Retracted: A Quantitative Enhancement Mechanism of University Students' Employability and Entrepreneurship Based on Deep Learning in the Context of the Digital Era

Scientific Programming

Received 29 August 2023; Accepted 29 August 2023; Published 30 August 2023

This article has been retracted by Hindawi following an investigation undertaken by the publisher [1]. This investigation has uncovered evidence of one or more of the following indicators of systematic manipulation of the publication process:

(1) Discrepancies in scope
(2) Discrepancies in the description of the research reported
(3) Discrepancies between the availability of data and the research described
(4) Inappropriate citations
(5) Incoherent, meaningless and/or irrelevant content included in the article
(6) Peer-review manipulation

The presence of these indicators undermines our confidence in the integrity of the article's content and we cannot, therefore, vouch for its reliability. Please note that this notice is intended solely to alert readers that the content of this article is unreliable. We have not investigated whether authors were aware of or involved in the systematic manipulation of the publication process.

Wiley and Hindawi regrets that the usual quality checks did not identify these issues before publication and have since put additional measures in place to safeguard research integrity.

We wish to credit our own Research Integrity and Research Publishing teams and anonymous and named external researchers and research integrity experts for contributing to this investigation.

The corresponding author, as the representative of all authors, has been given the opportunity to register their agreement or disagreement to this retraction. We have kept a record of any response received.

Building extraction from high-resolution aerial images is critical in geospatial applications such as telecommunications, dynamic urban monitoring, updating geographic databases, urban planning, disaster monitoring, and navigation. Automatic building extraction is a massive task because buildings in various places have varied spectral and geometric qualities. As a result, traditional image processing approaches are insufficient for autonomous building extraction from high-resolution aerial imaging applications. Automatic object extraction from high-resolution images has been achieved using semantic segmentation and deep learning models, which have become increasingly important in recent years. In this study, the U-Net model was used for building extraction, initially designed for biomedical image analysis. The encoder part of the U-Net model has been improved with ResNet50, VGG19, VGG16, DenseNet169, and Xception. However, three other models have been implemented to test the performance of the model studied: PSPNet, FPN, and LinkNet. The performance analysis through the intersection of union method has shown that U-Net with the VGG16 encoder presents the best results compared to the other models with a high IoU score of 83.06%. This research aims to examine the effectiveness of these four approaches for extracting buildings from high-resolution aerial data.

1. Introduction

Collecting urban geographic information and updating data timely are crucial and vital challenges for better management of cities in the fast urbanization and building of megacities. The accuracy of information extraction may be considerably improved by using high-resolution remote sensing images. Experts and scholars from all over the world have focused on remote sensing data classification methods in recent decades, ranging from supervised and unsupervised classifications based on traditional statistical analysis [1]. Among these, the pixel-based statistical classification approach has emerged as the most popular and well developed, with promising results in particular domains [2]. On the other hand, traditional pixel-based classification algorithms primarily use spectral data and have limited effectiveness in categorizing high-resolution multispectral urban images with similar spectra into separate categories [3]. To develop more accurate categorization maps, geographic information such as geometric and spatial characteristics and textural information must be used.

In recent years, object-oriented classification algorithms have attracted researchers' interest [3, 4]. It has been demonstrated to have the ability to overcome the suffering from some forms with per-pixel analysis, such as the omission of geometric and contextual information. The fundamental concept is to divide the image into objects with specific meanings and then categorize them using the items spectral, form, and textural properties. This technique considers additional discriminative features and conforms to human visual interpretation patterns, resulting in a new way of thinking about data extraction [5]. While several studies have demonstrated the benefits of object-based classification over pixel-based classification, there has been less focus on its possible drawbacks. However, the object-based technique has its own set of constraints. Image segmentation errors include both over-segmentation and under-segmentation. These segmentation issues can affect the categorizing process in two ways: (1) Poorly segmented image objects with over-segmentation or under-segmentation errors produce image objects that span multiple classes, introducing classification errors because all pixels in each mixed image object must be assigned to the same class; (2) features extracted from poorly segmented image objects with over-segmentation or under-segmentation errors do not represent the properties of real objects on the Earth's surface (e.g., shape and surface area), so they may not be useful and may even reduce the accuracy of the classification.

Image segmentation is an essential and vital phase in (GEographic) Object-Based Image Analysis (GEOBIA or OBIA). The quality of image segmentation significantly influences the final feature extraction and classification in OBIA. In traditional segmentation methods, images are usually divided into several disjoint regions based on grayscale, color, texture, and shape. Typical segmentation methods include pixel-based statistical classification, segmentation methods based on thresholds, edges, regions, and graph theory, and object-based image segmentation.

The basic idea of the threshold-based segmentation method is to calculate the grayscale threshold based on the grayscale features of the image and compare the grayscale value of each pixel of the image with the threshold to obtain its category. For example, Li et al. [6] used the wavelet transform and adaptive global threshold method to extract the labelling information of building groups according to the distribution and texture characteristics of building groups to achieve segmentation; Wu et al. [7] proposed a method based on the line intercept histogram. Multi-threshold segmentation methods and edge-based segmentation methods [8] mainly perform edge detection based on the sudden change of image edge grayscale, color, texture, and other features. Differential operators such as Prewitt [9] perform edge detection on the image, identify the edge information of the image, and complete the segmentation. The basic idea of the segmentation method based on graph theory is to associate the image segmentation problem with the minimum segmentation problem of the graph and finally realize the segmentation effect. For example, Felzenszwalb et al. [10] introduced an image segmentation method based on graph representation, proposed a variable component model algorithm based on the greedy clustering algorithm, and established a segmentation algorithm based on graph theory. However, due to the rich spectral information contained in remote sensing images, traditional feature extraction methods still have significant limitations for demanding remote sensing image segmentation application scenarios, and their classification accuracy cannot meet the actual needs for dealing with huge image data and serious image interference. Therefore, traditional classifiers are unsuitable for complex image classification and, more precisely, building extraction.

Urban system studies are promising for using particular resolution and very high spatial satellite image data. Thus, for Earth monitoring, the development of various sensors has substantially expanded the availability of high-resolution remote sensing images since the launch of the first satellite, giving accurate terrestrial scene interpretation and an enormous potential for meaningful. Identifying rooftops is one of the most challenging satellite image analyses, but essential tasks for object extraction. Many remote sensing applications, such as disaster monitoring, geographic databases, urban planning, etc., can benefit from this data. However, with high spatial and spectral quality RS data, manually distinguishing buildings from other objects and delineating their outlines are time consuming and costly. As a result, there have been several attempts to develop automated building extraction technologies.

Some algorithms for building detection based on high-resolution satellite and aerial data use specific building appearance criteria, such as uniform spectral reflectance values. The fundamental issue with these techniques is that the building is confused with other objects having similar spectral reflectance. Many methods for building extraction use multispectral images that provide for a scene set criteria height information, like relatively homogenous structures following a given pattern. However, these techniques are severely constrained since the established criteria only work for specific types of buildings and do not apply to regions with complex and varied structures. Different data sources might provide each other with complementing information.

In recent years, deep learning has shown significant promise for meeting the challenging demands of remote sensing image processing. Deep learning has shown to be a very effective collection of technologies in recent years, sometimes even surpassing human abilities to perform highly computational jobs. The RS community's interest in deep learning approaches is expanding rapidly, and several architectures have been developed in recent years to handle RS difficulties, frequently with excellent results. Deep learning is an emerging machine learning algorithm that has attracted extensive attention from researchers because of its remarkable effect on image feature learning. Compared with traditional image classification methods, it does not require artificial feature description and extraction of target images but learns features from training samples autonomously through neural networks and extracts higher-dimensional and abstract features, and these features related to the classifier are closely related and solves the difficult problem of manual feature extraction and classifier selection. It is an end-to-end model. The essential advantage of the deep learning-based image classification method compared to the traditional image classification method is that it can automatically learn more abstract data features through the deep architecture without designing specific artificial features for specific image data or classification methods, significantly improving the performance of image classification. Deep Learning (DL) outperforms its predecessors significantly; it is based on a traditional neural network. Furthermore, in order to construct multi-layer learning models, DL uses both transformations and graph technologies at the same time.

The latest DL algorithms have achieved excellent results in various applications, including natural language processing (NLP), visual data processing, and audio and voice processing. Convolutional neural networks (CNNs) with more hidden layers have a more complicated network structure and can learn and express features more effectively than classic machine learning approaches [11, 12]. In remote sensing, the use of CNN has become crucial with the appearance of multispectral data at a very high spatial resolution. However, Figure 1 shows the number of publications in the last six years that use CNN and different techniques to classify high-resolution satellite data. This exponential number of publications shows the importance of the deep learning approach in automatic object recognition from high and very high spatial and spectral resolution images.

High-resolution remote sensing images have rich spatial information but contain fewer bands. In order to extract abstract features with sufficient discriminative power and robustness, in recent years, people mainly automatically extract deep-level features from image data through learning methods. CNN is commonly used in remote sensing image classification and can be divided into patch-based CNN and fully convolutional neural network (FCN) [13]. Patch-based CNN can effectively learn the spatial-spectral joint features of the pixels to be classified and their neighborhoods and has been widely used in the field of hyperspectral classification [14]. However, the network has a large number of repeated computations, which limits its application in large-scale high-resolution remote sensing imagery tasks. The trained FCNN can classify all the input image pixels through one forward pass, which is more efficient than the patch-based CNN [15]. Therefore, FCNN is widely used in large-scale high-resolution remote sensing image building extraction tasks [16]. The learning of image features by CNN is realized by optimizing each layer of convolution kernels in the network. The static structure of the network determines the mode of feature learning, and the data determines the specific feature extraction results, thus showing certain robustness. The feature fusion methods used in Residual Networks (ResNet) and DenseNets (DenseNet), that is, feature map addition and feature map connection, have a profound impact on CNN optimization research.

Building extraction from remote sensing images and comparing the performance of different models of the semantic segmentation network is our primary motivation for this paper. However, this paper allowed us to:

(i) show the importance of the deep learning model in the classification of satellite images with very high spatial resolution;

(ii) minimize subjectivity in urbanized areas with the most important step in the classification process being segmentation;

(iii) compare the four improved DL architecture (U-Net, LinkNet, FPN, and PSPNet) with five different initialized and pre-trained encoders (VGG16, VGG19, ResNet50, DenseNet169, and Xception);

(iv) improve overall classification accuracy in the Massachusetts aerial image dataset.

2. Related Works

2.1. Semantic Segmentation. The semantic segmentation of remote sensing images aims to assign a land cover label to each pixel in the image, which can be understood as a pixel-level classification problem. Fully convolutional neural networks (FCN) were suggested by the authors in [17] to overcome the limitations of convolutional neural networks applied to the field of semantic segmentation. FCN has usually adopted an encoder-decoder system, with the encoder being a subsampling network, which is mainly used to learn multilevel semantic features. The decoder is generally defined as an oversampling network and is used primarily to map the semantic features learned by the encoder to the pixel space of the original resolution for pixel-level classification. Currently, in the field of remote sensing, researchers have made many improvements to FCN based on the characteristics of remote sensing images. For example, considering the rich and diverse categories of remote sensing objects and complex boundaries, Long et al. [18] improved the decoder by designing deconvolution and jump connections, improving the extraction effect of the edge details of the remote sensing object. To solve the problem of fuzzy edge details of objects extracted, the FCN method was proposed [19] by reducing the expansion factor of hole convolution to aggregate local features. Aiming at the multiscale problem of ground objects in complex remote sensing scenes, Hamaguchi et al. [20] proposed using a closed convolution neural network to complete information diffusion between feature maps at different levels to achieve multiscale feature fusion. As discussed elsewhere [21], based on the idea of clustered convolution design, an efficient spatial pyramid network with holes is proposed to complete the multiscale information extraction of remote sensing features. Moreover, considering the problem that FCN cannot adaptively take the long-range dependencies between different objects because of the fixed receptive field, the researchers used recurrent neural networks, self-attention mechanisms, and other methods to model the long-range contexts of remote sensing objects further to improve the semantics of segmentation accuracy [22].

2.2. Building Extraction. Several authors have utilized deep learning models to extract urban features from image data with very high spatial resolution, and with the progress of convolution, the degree of feature abstraction continues to increase, and the receptive field also increases, which inevitably leads to the loss of spatial details. Most of the FCNs used for building extraction use an encoder-decoder structure, which has the characteristics of level-by-level decoding and can recover spatial information. U-Net effectively recovers spatial information by fusing the feature maps of the encoded segment and the corresponding decoded segment and shows excellent potential in the task of building extraction [23]. In addition, buildings in high-resolution images have multi-scale characteristics, and the characteristics of vertical imaging in remote sensing images make their semantic features quite complex. There are many ground objects with similar colors and textures to building roofs.

The U-Net family [24] suggested two innovative classifiers for multi-object segmentation to extract roads and buildings. The multi-level context gating U-Net (MCG-U-Net) and the bi-directional ConvLSTM U-Net model are the two models discussed. The proposed methods generate detailed segmentation maps that preserve boundary information even in complex backgrounds by combining tightly-coupled convolutions, bidirectional ConvLSTM, and squeeze-and-excitation modules. The researchers also devised an essential efficient loss function known as boundary-aware loss (BAL), which allowed a network to focus on complex semantic segmentation regions such as overlapping areas, tiny objects, complex objects, and object boundaries while still delivering high-quality segmentation results. To employ building features from high-resolution aerial images, researchers [25] developed a unique deep neural network called the Seg-U-Net approach, which is a blend of Segnet and U-Net algorithms. They utilized the Massachusetts building dataset for their analysis. Consequently, the accuracy of the contributions increased to 92.73 percent. The authors in [26] established a unique multi-task loss to solve the difficulty of retaining semantic segmentation borders in high-resolution satellite images. The loss is based on differing output representations of the segmentation mask, according to the researchers, and biases the network to focus more on pixels near borders. The authors demonstrate that the technique outperforms state-of-the-art methods by 9.8% on the Intersection over Union (IoU) measure without extra post-processing steps using the Inria aerial image labeling dataset. The U-Net model with ResNet50 as an encoder was used in [27] to increase and improve the accuracy to extract buildings from the Massachusetts dataset.

3. Methodology

3.1. Sematic Segmentation with Fully Convolutional Network. To improve pixel-level image segmentation by traditional CNNs, the authors in [18] proposed a fully convolutional neural network, which achieves high accuracy in image-level classification and regression tasks, usually by connecting multiple fully connected layers after multiple convolutional layers. The N-dimensional feature vector is used to predict the probability value of each N category, and then the category of the input image is obtained. The difference between the above task and the extraction of the building in remote sensing images is that each pixel in the input image is classified to obtain a pixel-level classification result. Although CNN can define sliding windows centered on individual pixels and model the window features to obtain semantic segmentation results at the pixel level, the time complexity increases significantly due to the large amount of duplicate information generated by the overlapping areas between adjacent windows. In addition, the choice of window size will also be a challenge: A too-small window will lose target contextual information and reduce accuracy; a too-large window will increase the computational and memory load.

To address these issues, FCN has outperformed CNN. FCN uses deconvolution to up-sample high-dimensional feature maps to obtain prediction results similar to the input image, rather than utilizing fully connected layers to create feature vectors to forecast probabilities after multilayer convolution and pooling, as shown in Figure 2. This network topology prevents the propagation process from losing spatial information from the input image, allowing each pixel in the image to be predicted. Furthermore, the FCN does not have to perform a window-by-window calculation on the picture, dramatically improving computational efficiency.

Although FCN enhancement can reach the same segmentation result as the input image size, the predicted image is frequently too smooth, resulting in more severe information loss. The fundamental reason for this is that the input image is clustered many times, allowing neurons at the tail end to receive more information, resulting in a broader perceptual field. However, the image loses information, as a result making the edge contours extracted less desirable. Consequently, FCN integrates the low-dimensional feature map into the feature pyramid with the output after deconvolution to overcome the problem mentioned above and increase the accuracy of extracting detailed information. Consequently, U-Net [23] extends this idea of merging low dimensional features with high-dimensional features.

3.2. Model Used

3.2.1. U-Net Architecture. Figure 3 depicts the U-Net structure, consisting of two feature encoding and decoding steps. The raw input is convolved and subsampled layer by layer in the feature encoding step to obtain high-level semantic features with lower spatial resolution. In the decoding step, the underlying features are increased by a factor of 2 layer by layer through the upward convolution operation, concatenated with the same layer features in the encoding step, and returned to

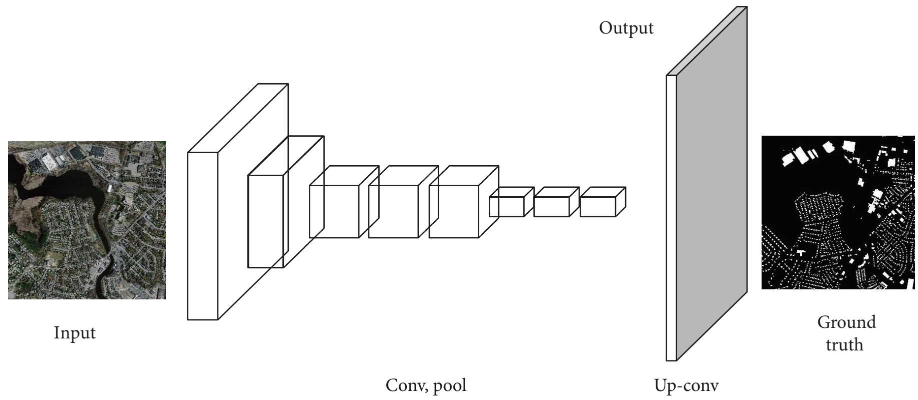

FIGURE 2: Architecture of fully convolutional neural networks.

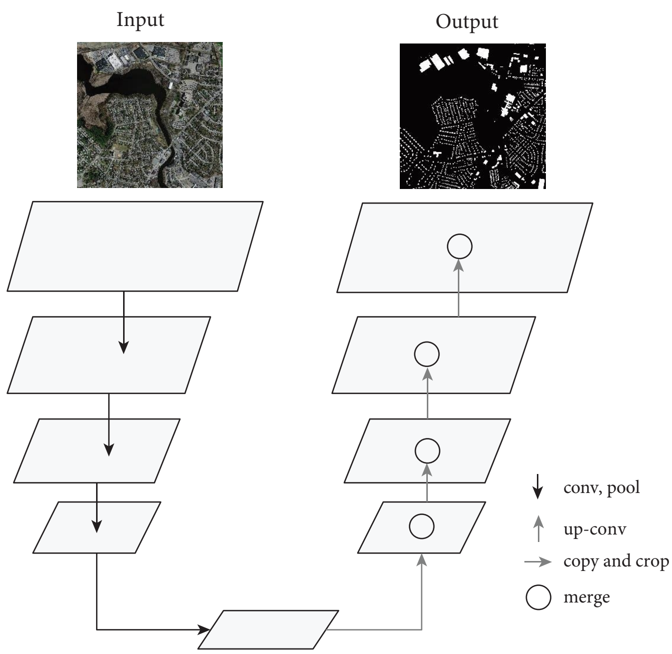

FIGURE 3: Architecture overview of U-Net.

the original image scale. At the original scale, the difference between the current model predictions and the ground truth reference is used to form the network parameters via back-propagation. U-Net only performs image pixel class classification in the last layer. Although U-Net uses some information from the previous layers in the encoding step, its ability to generalize to multi-scale information is limited.

3.2.2. Pyramid Scene Parsing Network (PSPNet). Multiscale information is also essential for enhancing the accuracy of semantic segmentation. The multiscale receptive field can learn information from objects of different sizes combined with the image scale context. For example, global scene classification can provide category distribution information for semantic image segmentation, and the pyramid clustering module obtains category distribution information by using clustering layers with larger convolution kernels. A spatial pyramid scene parsing network (PSPNet) [28] was proposed to acquire information about the overall scene. As shown in Figure 4, to extract the features from the input image, the convolutional neural network (CNN) model is used and the feature map is sent to the pyramid clustering model. In addition, to extract multiscale information from the images, the model integrates four parallel clustered features of different scales and transforms any size feature map into a fixed-length feature vector. To capture global features, 1x1 convolutions is used to reduce the number of channels to 1/4 of the original size after each clustering operation at different scales. Before ungrouping, the feature maps are restored to their original size using bilinear interpolation, and then connected to the feature maps before pooling. Finally, a convolutional layer generates the final prediction result. The spatial pyramid pooling model leverages distinct spatial information and combines global and local information to get a global understanding of the scene.

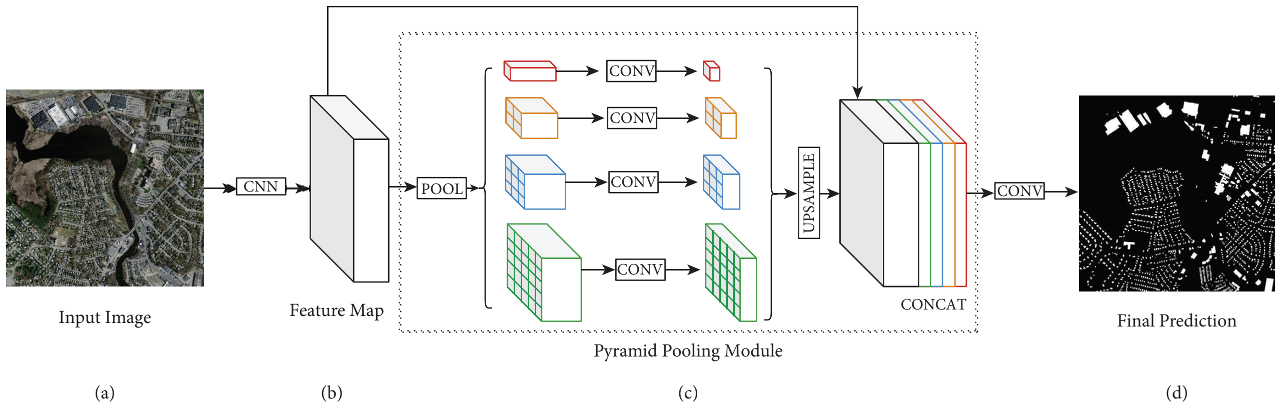

Figure 4: Architecture overview of PSPNet.

3.2.3. LinkNet. LinkNet, a real-time semantic segmentation network, was suggested by [29]. DeconvNet and SegNet employ clustering indices to recover spatial information lost during subsampling, whereas LinkNet sends spatial information directly from the encoder to the matching decoder, conserving as much of the image's spatial information as feasible. As shown in Figure 5, this method directly connects the shallow feature map in the encoder module to the decoder module of the corresponding size, that is, the output of each encoder module is used as the input of the corresponding decoder module, which not only uses the accurate position information of the shallow layer but also avoids adding redundant parameters and computations, resulting in improved computational speed while ensuring accuracy.

3.2.4. Feature Pyramid Network (FPN). Convolution and pooling operations are performed on the original image in convolutional neural networks to create feature maps of various layers and sizes. The network surface layer is more interested in detailed information, but the deep layer is more interested in semantic information, which might assist us in precisely detecting the target. As a result, the typical convolutional neural network makes predictions based on the feature maps of the final convolutional layer. The FPN is an end-to-end network in which feature maps are created through a succession of convolutional processes, predictions are formed at each step, and feature maps are utilized for each prediction layer identified at the appropriate resolution [30]. This guarantees that each layer has sufficient resolution and solid semantic characteristics. By weighing the outcomes of each prediction step, the FPN gets the final loss function. The principle is to accumulate surface and deep features, as the surface features provide more accurate location information. In contrast, the deep network's location information is inaccurate due to multiple subsampling and oversampling operations, and their combined use builds a deeper FPN (Figure 6) that integrates multiple layers of feature information and produces various features.

3.3. Backbone of Network. This study adopts models with end-to-end fully convolutional neural network structures, consisting of a decoder and an encoder. The encoder learns the target features hierarchically to gradually reduce the spatial resolution and gradually increase the receptive field. Among the features learned by the encoder, shallow features have more spatial information, including edge, contour, and location information, while deep features have more semantic category information. The decoder restores the spatial resolution of the features learned by the encoder and produces the prediction results with a similar spatial resolution as the input image. Considering in remote sensing that the scales of buildings images are quite different and there are both large buildings and small residential buildings in the same image, the spatial information lost in the encoding process should be compensated in the network design process, and the features of different scales should be integrated for decoding.

Verify the importance of the depth of the decoder and encoder layers and improve the proposed networks. This paper uses VGG16, VGG19, ResNet50, Densenet169, and Xception as pre-trained encoders on a large ImageNet dataset [31]. The addition of the encoder-decoder module aims mainly at improving the detailed information of the segmentation by restoring the original pixel information.

3.3.1. VGG as Backbone. VGG is a 16–19 layer deep convolutional network used by the Visual Geometry Group (VGG) at the University of Oxford in the 2014 ILSVRC (ImageNet) competition based on the AlexNet network. The model achieves a success rate of 92.5% in the top 5 of the validation set [32]. It inputs a color image of size $224*224$ px and classifies it into one of 1000 classes. Then, it returns a vector of size 1000, which contains the probabilities of belonging to each class. The automatic feature extraction exploits only the convolutional part of a pre-trained network. It uses it as a feature extractor of the images to feed the classifier. Using a multi-scale learning strategy to increase the amount of data, the model shows that the deeper the network, the better the results.

3.3.2. ResNet as Backbone. In [33], a ResNet to solve the problem of degraded deep network learning is proposed. ResNet adds constant mapping using a shortcut structure, which maps features X at the lower level directly to the

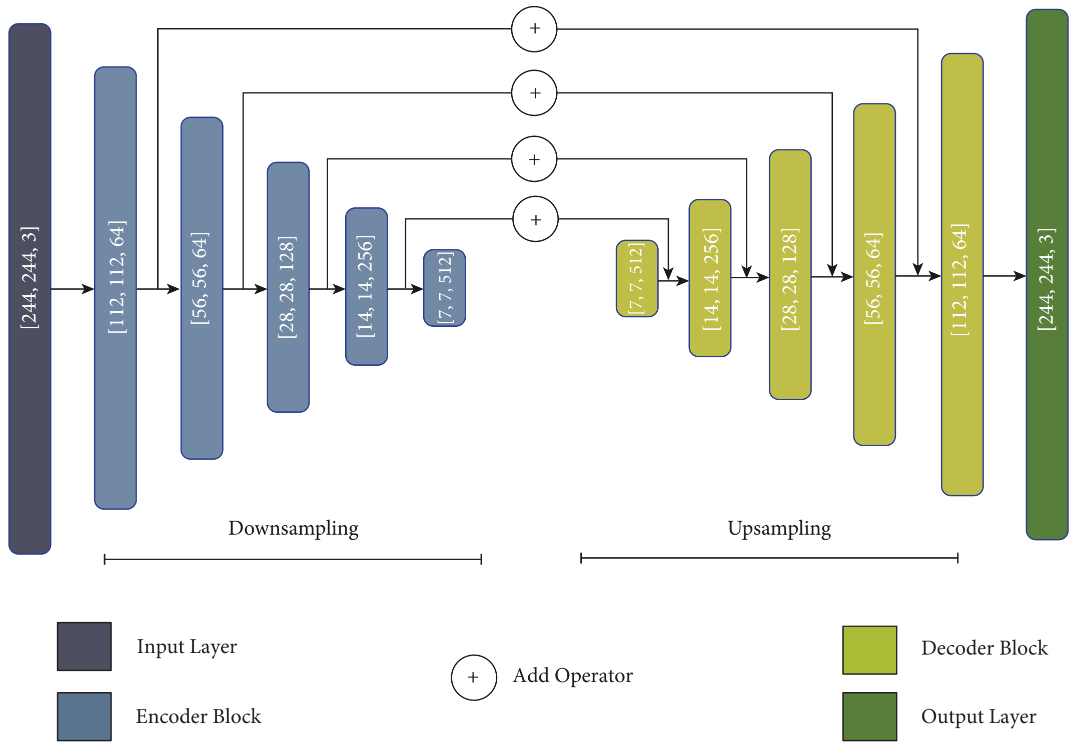

Figure 5: An illustration of the LinkNet architecture.

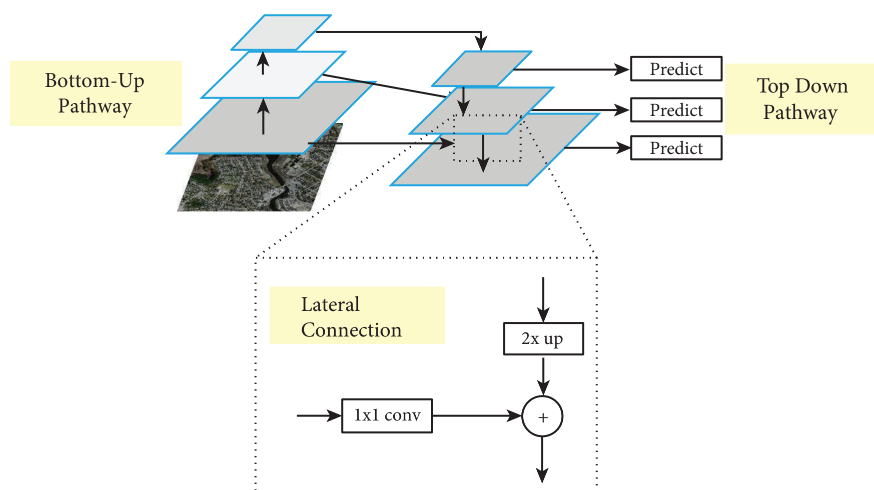

Figure 6: An illustration of the FPN architecture.

network at the higher level. Assuming that the input to a neural network segment is X and the desired output is $H(X)$, the shortcut converts the original learning target $H(X)$ to $H(X)-X$ so that the whole network needs to learn a portion of the difference between the output and the input, simplifying the target and the difficulty of learning the network.

3.3.3. DenseNet as Backbone. Based on the ResNet network, Huang et al. [34] proposed a DenseNet model that connects each layer of the network to all previous layers in a feed-forward way while designing each layer to be particularly narrow and learning very few feature maps to reduce redundancy, which achieves accuracy comparable to ResNet on ImageNet but requires much fewer parameters.

3.3.4. Xception as Backbone. With a separable depthwise convolution, Xception replaces the inception modules [35] and adds residual links. This type of approach considerably, without changing the number of parameters, reduces the use of resources during the matrix calculation.

Usually, the encoder structures in segmentation tasks are similar, mainly derived from the network structures used for classification tasks. This has the advantage that the weighting

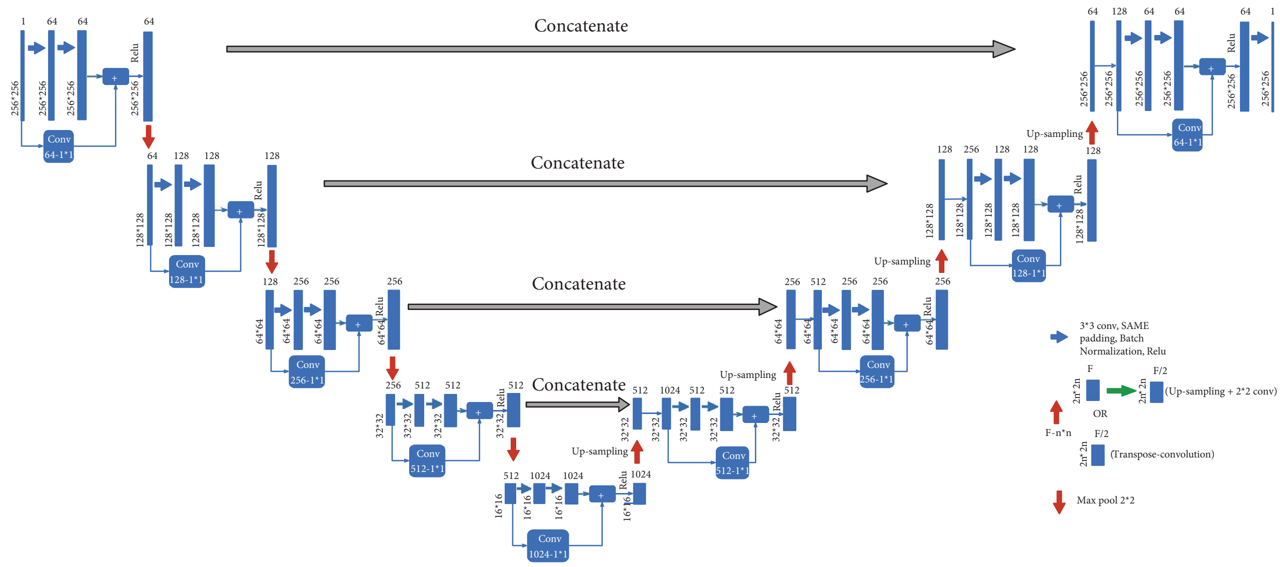

Figure 7: An illustration of the U-Net model with ResNet backbone.

parameters of the classification network trained in the large database can be borrowed to achieve better results through transfer learning. Therefore, the decoder difference largely determines the effect of a segmentation network based on the encoder-decoder structure.

An example of the Res-U-Net (U-Net model with ResNet backbone) is shown in Figure 7.

3.4. Dice Loss Function. The cross-entropy loss function (equation (1)) is often used in binary image segmentation problems. The improvement of cross-entropy is that it is easy to calculate the gradient, but when used in the building extraction problem, it will focus more on identifying the categories with high proportion due to the imbalance of samples, making it difficult to extract categories with few samples. After statistics, the ratio of building to non-building pixels in the Massachusetts dataset is about 1 : 10. To solve this problem, this study chooses the dice loss function to complement the cross-entropy loss function to reduce in building extraction the impact of sample imbalance, which is defined as equation (2),

$$L_1 = -\sum_{n=1}^{N} \left(y_n' \log y_n + (1 - y_n')\log(1 - y_n) \right), \quad (1)$$

where y_n' represents the true label class, building pixels are 1, non-building are 0, $y_n \in [0, 1]$ represents the predicted class probability, N is the total number of pixels in a sample, and n is one of the pixels,

$$L_2 = 1 - \frac{2\sum_{n=1}^{N} p_n \times t_n}{\sum_{n=1}^{N} p_n + \sum_{n=1}^{N} t_n}, \quad (2)$$

$$L_3 = L_1 + L_2, \quad (3)$$

where p_n and t_n represent the predicted category and the true label category of the pixel, respectively, and the rest of the parameters are defined in the same way as in formula (1).

According to equations (1) and (2), when there are too many non-building pixels, the cross-entropy function will make the network tend to reinforce the learning of non-building and increase the predicted category probability of non-building pixels to reduce the loss. In contrast, the dice loss function only focuses on the correct classification of the building pixels. Therefore, in this study, the dice loss function $L1$ (equation (1)) and the cross-entropy loss function $L2$ (equation (2)) are added to obtain a composite loss function $L3$ (equation (3)) that combines dice and cross-entropy, which improves the performance of the network classification ability when buildings have few pixels.

4. Experiments and Analysis

4.1. Data Description. The Massachusetts dataset, created by Mnih [36], was captured in Massachusetts, USA, and contains labels for buildings and roads, which were used in this experiment only for building extraction. The dataset contains 137 training images, 10 test images, and 4 validation images, with 3 bands of red, green, and blue, all 1500 pixels in length and width, and a spatial resolution of 1 m, covering an area of approximately 340 km^2. As mentioned in Figure 8, an original RGB image with its validation mask whose objects (buildings in this case) are shown in binary.

4.2. Data Augmentation. In general, the larger the amount of data, the more easily the model can learn representative features. Due to the high cost of acquiring new data, there are various data enhancement techniques to increase the amount of data, such as zooming in, zooming out, rotating, flipping, color changes, etc. In this experiment, zooming, rotating, and horizontal and vertical flips were used to enhance the data. Figure 9 depicts the results: Figures 9(a) and 9(b) show the original raw image and the modified image, respectively.

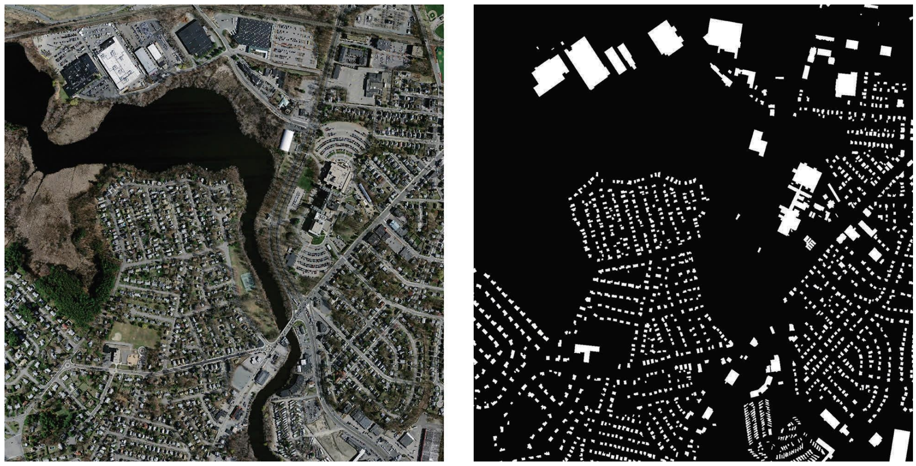

Figure 8: An example of the original and ground truth mask of testing Massachusetts buildings' dataset.

4.3. Implementation Details. The internal parameters of the neural network can be obtained by iterating the optimization algorithm, while some hyperparameters need to be set artificially to guide the model during learning, such as learning rate, optimization function, weight decay parameter, etc.

The optimization problem is one of the most important research directions in computational mathematics. In the field of deep learning, the choice of the optimization algorithm is also the top priority of a model. The Adam optimization [37] function was used in this paper; it is one of the most popular optimizers in deep learning. It is suitable for many types of problems, including models with sparse or noisy gradients. Its ease of fine-tuning makes it possible to achieve good results quickly. The Adam optimizer combines the advantages of AdaGrad and RMSProp. Adam uses the same learning rate for each parameter and adapts independently as learning progresses.

The learning rate is considered as one of the essential hyperparameters for optimizing deep neural networks; by acting on its convergence, it sets the conditions of its operation before the learning process. Indeed, a too high learning rate leads to essential weight updates, and the convergence becomes unstable. On the other hand, for a low learning rate, the convergence is slowed down with a possibility of falling into local minima. The popular approach used in deep learning to have the optimal learning rate is to start learning with a high value to accelerate the gradient descent and reduce it later to improve the accuracy [38]. Practically, this involves initializing an $\alpha 0$ to a high value at the beginning and then decreasing it by a constant multiplicative factor during the learning phase until the validation error reaches a stable value or when the learning error does not decrease anymore [39].

The initial learning rate was 0.0001; it could be formulated as in equation (4),

$$lr = 0.0001 \times \left(1 - \frac{iter}{\max iter}\right)^{0.9}. \tag{4}$$

In our experiments, the training and testing process for building detection was implemented in the PyTorch framework using the Nvidia TesUla K80 graphics card. The batch size was 16 with 100 epochs.

4.4. Evaluation Metrics. To validate the semantic segmentation performance of the proposed method, in this paper, we use four indicators (precision, recall, F1 score, and IoU (intersection over union)) to evaluate the performance of different methods on the dataset. The IoU indicator is, often referred to as the intersection over union ratio, also known as the Jaccard index, and it is a statistic for determining how accurate an object detector is on a given dataset, which is often used not only in semantic segmentation evaluation but is frequently used in object detection problems, such as remote sensing images. As the name suggests, IoU is the ratio of intersection and union between the target and the prediction (equation (5)),

$$J(A, B) = \frac{|A \cap B|}{|A \cup B|} = \frac{A \cap B|}{|A| + |B| - |A \cap B|}, \tag{5}$$

where A represents the buildings and characteristics predicted by different methods and B represents the map of the actual characteristics of the building.

The precision is expressed as the ratio of the number of correctly predicted positive samples to the number of all predicted positive samples,

$$Precision = \frac{TP}{TP + FP}. \tag{6}$$

The recall is expressed as the ratio of the number of correctly predicted positive samples to the number of all positive samples in the test set,

$$Recall = \frac{TP}{TP + FN}. \tag{7}$$

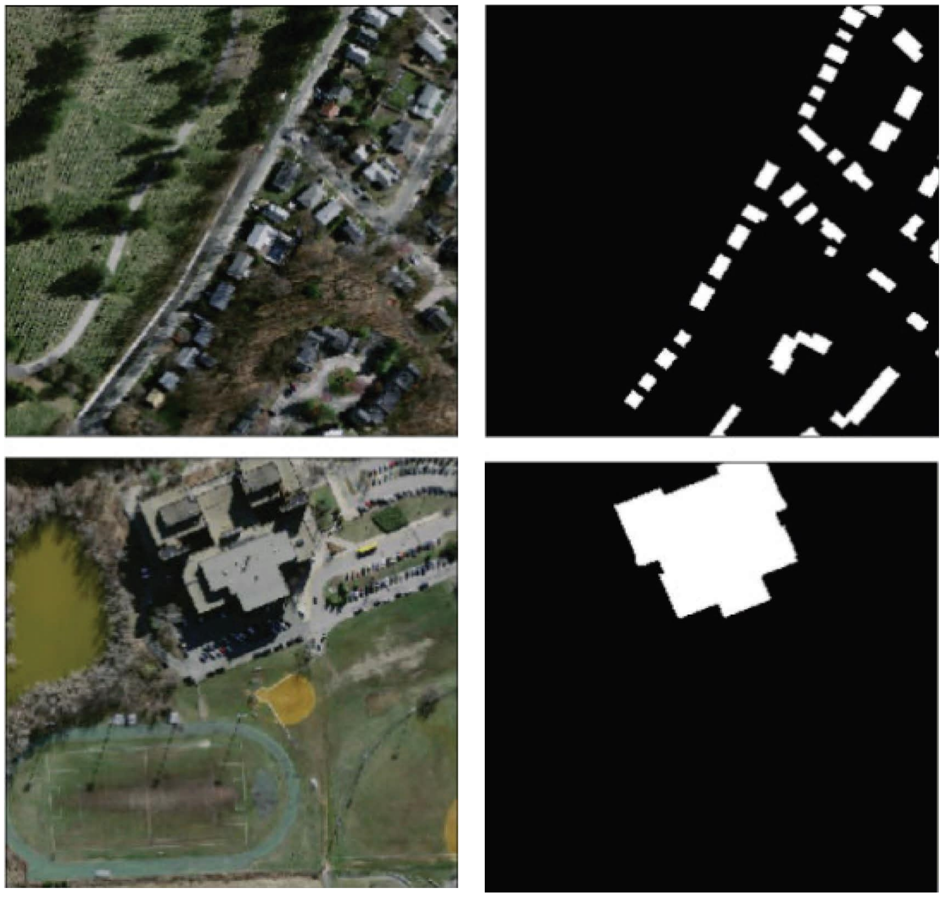

FIGURE 9: Examples of data augmentation pre-processing. (a) Transform image and (b) transform ground truth mask.

F1score is the geometric mean between precision and recall, also known as the harmonic mean, and is an index to measure the precision of the binary classification model,

$$F1\ score = \frac{2 * Precision * Recall}{Precision + Recall}, \tag{8}$$

where TP (true positive) refers to the number of correctly classified positive samples, FP (false positive) refers to the number of negative samples mislabeled as positive samples), TN (True Negative) refers to the number of correctly classified negative samples), and FN (False Negative) refers to the number of positive samples incorrectly marked as negative samples).

5. Results

The proposed networks are built with deeper encoding and decoding layers to achieve better building segmentation results. The FCN method uses a simple convolutional coding layer. Due to its low encoding and decoding layers, it cannot fully extract the variable features from the building features, which leads to poor building feature extraction results.

This research undertakes five experiments based on VGG16, VGG19, ResNet50, DenseNet169, and Xception as a backbone for comparative analysis to demonstrate the relevance of the depth of encoder and decoder layers in building the network for each model. In this work, the efficiency of several deep learning-based models (U-Net, FPN, PSPNet, and LinkNet) in extracting buildings from high-resolution aerial images was evaluated, and in this case, IoU technique, Fscore, precision, and recall were implemented and used. Each of these models may offer several distinct advantages over the others. For example, the U-Net with VGG16 is a shallower model than others and has a basic network topology. On the other hand, PSPNET architecture considers the image's global context when predicting local level predictions, resulting in improved performance on benchmark datasets such as cityscapes and PASCAL VOC 2012.

Because the buildings in each region have various distribution characteristics, and it is difficult for each approach to reach a full optimum impact in different locations, the results of FPN in the test set are not as excellent as the other techniques, as shown in Table 1, but U-Net with VGG16 surpasses all other methods in IoU at the same time. Second, we have LinkNet, which is always using the VGG16 decoder, followed by VGG19, which outperforms U-Net in recall and has an interesting Fscore that is very near top model. Based on this first IoU comparison, we may infer that the U-Net and LinkNet classifiers perfectly match the VGG decoder.

Table 1: Comparison metrics of the models tested in this study.

Model	Encoder	IOU	$F1$-score	Precision	Recall
PSPNet	VGG16	0.7784	0.8743	0.8405	0.911
	VGG19	0.7772	0.8735	0.8426	0.9068
	ResNet50	0.7176	0.8452	0.8261	0.8653
	DenseNet169	0.6669	0.7946	0.7762	0.8139
	Xception	0.6528	0.7844	0.7566	0.8144

Table 2: Comparison table between three other models using IoU metric.

Model	IoU
MHA-Net [41]	0.7446
ABNet [40]	0.8165
U-Net + ResNet50 [42]	0.8263
U-Net + VGG16	**0.8302**

Second best Fscore is for LinkNet with the DenseNet169 encoder, followed by ResNet50.

Table 2 compares the test data to numerous novel segmentation approaches reported on the aerial image dataset in the previous two years. When compared to the AttentionBuildNet (ABNet) model provided in [40], our findings suggest that the U-Net approach with VGG increases the IoU by 1.73 percent. A second comparison is with the MHA-NET models provided by [41], in which our model has a UoI of 11.5 percent, a significant improvement over the MHA-NET models. When compared to the Res-U-Net approach described in [42], VGG U-Net improves IoU by 0.52 percent [42].

Figure 10 depicts the experimental visualization, where Figure 10(a) is the original image of the data set in the Massachusetts region and Figure 10(b) is the original image labelling. Figures 10(c)–10(e) illustrate the best possible outcomes of each model, PspNet, LinkNet, and U-Net (e). In comparison to the segmentation findings, the prediction results show that the U-Net technique in this study can better differentiate the borders between buildings, create fewer misclassified pixels with less loss of edge information, and capture crisper features. It can produce a more precise and realistic extraction. A well-defined segmentation enables for better categorizing of the sought objects. The findings of the proposed model were fascinating for both high and low density areas.

There are several types of buildings (large shopping mall, residential, industrial, etc.), and as shown in Figure 11, U-Net can better distinguish the large buildings with a high accuracy compared to PspNet, which finds much difficult to extract them better. This is due to the structure of the building, which has a remarkable similarity to the parking lots. However, with a simple building structure, as shown in the first row of Figure 11, most models are also closer to the ground truth. Solar shadows on the building itself can influence the building extraction too much. The results of building segmentation in a large area can reflect the degree of model training, as shown in Figure 12. It can be seen from the segmentation results that neither of the two-deep neural networks (PspNet and LinkNet) can fully achieve accurate building segmentation, which indicates that there is still a gap between the trained model and the actual segmentation model. On the other hand, we can see that Figure 12 confirms even more that U-Net with vgg16 distinguishes buildings better and can adapt to different types of high resolution remote sensing images. Furthermore, we can see that U-Net with vgg16 represents less False Negative than the other models and less False Positive due to the shadow caused by the buildings, which represents a significant challenge to increase the accuracy.

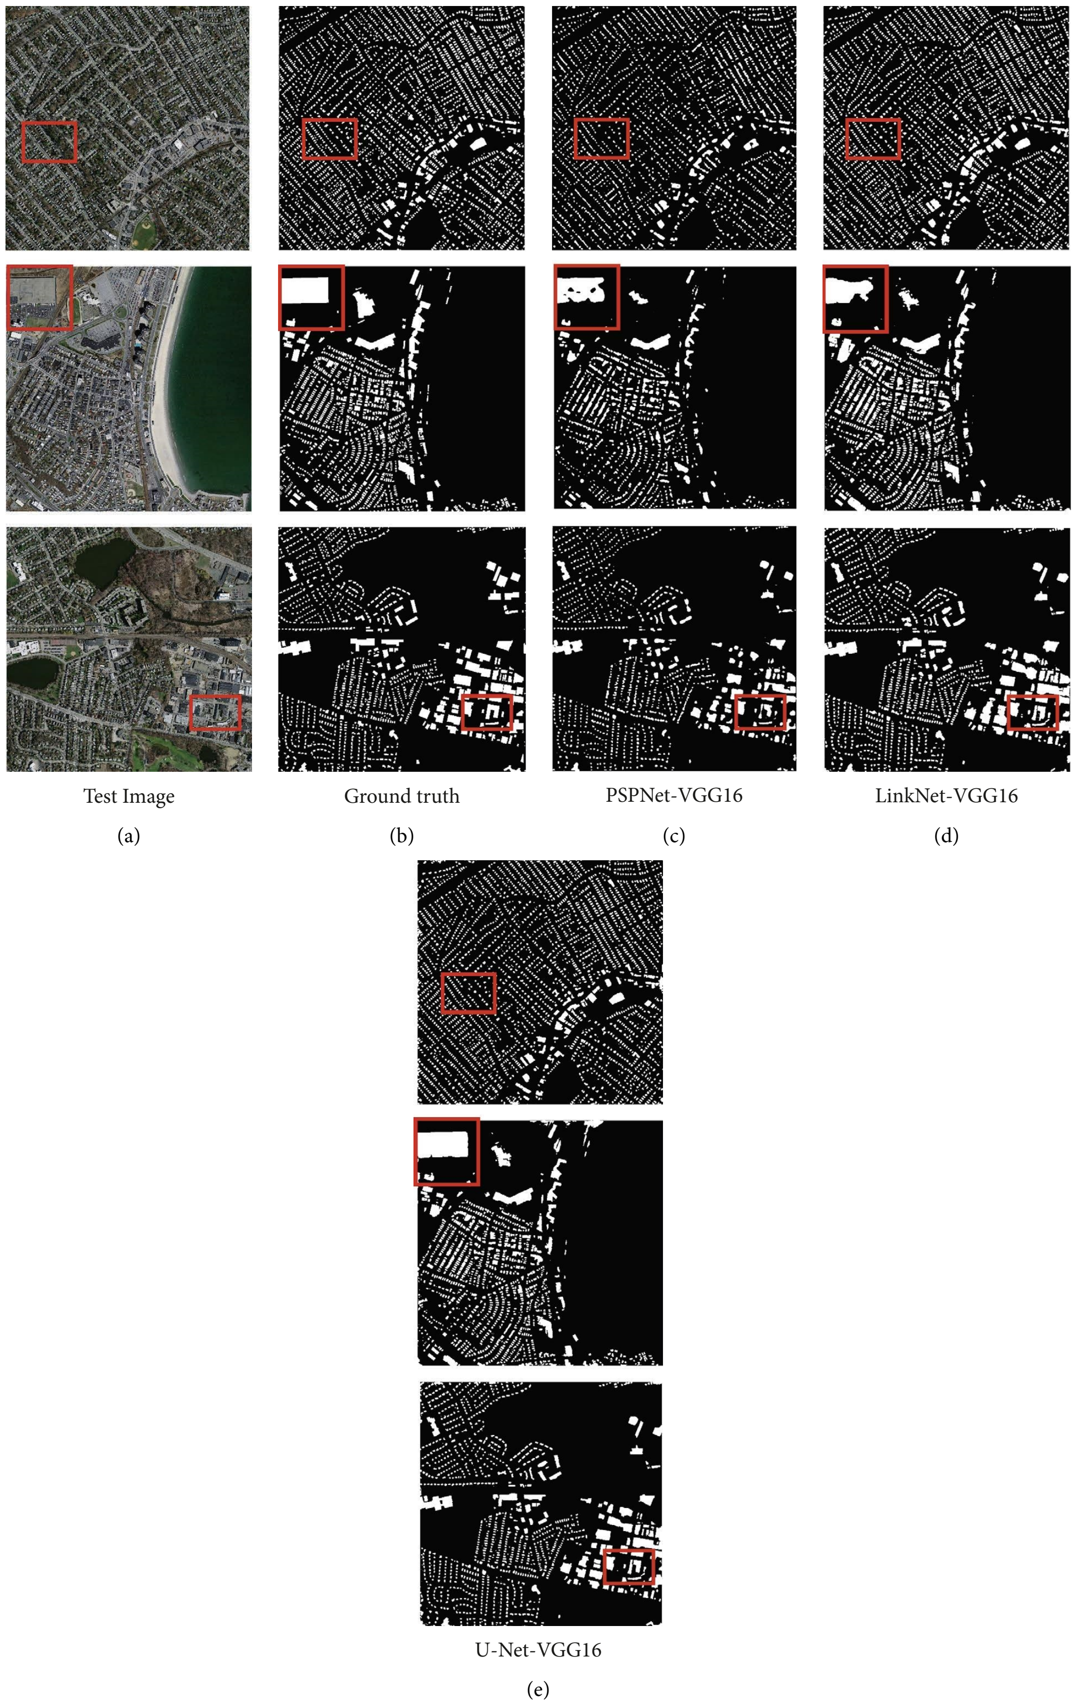

FIGURE 10: Examples of the extracted results on the Massachusetts building dataset. (a) Test image, (b) ground truth, (c) PSPNet-VGG16, (d) LinkNet-VGG16, and (e) U-Net-VGG16.

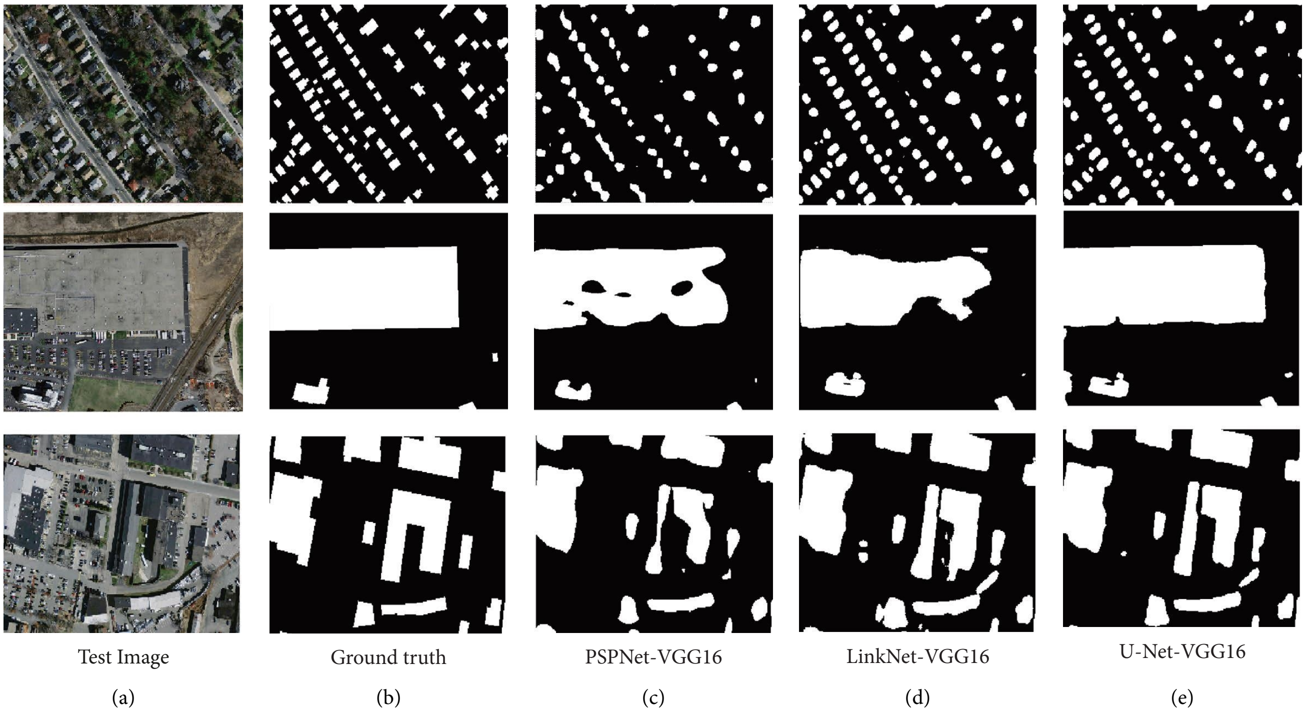

Figure 11: Performance comparison of building with different textures. (a) Test image, (b) ground truth, (c) PSPNet-VGG16, (d) LinkNet-VGG16, and (e) U-Net-VGG16.

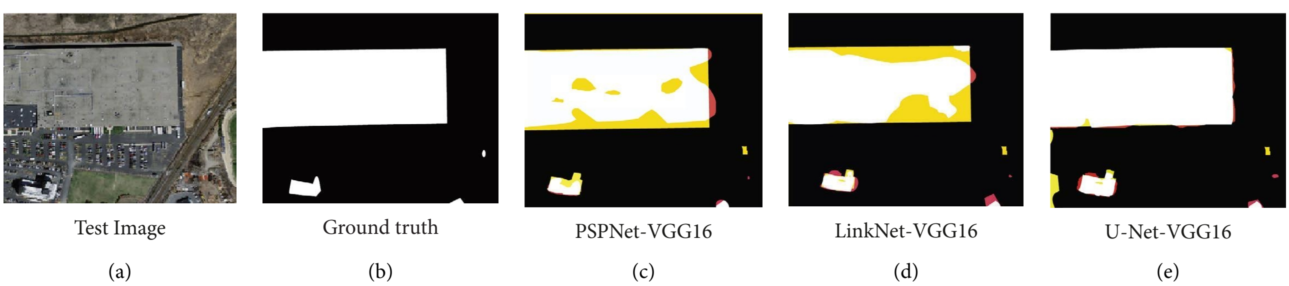

Figure 12: Visual comparisons. White = TP (the predicted result is a building, and the ground truth is also a building), black = TN (the ground truth is a non-building, and the predicted result is a non-building), yellow = FN (the ground truth is a building, and the predicted result is a non-building), and red = FP (the ground truth is a non-building, but the predicted result is a building). (a) Test image, (b) ground truth, (c) PSPNet-VGG16, (d) LinkNet-VGG16, and (e) U-Net-VGG16.

6. Conclusions

Building segmentation from remote sensing images must be accurate and automated for applications such as urban planning and catastrophe management. The current state of development of key deep learning approaches for image categorization and building instance extraction from high-resolution remote sensing images is discussed. Furthermore, this paper mainly focuses on the four most advanced autoencoder methods U-Net, PSPNet, LinkNet, and FPN, with an improvement of the models using VGG, ResNet, DenseNet, and Xception as backbone. The feature similarity of different pixel types was weakened to effectively separate pixels from urban and complex background areas. Considering that existing classical image classification methods based on deep learning have many limitations, such as generating blurred edges and losing detailed information. Since environmental information and building information are easily confused, which leads to mediocre extraction results, a new loss function is proposed, which allows the model to update the parameters faster and more stably. Training and testing are performed on the Massachusetts aerial image dataset with a coverage of 340 km^2. The results show that the U-net model with VGG16 as backbone achieves the best result with 83.06%, where it outperforms all presented models.

In addition, the presence of solar shadows, occlusions, and differences in the characteristics of the building itself will have some impact on the integrity of the building extraction. It is not exhaustive to consider only the color or brightness characteristics of the pixel itself and its local area. In future work, it is necessary to study the shadows and occlusions of buildings in the image to improve the building extraction effect.

Data Availability

The Mssachusetts Building data used to support the findings of this study are available at https://www.cs.toronto.edu/~vmnih/data/.

Psychological education is beneficial in maintaining the psychological health of college students, resolving psychological issues, and creating a harmonious campus and society. Mental health education for college students is a development-oriented basic education activity that contributes significantly to educational quality. To improve the accuracy of college students' mental health assessments, a model for mental health education for college students based on fine-grained parallel computing programming is proposed. This study uses a deep learning algorithm to subdivide the classification of an emotion dictionary, which can be classified by adding negative word lists, polarity conversion dictionaries, and online dictionaries, among other things, based on the theory of ecological instantaneous evaluation. It can be used for both multiclass and detailed emotion analysis. The model is more accurate in assessing the mental health of college students, according to the results of the study. The current emotional state of users can be identified, as well as signs of psychological risk, using emotional analysis of Weibo data, which will become a valuable resource for users seeking clinical psychological consultation in the future.

