MnO_2 nanostructures has been studied. The galvanostatic charge-discharge is also performed using the biologic sp-50 electrochemical workstation. Figure 5 depicts the charge-discharge performance of the electrodeposited MnO_2 for the first few cycles.

The potential-time curve was measured from 0 to 0.8 V versus the reference electrode for more than 300 cycles, 0.1 M Na_2SO_4 was used at a current density of 0.5 mA cm^{-2}. The curves are almost linear and present in the form of typical symmetrical triangle shape which indicates the pseudocapacitance of MnO_2. The composition of MnO_2-GO has a high charge and discharge time compared to MnO_2. Thus, it reported to have increased specific capacitance of MnO_2-GO. Sebastin et al. have reported that multilayered film electrodes show good electrochemical properties [6]. Hence, the obtained results indicate that these newly synthesized films could be used as potential applications in electrochemical capacitors.

Figure 6 clearly shows the variation in specific capacitance with respect to the cycle number of MnO_2 and MnO_2-GO electrodes. In which MnO_2 has the specific capacitance of 80 F/g for the first cycle whereas MnO_2-GO has the specific rate of capacitance up to 140 F/g for first cycle. MnO_2-GO displays high specific capacitance compared with MnO_2. Furthermore, the linear line indicates the cycling performance of MnO_2 and MnO_2-GO. It shows the films have retained almost 95% of their specific capacitance even after 300 cycles. With these promising results, these materials can be used as an ideal material in supercapacitor applications.

Addition of MnO_2 to graphene oxide sheets addresses the low volumetric density of graphene-based electrodes. This would prevent the agglomeration of the sheets which happens due to Van der Waals attraction between the nano-
FIGURE 6: Cycling ability of MnO_2 and MnO_2-GO.

particle and the porous material [18]. Elastic constraint is provided by the carbon skeleton of GO. This avoids the dissolution of the electroactive property of MnO_2. A simple microwave-assisted technique can rapidly green synthesize MnO_2/GO composites by simple deposition of the nanoparticle onto the sheet [19]. Previous studies stated that doping of MnO_2 increases the specific capacitance by three times when compared to pure GO sheet or pure birnessite MnO_2 [19, 20].

The ratio of the MnO2 by weight plays a crucial role in the capacitance performance. With an increasing mass ratio, the specific capacitance tends to increase which coincides with the results we have obtained for the current study [21]. Composites tend to have higher diffusivity and mobility of charges than disordered MnO2. Changing the crystal structures and orientations of MnO2, it is suggested that

GO/MnO2 performance as an active material can be greatly influenced. Eco-friendly techniques under milder conditions are found to be more feasible to control the shape and dimension of the nanoparticle [22]. Controlling oxygen functional moieties and doping of heteroatom on the GO sheets can aid in manufacturing hi-performance electrode materials.

Synthesis method has a great influence on the electrochemical performance of MnO_2/GO nanocomposites. The specific capacitance of current study is quite low when compared to previously reported nanocomposites. We infer that the microwave technique opted by might not have supported the formation of proper crystal formation in MnO_2. As it was already reported that crystal structure positively influences the specific capacitance of a capacitor material. The nanoparticle used in this study does provide high energy density to the porous GO, but the structure of the lattice might not be at its very best. GO ensures upgraded cyclic performance and stability. The microstructure of the sheets with functional groups portrays different properties in various orientations and dimensions for the given nanocomposite. This gives the rational feasibility to optimize this nanocomposite and maximize it to its potential. Nanotubes and nanofibers offer high and rapid diffusion due to its one dimensional orientation.

This shortens the ion diffusion pathway which leads to high conductivity and enhanced mechanical properties. Flexibility is also attained by the capacitor material. Similarly, two-dimensional GO is also regarded as an ideal conductive substrate with enhanced specific surface area, conductivity, and ultralow density. Compared to nanotubes, the diffusivity is quite low for GO. Activated form of carbon is mostly opted for fabrication of storage devices owing to its three-dimensional structure and rich functional groups. Although a rich porous support structure is provided in

the current study for the nanoparticle the performance yielded was quite less. Orderly channels without obstructions can further maximize the electrochemical performance of MnO_2. They accelerate the ion transport and make the diffusivity easier for MnO_2.

Hence, the current material can be experimented with by incorporating additional channels in the Go sheet to see if the performance could be improved. Even the graphitization of the sheet makes conducive improvement in the transfer of charge between the nanoparticle and the carbon base. Low graphitization of the sheet used in the current study might also be the reason for low performance of the capacitor material. In the previous years of effort has been taken to explore the potential of MnO_2/GO composites for their capacitance function. Exciting outcomes have been accomplished so far. There are still many drawbacks in the nanoparticle that hinder its electrochemical property if not set right. A few have already been discussed above [23]. Efforts need to be taken to focus on developing new generation nanoparticle combinations with potential doping to address all drawbacks mentioned above. Table 1 represents the previously reported outcomes on MnO_2/GO composites for supercapacitor applications.

4. Limitations and Future Scope

A greater amount of testing and research into MnO2-GO materials is required in order to produce better supercapacitors in the future. Aspects such as poor structural stability and reduced ion diffusion need to be addressed as well [38–44]. Researchers should look into and test high-capacitance materials that can be reversed and modified, when necessary, as well as rapid cation diffusion at high charging and discharging rates.