1. Introduction

From the relationship between college students' psychological quality and ideological and moral quality, good psychological quality is helpful to the formation and consolidation of good moral character. The psychological quality of college students is not perfect; their cognitive level is superficial and one-sided; their emotional will is defective; their personality development is clearly unbalanced; and their ideological and moral progress is hampered [1]. Paying attention to college students' mental health, creates and improves a relevant system for college students' psychological crisis intervention, tracks college students' mental health status in real time, and intervenes in college students who are experiencing a psychological crisis. College students, as social beings, must interact with others and rely on the support of their families, schools, and society [2, 3]. As a result, social support is crucial in college students' mental health education. Colleges and universities should prioritize assisting college students in developing a strong social support system as part of the process of strengthening and improving their mental health education.

At present, the traditional mental health assessment is mainly based on self-assessment questionnaires and structured interviews [4], and data and information are obtained from the assessed through interpersonal interaction, so as to assess the mental health status of the assessed. Although this traditional mental health evaluation method subjectively grasps the mental health status of the subjects from the scale point of view, there is a deviation of social expectation response in the implementation process and evaluation tasks [5, 6], and the evaluation is not good [7, 8]. Some researchers have begun to apply ecological transient assessment theory and social network data to mental health assessment tasks. Methods Data labels are marked by expert analysis or self-rating scale, data sets are formed, data features are extracted [9], and models are trained to realize the automatic assessment of mental health [10, 11]. The traditional mental health education model is mainly based on teachers' "teaching". This model turns the training process into a simple "knowledge inheritance" process. Although students can master the system, they master solid psychological theories and concepts, but ignore this model. Let students learn independently. Even in some universities that use the Internet for mental health education, the form is too simple and the effect is not ideal.

With the advent of the "Internet plus" era, new technologies represented by artificial intelligence are gradually reshaping the education service system and opening the closed door of existing education [12, 13]. Interaction with network education is common, which opens up new possibilities for university mental health education development. Some universities are forming three- to four-level mental health education networks, such as school-based counseling centers for college students' mental health education, undergraduate and faculty mental health education workstations, and college student mutual aid associations. A model of mental health education for college students is proposed in this paper, which is based on fine-grained parallel computing programming and includes a concrete action plan and implementation scheme.

This paper studies and innovates the aforementioned problems from the following aspects:

(1) We propose an evaluation model of college students' mental health based on multimodal data fusion. Maximum rule is used to fuse and calculate multimodal data, and latent conditional random field algorithm is used to accurately evaluate the mental health level of individuals, taking into account the psychological changes of students in a specific period of time.

(2) Constructing psychological early warning model based on granular emotional dictionary. It uses the change of user's emotional state as the result display output, and makes early warning analysis of psychological crisis events by screening the signs of psychological crisis.

The paper is divided into five parts, and the organizational structure is as follows: Section 1 introduces the research background and current situation of college students' mental health education, and puts forward and summarizes the main tasks of this paper. Section 2 introduces the theoretical basis of college students' mental health education research. Section 3 introduces the realization of college students' mental health education model based on fine-grained parallel computing programming. Section 4 compares the performance of this model through experiments. Section 5 is the full-text summary.

2. Related Work

2.1. Research Status and Development Trend of College Students' Mental Health Education. Tao believes that mental health is a lasting psychological state in which a person can adapt well, have vitality and give full play to his physical and mental potential [14]. This is not only a relief from mental illness but also a condition for active prosperity. Eisenberg believes that mental health should include three aspects: normal mental state, harmonious interpersonal relationship, and complete social adaptation [15]. Wang et al. [16] proposed 10 standard levels of circadian rhythm consciousness, which represent psychological activity intensity, psychological activity tolerance, psychological rehabilitation ability, psychological self-control, self-confidence, and social interaction environment adaptability. This paper summarizes the contents of mental health education from many dimensions, such as emotion regulation and will exercise, in order to better carry out mental health education, promote mental health education, and lay a good foundation for the development of students' mental health from the perspective of comprehensiveness, balance, and development of college students' mental health education. By synthesizing the experience and lessons of predecessors, Mc and others summarized the contents such as holding lectures, strengthening public relations, conducting a health survey, improving the network education system, and actively advocating self-education. In the network age, the network education system and curriculum education methods are quite extensive [17]. Zhang examined the significance of mental health education for college students and discussed the specific working mechanism as a result [18]. According to Gong, mental health is the key connotation of life growth and plays a critical role in students' life growth, and the meaning of life also plays a significant role in maintaining and developing college students' mental health [19]. In the end, the meaning of life and mental health are complementary, which is critical for a thorough examination of college students' mental health education.

Many domestic researchers have conducted in-depth research on the effect of college students' mental health education, showing the characteristics of various methods and in-depth contents. Meng et al.'s research results show that 84% of college students like the teaching methods of mental health courses [20], while Yu et al.'s research results show that mental health education plays an important role in improving mental health, and college students and other educational methods have different effects [21]. The research results of Xin et al. show that mental health education is an effective way to improve the mental health of ethnic minority college students [22]. Li tracked the mental health of 449 students for 2 years and found that mental health education can significantly improve students' mental health. The most effective method of mental health education is psychological lecture [23].

The content, methods, and methods of personnel training, among which the specific methods of personnel training are the most prominent, will be the most important topics in future research on college students' mental health education. The following are the different types of mental health education training available in universities. We established a specialty devoted to cultivating college students' mental health education practitioners, improving the systematization and standardization level of personnel training, and laying a solid foundation for the school's long-term development, starting with the school's own orientation and educational resources. Students should be given mental health education.

2.2. Research on Fine-Grained Parallel Computing Programming. Thread-level speculation technology on general-purpose processors can take advantage of granular parallelism, fine-grained operations correspond to threads on general-purpose processors, and task creation and allocation are managed by the runtime system as a thread pool. Xian has invested a lot of money in developing new general-purpose CPUs, which combine reconfigurable computing technology [24] with Intel X86 architecture and apply reconfigurable computing to information security chips and cryptographic chips.

Paji et al. put forward a new programming model, which allows programmers to declare applications as a group of tasks that can be executed in parallel, and describe the dependencies between tasks as Promise [25]. Then, the concurrent tasks are automatically mapped to reconfigurable computing resources in the airspace for execution. This technology effectively makes use of fine-grained pipeline-level parallelism in applications. Kashi et al. designed a pipeline processing unit and interconnection network architecture, which includes coarse-grained and fine-grained data paths, encapsulated these architectural features as an execution mechanism, and provided a compiler to allow programmers to write programs for reconfigurable processors. Use complex control flow and advanced programming tools to create high-performance applications [26]. Liu et al. designed a programmable register shared by several reconfigurable arrays and provided it to programmers as a programming method. When programmers write programs for reconfigurable processors, they can choose the stream processing mode or the private mode of the register according to the characteristics of the application.

3. Methodology

3.1. Construction of the Theoretical Model of Influencing Factors of College Students' Mental Health. Mental health education for college students is a systematic project of cooperation among schools, families, and society [9]. College students' mental health education aims to help educators to cultivate students' good psychological quality and improve their psychological quality using the theories and technologies of psychology, pedagogy, and even psychiatry according to the characteristics of college students' physiological and psychological development. Psychological function can bring students' full potential into play, and promote the overall improvement of students' comprehensive quality and individual harmonious development of students' education.

Human ideology is not static; it evolves in response to changes in social practice. The shift in ideological activities is particularly noticeable during periods of active social change. The ebb and flow of ideological activities among today's college students is also consistent with the era's characteristics. Young college students are under a lot of psychological and emotional pressure as a result of the transitional period's social and economic development, and they are prone to strong emotions like loneliness and anxiety. Preventive education is required in psychological education in order to improve college students' self-defense awareness and survival skills, improve their psychological quality, guard against potential risk factors, and improve the quality of education in order to provide scientific and effective psychological intervention for students with problems.

Various functional elements in the individual psychological adaptation system, including defense mechanism, are constantly influenced by the ecological and cultural background and family upbringing in the process of individual development and gradually form the psychological characteristic structure with specific cultural background and cultural value and the formation of culture-oriented laws and regulations.

Families also pass on the physiological characteristics formed in the process of biological adaptation to the next generation through genetic methods, forming specific physiological and functional characteristics of specific countries. In the process of psychological adaptation to environmental input and output, the defense mechanism system in turn affects the entropy state of the psychological adaptation system, and then affects the mental health state. Their specific relationship is shown in Figure 1.

Many studies have shown that the use of negative psychological defense mechanism will decrease with the increase of individual interpersonal emotion, interpersonal atmosphere, and positive sense of life goal value. The psychological living space of college students includes not only the past and present frame of reference, but also the future trend reference. Correspondingly, adaptation always occurs under different psychological space-time standards, and there are differences in the sources of psychological space-time, so information processing and behavior supervision can have different time schedules.

College students' mental health education is not limited to solving a few students' psychological problems, but also to comprehensively improve students' psychological quality and promote their healthy growth and success. Healthy personality and good personality will enable students to fully tap their psychological potential, continuously improve their competitiveness and strive to realize their self-worth.

3.2. Mental Health Assessment. Mental health is a harmonious state of individual psychological function balance, and the most common abnormal state of mental health is anxiety and depression [1]. College students are in the transition period between campus and society, under the pressure from all sides, and are prone to expose various psychological problems, among which depression is particularly prominent [20].

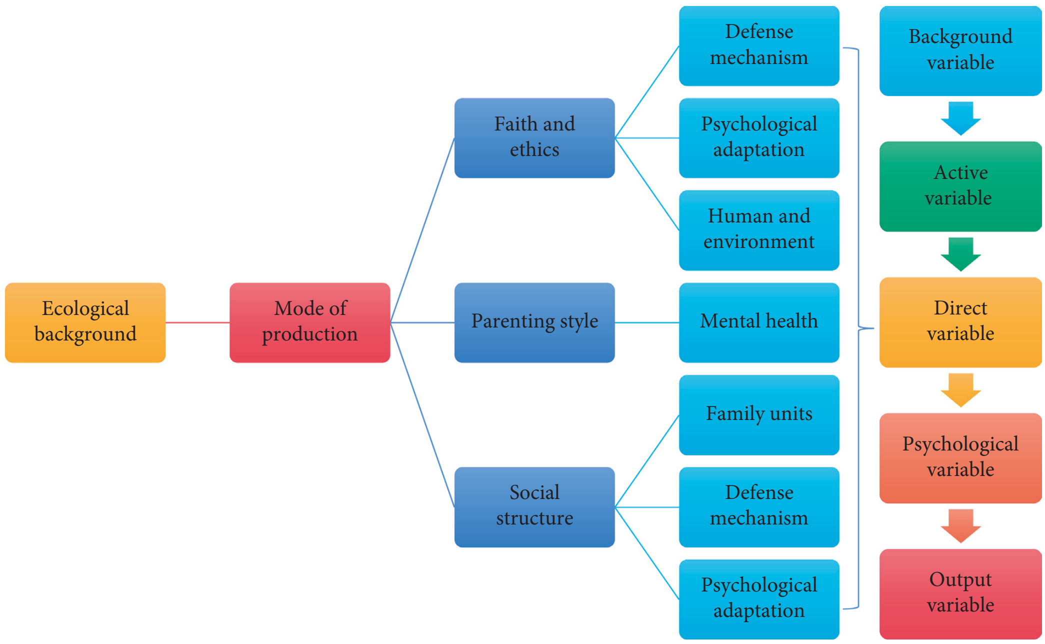

Figure 1: Formation mechanism of mental health status.

People require a sense of belonging, but a lack of belonging frequently leads to mental illness, and positive interpersonal relationships are critical in preventing psychological issues. Counselors and teachers make up the majority of the school administration. Their job is to look after every student, especially introverted students, by anticipating their needs, communicating care and love to them, and preventing emotional and relational support. Mastering all scientific and cultural knowledge requires a strong psychological foundation. Slow thinking, a lack of interest and motivation to learn, and a lack of understanding of basic learning methods, all of which contribute to low psychological quality, make it difficult to survive in society, let alone for college students involved in complex scientific creation or knowledge innovation activities.

Design the evaluation model of college students' mental health based on big data, in order to obtain ideal diagnosis results of college students' mental health. The cumulative value S_{ikj} of the comparison result between the characteristic word w_{ij} of text T_i and all characteristic words of text T_k is as follows:

$$S_{ikj} = \sum_{r=1}^{r=n_k} S_{ikjr}. \tag{1}$$

There are great differences among the feature words in the same text. There is at most one feature word identical to w_{ij} in the text T_k, so the value of S_{ikj} can only be 0 or 1. It can be obtained that there are the same number of feature words in the text T_i and the text T_k. The formula of S_{ik} is as follows:

$$S_{ik} = \sum_{j=1}^{j=n_i} S_{ikj}. \tag{2}$$

Text similarity is the ratio between the same number of feature words and the smaller T_i, T_k total number of feature words in different texts, and the similarity P_{ik} between text can be obtained as follows:

$$P_{ik} = \frac{S_{ik}}{\min\left(n_i, n_k\right)}. \tag{3}$$

The clustering index scales adaptively, sets a fixed threshold, classifies the texts whose similarity is higher than the threshold into one category, and uses the obtained clustering results as the evaluation index.

Traditional computing systems use an I/O bus to connect functional devices. It is easy to use and powerful, but data transmission between functional units must go through the slow I/O bus. With the increased communication frequency between general-purpose processors and various DSA in the era of DSA (domain-specific architecture), most computing chips turn to SoC to integrate general-purpose processor and DSA. When switching multiple sets of configuration information, the configuration controller and data path must satisfy the control dependency between infinite periods. As a result, the runtime data path frequently waits for the configuration controller to query the status before manually loading the configuration word, reducing the data path's utilization rate.

In order to solve the problem that the complex control flow, especially the variable-length loop, is difficult to be efficiently executed on the reconfigurable data path with limited computing resources, this chapter adds the active loading mechanism of data flow execution based on the dynamic scheduling of the classic dynamic reconfigurable processor. The active load execution mechanism simplifies the design of the compiler and effectively handles the complex control flow shown in Figure 2.

The compiler must determine the execution order of operators for dynamic scheduling and manual loading of reconfigurable processors, so the hardware architecture is represented by the compiler as a two-dimensional table, and

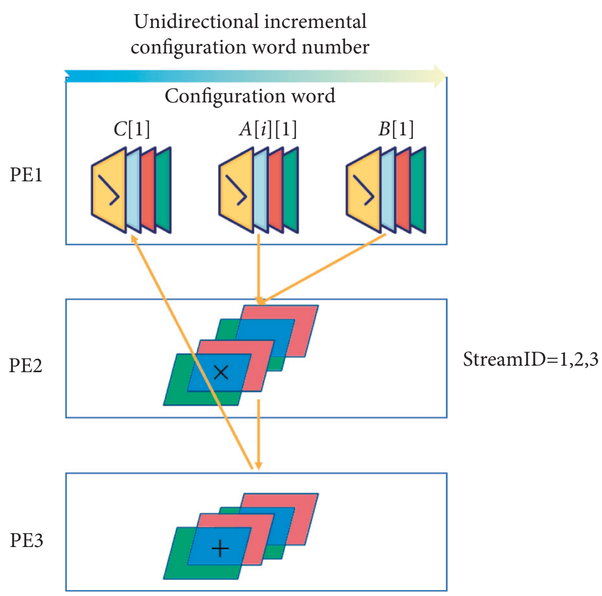

Figure 2: Models of hardware architecture considered by compilers under different execution mechanisms.

the compiler must determine the relative relationship of each operator. The compiler only needs to decide which processing element PE (Processing Element) to execute the operator on in reconfigurable processors with dynamic scheduling and dynamic loading. The processor's hardware architecture is spatially separated, so the compiler does not need to consider the operator. In today's technologically advanced society, college students frequently publish text, images, expressions, and other modal data on social media platforms at the same time to express their thoughts and feelings. Different types of modal data can be combined to provide more descriptive information. A more comprehensive and systematic analysis and evaluation of students' mental health can be achieved by integrating and understanding multimodal data.

The effective fusion of multimodal information is the key problem in multimodal emotion calculation [27]. It uses the maximum rule to calculate the emotional tendency values of text and images, and accurately judges the students' psychological state by fully considering emotional factors. When the specific calculation process is expressed by

$$\begin{aligned} P'_j &= \max_i \left(P_{ij}(n)\right) \quad i = 1, 2,\ j = 1, 2, \\ P_j(n) &= \frac{P'_j(n)}{\sum_j P'_j(n)}. \end{aligned} \tag{4}$$

Among them, i and j are the number of classifiers and categories and $P_j(n)$ is the probability value of the j-type emotion category.

LSTM (long short-term memory) is mainly controlled by three gates that enter and exit the information flow in memory: input gate, forgetting gate, and output gate. The values of these gates can mainly help the network avoid erroneous gradient update.

In LSTM network, the forgetting gate f_t is mainly responsible for what information the network will discard, that is, the forgetting gate will determine how many cell states C_{t-1} of the last moment can be retained in the current cell state C_t, and the gate will read h_{t-1}, x_t and output a value between [0,1] to each C_{t-1}, where 1 means "completely retained" and 0 means "completely discarded".

The formula of the forgetting gate is as follows:

$$f_t = \sigma\left(W_f \cdot [h_{t-1}, x_t] + b_f\right). \tag{5}$$

Here, h_{t-1} represents the output of the LSTM network at the last moment, x_t represents the input of the LSTM network at the current moment, W_f represents the weight matrix of the forgetting gate, b_f represents the bias of the forgetting gate, and qw represents the connection operation.

Feature extraction is performed as convolution operation, and convolution operation in image domain can be regarded as a weighted summation process. Each element of convolution kernel is multiplied by each pixel in this region of the image, and the calculated sum of products is activated by the value of this position in the next feature map.

There is a relationship between the size of convolution kernel and the step size of sliding convolution kernel, and the specific relationship is expressed by formula 1.

$$O_{fmN} = \frac{I_{fmN} - K_{\text{size}}}{K_{\text{stride}}} + 1, \tag{6}$$

where O_{fmN} represents the size of the output feature map, I_{fmN} represents the size of the input feature map, K_{size} represents the size of the convolution kernel, and K_{stride} represents the step size of the convolution kernel sliding.

In this paper, a time-series analysis model based on implicit conditional random field algorithm is proposed, which can dig out the internal development rules of various mental health levels in a period of time and find out the relationship between emotional changes and mental health. The process of mental health assessment model is shown in Figure 3.

3.3. Early Warning Model of College Students' Mental Health.

Owing to the complexity of emotion and the imperfection of research rules, the definition of emotion is not clear up to now. Owing to the universality and complexity of emotions, it is difficult for the computational model represented by hidden Markov model to simulate the change of emotional state. In this paper, emotional modeling is carried out from the perspective of text emotional analysis. Words expressing emotional state are digitized by polarity and intensity, and human virtual emotions are modeled and formalized by mathematical methods, which is convenient for emotional research and analysis.

Owing to the rapid evolution of network words, new network words that do not exist in the emotion dictionary may appear in the process of emotion analysis. Use so-PMI (sentiment orientation-point wise mutual information) method to calculate the semantic similarity between words, and then obtain the weight of new words from the network.

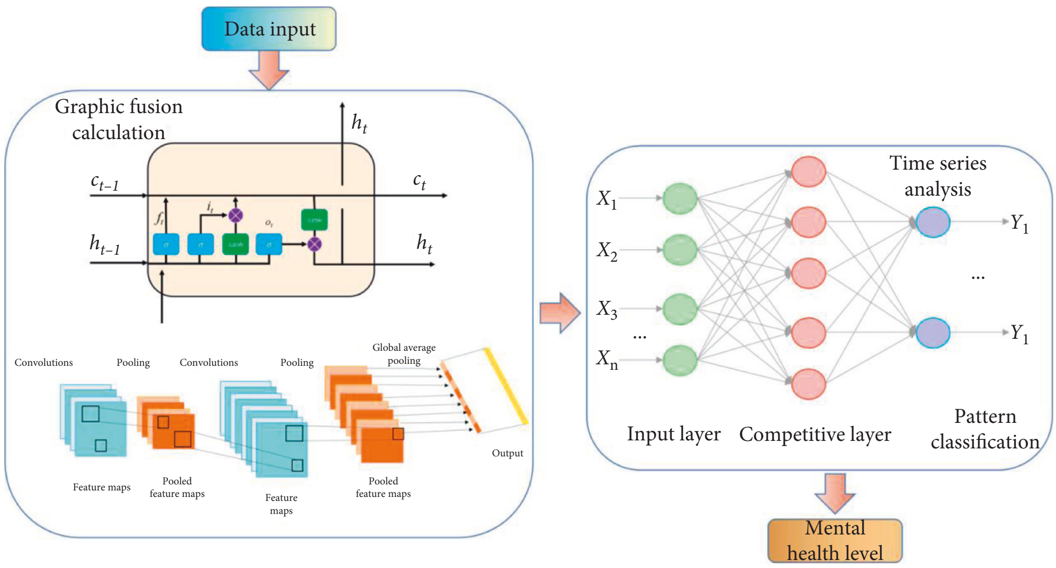

FIGURE 3: Process of the mental health assessment model.

In order to avoid emotional deviation caused by simple addition, the number of evaluation words and the proportion of evaluation words are comprehensively considered, and a more suitable range is obtained through intermediary coefficient. We have

$$W_i(\text{word}) = \sum_j \gamma^{\text{PMI}\left(\text{word},w_{ij}\right)}, \text{SO}(\text{word}) = \max_i (W_i). \quad (7)$$

w_{ij} is the j benchmark word in the i-type emotion category and γ is the mediation coefficient.

Through the aforementioned analysis, this paper proposes an emotion analysis algorithm based on weighting factors, combining the calculation methods of emotional vocabulary weight and modification weight:

$$\text{SO}(S) = \max \sum \alpha^{C_i w_{ij}}. \quad (8)$$

Among them, SO (S) is the emotional tendency value of the sentence S, w_{ij} refers to the emotional value of the ith emotional word w belonging to the emotional category j, C_i refers to the weight factor that modifies the emotional word, α is the mediation coefficient, when $\alpha = 1$ is used, the text tends to be the category with the largest number of emotional words in the sentence, and when $\alpha = 1$ is used, the text tends to the category with the largest emotional intensity in the sentence.

According to the aforementioned analysis, the basic process of psychological early warning is obtained (Figure 4):

(1) Access the Weibo text data in the web page in real time and store it in the local database

(2) Add stop words list to get useful words for tags

(3) Emotional dictionary is used to extract emotional words to minimize the omission of emotional words caused by incomplete rules

(4) The final weight is calculated according to the improved SO-PMI algorithm

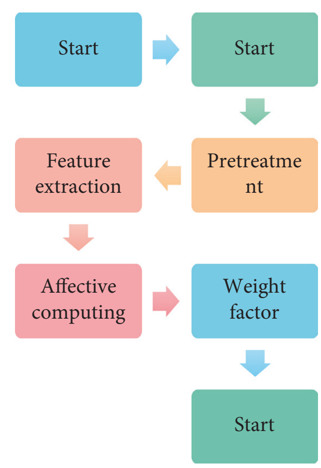

FIGURE 4: Basic process of psychological early warning.

(5) According to the weight-based sentiment analysis algorithm, the sentiment value of the text is calculated and displayed through the sentiment trend graph output

4. Experiment and Results

In order to verify the effectiveness of the proposed evaluation model of college students' mental health, college students were selected as the research object, and questionnaires were distributed to college students through the network. In this paper, the collected questionnaires are clustered to verify the model. Figure 5 shows the statistical results of data processing ability based on Big Data.

It can be seen from Figure 5 that using this model to evaluate college students' mental health can cluster Big Data well from a large number of data, and the model evaluation is accurate. It can be seen from Table 1 that the evaluation results of mental health consistency of college students using this model are all less than 0. It shows that the index system

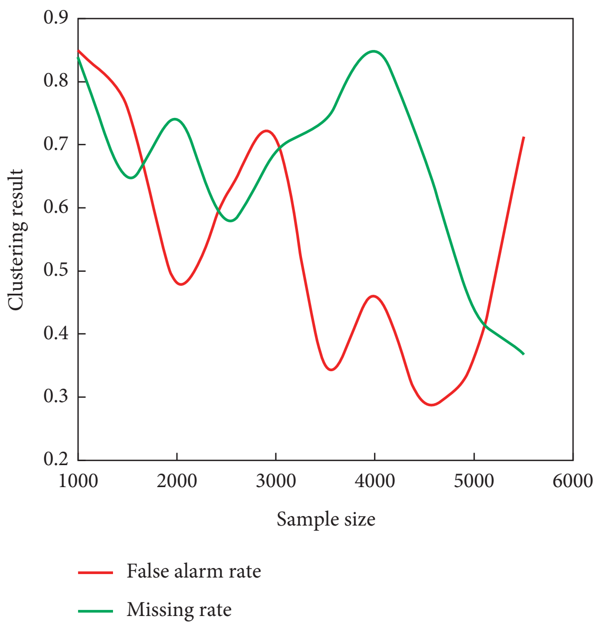

Figure 5: Data clustering result.

Table 1: Consistency judgment result.

Index	Judgment result
Emotion regulation	0.016
Learning influence	0.044
Life influence	0.032
Career influence	0.038

of college students' mental health constructed by this model can meet the judgment requirements and pass the consistency test.

The weight of the evaluation index system of college students' mental health is obtained using this model, and the evaluation results of the first-level index of college students' mental health are shown in Figure 6.

It can be seen that the model in this paper can effectively get the evaluation results of college students' mental health, and find that the overall mental health of college students is in good condition. From the evaluation results, it can be seen that the evaluation results of college students in improving ability, learning strategies, and self-development have low scores.

The accuracy is obtained by comparing the scale scores with the model evaluation results, and the experimental results are shown in Table 2.

Health and depression are at two extremes. In the longitudinal development, health students are mostly in a positive and positive state, while susceptible students continue to be depressed and have a negative attitude towards external stimuli. Therefore, the model can better capture the psychological characteristics of these two categories, and can effectively judge whether students are prone to depression.

Compared with previous studies, this study uses deep learning algorithm to process the network content data, which can obtain deep semantic knowledge and true emotional polarity of modal data such as text and image, and it takes more time to evaluate than traditional machines. The algorithm also has many advantages. By analyzing the content posted by students online in real time, it can quickly judge and continuously track the mental health status of students.

In order to evaluate the impact of active loading mechanism on the performance of specific applications, this study selects five applications with long and variable loops, and manually compiles configuration information from the two execution mechanisms. The evaluation results of the simulator show that after using the active loading execution mechanism, the performance of these five applications is improved by 1.33 times on average compared with passive loading. In order to analyze the reasons for the performance advantages, in this study, we analyzed the cycle-by-cycle execution state of eight PEs on the simulator and obtained Figures 7 and 8.

It can be seen that the time spent by actively loaded PE in configuration and blocking state is obviously less than that in passive state. Further analysis reveals two reasons: as the active loading mechanism does not have to wait for the configuration word sent by the configuration controller, the time of each PE in the blocking state is greatly reduced. The loaded configuration word can still be executed, which reduces the time spent by PE in configuration.

Negative emotions play an important role in psychological crisis intervention, and in psychological counseling, whether the counselor has negative emotions and the duration of negative emotions are important criteria for evaluating the psychological state. The research goal of this paper is to establish an early warning mechanism of psychological crisis and to identify negative emotions through experimental tests and case analysis.

The psychological early warning model of this paper evaluates and tests the negative thoughts of Weibo users. This paper analyzes the user's emotional dynamic tendency by constructing the user's emotional trend chart, which fully reflects the user's psychological reaction and has important reference significance (Figure 9).

The emotional trend chart shows that user 1's negative emotional state is always frequent, and multiple Weibo messages are frequently sent in a short period of time to express strong and concentrated emotions. Negative emotions make up 59% of Weibo texts, and the negative emotions of a single Weibo text can reach −18, drawing the attention of relevant staff. These crises can be avoided if timely and appropriate interventions are implemented. College students are the most active group of Internet users. With the rapid advancement of information technology, the Internet has become an indispensable part of college students' study and life, allowing them to keep up with current events, obtain information, express emotions, and have fun. As a result, establishing a good network position and providing good network mental health education has become a new requirement for the development of college mental health education.

Compared with the traditional mental health education, online mental health education has a unique advantage, that is, college students can receive psychological services at any time through the mental health education website without being limited by time and space. Focus on online tutoring,

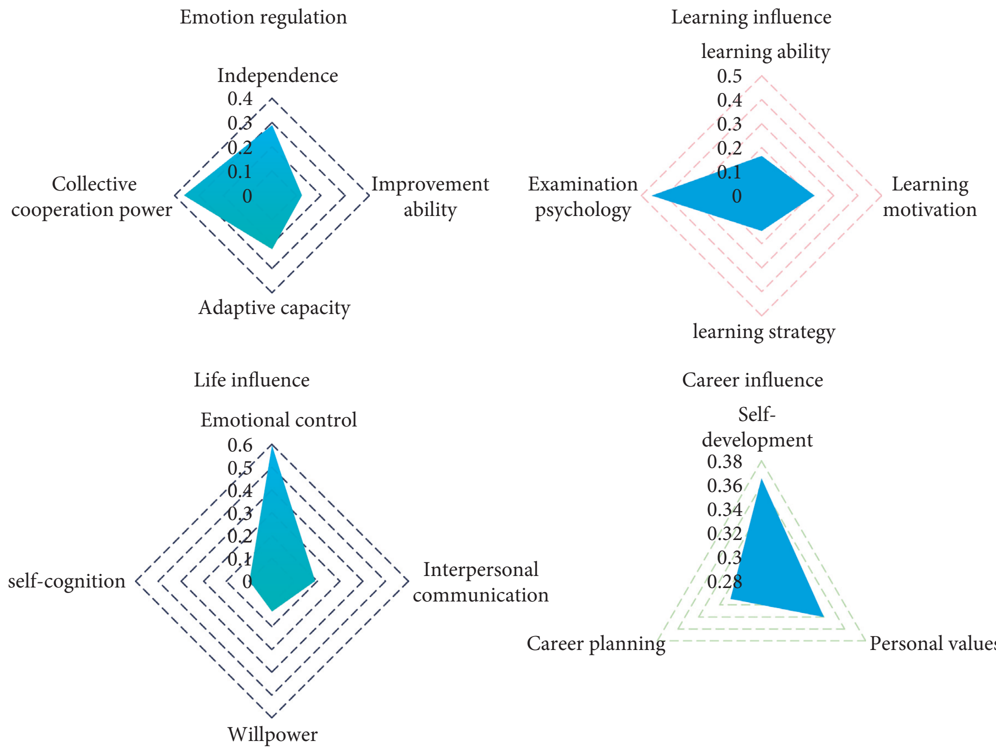

Figure 6: Evaluation results of secondary indicators.

Table 2: Mental health assessment results.

Project	Assessment result (%)
Health	92.14
There may be depression	78.96
Existence of depression	84.57
Average accuracy	84.86

online communication and discussion, so that confused students can broaden their thinking in time and solve various problems and puzzles in their study and life in time and strengthen the network mental health education team. With the development of network technology, the school will soon cultivate a new type of mental health education team, which will network the psychological dynamics, psychological changes, and psychological needs of college students and provide services and services scientifically.

5. Conclusions

Mental health education for college students is a challenging foundational, systematic, and innovative project. In some ways, this is not only a problem that exam-oriented education has left us with in the past, but also a demand of today's rapidly evolving society. The highly volatile and efficient evaluation model driven by Big Data is useful for addressing college students' mental health issues. The average accuracy rate of a mental health education model created by college students using fine-grained parallel computing programming is 84.86%. The model can effectively reveal the changing trend of students' psychological characteristics if it can accurately understand their mental health status. The accuracy of Chinese emotional analysis can be improved by utilizing bilingual knowledge, including Chinese and English, and constructing a relatively complete and detailed dictionary of emotional norms of Chinese vocabulary. Experiments show that the method proposed in this paper can produce good results, but it still has flaws. In the next step, this paper will investigate the aforementioned aspects in order to develop a more appropriate method in the field of psychological early warning.

This study conducts in-depth research and analysis on the intelligent monitoring and early warning of public safety machines in the construction of smart cities, taking risk management theory as the theoretical basis and combining it with the actual situation, i.e., constructing a public safety risk management framework under the background of proposing urban refinement management, a typical case for in-depth analysis, and understanding how the community carries out public safety risk prevention and control through research and interviews and other research methods, mainly including the overall design and the design of application modules for the robot. Based on studying the existing research and combining the advantages of each research method, this study proposes a method suitable for the analysis of this study, which can improve efficiency and accuracy. The robot application module design part, around the system's main emergency command object, i.e., the robot, details its design in four aspects: data communication, situation display, auxiliary decision-making, and command and dispatch. The technical environment for system development is given, the development framework based on BS structure and the development and implementation of data interface modules are detailed, and the development and implementation of the robot application module are explained in detail. Finally, the system functions and performance, and further optimization directions are given based on the analysis of the test results.

1. Introduction

In response to the intricate and complex situation of urban public safety, urban public safety monitoring and management have become more and more complex, and the diagnosis, discovery, and early warning of urban public safety events are difficult to be realized by a single data source and traditional spatial data type; therefore, with the development of the internet, internet of things, social network, and integrated observation system, the process of urban public safety monitoring has been constructed by satellite, UAV, and ground video monitoring [1]. The urban three-dimensional public safety monitoring network is composed of mobile phones and GPS devices. The massive spatiotemporal data generated by urban public safety monitoring mainly include video, image, remote sensing image, vector map, and trajectory data. These data not only contain rich temporal, spatial, and semantic information but also have multidimensional, multiscale, and multitemporal characteristics and multimodal features. The multimodal characteristics of public safety monitoring data make the same spatiotemporal object that may have many different forms of data description, and the different modal data have the characteristics of low-level feature heterogeneity and high-level semantic correlation, in the process of urban public safety diagnosis, discovery, and early warning, and the traditional unimodal data retrieval is far from satisfying the retrieval of different modal data of the same event, how to deeply analyze the connection between the data of different modalities, and how to analyze the data of different modalities? It is necessary to deeply analyze the connection between data of different modes, establish a correlation between data of different modes, and realize efficient cross-modal retrieval of data of different modes of the same event to support accurate, rapid diagnosis, timely detection, and early warning of urban public safety [2]. The core problem of cross-modal retrieval technology is the need to analyze and establish a correlation between data of different modalities, and to achieve cross-modal retrieval between data of different modalities. In recent years, the research on cross-modal retrieval technology for ordinary text, image, and video has been rapidly developing in the computer field, but the research on cross-modal retrieval of multimodal spatiotemporal data with typical spatiotemporal characteristics and rich semantic information is less. With the development of three-dimensional public safety monitoring networks in cities, research on cross-modal retrieval techniques for multimodal public safety monitoring data has become the key to support diagnosis, discovery, and early warning of urban public safety events [3]. Therefore, cross-modal retrieval for urban public safety monitoring data, association construction of multimodal spatiotemporal data, spatiotemporal indexing methods considering spatiotemporal semantics, and cross-modal retrieval methods are the focus of this study.

The concept of urban public safety governance has also emerged. Cities are the most concentrated areas in terms of human and material resources and financial resources and are important representatives of the economic development of a region. As the scale of cities continues to expand and the level of urbanization continues to rise, a variety of urban public safety events pose a great threat to people's lives and safety. From the theoretical point of view, this study combines many research directions based on the discussion of urban public safety risk generation mechanisms with existing theoretical results and key perspectives, such as public safety, polycentric governance, and risk governance. Based on the detailed research in the field of management, the current situation of urban public safety combined, the establishment of public safety governance analysis framework, combined with the existing public safety governance problems, analysis, and research of public safety governance strategies, and the ways to improve urban public safety based on risk management (such as effective governance), the urban public safety governance proposed to propose improvement strategies, based on research results for exploration and improvement [4]. It is of positive theoretical significance because it can effectively combine theory and practice and further improve the theoretical system related to urban public safety governance.

Based on the background of emergency response to public safety events, this project researches and implements a robotic command-and-control system for public safety. On the one hand, it uses the advantages of robots' spatial accessibility, real-time controllability, and cooperation to improve the control of the emergency command-and-control system on the situation at the incident site, and uses the command-and-control system to solve the problems of slow response, weak command, control, and information occlusion in the response of individual robots. On the other hand, the use of advanced networks to achieve remote command and control, and the use of network technology, WebGIS, real-time data transmission, remote communications, artificial intelligence, and other real-time presentation of the scene situation, through the auxiliary decision support-related methods to assist commanders to quickly respond to events, improve the overall situation of each node robot to the scene of the grasp, decision-making, collaboration between each other, and the efficiency of implementation. Although actively exploring the integration and sharing of public safety video, innovative access methods, and following the relevant access specification requirements, the development of networking and integration of work programs, guidance around the integration of social video resource networking, the current public safety video surveillance is still in the public security organs to build, manage, and use as the dominant state, in the use of things that still have considerable space for mining. How to optimize the management mode of public security video surveillance resources based on the existing video network and video sharing service platform solves the problem of sharing and common use of public security video surveillance among departments. Our study is more efficient, more accurate, and more cost-effective than other studies. It has become a major issue nowadays to maximize the benefits of public security video surveillance resources, enhance the effectiveness of three-dimensional comprehensive prevention and control, improve public services and urban management, and enhance the ability of public security information to benefit the public.

2. Related Works

The city is a dense and complex special structural system. With the continuous progress of the economy, technology, and culture, the modern city is mainly driven by industrialization and informationization and gathers a huge number of elements to form an open and complex giant system. The close dependence, gradual differentiation, evolutionary change, and no-linear interaction among the elements in them are transformed into different distributions of time, space, and function through rise and fall. The city gathers many people and serves as the basic carrier of their productive life [5]. At the same time, human activity constitutes and governs the operation and development of cities. The individual units active in the city are constantly moving and changing, and present the normality and evolution of the city in a relatively stable group organization behavior. As an important component of smart city construction, it is crucial to cultivate a safe urban life form and create a smart and safe city [6]. The risk management model is constantly improved and optimized with the help of big data thinking and technology, and the systems and equipment related to comprehensive public safety emergency response, monitoring and surveillance, prevention and early warning, rescue, and command are constantly innovated, and the research of core hardware and software and the exploration of overall solutions are gradually launched [7].

In terms of subjects, some scholars believe that shaping the role of government guidance, community autonomy, and individual participation is a necessary path to optimize community public safety governance; in terms of platform construction, some scholars believe that the emergency management system is an important carrier for handling and transmitting various types of information in public emergencies and aiding emergency management decisions and that vigorously promoting the construction of emergency management information technology is an important means to effectively deal with urban emergencies [8]. It is an important means to effectively deal with urban emergencies, promote the effectiveness of government emergency plans, and enhance the emergency management capacity of urban communities [9]. In terms of mechanism, some scholars emphasize the need to insist on shifting the focus of public safety supervision downward and moving the gate forward, and to establish a sound organizational network for public safety supervision at the grassroots level; at the same time, it is necessary to absorb social forces utilizing social governance, mobilize multiple subjects, and integrate resources from all sides to realize the socialized operation of public safety supervision [10]. From the perspective of holistic governance theory, the establishment of a unified and integrated leadership institution for community public safety governance is the essence of cross-border cooperation, the partnership of institutions in different fields is the basic tool for cross-border cooperation, and the information network platform is the technical support for cross-border integration [11]. From the perspective of governance and collaborative government, some scholars also believe that a shift from loose cooperation based on government monopoly to an institutionalized collaborative model under government leadership should be realized among multiple subjects [12].

The rapid development and large-scale application of information technology have led to the gradual evolution of command-and-control systems with computers as the core, but the application of information technology in the system lags far behind the development of information technology itself. On the one hand, the system often shows a lag in intelligent assistance, failing to effectively combine various multimedia technologies, high situational awareness technologies, and intelligent auxiliary decision-making technologies. On the other hand, the relevant research focuses on face-to-face command and control, and not fully applies the development of reconnaissance and positioning technology, communication technology and network technology, and the implementation of remote command and control of the scene rescue personnel and their equipment, "man-machine" integration, and "full-area real-time dynamic" efficient command. With the development of intelligent robotics, a variety of special intelligent robots began to be developed and applied, such as rescue operation robots, reconnaissance robots, and fire robots, to provide strong support for the handling of public safety events. However, robots often perform tasks as independent individuals in incident response, mostly showing problems such as scattered emergency forces, slow response, weak command and control, and low efficiency in collecting and sharing information on-site.

3. Intelligent Monitoring and Early Warning Analysis of Public Safety Machines for Smart City Construction

3.1. Intelligent Monitoring System Design for Public Safety Machines in Smart City Construction. Public safety is a very complex system, and realistically, compared to national security, urban security, and social security, public safety is most closely related to people's daily lives. In other words, anyone who lives in a city has a great relationship with the public safety of the city [13]. From the previous research results on the connotation of public safety for other scholars, it can be found that the current research on the connotation of public safety is mainly focused on three aspects: one is the research on behaviors that endanger public safety at the legal level, the second is the research on professional public safety work, and the third is the research on public safety technology from the scientific perspective. By combining the research results of other scholars and the current direction of public safety research, public safety can be defined. Public security is the security of society and citizens, and from the perspective of public administration, it means that the external environment, basic values, interests, and institutions in the public sphere can maintain a fixed direction of progress and, as expected by everyone, ensure that the normal production life of society and citizens is not accordingly threatened.

From an economic point of view, a city is a network of economic factors and markets that intersect within a certain spatial area; from a geographical point of view, it is a dense agglomeration of people and houses in a suitable location; from a sociological point of view, a city is a form of social organization in which secondary and tertiary sector workers are the main population. The city is a complex of political, economic, and cultural elements that form a special area in which the inhabitants especially live, i.e., relatively free from agricultural production activities. It is clear from this that the key to urban security lies in the construction of a relatively stable system that brings together the various urban elements. However, the complexity of the various elements of the city itself makes it vulnerable to various factors in the process of managing the safe operation of the city, which in turn leads to the emergence of public safety problems [14]. As a basic element of the national structural system, the security of the city is related to the security of the whole country, so the upper layer of urban security is national security, and it is very important to manage urban public security well. This can be summarized that urban public security also means security from the perspective of the city; in particular, it also means that the city needs to follow certain laws and patterns in the process of development to ensure the stability of its operation, as shown in Figure 1.

Diagnostic analysis, discovery, and early warning of urban public safety events require spatiotemporal data of different modalities as data support, which is a gradual process of query conditions from rough to precise, so cross-modal retrieval of multimodal spatiotemporal data needs to be realized based on different needs at different stages. The multimodal spatiotemporal data retrieval for public security monitoring requires not only fast retrieval speed but also comprehensive consideration of cross-modal retrieval based on time, space, and semantics [15]. Based on the semantic-based multimodal spatiotemporal data association model and the spatiotemporal semantic integration indexing method proposed in the previous study, the spatiotemporal

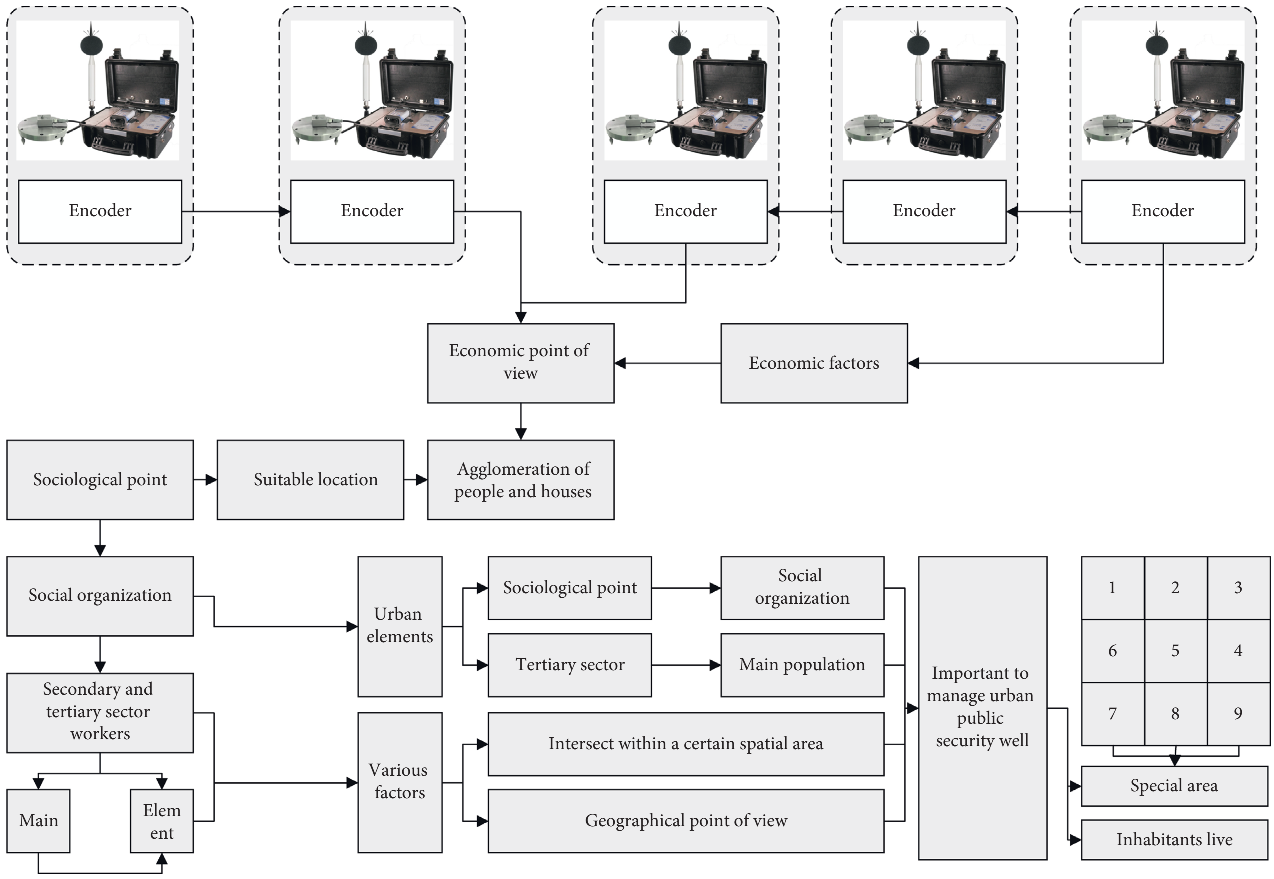

Figure 1: Intelligent monitoring framework of public safety machines for smart city construction.

association retrieval model will be studied from two aspects of spatiotemporal change objects and spatiotemporal change processes, and the cross-modal retrieval method for spatiotemporal change objects and the cross-modal retrieval method for spatiotemporal change processes will be proposed for the cross-modal retrieval needs of multimodal spatiotemporal data.

After the incident information is updated, the relevant plan is activated according to the basic characteristics such as the type and level of the incident. The relevant emergency members of the plan and the robot emergency team will arrive at the emergency site and immediately start a series of emergency rescue work following the contents specified in the plan. Referring to the laws and regulations related to emergency plans, the emergency plan of the robotic accusation system should form a system to formulate special emergency plans and on-site emergency disposal plans for all levels and types of accidents and all sources of danger that may occur, and clarify the responsibilities of relevant departments and relevant personnel in each process beforehand.

During the incident, and after the incident, in the preplanning management, in addition to the overall and special preplans for an incident emergency, the relevant preplans for robot emergency should be effectively supplemented so that the corresponding robot preplans can be activated according to the actual situation after the incident occurs to make a quick response. The robot command-and-control system's preplanning library mainly includes three major categories, as shown in Table 1.

To get rid of the problem that most of the cases can only see but not use the plan, the robot accusation system adopts intelligent process management of the plan, completes the process decomposition, analyzes each key node, and controls the progress of each key node [15]. The system provides a template for the preparation of the plan, and the user can enter the specific content and control the process of each key node in the plan, such as information reception, information transmission, and incident response. When an emergency occurs, the robot accuses the system of initiating and monitoring the process of the plan. First, according to the keywords of event type, level, and scope, the most similar plan in the plan database is automatically or manually matched, and the content of the plan is amended according to the actual situation. Then, each process task is issued according to the content of the plan, and the emergency resources involved are reasonably allocated. Finally, the task execution and resource dispatching are monitored in real time.

It is important to accurately locate the dynamic risk evolution in the city, advance the risk identification milestone and design, build a real-time chain-triggered strain mechanism for the local subsystems of the city, identify urban disaster risks as early as possible, and stimulate the

Table 1: Classification of preprogrammed.

Plan system	Illustration	Value
Comprehensive emergency plan	In general, it elaborates on the emergency guidelines, policies, emergency organization structure, and related emergency responsibilities for handling accidents	5
Special emergency plan	The basic requirements and procedures for emergency actions, measures, and guarantees are comprehensive documents for dealing with various accidents	8

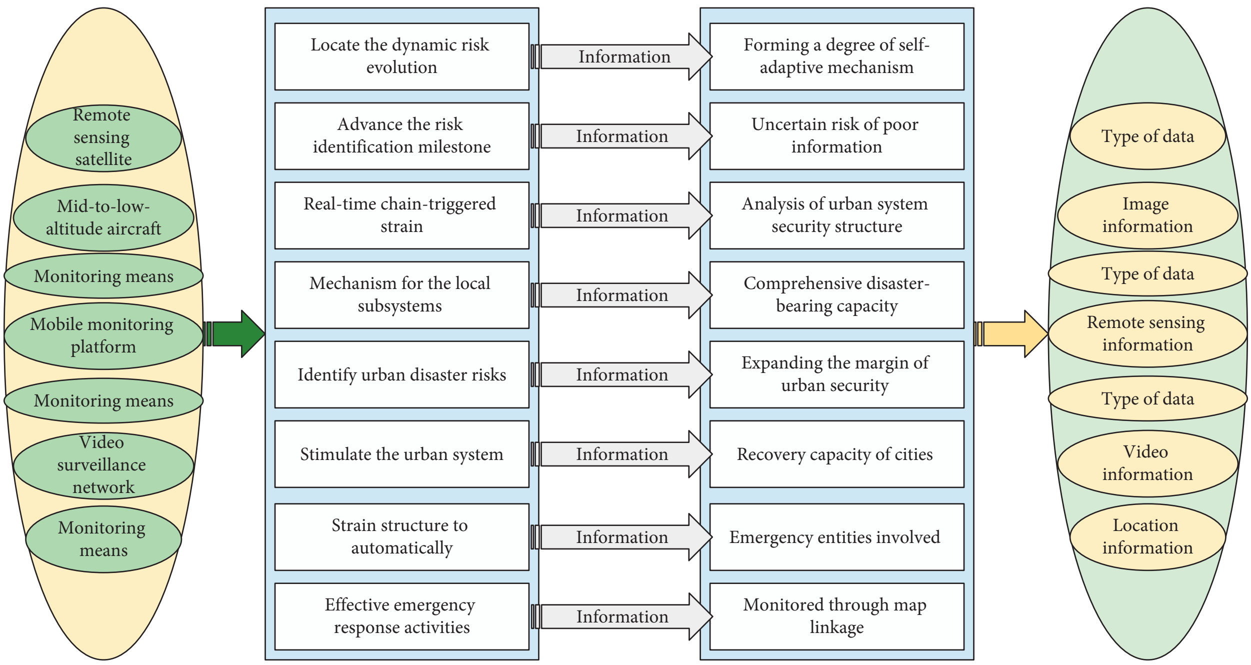

Figure 2: Public safety stereoscopic monitoring data acquisition and main data types.

urban system strain structure to automatically adjust to intervene in effective emergency response activities, thus forming a degree of self-adaptive mechanism for the uncertain risk of poor information. In addition, through the analysis of urban system security structure, it is easy to see that expanding the margin of urban security and improving the comprehensive disaster-bearing capacity and post-disaster recovery capacity of cities are important ways to ensure urban security, as shown in Figure 2. In the action phase, specific tasks are given to the robots and other emergency entities involved according to the specific content of the disposal plan, and the execution of the tasks is monitored through map linkage. In the above model, the arrows indicate the information flow, which runs through the whole process of the command-and-control system. The information involved in the robotic command-and-control system is generated and derived from the external environment and has the general characteristics of ordinary information, i.e., timeliness, transferability, dependency, sharing, falsifiability, and utility, so that the whole process of information acquisition, transmission, processing, and utilization is subject to higher requirements.

From the perspective of information flow in the command-and-control system, the data flow of the command-and-control system is analyzed [16]. The information sources of the command-and-control system mainly include two parts: the disaster site and the related emergency platform. As the main execution entity of the accusation system, the information of the robot includes the information of the body and the environmental information collected at the disaster site. The robot body information includes robot status, power, and other parameter information, while the disaster site information may include on-site video, pictures, and other sensor information. After the information is collected, the event emergency scene is presented to the commanders after the analysis and processing of the original data. After the commanders have sufficient knowledge of the event scene posture, they assist in developing the event disposal plan with the help of decision support-related methods. Finally, the commanders issue emergency rescue tasks to the executing entities on-site according to the disposal plan and monitor and adjust the emergency rescue process of the executing entities through real-time information feedback.

Different from traditional spatial data, public safety monitoring data not only have the massive and unstructured characteristics of traditional spatial data but also have multimodal characteristics. The multimodal characteristic refers to the data description of the same spatiotemporal object with multiple different forms and the characteristics of low-level feature heterogeneity and high-level semantic correlation between different modal data. For example, if the police want to use public security monitoring data to arrest a suspect, the police may identify the location of the suspect through the description of several different modal data such as video data and trajectory data of transportation. The multimodal nature of public safety monitoring data provides the possibility to support deep cross-modal analysis, mining, and application of multisource spatiotemporal data.

3.2. Design of Intelligent Monitoring and Warning Methods for Public Safety Machines. The key to making the huge amount of public data useful is data application, and the prerequisite for data application is data openness. Because of the limited technical power of the public sector itself, Hangzhou has introduced private organizations to provide technical services for the "City Brain" project [17]. According to the basic logic of "City Brain," it is easy to see that the private sector plays a leading role in the whole chain from data collection to data application. Taking traffic congestion as an example, the private sector has access to real-time video data from road video surveillance and can use the road traffic data it obtains to analyze and build models through algorithms to promptly adjust signals on-ramps and other roads to alleviate prolonged congestion; it can even use big data technology to make predictions based on real-time road conditions and plan routes for special vehicles such as ambulances. Private organizations can submit data requirements to the relevant departments according to their needs and perform operations such as cleaning, mining, and application of the data acquired after approval and consent. According to the complete chain of big data application, it is not difficult to find that while realizing the value of data, there is a possibility of data security problems occurring in each link of data collection, data cleaning, and data mining.

$$\begin{gathered}\Gamma_{ij} = \sum_{k=1}^{m} w_k^2 \gamma_{\mathrm{ijk}},\\ \sum_{i=1}^{p} \Gamma_{i\alpha} \leq \sum_{i=1}^{p} \Gamma_{i\beta}.\end{gathered} \tag{1}$$

Cities are complex systems, and the construction of smart cities involves different fields, and to share resources and information data, the platform to be built needs to be cross-agency and cross-departmental, which is a complex and systematic project. In this process, the fields with great strategic significance, strong driving force, urgent realistic needs, and wide and large benefits are selected to build relevant projects and works, to achieve results in the short term and form a systematic model; in this way, we can achieve results in a short period and form a systematic model, summarize experience and practice, gradually expand the application area, and lay the foundation for subsequent construction. The development of various construction and management specifications, including basic network standards, information service standards, and security standards, can guarantee the stable, safe, continuous, and efficient operation of the smart city system. The information infrastructure should be optimized and improved, technical standard specifications, application standard specifications, and operation and maintenance standard specifications including perception equipment and cloud foundation should be established to guide and regulate the smart city, and the engineering projects should be incorporated into the assessment system for regular review and evaluation against them to ensure that the project construction effectively promoted, as shown in Figure 3.

The top-level design of a smart city takes a holistic view, integrates all levels and elements of the system, involves multiple participants, and defines unified goals. It follows the principles of integrated planning, collaborative integration, resource integration and sharing, and services for the benefit of the people, and is people oriented and city specific [18]. Its construction program needs to have a wide range of universality; integration of academic, administrative, investment, and other authorities' demands; a combination of guiding programs and unified data formats and interfaces; and attention to the design of the city management system and operational development environment in addition to the technical aspects. The construction of smart cities requires timely, accurate, and comprehensive access to all kinds of data and information from the operation of the city, and in this process, intelligent infrastructure is the main source of providing information, and the establishment of a perceptible infrastructure layer is the underlying foundation in the technical architecture of smart cities. The data of each business area are usually distributed in independent subsystems, and the amount of data is very huge. The data extracted from the database have inconsistent formats and are incomplete data, which may not meet the requirements of the destination library, and when there is a software upgrade, the database architecture and the form of storage behind it are different, which are bound to bring about the upgrade, conversion, and processing of data, and the conversion of data is now. The conversion of data nowadays is inefficient, and in the application of IoT, there is also the problem of integration of old and new system interfaces and cross-system interfaces that cannot be accessed, resulting in the problem of data conversion and transmission. Therefore, the establishment of a unified data interface can realize high-speed data conversion and effective transmission.

$$\begin{gathered}w_i = \frac{\sum_{i=1}^{p} \Gamma_{ij}^2}{\sum_{i=1}^{p} \cdot \sum_{i=1}^{p} \Gamma_{ij}^2},\\ R(j) = \sum_{i=1}^{p} w_j^2 \Gamma_{ij}^2.\end{gathered} \tag{2}$$

The rule of law is to manage according to laws, regulations, and systems, using the rule of law thinking and the rule of law to solve the persistent problems of urban governance; intelligence is the future of urban refinement management; the key is to fully use modern technology and information technology, relying on the system platform to achieve information sharing, rapid linkage, and intelligent management; and standardization is to improve the

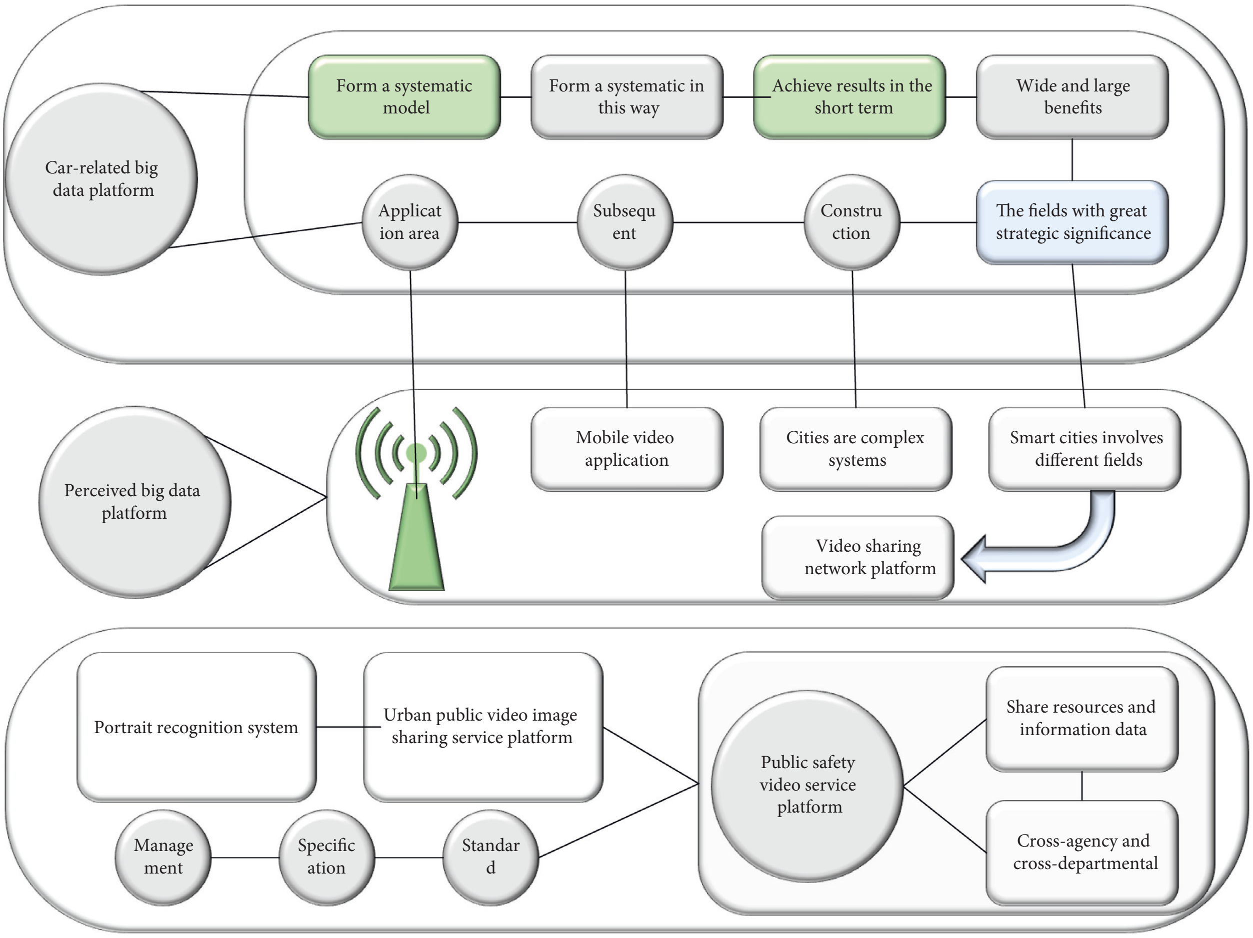

Figure 3: Public security video surveillance application system.

standard system for urban refinement. Standardization is to provide the basis for urban refinement management through a sound and complete standard system, integrating and unifying, bridging, and supplementing the scattered management standards of various departments, making them quantifiable, assessable, and traceable; socialization is to realize the diversification of management subjects, relying only on government departments for management that is not enough; and only by integrating the power of social, market, and other diversified subjects can we achieve the level of refinement management, requiring the social diversified subjects to do their duty while the government management responsibilities are in place [19]. Refinement in the field of urban management is to apply the concept of refinement in the process of urban management, to put people first, to seize the breakthroughs, to continuously promote the shortcomings, to promote the safety, order, and comfort of the city based on precise and scientific regulations and standards, to supplement with efficient and intelligent information technology tools, to adhere to the synergistic pattern of multigovernance, and to meet the interests of all social classes with better quality services and more humane management, as shown in Figure 4.