5. Conclusion

An electrochemical deposition approach was used to deposit MnO_2 and varied concentrations of MnO_2-GO composites on an SS substrate in this investigation. The CV curves depicted the electrochemical performance of pure and composite materials synthesized in various ratios. In comparison to pure, 10 mg, and 20 mg GO added MnO2 thin films, the 15 mg GO-MnO_2 electrodeposited film has a high current density. Because it covers the highest area of MnO2 in the composite, increasing the GO tends to lower the film's performance. The charge storage behavior of the films is demonstrated by galvanostatic charge-discharge analysis, galvanostatic charge-discharge curves have been conducted with different composition of GO to ensure the effective capacitance which shows that MnO2 and MnO_2-GO thin films have specific capacitances of 80F/g and 140F/g for the first cycle, respectively, and that the composite retains approximately 95 percent of capacitance after 300 cycles. When compared to previously published nanocomposites, the current study's specific capacitance is quite low. We deduce that the microwave approach used may not have promoted the creation of appropriate MnO_2 crystals. Despite the fact that the nanoparticle was given a rich porous support structure in the current work, the results were disappointing. MnO_2 electrochemical performance can be improved even further by having clean, unobstructed channels. Although the nanoparticle utilized in this study provides a high energy density to the porous GO, the lattice structure may not be optimal. Low graphitization of the sheet utilized in this investigation could possibly be a factor in the capacitor's poor performance.

Data Availability

The data used to support the findings of this study are included in the article.

A new strategy for supercapacitor formation was carried out in the study using electrodes made of graphene oxide (GO) and manganese dioxide (MnO$_2$) nanocomposites. To the present knowledge, only a few investigations have been carried out concerning the synthesis of GO-MnO$_2$-based nanocomposites and their electrochemical properties, with varying mass ratios, as well as the change in electrochemical properties of their components as MnO$_2$ and GO were tested individually for the enhanced stability and performances. A synthetic method was performed successfully to manufacture MnO$_2$/GO nanocomposites. The findings of the present study show that the composites have a lot of potential as an effective conduction property. A composite of graphene oxide supported manganese dioxide nanocomposites fabricated with the simple soft chemical route. As-prepared nanocomposites can be improved in performance by the interactions between GO and MnO$_2$.

1. Introduction

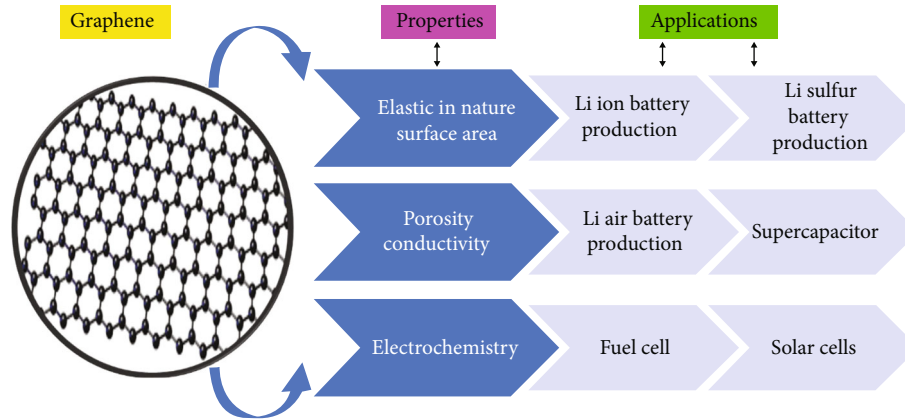
In the last few decades, the importance of nanomaterials was enormously increased due to their unique features and mechanical properties. Various approaches have been implemented to develop a vast number of nanomaterials through the dedicated synthesis methods of top-down and bottom-up methods which are considered as the most common and commercial techniques for nanomaterial synthesis. Nanofragmentation is considered as one of the effective and most promising methods in the field of nanotechnology to generate and tune the nanomaterials into different unique


Figure 1: Mechanical and electrical properties and their applications of graphene.

nanostructures like nanotubes, nanofibers, and nanorods. This makes them valuable for real-world applications concerning its property which have also been discussed in Figure 1 with the various phenomena. Energy is considered to be one of the most significant needs in today's world, and it is used in various forms [1, 2]. Nonetheless, rising energy demand causes natural issues and the exhaustion of petroleum derivatives such as fossil fuels. Therefore, a serious examination of energy stockpiling and conversion has gotten a great deal of consideration as far as future innovation advancement. Due to its powerful thickness, long cycle life, and quick charging rate, supercapacitors are increasingly being used to supplement or even replace batteries in a variety of applications [2, 3]. The M_{30} electrode has the largest specific capacitance; they can be credited in the form of joined concepts to make MnO_2 as a redox potential of pseudocapacitance and reduced graphene oxide (rGO) as an electrical twofold layer capacitance. The M_{30} electrode's further developed performance could also be attributed to its high graphene carbon content, which helps in diminishing the cationic way into the terminal network that is electrode matrix and bringing down move obstruction which is transfer resistance.

There is a large demand for both conventional and nonconventional energy resources as there is a sudden rise in population and also an increase in living standards. There is a need for nonconventional renewable energy sources due to the increase in greenhouse gas and the depletion of fossil fuels. Therefore, electrochemical energy systems are found to be the alternative for this problem [4]. Recently, electrochemical capacitors like supercapacitors have been introduced over conventional energy stockpiling because of their powerful thickness and energy density when compared to the conventional and recent batteries in Figure 2. They have been used in dc motor drives, robots, electric vehicles, and even UPS (uninterruptable power supply) systems. Due to the charge capacitance, the storage of supercapacitors is subdivided into three different types such as electrical double-layer capacitors (EDLCs), psuedocapacitors, and hybrid or mixed electrodes; recent advancements in the supercapacitance are discussed in Figure 3. The best supercapacitors are the ones that should possess maximum energy

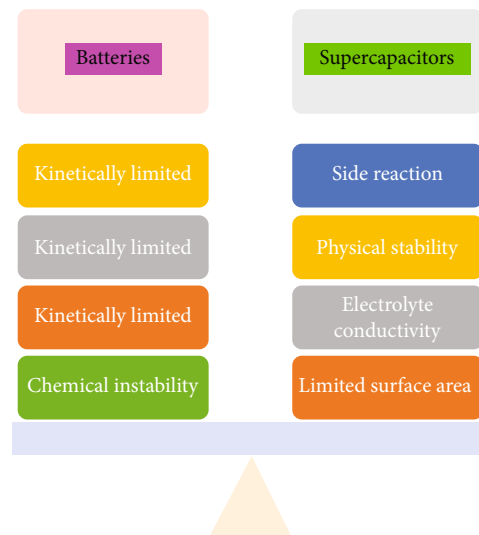

Figure 2: Comparison of batteries' and supercapacitors' performances.

storage capacitance. The supercapacitor capacitance value is decided by two storage principles, which both grant indivisibly to the total capacitance [5].