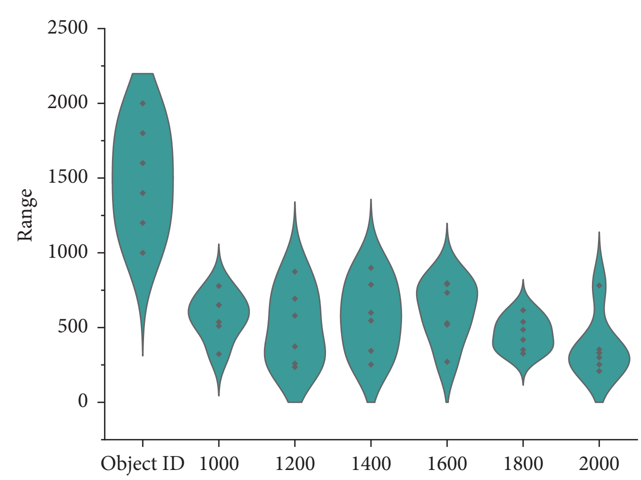

Figure 4: Monitoring early warning calculations.

In the case of data opened to the private sector by the public sector, not all public data can be opened to the private sector without conditions or boundaries. If public data involve the privacy of citizens, internal government secrets, secrets of commercial organizations, etc., and are opened to the private sector without conditions, there is a risk of improper use of the data by the private sector for profit.

$$z^{(1)}(t) = \left(z^{2}(2) + \frac{b}{a}\right)e^{-\alpha t} - \frac{b}{a}. \tag{3}$$

Public data should be classified into visible and useable data, visible and unavailable data, and unavailable and invisible data according to its level, importance, and confidentiality, and the data provided by the public sector to private organizations should be further subdivided on this basis. This will pose a great challenge to the security and authority of the government, and will also lead to security problems such as misuse of personal private data and theft of confidential business information by private organizations [20]. The government management center should be responsible for the senior leadership of government departments, and the team should be composed of full-time video information technology service personnel, supplemented by business departments and professional companies' research and development personnel, and clarify the responsibilities and tasks of the government management center and various industry departments, and following the division of responsibilities and the actual work needs of each department, video resource application authority should be reasonably allocated, and each division of the duty, working closely together to grasp the video surveillance construction, management, application, maintenance, and other aspects of the work, becomes the primary link to ensure that the video application is to deepen and enhance the use of benefits.

4. Analysis of Results

4.1. Intelligent Monitoring System Performance Results. It is also a highly practical and operational issue. From a practical point of view, different regions have different management requirements, and it is equally necessary to conduct in-depth research on this aspect in the process of public security governance and seek more effective management models. However, from the overall situation, there are still shortcomings in the overall public safety governance research, which leads to governance work greatly affected. In the process of urban public safety governance, it is necessary to pursue the alignment of interests, and the law is the basis for ensuring the alignment of interests and achieving efficient management. In the process of urban public safety governance, legalization is the key to ensuring the stable operation of the government administrative system and the autonomous system and is an important basis for coordinating the interests of the government and the interests of society. From the current situation of public safety governance, there is not yet a perfect system of laws and regulations for disaster mitigation and relief, which leads to the problem of unclear responsibilities in the process of urban public safety governance, especially when it comes to how to do the reconstruction and rehabilitation work within the shortest practice after the occurrence of a public safety incident, which is a lacking area at present.

The first is the most fundamental need for survival, which is reflected in access to food and drinking water. In the preparation of emergency shelters, in addition to the preparation of these substantive materials, it is necessary to calculate the amount of material distribution and the number of days of supply through the statistics of the number of evacuees and emergency materials in the place, so that the managers can improvise and deploy in time to guarantee the needs of evacuees; the second is the living needs, namely, rest and accommodation, washing, and excretion. In this process, it is necessary to monitor in real time the status of various pipeline networks, stability, and safety of the built accommodation facilities. In conventional emergency shelters, it is necessary to send stationed or testing personnel, but in the construction of smart cities, such workforce can be saved, as shown in Figure 5.

Access to information data and command platforms is required. These include the collection of the situation of people on-site and the monitoring of the status within the premises; a management platform that can display information and assist in decision-making; and the proficiency in changes in the surrounding environment to make predictions about the disaster situation and assist in decision-making about the next action instructions. The second is the demand for service output: through broadcasting and communication equipment, the command of the actions of the groups in the place; giving feedback and emotional reassurance to the affected groups; and the collection of the needs of the affected groups in the place. From the analysis of the top-level design of the smart city, promoting the construction of the smart city in various fields is not limited to the stacking of smart hardware in this field; similarly, the establishment of the emergency shelter cannot just be limited to the intelligent facility configuration of the place itself but should rely on the whole intelligent emergency system, from the four levels of the technical architecture layer by layer. Otherwise, it is an isolated set of intelligent hardware, without connecting it through a high-speed transmission network, without relying on the platform of cloud computing and big data processing and calculation, without forming the whole data sharing, without using the output of artificial intelligence and other technologies, etc. In this way, it also fails to grasp the essence of a smart city, and the manager cannot perceive the state of everything in the place in real time and cannot instantly obtain the needed data and information. It is not possible to capture the needs of citizens and make emergency responses in the first place, as shown in Figure 6.

When introducing larger-scale element information data, it will be possible to obtain more comprehensive element causality results, thus providing complete decision support for urban areas and overall fire emergency response capability improvement. When many similar cases of fire accidents introduced, the basis for risk diagnosis is enriched, and more references are available for judging the evolution of risk signs mapped by the state of each element in the grid cell, which will greatly specify the degree to which different elements affect the risk in different grid cells. Thus, the model can be used to create differentiated and dynamic capacity requirements and evaluation models for the grid cells at the end of the city and for the intermediate levels, thus providing a set of management technology solutions for urban fire safety adaptive mechanisms. The key to the

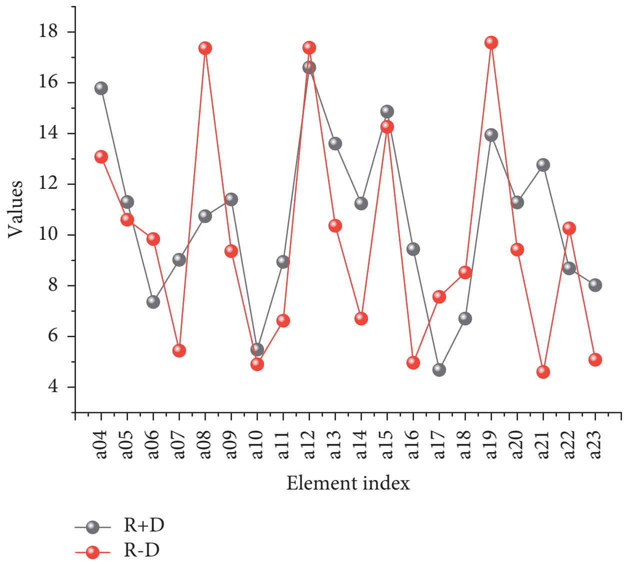

Figure 5: Centrality and causality of risk elements of grid cells.

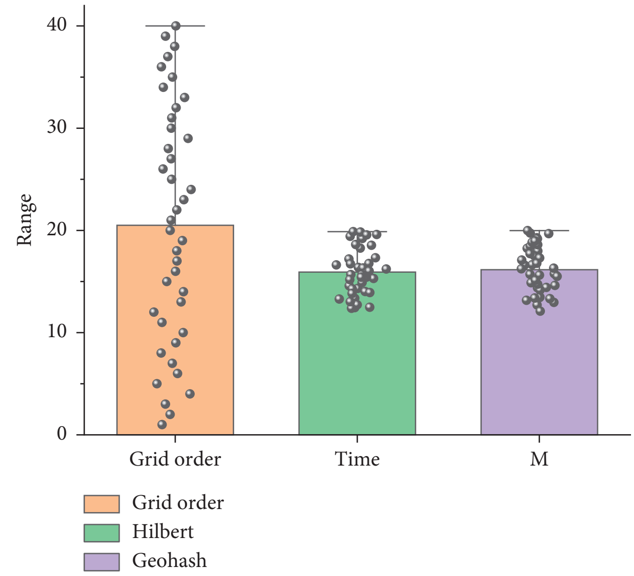

Figure 6: Operational efficiency.

sublimation of the comprehensive analysis from objective and correct to accurate and timely, in addition to the further optimization of the abovementioned model principles, lies in the maturity and improvement of the smart city platform, intelligence system, and the sharing mechanism of multifaceted information and data resources. Therefore, based on the actual operation of the experiments throughout this round of empirical calculations, fully combined with the current situation of urban risk governance, and oriented to the new era of urban regional fire safety risk diagnosis practice and adaptive mechanism construction tasks, the theoretical research of related initiatives is further carried out in the following from three aspects.

4.2. Intelligent Monitoring of Early Warning Results. As far as the regulatory platform itself is concerned, the lack of uniformity in the regulatory platform makes it possible for differences and disagreements to exist in the monitoring results of the same data, which adversely affects the timely implementation of government decision-making and emergency disposal, as the relevant personnel needs to verify the authenticity of different monitoring results before they can make decisions on whether and how to carry out emergency disposal, which misses the best timing. The lack of regulatory monitoring of the definition, algorithm, testing, and release of public data will make the use of public data by private organizations out of the control of the public sector, and private organizations may perform certain illegal and unlawful operations on the data in pursuit of commercial value, resulting in unpredictable, uncontrollable, or even irreversible consequences. With the advent of the cloud era, cloud technology has provided great convenience for data storage, etc. However, after the business goes to the cloud, the public sector's control over its data and business systems is weakened, and some of the management and operation, and maintenance rights are controlled by cloud service providers, and there is a lack of effective regulatory mechanisms and supervision means for cloud service providers, which may tamper, use, backup, or even sell public data on the cloud-based on their interests, resulting in serious public data security problems, leading to some public sectors' data on the cloud have doubts, as shown in Figure 7. Controls on network access are also not very strict. The inability to fully guarantee basic security means that data held within the public sector is at risk of external intrusion, and the leakage of certain confidential and sensitive data will have an extremely negative impact on the stability of society. In terms of monitoring technology, an immature and incomplete monitoring system may not be able to promptly detect hidden data risks, resulting in emergency response work not being carried out in the first instance and the damage caused by data security problems not being kept to a minimum.

As far as emergency disposal technology is concerned, without advanced disposal technology, even if the monitoring system issues a data security alert for the first time, it cannot make a rapid response, or even if the emergency disposal system makes rapid disposal at the first time, it cannot respond to and thoroughly solve the emergency data security problem due to its low technical content, which will likewise produce security problems such as leaking personal privacy, commercial secrets and state secrets, and so on. The use of big data technology to achieve analysis and prediction is related to the amount of data, algorithms, and objectives. To achieve data prediction, it is necessary to have sufficient data volume, mature algorithms, and clear objectives.

The retrieval time overhead increases with the increase in data volume, but the overall retrieval time overhead of this study's index is lower than that of the combinatorial index, which is mainly because this study's index merges the retrieval results of multiple behavioral processes, while the combinatorial index also requires the retrieval results of

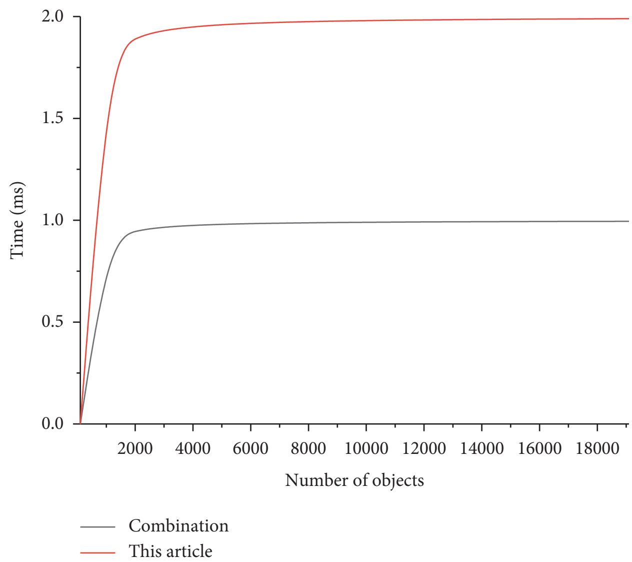

Figure 7: Comparison of early warning performance.

temporal, spatial, and semantic associations in each behavioral process retrieval separately before this merging. In addition, as the data volume increases, the retrieval time of this index grows slower and the gap between the retrieval time of this index and that of the combinatorial index gradually increases, mainly because as the data volume increases, the retrieval time is not only affected by the number of retrieval results merged but also by the semantic saturation, with the increase in data volume, the semantic information contained in the data content tends to be saturated, i.e., the amount of keywords tends to be stable, and the time of the word dictionary matching stage tends to be stable. The above experimental results indicate that the retrieval performance of this study's index for the event change process is better than that of the combinatorial index, and the larger the data volume, the higher the retrieval performance of this study's index.

5. Conclusions

In this study, we propose a semantic-based multimodal spatiotemporal data association model for the characteristics of low-level feature heterogeneity and high-level semantic correlation of multimodal spatiotemporal data. Based on the feature-semantic mapping mechanism of spatiotemporal data, the model uses ontology theory to construct a semantic expression model of multimodal spatiotemporal data and realize the normalized semantic expression of multimodal spatiotemporal data; on this basis, the temporal correlation, spatial correlation, and semantic correlation calculation methods of multimodal spatiotemporal data are proposed to realize the correlation construction and correlation metric of multimodal spatiotemporal data, which provides model support for public safety monitoring-oriented data. It is found that smart cities have not paid enough attention to the field of urban public safety, and there are no in-depth development and application in smart emergency response. The robot application module is combined with related technologies to develop and implement four aspects of robot data communication, situational display, auxiliary decision-making, and command and dispatch. Public data security management is a continuous project, and due to the differences in the interests of the subjects, the supervision mechanism should be carried out throughout the process, while technical means, policies, and regulations need to be constantly improved to cope with new problems that constantly arise. In the future, we will conduct more in-depth research on this basis and apply it in practice.

By combining the advantages of online teaching and offline teaching under digital technology, blended teaching can break the limitation of time and space, which reflects the transformation of the "student-centered" teaching paradigm. With the expansion of the blended teaching scale, how to analyze and match the features through the data of learners' learning behaviors to improve their learning efficiency and teachers' teaching level and quality has become an urgent problem. Therefore, in this paper, collaborative design is carried out for blended English teaching platform in higher vocational colleges, where students' cognitive ability and difficulty of teaching resources are cooperatively matched. At the same time, blended recommendation of teaching resources is implemented based on collaborative filtering algorithm, thus developing a matching algorithm in light of the above dynamic adjustment. The results of the iterative test show that the platform can optimize the current English teaching mode and enhance the learning feedback between teachers and students, thus improving students' English learning level.

1. Introduction

At present, Internet not only plays an optimization and integration role in the allocation of production factors, but also is introduced into the basic requirements of public English teaching in colleges. It emphasizes the significance of actively introducing computer and network technology that can enhance students' consciousness and enthusiasm in English learning. Under the background of the new situation, with the rapid development of network information technology in China, various English autonomous learning platforms came into being [1–3]. Compared with traditional English learning methods, the network-based learning model can meet the diverse needs of students' learning resources, which helps students to manage their learning time flexibly. Moreover, it gives full play to the guiding role of network learning for students, which quickly improves students' English learning efficiency and effect. Under the above platform, students can be engaged in online English learning by combining the hot issues and contents that they are interested in and accumulate experience in English learning. However, in the face of massive learning resources, there is a serious problem of overload information, especially in the field of basic English teaching. The selective difficulty caused by information overload makes it difficult for learners to quickly find the learning content suitable for their own abilities, which not only delays their valuable time and reduces their learning efficiency, but also causes resistance to English learning [4, 5].

Combining blended teaching mode with digital technology can meet all kinds of needs of English teaching development. This teaching method of combining theoretical knowledge with practice can improve the traditional way of students' class learning and provide guarantee for the all-round development of their ability. In addition, the blended teaching mode provides rich resources for students, which can comprehensively improve students' comprehensive comprehension of English knowledge [6, 7]. At present, the application of the blended teaching mode is superficial, teachers have failed to strengthen the reform of traditional classroom teaching methods and create a learning environment based on the network platform. Therefore, it is significant to research the collaborative design of blended English teaching in higher vocational colleges under digital technology, which can integrate the public English teaching mode and methods with modern teaching forms, so as to promote the effective development of English teaching.

2. Establishment of Blended English Teaching Platform

2.1. Connotation of Blended Teaching

2.1.1. Significance of Blended Teaching. The implementation of blended teaching involves students, teachers, colleges, and other subjects. In fact, it has formed a complex system, which also brings challenges to blended teaching [8]. However, digital technology gives a good solution. Various Internet tools such as Internet system management platform and Internet information storage provide technical support for blended teaching system management that mainly includes teaching evaluation system, teaching resource sharing system, teaching curriculum arrangement system, etc. Through the blended teaching mode, teachers can not only teach through the network but also make preparation for class, assign homework, correct homework, and answer questions online. Similarly, students can interact with teachers online to solve the confusion about English learning [9, 10].

2.1.2. Digital Support for Blended Teaching. The development of digital technology provides a reliable mobile platform for blended teaching. Students' extracurricular practice cannot be separated from the support of abundant network resources, so the interactive design of learning content, including content structure design, multimedia presentation design, problem design of teaching content, and operability design of teaching tasks cannot be separated from the support of mobile platform [11, 12]. The use of the mobile platform can greatly expand the space of class, and teachers can communicate with students through various ways, such as network teaching platform before and after class, so as to keep abreast of students' learning situation and their feedback. Especially, the establishment of college resource sharing platforms has created a harmonious, open, interactive, and exploratory environment for students, which enables students to freely discuss problems with online students or teachers equally and easily through the network, and always maintain a positive self-activation state in the learning process.

2.1.3. Existing Problems. Due to the characteristics of learners and learning resources, the traditional network teaching platform cannot effectively adapt to the blended teaching mode, and it is difficult to integrate the learners' changing cognitive ability and the difficulty of learning resources for personalized collaboration. In addition, most online English teaching resources are simply piled up, which is not only a lack of semantic and logical hierarchy of knowledge points but also a lack of marking of knowledge points.

2.2. Recommendation of English Teaching Content

2.2.1. Recommendation Based on Teaching Resources. Recommendation based on teaching resources is to use the content attributes of teaching resources to predict the information related to it and users' personal information. The system recommends learning resources for learners that are similar to their past studies, hobbies, and abilities [13]. This method can not only avoid the cold start problem of learning resources but also analyze the relationship between learning resources first and then implement the recommendation [14]. It finds the relevance of resources in terms of content according to the annotation metadata and then recommends similar learning resources to users based on user's historical learning records, as shown in Figure 1:

We model the metadata of learning resources, then discover the similarity between learning resources through these metadata, and finally, make recommendations according to the similarity. Content-based recommendation only considers the nature of objects and forms a set of objects according to tags. If the learning resources that users like appear in this set, other objects in the collection are recommended to them [15, 16]. In addition, it needs to use related technologies to describe learning resources and learners' personal information, as well as strategies and algorithms that can compare personal information with content description. Its architecture diagram is shown in Figure 2:

The recommendation system only uses the current user's preferences and related historical learning records to build the personal information model, which presents the reasons why content resources are recommended by the way of display (content features or descriptions). In addition, it can also recommend new content without any comments from users, which can make good use of learners' interests and receptivity to model, thus making the recommendation result more accurate [17, 18].

2.2.2. Recommendation Based on Learner's Ability. Accurate mastery of students' English knowledge and learning ability is helpful to better implement the "online" part of blended teaching. The recommendation based on learners' ability is based on learners' personal characteristics (existing knowledge base, cognitive characteristics, learning style, etc.) and demographic information (age, gender, place of residence, interest, etc.). First, the algorithm takes learners' personal data to automatically cluster and group students and then recommends different learning contents according to specific learners' abilities. Learners can choose their own learning materials, learning methods, and evaluation methods that best suit their own characteristics. The basic process of the recommended algorithm is as follows:

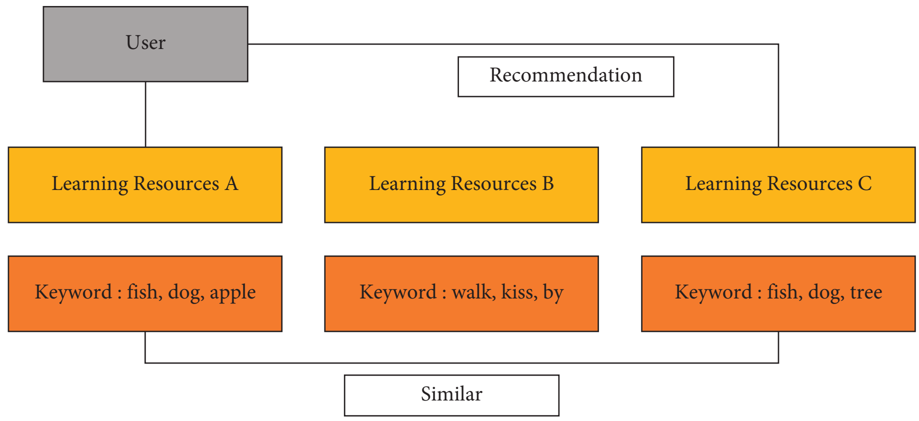

FIGURE 1: Recommendation of English teaching content.

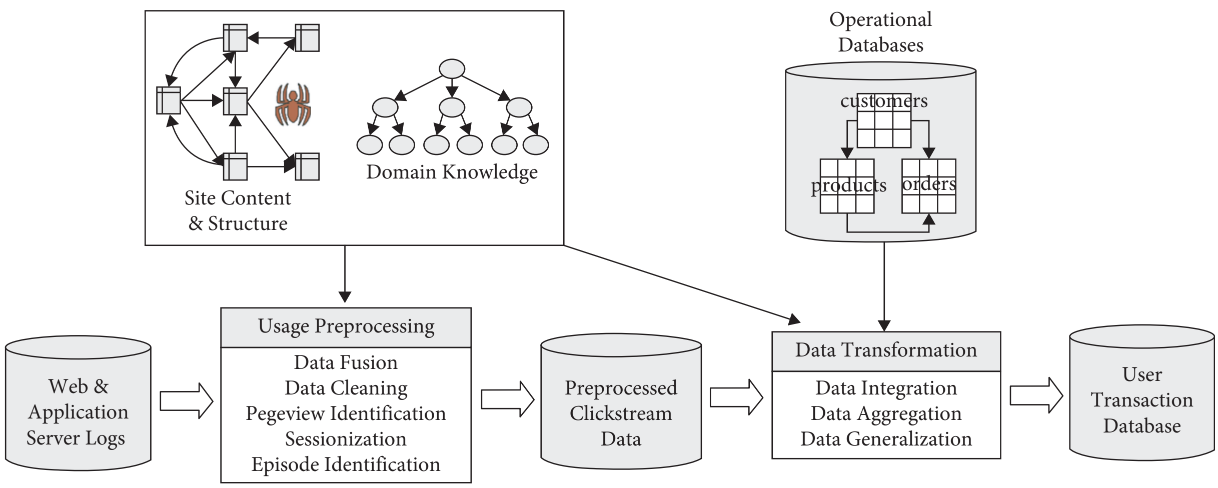

FIGURE 2: Framework of recommendation on English teaching content.

(1) Obtain information of learner's ability

(2) Look up the matching information of ability and difficulty

(3) Search for learning resources by using the information of difficulty matching

(4) Check the recommended result set, and if the result set is larger than the preset list length, go to step (6); if it is less than the preset list length, continue to (7); otherwise, return to (5);

(5) Output and display the recommendation list

(6) Reduce the difficulty standard to retrieve learning resources again and back to (4)

(7) Increase the difficulty standard, re-search the learning resources, and back to (4)

2.2.3. Recommendation Based on Collaborative Filtering. Both user-based recommendation and teacher-based recommendation need to obtain relevant information. User-based recommendation needs to obtain user's rating data and their "interests and abilities," while teaching-based recommendation needs to obtain teacher's curriculum design [19]. Collaborative filtering recommendation can overcome the problem of recommendation based on users, teachers, and English teaching resources. When the description information of teaching resources is incomplete or difficult to obtain, collaborative filtering algorithm can make recommendations through feedback from other users.

The biggest feature of the collaborative filtering recommendation algorithm is that it considers the similarity between users and makes full use of collective wisdom; that is, it digs out a small number of user groups (clustering grouping, which is called neighbors in collaborative filtering) that are similar to their interests and abilities among users. Afterward, an ordered list is formed according to the collection of objects related to them for recommendation [20, 21].

2.2.4. Blended Recommendation. Due to the personalized differences of users' learning, it is not only users' ability and resources that can be used as the basis for recommendation but also can be based on their learning records, hobbies, and learning results. In addition, collaborative filtering recommendations can be made according to users with the same ability level and learning resources. Because of the difficulty of learning resources and the error of cognitive ability calculation, an algorithm may only be suitable for parts of learning resources or learners. It is necessary to establish a configuration framework of individual-based learning resources or individual learner recommendation algorithm. In addition, the framework of the recommendation algorithm is generally based on a configurable mechanism. Therefore, the usage scenarios, targeted users, data on which recommendation depends, recommended data sources, and applicable scope of the recommendation algorithm are analyzed. Moreover, combined with the configuration parameters of data, a configuration framework of blended recommendation algorithm is designed, which designs all kinds of recommendations into system processes that can be called independently and specifies the storage locations of input data and output results, thus realizing the separation of the recommendation algorithm from the system platform and achieving the goal of dynamically configuring or adjusting the recommendation algorithm. Under the framework, the general flow of this recommendation algorithm is as follows:

(1) Learner user login
(2) Open the page that contains the function of recommendation
(3) Income navigation information for the page and user parameters
(4) Search the recommendation algorithm configuration table of users and page positions
(5) Obtain the type, dependent data, and the output position of the result the in recommendation algorithm
(6) Obtain recommended dependence data
(7) Call the recommendation algorithm process to transfer recommendation dependent data and user information
(8) Recommend the algorithm to be executed, record the output result to the established position, and notify the caller to complete it
(9) Check the recommended calculation automatically
(10) Obtain a recommendation result list according to the calculation result mark

The whole process involves learner, pages, background algorithm scheduler, the process of recommendation algorithm, and detection program, whose collaborative design process of teaching resources is shown in Figure 3.

Algorithm 1 shows the recommendation algorithm.

2.3. Microservice Architecture. Because the online English learning platform is a multiuser system based on the Internet, the microservice architecture is adopted in this system architecture model [22]. Microservice architecture is an architecture style, which organizes a series of collaborative services into a system to support business. The aim is to decouple the whole scheme by splitting the functions into discrete and independent services where each microservice can be independently developed, deployed, run, and upgraded. Compared to the traditional Java Web development method, the microservice architecture can be implemented by means of containers or virtual machines [23].

In order to follow the development principle of “low coupling, high cohesion” and realize the robustness and scalability of the code, layered technology is adopted for the establishment of this platform. Different layers are responsible for different functions, and the layers are combined through API interface calls, as shown in Figure 4.

In order to better reduce the coupling between layers, the software implementation is generally divided into three-tier architecture, and object-oriented programming is adopted. The upper layer calls the lower layer through interfaces, while the lower layer provides services to the upper layer, which is the implementation class of the lower layer interface. The API interface of the service standard is the same, and the service provider can change it. The three-tier architecture consists of a user interface layer, business logic layer, and data access layer, each of which has the following functions:

(1) User interface layer, which is responsible for interacting with users
(2) Business logic (BL) layer, which is mainly aimed at the operation of specific problems, can also be represented as the operation of data layer and the logical processing of data business
(3) Data access layer, which mainly operates on the database, not data, and specifically provides data services for the business logic layer or user interface layer

3. Testing of the Platform

3.1. Test Method. During the test, the recorded data of users’ learning process are used, and more than 100000 user information, 40000 English sentences, 30000 words pronunciation data, and 500 English article data in the system are selected. The test process used user tables, user learning tables, teaching resource tables, and so on. In order to better realize blended teaching, the learner’s test and feedback are recorded. The matching index of resources is defined as the ratio of learning score and cognitive ability of resources; that is, after the user finishes learning, the learning content is tested by the test bar, and the obtained score is divided by the user’s cognitive ability and multiplied by 100%, as shown in formula (1). If the recommended learning materials meet the user’s cognitive ability, users will be asked to complete the relevant test questions after learning the resources, so as to check whether they have mastered the knowledge and ability contained in the resources. If the user fails to complete the learning or test questions, it means that the recommendation does not meet their cognitive ability. Otherwise, it means that the resource is in line with the user’s cognitive ability.

$$\text{MatchRate}\,(\%) = \frac{\text{TestSore}}{\text{CogAT}} \times 100\%. \tag{1}$$

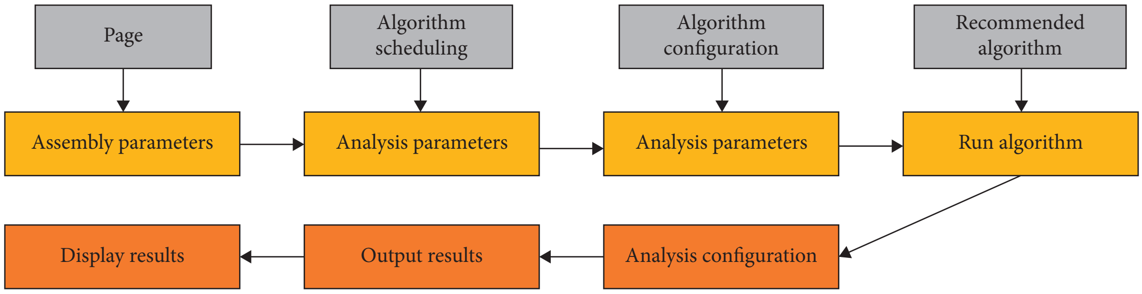

FIGURE 3: Collaborative design process of teaching resources.

```
Public float repeat value (Document doc1, Document doc2) {
  Float keyword TFIDF = 0.0f;
  Float doc1 TFIDF = 0.0f;
  Float doc2 TFIDF = 0.0f;
  For (String word: doc1.getContentTerms().keySet()) {
    If (doc2.getContentTerms().containsKey (word)) {
      Keyword TFIDF += doc1.getContentTerms().get(word);
    }
    Doc1 TFIDF += doc1.getContentTerms().get(word);
  }
  For (String word: doc2.getContentTerms().keySet()) {
    Doc2 TFIDF += doc2.getContentTerms().get(word);
  }
  Return (keyword TFIDF/doc1 TFIDF) * (keyword TFIDF/doc2 TFIDF);
}.
```

ALGORITHM 1: Recommendation algorithm.

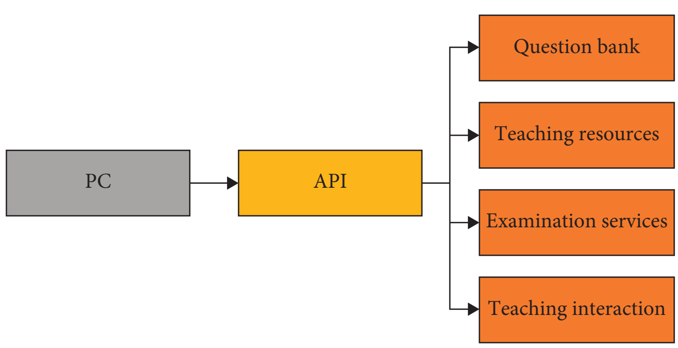

FIGURE 4: Architecture of blended teaching platform.

In the formula above, MatchRate indicates the degree of matching between learning resources and users' abilities, TestScore indicates the test scores of users after learning resources, and CogAT indicates users' cognitive abilities.

The evaluation system consists of process evaluation (mainly online evaluation) and summative evaluation (mainly offline evaluation). Online learning is mainly scored by online quantitative indicators, while offline learning is mainly scored by offline nonquantitative indicators. The blended teaching mode is mainly synthesized from the three processes before class, during class, and after class and the final evaluation. In each process, students can get online quantitative index scores and nonquantitative index scores evaluated by teachers.

TABLE 1: Test results of blended English teaching platform.

Grouping parameters	Iterations	Cluster average diameter	Calculation time (seconds)
3	80	4.6	1265
8	40	6.2	1038
12	20	6.9	1728
29	10	7.4	1189

3.2. Test Results. Firstly, the cognitive abilities of learners' users are calculated and grouped according to their cognitive abilities. The main basis of grouping is the geometric length of students' cognitive attribute vectors that mainly includes

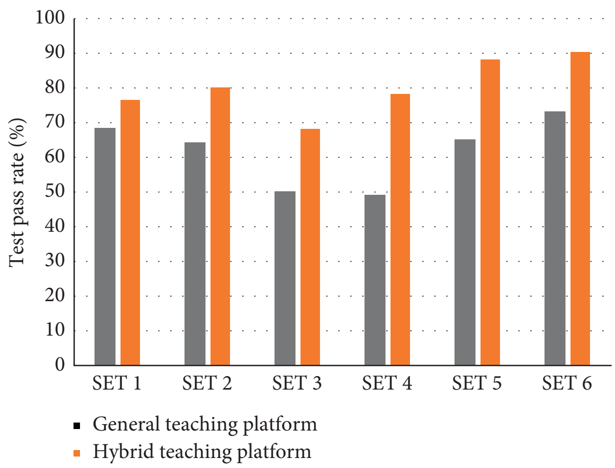

Figure 5: Comparison of students' test pass rate.

the cognitive abilities of age, vocabulary, and learning duration. The test results of grouping number and execution efficiency of related algorithms are shown in Table 1.

According to the results in the table above, when 8 groups are selected in groups and 40 iterations are selected, the execution efficiency is relatively high. In addition, the test results of college learners divided into 8 groups are in good agreement with the actual subjective judgment. The guiding significance of the test data lies in that we are basically in accordance with the actual test results. When students are grouped according to different learning stages, the cognitive abilities of students in each group are similar. If the grouping span is too large, the difference of cognitive abilities within the group will be larger, and the matching degree may decrease according to the recommendation of clustering grouping.

The matching effect of teaching resources is compared. For six groups of data, the number of users who have successfully passed the test on the blended English teaching platform is compared with the number of users who have passed the test on the original platform (the matching coefficient is over 60), and the result is shown in Figure 5.

It can be seen from the figure that under the original teaching platform, the lowest pass rate of users from SET1 to SET6 is below 50%. After adopting the blended recommendation algorithm, the collaborative feedback between users and teachers is obviously improved, and the test pass rate of students under the blended teaching platform remains above 65%, which is significantly higher than that of ordinary teaching platform. It shows that the promotion effect of the blended teaching platform on students' English learning is targeted and meets the learning ability of users. For teachers, the appropriate evaluation mechanism enables the platform to be used as an effective auxiliary tool for English teaching in higher vocational colleges, so as to truly advance learning and teaching through evaluation.

4. Conclusion

The blended English teaching mode based on digital technology can integrate modern technology with traditional teaching, and greatly improve the teaching quality of English in higher vocational colleges. By analyzing the shortcomings of blended English teaching at present, this paper designs a blended network teaching platform for higher vocational English, including the recommendation of teaching resources, overall structure, collaborative codes, etc. Moreover, the platform matches students' cognitive ability with the difficulty of teaching resources and tests the platform through the users' learning records and test completion. The results show that the collaborative feedback between users and teachers is significantly improved after the blended recommendation algorithm is adopted, and the test pass rate of students is above 65%, which is apparently higher than that of ordinary teaching platforms.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Academic Editor: Tongguang Ni

In the era of artificial intelligence, the traditional English teaching methods cannot meet the increasing demand of course learning at this stage. Therefore, in this paper, a brand-new English teaching model based on strategic reasoning mechanism is designed by analyzing the problems faced by construction of network curriculum in universities. By introducing the idea of artificial intelligence, the student model and teacher model are designed, and the separation of teaching content and teaching strategy is realized. The development of the system adopts B/S structure and relies on lightweight J2EE multitier framework. At the same time, the overall architecture, functions, and processes of the teaching system are analyzed and designed. The system is convenient to transplant and expand, which has certain practical value and can provide reference for the design of various teaching systems and the innovation of teaching modes.

1. Introduction

With the continuous penetration of information technology into the field of education, artificial intelligence has played an important role and has been paid attention to and recognized by more and more educators [1, 2]. Artificial intelligence, as a rapidly developing technology, has brought new advantages to the reform of college English teaching and provided a possible path for the construction of efficient and high-quality college English teaching. The interaction and infiltration between artificial intelligence technology and college English teaching has promoted the diversified development of teaching methods and modes, thus playing an active role [3]. Reform of college English teaching from the perspective of artificial intelligence is reflected not only in the improvement of teaching quality, but also in the improvement of students' interest in English learning. It is conducive to upgrading college English teaching from static passive learning to dynamic active learning, thus leading to the overall optimization of college English teaching ecology [4]. Relying on artificial intelligence, the teaching of listening, speaking, reading, and writing can be more vivid and three-dimensional, thus creating a modern intelligent English teaching system which is not to promote the complication of college English teaching, but to use advanced technology to present English in the simplest and most popular way for students, creating new perspectives and possibilities for college English teaching.

With the rapid development of artificial intelligence and network technology, web-based foreign language teaching websites or software appears one after another. However, the current online English teaching systems are mainly based on students' self-study and teachers' off-line answers, where students cannot get corresponding guidance [5]. In addition, there are also numerous English databases, online dictionaries, and online translation websites on the Internet. These tools can only translate and explain specified words and phrases, but cannot analyze a certain sentence and actively give learning guidance. Therefore, it is of great significance to study a new English teaching model with intelligent analysis function and corresponding learning guidance for different students.

2. Related Theories

2.1. Object-Oriented Knowledge Representation. The core idea of object-oriented technology includes objects, classes, encapsulation, and inheritance. Classes, subclasses, and instances form a hierarchical structure, which supports the classification and representation of knowledge and enables knowledge to be organized in a certain form [6, 7]. Object-oriented knowledge representation is mainly based on abstract data types, which is convenient to represent the static characteristics, real-time state, and interobject association of complex objects.

Because each object has three important parts: inherent attribute, operation behavior, and relationship with other objects, four base classes are established according to the object-oriented idea: attribute class, behavior class, entity class, and relationship class. The conceptual model of object-oriented knowledge representation is shown in Figure 1.

The attribute class is used to represent all the basic attributes of objects, the behavior class is used to represent all the basic behaviors, the relationship class is used to represent all possible relationships between entities, and the entity class is used to represent all objects. Commonly used knowledge representation methods [8] are the following:

(1) Predicate logic representation:

The main knowledge in artificial intelligence is often expressed by first-order predicate logic. Predicate logic representation can express things that cannot be expressed by propositional logic, but it still has some shortcomings for the representation of complex problems.

(2) Production rule representation:

Production rule is a widely used knowledge representation in expert system at present. The knowledge of causality is generally expressed by production. Its basic form isas follows:

IF P THEN Q

in which P is the precondition of the production formula; Q refers to the conclusion or operation obtained when condition P is satisfied. The meaning of the production formula is expressed as follows: if the premise P is satisfied, the conclusion Q can be deduced or the operation specified by Q can be performed.

2.2. Strategy Reasoning Mechanism

2.2.1. Data-Driven Forward Chain Reasoning Algorithm. According to the existing information of the problem, the context is established by adopting the rule forward. If the condition of the rule can be correlated with the existing facts, the rule is considered to be available. If there are several rules that satisfy the conditions, the conflict resolution strategy is used to select one, and add the fact of the rule to the context [9]; then repeat this process until the problem is solved or reasoning fails. The algorithm is described as follows:

Procedure Forward Beasoning (rulers)

{while (context fact ≠ target fact) Do

Call the procedure Select_rulers to generate available rule sets;

While (R ≠ NULL) Do

{Call the procedure Conflict _ Resolution (R) to resolve conflicts and generate executable rules; Call Operration _ block to add the conclusion of the rule to the dynamic context; }

}

2.2.2. Goal-Driven Backward Chain Reasoning Algorithm. By assuming factual goal and searching the knowledge base, the rule set that may match the fact can be found out, and then check the condition part of each rule in the rule set. If a rule can be correlated with the current data provided by the user, add the conclusion part of the rule to the database. Otherwise, take the condition item of the rule as a target, recursively executing the described process until all the subtargets appear in the context or the subtargets are not further solved [10]. For the latter, backtracking recurs again. The algorithm is described as follows:

Procedure Backward Reasoning

Set the initial reasoning goal and set the initial fact DB; Generating an optional rule set R by using the initial target matching rule;

While (R ≠ NULL) Do

{Take one in order as an executable rule; Record the condition position of dynamic database and target library; Call the procedure for recursive + backtracking antecedent matching;

IF (each sub-goal in the target library appears in the dynamic DB) THEN

Add to rule base;

}

IF (natural number) output reasoning failed;

Exit.

2.2.3. Framework Reasoning. First, find a description suitable for all current problems, and then use context reasoning of the framework to find the undiscovered facts, and make relevant operations among the factors (Figure 2).

Specific framework reasoning can be divided into static and dynamic. For static framework, static knowledge is used to represent framework, which corresponds to Rule and static fact in production system [11]. Dynamic framework is a dynamic information set generated in the process of framework reasoning, corresponding to Rule_based. This paper adopts the static reasoning framework, and its implementation code is as follows:

Procedure Frame Handler

Set initial information and dynamic framework set; Set the reasoning end flag to False;

While (reasoning end flag = False) Do

Taking out the activated static framework;

{Whi1e (current framework ≠ NULL) Do

{IF (query reasoning = True)

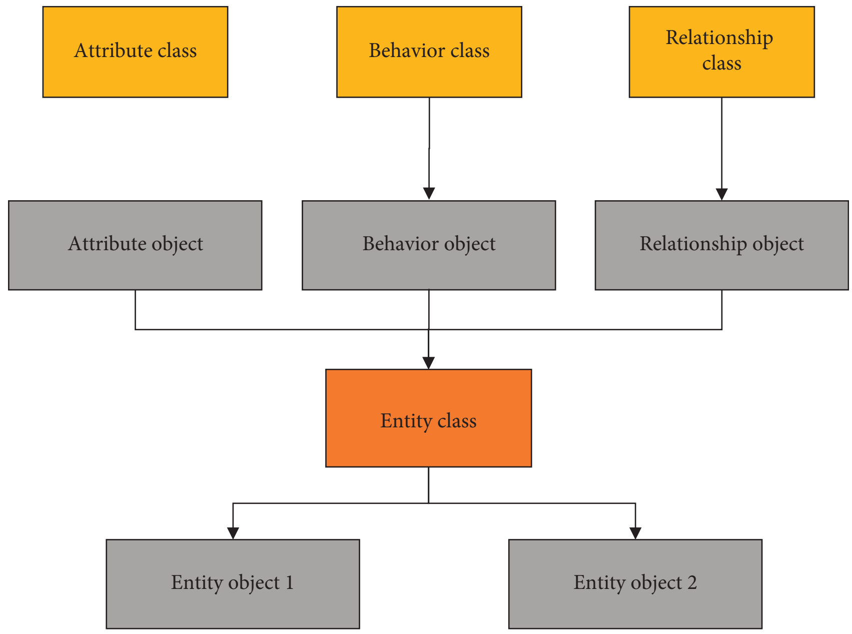

Figure 1: Conceptual model of object-oriented knowledge representation.

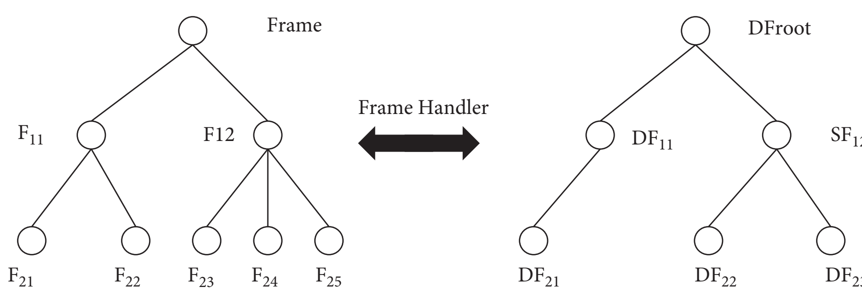

Figure 2: Process of framework reasoning.

{Take the case face value of corresponding factors; goto A}

IF (default reasoning = True)

{Take the side value of the framework factor; goto A}

IF (inheritance reasoning = True)

{Take the subframe, get the side value of the framework factor, and call recursively; goto A}

IF (procedural reasoning = True)

{Call the corresponding procedure and get the side value of the framework factor, goto A}

A: fill in the static framework (or dynamic) corresponding factors of the side value of the factor;

Reset the current static framework;

Set the reasoning end flag False or True (according to the reasoning situation);

}

}

2.3. J2EE Architecture. Java, often used as one of the back-end development languages of websites, has integrated many convenient frameworks. The system of education and learning platform is developed by J2EE with the object-oriented characteristics of Java [12, 13]. By combining MVC pattern and related frameworks, distributed architecture and cluster are used to improve the throughput of the system and make its architecture simpler and clearer. To make a dynamic website system, it is necessary to provide a server and database for web applications, so as to analyze and display front-end pages, handle business logic, and read related data.

J2EE architecture reduces the cost and complexity of developing multitier applications by providing a middle-layer integration framework. The middle layer can meet the requirements of high reliability, practicability, and scalability [14]. The unified development platform of J2EE can support the implementation of existing applications and can also fully support Enterprise Java Beans, which enhances the security mechanism and improves its performance [15]. The framework is shown in Figure 3.

2.4. Lightweight Framework. Lightweight framework is a programming pattern relative to heavyweight framework (typically EJB) [16]. This is because J2EE platform is a service provided by multiple suppliers, which comprehensively develops enterprise-level application products. On the one hand, the lightweight framework can be developed by simple

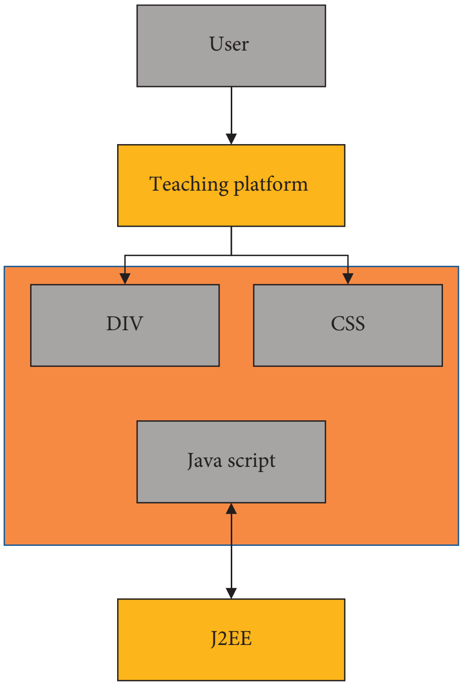

Figure 3: Interactive framework of J2EE.

Java Beans method, which can reduce the dependence of applications on containers and improve the development efficiency. On the other hand, most lightweight frameworks belong to open-source projects, and there are a large number of ready-made source codes, which help to reduce the difficulty of developing projects. In addition, lightweight framework has the following advantages [17, 18]:

(1) Adopt control inversion mode and aspect-oriented programming. It is not necessary to write a lot of code for executing developers, abnormal or managed connections, and it is easy to solve the dependency problem of objects. This not only separates the business logic from the basic framework, but also reduces the complexity and enhances the maintainability of the application.

(2) Lightweight framework provides management business. Due to its modular attribute, it is not required that business objects must follow the specific interface of the platform. Developers can develop based on POJOs to improve the efficiency.

3. Architecture Design of English Teaching System Based on Strategic Reasoning Mechanism

3.1. Overall Architecture. The systematic architecture is designed as B/S three-layer structure. B/S structure is easier to improve and expand than traditional C/S structure. The C/S structure requires that every terminal client must install the client program; otherwise it cannot work. This limitation makes poor compatibility and universality of the C/S structure [19].

The three-layer model of B/S structure includes the presentation layer (PL), the logic layer (LL), and the data layer (DL). The structural diagram is shown in Figure 4.

The presentation layer, also known as the interaction layer, is the interface between users and the whole system. It provides the user interface of application programs for displaying data and accepting data input by users. The client can run the software only by installing a WEB browser.

The business layer is a WEB server, which realizes the business functions of applications, and almost all business processing is managed in the middle layer. The middle layer is user-oriented, and the information input by the user interacts with the data layer through the middle layer, which mainly processes data business for specific problems [20, 21].

The data layer is a database server with student model and teacher model, while all kinds of data analysis, processing, and other operations ultimately come down to the access to the database in data layer.

Among them, the access between layers is strictly limited, and the logic layer can only access the data layer, while the presentation layer can only access the logic layer. Instead of directly accessing the database, users should connect to the middle layer and interact with the database through the presentation layer [22].

3.2. Functional Architecture. This system includes four kinds of users: experts, teachers, students, and administrators. When users log in, they have different module operation permissions according to different identities.

Expert: Expert refers to a senior English expert who has authoritative and profound knowledge in the field of English major and can thoroughly analyze the knowledge points, degree, and certainty involved in English test questions and give the system samples in the established format. The main permissions include knowledge base maintenance (adding, querying, modifying, and deleting static knowledge base and dynamic knowledge base), sample maintenance (adding, querying, modifying, and deleting), and password modification.

Administrator: they refer to the staffs who have the right to maintain the system daily. The authority mainly includes the management of system users, and the management of question bank includes adding, inquiring, modifying, and deleting.

Teachers: they are English teachers. One or several English teachers are assigned to each course according to the number of students' elective courses. Teachers' rights include viewing students' information, mastering students' learning progress, analyzing the knowledge of designated students or groups, organizing examinations, and analyzing test results.

Students: they refer to the registered students in this system. Their main rights include taking part in online learning in online classroom, self-study, examination, using intelligent analysis or diagnosis system to analyze the knowledge points they have learned, and obtaining relevant suggestions, intensive exercises, personal information modification, etc.

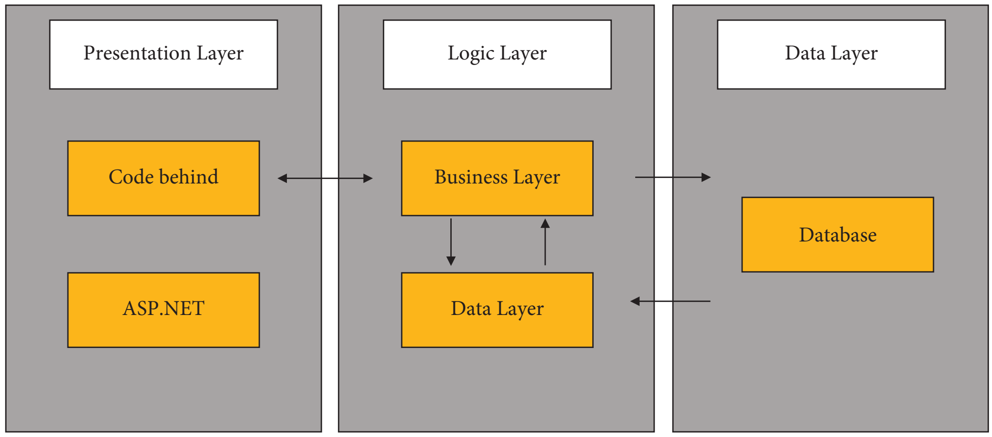

Figure 4: B/S architecture.

The system consists of three subsystems, namely, online teaching system, web-based teaching resource database, and teaching management system. The online teaching system is the main system, which mainly provides students with the functions of online real-time receiving and autonomous learning after class. The web-based teaching resource database is the supporting system of the main system, which contains all the resources of teaching and learning, such as courseware, video and audio material database, learning strategy database, corpus, and various teaching resource databases. Students can obtain materials from the resource pool to strengthen or expand their knowledge, while teachers can integrate the materials in the database for teaching or testing.

The online teaching management system is another supporting system, which mainly records, monitors, evaluates, and feeds back the teaching process, including registration module, grading test module, online learning record module, score analysis, and evaluation feedback module. The system manages the students' learning process when they have registered for courses online, analyzes the learners' learning progress, knowledge points, and grades, and establishes corresponding learning files for storage, so as to dynamically track and evaluate the students' learning activities.

4. Systematic English Teaching Mode Based on Strategic Reasoning Mechanism

4.1. Database Design. The data table of the systematic database can be roughly divided into the following types.

User information table: it contains 3 kinds of user information in the system, including user name, password, and user category.

Knowledge point table: it contains all knowledge points of English vocabulary and grammar, including category, name, difficulty level, number, knowledge point association level, and attribute.

Question bank table: its function is to save English test questions provided by experts, including questions, options, and answers.

Rule knowledge base table: it refers to the domain knowledge of experts in the form of rules, including object, object attribute, type, credibility, and fact description.

Strategy base table: the reasoning result descriptions of teaching strategy and learning strategy are saved in this table.

History information table: it is mainly used to save the history of visiting, learning, and practicing of various users.

Analysis table: it includes exercise analysis, knowledge point analysis, learning mastery analysis, and group analysis. It is used to determine feedback results in relevant situations.

4.2. Teaching Process. The traditional teaching mode is generally based on the teacher as the center to educate, while students passively accept knowledge. The Internet-based autonomous learning teaching mode is a new teaching mode with students as the center and teachers playing an auxiliary role. It strengthens students' ability to acquire, process, use, and memorize knowledge, which is of great significance for the learners to understand the research process, improve their quality, and cultivate the awareness of lifelong learning in the cognitive process. The teaching mode of a unit module is shown in Figure 5.

The process is based on the teaching unit as a cycle. For a certain teaching unit, firstly the teaching objectives and learning objectives of the unit are set, and the methods to achieve the objectives are provided. After entering the online class or autonomous learning system, the system provides rich learning resource and forms for students to choose, whether it is the learning of vocabulary and grammar in language knowledge or the learning of listening, speaking, and writing in language skills. It can be a video explanation or a small game of set scene. The next stage is the class training. In this stage, the teacher guides the students in reading, writing, and translation; then, students form a group for interactive training. The fourth stage is the practice, which mainly trains the students' communication skills and improves their relevant abilities by designing a series of activities combined with the social reality which include group discussion on current affairs at home and abroad and filling in the application form for studying

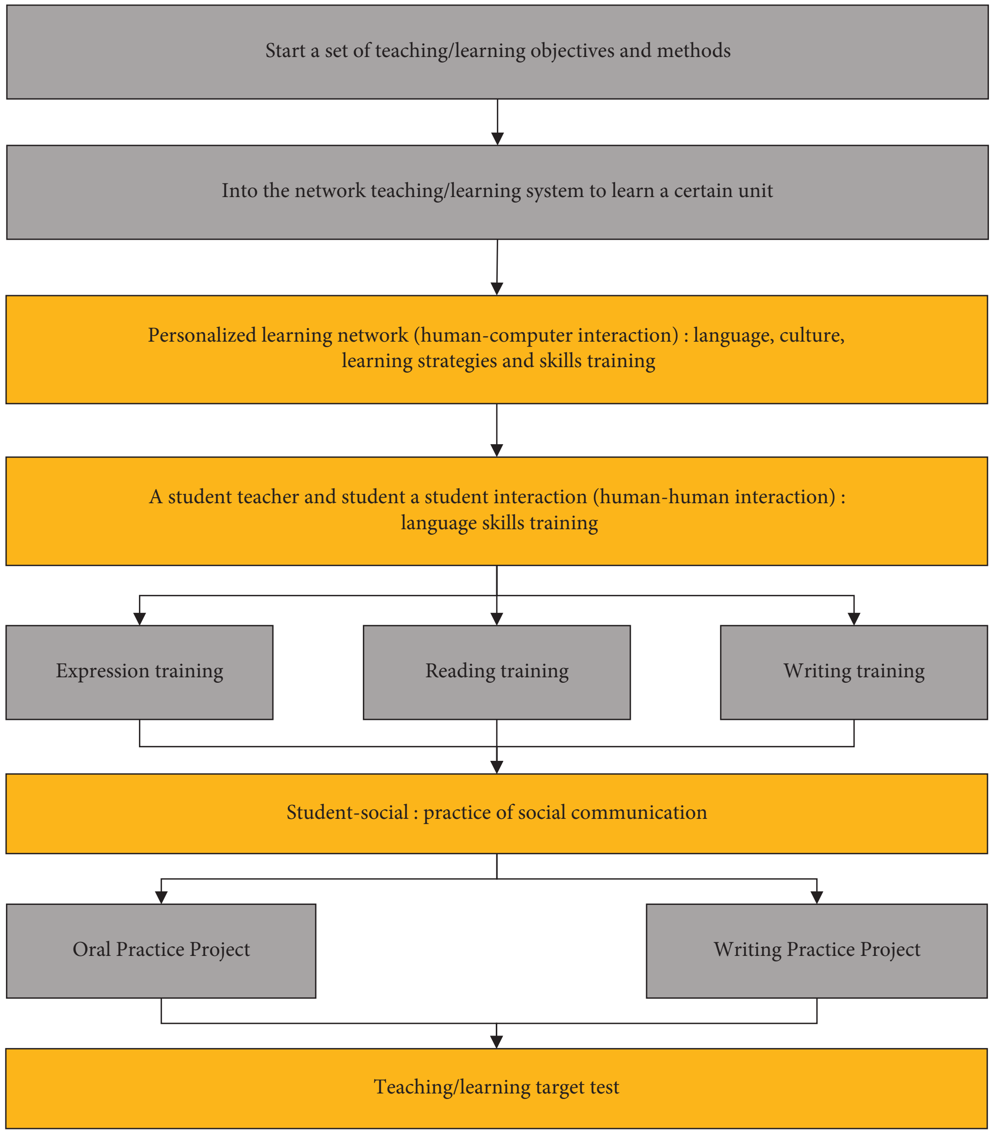

Figure 5: Structure of systematic English teaching mode.

abroad. After the completion of the above stages, users will enter the teaching/learning test. If the preset teaching objectives and learning objectives are reached, the cycle will end and users will enter the next cycle. Otherwise, the students will return to restudy according to the mastery of knowledge and skills which contains three kinds of situations: return to communication layer, return to language skill training layer, and return to language learning layer.

4.3. Construction of Knowledge Base. The key point of establishing intelligent teaching mode is the construction of knowledge base, which involves the division of knowledge points. In fact, the basic understanding and memory unit of knowledge concept constitutes the whole teaching content. When learners associate each knowledge unit, the overall structure of the concept can be formed, which is beneficial to understanding and reviewing.

In this teaching mode, the mastery degree of knowledge points is set as 1–6 to quantify the students' understanding of a certain knowledge point, which means that they have mastered, comprehended, understood, not understood, learned, and not learned. The first four are used to describe the degree of mastery of the knowledge point, and the last two are used to judge whether the knowledge point is included in the learning process. When a student first browses a knowledge point, the knowledge point is added to the student's knowledge point model and marked as learned. When they complete a test about the knowledge point, the system will carry out intelligent diagnosis according to the knowledge point and related knowledge points and analyze the students' proficiency level and the causes of errors, thus giving learning suggestions.

The framework of knowledge points judgment in this system is composed of four factors, namely, score, reading capacity, accuracy, and elapsed time. Factor 1, score, refers to the idea that after entering the system, the student first conducts some knowledge tests within the specified time to roughly understand the overall situation of the their mastery of relevant knowledge. The remaining three factors refer to the completion of the students' systematic learning of the knowledge of the unit and the completion of the exercises in the unit. This framework encodes the four factors that determine students' learning level, and the coding order is "S," "R," "C," and "T," while each factor may have multiple values. Infer factor belongs to inheritance reasoning and is a subframe, also known as the lower framework, which is a further logical reasoning of the objective described by the current framework. The lower framework is named according to the infer factor of the upper framework, which can be expressed by production rules.