As an alternative to ruthenium oxide (RuO_2) (which is widely used in metal oxide supercapacitors), manganese oxide (MnO_2) offers the advantage in terms of high hypothetical capacitance, cost proficiency, and less toxicity as well as environmental safety [6, 7]. MnO_2 has been used for lithium batteries, sensors, catalysts, and alkaline Zn/MnO_2 cell applications; under ambient settings, MnO_2 is perhaps considered as the most steady manganese oxides, with remarkably strong physical and excellent compound properties. These mixtures' high polymorphism and underlying adaptability have given them a wide scope of uses, including catalysis, biosensors, and energy stockpiling. MnO_2 electrodes have set up themselves as a conceivably ideal terminal material for replacing RuO_2 in supercapacitors because of their high explicit capacitance, natural similarity, and cost viability [8–11].

The main concerns regarding for advancement of active materials in supercapacitor development were underlying
Figure 3: Recent advancements in supercapacitor.

adaptability and dependability, quick cation dissemination under high charge-release rates, high reversible capacitance, and natural friendliness. In general, manganese is a change metal component that can exist in different types of stable oxides, viz, MnO, Mn_3O_4, Mn_2O_3, and MnO_2, and crystallizes in different types of crystal structures [12, 13]. Usually, MnO_2 is amorphous. Deposition of Fe does not change the amorphous nature of MnO_2 but changes its surface morphology that results in increased porosity, increasing the pseudocapacitive performance of MnO_2 [1, 14, 15]. Both active and inert electrodes may be used in high surface area, conductive materials for capacitive supercapacitors that utilize infinitesimal charge partition, or quick, reversible redox responses in the active materials for pseudocapacitance [16, 17].

Graphene is a 2D (dimensional) single-layer hexagonal lattice closely packed by sp^2 carbon molecules with a carbon-based nanostructure, namely, carbon-carbon distances of 0.142 nm between the atoms. Over the most recent days, the emergence of graphene-mediated materials is used for the fabrications of graphene-based composites which are made a lot of consideration in the field of science and technology because of their novel properties like high mechanical strength, great thermal and electrical conductivity, innate adaptability, and good optical and electrochemical features. It is the first crystal that is steady at normal temperature conditions, especially at room temperature [17–20].

Since its experimental discovery in 2004 [18], graphene has been utilized in a variety of applications. In light of its uniqueness, it has piqued the interest and imagination of scholars. It has high surface region, great conductivity, and other unique qualities the ease with which it may be functionalized, the mechanical qualities that it has, and as a result, graphene nanosheets have gained a lot of attention. There is a lot of excitement about the possible applications in a variety of technology fields, nanoelectronics, batteries, and supercapacitors, to name a few sensors and field-effect transistors [21–23].

Graphene has high conductivity and surface area that can be considered as an ideal choice for use in supercapacitors because of its capacitance values in the selected mate-

rials which are directly proportional to its surface area. As surface area increases, its energy storage value also increases. The capacitance value of graphene materials varies and depends on how they have been stacked. If the surface area of the graphene sheet increases, it can easily be accessible to electrolytes and contributes to the capacitance. So improper stacking of graphene also leads to less capacitance. Hence, avoiding the inner or outer sheet restacking can help graphene in increasing the performance of energy storage. Thus, graphene-based nanomaterials provide an ideal platform to develop various potential materials in the branches of electronics, energy storage devices, and biosensors. The electrons are generally delocalized on either side of the single graphene sheet layer sheet which acts as a barrier and prevents the sheet from restacking; at the same time, these electrons can be useful for identifying other surfaces to bind. Oxidation and shedding of graphite lead to the development of hydrophilic graphite oxide known as graphene oxide. The single-layer oxide of graphene possesses several oxygen species in its structure and aids in various chemical modifications. Hence, numerous graphene-based functional nanomaterials can be generated according to their chemical modifications.

Graphene oxide possesses good mechanical stability and can act as appropriate support for stacking manganese oxide in electroactive materials for supercapacitor applications [24]. The single-layered graphene oxide gives a high surface region for the deposition of MnO_2 nanosheets without any restocking and helps in adhesion to other nanostructures. With the high surface region and high stacking effectiveness of the MnO_2-GO composite, the particular capacitance value increases [25].

The present study focuses on the development of a MnO_2GO-based supercapacitor that should attain good electric conductivity. MnO_2 and MnO_2-GO composite can be synthesized by a simple and economical electrodeposition method.

2. Materials and Methodology

2.1. Synthesis of MnO_2-GO Nanocomposites. Advanced Hummers and Offeman's method was used to synthesize GO. Approximately 10 milligrams of graphene oxide with MnO_2 was added and processed using an ultrasonicator after dispersion, after which the reaction mixture was boiled under the microwave; then, the reaction mixture was mixed into the solution of 10 ml of $FeCl_3$ and 1 M H_2SO_4; this solution was added for about 2 hours using the syringe. The sample mixture was then emptied into 20 ml of double-distilled water added after stirring. Centrifugation was used to obtain MnO_2/GO nanocomposites, which were then washed several times with water. The overall process has been schematically represented in Figure 4 [26–28].

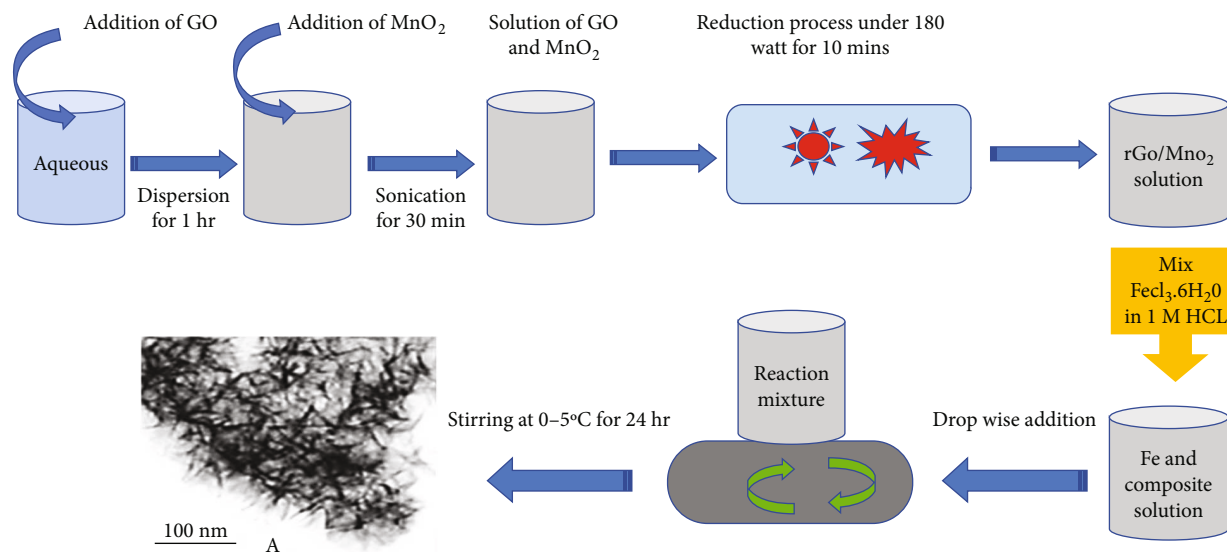
2.2. Fabrication of MnO_2-GO Supercapacitor (SC). MnO_2-GO nanostructures were deposited on current collector substrates by the electrodeposition method by constant potentiostat mode. The stainless steel (SS) substrate was cut and polished into 1×1 cm and then washed by ultrasonication for 15 min in deionized water. Electrodeposition was carried


FIGURE 4: Schematic overview of nanocomposite formation under controlled conditions.

FIGURE 5: (a) MnO_2 and (b) MnO_2-GO substrate.

potentiostatically at 0.8 V for 30 min using the as-prepared SS substrate considering it as the testing electrode. Platinum and silver/silver chloride terminals were utilized as counter electrodes (reference), individually. The electrolyte was prepared by 20 mg of GO mixed with 25 ml deionized water and dispersed by ultrasonication; then, 0.1 M of $MnSO_4$ arrangement was added. The pH of the arrangement was made to 10 by adding 1 M NaOH. The resulting films were rinsed in deionized water and dried at room temperature [14, 27, 29].

2.3. Substrate Characterization. The construction of fabricated nanocomposite thin films was portrayed by powder XRD (Skillet logical XPert Pro MRD diffractometer, Amsterdam, Netherland), worked at 40 kV and 30 mA, and furnished with Cu radiation at a wavelength of 0.15406 nm. The functional groups of electrodeposited MnO_2-GO nanocomposites were analyzed by FTIR-ATR. The local type of

functional groups in the nanocomposite was recorded in the scope of 3000-500 cm^{-1} (Fourier transform infrared spectrometer, Shimadzu, Japan).

2.4. Transmission Electron Microscopic Analysis. Transmission electron microscopy was utilized to inspect the morphologies of as-obtained products to determine their shape, size, and dimensions (TEM). All experiments were conducted utilizing a three-anode framework comprising of a functioning electrode made of exposed or modified glassy carbon (GCE, 3 mm in width), a reference electrode made of saturated calomel (SCE), and an assistant electrode made of platinum wire.

3. Result and Discussion

3.1. XRD Analysis. Figure 5 shows the XRD pattern for the MnO_2 and MnO_2-GO deposited films, Figure 5(a)

FIGURE 6: (a) MnO$_2$ and (b) MnO$_2$-GO.

(a) (b)

FIGURE 7: TEM micrograph of nanocomposite morphology: (a) 100 nm magnification of nanostructure; (b) 500 nm-based magnification of nanostructure.

represents MnO$_2$, and Figure 5(b) represents MnO$_2$-GO substrate. All the diffraction peaks for the MnO$_2$ thin film have good agreement with the reference JCPDS (no. 65-1298), further indexed to orthorhombic MnO$_2$ (orthorhombic crystal structure). The sharp peak tends to the small grain size found as 12 nm by Scherer's formula. The diffraction pattern of MnO$_2$-GO composite also exhibits the same as MnO$_2$ except for the peak around 26° which is due to the presence of GO. It affirms the presence of MnO$_2$ and GO in the composite. The top at 26° weak and broad peak is referred from the research article of [24] The average XRD patterns and Raman spectra of chemically synthesized GO-MnO$_2$ nanocomposites were investigated when the MnO$_2$/GO feeding ratio was varied. As indicated by the report of the most concentrated GO peak around the 2 theta 10, 2°, the (001) reflection is comparative, and because of the introduction of oxygen-containing functional groups on the graphite sheets, the interlayer dividing (0.87 nm) was a lot bigger than the interlayer of pristine graphite (0.34 nm).