Taking the judgment that students have mastered the knowledge as an example, the framework rules are as follows:

Rule

Frame name: state decision rule,

Factor 1: score ("very high, more than 90"),

Factor 2: reading capacity ("all, 100%"),

Factor 3: accuracy rate ("very high, above 95% "or" high, 70%–94%"),

Factor 4: elapsed time (less than or equal to "average shortest time"),

Infer factor: judge the learning level of the student as "mastered").

This framework corresponds to different combinations of the values of the four factors and can be simplified to a simple table structure without nesting:

Rule (1, "mastered," [S1, R1, C1/C2, T1]).

Here, "/" is used to indicate the relationship of "or" in the rule. Because the fact and rule of Prolog cannot express the relation of "or" in a clause at the same time, the accuracy rate of answering questions can be one of two cases to split into clauses.

The infer factor corresponds to another framework, which can further evaluate or suggest the student's learning level as "mastered," for example,

Rule

Frame name: learning level is "mastered"

Factor 1: value of level judgment ("excellent"),

Factor 2: value of cognitive ability ("high"),

Factor 3: value of teaching strategy ("enter the next unit").

4.4. Strategy Reasoning Mechanism. Reasoning is a process that starts from the known conditions and gives the corresponding results by querying the relevant rules in the strategy base. According to the characteristics and objectives of the system, the data-driven method is adopted as follows:

(1) Initialize the rule base and add the known facts into the rule base according to the format required by the system.

(2) According to the state of the current student model, the known facts (known conditions) are extracted and added to the comprehensive database.

(3) According to the known facts, the rules existing in the rule base are matched. If contained, execute step 4; otherwise execute step 7.

(4) Execute the selected rules and marked rules. If necessary, execute the rules; otherwise the conclusion will become new facts and be put into the database.

(5) Search the comprehensive database. If there is a solution to the problem in the database, it indicates that the problem is solved and the solving process is finished. Otherwise, return to step 3.

(6) If there are unused rules in the rule base, and they do not match the facts in the comprehensive database, it means that the problem has no solution and the process is terminated.

(7) If there are no unused rules in the rule base, it means that the problem has no solution and the process is terminated.

If the process of solution fails, it means that the system has not recorded this situation into the comprehensive database. The system should give teaching suggestions according to the student model and basic teaching principles. The basic teaching principle refers to something with obvious regularity in the teaching process [23]. Although it cannot reflect the teaching experience of individual teachers, it is still scientific and effective in accordance with the basic teaching rules. In the process of systematic reasoning, multiple rules may satisfy the conditions. In this case, the priority of rules should be set to resolve the conflict of rules.

5. Conclusion

Implementing research on the innovative teaching mode of college English class in the era of artificial intelligence can catalyze the reform of English teaching. Therefore, in this paper, a teaching mode of English teaching system based on the mechanism of strategic reasoning is proposed. By introducing the idea of artificial intelligence, the student model and the teacher model are designed to separate the teaching content from the teaching strategy. Through the design of system database and teaching process, aiming at the construction of knowledge base, a strategy reasoning mechanism suitable for English teaching is put forward where a lightweight framework is adopted to provide the combination of presentation layer, logic layer, and data layer, which improves the development efficiency. It is a convenient system for transplantation and expansion and has certain practical application value; at the same time, it can provide reference for the design of various teaching systems.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Collaborative design is an important link in building construction at present, while the communication and cooperation among disciplines need further regulation. In order to maintain the cost-effectiveness and design quality of building engineering in the competitive environment and obtain higher economic benefits, the design team must ensure the collaborative design quality of building engineering. Based on the analysis of collaboration theory and collaboration mechanism, a collaborative design platform for caves in Henan province is constructed under the current cloud environment. In addition, the requirements and non-functional requirements of the platform are analyzed, and the overall structure with each part is designed specifically, hoping to improve the quality of collaborative design effectively.

1. Introduction

For the building industry, the traditional design presents a linear pattern. After the independent design of each major is completed, the information *r* is relatively independent, which is not conducive to the integration of design data and information [1].The collaborative design mode under the building cloud platform can enable all majors to design collaboratively in a parallel way and solve the problem of noncommunication data through the building cloud platform [2]. Furthermore, different forms of architectural design can be displayed on the same platform, and all designs are completed in three-dimensional state, without space imagination of two-dimensional drawings [3].

Henan province is located in the transition zone between the second and third steps in China, and its topography is very complex, with many types of geographical features such as mountains, hills, basins, and plains. Under the influence of specific natural environment, residents living in mountainous areas, hills, tablelands, and gullies have created cave dwellings with local characteristics. Cave villages contain the ecological wisdom of residents' site selection and construction. However, compared with ordinary villages in plain areas, the economic development of Henan cave villages is generally backward, the economic industry of the villages can no longer meet the employment needs, and a large number of rural populations, especially the young and middle-aged people, are constantly flowing into cities. It directly leads to the aging and waste of cave villages. Therefore, it is necessary to carry out innovative research on collaborative design mechanism of Henan caves. In this paper, Henan cave dwellings are taken as the research object, and its design collaboration platform is built, hoping to realize the innovation of architectural design innovation mechanism.

2. Overview of Collaborative Design in Henan Cave Dwelling

2.1. Synergy Theory. German physicist Haken established the synergy theory and put forward that competition is the premise of synergy. The open system develops from stable state to unstable state, and the system spontaneously forms a new relatively stable state through internal synergy effect. In this process, with the change from disorder to order, from discrete to whole, it can generate new energy exceeding the total of each subsystem [4].

The understanding of "cooperation" can be divided into narrow sense and broad sense. The narrow sense only contains the meaning of cooperation. Broadly speaking, it includes the dual states of cooperation and competition, and the final result is a win-win situation. [5] The cooperation described in this paper is generalized cooperation. Participants in various industries and their behaviors form a social system, and participants are in a state of constant competition that can highlight the significance of cooperation. In the process of competition, participants absorb other people's knowledge for their own use, or provide their own knowledge to others in the process of cooperation, so that they can be integrated in the process of giving and receiving. New energy can be generated, which exerts greater efficacy and producing a cooperative effect of $1 + 1 > 2$. Therefore, collaborative behavior is a spontaneous and indispensable link in the development of industry and society, a catalyst to promote knowledge and technology innovation, and of great significance to advance science and society [6, 7].

2.2. Collaborative Design of Henan Cave Dwelling

2.2.1. Design Basis of Henan Cave Dwelling. The parapet wall is set on the kiln face in Henan cave dwelling, that is, the top of the kiln, and the flower wall is formed by brick carving, and the overlapping neckline is similar to the courtyard wall. The face of the kiln is also decorated in the form of the hanging flower gate building on the door wall, and embossed patterns are made on the kiln face and wall. The face decoration of the kiln is relatively complex, and the whole kiln is decorated with brick carving pattern of hanging flower curtain. Referring to the modeling characteristics of the garden's hanging flower gate building, bas-relief is generally made on the surrounding parts, with the top circle and the bottom square so as to conform to the cosmology of "unity of nature and human." In addition, there are "upper bright windows" on the door of the cave dwelling, and the window lattice will be carved with simple patterns. Niches will be set on the east and west sides of the cave door to worship relevant gods, and corresponding carvings will be made around the niches, as shown in Figure 1.

2.2.2. Design Characteristics of Henan Cave Dwelling. Building multi-agent synergy mechanism is divided into internal coordination and external coordination. The internal synergy mechanism is based on the interior of the multi-agent coordination system. According to its own characteristics, by establishing a reasonable organizational structure, information transmission mode and benefit distribution standard, and so on, it gives full play to the maximum advantages of each subject so as to achieve common goals and strive for the maximization of overall benefits. The external synergy mechanism is to promote the cooperation of all subjects in the system through external conditions, such as policy, market, and environment [10]. The establishment of the synergy mechanism is conducive to the cooperation of all participants in the competition. Through mutual learning, integration, and innovation, the core values of enterprises can be enhanced, and the risks brought by environmental changes can be resisted [11]. The scope of this paper is the multi-agent internal synergy mechanism, which can overcome the shortcomings in the process of building construction and show its advantages of development by jointly establishing the work flow and rules system.

Figure 1: Front eave wall of Henan cave dwelling.

The characteristic of Henan cave dwelling is that almost every component is decorated with carving and color, and the techniques used by different decoration carriers are also different. In the selection and use of patterns and patterns, according to the shape of decorative parts and material characteristics, the conformal processing and the application of art according to the material fully show the beauty and artistry of the material, as shown in Figure 2.

Although there are many types of decorative themes and patterns, there are also repeated patterns. The same kind of pattern is in different positions; the outline of the graph and the combination of the graph expression are not the same. From the point of view of the decorative parts of the pattern and the graphic expression of the pattern, the pattern will adopt the conformal processing techniques according to the morphological changes of the decorative parts so that the pattern is highly consistent with the body, which reflects a high degree of coordination both from the content and form expression.

3. Demand Analysis

3.1. Business Analysis. In order to carry out innovative design of Henan caves, A Design Institute is selected as the design company to carry out the construction of collaborative design platform.

A Design Institute employs nearly 200 people, including about 120 designers, more than 50 project managers, and project procurement and other management departments. The number of large and small projects carried out in a year exceeds 30, and the projects are generally managed by stages, such as establishment stage, feasibility study stage, project preliminary design stage, detailed design stage, construction management stage, and so on. The project is initiated by the management department, and the preliminary work of the project is carried out after being approved by the leaders of the company, including planning, engineering estimation, and other work, and the planned tasks are distributed to the

Figure 2: Characteristics of Henan cave dwellings.

design department to carry out the design. Then, the department of design will carry out the management according to the requirements, including the preparation, modification, audit, capital raising, and countersignature of the design documents, and finally submit the construction drawings for the project construction. In the process of construction, there will be design alteration and construction rework, and so on. After the final construction of the project is completed, the department of management prepares the completion data and organizes the acceptance of relevant parties of the project. If the acceptance fails, rectification is required, and the project will be delivered after the acceptance of the project is passed.

Co-design of cave dwellings project mainly includes general layout, architecture, structure, water supply and drainage, heating, ventilation, and electricity, and some unconfigured design majors usually choose outsourcing design. Professional design software includes AutoCAD, Revit, MicroStation, and other domestic CAD software. According to the requirements of the project owner, the project design includes both 2D drawing design and 3D model design. Like most architectural design company, *Z* Architectural Design Institute still focuses on 2D drawing design with supplement of 3D modeling. In order to cultivate the 3D modeling ability, a BIM team of 10 people was set up to carry out 3D forward design and explore the modeling mode of 3D model, the process of model verification, model demonstration and construction management, and so on.

The traditional project drawing proofreading is that after printing the drawings, the personnel are organized to hold a meeting for centralized audit, fill in the drawing audit sheet, feed back to the designer, and then print the drawings again for audit. After many times of printing and modification, the final version of the project construction drawings is finally formed until there is no review and modification opinion. The process of drawing proofreading is very time-consuming of paper and personnel [12]. When the design task is tight, the designers often work overtime to solve the project design schedule, and employees will complain about it. In addition, management includes project manager, construction management, project cost, safety administrator, and data management, and project resources, plans, and costs are managed through the existing project management system [13].

Generally, the project site is located in different places, and the information is communicated with the staff in the office of the design institute by telephone and e-mail, so it is difficult to record the process information through the project event document [14]. Design drawings are generally transmitted through instant chat software and network disk, and the confidentiality of project information is uncontrolled [15]. If the updated drawings are not transmitted in time or the notes are inaccurate, it is easy to cause information asymmetry, which makes the design and construction inconsistent and requires rework.

Without the management of document system, the project documents are scattered on the computers of project personnel. There is no unified standard for the line shape, line color, drawing frame, and font of project drawings, and the drawing naming is not strictly in accordance with the specification requirements. When the project is completed and delivered, the final archived drawings and forms of the project often have errors in version and content, part of the project management information is even missing, and some forms specified in ISO quality system are often filled in after the completion of the project, which has laid hidden dangers for the design quality management and also brought certain difficulties to the project settlement and subsequent maintenance and reconstruction of the project. The existing OA system has solved the audit and archiving of office documents, and the project management system solves the tracking management of project resources, plans, and costs but cannot meet the requirements of design management.

3.2. Overview of Platform Requirements. The co-design platform of cave dwellings needs to support the existing professional design software, can flexibly customize the catalogue structure of engineering projects, store and manage various documents and materials of projects, and support online proofreading and annotation of 2D design drawings and 3D models. The platform is deployed in the local area network of the company and can be published on the Internet for access by other participants of the project. The platform also needs to have API interface to realize data interaction with other systems.

3.2.1. Synchronize the Architecture. Reduce the repeated entry of project data, automatically import the project management architecture in the project management system into the design management platform, and automatically give information such as attributes so as to realize data flow between information system platforms through middleware.

3.2.2. Document Management. The first consideration of the design platform is to serve the project personnel, who design the project through professional design software and compile the project management documents with office software. The design software includes AutoDesk software and Bentley software; the office software includes Microsoft Office and Adobe Reader [16]. There are many kinds of applications where many formats of files have been produced, and these files are scattered in the minds of project personnel, which requires a compatible platform. The files of the whole project are stored in the project directory according to certain rules, which can be accessed by project personnel with project authority, thus improving the security, accuracy, and timeliness of project information, as well as the communication efficiency of project participants.

For files about co-design of cave dwellings on the platform, fuzzy search can be performed by file name, or advanced search can be performed by file attribute [17] which is convenient for users to find the required files quickly when they are unfamiliar with the project folder structure.

3.2.3. Standardize Design Standards. Project design documents are designed by the professional designers who participate in the project according to the distribution of project work packages, so it is necessary to formulate a unified project rule to constrain the project personnel to carry out standardized work [18]. The design platform needs to set template files and document coding rules and unify the file design and naming requirements of project personnel so as to realize the standardization of design documents.

3.2.4. Collaborative Design. The co-design management platform of cave dwellings needs to integrate design software, office software, and so on so as to read files on the design platform for editing and modification or read files for editing and modification in software [19]. Reference design is needed between upstream and downstream disciplines. Once the file path is changed in Windows, its reference will be invalid. The management platform should support the reference relationships between design documents and maintain relationships of these dynamic reference [20]. Design files will generate multiple versions of files due to design problems or external condition table updating. In file reference design, it is necessary to support the file to automatically update the reference content with the version, that is, the latest version of the reference file.

3.2.5. Process Management. The co-design platform of cave dwellings should have the function of document flow management, display the current process status of documents, support serial processes and parallel processes, and realize the associated setting of workflow and role permissions [21]. When the status of the document changes in the process, it needs to get the function of reminding and guiding so that the annotation information in the process of document circulation can be saved and can be viewed at any time.

3.2.6. Real-Time Update of Data. After the project personnel upload or update the document, it can be read in real time by other personnel with access rights. The server should support distributed storage management, ensure that the project team members in different places can access the latest data in real time, eliminate geographical restrictions, and provide the functions of local cache and incremental transmission in different places. At the same time, it is also necessary to support flexible timing synchronization of project documents in different places.

3.2.7. Project Data Security. The account of the company's design management platform uses Windows domain account to realize single sign-on. The external cooperators of the company are assigned to log in with the new platform account [22]. There are many project participants, and under the premise of sharing project documents, it is also necessary to ensure the safe access and storage of information content. The design of the management platform needs to satisfy the login of account password and assign appropriate permissions according to the role of the project so as to prevent users from viewing some unauthorized project files, which can ensure data integrity from being used by unauthorized users, ensure that unauthorized users cannot make unauthorized modifications to data, and ensure that users with permissions can access data and resources timely. In addition to authentication, it is also necessary to encrypt the transmission of project files to ensure the safe transmission of data on LAN and Internet.

3.2.8. Platform Access. The co-design management platform of cave dwellings needs to provide data management and storage on the server side, which provides the access to the server through the client side. In addition to carrying out collaborative work, it is also necessary to meet the needs of collaborative work on the Internet and with proxy server to publish to the Internet to ensure data security [23]. For multiple workplaces, multisite expansion deployment can be realized, where LAN and Internet users all obtain access of desktop client and browser.

3.3. Nonfunctional Requirements of the Platform. On the premise of meeting the functional requirements of the information system, the co-design management platform of Henan cave dwellings studied in this paper also needs to meet the nonfunctional requirements, such as rapid response and stable operation of the platform. Nonfunctional requirements are mainly reflected in the following aspects:

(1) *Response Time*. When platform users edit or view folders and documents, the reading of documents should be presented to users within the acceptable range of users, and the response time should be less than 1 s.

(2) *Number of Concurrent Users*. When a large number of users access the platform at the same time, the platform needs to have good concurrent processing ability to meet the processing requests of a fixed number of users [24]. This research requires that the platform can carry at least 200 users.

(3) *Ease of Use*. The interface is simple and operation is simple, while the structure is clear. The client can use it after simple training.

(4) *Maintainability*. The co-design management platform of cave dwellings has an independent maintenance interface, which can set and maintain the platform to meet the configuration requirements of client users [25].

(5) *Disaster Tolerance*. The platform needs to have a certain disaster tolerance capability, and it needs to have an automatic recovery function when encountering unexpected situations, such as fire and earthquake.

(6) *Extensibility*. The platform needs modular architecture, and the modules have strong independence [26]. It can select functional modules according to users' requirements, otherwise expand the use function by adding modules, and it will not affect use with the expansion of requirements which integrates with other information systems to realize data interaction.

4. Design of the Platform

4.1. Overall Structure. The co-design platform database of cave dwellings is used to store the platform directory, users, permissions, attributes, processes, and other information, and the file server is used to store the files. In addition, the platform is applied to project personnel, and the interaction between the client and the server is connected to realize the functions of user login, permission control, file reading, system maintenance, and so on. The application layer is responsible for content display and provide clients for users to send and receive commands. The application layer uses the integration server and file server to interact with the database and file storage devices [27]. When the application layer sends instructions, the integration server and the file server are responsible for transmitting the instructions to the database and the file storage device, respectively. When that database and file storage device send the original data, the integration server and file server interpret it and send it to the application layer [28]. The logic architecture diagram of the platform is divided into three layers: application layer, logic layer, and data layer, as shown in Figure 3.

Considering that the project personnel are scattered in different office locations, the platform can be accessed on both LAN and Internet, and the efficiency of access should be considered. The form of coexistence of platform C/S and B/S mode is selected, which effectively solves the need of designers to carry out the co-design of cave dwellings through platform client in the company. At the same time, it also solves the need for the personnel of different project departments to access shared files through browsers.

4.2. Specific Design

4.2.1. Functional Design. According to the demand analysis, the functions of co-design platform of cave dwellings are divided into four blocks: environment configuration, co-design of cave dwellings, drawing proofreading, and data storage of cave dwelling patterns. The design diagram of the main function tree of the design platform is shown in Figure 4.

In the environment configuration, multiple data sources can be created, and each data source can include multiple projects [29]. Administrators log in to a data source, synchronize Windows domain control users, create new logical users for the use of project partners, and set up project roles for all users. Figure 5 shows the relationship among data sources, projects, and accounts on the platform.

A Design Institute already has a project management system, but the API interface of this system is limited, so it can only provide data values and cannot import data. Therefore, the project management system data outputs them to the design management platform in one direction. In addition, this platform needs to realize the synchronization of project architecture and project attribute data from the existing project management system through secondary development so as to achieve data synchronization between the platform and the project management system [30]. Because the project management system does not open the corresponding API, this development only realizes one-way data transfer from the project management system to the design management platform and realizes one-way data transfer through intermediate files.

In collaborative design of cave dwelling patterns, users can integrate, read the documents on the platform, and edit and update the contents of the documents according to the design software of this major. When the documents encounter an upgraded version, they can update the version of the documents through version management and keep the latest version as an active editable version. At the same time, in the process of design, collaboration among specialties can be carried out by referring to the design, and the content of platform documents about cave dwelling patterns can be shared in real time to improve the collaboration efficiency among specialties [31]. Users can also communicate project information in time through message service on the platform, customize document attributes according to the needs of the project, and search documents through basic attributes of documents. After the final assembly model is generated, it can be converted into a lightweight file called i-Model for collision check and calibration.

During the process, it is necessary to review the drawings and documents of cave dwelling patterns, which is a mandatory requirement in design management. Usually, it is necessary to carry out intradiscipline audit, interdiscipline fund raising, and interdiscipline countersignature and change the process status by setting judgment conditions. If there is any modification, it will be returned and submitted for review again until it is approved. The whole audit process is carried out on the platform, and the review is recorded to facilitate the subsequent ISO review.

In the safe storage of data, it is required to store data centrally and view the operation records of the platform to meet the needs of various access modes in different places, and the influence on the bandwidth in the process of document transmission ought to be considered. Through the distributed storage deployment architecture in different places and the incremental document transmission technology, the requirements of the platform data transmission on the network bandwidth can be reduced, which improves the efficiency of collaboration in different places.

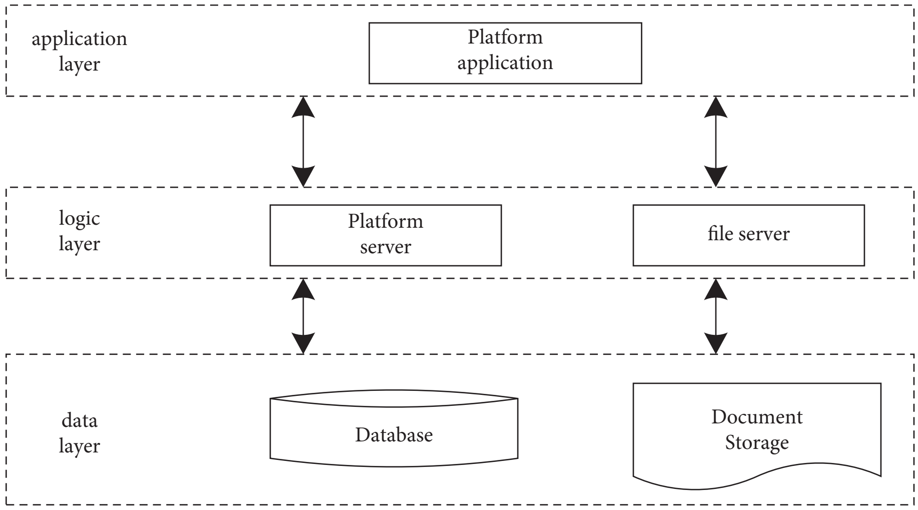

Figure 3: Logical architecture diagram of architectural design management platform.

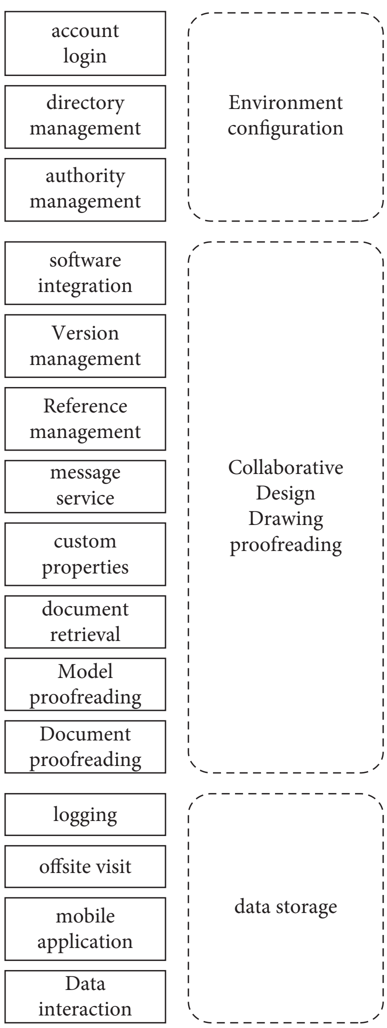

Figure 4: Function tree diagram.

4.2.2. Mechanism of Data Storage. Centralized management of cave dwelling patterns documents distributed on project personnel's computers ensures the unified control of project contents, while real-time synchronization of data can make project participants get the latest information, which improves the efficiency of collaborative work *i*.

With the platform under database + file storage mode, the project files are stored in the server, while the relationships between files and attribute *i* are stored in the database [32]. Multiple projects under one data source can be managed, and multiple projects under separate data sources can be achieved by establishing multiple data sources.

The designer's client adopts the standard client/server (C/S) access mode, which meets the high-performance collaborative work requirements of designers. For the external participants of the project, project site personnel, or business travelers, the browser/server (B/S) access mode is adopted to meet the needs of project document sharing without installing any application programs. At the same time, it provides access methods for mobile devices, including mobile phones and tablet computers, and provides engineers with the function of accessing project-wise data anytime, anywhere.

(1) Audit Management. All users' operations on the document, including username, operation action, operation time, and user's additional annotation, will be automatically recorded by the platform, which is convenient for users to review and track later.

(2) Data Storage. The platform data storage adopts the scheme of combining relational database with file system in Windows, which unifies the storage access mode and can support the storage of multiproject data in multidata sources.

File storage about cave dwelling patterns adopts NTFS (New Technology File System), which is the default of Windows server. It is a disk format specially designed for network, file encryption, and other security features, which supports long file names, data protection, and data recovery. Considering the economic cost of storage, the file storage server of the platform is not set up separately but is deployed together with the integrated server.

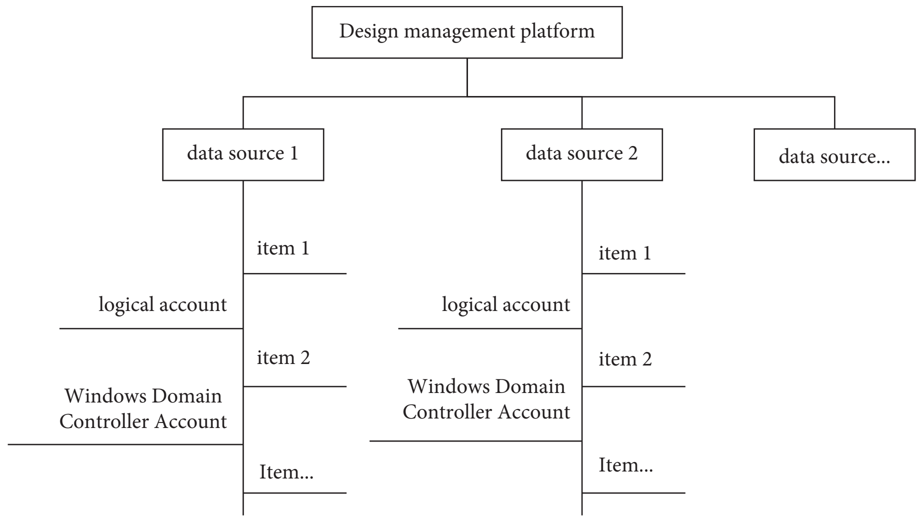

Figure 5: Diagram of data source design.

Database storage supports SQL Server and Oracle to store structured data. By creating an association between project-wise and database through ODBC and employing it to create a new project-wise data source, it provides access for clients. The database stores the account information, document attributes, folder attributes, workflow, application relationship, platform settings, and other contents of the platform.

(3) Remote Cache Technology. In order to improve the speed of users visiting the server in different places, a cache server can be deployed in different places to store local copies of documents. Through the association of storage areas, there are many storage areas in the data source, each storage area is located on a different computer, and real-time data synchronization is realized through the network.

Data synchronization between remote servers and local servers will take up much network resources. In order to reduce the network load, the real-time synchronization of a large amount of data in different places is realized by using the technology of Delta File Transfer, DFT). When a user reads a document, the platform will query the cache server to determine whether the latest copy of the document is on the cache server. If the cache copy does not exist, then the cached copy will be transmitted from the server to the client; at the same time, if the cached copy is out of date, only the modified part of the document will be transferred to optimize the document transfer. Similarly, when a user uploads an updated document, only the modified part of the document is transmitted, which greatly reduces the number of network transmissions and improves the efficiency of network access.

4.2.3. Database Design. Project-wise supports SQL Server and Oracle database, and SQL Server has been used as the database of company information system in A Design Institute, so the database of this platform still select SQL Server.

According to the co-design platform of cave dwellings business analysis of the defined object, its responsibilities can be fully described from the defined data items where an object has only one responsibility. Minimizing the data redundancy of the table ensures the accuracy of the data and effectively improves the performance. In this paper, the database is divided according to the platform components, and the tables of different components are related by the primary keys of the related tables to ensure the independence of tables corresponding to components and facilitate the reconstruction of table structure in secondary development.

The platform database mainly includes four data tables: the main function table of the platform, including users, project folder creation, document storage area, and documents. Set the relational database in the database, as shown in Figure 6.

Because of the huge database design of the co-design platform of cave dwellings, this chapter only lists some contents, such as creating users, creating projects, creating documents, setting processes, accessing records, message boxes, and so on. In addition, the platform creates new users, stores user information, and gives users initial permissions. While in the process of creating new projects and documents, the system records its corresponding attribute information, sets the storage path, and can add project attributes and set project personnel permissions. Afterwards, the users can set the process for the document and carry out the process flow. In the process of document review, the system records the actions and information of the operator and triggers a message box in association with the corresponding documents and notices to inform the corresponding agents. All operations in the platform are recorded and can be viewed at any time.

Finally, add new database tables used in secondary development, such as user-defined design attribute module table, which mainly defines project folders and their attributes; the user-defined module of drawing review process mainly defines status, process, process status approver,

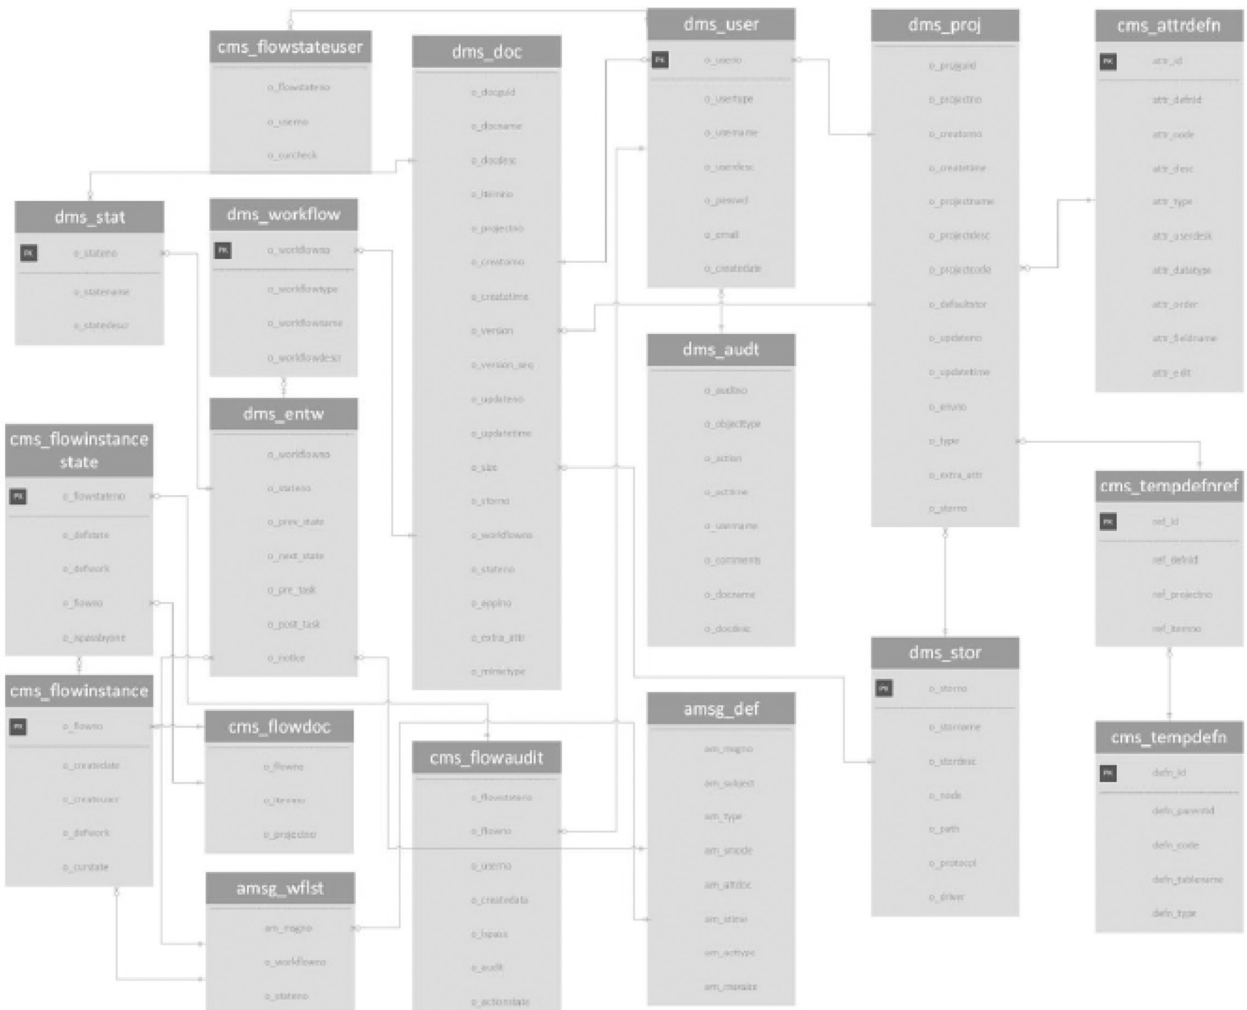

Figure 6: Database diagram.

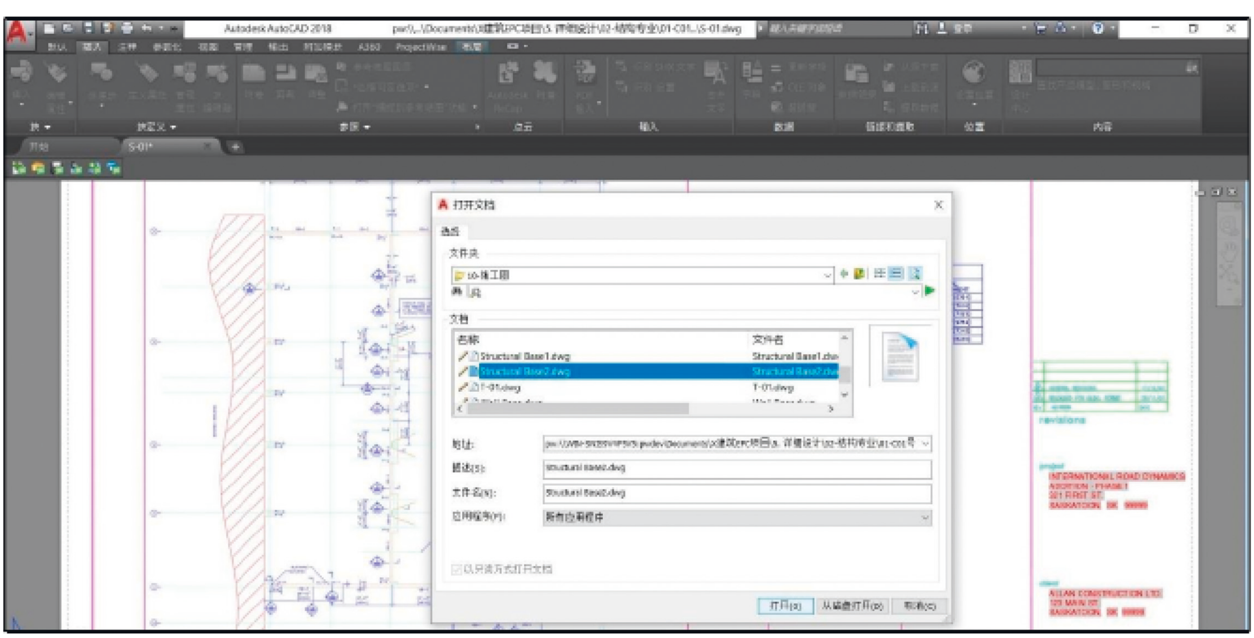

Figure 7: Input of project document diagram.

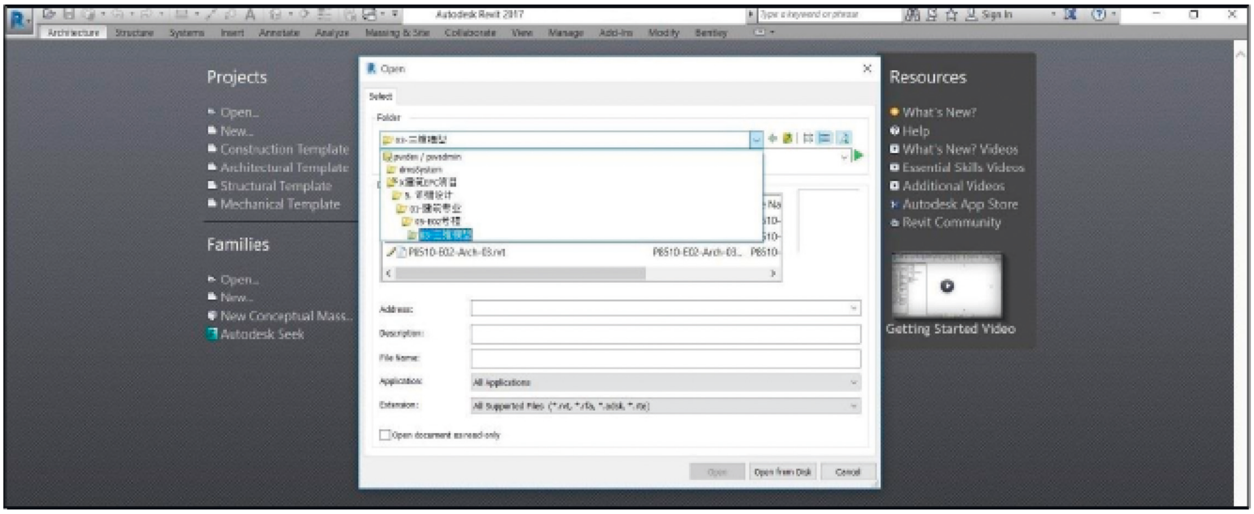

Figure 8: Integration page.

Table 1: Function tests.

Test function	Test methods and test steps	Test Results
User login	The user enters the user name and password to test the system login function	Pass through
Configuration management	Create a new data source, set the network connection method, set the system permissions, configure the process, configure the environment properties, configure the message box, configure the application	Pass through
User settings	Create new users and synchronize domain control users. User account creation, import, and synchronization are all normal	Pass through
New project	Import project schemas, plans, and properties. Import the MPP document exported from the project management system on the platform. According to the import steps, the content is imported normally	Pass through
Folder management	Operates on the folder menu. New, open, copy, cut, paste, rename, delete operations are normal	Pass through
Document management	Operates on the document menu. New document, new version, open, copy, cut, paste, rename, start process, delete are normal	Pass through
Application integration	After installing the integrated plug-in, the corresponding documents on the project-wise platform can be opened in MicroStation, AutoCAD, and Revit software and the reference documents can be read. Double-clicking a document on the platform can launch the corresponding application to perform operations such as checking out, editing, and checking in. You can also select documents on the platform to perform operations such as checking out, editing, and checking in in the application. It is verified that the integration of platform and software is bidirectional	Pass through
Reference design	In the design software, through the "file link" method, select the file on the platform to carry out the reference design, and the referenced document is only displayed and cannot be modified	Pass through
Publish *i*-Model files	Publish final assembly model RVT files and DGN files as *i*-Model files Open a lightweight read-only model; you can browse the model and view build property information, but cannot edit it	Pass through
Drawing review	Select process, select reviewer, transfer status, and submit review comments Every operation and review comments of process submission and rollback are saved for authorized users to view the review process records at any time	Pass through
Model proofreading	The final assembly model performs model collision, annotation, and so on Select the relevant professional components that need to be checked for collision, and the software will automatically start the collision check and list the collision points in the model. Click on a collision point to redline and generate an independent annotation file without affecting the content of the source file	Pass through

process review log record, status and process association, document and process association, and message box and process association.

5. Implementation and Test of Platform

5.1. Implementation of the Platform. Users can normally access the project-wise platform in local area network and other places and carry out collaborative work by logging into the client of the project-wise platform. Every user logs in through his/her personal account. And no matter what kind of network he/she connects to the project-wise platform, the content of the user interface is consistent. it can be selected to insert linked documents on the platform to carry out collaborative design, as shown in Figure 7.

when the plug-in is installed, the "Bentley" column is displayed in the menu of Revit software. Click the "Open" button, and a login dialog box of the design management platform will pop up. After logging in, users can select the document of the design management platform to open and carry out model design, as shown in Figure 8.

5.2. Testing of the Platform. Through detailed tests of various system functions of the system, the test results are all passed, as shown in Table 1.

6. Concluding Remarks

In recent years, with the acceleration of urbanization, the domestic construction industry has experienced a period of rapid growth. The huge inefficiency and waste in the construction industry make people consider how to reform the production mode and organization mode of construction projects. With the development of cloud environment, the concept of collaborative design came into being. By applying to the co-design of cave dwellings, it is able to effectively deal with various data in the design stage and strengthen the communication between designers. In this paper, the collaborative design methods under the building cloud platform are combed in detail, and the platform is designed and implemented. Finally, the results of tests are excellent.

In order to effectively solve the problem that the radar detection system is difficult to detect the "low, small, slow" UAV, the high-performance computing early warning neural network is used to recognize the air UAV in real time and extract the target category and image space location information; the PSO algorithm is used to optimize the parameters of the anti-UAV to ensure that the anti-UAV not only relies on factors but also fully combines the dependence of the visual field factor to quickly obtain the optimal solution through analyzing the high-performance computing early warning neural network in this paper. This algorithm is used to initialize the anti-UAV resources and improve the global optimization capability of the algorithm proposed in this paper. Finally, the experimental results show that the proposed PSO algorithm has better high-performance computing early warning performance to meet the actual needs of network high-performance computing early-warning neural networks.

1. Introduction

With the continuous development of anti-UAV high-performance computing early-warning analysis technology, the ways for people to obtain anti-UAV high-performance computing early warning information are also increasing. Among them, relying on its huge information content, the anti-UAV high-performance computing early warning technology can be used to share resources. By using the computer Internet, the anti-UAV high-performance computing early warning information you need can be obtained. Although users themselves can use the anti-UAV high-performance computing early warning to quickly obtain relevant data, the required data information cannot be achieved by the general browsing and query methods due to the huge amount of data information [1, 2]. In order to effectively solve this problem, Anti-UAV high-performance computing early warning technology came into being. This technology can speed up the user's access to data information, although the required data information is still not accurately obtained under such conditions. The conventional recommendation method has greatly reduced the accuracy of Anti-UAV high-performance computing early warning when processing batch data information requests. In the anti-UAV high-performance computing early warning information environment, the target information data can be obtained from the massive data information and sent to the target user simultaneously to determine the development direction of the anti-UAV high-performance computing early warning.

Regarding the shortcomings of the traditional anti-UAV testing method, the PSO algorithm calculation method in the anti-UAV detection method is adopted, the code characteristics in the detection method are compared with the true characteristics of the notified safety defects, and the similarity matching degree is used to check the Anti-UAV code for defects [3]. This method can be used to better improve the accuracy and work efficiency of detecting defects, and deal with the situation that the current anti-UAV detection method cannot quickly deal with the legacy anti-UAV and the complex structure of the anti-UAV [4]. Real-time analysis of the UAV flight trajectory in the continuous time domain is performed through the PSO algorithm to obtain the predicted trajectory results of the corresponding

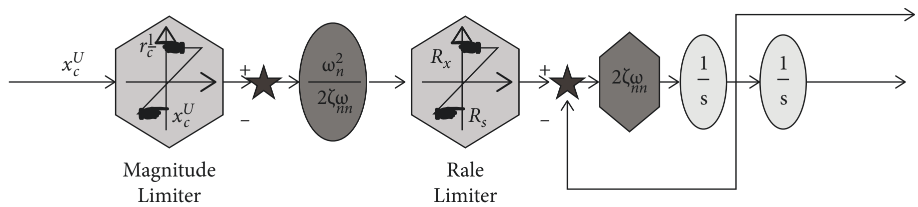

Figure 1: Structure diagram of the second-order control system. The state expression force of the second-order reference model.

UAV in the next stage and realize the full monitoring and prediction of the flight behavior of the UAV in the air. This method has high computational real-time and accuracy and can give anti-UAV capabilities to airports, military units, no-fly zones, and other important venues in the field of machine vision [5–8].

2. Method and Material

2.1. Mathematical Model of UAV Motion. In order to accurately reflect the motion state of the UAV and facilitate the simulation calculation, the impact of the UAV's elasticity is not considered, and the Earth is assumed as an inertial reference frame, ignoring the influence of the curvature of the Earth in this paper [9]. Establish a three-degree-of-freedom model of the UAV.

The motion equation of the UAV in the ground coordinate system is as follows:

$$\begin{cases} \dot{x} = V \cos\gamma \cos\beta + \omega_x, \\ \dot{y} = V \cos\gamma \sin\beta + \omega_y, \\ \dot{z} = V \sin\beta + \omega_z. \end{cases} \tag{1}$$

The motion equation of the UAV in the track coordinate system is as follows:

$$\begin{cases} \dot{V} = \dfrac{T\cos\alpha - D}{m} - g\sin\gamma - \dot{\omega}_x\cos\gamma\cos\beta - \dot{\omega}_y\cos\gamma\sin\beta - \dot{\omega}_z\sin\beta, \\ \dot{\beta} = \dfrac{(L + T\sin\alpha)\sin\varepsilon}{mV\cos\gamma} + \dfrac{\dot{\omega}_x\sin\gamma}{V\cos\gamma} - \dfrac{\dot{\omega}_y\cos\beta}{V\cos\gamma}, \\ \dot{\gamma} = \dfrac{(L + T\sin\gamma)\cos\varepsilon}{mv} - \dfrac{g}{V}\cos\gamma + \dfrac{\dot{\omega}_x\sin\gamma cos\beta}{V} + \dfrac{\dot{\omega}_y\sin\gamma\sin\beta}{V} - \dfrac{\dot{\omega}_z\cos\gamma}{V}, \\ \dot{Q} = \omega_z\cos\varepsilon + \omega_y\sin\varepsilon, \end{cases} \tag{2}$$

where, (x, y, z) is the position of the UAV; V is the flying speed of the UAV; α is the angle of attack; ε is the roll angle; γ is the flight path angle, and β is the course angle; Q is the pitch angle; T Expressed as the UAV thrust; D is the drag force; L is the lift force; m is the mass of the unmanned position: g is the acceleration of gravity; $(\dot{\omega}_x, \dot{\omega}_y, \dot{\omega}_z)$ and $(\omega_x, \omega_y, \omega_z)$ are the components of wind acceleration and wind, respectively, on the three coordinate axes.

In order to better adapt to the requirements of UAV control stability, it is necessary to further consider the speed and bandwidth constraints of state quantity and input quantity in the control system design process. The difficulty of this problem lies in how to mathematically describe the speed and bandwidth constraints of the control commands in the actual system. Therefore, a second-order reference model with nonlinear links is introduced to reflect the response characteristics of the actual system to control commands. The second-order reference model structure with amplitude, speed rate, and bandwidth constraints is shown in Figure 1.where sat$(\cdot)$ is the saturation function; x_c^0 is the input commands; x_c is the output command; x_c^L is the upper limit amplitude constraints of the command, x_c^U is the lower limit amplitude constraints of the command; $\pm R_x$ is the speed constraints of the command; ζ_n and ω_n are the damping ratio and natural frequency of the second-order reference model, respectively frequency, according to these two parameters, the command bandwidth constraint is as follows:

$$\omega_b = \omega_n\sqrt{1 - 2\zeta_n\omega_n + \sqrt{2 - 4\zeta_n^2 + 4\zeta_n^4}}. \tag{6}$$

$$E_c = \mathrm{sat}\left(x_c^0, x_c^L, x_c^U\right) - x_1, \tag{3}$$

$$E_c' = \mathrm{sat}\left(E_c, -\frac{2\zeta_n R_x}{\omega_n}, \frac{2\zeta_n R_x}{\omega_n}\right), \tag{4}$$

$$\begin{aligned} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} &= \begin{bmatrix} 0 & 1 \\ 0 & -2\zeta_n\omega_n \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ \omega_n^2 \end{bmatrix} E_c', \\ \begin{bmatrix} x_c \\ \dot{x}_c \end{bmatrix} &= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \end{aligned} \tag{5}$$

When the second-order reference model is introduced into the control system design process, the input of this link is the input quantity to be designed $\gamma_c^0, \alpha_c^0, Q_c^0$, and the output of this link is the executable control quantity γ_c, α_c, Q_c. In the meantime, the second-order reference model link can also provide the derivative γ_c, $\dot{\alpha}_c$, $\dot{Q}_c\}$ of the virtual control variable, which can avoid the direct analytical calculation of the virtual control variable. In addition, the introduction of the second-order reference model link greatly improves the autonomy of control-oriented modeling.

2.2. Design of Controller. Assume that the dynamic system of the UAV is a first-order nonlinear system:

$$\dot{x} = Ax + Bu, \tag{7}$$

where

$$\begin{aligned} x &= [x_1(t), x_2(t), \ldots, x_m(t)]^T \in R^m, \\ u &= [u_1(t), u_2(t), \ldots, u_n(t)]^T \in R^n. \end{aligned} \tag{8}$$

They are the status of the flight control system and the input of the controlling quantity; $A \in R^{m\times n}$ is the system matrix and $B \in R^{m\times n}$ is the input matrix simultaneously. The purpose of the control system is to establish a suitable control scheme to ensure that the state vector quality can accurately track the constrained ideal $x_d \in R^{m\times n}$. Define the tracking error as follows:

$$e = x_d - x. \tag{9}$$

In addition, the sliding form surface is expressed as follows:

$$s(t) = e(t) + k\int_0^t e(\tau)\mathrm{d}\tau, \tag{10}$$

where $k = \mathrm{diag}(k_1, k_2, \ldots, k_m) \in R^{m\times m}$ is a nonzero positive definite matrix. If the UAV is under ideal conditions, the various parameters of the system are known and constant. The ideal controller can be designed as follows:

$$u^* = B^+[-Ax + \dot{x}_d + Ke]. \tag{11}$$

Among them, $B^+ = (B^T B)^{-1}B^T$, substituting equation (11) into equation (S) to get the following equation:

$$\dot{e} + Ke = 0. \tag{12}$$

In the above formula, if K satisfies the Huiwitza polynomial when t tends to infinity $\|e\| = 0$. However, the mathematical model of the system cannot be accurately obtained, and the UAV will be subject to parameter perturbation and external interference during flight. The controller based on sliding mode control cannot deal with the influence of these uncertain factors well. Therefore, it is necessary to design an intelligent, Robust control system to achieve accurate tracking of the flight trajectory. At the same time, the system must have a certain anti-interference ability.

The design of the intelligent control system is shown in Figure 2.

The identification of the system and the approximation of the function can be realized through a pure wavelet neural network, and this will also lead to other problems, such as the expansion of the network structure. In addition, the recurrent neural network can realize the identification of nonlinear systems, but it is not stable enough and the learning algorithm is also more complicated. The controller based on the PSO algorithm can not only solve the stability problem but also approximate the ideal mathematical model and reduce the dependence on the mathematical model.

The purpose of this paper is to reduce the high-performance computing early warning neural network overhead of the underlying network under the premise that the underlying network resources are limited, and path segmentation is not supported. A binary combinatorial optimization model for the anti-UAV high-performance computing early warning neural network problem is established.

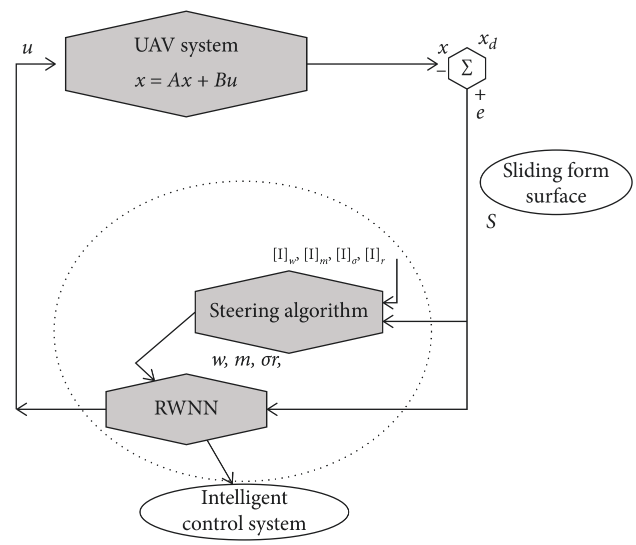

Figure 2: Intelligent control system structure.

First, define the remaining available CPU and memory resources of the underlying node $n_S \in N_S$ as $\mathrm{cpu}'(n_S)$ and $\mathrm{memory}'(n_S)$, respectively, and the remaining available bandwidth resources of the underlying link $e_S \in E_S$ is $b'(e_S)$.

$$\begin{aligned} \mathrm{cpu}'(n_S) &= \mathrm{cpu}(n_S) - \sum_{\forall n_V \perp n_S} \mathrm{cpu}(n_V), \\ \mathrm{memory}'(n_S) &= \mathrm{memory}(n_S) - \sum_{\forall n_V \perp n_S} \mathrm{memory}(n_V), \\ b'(e_S) &= b(e_S) - \sum_{\forall e_V \perp e_S} b(e_V). \end{aligned} \tag{13}$$

Among them, $n_V \perp n_S$ is defined that the virtual node n is allocated to the bottom node n, and $e_V \perp e_S$ is defined that the virtual link n is allocated to the bottom links.

The available bandwidth of any path $P \in P_S$ is expressed as the minimum remaining bandwidth along the path between two lower-level nodes.

$$b(P) = \min_{e_S(i,j)\in P} b(e_S(i,j)). \tag{14}$$

Let M_N be a binary $m \times n$ matrix, which represents the high-performance computing early warning relationship of the node. Each row vector and column vector represent a virtual node and the underlying node, $m = N_V|$, $n = |N_S|$, When the virtual node n_V^i is assigned to the bottom node n_S^i, the value of $M_N(i,j)$ is 1. Otherwise, it is 0. For the same anti-UAV request, each virtual node can only be assigned to one bottom node, and two virtual nodes cannot be assigned to the same bottom node simultaneously. The constraint conditions are formalized as follows:

$$\begin{aligned} &\sum_i^m M_N(i,j) \le 1, \quad j \in \{1, 2, \ldots, n\}, \\ &\sum_j^n M_N(i,j) \le 1, \quad i \in \{1, 2, \ldots, m\}. \end{aligned} \tag{15}$$

The remaining available CPU and memory resources of the underlying node n_S^j need to be able to meet the needs of

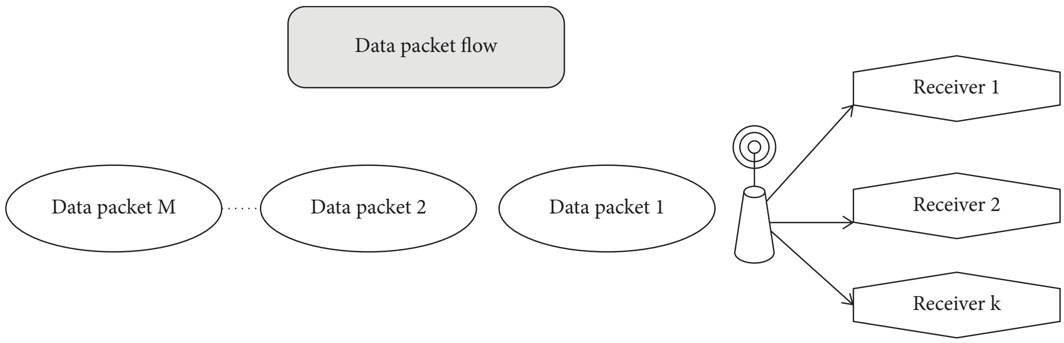

Figure 3: System model.

the virtual node n_V^i, and the node is within the constraint range of the requested location of n_V^i, before n_V^i can be alerted to the underlying node n_S^j by high-performance computing. The distance between nodes n_V^i and n_S^j is represented by Euclidean distance dis (). The remaining available CPU and memory resources of the underlying nodes and the node constraints are, respectively,

$$\begin{gathered}M_N(i,j)\left(\mathrm{cpu}'\left(n_S^j\right)-\mathrm{cpu}\left(n_V^i\right)\right)\geq 0,\\ M_N(i,j)\left(\mathrm{memory}'\left(n_S^j\right)-\mathrm{memory}\left(n_V^i\right)\right)\geq 0,\\ M_N(i,j)\times\mathrm{dis}\left(\mathrm{loc}\left(n_V^i\right),\mathrm{loc}\left(n_S^j\right)\right)\leq D_V^i,\end{gathered}\tag{16}$$

where, $M_N(i,j)\in\{0,1\}$, $i\in\{1,2,\ldots,m\}$, $j\in\{1,2,\ldots n\}$.

The anti-UAV high-performance computing early warning neural network model in this paper is shown in Figure 3 [10].

(1) The system model includes a source node and K ($K>2$) receiving nodes are configured, and the packet set needs to be broadcast to K receiving nodes. In this paper, it is assumed that the source node is within a period of time. Broadcast data packet within Δt

(2) The receiving node sends ACK or NAK information to the source node, the source node receives and maintains the feedback matrix table T, $T=(K,N)$, and the matrix element $T(i,j)$ indicates whether the receiving node correctly receives the data packet. Here, $R_iP_j 1\leq i\leq K$, $1\leq j\leq M$.

(3) In short, here, it is assumed that all control messages ACK or NAK are sent instantaneously and are not lost.

(4) The node R_i data packet loss rate obeys the binomial distribution with the parameter of p_i ($i=1,2,\ldots,K$).

In this article, if it is considered that there are n packets of the same size in the network, they need to be sent and to be packeted and expressed $X_1,X_2,\ldots,X_n$. The source node encodes the random linear asynchronous or the packet lost by the receiving node, and the new packet Y_i is expressed as follows:

$$Y_i=\sum_{j=1}^{n}g_{ij}X_j.\tag{17}$$

The coding coefficient g_{ij} $(1\leq j\leq n)$ is a value randomly selected from the defined area F_q. After each receiving node receives n coded packets, it can decode the original packet through the next linear equation.

$$\begin{bmatrix}X_1\\X_2\\\vdots\\X_n\end{bmatrix}=\begin{pmatrix}g_{11}&\cdots&g_{1n}\\\vdots&\ddots&\vdots\\g_{n1}&\cdots&g_{nn}\end{pmatrix}^{-1}\begin{bmatrix}Y_1\\Y_2\\\vdots\\Y_n\end{bmatrix}.\tag{18}$$

The PSO algorithm introduced in this paper is divided into a data broadcast stage and a retransmission stage. The specific steps are as follows:

(1) The source node broadcasts N data packets to K receiving nodes, and each data packet is sent at a certain time interval. The source node establishes a feedback matrix T through the received ACK or NAK feedback information and maintains the update.

(2) The source node enters the retransmission phase after the time $M\Delta t$ after broadcasting N packets. All lost data packets form a set $D=\{X_1,X_2,X_3,\ldots,X_n\}$, and the largest coefficient $M_{\max}$ in the coefficient vector $G=\{g_{i1},g_{i2},g_{i3},\ldots,g_{in}\}$ $(1\leq i\leq M_{\max})$ (selected randomly from the limited domain F_q) is used to encode all the lost data packets to generate $M_{\max}$ coded packet. $M_{\max}$ is the maximum number of lost data packets in all receiving nodes, which is determined by the following formula:

$$M_{\max}=\max_{i\in\{1,2,\ldots,K\}}\left\{\sum_{j=1}^{K}T(i,j)\right\}.\tag{19}$$

(3) After resending the encoded data packet, each receiving node estimates and displays the arrangement of its own encoding vector matrix G. $M_{\max}$ r_i If $r_i\neq N$ means that G has not reached the full arrangement for the node R_i, then the node R_i will notify the source node how many coded packets need to be retransmitted before G can reach the full arrangement. The required coded packets are

expressed through N_i, the specific situation is shown in the following formula [11]:

$$N_i = \begin{cases} N - r_i, r_i \leq N, \\ 0, r_i \geq N. \end{cases} \tag{20}$$

In the formula, $i = 1, 2, \ldots, K$

If the receiving node R_i receives a $M_{\max}$ coded packet in the data retransmission phase, N_i is 0. If the node R_i loses 2 encoded packets, then $N_i = 2$.

(4) The source node updates $M_{\max}$ according to the N_i value fed back by each receiving node and generates $M_{\max}$ coded packet in the new retransmission stage. The algorithm is shown in equation (4).

(5) (3) and (4) are repeated until the vector matrix of all receiving nodes is equal to N. That is $M_{\max} = 0$, if there is no lost packet, the receiving node can use the Gaussian elimination method to decode the original data packet.