3.2. FTIR Analysis. FTIR analysis was carried out for SS modified MnO$_2$ and MnO$_2$-GO thin films; as shown in Figure 6, the results show several transmittance peaks for

MnO$_2$ thin films; it represents Figure 6(a) MnO$_2$ and Figure 6(b) MnO$_2$-GO. The strong peak at 546 cm^{-1} is given to the Mn-O stretching vibration of MnO$_2$, and the peaks at 981, 1089, and 1552 are due to the vibration of O-O and OH bending vibrations. For MnO$_2$-GO film, the peak at 546 cm^{-1} for MnO$_2$ and the peaks around 1554 cm^{-1} 1432 cm^{-1} are also found which are attributed to the C=C vibrations and O-H vibration of graphene oxide. It clearly shows the presence of MnO$_2$ and GO in the MnO$_2$-GO film. The functional group peaks of MnO$_2$ and GO have been crosschecked from the research publication of [30].

3.3. TEM Analysis. Image of graphene oxide nanosheets were viewed by transmission electron microscopy. The as-synthesized GO sheet is discovered to have a smooth surface. With generally high magnification, the manganese oxide nanoparticles were covered with nanosheets of graphene oxide nanoparticles, and more insights concerning the morphology of nanocomposites were investigated, in which GO nanosheets are made out of several layers and the length of each MnO$_2$ nanoparticle is cut formed as slice with scales going from 30 to 50 nm. Moreover, MnO$_2$/GO arrangement of nanocomposites can be ultrasonicated in ethanol for

about an hour with little deficiency of MnO_2 from GO, demonstrating that MnO_2 adsorption on the outside of GO is steady. These recently mentioned properties are those of manufactured MnO_2/GO nanocomposites.

TEM was used to examine GO/MnO_2-based nanocomposites, which were prepared straight from the reaction mixture with no contamination of the surface coating. The surface of the graphene oxide sheet was disordered. The dissolved nanoneedles are less ordered or unbounded as a result of the crystallization process. The sample's morphology was observed as heterostructure nanocomposites in Figure 7 with diameters ranging from 20 to 500 nm. Figure 7(a) shows the resolution of composites at 100 nm scale range where the clear observations of the nanostructure are observed. In Figure 7(b), the structure of nanocomposites was observed with a 500 nm scale range for the comparison in the morphology and shapes of the composites, which was further corroborated with [17, 26, 31]. According to the report of [27, 32], the less arranged precursors on GO sheets rapidly evaporated with the development of extra nanoneedles through a dissolution crystallization mechanism as the reaction advanced from 1 to 10 minutes. The morphology of samples with a more extended response time of 30 minutes showed no discernible differences, implying that the crystal formation process was nearly complete after that time [33, 34].

In this study, MnO_2/graphene oxide nanocomposites were effectively formed using a simple wet-chemical process. MnO_2 is completely covered on the outside of GO nanosheets, according to TEM investigations, and the elements and composition were confirmed by EDX and FT-IR. The content, as well as the crystal structure, was investigated using XRD.

4. Conclusion

In this work, pristine MnO_2 and MnO_2-GO composites were successfully coated on SS by the electrodeposition method. The obtained coatings were homogeneous and showed a very good adhesion on the metal substrate. The coated substrates were characterized using XRD and FTIR. The primary properties were examined utilizing the X-beam diffraction method. From the outcomes, we discovered the orthorhombic structure of MnO_2 with a molecule size around 12 nm. Besides, we conclude with the presence of MnO_2 and graphene sheets in the composite. FTIR spectrum confirmed the presence of Mn-O stretching vibration and bending vibration of graphene oxide in the composite.

Graphene has a distinct chemical makeup and a wide range of properties, including exceptional electrical, optical, thermal, and mechanical capabilities. To meet the increased demand for thin-film processing, composite-mediated integration has evolved in recent technologies, and a number of synthetic techniques, including chemical and physical methodologies, have been created for device integration as well. Graphene has been composited with polymers, semiconductor nanoparticles, metals, metal oxides, sulphides, alloys, carbon nanotubes, organic molecules, and other materials. The enhancement of the properties of these composited materials is based not only on the individual components but also on their interaction.

In this study, authors are experiencing the advantage of making novel and an innovative supercapacitor (SC) which was made out of nanocomposites, which had excellent advantages over other conventional capacitors and other electronic devices. The advantages include the following: they are most commonly used in electric hybrid vehicles, military types of machinery, communication devices for uninterrupted power supply in mobiles, and laser devices.

There are certain challenges to overcome; the supercapacitors are cost-effective and highly dense in energy. Recently, many initiatives have been started to overcome the problems associated with the low energy density developed by the SCs which are developed from nanostructure-mediated electrodes with enhanced capacitance. Higher operating voltages can help you save money on your energy bills. The energy density increases as the working potential window widens, needing less material, separator, and electrolyte to store the same amount of energy. A high cell voltage means that fewer cells must be connected in series to form a specific voltage system, reducing the load on external voltage-balance circuits, which are now widely utilized. Last but not least, electrode materials for SCs have sparked a lot of attention in recent years as a way to create cost-effective and high-performing energy storage devices. Waste materials are a cost-effective way to make supercapacitor electrodes for this purpose, albeit they still need a lot of work (fabrication methods, electrolyte selection, etc.) before they can be sold as raw electrode material in the commercial market.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare no potential conflict of interest.

Heat exchangers with unique specifications are administered in the food industry, which has expanded its sphere of influence even to the automotive industry due to this feature. It has been used for convenient maintenance and much easier cleaning. In this study, two different nanomaterials, such as Cu-based nanoparticles and an organic nanoparticle of Chloro-difluoromethane (R_{22}), were used as nanofluids to enhance the efficiency of heat transfer in a turbulator. It is simulated by computational fluid dynamics software (Ansys-Fluent) to evaluate the Nusselt number versus Reynolds number for different variables. These variables are diameter ratio, torsion pitch ratio, and two different nanofluids through the shell tube heat exchanger. It is evident that for higher diameter ratios, the Nusselt number has been increased significantly in higher Reynolds numbers as the heat transfer has been increased in turbulators. For organic fluids (R_{22}), the Nusselt number has been increased significantly in higher Reynolds numbers as the heat transfer has been increased in turbulators due to the proximity of heat transfer charges. At higher torsion pitch ratios, the Nusselt number has been increased significantly in the higher Reynolds number as the heat transfer has been increased in turbulators, especially in higher velocities and pipe turbulence torsions.