The PSO algorithm is based on a complex adaptive system and belongs to a random search algorithm. This is also collective intelligence; everyone works together to solve problems. w belongs to the convolutional neural network group algorithm, which is a more important and changeable parameter and plays an important role in the improvement of the algorithm. If w becomes larger, the speed will become smaller, which is beneficial to the overall retrieval. If you use w to reduce the time, the speed will be shortened, which is good for local search. How to control the value of w and effectively solve the problem is a hot spot in the research process. Related research has proposed a linearly decreasing inertia weight, namely LDW, which linearly changes w to improve the convergence of the algorithm.

$$w = w_{\max} - \frac{t \cdot (w_{\max} - w_{\min})}{t_{\max}}. \tag{21}$$

In the formula: the value of w is $[w_{\min}, w_{\max}]$; t is the current iteration number; $t_{\max}$ is the maximum value obtained.

When w decreases linearly, the initial convergence speed decreases, and then as w decreases, the diversity of the algorithm decreases, and the local optimum is achieved. In this paper, we use a nonlinear weighting method to solve the deficiencies in the convolutional neural network group algorithm.

$$w = w_{\max} - (w_{\max} - w_{\min}) \cdot \ \arcsin\left(\frac{t}{t_{\max}} \cdot \frac{\pi}{4}\right). \tag{22}$$

According to the above formula, when the value of t is small, the approximate value of w is equal, and when the value of w is large, it is very advantageous for global search. In the process of increasing t, w decreases nonlinearly, and the value of w is relatively small, so the good local search ability of the algorithm is ensured, and the global search and local search can be adjusted flexibly. Generally speaking, the best design problem can be solved by using a three-layer structure network. Therefore, a three-layer neural network is used, namely input and output and implicit layers.

(1) Network initialization: Each level has a corresponding right coefficient, and a random small nonzero number is given to realize the threshold initialization of each level and determine the learning speed and neuron excitation function.

(2) Output calculation of each layer. First, realize the input of the sample $X = (x_1, x_2, \ldots, x_n)$ and realize the output of $Y = (y_1, y_2, \ldots, y_n)$, and calculate the neuron output by the following formula:

$$\begin{aligned} H_i &= f\left(\sum_{j=1}^{m} w_{ij} - a_i\right), \quad i = 1, 2, \ldots, q, \\ O_k &= \sum_{i=1}^{q} H_i w_{ki} - b_k, \quad k = 1, 2, \ldots, L. \end{aligned} \tag{23}$$

In the formula: H belongs to the hidden layer output. Number of nodes; a is the threshold activation function; the connection weight of the input layer and the implicit layer. O refers to the output of the output layer. B is the connection weight between the hidden layer and the output layer representing the threshold.

(3) Calculate the error e between the network output O and the expected output O_1.

$$e_k = O_{1k} - O_k, \quad k = 1, 2, \ldots, L. \tag{24}$$

(4) Update network connection and threshold:

$$\begin{aligned} w_{ij} &= w_{ij} + \mu H_i (1 - H_i) x(j) \sum_{k=1}^{L} w_{ki} e_i, \quad j = 1, 2, \ldots, m; \ i = 1, 2, \ldots, q, \\ w_{ki} &= w_{ki} + \mu H_i e_k, \quad i = 1, 2, \ldots, q; \ k = 1, 2, \ldots, L, \\ a_i &= a_i + \mu H_i (1 - H_i) x(j) \sum_{k=1}^{L} w_{ki} e_i, \quad j = 1, 2, \ldots, M; \ k = 1, 2, \ldots, L, \\ b_k &= b_k + e_k. \end{aligned} \tag{25}$$

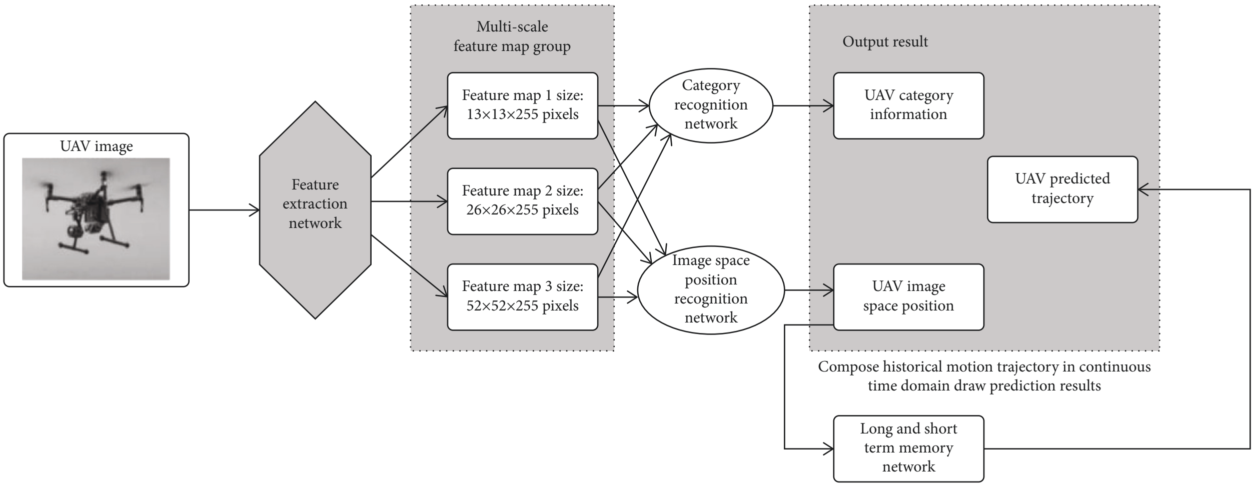

Figure 4: AUNN network structure.

The values of w_{ki} and w_{ij} can be adjusted by the network error e and the above formula, and the values of a and b can also be adjusted by e.

2.3. Composition of System. The designed anti-UAV recognition and trajectory prediction neural network, AUNN). (AUNN) is composed of 4 links of UAV feature extraction, UAV type recognition, UAV image space position recognition, and UAV image space trajectory prediction, as shown in Figure 4.

First, the algorithm can obtain the multiscale deep semantic feature information of the UAV from the aerial UAV image captured by the imaging system through the feature extraction network; Subsequently, the obtained multiscale and high-dimensional feature maps are sent to the UAV type recognition network and the UAV image space position recognition network, to figure out the target UAV category and image space position. According to the change trend of the corresponding UAV's image space position center in a certain time domain, the historical movement trajectory of the UAV in the changed time domain is constructed. Finally, combined with the historical motion trajectory, the predicted motion trajectory of the target UAV in the future time domain is analyzed and output with the PSO algorithm, and the real-time recognition and tracking of the UAV in the current time domain and the trajectory prediction in the future time domain are completed.

Anticipating in the anti-UAV defect inspection, usually based on the behavior of other users in the community, your own participation behavior can be adjusted. According to the above-mentioned user behavior characteristics, the anti-UAV defect detection manager uses incentive guidelines and other methods to reasonably check the anti-UAV defects to improve the user's participation. This kind of management scheme manages the anti-UAV defect detection information resources intelligently. Anti-UAV high-performance computing early warning intelligent management: The anti-UAV defect inspection manager analyzes the user's behavior data and browsing history, and other user resources, explores the needs of users, predicts the user's behavior tendency, and provides users with personalized services that meet their needs, and ultimately realizes the added value of service experience through the organization and regeneration of information.

This article refers to the interactive mechanism model of enterprise knowledge management and service innovation and summarizes the anti-UAV high-performance computing early warning platform model (see Figure 5) to clarify the shortcomings of the anti-UAV, how to configure information, and use data to improve community environment and improve the viscosity of user participation.

The management of any information resource is a process, and the detection of the defects of the anti-UAV consists of several related ordered rings, which constitute the entire organic ring. Intelligent management refers to the analysis of information resources in anti-UAV high-performance computing early warning based on the above three links of resource accumulation, resource arrangement, and resource utilization. Please refer to Figure 6 for the specific process.

It can be seen from Figure 6 that the resource storage ring contains information storage and information collection. In the resource storage link, the anti-UAV system detects the collected anti-UAV defects. The data sorting link includes the sorting of the results of information organization, information analysis, and information data analysis. For target user data, the system data of the mobile phone is analyzed and compared, and in-depth, intelligent operations are taken to make it effective and reasonable. Resource utilization includes a system recommendation link, which classifies and organizes target users through the analyzed data, provides effective and systematic data to corresponding users, and improves resource utilization efficiency.

2.4. Algorithm Implementation. In order to quickly and intuitively obtain the category and location information of aerial UAV, it is first necessary to identify and locate the UAV in the image or video stream data captured by the

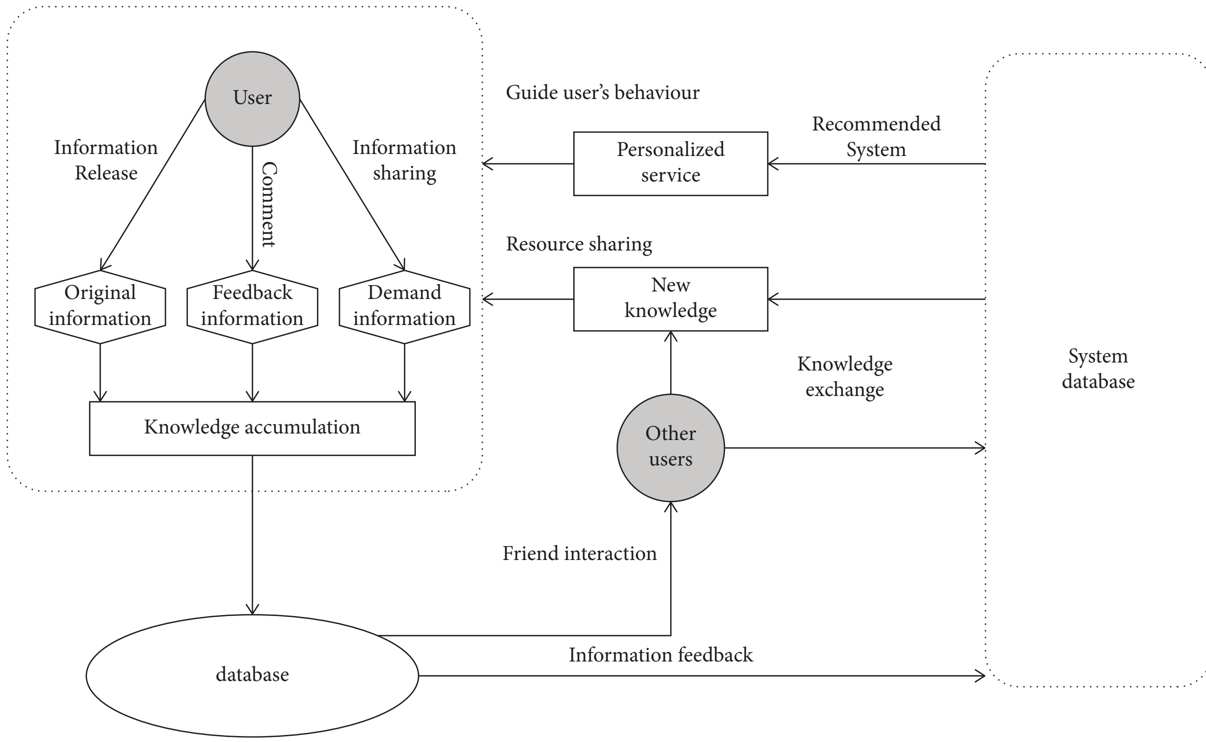

Figure 5: Anti-UAV high-performance computing early warning platform.

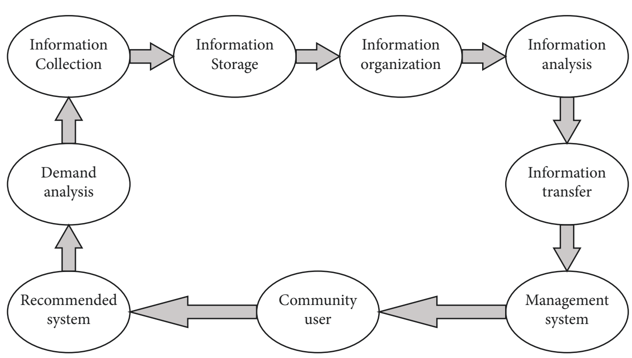

Figure 6: Anti-UAV high-performance computing early warning process.

camera. Orienting at ground-based computing platforms, in view of multiscale and multitarget UAV recognition tasks in the air environment, a UAV Feature Extraction Network (UFEN) is designed as the backbone of AUNN to extract deep semantic information of aerial UAV and use the YOLO V3 (you only look once) target recognition network as the middle layer (neck) and top layer (head) of the AUNN network to complete the target category and image space recognition calculations.

2.4.1. UAV Feature Extraction Network. The UFEN network is a deep residual network, which is composed of a standard convolutional layer, an expanded convolutional layer, and a stack of cyclic residual modules. The network structure of UFEN is shown in Figure 7.

Since the ground-based platform is shooting aerial UAVs, the distance from the UAV to the ground-based detection unit is generally 45 m. At this time, the amount of semantic information in the foreground of the UAV in the image is much smaller than the amount of background semantic information, and the whole colored sky dominates the background. When using the same effective size convolution kernel, the receptive field of standard convolution and the receptive field of expanded convolution is shown in the following equations:

$$r_n = r_{n-1} + (k_n - 1)\prod_{i=1}^{n-1} s_i, \tag{26}$$

$$r_n = r_{n-1} + d(k_n - 1)\prod_{i=1}^{n-1} s_i, \tag{27}$$

where r_n is the receptive field of each unit in the nth convolutional layer; i is the first $n-1$ layer of convolution, the index value of each layer of convolution; k_n and S_i are the size and step size of the convolution kernel of the nth convolutional layer, respectively; d is the expansion convolution coefficient.

By comparing equations (26) with (27), it can be seen that under the premise that the moving step of the convolution kernel is the same as the input image size, the receptive field of expanded convolution in the same layer network is larger than that of standard convolution. For images of aerial UAV, expansion convolution can more effectively obtain the deep semantic features of the image and reduce the multiple redundant calculations of the

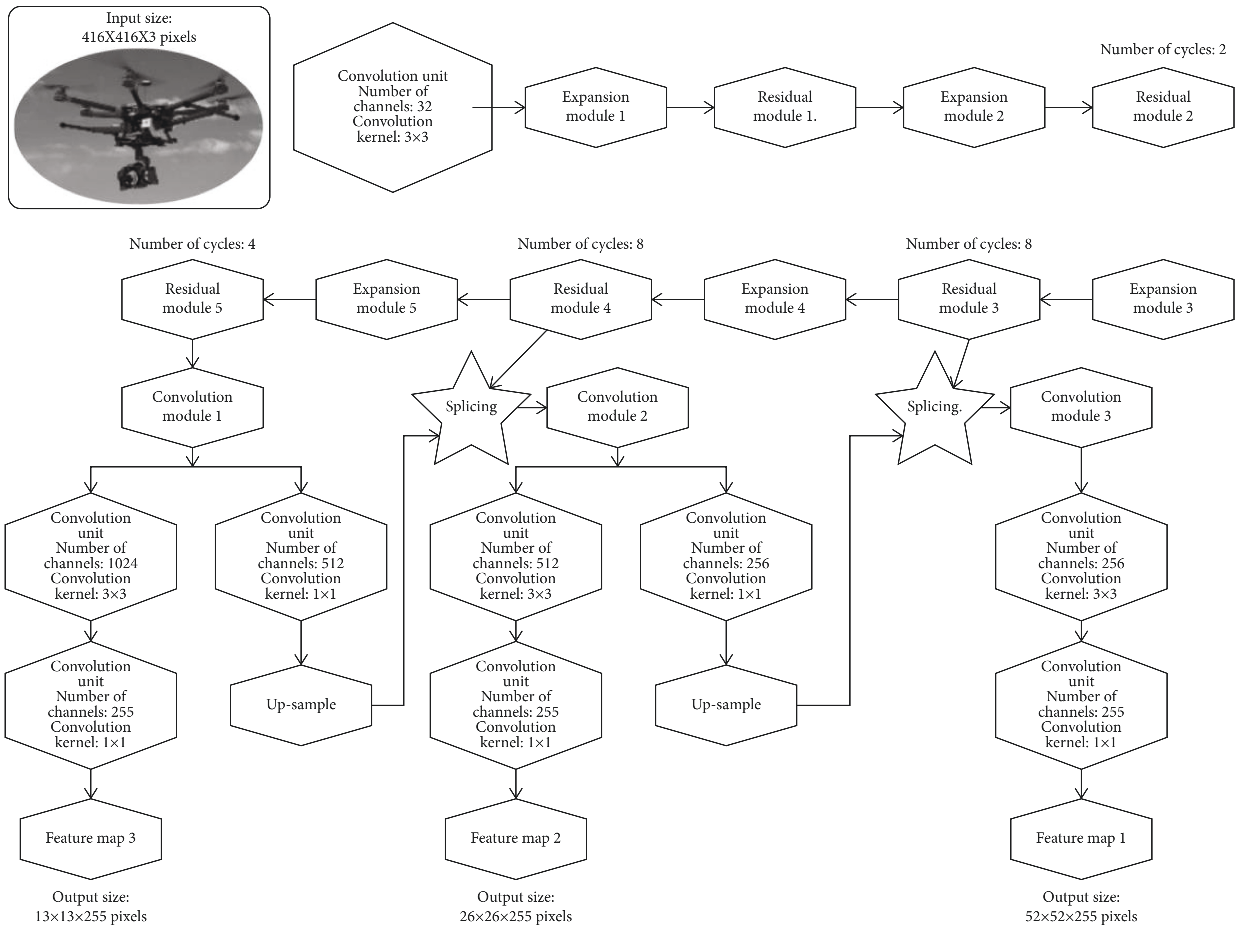

Figure 7: NFEN network structure.

background environment in the standard convolution iteration process. However, due to the discontinuous sampling of the convolution kernel during the calculation process of the expansion convolution, for small aerial UAV targets, the sky dominates loss of spatial hierarchical information, and the inability to reconstruct small object information are prone to occur, as shown in Figure 8(a). In order to solve the above problems, the expanded convolution module with a zigzag structure is used to replace the standard convolution [12, 13] to avoid the expansion convolution kernel with no spatial structure connection to skip or dilute the semantic information points of the UAV. The calculation method of the expanded convolution module with a saw tooth structure is shown in the following formula:

$$\text{Feature} = \text{conv}_{\text{dil}}^{5}\left[\text{conv}_{\text{dil}}^{2}\left(\text{conv}_{\text{dil}}^{1} * \text{input}\right)\right]. \tag{28}$$

In formula (28): input is the input data; Feature is the feature map obtained after calculation; conv_{dil} is the expansion convolution calculation; 1, 2, and 5 are the expansion coefficients. Meanwhile, the expansion coefficient of the high-dimensional expansion convolution is controlled, and the maximum expansion coefficient M_i in the expansion convolution is as follows:

$$M_i = \max\left[M_{i+1} - 2r_i, M_{i+1} - 2\left(M_{i+1} - r_i\right), r_i\right]. \tag{29}$$

In formula (29): r_i is the receptive field of the i-th expanded convolution. The expanded convolution module structure of the sawtooth structure is shown in Figure 9 and Table 1.

After the above mixing and matching, the zigzag structure is fused and convolved, and the full coverage calculation of the feature map information points, as shown in Figure 8(b), is realized. That is, the larger receptive field can be used to extract global semantic information, which also prevents ignorance of target feature information.

When performing deep semantic feature extraction on multiscale UAV targets, due to the continuous deepening of the network and the increase in the number of loop iterations, the size of the feature map will be reduced after each convolution calculation. The small-scale UAV target with less semantic information has a smaller feature map area in each layer. When the network depth is too large, the feature information of the small target will be difficult to be distinguished, and the internal detail texture in the deep semantic information will be weakened. In order to improve the recognition efficiency of small targets, it is necessary to condense deep semantic information and retain shallow feature information [14, 15]. UFEN uses a residual model. Each residual module is composed of two residual units. Each residual unit is shown in Figure 10 including convolutional

layer, batch normalization layer, and activation function layer. Among them, the activation function uses Leaky ReLU. Each residual module can integrate the shallow semantic information and deep semantic information inside the module, connect each subsegment network with a shortcut method, integrate large-size, low-dimensional features and small-size, high-dimensional features to improve the accuracy of multiscale target recognition, control gradient propagation, and prevent gradient dispersion or gradient explosion. The residual module structure in UFEN is shown in Figure 11. UFEN has a total of 5 residual modules, which are, respectively, connected to the 5 expansion convolution modules. The first

2.4.2. UAV Target Recognition Network. After UFEN completes the feature extraction of the UAV target and generates 3 feature maps with scales of 13×13, 26×26, 52×52, respectively, AUNN will use the YOLO V3 target recognition network to identify the feature map group.

The YOLO V3 target recognition network will mesh the recognition area on the input feature map, and the number of grid divisions corresponds to the size of the input feature map. The anchor box in each grid in the feature map is responsible for identification and detection, and the information N contained in each grid is expressed as follows:

$$N = \left[b_x, b_y, b_w, b_h, p_0, p_1, \ldots, p_c\right] \times B, \tag{30}$$

where b_x, b_y, b_w, b_h are the coordinates and size information of the central point of the current prediction frame; p_0 is whether the target is included in the current grid and the accuracy of the target location; $p_0, p_1, \ldots, p_c$ is the probability that the target in the frame belong to the type to be identified. If the target center falls in the semantic information pixel point of a certain feature map, the grid will detect the target in this area, B is the number of anchor boxes, and the confidence value Po is the product of the probability of detecting the target and IOU (intersection over union), which is shown in the following formula:

$$\text{confidence} = P(\text{object}) \times \text{IOU}_{\text{pred}}^{\text{truth}}, \tag{31}$$

where P (object) is whether there is a target in the grid. If it exists, the value is 1, and the value is 0 if it does not exist; IOU is the occurring simultaneous ratio, that is, the truth frame truth generated by the target and the range frame pred generated by the target recognition, the expression is shown in the following formula:

$$\text{IOU} = \frac{\text{DR} \cap \text{GT}}{\text{DR} \cup \text{GT}}. \tag{32}$$

In the formula: DR is the detection result; GT is the ground truth, and the result of the intersection of the detection target and the ground truth is shown in Figure 12.

By calculating the IOU between the detection target range frame and the ground truth, the network can distinguish the foreground target from the background target.

For feature maps at different scales, when each divided grid classifies internal targets, it needs to predict the class probability of the internal c targets, that is, the probability of the i-th target falling in the grid $P(\text{Class}_i|\text{object})$:

$$\begin{aligned} P\left(\text{Class}_i|\text{object}\right) &= P(\text{object}) \times \text{IOU}_{\text{pred}}^{\text{truth}} \\ &= P\left(\text{Class}_i\right) \times \text{IOU}_{\text{pred}}^{\text{truth}}. \end{aligned} \tag{33}$$

Each grid in the YOLO V3 network must first calculate whether there is a target inside. When it is determined that a target exists, the classification of the target will be judged according to its category prediction probability. When the target's prediction probability of a certain category exceeds the threshold and is greater than other classification prediction values, the target is considered as the current category.

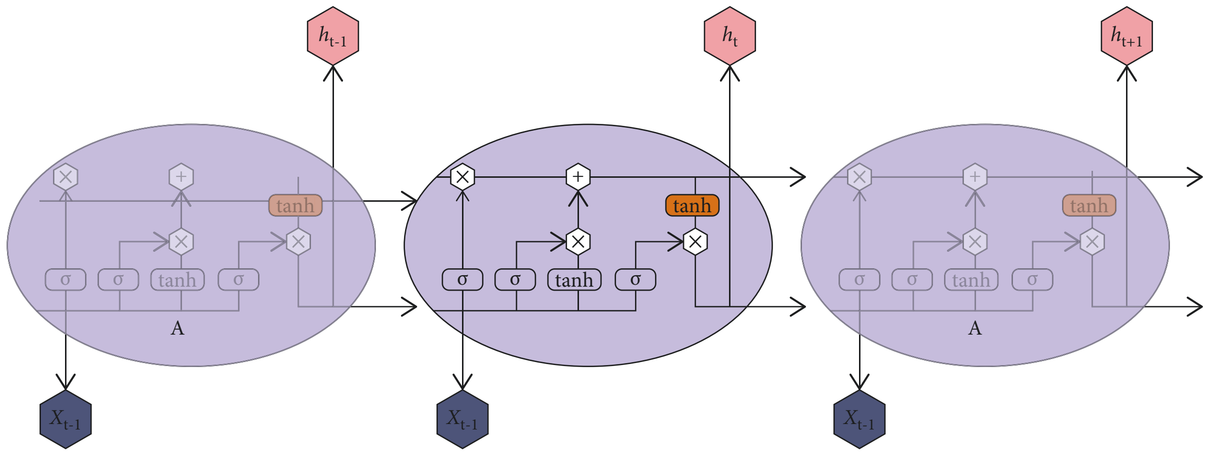

Figure 13: PSO algorithm structure.

For the judgment of the target's position information, YOLO V3 will continuously learn and correct the size of the anchor box through fine-tuning iteratively so that the result of the prediction frame is close to the truth frame. The adjustment process is shown in the formula:

$$\begin{cases} b_x = \sigma(t_x) + c_x, \\ b_y = \sigma(t_y) + c_y, \\ b_w = p_w e^{t_w}, \\ b_h = p_h e^{t_h}. \end{cases} \tag{34}$$

In formula (34): c_x and c_y are the coordinates of the upper left corner of the corresponding grid on different scale feature maps; t_x, t_y, t_w and t_h are the deviation between the prediction box and the truth frame; p_w and p_h are the length and width dimensions of the anchor box, and finally, the coordinates b_x and b_y of the upper left corner of the prediction frame and the corresponding length and width b_w and b_h of the prediction box are obtained.

The UAV trajectory prediction network will take the UAV space historical time domain motion trajectory as input data, use the long and short term memory network PSO algorithm to learn the flight behavior characteristics of the UAV, and use the image space position in the existing time domain to predict the iteratively, position of the image space in the future time domain.

Long and short term memory network is an RNN optimized network that overcomes the problems of gradient explosion and gradient disappearance. Compared with the traditional recurrent neural network (RNN), LSTM has an additional "forget gate" mechanism, which determines whether to forget the content of the moment through the correlation between the input and output at a certain moment and the previous moment, so that only important information is retained in all periods [15]. The structure of the PSO algorithm unit is shown in Figure 13.

x_t is the current UAV image space motion trajectory of input in the time domain; h_t is the UAV image space prediction motion trajectory of output in the next time domain; A is the calculation unit in the PSO algorithm. Each unit is connected from beginning to end, the calculating unit in the same layer will use the output of the previous layer as the input of the next layer; σ (sigmoid) and tanh are the activation functions.

A reshaped trajectory matrix C will be introduced from left to right in the LSTM unit. For the input information at time t, the matrix passed in from the left end in the LSTM unit is C_{t-1}, and the matrix passed out from the right end is C_t. Among them, the C_{t-1} matrix is multiplied by a coefficient by the multiplier, and then linearly superposed by the adder, and finally C_t is obtained.

The h_{t-1} matrix on the left is connected with the input h_t matrix, and the coefficient f_t is calculated by the sigmoid function through a linear unit. The coefficient is the multiplier coefficient in the x matrix transfer process. The expression is shown in the following equation:

$$f_t = \sigma\left(W_f\left[h_{t-1}, x_t\right] + b_f\right), \tag{35}$$

where W_f and b_f are the undetermined coefficients to be learned during the training process. In the "forget gate" of LSTM, if the output of the sigmoid function is 1, the input will be completely remembered; if the output is 0, the input will be completely forgotten; if it is the intermediate value of 0~1, the input will be remembered in proportion.

Finally, LSTM passes the input information through a "forget gate" again to generate an output h_t. h_t generated has two parts. One part is passed to the same layer unit, and the other is passed to the next layer unit. Then the final output predicted trajectory at time t of the LSTM unit is as follows:

$$h_t = \sigma\left(W_t\left[h_{t-1}, x_t\right] + b_t\right) \times \tan hC_t. \tag{36}$$

Through the above calculations, AUNN has been able to obtain the category information and location information of the target UAV, and project the center point of the continuous frame recognition position of the target UAV to the time domain coordinates to obtain the historical time domain motion trajectory of the UAV image space, and use the PSO algorithm to predict the position of the UAV in the future time domain. The feedback flow of the calculation process is shown in Figure 14.

3. Experimental Results and Analysis

The initial learning rate in the training phase is set to 0.001, and the learning rate is gradually increased in the first two generations. When the number of iterations is 380 times, the learning rate is reduced until the learning rate reaches 0.000001, which will not decrease, by which the loss function is further converged, and the learning rate curve is shown in Figure 15.

In order to verify the computing power of AUNN, an image data set for aerial UAV recognition was constructed based on the military and civilian fields. There are a total of 760 images in the data set, which are classified into reconnaissance, payload/control, and offensive targets according to the UAV's structure, functions, and executable tasks. The data components of each type of UAV are shown in Table 3.

The verification platform is DELLZ840, the CPU configuration of the central processing unit is Intel Xeon E5-2643 V3, the main frequency is 3. 4 GHz, the GPU is Quadro P5000, and the running memory is 32 GB, and the computing environment is Ubuntu 18.04. During the test, the IVFNN programming language was Python 3.7, with Tensorflow 2.0 and Opencv 3.2 as auxiliary high-level APIs.

After AUNN completes training, the total loss curve of the network is shown in Figure 16. After about 40,000 iterations, the final loss stabilizes at about 0. From the loss curve, it can be seen that the results of AUNN network training are relatively ideal.

AUNN's network training curve has a good convergence state, without gradient explosion, dispersion, disappearance, etc., which proves that the network designed by this research has a good feature learning ability. The average target recognition rate of AUNN is 82%, the average trajectory prediction rate is 80%, and the calculation speed is 24 frames/s. The network's UAV recognition and trajectory prediction effects are shown in Figure 17. Figures 17(a)~17(c) recognition effect of the 17 Figure network on command UAV, scout UAV, and attack UAV; Figures 17(d)~17(f)

correspond to the attacca trajectory prediction effect of 3 types of UAVs.

According to the results shown in Figure 17, AUNN can accurately identify and locate multitarget UAVs in the air under a ground-based platform. In the meantime, it can predict the UAV image space in the future time domain based on the current UAV image space trajectory to achieve rapid and accurate early warning for the “low, small, slow” UAV target, and provides machine vision support for the anti-UAV system.

4. Conclusion

The imbalance, turbidity, and instability of the high-performance computing early warning neural network in the use process are more important in the daily use process. The PSO algorithm in this paper can realize the optimization processing of the support vector regression model. While constructing the network high-performance computing early warning model, it uses three sets of different time granular data in the MAWI data set to carry out a detailed analysis with sample analysis. Finally, the experimental results show that the method proposed in this paper has better early warning performance for high-performance computing and can effectively solve the early warning problem of network high-performance computing. Finally, the flight state curve of the UAV is obtained through simulation, which verifies the effectiveness of the control law design. Therefore, this method can solve the flight control problem of UAV in complex situations.

Distribution network line loss calculation refers to the calculation of the electrical energy loss, which is generated by all components in a distribution network system in a given period of time. Distribution network, as the end of the power network, is directly connected with users; there are many equipment on the network; the system has impedance, electric energy in the process of conversion, transmission and distribution with a lot of loss, so the calculation of distribution network line loss has very important economic significance. In addition, with the development of power network construction, the rationality of distribution network topology design and the comparison of practical effects of various measures need the guidance of line loss calculation. Line loss and line loss rate is one of the main criteria to reflect the operation of distribution system. Reducing line loss of distribution system is very important for the effective use of power and economic operation of distribution system. In order to better find the effective reduction method and lay the foundation for the scientific establishment of linear contraction targets. This study uses a line loss calculation method based on BP neural network. The method uses the super matching property of the network to map the complex nonlinear relationship between the line loss and the characteristic variables and stores the evolution of the line loss changes with the changes of the structural and operational variables of the distribution line. On the basis of analyzing the theoretical methods, management methods, and various loss reduction measures of power loss calculation, this study also analyzes the status quo and existing problems of line loss analysis and calculation and collects data from line loss calculation and theoretical line loss calculation methods. This study discusses in detail the method and idea of the application of the improved neural network in the estimation of distribution network line loss, and it is used to predict the line loss in a certain area, and the prediction result is good.

1. Introduction

Power generation and transmission systems transmit power to users through the distribution network, and the distribution network is directly connected to users at the end of the power network [1]. Due to the characteristics of low voltage grade, aging equipment, and long power supply radius of the distribution network, the line loss of the distribution network is more serious, accounting for more than 20% of the line loss of the power network at all voltage levels [2]. In recent years, as most countries in the world are in a state of insufficient energy, the contradiction between supply and demand and between the energy supply side and the energy purchase side is increasing [3], so how to prevent our country from falling into energy conflict has become a key domestic issue in recent years [4]. In the power system, line loss, as an important index to evaluate the efficiency and economy of power grid operation, has always been one of the important research and management contents of power grid companies [5]. Reasonable calculation and prediction of line loss rate is a method to effectively improve the management of power grid company, reduce power loss, and increase power grid income. Therefore, how to improve the accuracy of line loss rate prediction has very important practical significance. In recent years, many new methods for theoretical calculation of power distribution system line loss have emerged, and the calculation accuracy has been improved [6]. Add line loss calculation function and calculate line loss on time, to ensure that the system line loss can always be in the management of the management personnel. Design automatic line loss management system and improve load management device [7, 8]. The traditional manual management way already cannot adapt to the current management needs, the previous theoretical line loss is mostly artificial calculation, calculation workload is big, calculation cycle is long, and only a rough calculation for simple lines is impossible to calculate for complex circuit; limitation is very big; this requires us to use a computer for line loss calculation [9, 10]. It is very urgent to study the simple and effective computer aided distribution network line loss calculation method and implementation. This is also a more accurate calculation of the theoretical line loss and its distribution in the network and the institutionalization, standardization, and standardized line loss calculation work of the inevitable requirements.

2. Application of BP Neural Network Algorithm

2.1. Distribution Network Line Loss Calculation Scheme. Theoretically, the BP neural system can map all nonlinear relations and effectively deal with the nonlinear relations between characteristic variables and line losses [11]. For the selection of input variables and output variables of neural network, in a certain period of time, the line loss of distribution lines is related to many characteristic parameters, such as the active power supply of distribution lines, the reactive power supply, the capacity of distribution transformers, the length of distribution lines, the number of distribution transformers, and the total number of truncation of distribution lines [12]. Calculation scheme of line loss of distribution network using BP neural network is shown in Figure 1:

In this study, the relationship between the four characteristic parameters and line loss is analyzed. When applying neural network to modeling, the active power supply, reactive power supply, distribution capacity, and distribution line length are taken as the input of neural network, and the line output is taken as the output. Neural network structure is shown in Figure 2:

2.2. Raw Data Acquisition and Processing. The process of data sampling and sample selection is as follows.

2.2.1. Attribute Selection. During network modeling, it is necessary to input feature weights that can characterize the problem, which imposes certain requirements on the fault information on the shaping device. The number of attributes determines the success of network recognition to a large extent, so the choice of attribute number is directly related to the accuracy of calculation [13]. In addition, the selection of the number of attributes must take into account the difficulty of obtaining data, whether it is correct and perfect, and the selection of the number of attributes must consider various factors.

There are many characteristic variables that affect line loss in a distribution system. According to the above, there are many characteristic quantities that satisfy the above conditions, such as the total number of distribution lines, the number of distribution changes, the length of distribution lines, distribution capacity, and the distribution of the total reactive power and total active power of the distribution cabinet.

According to the strength of the correlation between the line loss and characteristic variables of the distribution system, this study chooses the total effective power of the line, the total response capacity of the line, the distribution voltage capacity, and the length of the distribution line as the input and output, that is, the line loss.

2.2.2. Data Collection. Select a portion of distribution system data in a specific area and sort the data by network code number. In order to match Matlab programming calculation, it is formatted into the matrix form. The data are divided into practice samples and test samples.

2.2.3. Data Processing. Before creating a network, make preparations. Since the data sizes of different samples are usually different, direct input without processing will affect convergence and processing speed. Therefore, data samples need to be standardized. Chemical processing can ensure that the data size is relatively close, avoid calculating some data with small sample size due to large size difference, and improve the accuracy of data processing [14]. The normalized calculation formula is as follows:

$$x_k = \frac{x_k - x_{\min}}{x_{\max} - x_{\min}}, \tag{1}$$

where $x_{\max}$ and represent the maximum and minimum input values in the input data.

2.3. Neural Network Building and Training. In the Matlab platform, the Matlab language is used for neural programming, and the data on the input samples have been standardized. The results after exercise were compared with actual data for easy comparison.

In the modeling and training process of the nervous system, training samples are represented by variable corpus, production samples are represented by t, and untrained samples are represented by the network created by Newff. After setting the corresponding parameters, it can continue [15]. About training, this study covers two main commands. The first is the network, which is used to define the coach's goals [16]. Teaching ends only when the error is below the target value. In general, the default root mean square error (MSE) is the main index to measure the validity of this error. The second is the network. During this period, this command is mainly used to set the maximum number of repetitions. When the number of repetitions exceeds the set limit, the exercise will automatically end.

As can be seen from the training results, the training process of the network was repeated for a total of 6 times, reaching the precision set by the training network. Therefore, the network training was stopped to prevent the network from falling into an overly suitable state. At this point, the mean exponential error and repetition rate of the

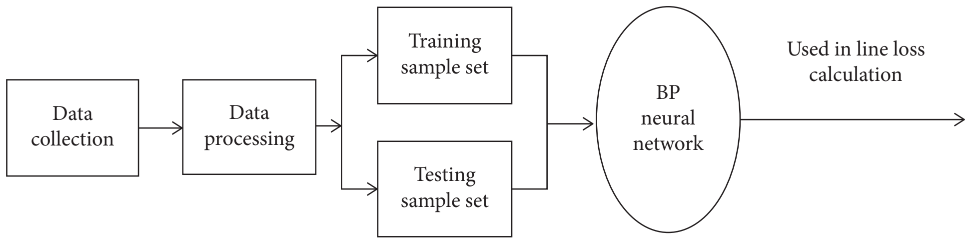

Figure 1: Calculation scheme of line loss of distribution network using BP neural network.

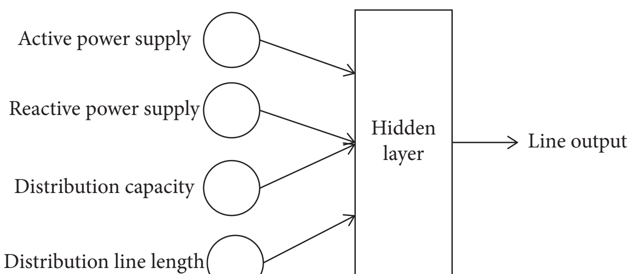

Figure 2: Neural network structure.

training samples were 0.00152 and 1.00E − 5, respectively, and the accuracy was already very high.

The larger the error target is, the more iterations need to be carried out, and the two are obviously positively correlated. Curve of mean square error and iteration times is shown in Figure 3:

Figure 4 shows that the mean square error of the training sample decreases with repetition, and the mean square error of the validation sample and test sample decreases correspondingly. However, the training performance of the nervous system is not higher with higher accuracy of training because the success rate of network generalization will be reduced, so it is necessary to avoid excessive online training.

Figure 5 is a linear regression analysis of the calculated loss frequency and the actual value obtained through the neural network model based on sample data. The deduction is the calculated line loss and the horizontal axis is the actual line loss. $R = [-1, 1]$ indicates the fitness level, and the higher the R value, the better the nervous system and computational performance. Neural network sample test results are shown in Figure 5:

Figure 5 is a sample of the nervous system. It can be seen that the calculated value of theoretical line loss in the figure is quite close to the actual value, and the error accuracy meets the requirements of actual calculation.

3. Line Loss Prediction Simulation of Distribution Network

3.1. Data Processing. In order to verify the feasibility of calculating the BP distribution line losses of the BP neural system studied in this study, simulation and empirical analysis were performed based on the daily load consumption of distribution users in a region within a region for 100 consecutive days. Distribution station area structure diagram is shown in Figure 6:

Based on the above analysis, for a specific location area, the change of energy consumption of each load node in the station area is the main reason for the change of energy loss value. Therefore, the daily response force of stress nodes is applied to the nervous system, and then, the loss rate of the line is obtained with the power. On this basis, combined with LM algorithm, the neural network model for calculating the line loss is obtained.

As for the sample data, they mainly contain 1 dependent variable and 16 independent variables. In short, the BP nervous system has 1 production node and 16 input nodes. The number of nodes is four, the hidden layer is one level, and the 16-4-1 network structure is defined, which is a network structure with 16 input nodes, 4 hidden level nodes, and one production node. In order to fully meet the training requirements of BP neural network, the data are processed to obtain independent variables, but there is no need to calculate the ratio of training variables.

3.2. Simulation Results. In six consecutive repetitions, the variance of the validation data did not decrease, but increased, exceeding the expected number of failures, so the online training ended automatically. At this point, the repetition estimation and root mean square error of training samples are very small, which are 1.08E − 7 and 7.05E − 8, respectively.

In the process of repeated online training, the average error of samples decreases gradually, and the average error of test samples and confirmation samples decreases gradually, but improving generalization ability is the main purpose of online training. The goodness of fit of the sample data is very close to 1, which achieves the expected requirements. Data simulation results are shown in Table 1:

In this study, the daily power consumption data of users in a certain distribution area for 100 consecutive days are used for network training, and the relationship between daily energy consumption and load node line loss ratio in the distribution station area is obtained, and then, the corresponding relationship is established on this basis. Table 1 shows that the absolute difference EA of all sample data is less than 1%, and the calculated results have good reliability. The relative difference is less than 5%, and the corresponding mean difference is 2.31814. Figure 7 shows a detailed fit of these test samples. Therefore, in the process of creating the online model, the representative of the sample should be

considered when selecting the model, and its own structure should be considered to enrich the training sample as much as possible. Comparison diagram of sample fitting degree is shown in Figure 7.

4. Conclusion

Comprehensive and accurate theoretical calculation of line loss is very important. The clear composition of line loss and its distribution not only helps power supply companies to make plans and improve production and operating conditions but also plays an effective role in saving energy and reducing voltage [17, 18]. The lack of proper development plans over the years resulted in complex structures with many line segments and some lines with fine diameters, resulting in variables that did not meet the $R << x$ criteria for calculating energy flow. Based on this situation, some scholars use improved algorithms after research, such as the matching energy flow method, the improved repetition method, the before and after conclusion method, and the loop resistance method [19]. However, it is difficult to collect and satisfy the data required for these algorithms. The development of science and technology promotes the generation of several new algorithms which contribute to the development of distribution system [20]. The BP network model has a wide range of applications, and three-layer neural network is the main component of this type [21]. This model allows for very complex mappings that are linear to actions. The structure of the network is relatively simple, has high availability, and can perform arbitrary nonlinear adjustment of the input and output. These advantages make the BP nervous system quickly recognized by national scholars and widely used, such as imaging, data prediction, pattern analysis, and other fields [22]. Although BP algorithm has many advantages, it inevitably has disadvantages such as slow Internet speed, easy network oscillation, and easy to fall to the lowest point of the network. Scientists in China are determined to correct the inherent defects of BP algorithm and have achieved remarkable results. Xin et al. [23] used a model-based BP neural network algorithm to change the speed of the Internet. Jiang et al. [24] used an improved algorithm that uses the concept of simulated light lines to configure online speed learning. Using this improved algorithm can significantly improve network speed. Wang et al. [25] suggested that each weight should be relative to the initial learning rate. As the network adapts strongly, the learning rate corresponding to each weight has changed to achieve optimal results. The BP network model has many advantages. Now, more and more scholars have begun to study its application in line loss calculation of distribution system and have made some achievements. This is also a new development strategy of the artificial neural network model and opens up a new theoretical method for calculating the line loss of distribution system. However, overall, the current level is still exploratory. Due to the lack of general network design methods, neural networks are limited by practical use because they rely on experimental methods used in practice [26].

Therefore, this study focuses on the calculation of line loss and concrete practical calculation examples. In this study, a BP neural network model is used to calculate the line loss of the distribution system. The results show that using BP network to calculate the line loss of distribution system has the characteristics of the simple network model, fast training speed and high precision. Simulation results show that this method has great advantages in training time and calculation accuracy. It can simulate the optimal BP network type for the line loss calculation of the distribution system in a short time and has high calculation accuracy. In order to meet the needs of line loss management and analysis of distribution network, this study discusses a theoretical line loss prediction and analysis method using neural network and uses relevant algorithms and models. The prediction results also show that this arrangement of input samples may contain the main factors affecting row loss.

The biggest problem of this study is that neural network has a high requirement for data. However, from the current situation, the requirement of providing a large number of real data obviously does not meet the objective conditions, which is also the main direction of future scholars.

Modeling fire susceptibility in fire-prone areas of forest ecosystems was essential for providing guidance to implement prevention and control measures of forest fires. Traditional models were developed on the basis of random selection of absence data (i.e., nonfire data from unburned areas), which could bring uncertainties to modeling results. Here, a new model with the genetic algorithm for Rule-set Production (GARP) algorithm and 10 environmental layers was proposed to process presence-only data in the susceptibility modeling of forest fires in Chongqing city. To do this, 70% of 684 fire occurrence data (479) during the period of 2000–2018 were applied to train the proposed model. And, 30% of these fire occurrence data (205) and the same amount of no-fire data (205) were emerged as validation dataset. The results showed that, for some environmental layers (i.e., distance to the nearest road, land cover, precipitation, distance to the nearest settlement, aspect, relative humidity, elevation, wind speed, and temperature), their *P* values were less than 0.05, indicating that these 9 environmental layers have significant influence on the spatial distribution of fire susceptibility in Chongqing city. On the contrary, with a higher *P* value (i.e., 0.126), the slope layer has an insignificant effect on fire susceptibility in the study area. Furthermore, the results of receiver operating characteristic analysis (ROC) showed that the proposed model has a good performance with an AUC value of 0.869, an accuracy value of 0.732, a sensitivity value of 0.59, a specificity value of 0.873, a positive predictive value of 0.823, and a negative predictive value of 0.681. This study revealed the validity of the proposed model in modeling the susceptibility of forest fires.

1. Introduction

With intensive global warming and increasing urbanization, forest fires around the world occurred frequently in recent years, resulting in severe impacts on the safety of forest ecosystems [1, 2]. The geographical distribution of fire susceptibility was an urgent need to implement adequate management actions [3–6]. It was of importance to perform studies on modeling the susceptibility of forest fires [7, 8].

Meteorological factors (e.g., relative humidity, wind speed, air temperature, and precipitation) were thought to be important contributors to fire occurrence, which have already been adopted to forecast the fire risk in operational systems [9–12]. However, the occurrence of forest fires was also result of other environmental factors (e.g., land cover, topography, and human activity) [13, 14]. Thus, comprehensive models involving multiple factors were emerging in the development of modeling fire susceptibility [15, 16].

The similar development is also seen in the field of landslide susceptibility mapping [17]. Some studies reported that machine learning algorithms (e.g., random forest [18, 19], support vector machine [18], boosted regression tree [18], naïve Bayes classifier [20], and extreme gradient boosting [19, 20]) could be used for building comprehensive models.

Therefore, recent advances have mainly focused on utilizing machine learning algorithms to develop comprehensive models in fire susceptibility modeling. For instance, to map the fire susceptibility in Iran, Pourtaghi, literature [21] proposed Shannon's entropy and frequency ratio models for combining several environmental factors (i.e., topography data, soil texture, proximity data, normalized difference vegetation index, land use map, and meteorological data). Following that, literature [22] applied boosted regression tree, generalized additive model, and random forest to investigate the importance of 15 condition factors on forest fire and model fire susceptibility. Taking 10 ignition factors into consideration, literature [23] developed a fire susceptibility model using the neural fuzzy inference system at a tropical area. Thereafter, literature [15] established an evolutionary optimized gradient boosted decision tree model by incorporating 18 ignition factors of forest fires. In 2019, literature [24] utilized 10 related conditioning factors and occurrences data of previous fires to train the LogitBoost ensemble-based decision tree machine learning method for mapping the fire susceptibility at the Lao Cai region of Vietnam. Based on historical fire data and 8 risk factors, literature [16] proposed a new operational model with the ant-miner algorithm to predict the risk of forest fires in cloud-rich areas of southwestern China. More recently, involving 12 influencing factors, literature [25] employed a weighted approach to integrate the forest fire susceptibility outputs of different machine learning techniques in a forest-agriculture mosaic landscape of southern India.

Since the above models could not handle the presence-only data directly, a certain number of absence data (i.e., no-fire data from unburned areas) were generally required. However, areas lacking records of fire occurrence might not truly represent areas of fire absence [26, 27]. Therefore, the selection of no-fire data would bring uncertainties to modeling results. Recently, it was reported that genetic algorithm for rule-set production (GARP) could be a robust model, which could effectively deal with presence-only data [28–30]. Here, we made the attempt to apply GARP to propose a new model for modeling fire susceptibility.

Thus, the main objective is to propose a genetic algorithm-based model, which could process the presence-only data for mapping the susceptibility of forest fire. Furthermore, the susceptibility of forest fire in a mountain area of southwestern China was mapped and then was evaluated using a receiver operating characteristic analysis. Additionally, we try to investigate which environmental layers have significant influence on the susceptibility of forest fires in the study area. As a new attempt to process the presence-only fire occurrence data, the proposed model has the potential of being applied in other southwest regions of China and could provide guidance for the implementation of forest fire prevention and control measures.

2. Study Area

With an area of around 82,402 km^2, Chongqing city was selected in this research as the study area (see Figure 1). It was located in southwestern China, which was bounded by 105° 03′ to 110° 02′ E longitudes and 28°02′ to 32° 03′ N latitudes. This area was mainly comprised of high mountains and deep valleys with an altitude ranging from 73 to 2,797 m. It possesses a continental humid subtropical monsoon climate with an average relative humidity of 71–81%, an annual rainfall of 1,000–1,350 mm, and an annual average temperature of 16–18°C. The evergreen broad-leaved forest was the dominant vegetation type in the study area.

Due to its topographic, geological, and climate features, Chongqing city has experienced a more frequent occurrence of forest fires. This region was a typical area for carrying out studies on modeling the susceptibility of forest fires in mountain areas of southwestern China.

3. Materials and Methods

3.1. Input Fire Occurrence Data. With authorization access, fire occurrence data during the period 2000–2018 were applied for further studies. Locations of these fires were sourced from an operational monitoring system that was based on MODIS images and field surveys. Fire occurrence data includes attributes of latitude, longitude, and ignition time, which were accessed from Forest Fire Control Office of Chongqing and Forest Fire Protection Network of China in Chongqing city. In total, the number of fire occurrence data was 684.

Out of 684 fire data, 479 (70%) were randomly selected as the training sample and the remaining 205 (30%) were kept for validation purpose. Since GARP belongs to presence-only approach, which does not need the existence of no-fire data in training phase, only the same amount of no-fire data (205) were randomly sampled for model validation [31]. Finally, the total number of data used in this study was 889 (i.e., training sample: 479 and validation sample: 410), which is plotted in Figure 1.

3.2. Environmental Layers. Four groups of environmental layers influencing fire occurrence (i.e., annual weather, land cover, topographic, and human activity data) were used in the GARP approach (see in Table 1).

Daily weather data at 12 national stations across the study area were obtained first from the National Meteorological Network of China (https://data.cma.cn). Annual weather data (i.e., relative humidity, wind speed, temperature, and precipitation) were then calculated using daily weather observations during 2000–2018. Finally, annual weather data were interpolated to a grid of 1 km spatial resolution using the inverse distance weight method. Interpolations of annual relative humidity, annual wind speed, annual temperature, and annual precipitation were regarded as environmental layers in the following GARP approach.

Land cover was a crucial factor for fire occurrence, since it could provide specific information on the type and distribution of vegetation. Land cover data used in this study were obtained from the Resource and Environment Data Cloud Platform (https://www.resdc.cn/). These data have 1-km spatial resolution, which was an updated version of 2015 land cover data based on Landsat 8 remote sensing images in 2018. Land cover was regarded as one of the other environmental layers in the following GARP approach, which is illustrated in Figure 2(e).

Topography layers were considered other causes of forest fires. In this research, 20 digital elevation model images (ASTGTM2) with a spatial resolution of 30 m were downloaded from the Geospatial Data Cloud website (https://www.gscloud.cn/). To extract the elevation layer, ASTGTM2 data was were preprocessed using image mosaic and clipping operations in spatial analyst tools of ArcGIS software (version 10.2). Moreover, for matching the spatial resolution

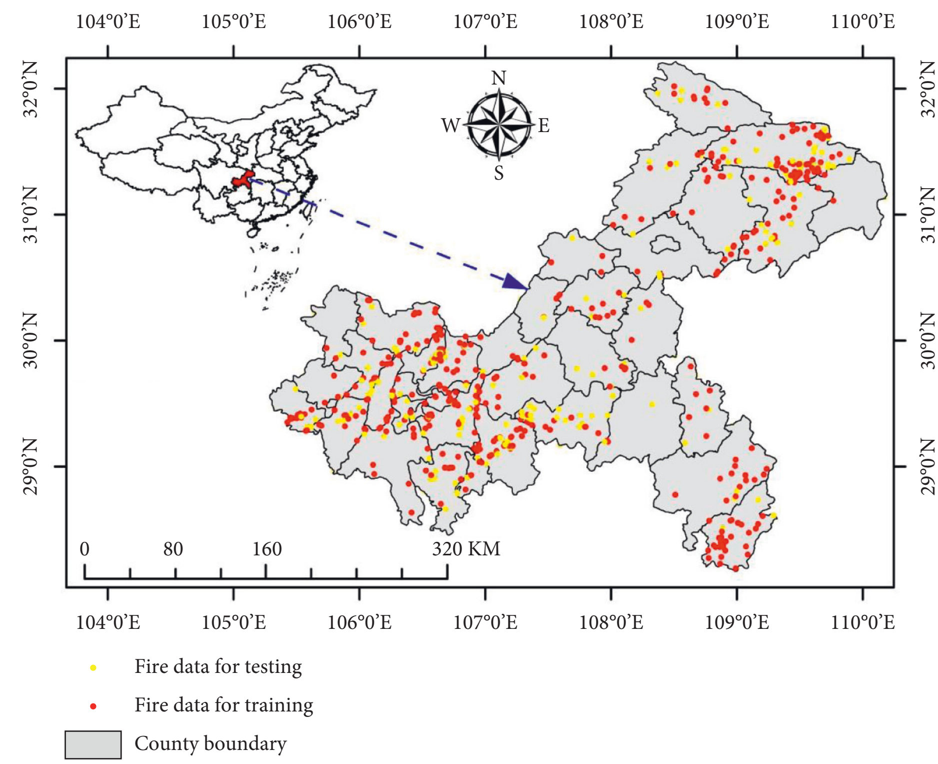

Figure 1: Locations of the study area and fire data.

Table 1: The details of data used in this study.

Category	Data	Type	Resolution/ scale	Source
Fire	Ignition	—	—	The Forest Fire Control Office of Chongqing and Forest Fire Protection Network of China
Annual weather	Relative humidity	Continuous	—	The National Meteorological Network of China (https://data.cma.cn)
	Wind speed	Continuous	—	
	Temperature	Continuous	—	
	Precipitation	Continuous	—	
Land cover	Land cover type	Discrete	30 m	The Resource and Environment Data Cloud Platform (https://www.resdc.cn/)
Topography	Elevation	Continuous	30 m	Geospatial data cloud website (https://www.gscloud.cn/)
	Aspect	Discrete	30 m	
	Slope	Continuous	30 m	
Human activity	Distance to the nearest road	Discrete	200 m	Baidu map (https://www.lbsyun.baidu.com/index.php)
	Distance to the nearest settlement	Discrete	1 km	

of other environmental layers, the bilinear interpolation was applied to resample the spatial resolution of elevation data (30 m) to 1 km. Based on resampled data, "Surface" tool of ArcGIS software was then employed to extract the other two topography layers (i.e., aspect and slope).

In addition, two other environmental layers (i.e., distance to the nearest settlement and distance to the nearest road) were used to assess the influence of human activity on fire occurrence. Based on settlement distribution and road network data in Chongqing city, we calculated the distance to the nearest settlement and the distance to the nearest road using a buffer analysis tool of ArcGIS software. These calculated layers were then discretized into equal intervals (i.e., distance to the nearest settlement: 0-1 km, 1-2 km, 2-3 km, 3-4 km, and >4 km and distance to the nearest road: 0–200 m, 200–400 m, 400–600 m, 600–800 m, and >800 m), according to our previous experience in this area [16].

3.3. Developing GARP Model. Through DesktopGARP program (version 1.1.6), a genetic algorithm for rule-set prediction (GARP) was performed in this study to model fire susceptibility (see in Figure 3). As an expert system and machine learning algorithm, this algorithm could develop a set of rules to relate fire occurrence data to environmental layers. These rules then could be projected

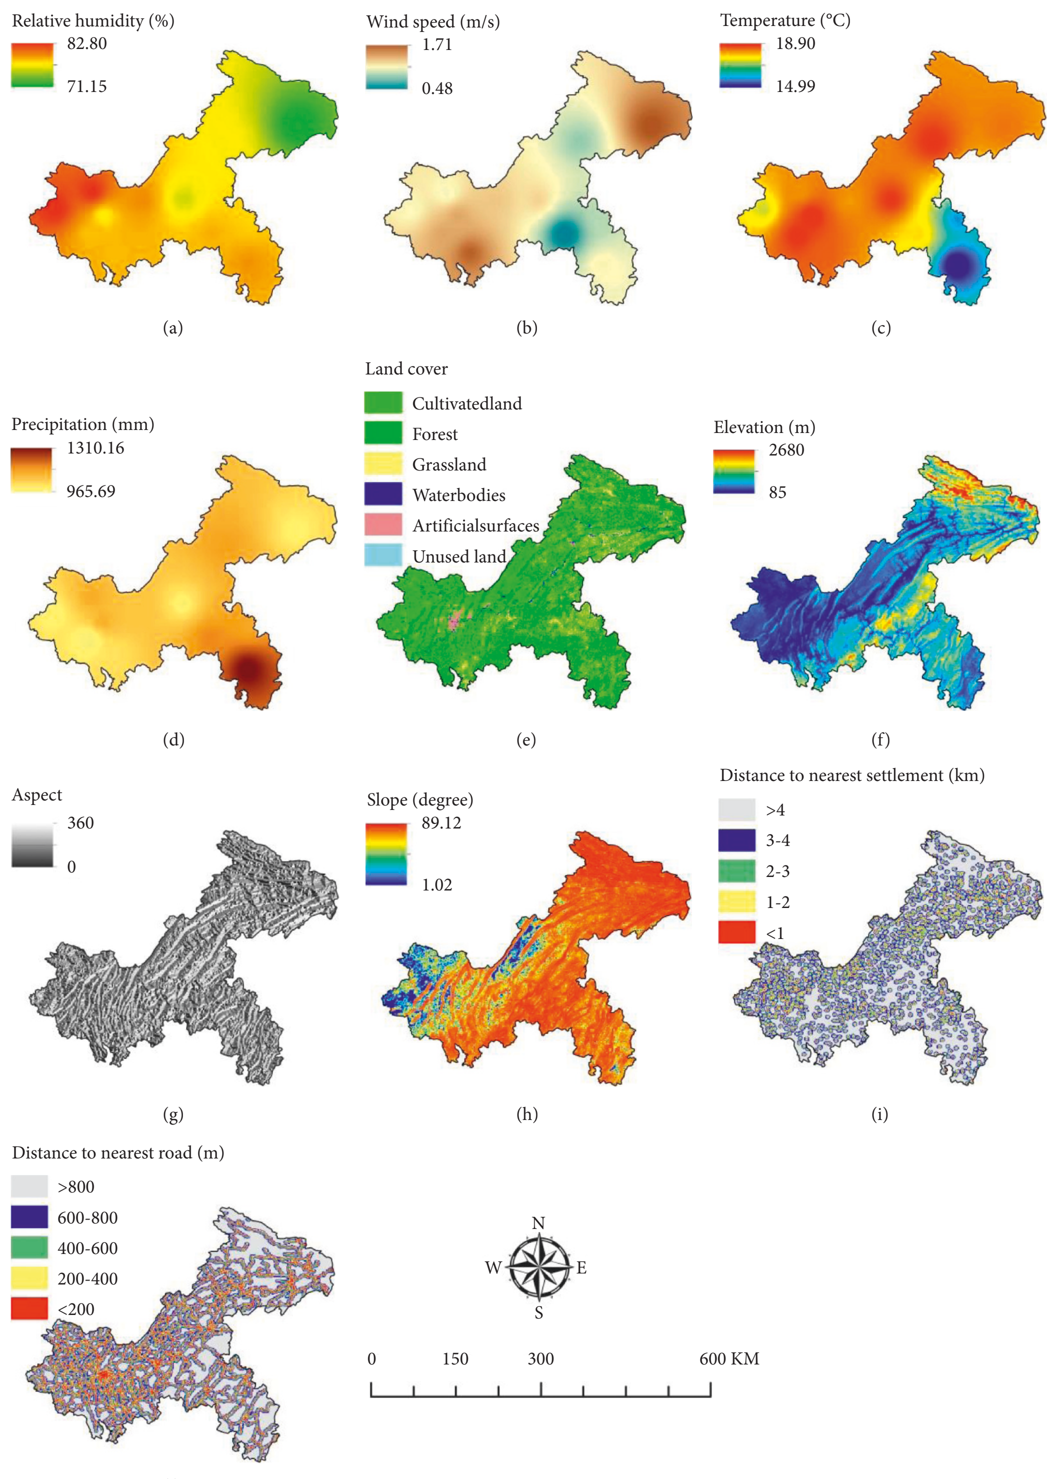

Figure 2: Environmental layers influenced the occurrence of forest fires: (a) relative humidity, (b) wind speed, (c) temperature, (d) precipitation, (e) land cover, (f) elevation, (g) aspect, (h) slope, (i) distance to the nearest settlement, and (j) distance to the nearest road.

onto a landscape and applied to model the fire susceptibility [32].

Before developing the GARP model, a jackknifing procedure was carried out to determine which environmental layers were more significant. This process was accomplished using an "environmental layers panel" in DesktopGARP, which could generate a set of tasks with various combinations of environmental layers. After running these tasks, a multiple linear regression was run to understand which environmental layers have a significant impact on resulting errors (https://www.nhm.ku.edu/desktopgarp/PrinterUM.html). Based on the analysis

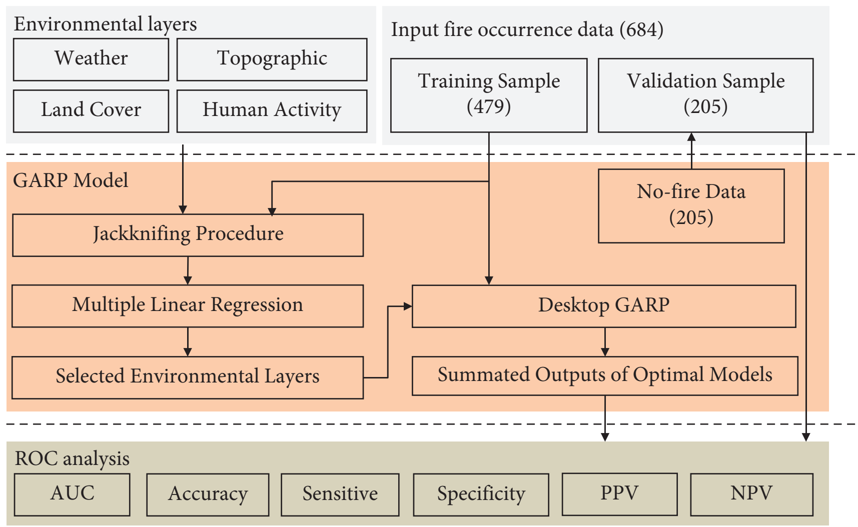

Figure 3: The flowchart of the proposed model: (a) data and processing, (b) model developing, and (c) model evaluating.

results, significant environmental layers were designated for subsequent experiments.

To optimize the parameters of the GARP approach, 200 models with max 1,000 iterations and a convergence limit of 0.01 were established in DesktopGARP (see Table 2). During the process of model building, the training sample (i.e., 479 data mentioned above) was internally divided into a 70%/30%. Then, 20 best models under 10% hard omission threshold and 50% commission threshold were selected using a subset approach in DesktopGARP. Finally, based on commission errors of these 20 subset models, output maps of 10 optimal models were imported into ArcMap software and summated using a raster calculator tool of spatial analyst extension. In the summated map, a higher pixel value means a greater potential of forest fires.

3.4. Evaluating Model's Performance. Based on the validation sample (i.e., 410 data mentioned above), the performance of the proposed model was evaluated using a receiver operating characteristic analysis (ROC). Area under curve (AUC) was measured and additional metrics could be calculated using the following formulas[24, 33]:

$$\begin{aligned} \text{accuracy} &= \frac{(TP+TN)}{(TP+FP+FN+TN)}, \\ \text{sensitivity} &= \frac{TP}{(TP+FN)}, \\ \text{specificity} &= \frac{TN}{(TN+FP)}, \\ \text{positive predictive value} &= \frac{TP}{(TP+FP)}, \\ \text{negative predictive value} &= \frac{TN}{(TN+FN)}, \end{aligned} \tag{1}$$

where TP is the true positive, FP is the false positive, FN is the false negative, and TN is the true negative

4. Results

4.1. Significant Layers Influencing Fire Susceptibility. Initially, 10 environmental layers influencing fire occurrence were selected to develop the GARP algorithm. However, to improve the effectiveness of proposed model, multiple linear regression analysis results in the removal of one environmental layer (i.e., slope). Specifically, the impact of environmental layers could be identified by P values in the multiple linear regression analysis. A smaller P value means a more significance of the environmental layer in modeling the fire susceptibility [34].

The results in Table 3 showed that P values of these layers respectively are as follows: distance to the nearest road ($P < 0.001$), land cover ($P < 0.001$), precipitation ($P < 0.001$), distance to the nearest settlement ($P < 0.001$), aspect ($P < 0.001$), relative humidity ($P < 0.001$), elevation ($P = 0.004$), wind speed ($P = 0.005$), and temperature ($P = 0.014$). All P values of these environmental layers were less than 0.05, indicating that the susceptibility of forest fires in Chongqing city was significantly influenced by human activities, land cover, and weather factors.

However, Table 3 further shows that the slope layer has a higher P value (i.e., $0.126 > 0.05$). This means that slope has an insignificant impact on the susceptibility of forest fires in Chongqing city. As a result, the susceptibility of forest fires was mapped using 9 environmental layers (i.e., distance to the nearest road, land cover, precipitation, distance to the nearest settlement, aspect, relative humidity, elevation, wind speed, and temperature), followed by performance evaluation.

4.2. Susceptibility Map of Forest Fires. After running the subset approach in DesktopGARP, 10 optimal models were developed and summated using ArcMap software. After that, a composite map was generated to illustrate the spatial

Table 2: Parameters setting in DesktopGARP.

Optimization parameters		Best subset selection parameters	
Runs	200	Omission measure type	Extrinsic-hard
Convergence limit	0.01	Omission threshold	10
Maximum iterations	1000	Commission threshold	50
Rule types	Atomic Range Negated range logistic regression	Total models under hard omission threshold	20

Table 3: Environmental layers influencing the susceptibility of forest fires.

Environmental layers	Coefficients	Standard deviation	t Stat	P value	Effect	Included or excluded
(Intercept)	44.165	0.452	97.634	$P < 0.001$	Significant	Included
Distance to the nearest road	−12.176	0.271	−44.856	$P < 0.001$	Significant	Included
Land cover	−9.574	0.271	−35.270	$P < 0.001$	Significant	Included
Precipitation	−3.104	0.271	−11.434	$P < 0.001$	Significant	Included
Distance to the nearest settlement	−2.987	0.271	−11.004	$P < 0.001$	Significant	Included
Aspect	−2.100	0.271	−7.738	$P < 0.001$	Significant	Included
Relative humidity	−1.497	0.271	−5.513	$P < 0.001$	Significant	Included
Elevation	0.781	0.271	2.877	0.004	Significant	Included
Wind speed	0.760	0.271	2.801	0.005	Significant	Included
Temperature	0.664	0.271	2.446	0.014	Significant	Included
Slope	−0.415	0.271	−1.530	0.126	Insignificant	Excluded

Note: environmental layers are ranked by P value.

distribution of fire susceptibility, in which a higher pixel value means greater model agreements and a higher fire risk level. Finally, the fire susceptibility map was categorized into 6 classes: very low, low, moderate, high, very high, and extremely high risks.

From Figure 4, it can be seen that high risk of forest fires (i.e., model agreements were higher than 8) primarily distributed in southwestern, central, and northeastern parts of the study area. This distribution was similar to that of human activity factors (i.e., distance to the nearest road in Figure 2(i) and distance to the nearest settlement in Figure 2(j)), which verifies a fact in Table 2 that distance to the nearest road and distance to the nearest settlement were more significant layers influencing the fire susceptibility.

On the contrary, Figure 4 displays that the risk of forest fires was low in the southeastern region of Chongqing city, where human activity was high and vegetation was rich. It is evident that a higher precipitation in this region (see Figure 2(d)) resulted in a changing distribution of forest fires. Also, the results in Table 2 verified that the precipitation layer was an important layer influencing the fire occurrence.

For the susceptibility map of forest fires (Figure 4), the area and percentage associated with each risk level can be found in Table 4. Specifically, 11.44% and 8.44% out of the whole study area were located in extremely high and very high fire susceptible areas. Moreover, 9.36% and 6.74% were located in high and moderate fire susceptible areas, respectively. Furthermore, 4.39% and 59.64% were located in very low and low fire susceptible areas, respectively.

4.3. Model Performance. As an effective technique to measure model's performance [18], a ROC analysis was applied in this study to evaluate the performance of the proposed model. In particular, based on the validation dataset mentioned above, the ROC curve was illustrated by plotting the false-positive fraction of the proposed model on x-axis and true-positive fraction of the proposed model on the y-axis. If the proposed model has no effect on fire susceptibility modeling, the ROC curve is close to the upper left corner (i.e., 1 : 1 line) and its AUC value will be 0.5 [11]. A value between 0.85 and 0.95 means a good performance of the proposed model [31].

The results in Figure 5 showed that the AUC value was 0.869, which indicates that the GARP model has a good performance. Moreover, Figure 5 demonstrates other 5 metrics to measure model's performance, that is, accuracy, sensitivity, specificity, positive predictive value, and negative predictive value, separately. Figure 5 shows that accuracy was 0.732, sensitivity was 0.59, specificity was 0.873, PPV was 0.823, and NPV was 0.681. These additional quantitative metrics further suggested the validity of the proposed model.

5. Discussion

5.1. Result Analysis. Unlike traditional models [16, 21, 22, 24], the proposed model does not require the input of no-fire data. This means that additional uncertainties caused by the selection of no-fire data would not affect the modeling results, since forest areas lacking records of fire occurrence might not truly represent areas of fire absence [26, 27]. Our obtained results also further verified that the proposed model has a good performance with an AUC value of 0.869 and accuracy value of 0.732, which were close to results of our previous studies in this area (i.e., accuracy values were from 0.58 to 0.79) [16].

However, for the proposed model, modeling tasks in this research might be more challenging. Specifically, due to

Table 4: Area and percentage of each risk level in the susceptibility map of forest fires.

Class	Area (km^2)	Percentage
Very low risk	46511	59.64
Low risk	3420	4.39
Moderate risk	5255	6.74
High risk	7300	9.36
Very high risk	6579	8.44
Extremely high risk	8920	11.44

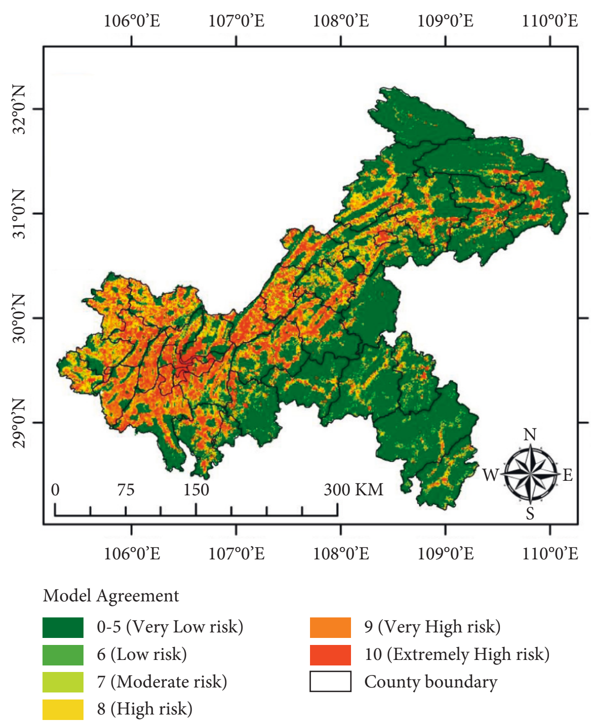

Figure 4: Susceptibility map of forest fires using the proposed model.

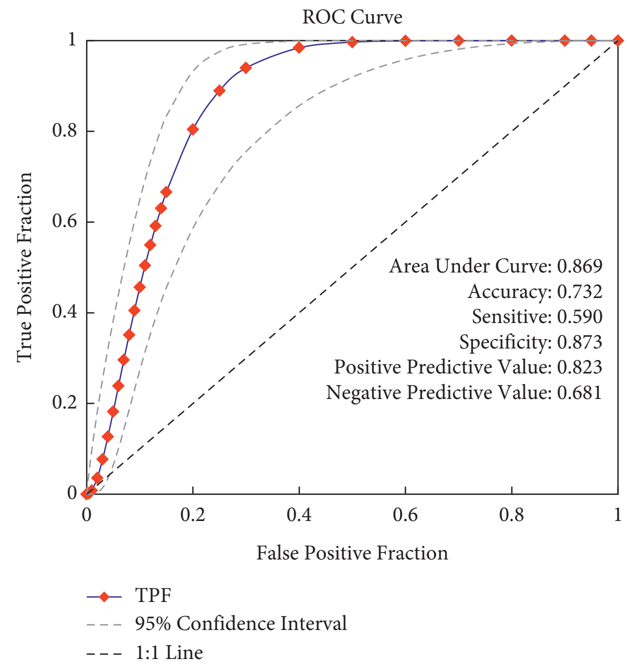

Figure 5: Performance evaluation of the proposed model using ROC analysis.

input limitations of DesktopGARP, annual weather data were applied as model inputs. Compared to daily weather data used in [16], the annual weather data might not be accurate indicators of weather conditions on the day of fire occurrence. Therefore, if daily weather data were applied in future studies, there was a further space for improving the accuracy of proposed model.

Compared to maximum entropy models (i.e., a different presence-only model [35]), the proposed model in this study has a higher accuracy. In particular, the maximum entropy models (Maxent) have been utilized to develop a new daily fire danger index [36], to predict the possibility of lightning-caused fire occurrence [37] and to examine the spatial distribution and temporal variation in forest fire occurrence [38]. Accuracies of these studies in terms of AUC value were 0.752 to 0.852 [36], 0.866 [37], and 0.816 to 0.847 [38]. These reported studies further verified the validity of the GARP model in modeling the susceptibility of forest fires.

Moreover, the results in Table 2 showed that the slope layer has an insignificant influence on fire occurrence in this research, even though slope could affect the fire spread rate [21, 24]. This is consistent with findings by Dlamini [26]. The main reason might be that the topography of Chongqing city (i.e., a famous mountain city in China) was dominated by high mountains and deep valleys (see Figure 2(h)). Figure 1 exhibits that fire occurrence data were primarily distributed in mountainous areas with steeper slopes. With low variations at these fire data locations [26], slope factor would have an insignificant effect on the modeling results.

Findings in Figure 2, Figure 4, and Table 2 indicated that human activities significantly influence the susceptibility of forest fires. The spatial distributions of high risks were similar to spatial distributions of distance to the nearest road in Figure 2(i) and distance to the nearest settlement in Figure 2(j). In a mountain city like Chongqing city, road network and settlement distribution mean an easy accessibility of facilities and services [39]. Therefore, these two factors could effectively reflect the intensity of human activities, which could significantly impact on fire occurrence.

Similar to the results in some reported studies [5, 16, 23], findings in Figure 4 and Table 2 indicated that land cover and weather factors greatly affect the fire susceptibility. The primary cause of this was that land cover and weather factors have great influences on fuel moisture and loading [26].

5.2. Improvement Strategy. Based on DesktopGARP program, a new model using the genetic algorithm was proposed in this study to model the susceptibility of forest fires. As a new attempt to process presence-only fire occurrence data, the proposed model would not bring uncertainties to the modeling results. And, our findings suggested that the proposed model has a good performance in modeling the susceptibility of forest fires. However, these findings should be interpreted guardedly.

The proposed method achieved better results in a mountain area of southwestern China. To further verify its validity, more studies need to be carried out in a wider range of forest ecosystems. Meanwhile, beyond environmental layers used in this study (i.e., annual weather, land cover, topographic, and human activity factors), more factors influencing the occurrence of forest fires should be considered in the building of the susceptibility model in future research.

Moreover, accurate weather data were critical to improve the model's performance [16]. In this study, due to input limitations of the DesktopGARP algorithm, the proposed model was only able to handle annual weather data. This would hinder the performance of the proposed model. Therefore, more efforts need to be devoted to future research to improve the performance of the proposed model in handling daily weather data.

Furthermore, the presence-only model showed a great advantage when absence data of species were unavailable [31, 32]. It has been successfully applied in spatial modeling of disease [28, 40, 41], habitat predicting of species distribution [42–44], and hazard mapping of natural disasters [45–47]. Since wildfires have similar conceptual and mathematical rules with plants or animals, ecological niche modeling would be an inductive approach to compute wildfires ignition and spreading likelihood [48]. Therefore, in future studies, more ecological niche modeling could be further considered for modeling the fire susceptibility.

6. Conclusions

As a very destructive natural hazard, forest fire frequently occurred in mountain areas of southwestern China. Numerous models were proposed to model the fire susceptibility, which could facilitate the implementation of effective prevention and control measures. However, since a certain amount of absence data are required to train traditional models, uncertainties could be introduced into modeling results. Thus, a new model using GARP approach was utilized to process presence-only data in modeling the susceptibility of forest fires in Chongqing city. Initially, 479 fire occurrence data were applied to train the proposed model with 10 environmental layers. In addition, 205 fire occurrence data and 205 no-fire data were used as the validation dataset. Based on them, the proposed model was evaluated using a receiver operating characteristic analysis with metrics of AUC, accuracy, sensitivity, specificity, positive predictive value, and negative predictive value. The results showed that distance to the nearest road, land cover, precipitation, distance to the nearest settlement, aspect, relative humidity, elevation, wind speed, and temperature layers have significantly influence on the spatial distribution of fire susceptibility in Chongqing city. Conversely, the slope layer has an insignificant effect on modeling results, since its P value was more than 0.05. Furthermore, the ROC results showed that AUC was 0.869, accuracy was 0.732, sensitivity was 0.59, specificity was 0.873, positive predictive value was 0.823, and negative predictive value was 0.681. These metrics revealed that the proposed model has good performance. To further verify model's validity, more studies need to be carried out in a wider range of forest ecosystems. Moreover, the performance of the proposed model could be improved by using accurate weather data in future research.

Data Availability

Data used to support the findings of this study are available from the corresponding author upon request.

Conflicts of Interest

All the authors do not have any possible conflicts of interest.

Depression is one of the most common psychological problems faced by human society. Because of less social experience, low psychological endurance, and the multiple responsibilities of future families and society, college students have become one of the most vulnerable groups to suffer from depression. This paper explores an automatic identification method to identify patients with early depression tendency through deep mining of online information of campus social platform users. First, we comprehensively analyze the common characteristics of emotion and behavior on the campus social platform for depression. Secondly, the experimental corpus is formed by preprocessing operations such as deprivation, word segmentation, and denoising of the original data. Finally, the depression recognition is transformed into a text classification problem, and a shallow support vector machine and a deep convolutional neural network model are, respectively, constructed based on the experimental corpus. Combined with the features of depression blog, the algorithm was further improved, and a dual-input convolutional neural network algorithm compatible with multiple features was proposed. The experiments showed that the recognition rate was effectively improved.

1. Introduction

Depression is one of the most common psychological problems faced by human society. The harm and impact of depression are very serious. Suicide rates among people with depression are very high, with 3,000 people with depression committing suicide every day worldwide [1]. Considering the personal suffering of depression patients, the impact on relatives and friends, and the resources spent on treatment, it can be said that depression has become a heavy burden on human society. In college students, a special group with less social experience and low psychological endurance, but also bearing multiple responsibilities of future family and society, the incidence of depression is significantly higher than that of the general population.

In order to fight against depression, people have done a lot of research on its causes, diagnosis, and treatment and put forward diagnostic methods based on psychology and physiology, such as various scales. Traditional diagnostic methods mainly obtain basic information about people's psychological and physiological states through verbal communication, questionnaires, physical examinations, etc. From this information, the basis for diagnosis is obtained. In the process of diagnosis, the acquisition, processing, and analysis of information consume a lot of time, money, and material. The traditional method also faces a problem: very low medical treatment rate. Due to the lack of understanding of psychological problems, many people do not realize that they are suffering from depression and do not know whether to seek help when they have problems with their physical and mental health. Some people have a biased understanding of psychological problems such as depression, and they avoid treatment because they feel that "family ugliness cannot be made public." There are also some people who cannot seek medical treatment due to the relative lack of medical resources. Coupled with the influence of factors such as a certain missed diagnosis rate in medical institutions, the overall actual consultation rate of patients with depression is very low. Traditional diagnostic methods can only detect a subset of the many people with depression—the ones who come to a medical facility for help. That is, other people will face depression helplessly. Passively waiting for depression patients to seek help as is currently done will result in very low rates of consultation and depression will continue to rage. If medical institutions can take the initiative to look for patients with depression, such as directly conducting psychological surveys on college students, the rate of seeing a doctor will be greatly improved. Of course, the cost of doing so is relatively high. Consider that when a person seeks medical help for depression, the depression has already taken a toll on him, and treatment is more difficult. We need "active defense," which is to detect the person when the depressive tendencies are not too severe, so that help or treatment can be given in a timely manner.

The advent of the Web2.0 era and the emergence of online social media, such as blogs, campus social platforms, and other social networks, provide a place for many people with depression tendencies to vent their emotions. At the same time, based on the analysis of massive interactive information on social networks, we may provide a platform for actively discovering people who are prone to depression [2]. Especially as each high school has its own social platform, the students of the school publish information on the social network, and the campus management department can master a large amount of social network data. These data record students' thoughts, opinions, and details about their lives. By mining the massive data in the campus social platform, a lot of important information and knowledge can be found. In our recent online information observation on campus network online users, we found that some users, due to the high pressure of life, showed many psychological problems [3]. In severe cases, the language manifestations of depression and suicide occurred.

This paper will propose a classification model based on natural language processing and machine learning that takes into account both generality and accuracy, to actively and efficiently discover students with depression tendency from campus social platforms. The method proposed in this paper allows us not to wait for depressed patients to seek help, but to actively search for people with depression tendency from the crowd, which will enable medical institutions and nonprofit organizations to gain the initiative in fighting depression. Since the recognition process is completed automatically by computer, the speed and accuracy have unique advantages compared with manual work, so that we can quickly and timely find people who are prone to depression and can find the target in time, which greatly improves the efficiency of intervention [4]. For college students with high network activity, it is appropriate to use the method proposed in this paper to assess the state of depression. This method will greatly improve the ability of universities and other institutions to deal with students' depression, thereby reducing the harm caused by depression to the student population.

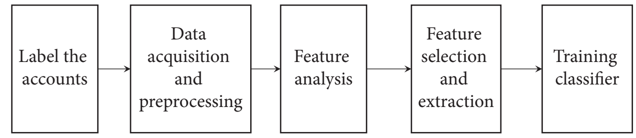

Figure 1: Classifier design process.

2. Identification Process

2.1. Model Design Idea. The campus social platform of colleges and universities is an important platform for students to communicate. It has the characteristics of huge user scale and convenient data acquisition. It is an important data source for campus management. Therefore, this paper selects users of a university campus social platform as the research object. Based on the data of campus social platforms, an effective method to automatically identify depression-prone users in campus social platforms is established. The process of model design is shown in Figure 1.

2.2. Annotated Account. This study is based on the assumption that "the language and behavior of campus social platform users who are prone to depression are different from normal users" [5]. To test this hypothesis, we first need to find a certain number of users who are prone to depression and normal users to establish a sample data set.

We randomly obtained a certain number of user IDs and manually labeled these accounts into two categories: "depressive tendencies" and "normal." In order to reduce the impact of class imbalance problem on the classifier, we do not keep the UID of all "normal" users. Then, the campus social platform information of these users is captured through the API provided by the Sina campus social platform, and after a certain preprocessing, it is used for training and testing the machine learning model. The labeling of the samples is done manually, and the process is as follows:

(1) Receive certain training, such as learning the basic knowledge of depression, diagnostic scales, and judgment of depression tendency.

(2) Groups that users with depression tendencies from campus social platforms may gather.

(3) Two of them independently annotated the obtained user set and divided the users into two categories: "with depression tendency" and "without depression tendency."

(4) The labeling results of the first two people were checked by a third person (the labeling rate was found to be more than 90% identical), and the labeling results were independently corrected.

2.3. Experimental Data Acquisition and Preprocessing. Data preprocessing is to process the original experimental data into experimental corpus that can be directly operated by the computer, and its operation mainly depends on the experimental data and algorithms. In this study, a supervised deep learning algorithm was used to perform binary

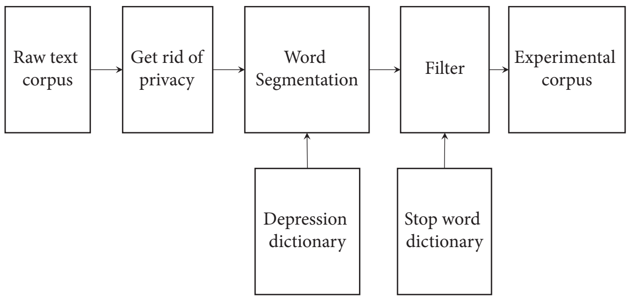

Figure 2: Text preprocessing process.

classification of text on campus social platforms, thereby realizing depression identification. Its preliminary work mainly includes labeling, word segmentation, denoising, feature, and algorithm selection; these operations have a direct impact on the subsequent experimental results. Reasonable preprocessing operations are a crucial step in text classification, and these operations are described in detail in this section.

Text preprocessing mainly includes word segmentation and denoising, and the specific process is shown in Figure 2. Since Chinese words do not have obvious delimiters like English words, it is necessary to divide sentences into words one by one through word segmentation. The language expressions of campus social platforms are relatively casual and do not strictly follow traditional language norms and often insert special symbols [6]. It belongs to the text with high noise content, and denoising processing is very necessary.

This experiment uses Jieba word segmentation implemented in Python to segment the text. Jieba comes with a dictionary containing more than 20,000 Chinese words, and its word segmentation speed and effect are relatively good. This experiment adopts Jieba's precise mode, which combined with the domain dictionary can cut the experimental data more accurately, which is suitable for text analysis of campus social platforms. In order to further maintain the integrity of the semantics, some domain terms and network neologisms are avoided to be excessively segmented [7].

2.4. Feature Selection. Data features are the main internal factors affecting text classification, and reasonable feature selection can effectively improve the accuracy of experiments. By researching and analyzing the characteristics of the "tree hole" campus social platform, referring to depression-related materials, we conducted in-depth mining from two aspects of the text itself and extended information and comprehensively extracted the characteristics closely related to the depression campus social platform. In terms of content, it mainly includes two features, namely, the semantic features of the text itself and the dictionary features. In addition, some features expanded from the content can also reflect the behavior of the campus social platform of depression [8]. To sum up, the features selected in this paper mainly include three modules: semantic features, extended features, and dictionary features. The specific description is shown in Table 1.

These three characteristics are described in detail below.

Semantic features refer to the semantic information contained in the text itself, which can reflect the structure and contextual semantic relationship and reflect the publisher's expression form and overall emotional trend, which is of great significance for recognition. This part of the features will be automatically extracted by deep learning algorithms. Dictionary feature is whether the text contains dictionary words. The anomalies of these campus social platform texts are mainly reflected in two aspects: emotion and behavior. For example, it contains a large number of negative words such as "pain," "life is better than death," and various kinds of thought expression and suicide methods such as "want to die," "cut your wrist," and "burn charcoal" are also frequent sentences in the "tree hole." These sensitive words fully reflect the patient's condition, so the dictionary features of these words are very important.

In this paper, a dictionary database is constructed for the field of depression campus social platform. The specific dictionary features are described in Table 2.

Affected by depression, the campus social platform behaviors of depressed patients have some notable characteristics, which are extended from the campus social platform content, so they are called extended characteristics, for example, the release time of the campus social platform, the length of the text, etc. These extended features are closely related to the symptoms of depression, and only by fully mining these valuable features can the identification of depression be optimal [9]. Through a comprehensive analysis of the symptoms of depression and the characteristics of the campus social platform, it is found that the text of the campus social platform for depression has many individual and abnormal characteristics and further artificially extracts each extended feature. The main features are as follows:

(1) Through statistical analysis, the most frequent update time is from 10:00 pm to 2:00 am.
(2) The language expressions of depression patients on campus social platforms are more casual, the format is not standardized, and the length is generally shorter.
(3) Depressed patients pay less attention to the outside world, and the general campus social platform is original.
(4) Depression is more self-focused, interacts with others, and pays less attention to others, while the first-person singular "I" is often used in language, and the plural "we" is used less.
(5) Patients frequently use emoji and some suicide-related symbols on campus social platforms.
(6) Depression is more inclined to be puzzled and rhetorical about life experiences on campus social platforms and use questions more frequently.

3. Depression Recognition Model

This paper designs three different models for student depression identification.

Table 1: Features and definitions.

Features	Definitions	Example
Semantic features	Semantic information of text expressions on campus social platforms	Text itself statement
Extended features	Expanded features strongly associated with depression in campus social platforms	Time, length, originality, etc.
Dictionary features	Sensitive vocabulary that reflects depression tendency contained in campus social platforms	Sentiment dictionary, keyword dictionary, etc.

Table 2: Dictionary features.

Feature		Feature definition
Dictionary features	Sentiment dictionary features	Whether contains the vocabulary of the emotional dictionary
	Emoji dictionary features	Whether contains the vocabulary of the emoji dictionary
	Mood particle dictionary features	Whether contains the vocabulary of the modal particle dictionary
	New word dictionary features	Whether contains the vocabulary of the online new word dictionary
	Keyword dictionary features	Whether contains the vocabulary of the keyword dictionary
	Suicide tool dictionary features	Whether contains the vocabulary of suicide tools dictionary
	Dictionary of behavioral symbols	Whether contains the vocabulary of the behavioral symbol dictionary

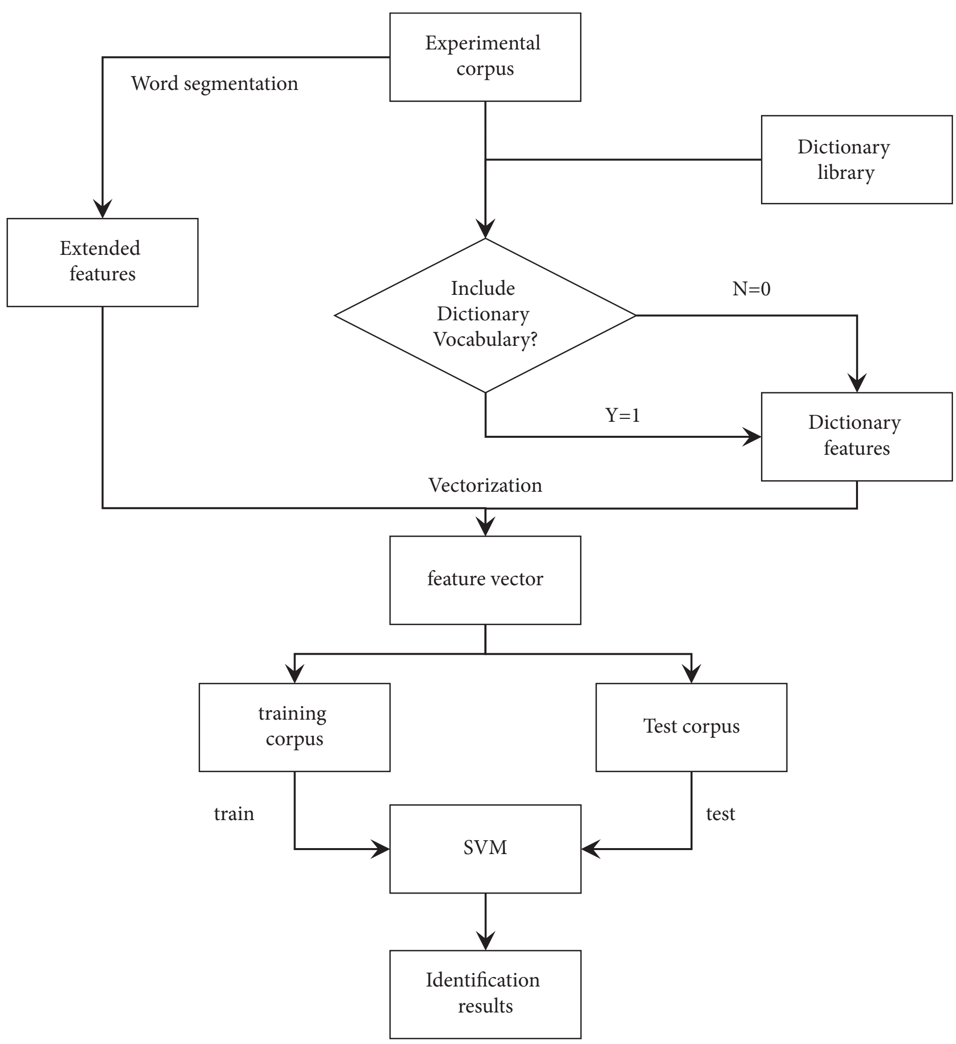

Figure 3: Identification algorithm based on SVM.

3.1. Depression Recognition Algorithm Based on Support Vector Machine. The input to the support vector machine algorithm is a vector, so the features need to be vectorized first [10]. In this paper, the support vector machine algorithm is used to classify text based on extended features and dictionary features, so it is necessary to vectorize these two features. The specific vectorization rules are as follows: In the extended feature, the description length of the campus social platform, the number of interactions on the campus social platform, the degree of social activity, the degree of collective attention, and the degree of self-attention are themselves numbers. Whether it is original, whether to use a positive expression map, and whether to use a negative expression map, the value of the feature value is 1, otherwise 0. The time feature is divided into day and night, corresponding to 1 and 0. All dictionary features are the number of corresponding dictionaries; if not, take 0.

The algorithm implementation process based on SVM is shown in Figure 3.

The SVM-based student depression recognition algorithm is as follows:

(1) Feature selection and vectorization: According to the feature selection and vectorization rules introduced above, on the preprocessed experimental corpus, Python language programming is used to realize the selection and vectorization of extended features, and the dictionary features are obtained by scanning the dictionary library.

(2) Model configuration: The experimental tool uses LIBSVM (A Library for Support Vector Machines) integrated tool for text classification experiments, which is the most widely used SVM algorithm tool developed by the Institute of Information Engineering, National Taiwan University. The tool is written based on C language, including standard SVM algorithm, probability output, support vector regression, multiclass SVM, and other functions and has call interfaces in JAVA, Python, R, MATLAB, and other languages. It is a relatively hot tool at present, and the experimental speed and effect are relatively good. This experiment calls the Python interface for model training.

(3) Model training and testing: The corpus is divided into training corpus and test corpus according to the ratio of 7:3, in which three types of dictionary features, extended features, dictionary features, and extended feature fusion, are trained and tested. The optimized parameters and training corpus are used as input for model training, and then the generated model is tested through the test corpus to output the experimental results.

3.2. Depression Recognition Algorithm Based on Convolutional Neural Network. The convolutional neural network model structure mainly contains five layers, each layer has its own function and is connected before and after. The input layer is used to input the processed matrix vector, which is converted from the word vector of the text. The main component of the convolution layer is a feature extractor (convolution kernel), which is mainly used to extract features and output feature maps. The convolution layer can contain multiple layers, and the front and rear layers are connected to each other. The pooling layer is mainly used to process a large number of feature maps output by the convolutional layer to reduce the amount of data while maintaining important feature information. The fully connected layer converts the features extracted by the previous layers into one-dimensional features [11]. The output layer takes the one-dimensional features of the fully connected layer as input and then uses a classification algorithm for classification, such as softmax logistic regression. The specific description of each layer is as follows:

The input layer is used to obtain experimental data, and the input of the convolutional neural network for text classification is a matrix vector. Therefore, it is necessary to convert the vocabulary into a vector and use the word vector of each word in the sentence as a row to form a matrix vector of the sentence. Convolutional layers are the fundamental operations in convolutional neural networks. The convolution operation is actually a mathematical operation. This operation generally includes input, kernel function, and output feature map. Convolution is a local operation, and the local feature information of the data is obtained by applying a certain size of convolution kernel to the local area of the input data. Pooling layers are nonlinear downsampling algorithms. The pooling function replaces the data at the position with the overall statistical value of the adjacent data at the current position, which plays a dimensionality reduction role and ensures that the output data does not change much. Commonly used pooling functions are the maximum pooling function and the average pooling function. The fully connected layer is to stitch together the two-dimensional feature vectors output by the pooling layer and output the probability of each category through the softmax layer.

This paper uses the word2vec tool to generate word vectors, and reasonable parameter selection can effectively improve the training efficiency. In this paper, based on the specific conditions of the experiment, several important parameters are selected as follows: Compared with the CBOW model, the training time of the Skip-gram model is longer, but the accuracy is generally better than that of the CBOW model. Considering that the experimental corpus is relatively moderate, in order to obtain better experimental results, the Skip-gram model is selected for this experiment. Depending on the size of the context window of the word, the reflected information is also different. Generally, a small context window is more conducive to learning contextual semantic features and relationships. According to the characteristics of the experimental corpus, this paper adopts two values of 5 and 10, respectively. The training algorithm of the experiment adopts softmax, which has better effect with rare words and is suitable for the scene of this experiment. The specific parameters are shown in Table 3.

The experimental process based on convolutional neural network is as follows:

Table 3: Model parameters.

Parameter	Definition	Value
Sentences	Can be a list, transformed from the original corpus	Depression campus social platform corpus text
Sg	Used to set the training algorithm, 0 corresponds to the CBOW algorithm, 1 corresponds to the Skip-gram algorithm	1
Size	Refers to the dimension of the feature vector	200
Window	Indicates the maximum distance between the current word and the predicted word in a sentence	5, 10
Hs	1 corresponds to hierarchical softmax algorithm, 0 corresponds to negative sampling algorithm	1

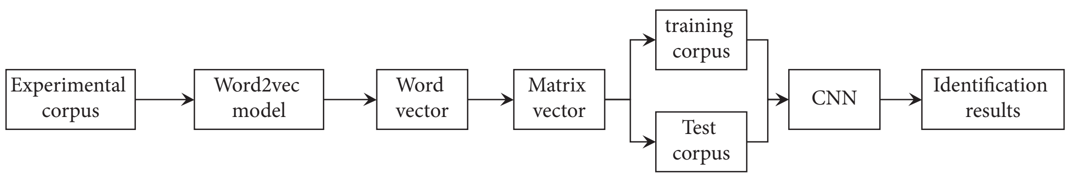

Figure 4: CNN-based recognition process.

(1) Word vector generation.

(2) Model parameter configuration: The algorithm used in this experiment is TextCNN, which is implemented in Python language based on the TensorFlow framework.

(3) Model training and testing: Divide the preprocessed experimental corpus into training corpus and test corpus in a ratio of 7 : 3, and use convolution kernels of 2, 3, and 4 to conduct experiments. First, the TextCNN model is trained through the training corpus and finally test corpus test model.

The whole recognition process based on convolutional neural network is shown in Figure 4.

3.3. Depression Recognition Algorithm Based on Dual-Input Convolutional Neural Network. As a shallow machine learning, support vector machine has better classification effect based on shallow extended features and dictionary features [12]. Convolutional neural network, as a deep machine learning algorithm, can automatically extract semantic features of text sequences for fast learning and efficient classification. However, neither of these two algorithms is compatible with all features at the same time, which reduces the recognition rate of depression to a certain extent. Expanding compatibility is the core of solving the above problems. This paper improves the convolutional neural network algorithm to achieve compatibility with all features.

By analyzing the model structure of the convolutional neural network, it can be found that its convolutional layer and pooling layer automatically extract features and feature dimension reduction for the input data, respectively. Finally, the extracted features are processed based on the full connection layer, and the predicted values are output through the full connection layer. The output is equivalent to all the features automatically extracted by the convolutional

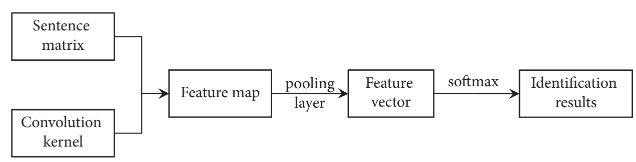

Figure 5: DI-CNN model structure.

neural network and finally classified by the output layer. Based on this, this paper proposes a dual-input convolutional neural network (dual-input-CNN, DI-CNN for short) algorithm. Its core idea is that the first four layers of convolutional neural network are unchanged; only the results of the full connection layer are integrated with the feature vector formed by the fusion of extended features and dictionary features and then classified through the softmax layer, so as to realize all feature fusion as input. The model structure is shown in Figure 5.

3.4. Experimental Results. In order to verify the influence of depression dictionary on depression recognition, the experimental evaluation standards used in this paper are precision rate P (precision), recall rate R (recall), and F-measure (F-measure) as evaluation standards. All experiments in this paper use this criterion, and they are defined as follows:

$$P = \frac{T}{E},$$
$$R = \frac{T}{N}, \tag{1}$$
$$F = \frac{2 \cdot P \cdot R}{(P + R)},$$

where T is the number of correctly classified samples; N is the actual number of samples of a certain category; E is the

Table 4: Experimental results.

Feature combination	P	R	F
Extended feature + dictionary feature + SVM	0.8280	0.7875	0.8072
Semantic features + CNN	0.6847	0.5507	0.6106
Extended feature + dictionary feature + semantic feature + DI-CNN	0.8305	0.8348	0.8321

number of samples predicted by the classification model as a certain category. The experimental results are shown in Table 4.

The experimental results and graphs show that the recognition rates of the three algorithms are DI-CNN, SVM, and CNN, respectively. At the same time, comparing SVM and CNN separately, the effect of SVM is better, which further shows that the artificially extracted shallow features have a better effect on the recognition rate of depression.

4. Application Prospects of the Model

The first threshold of depression treatment and research is identification. The identification of depression in this paper is only a preliminary judgment on whether there is a tendency to depression. However, in practical applications, this is only the initial stage, and the relevant medical staff still need to dig deep into the patient's situation. It mainly involves the following aspects: the cause of depression, the type of disease, the severity of the disease, etc. In fact, on the social platform, the campus social platform that is updated at high speed every day contains the daily life trajectories and emotional ups and downs of users. Fully mining this information can greatly reduce the workload of people and assist medical staff to implement treatment quickly and accurately. Therefore, in-depth analysis of the campus social platform for patients with depression can be carried out in the following aspects in the future:

(1) Mining user information based on the time dimension: Identification based on a single campus social platform will lead to fragmented information, and it is impossible to comprehensively obtain the patient's condition. From the perspective of time, track the campus social platform dynamics of a campus social platform user for a period of time, and comprehensively analyze their life trajectory and emotional fluctuations during this period, as well as the relationship between the two. In this way, it is easy to find the cause of the user's illness and further infer the patient's disease type.

(2) Mining user information based on spatial dimensions: tracking the location information disclosed by patients on campus social platforms and analyzing the user's environment, personal identity, surrounding crowd, and other information based on this spatial information. It can not only assist in judging the cause of the user, but also provide rescue information for rescuers.

(3) Depression grade assessment: Depression patients have different degrees of illness; some are in the initial stage of mood swings, while others may have serious suicidal tendencies. By grading depression, it is possible not only to quickly locate those patients with suicidal tendencies and take rescue measures, but also to prevent those primary ones in advance.

To sum up, further build a depression rescue chain with the school social platform as the core, fully tap the text information on the platform with the help of natural language technology, and monitor and extract the following user information: 1. The user's symptoms, etiology, degree of illness, and whether there are suicidal tendencies; 2. Personal information, social relations, time, and space. Based on this, the patient's condition and information knowledge map are, respectively, constructed to realize the full integration of technicians, medical personnel, psychologists, and rescuers. The knowledge map is mined and constructed by technical personnel, analyzed and diagnosed by medical personnel, and treated and psychologically counseled by medical personnel or psychologists according to different situations. If there is suicidal behavior, rescuers can quickly locate and rescue through the user information knowledge map. This will be the development direction of college students' depression identification and treatment.

5. Conclusion

In view of the current problems in depression identification, this paper proposes a depression identification method based on campus social platform text and deep learning. It not only effectively avoids the problem of patients not taking the initiative or cooperating, but also can obtain sufficient data for research. This method of turning passive into active discovery reduces the harm caused by direct diagnosis of patients and provides support for medical staff to quickly identify and treat patients. At the same time, in order to improve the feasibility and recognition rate of the algorithm, this paper has made the following improvements:

(1) The construction of the dictionary: fully excavate the vocabulary of depression on social platforms, and combine the characteristics of depression patients with negative emotional tendencies and suicidal tendencies in actions to construct three major emotional dictionaries, behavioral keyword dictionaries, and behavioral dictionaries. Suicide-related dictionaries are gathered into a comprehensive dictionary library for the depression campus social platform, which makes up for the lack of dictionaries in this field.

(2) Feature selection: Depression blogs have their own features, not only in the text itself, but also in some extended features that are closely related to

depression. This paper fully integrates semantic features, dictionary features, and extended features to ensure the optimal recognition rate of depression.

(3) Algorithm improvement: Based on the three selected feature modules, support vector machines and convolutional neural networks were used for experiments, but these two algorithms were not compatible with all features at the same time. Therefore, this paper proposes an improved two-input convolutional neural network, which realizes multifeature fusion input, and further improves the experimental effect.

Through comprehensive analysis and experiments, this paper still has some shortcomings, mainly involving the following two aspects:

(1) Although this paper extracts relevant features more comprehensively, the influence of each feature is different; for example, dictionary features, time in extended features, and other features can better reflect whether the user suffers from depression. Therefore, it is very necessary to weight each feature, which is also the next research direction.

(2) The convolutional neural network used in this paper is suitable for short text classification. Although most of the campus social platforms are short texts, there are also users who use long sentences to describe their situation comprehensively. At this time, it is easy to cause the mining of these information. Therefore, follow-up research can select different deep learning algorithms according to the length of the blog. If it is a long blog we can use a recurrent neural network.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

Digital technology plays an important role in promoting the development of the animation industry. With the rapid development of digital technology in China, the wide application of digital technology in the animation field has become a new method of animation production, which also is an important way for the development of animation major in colleges. This paper studies the collaborative innovation of animation majors in colleges under digital technology, combined with the driving effect of digital technology on animation major, and a collaborative innovation system of animation major based on digital technology is constructed. Based on this, a collaborative innovation platform for animation projects is designed, which is dominated by universities and supplemented by governmental enterprises. The basic functions of animation knowledge integration, animation knowledge maintenance, animation knowledge retrieval, and animation knowledge sharing are implemented. The platform not only innovates the teaching mode of animation major in colleges but also promotes the development of the animation industry, which has practical applicated value.

1. Introduction

Animation industry is the core industry of global economic development in the 21st century and is also a way of inheriting traditional Chinese culture [1]. The animation technology specialty has strong social practicality, which is of great significance for training animation professionals and promoting the development of the animation industry. At present, the enrollment of animation major in colleges is increasing year by year, with wide coverage and gradually increasing teaching difficulty. How to promote the reform of education in digital animation has become a problem faced by higher vocational colleges in China. The development of the animation field cannot be separated from computer technology, which is an important part of the animation field [2]. Under the influence of economic globalization, the wide application of computer technology in collaborative innovation of animation specialties is not only a sign of the arrival of the era of science and technology but also an effective measure to promote its evolution. The driving effect of computer technology is mainly reflected in computer technology in 3D animation, animation synthesis, paperless animation, and other fields [3]. On the one hand, the technology of virtual reality has been implemented in the animation field through computer technology; on the other hand, it has also achieved the development of other related industries. Therefore, the wide application of computer technology not only expands the expression space of animation, enriches the expression forms of animation works, and improves the efficiency of animation creation but also promotes the innovation of the animation industry, the spread of animation works, and the development level of the animation industry, which is conducive to the further advance of China's animation design industry.

2. Construction of Collaborative Innovation System of Animation Specialty in Colleges under Digital Technology

At present, the concept of animation design in China is relatively simple, with lack of innovation ability in the animation industry not high, and the design it is monotonous [4]. Science and technology, intelligence, and electronization are the main trends of the animation industry in the future. Traditional computer technology can only fulfill 2D animation and graphic animation, while the application of digital media technology makes animation design and production efficient, which greatly promotes the development of China's animation industry.

Collaborative innovation of animation specialty in colleges under digital technology needs to build a third-order practical teaching system, in progress, of professional skill studios (graphic design, animation production, and VR), animation R & D center, and entrepreneurial base for college students based on the curriculum design of animation major in colleges, as shown in Figure 1.

The collaborative innovation system of animation is based on animation practice, which cultivates professionals through skill training, animation research and development, and incubation base construction. Of course, the innovation and development of the animation major require not only the drastic reform of the course teaching in colleges and universities but also the cooperation between the government and enterprises and the collaborative innovation of the three parties above. Only in this way can we achieve the goal of cultivating professionals in animation.

Colleges should make use of digital technology to carry out public courses, professional courses, and postpractice to carry out the training of basic skills. They also need to design open practice for students of different levels and apply three-dimensional software, such as ZBrush and 3Dmax to the design of creative animation, model animation, and the achievement of teaching effect and evaluation [5]. Constantly, colleges are supposed to cultivate the consciousness of integrating diversified science and technology into animation production and design, among students, so as to improve their comprehensive ability and lay the foundation for their entry into the animation industry.

Enterprises should provide internship positions for students majoring in animation and set up three studios [6] for graphic production, 3D animation, and postproduction. They need to fully popularize the teachers by using AR technology according to the requirements of technical staff in enterprise and set up various technical centers such as hand-painted galleries, holographic projection, and animation industry base, to ensure more effective innovation of digital technology from a developmental perspective and the cultivation of professionals learned in the new era.

The government should provide more practical opportunities for students majoring in animation through policy inclination, give full play to the government's role as an organization and bridge, formulate supporting policies for related enterprises with school-enterprise cooperation, ensure full supervision and evaluation, and ensure the integration of production and education [7].

Under the background of digital technology, only through the deep cooperation of government, universities, and enterprises, the use of modern digital technology, the integration of manpower, material resources, and technology, and the establishment of a collaborative innovation platform of animation production technology can the innovation and practice of animation specialty be promoted.

3. Design of Collaborative Innovation Platform for Animation Projects Based on Digital Technology

Economic globalization promotes the development of technological innovation and the design of animation industry towards globalization, decentralization, and synergy, while knowledge is becoming an important element of the development in animation [8]. The animation industry involves the integration of technologies in computers, networks, process of graphics and images, signal processing, and other fields. It also includes basic techniques of digital media, a platform of digital media, service technology, and technology of application in the digital media field [9]. Combined with the collaborative innovation system of animation major, it is necessary to integrate the assets of universities, enterprises, and governments into their own systems and reorganize the animation assets of these parties in the form of knowledge, so as to really play their role and to build an ontology-based collaborative innovation platform for animation projects, which provides an online communication channel for universities, enterprises, and governments.

3.1. Demand Analysis. In the process of collaborative innovation of animation, knowledge is distributed in universities, governments, enterprises, and other units, involving a wide range. Knowledge about animation is also distributed in various departments, such as personal computers, enterprise servers, archives, personal minds, backup data, and the Internet. [10]. How to integrate scattered knowledge and realize exchange and sharing is a difficulty [11]. This study tries to integrate the animation resources of universities, governments, and enterprises and provides diversified paths for collaborative innovation of animation majors in universities by constructing a collaborative innovation platform; therefore, the platform needs to implement the following basic functions:

(1) Expression of animation knowledge: individual knowledge is one of the important sources of unit knowledge. Animation knowledge in universities, governments, enterprises, and other departments has its unique storage format. If animation knowledge is expressed and formalized randomly, it will cause the problem of knowledge heterogeneity [8]. Therefore, it is necessary to clarify the expression and formalization of animation knowledge, form a specific format of sublanguage and ontology library, and build a common ontology so as to provide a theoretical basis for the expression and formalization of individual knowledge, thus effectively reducing the heterogeneity of knowledge.

(2) Maintenance of animation knowledge: the maintenance of a date is an indispensable function for any knowledge application [12]. Collaborative innovation of animation major in colleges is a dynamic

process, and the discovery and updating of knowledge in the development process are inevitable. It is usually impossible to abstract and solidify all knowledge at the beginning of a project. Therefore, it is necessary to maintain and handle animation knowledge in good time. Therefore, this improves the expandability of the collaborative innovation platform of projects.

(3) Animation knowledge retrieval: the knowledge retrieval function of animation is the main means for users to acquire animation knowledge from the system, which is realized by querying, and it is also the main function of the collaborative innovation platform of animation projects that needs to be implemented.

(4) Animation knowledge sharing: actually, animation knowledge does not exist independently of data. Animation knowledge and data complement each other in supporting decision-making or information sharing. Universities, governments, enterprises, and other departments have different demands for animation resources, and their own animation resources may be lacking in other units [13]. Therefore, animation knowledge sharing is the core function of a collaborative innovation platform for animation projects, which can provide effective support for the innovative behaviors of universities, governments, and enterprises.

3.2. Overall Deployment. Through the design of the collaborative innovation platform of the animation project, all units involved in the collaborative innovation of animation specialty are connected with related knowledge (including explicit knowledge and tacit knowledge). Also, through the organization, management, and sharing of animation knowledge, participants can comprehend the dynamic development of animation specialties in time and all kinds of animation knowledge needed by their own, which provides a good managing platform for the spread of animation experience and knowledge.

There are many units and participants in the professional collaborative innovation of animation, and there exists independence among participants in time and space. Therefore, under the network environment, establishing a collaborative innovation platform for animation projects based on WEB can effectively realize the integration of knowledge flow, information flow, and business flow, which can promote sharing and management. If it is the general knowledge of animation project ontology or the hidden animation knowledge published on Wiki, blog, forums, etc., it needs to be packaged into the knowledge portal to meet the needs of users [14].

The animation collaborative innovation platform includes a physical network layer, infrastructure layer, basic service layer, service layer, user layer, and terminal, and the specific deployment is shown in Figure 2. Among them, the terminal is the basic interface between users and the system, which needs to reflect the basic needs of users [15]. Applications in the basic service layer are the core of the whole system [9].

3.3. Functional Design. Combined with the demand analysis and overall design of the animation collaborative innovation platform, its core functions are divided into animation knowledge integration, animation knowledge retrieval, animation knowledge maintenance, and animation knowledge sharing.

3.3.1. Animation Knowledge Integration. The animation collaborative innovation platform needs to gather information from universities, governments, and enterprises, which is stored in their respective databases and exists in the form of various business systems. In order to unite these units and integrate the advantages of animation resources, they ought to introduce the concepts of enterprise's dynamic alliance and project's cooperative subcontracting and integrate the process of animation knowledge [10]. At present, the animation industry's information systems of universities, enterprises, and governments are still mainly supported by relational databases. D2RQ provides a complete set of APIs to realize the access of relational databases to the semantic Web [16]. For us to transform the legacy data into RDF data [17], which has a higher semantic level and can be processed by knowledge processing, with the help of D2RQ, the animation knowledge of universities, enterprises, and governments is integrated and transformed, as shown in Figure 3.

In addition, during the development of the collaborative innovation platform for animation projects, many metadata, metaknowledge, business rules, and so on of animation majors are based on XML. Therefore, the animation knowledge contained in XML occupies a large proportion and takes up an important part of the collaborative innovation platform for animation projects, which must be considered. On this basis, an XML-based file is proposed to describe the organization and functions of enterprises, and it is integrated into the collaborative innovation platform of animation projects. The relationship between XML files and entities is constructed by MAPONTO technology, and the mapping is implemented by the Company owl ontology, and the mapping of the collaborative innovation platform of animation projects is realized on this basis [18]. The mapping from the XML document to ontology is shown in Figure 4.

3.3.2. Maintenance of Animation Knowledge. It takes a long time to develop animation projects in colleges, and animation knowledge is constantly updated and changing. Therefore, how to make ontology adapt to the changes of the outside world and maintain it in time [19] is an unavoidable problem in the management of animation knowledge by using ontology at present.

With respect of colleges and universities, the development of animation projects is a temporary process. After the development cycle of each project, the temporary alliance

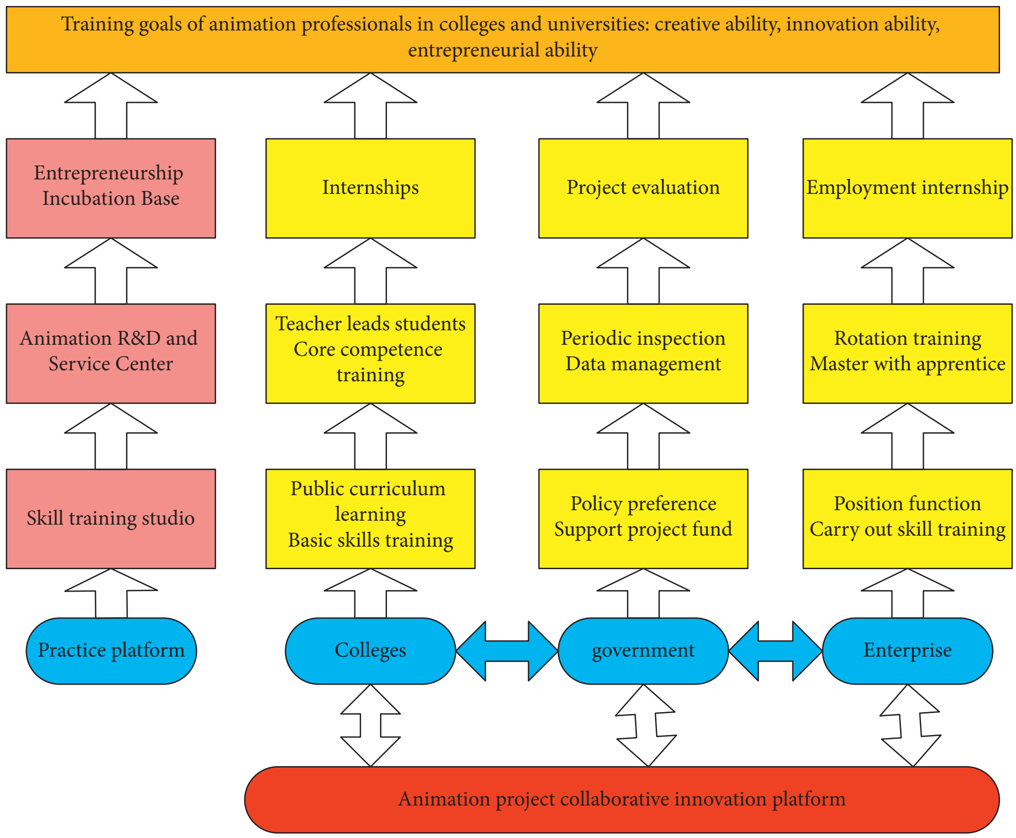

FIGURE 1: Collaborative innovation system of the animation specialty in colleges and universities based on digital technology.