1. Introduction

The heat exchanger is used to transfer heat efficiently between two fluids (gas or liquid) to another [1–3]. The most common heat exchangers are car radiators and radiators [4–6]. Heat exchangers are used in various industries such as air conditioning [7–11], automobile, oil and gas, and many other industries [6, 12, 13]. Heating equipment

in process systems such as refineries is generally divided into two general categories of furnaces and heat exchangers [14–19]. The difference between a furnace and a heat exchanger is in the heating source [20–23], which means that the heating source is liquid and gas [24–29]. While in a heat exchanger, the heating source is a hot fluid. In the furnace, according to the type of heating source, the heat transfer mechanism in the form of convection and radiation

is combined [30–33], while the heat transfer mechanism in the heat exchanger is only convection [34–36]. In general, heat transfer calculations from high-temperature plates lead to the simultaneous creation of different effects of heat transfer mechanisms on the characteristics of heat exchangers and other heat transfer equipment [37–39].

On the other hand, forced displacement in the heated layers of nanofluid around a rotating axis is still a fundamental issue that needs further study [40–45]. Access to smaller, lighter, and more efficient devices for better heat transfer has always been desirable in industrial equipment such as electronic components and heat exchangers [46–48]. Since nanofluids have a higher thermal conductivity than normal fluids, they have always been of interest in recent years [49–53]. Ho et al. conducted a limited-volume numerical study to investigate the free heat transfer of water/aluminum oxide in a cylindrical chamber with insulated inner walls and hot and cold outer walls. Based on their findings, the choice of different models for viscosity predicts different values for the Nusselt number [54, 55]. Xu et al. and Dalkilic and Wongwises investigated the combined displacement of water/aluminum oxide nanofluids in a right-angled triangular chamber [56, 57]. According to their reports, with an increasing amount of nanoparticles, heat transfer occurs [58].

Jahanshahi et al. conducted an experimental and numerical study with a finite volume method to investigate the free heat transfer of water/silicon oxide in square chambers with hot and cold vertical walls and horizontal insulated walls. According to their findings, the average unsalted number in all Riley numbers increases with the increasing volume fraction of nanoparticles [59]. Aminossadati and Ghasemi numerically investigated the natural displacement of water/copper oxide nanofluids in Grashev numbers and different volume fractions in a square chamber with local heating. According to their results, with increasing Riley number and volume fraction of nanoparticles, the average Nusselt number increases [60]. Basak et al. numerically examined fluid flow and heat transfer in natural displacement in hot-bottomed triangular chambers and cold lateral walls in a porous medium. The average Nusselt number increases [61].

In the present study, two different nanomaterials, such as Cu-based nanoparticles and an organic nanoparticle of Chloro-difluoromethane (R_{22}), were used as nanofluids to improve the heat transfer efficiency of a turbulator. It is simulated by computational fluid dynamics software (Ansys-Fluent) to evaluate the Nusselt number versus Reynolds number for different variables. These variables are diameter ratio, torsion pitch ratio, and two different nanofluids through the shell tube heat exchanger. One of the reasons for this choice is the current applications of this geometry in thermal insulation processes, cooling of various rotating machine components, and energy management in general.

2. Materials and Methods

2.1. Materials

2.1.1. Cu-Based Nanoparticle. A copper-based nanoparticle is a type of copper-based particle between 1 and 100 nm.

Like many other nanoparticle forms, Cu-based nanoparticles could be formed by natural processes or through chemical synthesis.

2.1.2. R_{22}. Chloro-difluoromethane is a complex type of hydrochlorofluorocarbon (HCFC). This colorless gas is commonly known as R_{22}, which is used for refrigeration or propellant properties.

2.2. Mesh Convergence. To achieve a correct numerical solution in simulating single-phase fluid flows when accurate flow information is not available, it is necessary to use classical smooth flow equations within the Reynolds number range to ensure smooth flow. The equations of mass, momentum, and energy survival governing the displacement flow problem in cylindrical properties can be summarized as follows:

$$\frac{1}{r}\frac{\partial}{\partial r}\left[\left(\rho_{nf}V_r r\right)\Gamma_1 - \Gamma_2 r\frac{\partial r_1}{\partial r}\right] + \frac{1}{r}\frac{\partial}{\partial \theta}\left[\rho_{nf}V_\theta \Gamma_1 - \frac{\Gamma_2}{r}\frac{\partial \Gamma_1}{\partial \theta}\right]$$
$$+ \frac{\partial}{\partial z}\left[\rho_{nf}V_z \Gamma_1\right] = \Gamma_3,$$

(1)

where r_1 to r_3 is explicitly defined in Table 1 for various situations.

It is clear that to solve the set of Equation (1), it is necessary to introduce the fluid and thermal properties of nanofluids. These properties include conductivity, viscosity, density, coefficient of thermal expansion, and specific heat capacity. After reviewing a large number of theoretical and quasiexperimental models presented by researchers to model the thermal conductivity and effective viscosity of water-copper oxide nanofluids and compare their results with each other, it was decided to use the models presented by Corsion. These models are semiexperimental, and their results are very consistent with the experimental results of others. The corrosion model for the thermal conductivity is

$$\frac{k_{nf}}{k_f} = 1 + 4.4 \, \mathrm{Re}_b^{0.4} \, \mathrm{Pr}^{0.66} \left(\frac{T}{T_{fr}}\right)^{10} \left(\frac{k_p}{k_f}\right)^{0.03} \varphi^{0.66}, \quad (2)$$

where Pr is the Prandtl number for the base fluid and Re_b is the Reynolds number for the brown motion of the nanoparticles and is obtained from the following equation:

$$\mathrm{Re}_b = \frac{2\rho f k_B T}{\pi \mu_f^2 d_p}. \quad (3)$$

As given in the momentum survival equations, the density changes in the Boeing force term follow the Bozinsky approximation. The effective density of the nanofluid, the Bozinsky term coefficient, and the denominator of the thermal diffusion coefficient are also calculated using the mixing law:

$$\rho_{nf} = (1 - \varphi)_{\rho_f} + \varphi \rho_{np}, \quad (4)$$

TABLE 1: Calculation of various parameters.