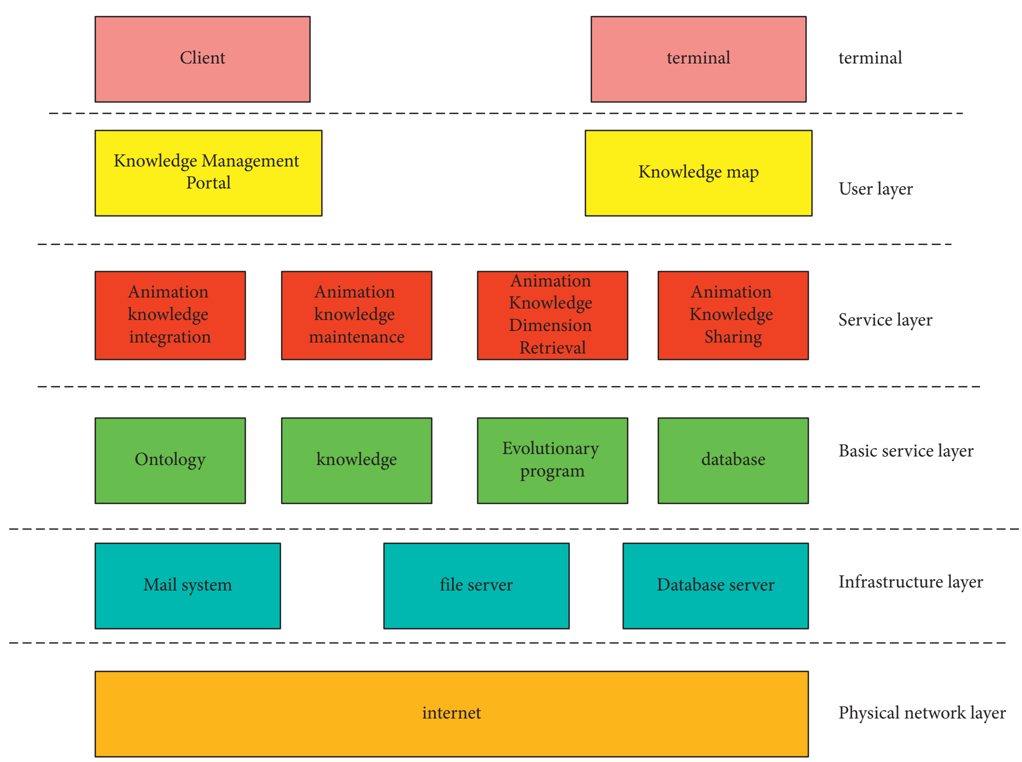

FIGURE 2: Deployment of collaborative innovation platform for animation projects.

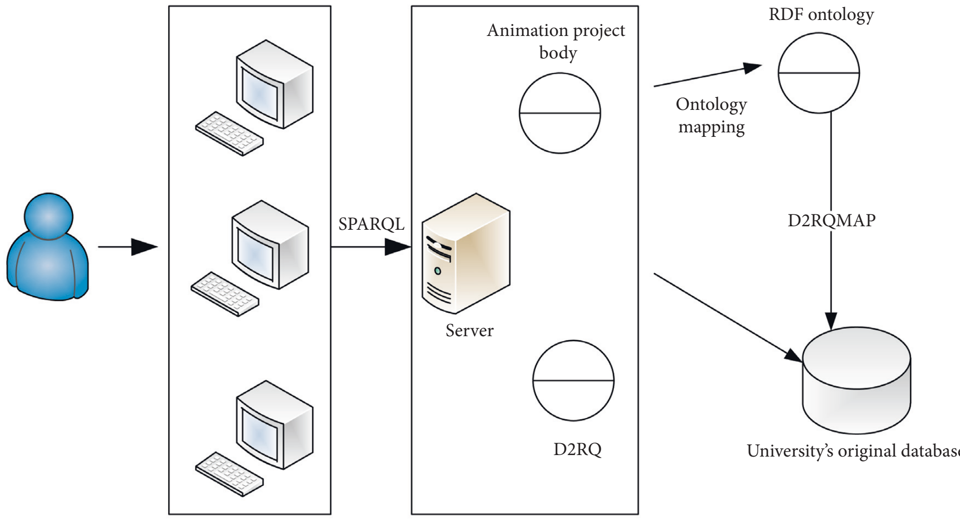

Figure 3: Data conversion of an animation specialty based on D2RQ.

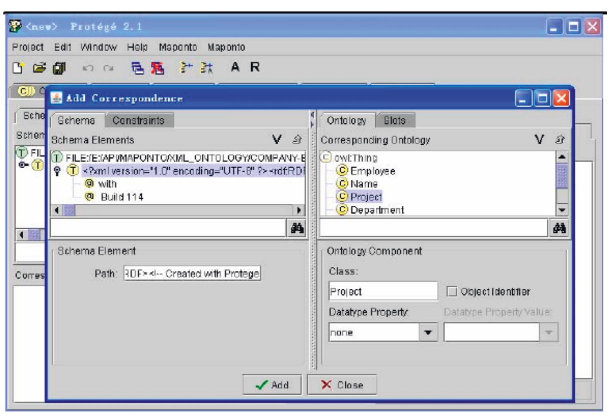

Figure 4: Mapping XML documents to ontology.

formed when participating in the project will be disintegrated. However, the experience of animation projects is sustainable. Compared with previous projects, the next development is different in creativity and production. However, its core technology is relatively stable [20]. Therefore, it is necessary to maintain the knowledge of animation design in each stage, which is mainly represented by the tasks of reusing, updating, and revising animation knowledge. However, up to now, the maintenance of the animation knowledge in colleges is only formal knowledge, and the most important thing is the ontology of animation major. The knowledge maintenance module is centered on the ontology of animation projects, and it updates and maintains knowledge in various ways on the basis of ontology evolution [21]. The ontology of animation projects provides a vocabulary collection in public for the development of animation projects, while the evolution of ontology is a method and technology, and combining the two is the best solution.

3.3.3. Animation Knowledge Retrieval. Establishing collaborative innovation platform for animation projects is to fully tap and utilize animation knowledge mastered by organizations and apply animation knowledge to project development so as to achieve the purpose of improving the efficiency of animation production. An excellent knowledge management system requires not only massive structural knowledge but also a good platform, which can convey the best knowledge to people who need it most in the shortest time, and the key is how to search and query. The knowledge query of the animation collaborative innovation platform is based on ontology, and the design of the knowledge retrieval module should fully consider the actual needs of users so that users can better understand the semantics of the knowledge they have learned and carry out the semantic query according to the vocabulary, semantic relations, and restrictions [22].

There are three retrieval methods of animation knowledge in the collaborative innovation platform of animation projects:

The first is an inquiry by browsing [23]. The system uses the visual interface, takes the animation project ontology as the main body by the built-in retrieval function, and passes the existing retrieval function to retrieve the current content. For example, when the user clicks "Personnel," the system will provide feedback information about people, such as who is in this project, which department it belongs to, and what is its responsibility? Compared with traditional information retrieval, it uses ontology-based semantic relations more and integrates scattered information, thus facilitating users' understanding of existing projects.

The second is customized inquiry. The user selects the corresponding words and associations and then generates a semantic query [11] on the interface given by the system. Compared with traditional methods, it is more flexible for users who do not need to know the syntax details of ontology queries. However, users must better understand the ontology and customize the query conditions and restrictions.

Third is advanced inquiry [24]. Advanced queries refer to advanced users who have some knowledge of the SPARQL language. It can directly organize and input SPARQL to query, analyze, and process them. Compared with the previous two methods, it requires users to be more familiar with SPARQL syntax and be able to write corresponding queries according to their own query requirements.

The basic flow of animation knowledge retrieval of the animation collaborative innovation platform is shown in Figure 5.

When searching for knowledge, the animation project ontology is like a conceptual view, and users do not need to know its internal structure. Ontology can hide the differences in animation professionals' knowledge, and it can become the source of animation knowledge by connecting with ontology through reasonable ways.

3.3.4. Animation Knowledge Sharing. In order to realize the collaborative innovation of animation major in colleges, we should not only achieve the interchange of data but also share and exchange knowledge levels. Due to a poor function of semantic expression, it is very difficult to exchange and cooperate knowledge among various units, while Web technology based on ontology and semantics can effectively solve this problem [25].

Knowledge sharing is the most important demand and one of the most important functions in the process of collaborative innovation platform. Compared with the traditional business model, the interactive relationship among enterprises, departments, and individuals in animation projects is a thorny issue [26]. In this study, the general animation knowledge of collaborative innovation platforms for animation projects is structured and formalized, which provides a basis for sharing and describing other knowledge and realizes the unification of knowledge. On the one hand, sharing animation knowledge refers to the ability to provide relevant information to different characters, which, on the other hand, is the sharing and dissemination of personal animation knowledge [27]. Therefore, the animation knowledge sharing process is designed as shown in Figure 6.

From Figure 6, it can be seen that animation knowledge can be published and pushed through the Web page, and users can give timely feedback according to the pushed information, which forms a circular data sharing process.

3.4. Database Design. The database is the keystone of the collaborative innovation platform of the animation project. In the development of the platform, many descriptions need to be supplemented by data.

On the one hand, all kinds of structured data about projects in collaborative innovation platforms of animation projects need to be stored in database. Only when data are used in combination with the knowledge described in ontology or business rules can they truly reflect the value. Therefore, it is necessary to create a mechanism to unify the management between data and knowledge, which provide a basis for users to better understand and use them. The collaborative innovation platform of animation projects mainly involves the ecological chain of animation Industry-University-Research, including design technology of animation modeling, researching mechanism of animation product, Chuangzhi Microsoft Technology Center, animation research and development center, laboratory of application in digital media technology, institutions of animation technology research, etc. The table of collaborative innovation platforms for animation projects is constructed, as shown in Figure 7.

On the other hand, the collaborative innovation platform of animation projects needs to be connected with the original system of colleges. The data accumulated in legacy systems contain much information related to the development of animation projects. Reusing and integrating of this information is also very important. To this end, the animation collaborative innovation platform should own an interface with the database so that users can simultaneously get the corresponding data when accessing knowledge; thus, the efficiency and quality of decision-making are improved. The database and ontology linked by mapping can implement the data sharing between the collaborative innovation platform of animation projects and other systems, as shown in Figure 8.

4. Application of Collaborative Innovation Platform for Animation Projects Based on Digital Technology

The development of an animation collaborative innovation platform has practical value and a broad prospect in the application.

4.1. Innovating Animation Teaching Mode. The animation collaborative innovation platform of the project contains abundant animation knowledge. By docking with the learning platform of animation courses in colleges, it can form a display platform of teaching achievement in animation. The platform includes the creation of 2D short films, 3D short films, and microfilm, as well as the appreciation of students' works and other columns. Students can learn the basic knowledge of 2D animation, create a two-dimensional animated short film, and upload it to the learning platform. With the basic learning of 3D animation, students can apply 3D animation technology to complete the production and demonstration of 3D animation. At the same time, special columns can be set up for students to shoot short videos and display animation technology at a higher level after mastering the basic knowledge of micromovies, which will be evaluated by teachers and classmates to show their capacity.

In addition, with the help of the collaborative innovation platform of animation projects, teachers can further extend and form a modular teaching process of computer animation specialty, which integrates basic theory teaching, creation of 2D animation short film, comprehensive design of 3D animation short film, creation of microfilm, design of digital illustration, and practical training, so as to cultivate students' professional interest and innovation and improve their professional skills in practical operation, which

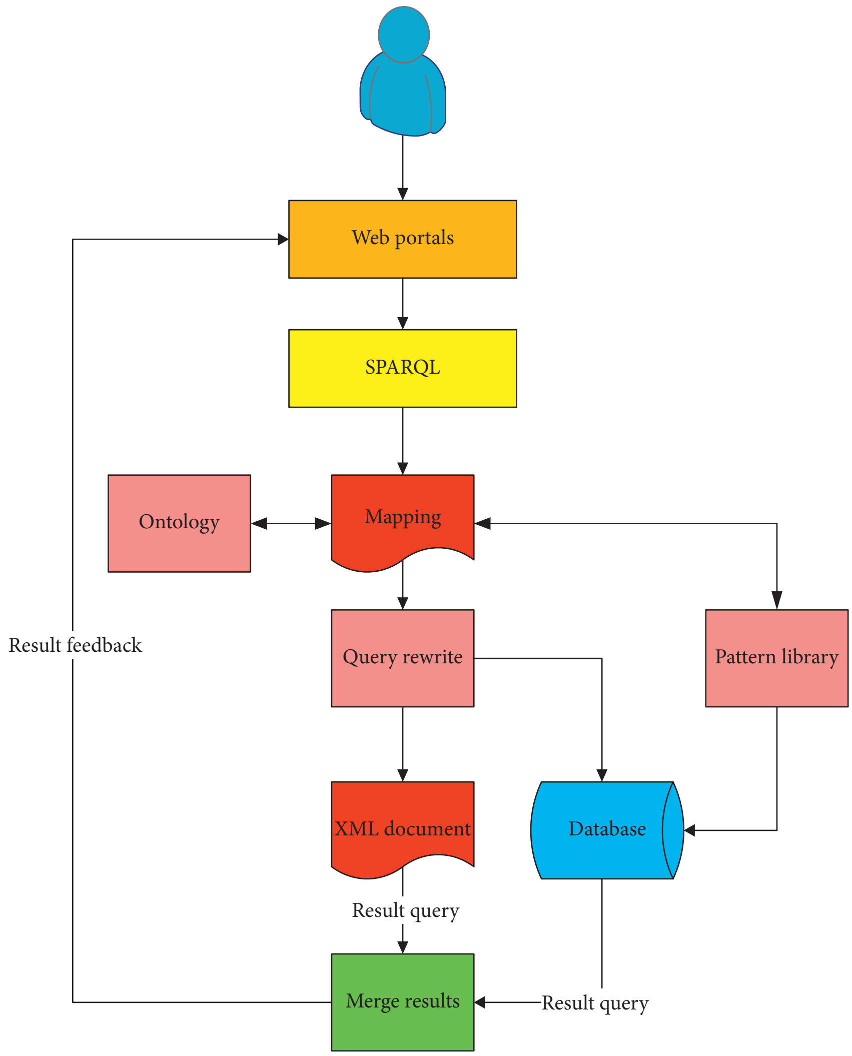

Figure 5: Basic processing flow of animation knowledge retrieval.

provides a practical teaching mode for training technology professionals.

4.2. Promote the Development of the Animation Industry. The collaborative innovation platform for animation projects integrates the communities of shared interest among government, enterprises, universities, etc., which takes the training of animation professionals as the starting point, serves society as the value orientation, and integrates society, industry, and education in the same field. Among them, the government, as a manager, provides policy and institutional and environmental support for the cooperation between universities and enterprises through "tangible hands." As the core element of the market economy, enterprises provide financial support for technical research through technology industrialization and use modern industrial colleges to transform human capital into economic profits. As the primary body in modern industrial colleges, colleges and universities pursue social values and are responsible for training high-quality skilled talents, delivering talents to society, and meeting the market demand for talents. So, balance the value orientation of the three is an important premise for collaborative innovation of the animation specialty.

The collaborative innovation platform of the animation project has formed a collaborative innovation model where the government takes the leading role and the school-enterprise is the main body. It has fully played the coupling effect of the industrial chain and the education chain, which enhance the dominant position of the school-enterprise in the collaborative innovation and collaborative education of modern industrial college, and then realized the effective allocation of innovation resources.

Animation project collaborative innovation platform should not only meet the needs of the government, enterprises, and universities but also be the fundamental guarantee for the survival and development of the animation industry. Through modern computer technology and communication technology, we can build enterprises a collaborative innovation platform for animation projects, which may customize a platform environment with information interaction, collaborative cooperation, and management for the government, enterprises, and universities. It is meant for

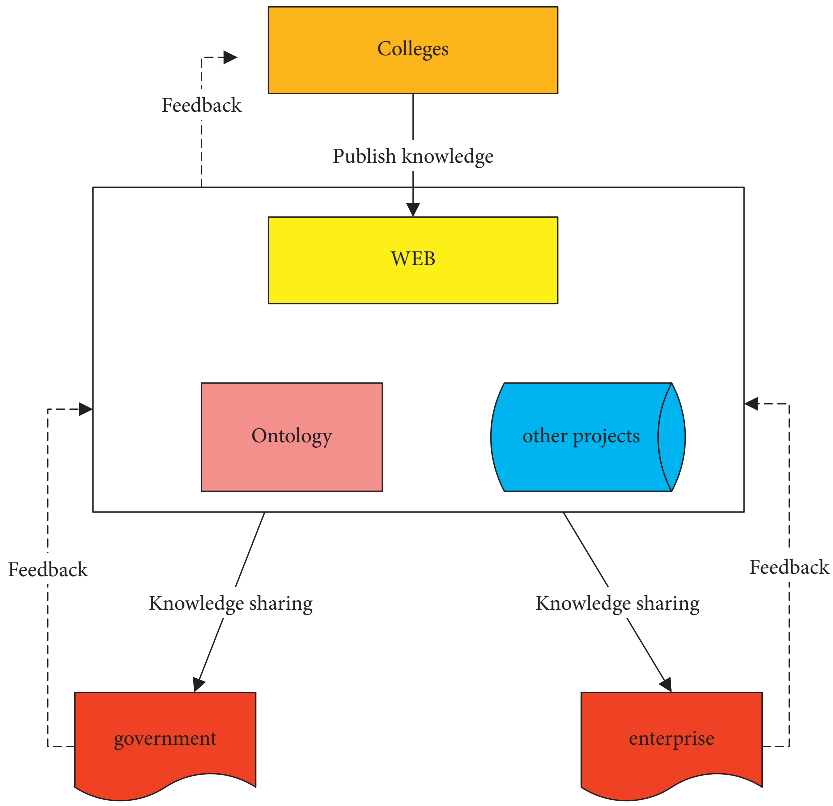

Figure 6: Sharing of ontology-based animation knowledge.

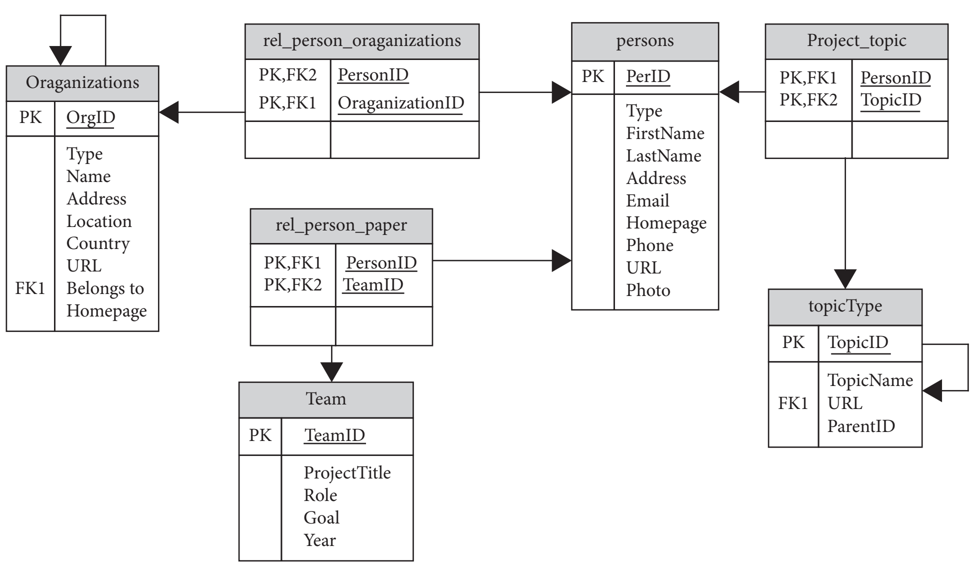

Figure 7: Structure of collaborative innovation platform database of animation project (part).

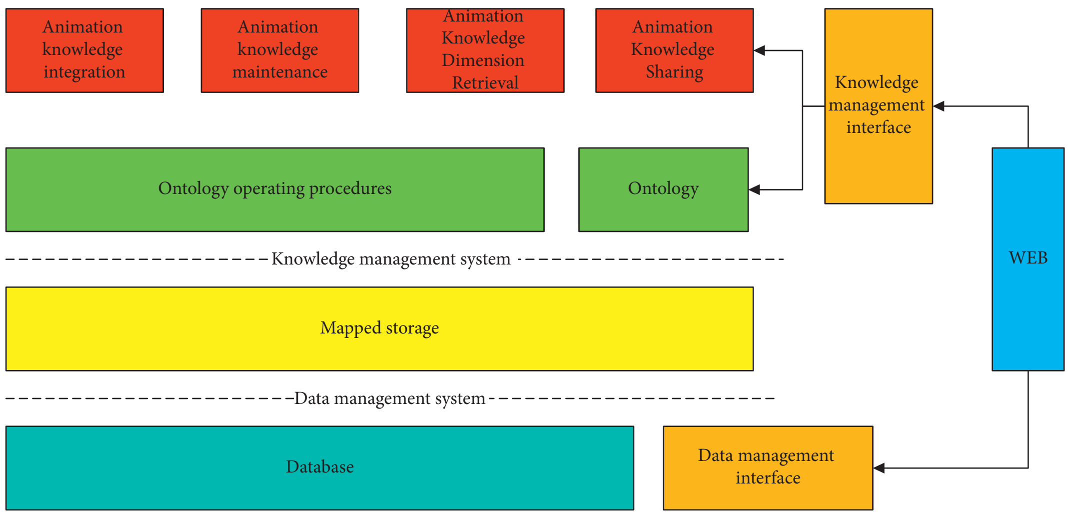

FIGURE 8: Docking of collaborative innovation platform of animation project with the existing data management system.

strengthening extracurricular practice, innovating animation design, training managers, developing characteristic industries, etc., which is an inevitable measure for the development of the animation industry in digital media.

5. Conclusion

Under the trend of economic globalization, competition among industries is becoming more and more fierce, so is the animation industry. Animation industry plays a very important role in the development of China's national economy. Under the background of digital technology, China's animation industry will gradually develop in the directions of science and technology, intelligence, and electronics. As the pioneer of the animation industry, the animation specialty in college needs to integrate a variety of technologies, strengthen extracurricular practice, and innovate in animation design. The collaborative innovation system of animation specialty in colleges under digital technology requires that the curriculum design of animation specialty in colleges and universities should be based on the curriculum design to strengthen the deep cooperation among government, universities, and enterprises. Based on this, the collaborative innovation platform for animation projects is constructed through the integration of technology in animation design and digital media, which can realize the integration, maintenance, retrieval, and sharing of animation knowledge. The application of a collaborative innovation platform can improve the soft environment of an animation project's development, promote the innovation of knowledge, accelerate the development of animation projects, improve the quality of animation works, and stimulate the overall competitiveness of the animation industry, which then effectively advance the region of the animation industry.

It is difficult for the traditional physical fitness evaluation methods to dig useful information from massive data, and the accuracy of physical fitness evaluation is low. Therefore, this study proposed a physical fitness evaluation method in the stage of physical exercise behavior based on Bayesian and data mining for the college students. The purpose was to set the association rules of exercise behavior stage, to mine the association mapping relationship in the data set by using frequent itemsets, to build a regression model and to select the best physical variables in the exercise behavior stage. The frequent itemset was used to eliminate the redundancy of physical fitness data, the causal relationship was used to sort the physical exercise behavior stage, and the transformation of physical fitness evaluation index system was realized through Bayesian network topology to realize the physical fitness evaluation in the physical exercise behavior stage. The experimental results showed that the accuracy of this method was as high as 97.62%, and the recall rate of fitness data evaluation was as high as 99.3%. At the same time, the effect of fitness evaluation was better in a short evaluation time.

1. Introduction

It is easy to understand the connotation of physical fitness literally. It mainly refers to the quality of the human body. The quality of physical fitness is affected by many factors, among which it is determined by innate inheritance and acquired basis [1]. To judge whether a person's physical fitness is good or bad mainly means that the shape of the body has the development level, the level of physiological function, athletic ability, physical quality development, and psychological development. These five aspects determine people's physical fitness level [2–5]. Relevant scholars put forward the theory of stage change, believing that behavioral change consists of four factors: stage of change, balanced decision, change process, and self-efficacy [4, 5]. By applying the theory to physical exercise behavior, it is concluded that the change of physical exercise behavior goes through five stages, namely, pre-expectation stage, expectation stage, preparation stage, action stage, and maintenance stage. According to the different behavioral stages of the college students' physical exercise, a comparative research was made to prove that the physical exercise assessment put forward by this study was effective.

Cheng and Wang built a physical health policy attitude assessment model to carry on an empirical analysis on physical health policy, policy satisfaction, the relations between and among policy behavior, and attitude toward policy model by applying the method of structural equation model. The method made an effective evaluation of the physical state. The accuracy was high, but the efficiency was poor [8]. He et al. designed a kind of Chinese urban adolescent physical fitness environmental assessment method [9], the application of standard index quantitative and qualitative screening based on the Delphi method, and analytic hierarchy process was used to index weight assignment. This method could improve the physical environment qualitative measurement accuracy and the content, but the poor efficiency of environmental assessment was low.

Hu et al. proposed the physique classification and evaluation method based on k-medoids method [10] and conducted psychological tests on the students, extracting psychological factors by principal component analysis and evaluating the physique state by a three-level fuzzy evaluation model. This method could reasonably classify the physique, but the efficiency of physique health classification and evaluation of the college students was not satisfactory. Zhang and Yun put forward the body posture evaluation method of the students through big data developed a set of scientific and reasonable body posture evaluation system to help the schools, teachers, and students understand their body posture and health status correctly through big data, scientifically and to guide the schools and teachers to formulate curriculum contents conducive to the students' physical and mental development and effectively evaluated their body posture. However, the evaluation accuracy was low [11].

In the modern society, with the highly developed information, the traditional statistical methods are difficult to find useful information from massive data. Data mining has become an important means of knowledge discovery based on big data. Therefore, this study proposed a physical fitness evaluation method at the stage of physical exercise behavior based on Bayesian and data mining. The specific research ideas were as follows:

Firstly, association rules of exercise behavior stage were set, association mapping relationship of data set was mined by frequent itemsets, and regression model was constructed.

Secondly, the best physical fitness variable in exercise behavior stage was chosen. Frequent itemsets were used to eliminate the redundancy of physical fitness data, and causality was used to rank the stages of physical exercise behavior.

Next, the physical fitness evaluation index system was transformed by Bayesian network topology to realize physical fitness evaluation at the stage of physical exercise behavior.

Finally, through the accuracy and efficiency of physical fitness assessment, the effectiveness of this method in physical fitness assessment of college students at the stage of physical exercise behavior was verified and a conclusion was drawn.

2. Data Mining of Physical Fitness of College Students at the Stage of Physical Exercise Behavior

2.1. Association Rules in Data Mining of College Students' Physical Fitness Data. Each test object determined a unique identification (TID), then each TID contained the following information: physical exercise behavior stage (field 1), gender (field 1), and physical fitness test index (field 11). The height and weight in the test index derive BMI, BMI = weight (kg)/height (M) 2, VO2max, and vital capacity were divided into weight composition (relative VO2max and relative vital capacity) respectively to form database D. Clementine12.0 data mining software requires type consistency and dimensionless processing of the data of input variables and output variables when modeling [12]. The type of input field of association rule data mining was generally required to be number, which could realize the digitization of physical fitness test data according to the national physical fitness measurement standard, that is, the test results could be scored as 5, 4, 3, 2, and 1 according to their advantages and disadvantages. In association rule data mining, the type of output field required to be set was character type (string), which meant that the output field "physical exercise behavior" was divided into five types as follows: pre-expectation stage, expectation stage, preparation stage, action stage, and maintenance stage. Association rule data mining was to find the minimum support min specified by the user in the transaction database D_ Sup and min_ All association rules of conf [13]. Set min as required_ Sup, "individual index score of physical fitness test" was taken as the input field and set min_ Conf, establishing the "association mining rules between physical exercise behavior and single indicators" model to explore the impact of physical exercise behavior on physical fitness and providing decision support for the college students' physical health with different physical exercise behaviors.

Since there were collinearity problems in the college students' physical health indicators, such as body weight and vital capacity, the principal component regression analysis was adopted. Principal component regression analysis transformed a group of multiple related data into a group of linearly unrelated variables through orthogonal changes, and the transformed group of variables was called the main component [14]. The main method of principal component analysis was F1 (the first comprehensive index), that is, the greater the variance of F1, the more information it contained. Therefore, the variance of the first comprehensive index selected in all linear combinations became greater. If the information contained in the first index selected was not enough to include all indexes, F2 shall be included on the basis of the first index until it was accepted. The input indicators could represent the information of all the original indicators [15]. The second stage was to construct a regression model from the principal components included. The constructed regression model was of great significance for the screening of regression variables. In a word, the principal component regression model could use a set of fewer variables to obtain the selection of the best variables [16]. The specific process was as follows:

Since each index was different in units, the value was also different, so the data must be standardized, and the processing method adopted Z change:

$$X_i = \frac{x_2 - x_1}{\gamma}. \tag{1}$$

In formula (1), x_1 and x_2, respectively, represent the physical health data of the college students were measured twice, γ represents the number of indicators, and n represents the standardized function of data. For principal component suitability test, such as Bartlet Test statistics and KMO test, if the p value obtained by Bartlet Test was less

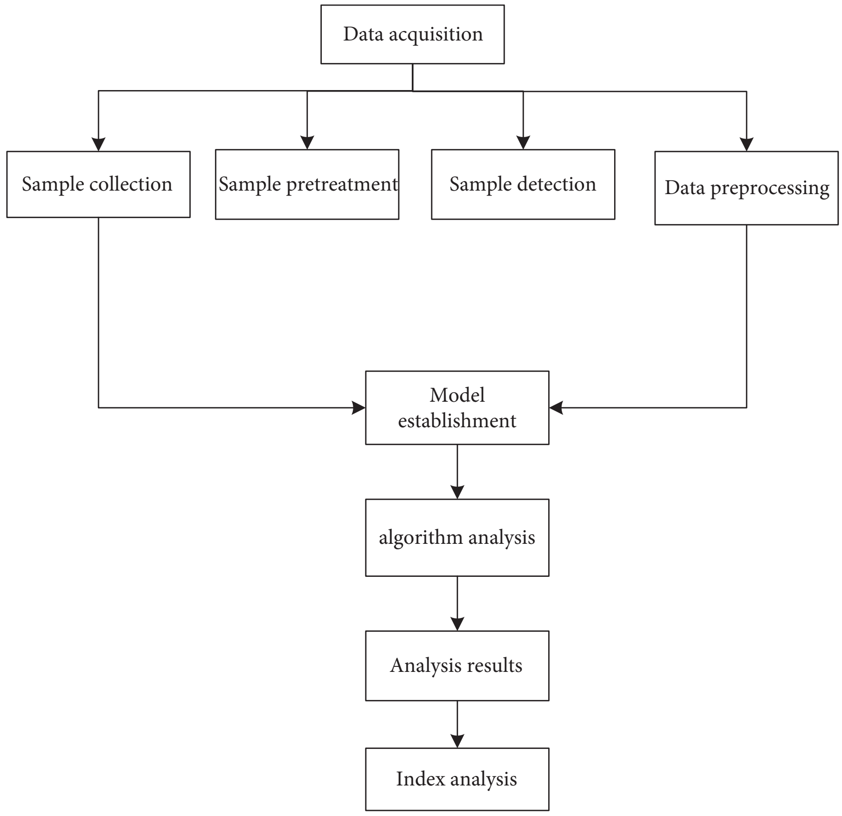

FIGURE 1: Data mining route of physical fitness of college students in physical exercise stage.

than 0.05 or the value of KMO test was greater than 0.5, the principal component analysis could be performed.

The correlation coefficient matrix between each index was calculated, and the correlation formula is as follows:

$$r_{ij} = \frac{1}{n}\sum_{i=1}^{k} x_{ikx_{jk}}. \tag{2}$$

The matrix of correlation coefficient was changed by R to make its variance reach the maximum value, and on this basis, the eigenvalue of R and I and their corresponding eigenvector were obtained.

The principal component formula was constructed according to the component coefficient matrix. It should be noted that the variables in the constructed expression were not original variables but standardized variables.

The construction of principal component regression equation required it to take the extracted principal components as independent variables and physical fitness score as dependent variables to establish a principal component regression model and select meaningful factors [17].

2.2. Redundancy Elimination of College Students' Physical Fitness Data Based on Frequent Itemsets. The process of physique data mining in the college students' physical exercise stage is shown in Figure 1.

Frequent Itemsets with support were greater than the minimum support threshold. The enumeration method could be used to enumerate all possible K itemsets, and then

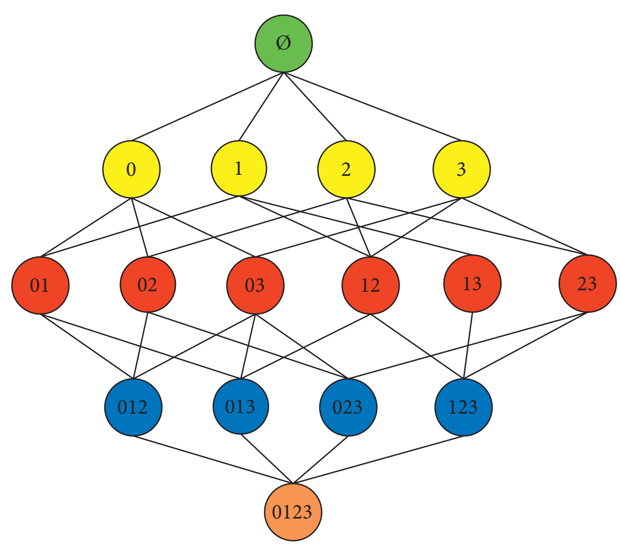

FIGURE 2: Frequent itemsets.

calculate the support of each itemset. A dataset with items could produce a set of items, and a set of items that met the support threshold could be small [18]. Obviously, enumeration was not an effective method when the data set was large. The frequent itemset enumeration lookup process was shown in Figure 2. As seen from Figure 2, there were altogether 15 data sets with 4 data sets.

In order to improve the efficiency of finding Frequent Itemsets, itemsets that were unlikely to reach the support

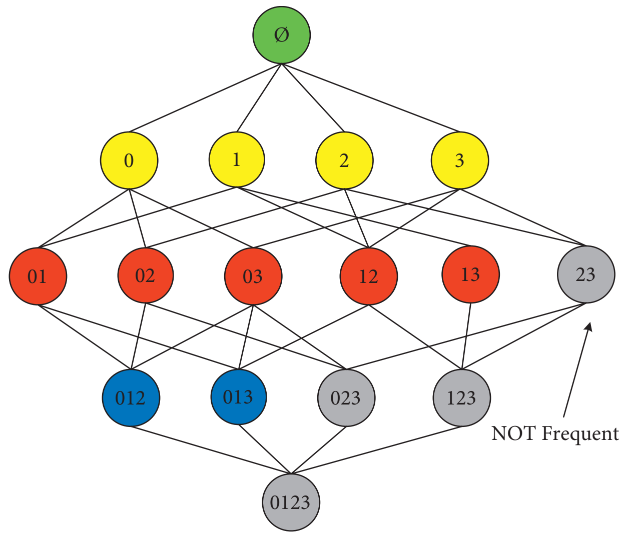

Figure 3: Frequent itemset data redundancy elimination.

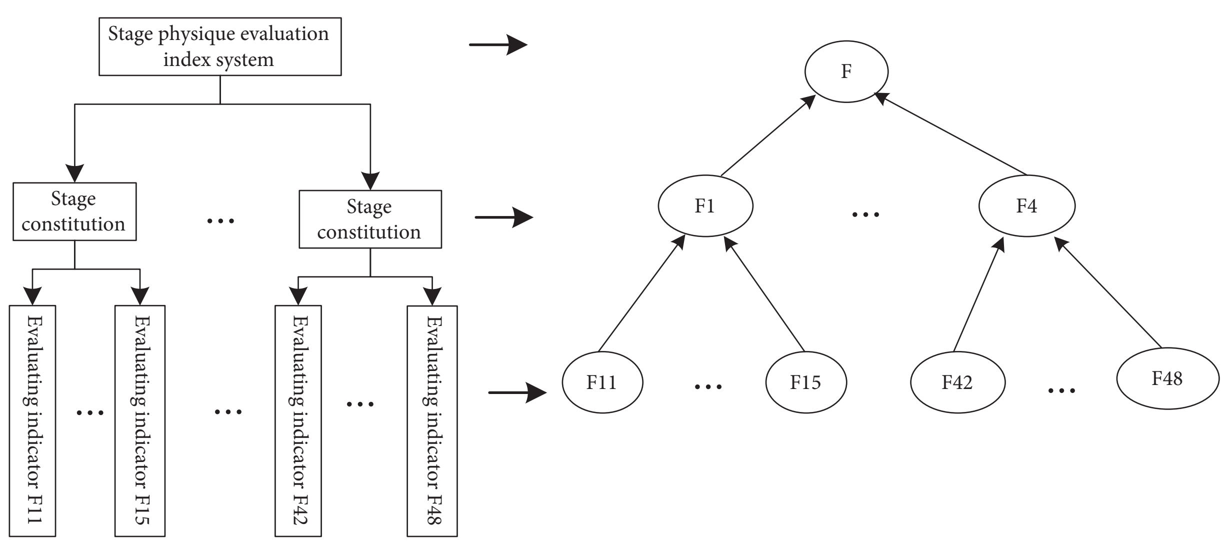

Figure 4: Initial topology of Bayesian network.

threshold were deleted. If the itemset was frequent, its subset must also appear frequently. Conversely, if a child itemset was infrequent, its parent set was not a frequent itemset. The redundancy elimination of frequent itemset data is shown in Figure 3, and the shaded itemset in the figure indicates that it is cropped out [19].

2.3. Physical Fitness Evaluation of College Students at the Stage of Physical Exercise Behavior Based on Bayes Theorem. Bayes theorem is a theorem for calculating conditional probability proposed by Bayes in the 18th century [20]. The main contents of the theorem include assuming that a complete event contains n mutually exclusive events, each mutually exclusive event is represented by $H_1, H_2, \ldots, H_n$ and its probability is $\mathrm{P}(H_i), i = 1, 2, \ldots, n$. It is found that event a occurs randomly with each mutually exclusive event, and when the conditional probability of event A when each mutually exclusive event occurs is known, that is $\mathrm{P}(A \mid H_i)$, then the probability of $\mathrm{P}(H_i \mid A)$ is as follows:

$$\mathrm{P}(H_i \mid A) = \frac{\mathrm{P}(H_i)\mathrm{P}(A \mid H_i)}{\sum_{j=1}^{n} \mathrm{P}(H_j)\mathrm{P}(A \mid H_j)}. \tag{3}$$

Bayesian network (BN) is also called causal probability network and reliability network. The core of this method is to construct the Bayesian network topology between variables based on causal relationship and analyze the occurrence probability of variables through structure learning, parameter learning, and reasoning analysis. The Bayesian network topology learning method based on the ranking principle of causality and the principle of reason pointing to result is adopted to make the constructed Bayesian network topology clear [21–23]. The transformation of physical fitness evaluation index system of college students in physical exercise stage is realized through the initial topology of Bayesian network, as shown in Figure 4.

Through the transformation of the index system, the Bayesian network topology lacks the causality between the evaluation indexes. In order to increase the causality between the indexes in the network topology and make the network structure more reasonable, this study adopted the social network analysis method to optimize the structure.

The Bayesian network topology was transformed through the index system, which lacked the causal relationship between evaluation indexes. In order to increase the causal relationship between indexes in the network topology and make the network structure more reasonable, the logical reasoning method was used to identify the causal relationship between nodes. Based on the Bayesian network topology, the key risk factors and key risk relationships in the social network were analyzed, and the middle centrality of points was used for physical fitness evaluation [24]. The greater the middle centrality of the node, the stronger its physique evaluation ability was. Its calculation formula is as follows [25–27]:

$$S_r = \sum_{j}^{n} \sum_{k}^{k} O_{jk}(r), \tag{4}$$

where $j \neq k \neq r$ and $j < k$, and $O_{jk}(r)$ represents the ability of point r to control the communication between point j and point k. Assuming that there were W_{jk} lines in the path between point j and point k, and $W_{jk}(r)$ lines passing through point r in the path, then

$$O_{jk}(r) = \frac{W_{jk}(r)}{W_{jk}}. \tag{5}$$

The middle centrality theory of line referred to the degree to which the relationship between two nodes in the network structure was located at the center of the whole social network structure [28]. The greater the middle centrality of the line between two nodes, the stronger the risk transmission capacity was. The calculation formula is as follows:

$$S_{x\longrightarrow y} = \sum_{j}^{n} \sum_{k}^{k} O_{jk}(x \longrightarrow y), \tag{6}$$

where $j \neq x \neq y \neq k \neq r$ and $j < k$, and $O_{jk}(x \longrightarrow y)$ represents the ability of relationship $x \longrightarrow y$ to control the communication between point j and point k [29]. Assuming that there were W_{jk} bars in the path between point j and point k, and $W_{jk}(x \longrightarrow y)$ bars in the path passing through the relationship $x \longrightarrow y$, then

$$O_{jk}(x \longrightarrow y) = \frac{W_{jk}(x \longrightarrow y)}{W_{jk}}. \tag{7}$$

On the above constraints, n experts in relevant fields were invited to judge the occurrence probability of the risk level of the node. The nth expert judged the probability of the risk level i, $i = \{1, 2\}$ of the node A_t, B_t, $t = \{0, 1, 2\}$ according to the seven-level language variables, transformed it according to the corresponding relationship, and calculated the triangular fuzzy probability PTI, n of the evaluation index with the transformed triangular fuzzy number.

$$P_{ti,n} = \left(x_{ti,n}, y_{ti,n}, z_{ti,n}\right). \tag{8}$$

The obtained triangular fuzzy probability was averaged. Averaging was the arithmetic average of the evaluation results of experts, which aimed to rationalize the final probability value [30]:

$$P_{ti,FAM} = \frac{P_{ti,1} \oplus P_{ti,2} \oplus \cdots \oplus P_{ti,n}}{n} = \left(x_{ti}, y_{ti}, z_{ti}\right). \tag{9}$$

The mean triangular fuzzy probability was defuzzified and calculated by the face value mean method:

$$P_{ti,AM} = \frac{x_{ti} + 2y_{ti} + z_{ti}}{4} \tag{10}$$

Normalize the probability value so that the sum of the final probability value was 1:

$$P_{ti} = \frac{P_{ti,AM}}{\sum_{i=0}^{2} P_{ti,AM}}. \tag{11}$$

According to the calculated root node prior probability distribution and child node conditional probability distribution and with the help of GENIE 2.3 software, the physical parameters of the college students in the stage of physical exercise were studied. Then to carry out the initial assignment to each node, the calculated probability value was imported according to the triangular fuzzy number, the subnode probability was calculated with the maximum likelihood estimation method built in the software, and finally, the probability value of each node was obtained, so as to realize the physical exercise behavior stage.

3. Experiment

3.1. Experimental Design. Determining the evaluation index was important in the comprehensive evaluation of college students' health. The intelligent health promotion service system focused on the internal functions of the body and used intelligent instruments to directly measure individual vital capacity, body composition, and cardiovascular and balance ability, including height, weight, vital capacity, and balance ability. The specific forms of physical exercise for the college students included running, core strength training, and vital capacity.

According to the *National Student Physical Health Standard* (2014), physical fitness test was conducted for 3969 students. The test indicators included height, weight, 50 m running, vital capacity, standing long jump, and sitting posture forward flexion. In addition, male students needed to measure 1000 m running and one-minute pull up, while female students needed to measure 800 m running and one-minute sit-ups. The BMI of the college students was divided into four grades: 17.2 (female)/17.9 (male)~23.9 is normal, ≤17.1 (female)/17.8 (male) is low weight, 24.0~27.9 is overweight, and ≥28 is obesity. SPSS17.0 and R language 3.4.4 software were used to analyze age, height, weight, and physical health indicators, including 50 m running, vital capacity, standing long jump, sitting body flexion and

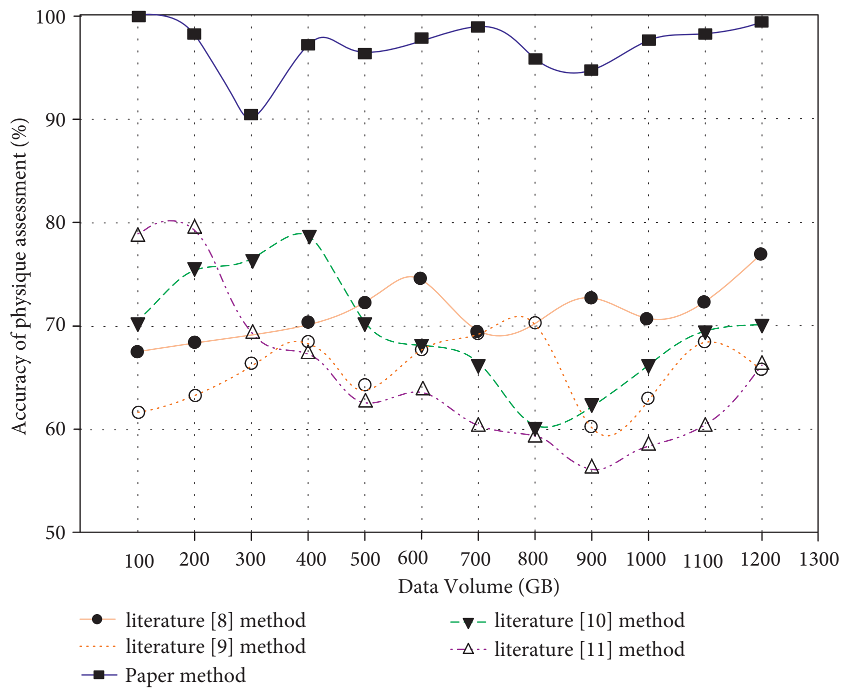

FIGURE 5: Accuracy of physical fitness assessment under different methods.

1000 m running (male), pull-up (male), 800 meters running (female), and sit-ups (female). The original data of 3969 students were carefully reviewed to delete the missing value data and retain the data of 3960 students. According to the needs of data mining, a physical database was created in the form of Excel 2010 according to gender, height, weight, and vital capacity, including sitting and lying precursor, standing long jump, sit-ups, pull up, 50 m running, and endurance (1000 m or 800 m). The original data were processed according to the standard.

3.2. Training Sample Preprocessing. For N samples $1, 2, \ldots, n$, there were p indicators $x_1, x_2, \ldots, x_p$. x_{ij} to represent the i-th physical fitness data and the j index result to obtain the physical fitness data matrix:

$$\begin{bmatrix} X_{11} & \ldots & X_{1p} \\ \ldots & \ldots & \ldots \\ X_{n1} & \ldots & X_{np} \end{bmatrix}. \tag{12}$$

Then, the mean and standard deviation were respectively expressed as follows:

$$X_{n1} = \frac{1}{n}\sum_{i=1}^{n} x_{ij},$$
$$S_j = \sqrt{\frac{1}{n-1}\sum_{i=1}^{n}\left(x_i - \overline{x_j}\right)^2}. \tag{13}$$

After standardization, the new data was

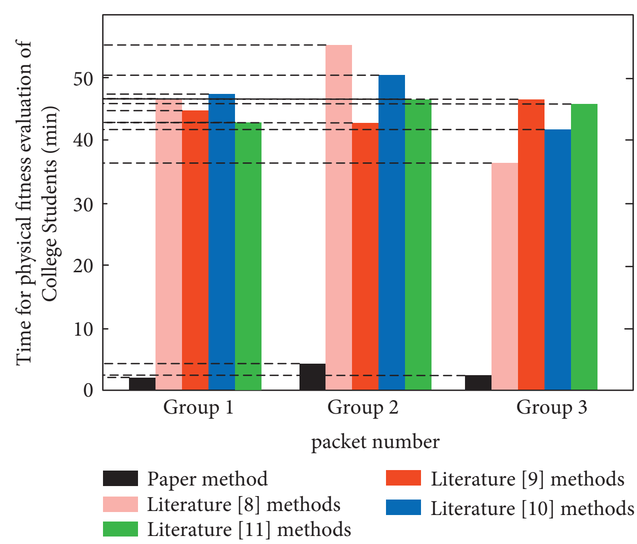

FIGURE 6: Time for the physical fitness assessment.

$$x'_{ij} = \begin{cases} \dfrac{x_{ij} - \overline{x_j}}{S_j}, & S_j \neq 0, \\ 0, & S_j = 0, \end{cases} \quad (i = 1, 2, \ldots, n\ j = 1, 2, \ldots, p). \tag{14}$$

Experimental verification was carried out according to the new standardized data results.

3.3. Experimental Result

3.3.1. Accuracy of Physical Fitness Assessment. In order to verify the effect of this method on physical fitness evaluation,

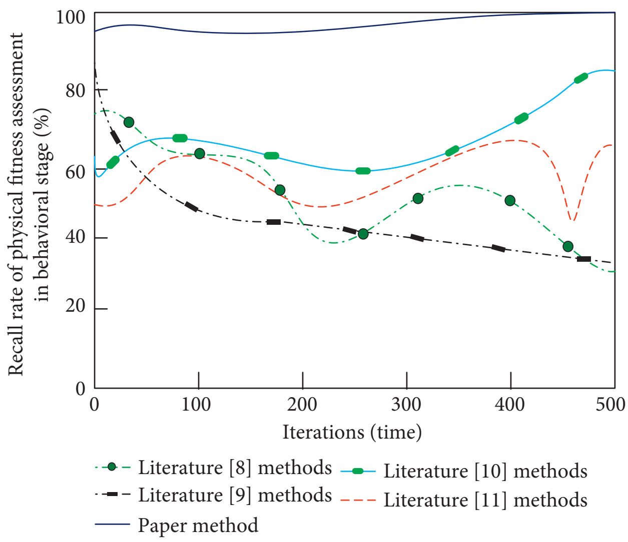

Figure 7: Recall rate of physical fitness data evaluation.

the methods of literature [8], literature [9], literature [10,] and literature [11] were compared with this method, and the evaluation accuracy results were shown in Figure 5.

It could be seen from the analysis of Figure 6 that when the data volume was 100 GB, the accuracy of physique assessment of literature [8] method was 67.42%, that of literature [9] method was 61.56%, that of literature [10] method was 70.23%, that of literature [11] method was 78.67%, and that of this method was 99.88%; When the data volume was 500 GB, the evaluation accuracy of literature [8] method was 72.15%, that of literature [9] method was 64.21%, that of literature [10] method was 70.27%, that of literature [11] method was 62.52%, and that of this method was 96.32%. When the data volume was 1000 GB, the evaluation accuracy of literature [8] method was 70.61%, that of literature [9] method was 62.88%, that of literature [10] method was 66.29%, that of literature [11] method was 58.37%, and that of this method was 97.62%, which proved the effectiveness of this method. This was because the method in this study adopted causality to rank the stages of physical exercise behavior and realized the transformation of physical evaluation index system through the Bayesian network topology structure, so that the accuracy of physical evaluation was greatly improved.

3.3.2. Physical Fitness Assessment Time. In order to verify the evaluation efficiency of this method, the methods of literature [8], literature [9], literature [10], and literature [11] are compared with this method, and the evaluation time results are shown in Figure 6.

By analyzing Figure 6, it could be seen that there were differences in evaluation time under different methods. For group 1, the evaluation time of literature [8] method was 47.5 min, that of literature [9] method was 45.0 min, that of literature [10] method was 48.2 min, that of literature [11] method was 43.6 min, and that of this method was 3.2 min. For group 3, the evaluation time of literature [8] method was 36.9 min, that of literature [9] method was 47.5 min, that of literature [10] method was 40.8 min, that of literature [11] method was 47.0 min, and that of this method was 3.7 min; On the whole, in the above three groups of experiments, the time of physique evaluation by this method was no more than 5 min, which showed that the physique evaluation efficiency of this method was high due to the optimal variables of physical fitness in the exercise behavior stage were selected, the redundancy of physical fitness data was eliminated by frequent itemsets, and the causal relationship was used to rank the stages of physical exercise behavior, so as to shorten the evaluation time of the method.

3.3.3. Evaluation Result Recall Rate. In order to verify the evaluation recall rate of this method, literature [8], literature [9], literature [10], and literature [11] were compared with this method, and the evaluation recall rate results were shown in Figure 7.

Figure 7 revealed that the recall rate was different under different methods. When the number of experimental iterations was 100, the data evaluation recall rate of literature [8] method was 64.5%, the evaluation recall rate of literature [9] method was 57.2%, the evaluation recall rate of literature [10] method was 70.6%, the evaluation recall rate of literature [11] method was 63.9%, and the evaluation recall rate of this method was 98.2%; When the number of experimental iterations was 300, the evaluation recall rate of physical data of literature [8] method was 50.8%, that of literature [9] method was 42.1%, that of literature [10] method was 67.5%, that of literature [11] method was 60.2%, and that of this method was 99.3%; The evaluation recall rate of this method was significantly higher than that of other methods, indicating that this method had a higher effect on physical fitness evaluation. This was because this study used frequent itemsets to mine the association mapping relationship in the data set and constructed the regression model and frequent itemsets could effectively improve the effect of physical fitness assessment by eliminating the redundancy of physical fitness data.

4. Conclusion

This study introduced a physical fitness evaluation method for the college students at the stage of physical exercise behavior based on Bayesian and data mining. The frequent itemset was used to mine the association mapping relationship in the data set to obtain the selection of the best physical variables. The data redundancy of the frequent itemset was used to eliminate, the causal relationship was used to sort the exercise behavior stage, the transformation of the physical evaluation index system in the physical exercise stage was realized through the initial topology of Bayesian network, and the physical evaluation in the physical exercise behavior stage was realized. The experimental results showed that

(1) When the data volume was 1000 GB, the accuracy of physical fitness evaluation in the physical exercise behavior stage of this method was 97.62%, which proved the effectiveness of this method.

(2) This method took less than 5 minutes to evaluate the physique in the stage of physical exercise behavior, which showed that the physique evaluation efficiency of this method was high.

(3) When the number of experimental iterations was 300, the recall rate of fitness data evaluation in the physical exercise behavior stage of this method was 99.3%, which showed that the evaluation effect of this method was high.

However, even though some progress in the physical exercise behavior stage of physical fitness assessment was made, it needed to be further improved.

Data Availability

The dataset can be accessed upon request.

Lifeboats are important equipment to ensure the safety of passengers when a serious accident occurs in the ship. Higher efficiency of lifeboat embarkation is beneficial to improving passenger survival. This study divides lifeboat embarkation into queuing and seat selection stages and studies the embarkation process of cruise passengers. According to the characteristics of two stages of the embarkation process, transfer rules of queue and activity rules of the passenger are proposed. Combined with the rules, 16 types of embarkation simulation scenarios are established. The simulation results show that the embarkation efficiency of the group passenger is lower than that of the individual passenger. When passengers select seats from outboard row to inboard row, the speed of embarkation is faster than that of random seating selection. Compared with only considering the queue length, the embarkation is more efficient if passengers also consider the seat availability of lifeboats when they transfer between queues. The analysis of the results proves that the embarkation efficiency can be improved through proper guidance on the behavior of passengers in queuing and seat selection.

1. Introduction

Maritime lifesaving is one of the important concerns for the operation of the cruise ship. If the ship cannot maintain its normal condition in case of a serious accident occurs, passengers need to abandon the ship through lifeboats. The embarkation station is usually located on one deck of the cruise ship, and all passengers need to embark on the lifeboat from the station. However, passenger panic will have a negative impact on the embarkation process in an emergency. Compared with ordinary passenger ships, cruise ships carry a large number of passengers. In order to ensure passenger safety, the highly effective organization of the embarkation process is essential.

For the safety of the ship passengers, some scholars have conducted research on the maritime lifesaving system. The lifesaving system of the ship is an integral part of emergency equipment in the process of abandoning the ship [1]. Divkovic and Dahlrot [2] introduced requirements in the process of lifeboat embarkation and launching based on IMO's (International Maritime Organization) *International Life-Saving Appliance (LSA) Code* [3]. They recruited 25 volunteers to participate in the lifeboat embarkation experiment and carried out the experiment for the lifeboat embarkation process of the cargo ship. It took three minutes and 52 seconds for all volunteers to embark on the lifeboat, which is 52 seconds longer than the three minutes required by LSA Code.

The safety, reliability, and other factors of lifeboat systems are very important to the safety of passengers. Abramowicz-Gerigk and Burciu [4] took the evacuation of offshore platforms as the research object, and they introduced the general evaluation method for marine lifesaving systems and selected liferafts as an example to conduct safety evaluation. In addition, the lifeboat system will also impact by other factors such as the matching degree between the lifeboat capacity and the number of assembled passengers [5], the human error in the operation of the lifeboat system [6], and the evacuation behavior of passengers [7]. Conversely, the process of embarkation and launching the lifeboat will also have a negative impact on the health of passengers [8]. The positions of objects or persons in the space could be collected by using wireless sensors or Internet of things devices [9–12]. Based on the existing lifeboat system, Andreadakis et al. [13] explored the possibility of establishing a wireless system for detecting the safety of passengers. Passengers wear bracelets with near-field communication or radio-frequency identification, and bracelets would record the relevant data through card readers when passengers embarked on lifeboats. Then, the system could allow the crew to obtain accurate evacuation statistics in real time.

When passengers arrive at embarkation stations, they will generally queue up to embark lifeboats under the organization of staff or by self-organization. Some scholars have studied the behavior of pedestrians in the queuing process. The service efficiency of the queue is usually affected by the organization of the queue, and the customer waiting time could be reduced by reasonable redistribution and management of the queue [14]. The pedestrian flow through services is also related to the number of servicers and service points [15]. In addition, the width, type, and the bottleneck in the path will have an impact on the movement of the pedestrian queue. Zhang et al. [16] analyzed the relationship between the bottleneck and pedestrian queuing characteristics through experiments. Köster and Zönnchen [17] added a loosely queuing model to the pedestrian flow model to simulate the movement behavior of pedestrians at the place of evacuation bottleneck. Zhuang et al. [18, 19] proposed an agent-based cellular automaton to study the aggregation of pedestrian flow at the bottleneck and the impact of self-organizing queue behavior on pedestrian movement efficiency.

The behavior of pedestrians has an impact on the queuing process, and some evacuation models are used to simulate queuing behavior. The cellular automata model as one of the evacuation models can be used to analyze the interaction between pedestrians. This model had been used to simulate the queuing behavior of pedestrians at the server window in the canteen [20, 21] and queuing behavior of students who evacuate from the classroom [22, 23]. Wu and Guo [24] constructed a microscopic pedestrian model with the potential field that can drive the movement of pedestrians. In the model, pedestrians can intersect with others at different angles, and they explored the impact of the intersection angle between passing pedestrians and queuing pedestrians on pedestrian movement efficiency. In another study, Zheng et al. [25] proposed a new concept of the queuing line, which divides the queuing process into walking and queue selection stages. Based on the social force model and queuing theory, they developed two microsimulation models to simulate these two stages. In considering the effect of walking distance [26] and volume [27] of the pedestrian in the queuing process, Yanagisawa et al. established the pedestrian queuing system [28] combined the queuing theory with the microspatial discrete model in pedestrian dynamics. Taking service windows as objects [29], they studied the influence of pedestrian tendencies, windows locations, queue length on pedestrian transit time, and entrance blocking rate.

Family and friends often travel together on the cruise tour. They usually will spontaneously form groups, which have a relevant influence on the crowd dynamics behavior, and groups usually tend to act together [30]. Pan et al. [31] discussed the influence of small group behavior on evacuation and established a multi-agent evacuation model. By changing the type of groups and widths of passage, they simulated unidirectional and bidirectional evacuation processes. Nguyen et al. [32] built two models that contained random and logistic regression models, and they combined the controlled behavior experiment of fire evacuation to simulate the process of individual and group evacuations.

There is a correlation between the group size and the walking speed of the group. The mean walking speed of the group decreased with the increase of the group size [33], but the total evacuation time would decrease when the number of the group increased [34]. The evacuation efficiency of groups with self-organized queues at the exit was higher than that without queues [35]. In the process of group evacuation, individual members would reunite with the group after separating [36]. If the group is made up of family members, the mutual assistance between family members would have a negative impact on the evacuation process [37]. Moreover, the emotions of pedestrians will have a certain impact on evacuation efficiency. The emotions would spread between group members [38], and the propagation of emotion could improve crowds' cognition of danger and increase the survival rate of pedestrians [39]. If the evacuation is guided by a group leader, the evacuation efficiency of the group would also be improved [40].

The embarkation process of lifeboats has its special characteristics: first, unlike ordinary queuing problems, the capacity of the lifeboat is limited, and it is also difficult for passengers outside the lifeboat to obtain internal information. Once the number of entered passengers is about to reach the capacity of the lifeboat, it has a negative effect on the embarkation efficiency if there are many passengers waiting outside the lifeboat. Second, group passengers tend to choose the same queue or enter the same lifeboat, and the embarkation process may be affected by group behavior. Finally, the space inside the lifeboat is extremely tight. The average area for each passenger is less than 0.3 m^2, and the space between seats is also used as the passage. If passengers who enter the earlier take seats near the door or inboard place, it will hinder the movement of subsequent passengers who would enter the lifeboat. At present, there are few studies on the embarkation efficiency of lifeboats by considering the behavior of passengers inside and outside the lifeboat. There are multiple lifeboats arranged on the cruise ship, and the rational embarkation process is particularly important for improving the efficiency of passengers.

The main contributions of this study are as follows: first, according to the embarkation characteristics of lifeboats, we divide the embarkation process into the queuing process outside the lifeboat and the seat selection process inside the boat. Second, depending on the behavior characteristics of passengers under self-organization or organization by staff, transfer rules between queues and activity rules of passengers are proposed. Third, the influence of rules on passenger embarkation efficiency is analyzed, and the feasibility of improving passenger embarkation efficiency through rational rules is confirmed.