Governing equations	Γ_1	Γ_2	Γ_3
Continuity	1	0	0
Momentum	V_r	μ_{nf}	$-\frac{\partial p}{\partial r} + (\rho\beta)_{nf} g(T - T_i)\cos\theta + \rho_{nf}\frac{V_\theta^2}{r} - \frac{2\mu_{nf}}{r^2}\frac{\partial V_\theta}{\partial_\theta} - \mu_{nf}\frac{V_\theta}{r^2}$
Momentum, θ	V_θ	μ_{nf}	$-\frac{1}{r}\frac{\partial p}{\partial\theta} + (\rho\beta)_{nf} g(T - T_i)\sin\theta + \rho_{nf}\frac{V_r V_\theta}{r} - \frac{2\mu_{nf}}{r^2}\frac{\partial V_r}{\partial_\theta} - \mu_{nf}\frac{V_\theta}{r^2}$
Momentum, z	V_z	μ_{nf}	$-\frac{\partial_p}{\partial Z}$
Energy	$C_{p_{nf}}T$	k_{nf}	0

$$\left(\rho c_p\right)_{nf} = (1 - \varphi)\left(\rho C_p\right)_f + \varphi\left(\rho C_p\right)_{np}, \tag{5}$$

$$(\rho\beta)_{nf} = (1 - \varphi)(\rho\beta)_f + \varphi(\rho\beta)_{np}. \tag{6}$$

The base fluid is specific heat density and capacity, in contrast to the conductivity, viscosity, and thermal expansion coefficient, which are considered during the numerical solution of the temperature variable, which is determined for the water-based fluid as the following correlation relations:

$$C_{pf} = 2 \times 10^{-6}T^4 - 3 \times 10^{-3}T^3 + 1.6T^2 - 357.7T + 342.82, \tag{7}$$

where $R^2 = 0.9995$ and $\rho_f = -0.0034T^2 + 1.7538T + 775.93$.

Although the above equations take more time to converge or so-called converge problem, it provides more accurate modeling results.

2.3. Computational Fluid Dynamics (CFD) Solver.

The nonlinear equation system is solved using the CFD solver in Ansys-Fluent software. This solver discretizes the equations by the volume control method but solves them in a coupled manner using the finite element method. The playback sentences are carefully double-discretized, and the Ray and Chou algorithm is used to couple the speed and pressure. Nonuniform networks network the computational domain with the organization. The criterion of $y^+ < 10$ is used for the boundary layer elements in all geometries that the size of the elements adjacent to the walls and the entrance grows with a ratio of 1.08. The minimum number of elements for the aspect ratio is 75 times 595428, and the maximum number of elements for the aspect ratio is 15 times 2530800. The output of the problem is calculated in the form of dimensionless Nusselt numbers and coefficient of friction in the inner and outer walls to express the amount of heat transfer from the walls and dynamic flow analysis using.

$$\mathrm{Nu}_i = \frac{\overline{h_i}D_h}{k_{nf}}, \tag{8}$$

$$\mathrm{Nu}_o = \frac{\overline{h_o}D_h}{k_{nf}}, \tag{9}$$

$$C_{f_i} = \frac{\tau_{w_i}}{0.5\rho_{nf}V_{in}^2}, \tag{10}$$

$$C_{f_i} = \frac{\tau_{w_o}}{0.5\rho_{nf}V_{in}^2}. \tag{11}$$

3. Results

3.1. Validation.

To determine the correct values of the variables and the accurate boundary layer modeling, the network independence test from numerical solution was performed using velocity and temperature profiles for different aspect ratios of the desired geometry. This test was performed for water fluid without considering nanoparticles. All networks have a boundary layer with the condition $y^+ < 10$, and the number of elements increases in both axial and radial directions. The criterion for selecting a network is to reach a single answer to increase the number of elements in all directions and the boundary layer. The results were validated by previous literature to continue the evaluations from simulations. It is depicted in Figure 1. As it is evident, the error percentage is negligible, and our simulations can be trusted.

3.2. Nusselt Number.

As shown in Figure 2, the effect of various diameter ratios (0.2, 0.15, 0.05, and 0) has been evaluated on the Nusselt number (Nu) in different Reynolds numbers. The Nusselt number has been increased for higher diameter ratios, especially in higher Reynolds numbers, as the heat transfer has been increased in turbulators.

As shown in Figure 3, the effect of various torsion pitch ratios (0.45, 0.30, 0.15, and 0) has been evaluated on the Nusselt number (Nu) in different Reynolds numbers. The Nusselt number has been increased for higher torsion pitch ratios, especially in higher Reynolds numbers, as the heat transfer has been increased in turbulators, especially in higher velocities and pipe turbulence torsions.

As shown in Figure 4, the effect of various R_{22} and Cu-based nanoparticles has been evaluated on the Nusselt number (Nu) in different Reynolds numbers. It is evident that for organic fluids (R_{22}), the Nusselt number has been increased, especially in higher Reynolds numbers, as the heat transfer has been increased in turbulators due to the proximity of heat transfer charges.
FIGURE 1: Validation between our simulations and Safikhani et al. [62].

FIGURE 2: Effect of various diameter ratios on Nusselt number (Nu) in different Reynolds numbers.

FIGURE 3: Effect of various torsion pitch ratios on Nusselt number (Nu) in different Reynolds numbers.

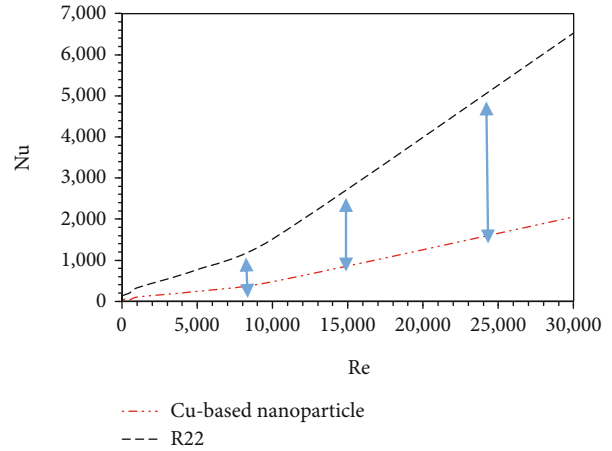

FIGURE 4: Effect of R_{22} and Cu-based nanoparticles on Nusselt number (Nu) in different Reynolds numbers.

4. Discussion and Conclusions

Despite the limitations of validating the problem, the correctness of the code can be ensured by solving classical governing equations for similar geometries, regardless of the rotation of the inner cylinder, and comparing the results of the present numerical solution with the work of others. Figure 1 shows a comparison between the present work results and the study of Safikhani et al. (2016), and there is an excellent correlation between these results for the two heat flux ratios of 0.5 and 2. The maximum numerical error for the Reynolds number is 9.2%. The amount of numerical error of the coefficient of friction between both numerical solutions in the inner and outer walls is negligible, which shows a good agreement between the results of these solutions.

Heat transfer media are usually composed of fluids such as water and oil with a lower thermal conductivity than these nanoparticles. For example, the thermal conductivity of copper is 700 times the thermal conductivity of water and 300 times the thermal conductivity of engine oil, or the thermal conductivity of copper oxide is about 60 times the thermal conductivity of water. Therefore, fluids containing fine particles of metal compounds, metal oxides, carbon nanotubes, graphene, or hybrids are expected to exhibit better thermal properties than pure fluids. The larger surface area of the nanoparticles increases the intensity of heat transfer from the fluid to the particles where the fluid is warmer than the nanoparticles and transfers heat from the particles to the fluid where the fluid is cold. To transfer heat by displacement, the particles must be easily displaced by the fluid. Due to technological problems, studies in this field have focused more on suspensions that include particulate matter suspended in millimeters and with a maximum of micrometers. Particles on this scale cause acute problems in the heat transfer equipment so that these particles quickly settle in the system and become clogged as they pass through the ducts, causing a significant pressure drop. In addition to the collision of these particles with each other and with the system's wall and equipment causing abrasion, it is theoretically determined that the smaller the particles, the higher their heat transfer level.

Power plants are considered one of the most important industrial centers of the country and have a particular sensitivity. This importance includes the various parts used in it, such as turbines, boilers, and converters. The transfer of thermal energy from one fluid to another in the industry is done by a heat exchanger device. There are two fluids with different temperatures in heat exchangers, which provide the conditions for heat exchange between the two fluids, usually exchangers. Thermals are used to cool a hot fluid, heat a fluid to a lower temperature, or both. The heat exchanger transfers energy between two fluids through an interface. Since nanoparticles affect the fluid's thermal properties, nanofluids in heat exchangers can be very efficient and helpful. Viscosity is the resistance to the relative motion of a fluid. This parameter plays a crucial role in momentum transmission between fluid layers, and its effect becomes more pronounced when there is movement between fluid layers. In liquids, viscosity is caused by the presence of van der Waals forces between molecules.

It should be noted that this simulation has been done with Ansys-Fluent software, and after designing the initial design using the study of existing articles and researches. Simulation is an educational technique that provides all or part of a clinical experience in a safe environment and helps a person learn without fear of personal weakness or fear of self-harm through interactive activities. The use of simulation in the industry is widely evolving worldwide. Its prevalence is influenced by technological advances, changes in ethical issues raised in learning industrial skills, the congestion of industrial environments for training, and the lack of manpower. Experts work in companies to help with the training process. Simulation has several benefits, including increasing personal safety, enhancing interactive and inclusive learning, helping to improve learners' problem-solving and critical thinking skills, and achieving self-regulated learning. However, despite all the mentioned advantages, it is noteworthy that due to the financial costs of providing simulation equipment and the need for proper cost management, especially in educational centers in the present era, the results of using similar types should be done through numerous researches. Instruments should be examined on learners' learning, and according to the effectiveness of different types of simulators, each of them was prepared and prepared for educating learners.

The main findings of this study are as follows:

(i) The Nusselt number has been increased for higher diameter ratios, especially in higher Reynolds numbers, as the heat transfer has been increased in turbulators

(ii) For organic fluids (R_{22}), the Nusselt number has been increased, especially in higher Reynolds numbers, as the heat transfer has been increased in turbulators due to the proximity of heat transfer charges

(iii) At higher torsion pitch ratios, the Nusselt number has been increased, especially in higher Reynolds numbers, as the heat transfer has been increased in turbulators, especially in higher velocities and pipe turbulence torsions

Abbreviations

Re: Reynolds number
Pr: Prandtl number
α: Twist angle (degree)
Nu: Nusselt number
μ: Viscosity (kg·m^{-1}·s^{-1})
f: Friction coefficient
D: Pipe diameter (m)
d: Wire diameter (m)
ρ: Density (kg/m^3)
h_f: Height (m)
g: Gravity (m·s^{-2})
h: Displacement heat transfer coefficient (W/K).