The other parts of this study are as follows: Section 2 provides the description of the research problem. The simulation model of embarkation is constructed in Section 3. In Section 4, simulation results are analyzed. The last section presents the conclusions and future works.

2. Description of the Research Problem

The embarkation and launching of the lifeboat are the final steps for passengers to abandon the ship. When passengers arrive at the embarkation station, they can embark on lifeboats under the guidance of the staff or by action themselves. To simulate the embarkation process, the embarkation model of the lifeboat and queue is established. The research object is a medium cruise ship with three lifeboats on each side of the embarkation deck. Figure 1 shows the embarkation area on the portside. Lifeboats 1 and 3 are double-deck lifeboats, and the capacity of these two lifeboats is 305 persons. Lifeboat 2 is a single deck, and its capacity is 146 persons.

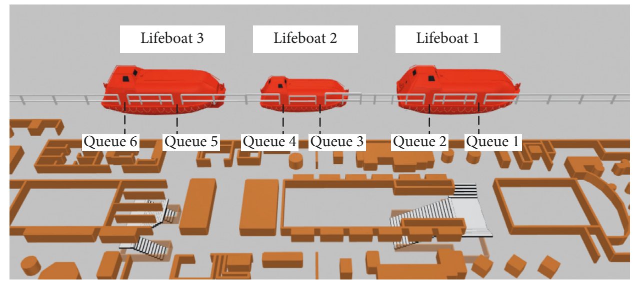

Figure 1: The embarkation area of lifeboats.

2.1. Queuing Model of Lifeboats. Queuing theory is mostly used to model pedestrians arriving at a service facility in a certain way. When pedestrians arrive at the service point, they stand in line and wait until their turn to be served. Once passengers have received service, they are usually assumed to have left the system. Queues models are mainly divided into M/M/C and M/M/1. In M/M/C model, pedestrians are placed in one queue, and pedestrians can receive services from multiple service points. In this queuing mode, pedestrians can only move in an orderly way, and the mobility of pedestrians is limited. This model is widely used in airport check in. In M/M/1 model, multiple queues are arranged in parallel, and each queue corresponds to a service point. This queuing can play the role of dispersing pedestrians. There are multiple queues for pedestrians to select, and some pedestrians may transfer between queues to choose the shortest queue.

The lifeboat embarkation model can be divided into two stages: the first stage is the passengers preparing to enter the lifeboat through the queue, and the second stage is the passengers selecting seats after they enter the lifeboat. The first stage of embarkation is similar to the queuing process. When passengers arrive at the embarkation area, they will form a queue to wait for the embarkation under the organization of staff or by self-organization. In the process of embarkation, the entrance of lifeboats can be considered as the service point, and passengers can be regarded as having received the queue service as long as they enter the lifeboats. According to the characteristics of lifeboat embarkation, the M/M/1 model is selected to simulate the embarkation process of passengers in this study. Each lifeboat has two entrances, and a queue is distributed in front of each entrance. Locations of queues are shown in Figure 1. In the initial stage, passengers are assumed distributed in the embarkation area and already wear life jackets. Passengers would move to the nearest lifeboat and form queues at the entrances of lifeboats.

2.2. Types of Embarkation Scenarios. As the capacity of the lifeboat is limited, passengers need to change queues when the lifeboat is full. Passengers generally prefer shorter queues since that can make them enter the lifeboat more quickly, which means that passengers may select the shorter queues by transferring between queues. Families or friends are traveling together on cruise ships, and they usually act in a group. The group passengers tend to preferentially select the same queue or enter the same lifeboat, while individual passengers will directly choose the nearest or shortest queue. Therefore, the transfer behavior can also be divided into transfers between queues of the same lifeboat or queues of all lifeboats. It is often difficult for passengers outside the lifeboat to verify the number of the remaining seats left inside the lifeboat. Hence, it is not beneficial to embark as there are many passengers waiting outside the lifeboat when the capacity of the lifeboat is nearly full. If passengers are under the guidance of the staff, these passengers could transfer among queues by considering the remaining seats of lifeboats.

Once entering the lifeboat, passengers may select seats at random. However, random seating selection may hinder the entry of subsequent passengers because of the narrow interior space of lifeboats. If passengers inside the lifeboat select seats from outboard row to inboard row under the guidance of the staff, then the passenger outside the lifeboat can enter the lifeboat smoothly.

Based on the above analysis, transfer rules of passengers between queues can be divided into four types: transfer between queues of all lifeboats (TAL), transfer between queues that belong to the same lifeboat (TSL), transfer between queues of all lifeboats based on the seat availability of lifeboats (TALSA), and transfer between queues that belong to the same lifeboat based on the seat availability of lifeboats (TSLSA). Activity rules of passenger can be divided into four types: the individual passenger selects seats from outboard row to inboard row (ISSOI), the individual

Table 1: Simulation scenarios of lifeboat embarkation.

		Activity rules			
		IRSS	ISSOI	GRSS	GSSOI
Transfer rules	TSL	TSL-IRSS	TSL-ISSOI	TSL-GRSS	TSL-GSSOI
	TAL	TAL-IRSS	TAL-ISSOI	TAL-GRSS	TAL-GSSOI
	TSLSA	TSLSA-IRSS	TSLSA-ISSOI	TSLSA-GRSS	TSLSA-GSSOI
	TALSA	TALSA-IRSS	TALSA-ISSOI	TALSA-GRSS	TALSA-GSSOI

passenger randomly selects seats (IRSS), the group passenger selects seats from outboard row to inboard row (GSSOI), and the group passenger randomly selects seats (GRSS).

The embarkation process is affected by the behavior of passengers, and the characteristic of the behavior of passengers under different rules is disparate. In addition, in order to analyze the difference between individual and group embarkation efficiency, different scenarios are needed to set for individual and group actions, respectively. Therefore, 16 types of embarkation simulation scenarios can be constructed by combining transfer rules and activity rules, as listed in Table 1. Each transfer rule contains four subscenarios. The influence of compound rules corresponding to each scenario on embarkation efficiency will be studied. The cabins on cruise ships are generally standard double rooms, and it is common for two people to travel together. Therefore, one group of passengers is composed of two people in this study.

2.3. Parameters of the Embarkation Model

2.3.1. Total Embarkation Time. For the lifeboat embarkation, the embarkation time is the most important index to measure the embarkation process. The total embarkation time includes the time for passengers to arrive at the queue, the waiting time in the queue, and the time for selecting seats in the lifeboat. The total embarkation time under one scenario can be defined as the time when the last passenger completes the embarkation process, as shown in the following equation:

$$T_{S(i)} = \max\left\{t_{S(i)}^{Pax(1)}, t_{S(i)}^{Pax(2)}, t_{S(i)}^{Pax(3)}, \ldots, t_{S(i)}^{Pax(j)}, \ldots, t_{S(i)}^{Pax\left(N_{Pax}\right)}\right\}, \tag{1}$$

where $S(i)$ represents the scenario i. N_{Pax} represents the total number of passengers. $t_{S(i)}^{Pax(j)}$ is the completion time of embarkation of the j th passenger in scenario i. $T_{S(i)}$ is the total embarkation time when all passengers complete the embarkation in scenario i.

2.3.2. Distribution of Numbers of Embarked Passengers within Time Intervals. Since passengers enter lifeboats through different queues, the completion time of embarkation is distributed discretely. In order to analyze the trend of the completion time of embarkation, the total embarkation time is divided into several time intervals, and the distribution of the number of embarked passengers within each interval is counted, as shown in the following equation:

$$NPA_{S(i)} = \left\{\sum_{l=0}^{6} PA_{S(i)}^{D(1)}(Q(l)), \sum_{l=0}^{6} PA_{S(i)}^{D(2)}(Q(l)), \ldots, \sum_{l=0}^{6} PA_{S(i)}^{D(k)}(Q(l)), \ldots, \sum_{l=0}^{6} PA_{S(i)}^{D\left(N_D\right)}(Q(l))\right\}, \tag{2}$$

where $D(k)$ represents the time interval k. N_D is the number of the time interval. $Q(l)$ represents queue l. $\sum_{l=0}^{6} PA_{S(i)}^{D(k)}(Q(l))$ represents the number of passengers who enter lifeboats through all queues and complete embarkation during the time interval k in scenario i. $NPA_{S(i)}^{D(k)}$ represents the set of the number of embarked passengers during all of the time intervals in scenario i.

2.3.3. Last Transfer Time. When waiting in the queue, passengers will transfer to the queue with fewer people by their preference or transfer to queues of the lifeboat with more empty seats under staff guidance. The timing of transfer out of the queue reflects the tendency of passengers to complete embarkation through the queue. Whether passengers act under their willingness or staff guidance is determined, and the earlier the leaving time of the last transferred passengers of the queue, the sooner the balance would reach between the number of people in the queue and the count of seats remaining in the lifeboat. The time of the last transferred passenger leaving the queue can be expressed as follows:

$$TQ_{S(i)}^{Q(l)} = \max\left\{tq_{S(i)}^{Q(l)}(1), tq_{S(i)}^{Q(l)}(2), tq_{S(i)}^{Q(l)}(3), \ldots, tq_{S(i)}^{Q(l)}(m), \ldots, tq_{S(i)}^{Q(l)}\left(N_{Trans}^{Q(l)}\right)\right\}, \tag{3}$$

where $N_{Trans}^{Q(l)}$ represents the number of passengers transferred out of queue l. $tq_{S(i)}^{Q(l)}(m)$ represents the transfer time of the m th passenger in queue l under scenario i. $TQ_{S(i)}^{Q(l)}$ is the leaving time of the last transferred passengers in the queue l under scenario i, which indicates that the number of passenger in the queue is less than or equal to the count of seats remaining in the lifeboat.

2.3.4. Number of Embarked Passengers through the Queue. The lifeboat has two entrances, and the difference in the number of embarked passengers between two queues can reflect the utilization efficiencies of the two queues. The number of embarked passengers through one of the queues of the lifeboat can be expressed as follows:

$$LPA_{S(i)}^{L(n)}(u) = \sum_{v=1}^{N^{L(n)}} \left(q^{L(n)}(u) \bullet L_p^{L(n)}(v) \right), \tag{4}$$

where $L(n)$ represents the lifeboat n. $N^{L(n)}$ represents the number of passengers entering lifeboat n. $L_p^{L(n)}(v)$ represents the v th passenger entering the lifeboat n, and its value is equal to 1. $q^{L(n)}(u)$ is the queue u of the lifeboat n. If the passengers entering the lifeboat n through queue u, $q^{L(n)}(u)$ equals 1. Otherwise, $q^{L(n)}(u)$ equals 0. $LPA_{S(i)}^{L(n)}(u)$ represents the number of people entering lifeboat n through queue u in scenario i.

3. Construction of Simulation Model

The embarkation process of passengers is a typical discrete event. AnyLogic [41] is a professional software of virtual prototyping environment for designing complex systems, and it is also widely used to simulate the behavior of pedestrian movement and queuing [42–44]. The software provides API interfaces, and users can customize functions according to the simulation needs. The social force model [45, 46] in the software is based on the Newtonian dynamics, and the different motivations and influences between pedestrians could be reflected by each force. Relevant studies showed that the behavior characteristics of pedestrians in evacuation could be simulated by the social force model, and the model has also been widely used in pedestrian evacuation simulation [47, 48]. Therefore, AnyLogic is used in this study to establish the embarkation scenario and simulate the embarkation process.

3.1. Construction of Simulation Scenarios. The simulation scenario is shown in Figure 2. In order to facilitate the simulation and observation of the embarkation process, the appearances of lifeboats are simplified. Hulls and seating areas of the lifeboat are retained, and passengers can enter the lifeboat through two entrances. Considering the obstruction effect of obstacles on the movement of passengers in the simulation process, the wall module of the software was used to build the hull and seat area. The elements constructed by wall modules can form obstacles in the scenario. Passengers need to go around these elements, and then the movement behavior of passengers in the narrow space of the lifeboat could be simulated. The number of passengers to be embarked is set based on the capacities of lifeboats, and there are 756 passengers in each case of the simulation. This study mainly studies the lifeboat embarkation process of the passengers. The initial condition is that the passengers are already located in the embarkation station and waiting for the captain's order to embark. The simulation is ended when all passengers have taken seats inside lifeboats.

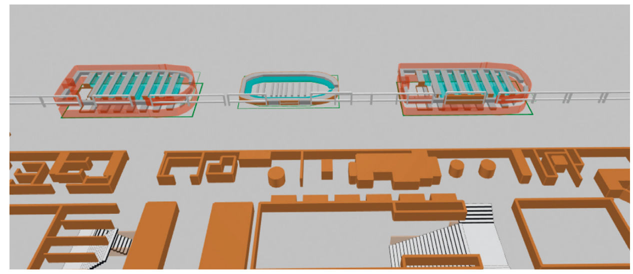

Figure 2: The simulation scenario.

The type, proportion, and speed of passengers in the evacuation simulation are stipulated in the IMO *Guidelines for Evacuation Analysis for New and Existing Passenger Ships* [49], as listed in Table 2. The parameters of passengers in the simulation are set according to Table 2.

3.2. Construction of Simulation Processes. Figure 3 shows the logic chart that is defined in the embarkation model. In the AnyLogic software, the logic chart is used to control the actions of pedestrians, and it consists of functional modules and connecting lines. The PedSource module is used to generate passengers. The group form of passengers can be defined in this module. The Lifeboat_Selection module can separate all of the passengers into several crowds, and functions can be called in this module to control crowds to choose the nearest lifeboat. The Output module includes Lifeboat_1_Output, Lifeboat_2_Output, and Lifeboat_3_Output modules, which could allocate passengers to the nearest queue of the current lifeboat. The pedServiceQueue module can simulate the queuing behavior of passengers, and this module adopts the rule of first in first out. When passengers enter the double-deck lifeboat, the Level_selection module determines whether passengers select upper or lower seats. Passengers who choose the lower seats will enter the lower level through the pedChangeLevel module. LookingForSeat module can realize the function of seat selection behavior of passengers. The Pedsink module is used to remove passengers from the current simulation scenario. In addition, the Cancel function in the pedServiceQueue module can redistribute transferred passengers to the Output module for the transfer process between queues in one lifeboat. If passengers wish to transfer between all queues, the passengers have been redistributed to the Output module and will be reallocated to the Lifeboat_Selection module once again. Then, the transfer behavior of passengers between all queues can be realized.

In the AnyLogic software, Java can be used to custom items that include functions, parameters, and so on. These

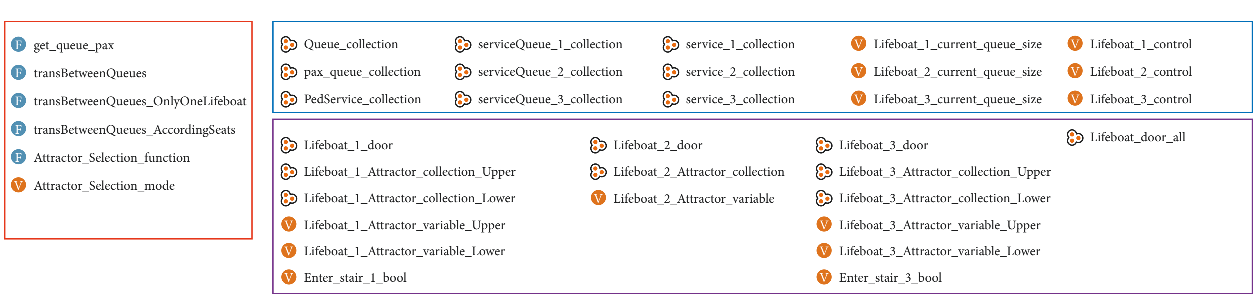

Figure 4: Functions and parameters of the model.

items can be called during the model run. Figure 4 shows the main functions and parameters that are defined in the model. The items defined in the red box are used to realize the function of the passenger transfer between queues and seat selection. The parameters of queues are defined in the blue box, and these parameters are used to obtain passengers' information in the queue. Parameters in the purple box are related to the position of seats and entrances of lifeboats. Details of the functions and parameters can be seen in Table S1 of Supplementary Materials.

    end
end
```

Figure 5: The pseudocode of the trans between queues.

queues and allows passengers to reselect other queues after they leave the longer queues.

Figure 6 shows parameters, the function, and the statechart of the passenger model. Items in the left part of the figure are the function and passengers' parameters, including ID, location, selected queue, and the wayfinding mode of the passenger. The chart in the right part is related to the current state of the passenger. If the passenger takes a seat, the status of the passenger is changed from standing to seating state by calling this statechart.

The embarkation simulation is run by combining the customized logic chart, functions, and parameters. The specific simulation process is shown in Figure 7, which includes the following steps:

Step1: select simulation scenarios, which include the ways of grouping, the transfer rule, and the preference of seat selection.

Step2: all passengers would be loaded into the simulation scenario, and passengers act alone or in groups based on the selected type of group.

Step3: passengers choose the nearest lifeboat and form queues at the entrances of the lifeboat. In group mode, passengers in the same group would select the same queue.

Step4: based on the selected scenario, passengers move forward in the queue and prepare to transfer between queues belong one lifeboat or all queues.

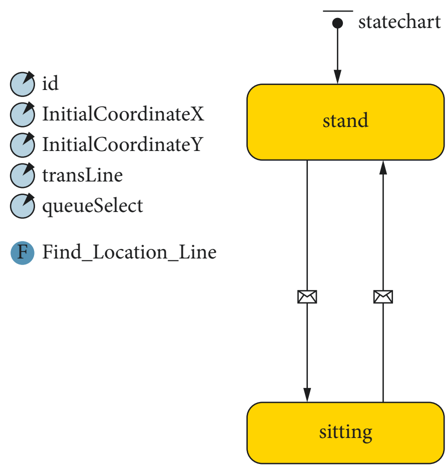

Figure 6: Parameters, the function, and the statechart of the passenger model.

Step5: judge lengths of all queues, the passengers at the end of the longer queue are randomly selected, and then these passengers would be transferred to the shorter queue. If in the rule of considering the seat availability of lifeboats, the number of remaining seats inside the lifeboat will first compare with the number of passengers in queues of the lifeboat. If the number of passengers in current queues is greater than or equal to the remaining seats, crowds of queues belonging to other lifeboats will not be transferred to the current queues even though the current queues are shorter. On the contrary, the extra passengers in the current queues will be transferred to queues of other lifeboats with more remaining seats. If there are still passengers remaining outside the lifeboat when the lifeboat is full, these passengers would be transferred to the queues of other lifeboats in the meanwhile.

Step6: passengers who are transferred would move to a new queue, while other passengers would stay in the original queue. As passengers continue to move forward in the queue, step 6 is repeated if they are selected to be transferred again.

Step7: when passengers enter the entrance of the lifeboat, they will choose the upper or lower seats with a probability of 0.5 if the lifeboat is a double deck. If the lifeboat is a single deck, passengers will directly select seats.

Step8: based on the preference of seat selection, passengers would choose seats randomly or from outboard row to inboard row and complete the embarkation process finally.

4. The Discussion of Simulation Results

Figure 8(a) shows the process of passengers moving towards lifeboats and forming queues. Figure 8(b) displays the process of passengers entering the lifeboat through the queue, and passengers in the red circle area were transferring between queues. The seat selection behavior of passengers is shown in Figure 8(c).

The embarkation characteristics of passengers were analyzed through simulations of 16 types of embarkation scenarios, and each scenario was run 100 times. The values in Figures 9–12, and S1 are mean values of the 100 simulation experiment results, and the error bars represent the standard deviation of the results.

4.1. Analysis of the Total Embarkation Time. Figure 9 shows the total times for passengers to complete embarkation in 16 types of scenarios. For scenarios of individual passengers, the embarkation time in the TAL-IRSS scenario is the longest, while the TSLSA-ISSOI scenario is the shortest. The total embarkation time of the TAL-IRSS and TSLSA-ISSOI scenarios is 1100 and 739 seconds, respectively, and the time of the TSLSA-ISSOI scenario is 32.8% less than that of the TAL-IRSS scenario. In scenarios of group passengers, scenarios that have the longest and shortest total embarkation time are the TAL-GRSS and TSLSA-GSSOI. The total embarkation time of the TAL-GRSS and TSLSA-GSSOI scenarios is 1199 and 891 seconds, respectively, and the time of the TSLSA-GSSOI scenario is 25.7% less than that of the TAL-GRSS scenario. It shows that values of total embarkation time were affected by transfer and activity rules.

From the perspective of transfer rules, the total embarkation time of the four subscenarios contained in TSL and TSLSA rules was smaller than the corresponding subscenarios under TAL and TALSA rules, respectively. It can be found that the embarkation efficiency of passengers transfer between queues of the same lifeboat was higher than they randomly transfer between all queues. The reason may be that the transfer between queues of the same ship can keep the balance of the number of people in these queues preferentially, which could improve the embarkation efficiency of the current lifeboat.

The total embarkation time of subscenarios under TSLSA and TALSA rules was shorter than that of TSL and TAL rules, respectively. This result indicated that transfer between queues based on the seat availability of lifeboats could reduce the behavior of passengers blindly moving to a lifeboat that has shorter queues but fewer remaining seats. In the same transfer rules, the total embarkation time of IRSS and ISSOI rules was smaller than that of GRSS and GSSOI rules, respectively, showing that the embarkation efficiency of the individual passenger is higher than that of the group passenger. In addition, the total embarkation time of IRSS and GRSS rules was longer than that of ISSOI and GSSOI rules, respectively, demonstrating that passengers could complete embarkation earlier if they select seats from outboard row to inboard row. When passengers selected seats randomly, passengers who entered at an earlier time may seat near the entrance hindered the movement of passengers who entered at a subsequent time, resulting in the increase of embarkation time.

4.2. Distribution Analysis of Numbers of Embarked Passengers within Time Intervals. Figure 10 shows the number distribution of embarked passengers within time intervals. Before 200 seconds, the embarkation completion rate of IRSS,

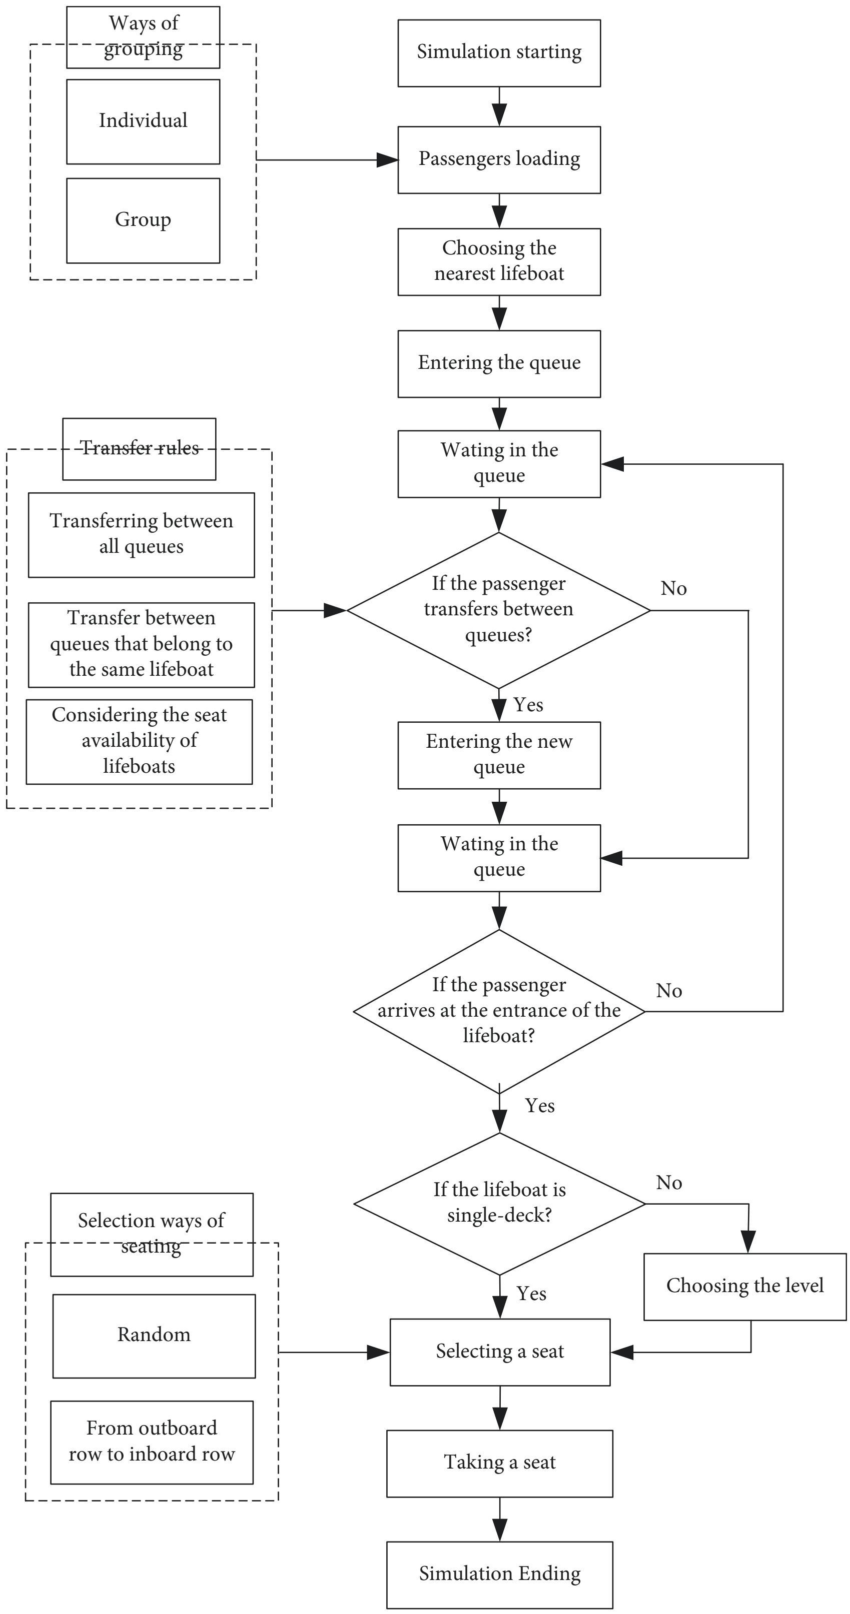

Figure 7: The process of passenger embarkation simulation.

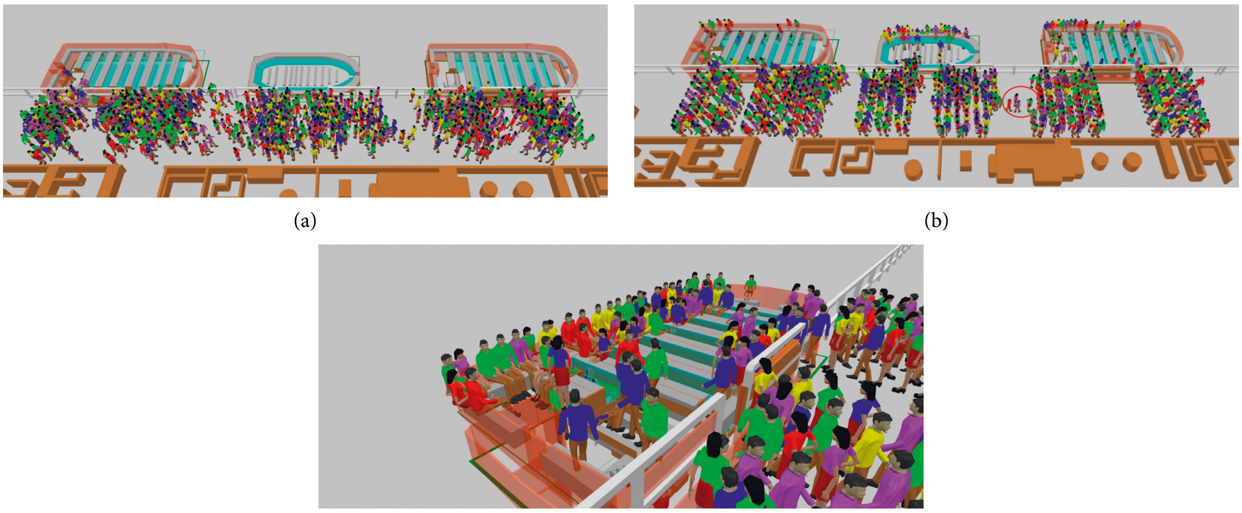
GRSS, ISSOI, and GSSIO rules is a little distinction under the four transfer rules. Within 200–600 seconds, the results of IRSS, GRSS, ISSOI, and GSSIO under different transfer rules gradually began to show obvious differences, which indicated that the embarkation efficiency was impacted by the transfer behavior of passengers. Moreover, the number of embarked passengers in the four subscenarios of TSLSA and TALSA rules was greater than that in the scenarios of



(a) (b)

(c)

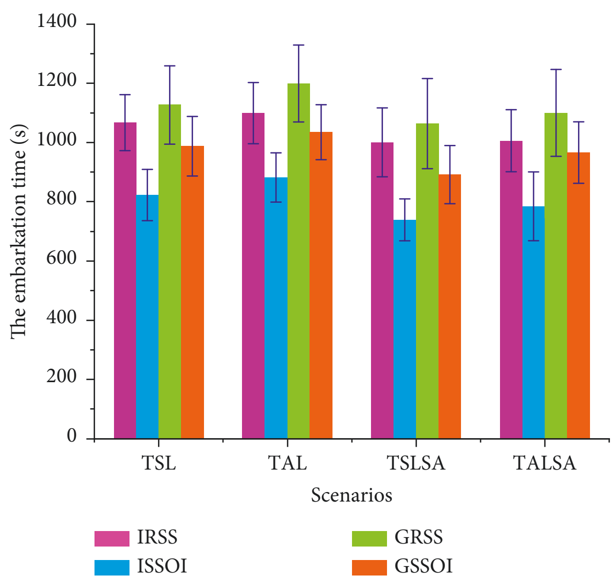

Figure 9: Total embarkation times of passengers.

TSL and TAL rules during this period. This phenomenon demonstrated that the queue transfer considering the seat availability of lifeboats could improve the embarkation efficiency of passengers, which was consistent with the result in Figure 9.

In all scenarios, the peak time of passengers' completed embarkation was around 100 seconds when they acted alone, and slightly more than 200 seconds when they acted in groups. The peak time in the two action modes was both in the early stage of the embarkation process. Figure 13 shows snapshots of the embarkation process. In Figure 13(a), the number of passengers in the lifeboat was small at the initial stage of the embarkation process, and passengers could quickly enter the lifeboat and take seats. In Figure 13(b), passengers at the entrance cause obstacles to subsequent entering passengers as the embarkation process progresses, which reduced the number of embarked passengers per unit time. Therefore, the embarkation efficiency would decrease as the number of passengers increased inside the lifeboat at the initial stage of the embarkation process. While in the middle stage of the embarkation, the number of embarked passengers decreased also related to the lifeboat 2. Lifeboat 2 can be filled earlier for its capacity is small. When lifeboat 2 is full, the number of passengers who could complete the embarkation would be decreased in unit time. Thus, the embarkation efficiency at this stage was also related to the state of lifeboats. As shown in Figure 10, the number of embarked people within 300-500 seconds suddenly decreased.

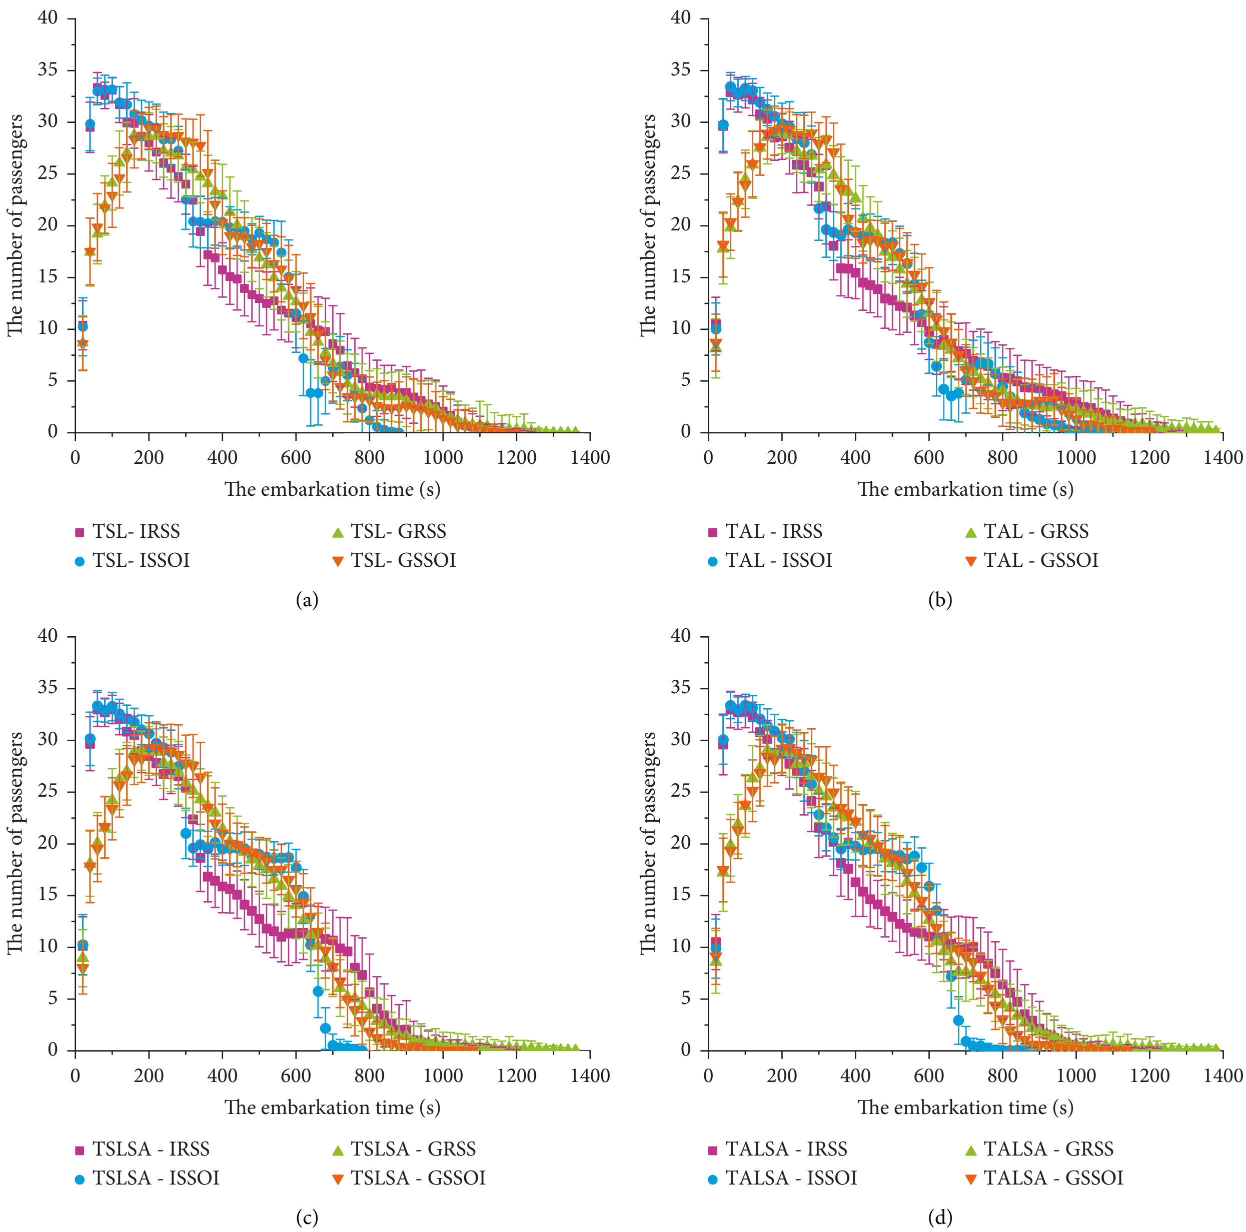

Figure 10: The number distribution of embarked passengers within time intervals. (a) The TSL rule. (b) The TAL rule. (c) The TSLSA rule. (d) The TALSA rule.

4.3. Analysis of the Last Transfer Time. Figure 11 shows the time of the last transferred passenger leaving the queue. In all scenarios, the last transfer times of queues 3 and 4 were significantly smaller than that of the other queues. Queues 3 and 4 belonged to lifeboat 2, and the capacity of this lifeboat was the smallest that could be filled full quickly. Therefore, the excess passengers in these two queues could be transferred to other queues earlier. Under TSL and TAL rules, the last transfer time of queues 3 and 4 was equal, indicating that excess passengers of two queues were transferred out simultaneously as long as lifeboat 2 was full.

In TSLSA and TALSA rules, passengers in these two queues would be gradually transferred to other queues in advance due to the consideration of the seat availability of lifeboats. Therefore, there may be a distinction in the process of passengers transferring out from these two queues, resulting in the difference in the last transfer time between these two queues. The last transfer time of queues 2 and 5 was significantly longer than that of the other queues. These two queues belonged to lifeboats 1 and 3, respectively. As these two queues were close to lifeboat 2, passengers in queues 3 and 4 would choose queues 2 and 5 as the prime target queues for transfer. Therefore, the number of passengers in the queues 2 and 5 was more than in queues 1 and 6, resulting in that the last transfer times of these two queues were also later than other queues.

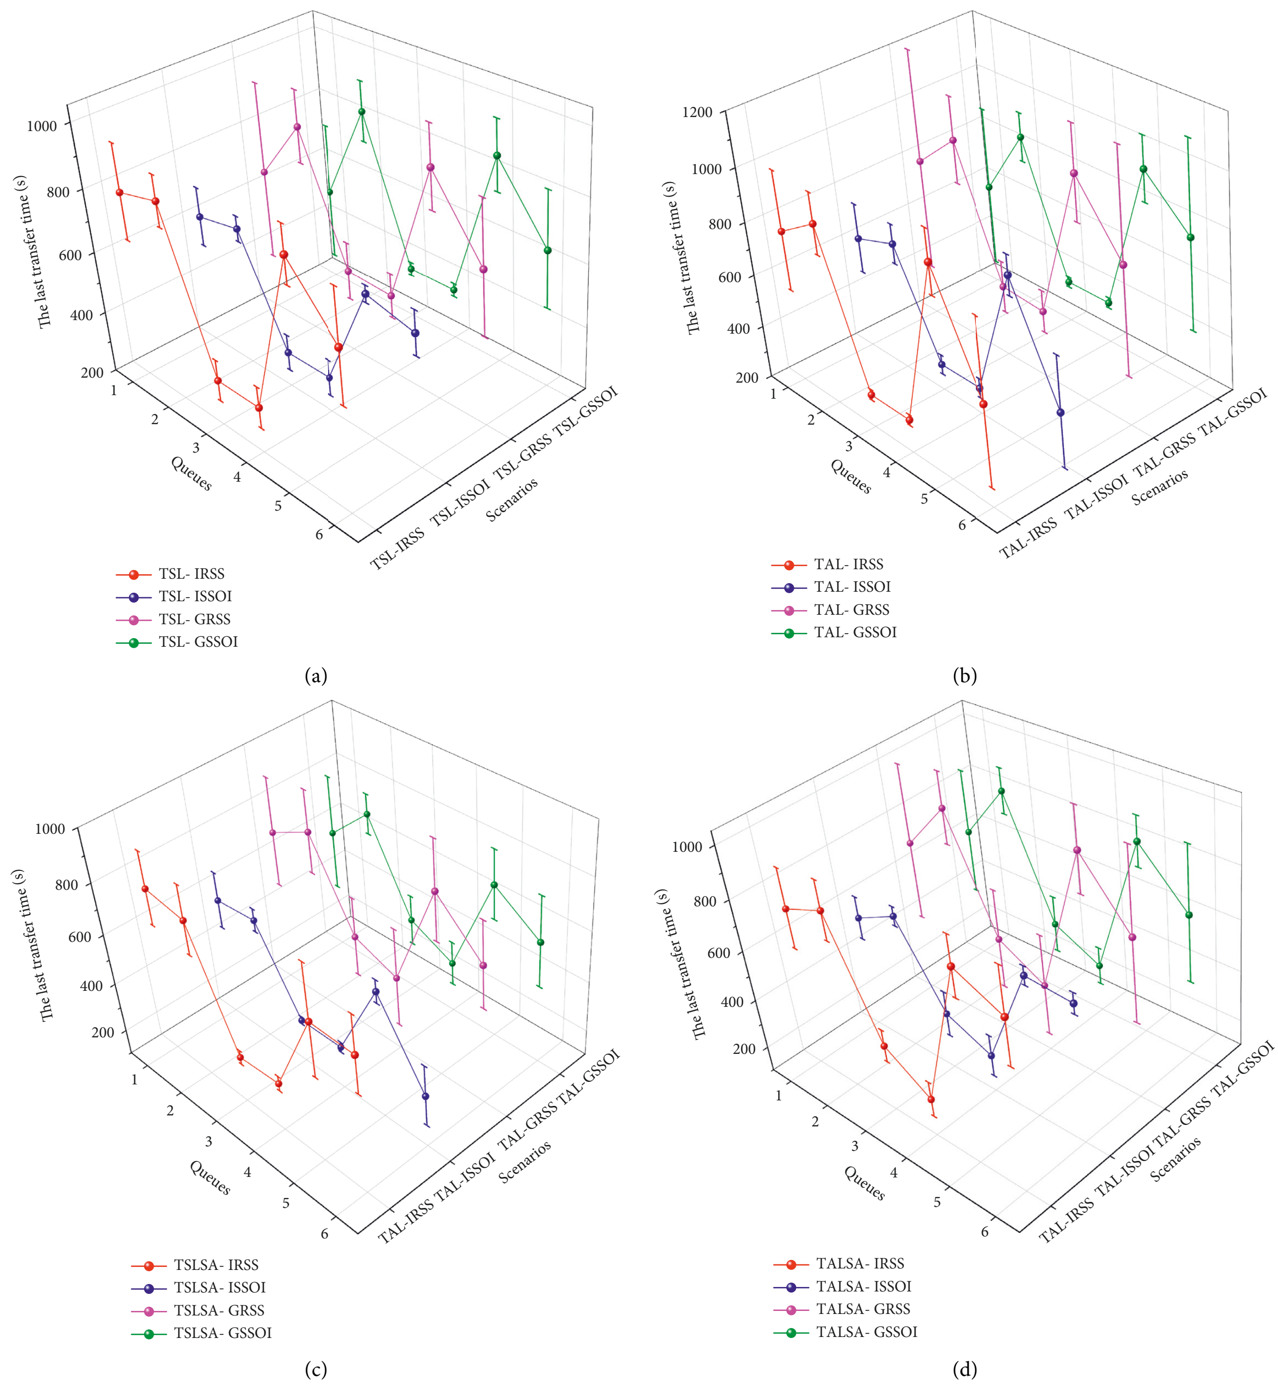

Figure 11: The time of the last transferred passenger leaving the queue. (a) The TSL rule. (b) The TAL rule. (c) The TSLSA rule. (d) The TALSA rule.

4.4. Analysis of the Distinction in the Number of Embarked Passengers between Two Queues of Each Lifeboat. Figure 12 shows the distinction in the number of embarked passengers between two queues of each lifeboat. Each cylinder represents the ratio of the number of embarked passengers from two queues of one lifeboat. The lower part of the cylinders of lifeboats 1, 2, and 3 represents the proportion of the number of embarked passengers entering through queues 1, 3, and 5, respectively. Conversely, the upper part of the cylinder represents queues 2, 4, and 6, respectively.

In most scenarios, the number of embarked passengers entering through queues 2 and 5 was more than that of queues 1 and 6. Especially for the TSL-GRSS, TSL-GSSSOI, TAL-GRSS, TAL-GSSSOI, TALSA-GRSS, and TALSA-GSSSOI scenarios, the difference in the proportion of embarked passengers between the two queues belonged to the same lifeboat was more pronounced. This distinction was

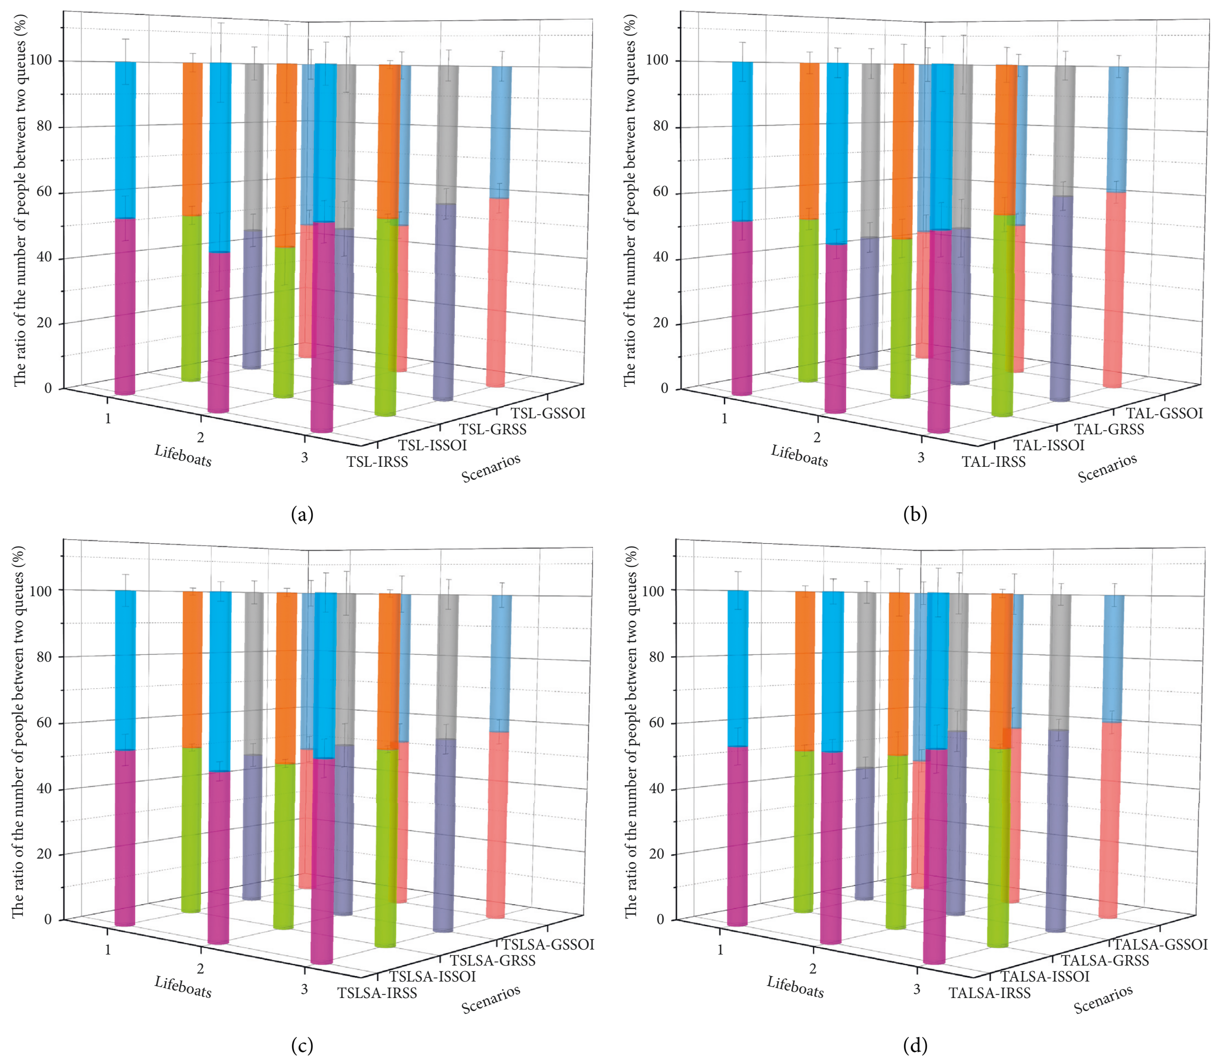

Figure 12: The difference in the number of embarked passengers in two queues of each lifeboat. (a) The TSL rule. (b) The TAL rule. (c) The TSLSA rule. (d) The TALSA rule.

Figure 13: Snapshots of the embarkation process. (a) The running time is 60 s. (b) The running time is 120 s.

mainly reflected in that there were more embarked passengers in queues 2 and 5 than in queues 1 and 6, which was consistent with the result in Figure 11. Compared with TAL and TALSA rules, the ratio of two parts of the cylinder under TSL and TSLSA rules was closer to 50%. As known from Figure 9, the total embarkation time of the four subscenarios under TSL and TSLSA rules was shorter than that under TAL and TALSA rules, respectively. It showed that the balance of the number of passengers in queues belong one lifeboat could be better maintained if passengers transfer between queues of the same lifeboat, which could also improve the embarkation efficiency.

5. Conclusions and Future Works

This study examined the lifeboat embarkation process of cruise passengers. By dividing the embarkation process into queuing and seat selection stages, transfer rules of queue and activity rules of the passenger were proposed. Based on the rules, 16 types of embarkation scenarios were constructed, and embarkation processes of these scenarios were simulated.

The simulation results showed that the embarkation efficiency of passengers was high in the early stage. As the progress of the embarkation, the passengers who had entered the lifeboat caused obstacles to the subsequent passengers, and the embarkation efficiency was gradually decreased. It was advantageous for passenger embarkation to select seats from outboard row to inboard row than select seats by random. The embarkation efficiency of passengers transfer between queues of the same lifeboat was higher than they randomly transfer between all queues. In addition, the embarkation efficiency would be improved again if the queue transfer was based on the seat availability of lifeboats. An obvious result of the study is that the total embarkation time of the TSLSA-ISSOI scenario is 32.8% less time than the TAL-IRSS scenario, and the total embarkation time of the TSLSA-GSSOI scenario is also 25.7% less than the TAL-GRSS scenario.

We also tested the embarkation time of passengers under the mixed rule, as shown in Figure S1. The mixed rule combines all transfer and seat selection rules, and it mainly reflects that some of the passengers acted autonomously under the guidance of the staff. The results show that the embarkation time under the mixed rule is longer than the single rule under the guidance of the staff (TSLSA-ISSOI and TSLSA-GSSOI) and shorter than the single rule under the autonomous action of passengers (TAL-IRSS and TAL-GRSS). Even if some of the passengers still kept their own willingness and did not act on staff guidance, the embarkation efficiency is still higher than that without the guidance of the staff. It is proved that under the guidance of the staff, appropriate queue transfer and seat selection rules can effectively improve the embarkation efficiency of passengers.

The limitation of this study is that the simulation result has not been compared with experimental data of the object ship. In order to perfect the rules proposed in this study and apply them to improve the embarkation efficiency of cruise ships, it is necessary to carry out passenger embarkation experiments and use experimental data to improve the queue transfer and seat selection rules in future work.

Academic Editor: Tongguang Ni

In order to improve the quality of modern physical education (PE) and let PE teachers get rid of the busy data management, this article puts forward the design of an assessment system about sports performance based on data mining and introduces the scheme of the system in detail. Based on NET three-tier architecture, the demand of users is analyzed, combined with web technology, SQL database platform, and the theory of data mining. The technical architecture of the system and the design of the database are discussed, and the realization of the functional module of sports achievement management is implemented. The system is tested so that the accuracy is verified in use. At the same time, the system runs well after testing and application. Through this system, PE teachers can realize the management and statistics of sports performance, reduce the intensity of teachers, and enable PE teachers to devote themselves to improving the quality of PE teaching.

1. Introduction

In the process of China's social and economic progress, China's education system is undergoing continuous reform, and the requirements for comprehensive physical fitness and high-quality talents are getting higher than before. In modern society, students not only need good grades but also have a demand for physical fitness so that they can make advances in future work [1]. This also meant that physical education is the foundation of other disciplines, students' sports test also began to count their total scores, and the view that sports is not so important has been gradually changed [2]. As for the calculation of sports achievement, it is mainly through the test of students' PE class, such as high jump, long jump, and 300-meter dash, which are converted into specific scores according to the relevant regulations of the school. Because of the diverse content of PE courses, much achievement data are produced in the implementation of testing. Teachers have to implement the data conversion and input them into the school educational administration system. The results are made by hand movement under heavy workload so that the work efficiency cant be improved, which restricts the sustainable development of physical education [3, 4]. To solve these problems, we need a data statistics and analysis system that can make PE teachers get rid of heavy tasks, effectively solve these problems, and optimize inner work so as to give full play to the guiding role of teachers in PE teaching.

With the rapid development of computer technology, data mining is constantly improving, and more and more companies and enterprises are beginning to use data mining technology to improve their own management system [5], which constantly promotes the prosperity of their companies. For data mining technology, it is widely used in major companies. However, the application in colleges is relatively less because colleges pay more attention to theoretical knowledge, and data mining technology is less used in the management system of colleges [6–8]. But in fact, this is a loss to the management system of colleges. Due to the lack of application, the related management of students is rather heavy, which results in lower working efficiency. The data mining technology has the advantages of good performance, simple operation, and easy employment. Due to these advantages, the rapid development of this technology is constantly promoted [9]. In view of the problems in modern PE teaching, this article utilizes information mining innovation to understand the programmed handling and analysis of data on sports achievement, which is convenient for students to inquire about their scores and teachers' statistics so as to continuously improve the efficiency and teaching quality of the college.

2. Introduction to Related Technical

2.1. ASP.NET Technology. ASP.NET is developed by integrating ASP and NET technologies [10, 11]. ASP.NET is applicable to a wide range of each field, such as the dynamic process of website design. Compared with other technologies, ASP.NET has its own unique advantages. It mainly includes the following points: (1) ASP.NET is a newly developed technology, which is popular among people, and it integrates the advantages of both ASP and NET technologies; (2) ASP.NET has a wide range of database resources, and it can translate many languages, which is convenient for people to use; (3) ASP.NET has been developed on the basis of various technologies, which has many functional advantages and is easier to operate than others [12, 13].

It can be seen from Figure 1 that ASP.NET is mainly composed of three parts, which are mainly divided into the user layer, business logic layer, and data access layer.

(1) The user layer, also known as the presentation layer, is a layer directly facing customers, and all interaction between users is the responsibility of this layer. Therefore, in the application of this layer, It is necessary to build a concise appearance to facilitate users' operation [14].

(2) Business logic layer located in the middle layer is mainly used to calculate and process business-related logic. This layer plays a connecting role and is the core layer of the three layers [15].

(3) Data access layer, which mainly represents various operations on the database, provides various data services for the previous layer and feeds back the processing results.

These three layers are related and interlocking. Reasonable adjustment of these layers can not only improve the operating efficiency of the company but also improve the economic benefits of the enterprise. Moreover, these components have their own unique advantages, and at the same time, the operation and use are relatively simple and practical.

2.2. Database of SQL Server. SQL is a structured language for querying, and SQL Server is a database management system. The database management system is used for storing all kinds of data used in the system, and at the same time, various operations of data, including query, modification, and deletion, are realized by transferring SQL statements. This kind of database management system is mostly used to develop a distributed system, which is convenient to operate. Moreover, it is powerful, can realize various functions of accessing and operating data, and provides a concise user interface to learn [16, 17].

The database system of the sports assessment system is SQL Server 2005, which was chosen because of its unique advantages, as follows: (1) the application of distributed view greatly improves the speed of accessing the database and the work efficiency, while the distributed view can quickly locate the data [18]; (2) it supports multiple development languages, including XML and other languages; (3) it has better performance and higher reliability; (4) it encapsulates a variety of technologies that are commonly used to realize data integration; (5) SQL Server 2005 provides users with a virtual network of the interface system.

2.3. Data Mining. In brief, data mining is to extract or "explore" knowledge from data in quantity [19, 20]. Many people regard data mining as another term data that is commonly used.

It is synonymous with knowledge discovery in database (KDD) in mining database, while others just regard data mining as a link of KDD, which is a process of extracting useful patterns from data automatically and efficiently using specific algorithms of data mining. KDD is a cyclic process including data mining and data preparation.

At present, there is no exact definition of "data mining." A relatively accepted definition is put forward by W.J. Frawley, G. Piatetsky-Shapiro, and others: that is, data mining is an extraordinary process to obtain patterns that are correct, novel, potentially applicable, and finally understandable from data [21].

Information mining is a multistage process and can, for the most part, be isolated into three principal stages: information readiness, information mining, and result articulation and translation. KDD is an iterative process of the three stages. The specific process can be described in Figure 2 [22].

2.3.1. Stage of Data Preparation. Data preparation represents the biggest extent in the entire course of information mining, which as a rule, comes to around 60%. This stage can be additionally separated into three substeps: information choice, information preprocessing, and information change [23–25]. Information determination basically alludes to separating pertinent information from the current dataset or information distribution center to frame information focused on. Information preprocessing processes the extricated information to meet the necessities of information mining. Its main job is to check spelling mistakes, remove duplicates, and make up incomplete records. Data transformation is mainly to normalize data. For example, continuous data is converted into discrete data to facilitate symbol induction; likewise, the discrete data can be converted into continuous data in order to unify the dimension (or dimensionless) so that all index data can be uniformly processed in various algorithms.

2.3.2. Stage of Data Mining. At this stage, the task of mining, such as data classification, clustering, discovery of association rule, or sequential pattern, should be determined first

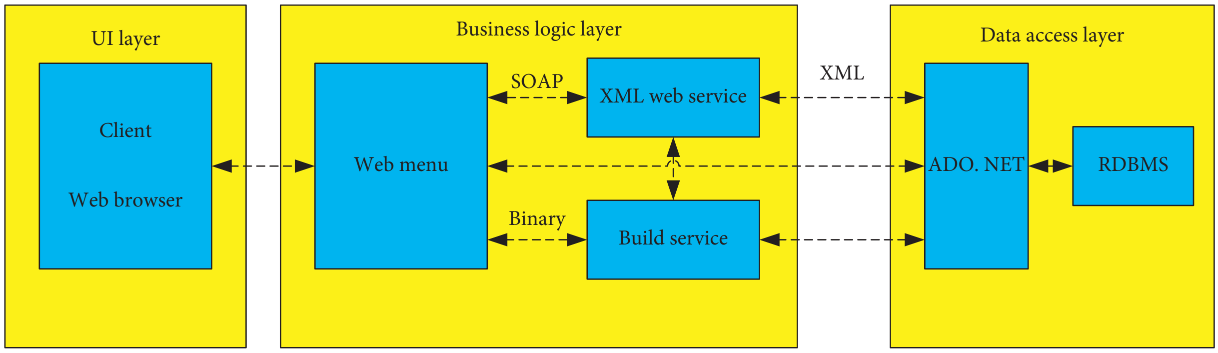

Figure 1: Three-layer structure based on ASP.NET.

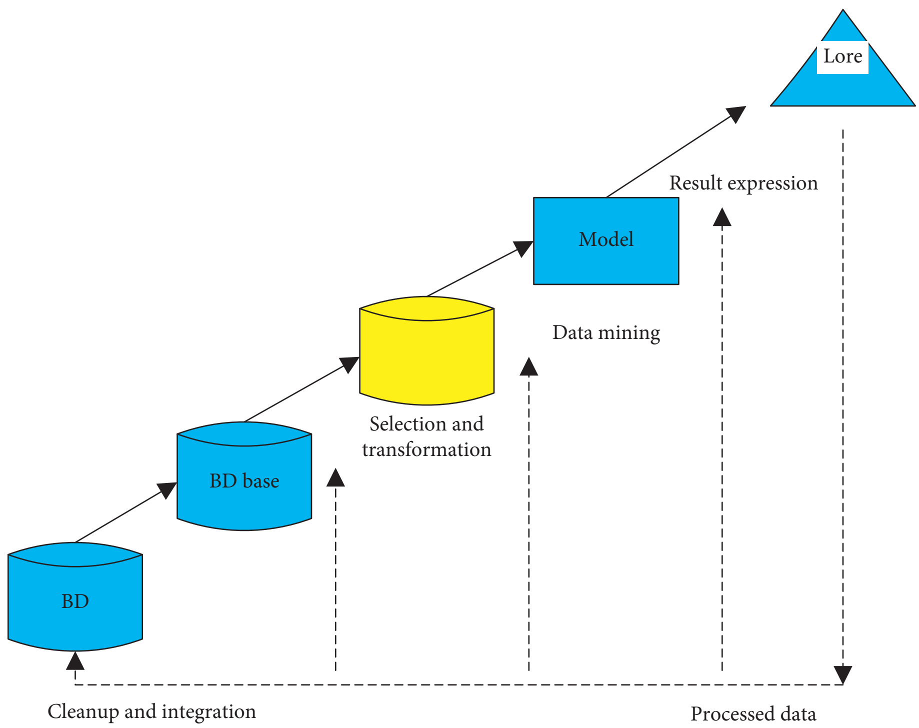

Figure 2: Process knowledge discovery in database.

[26]. After determining the mining task, it is necessary to decide which mining algorithm to use. The choice of algorithm is the most important factor in the data mining stage and the key factor related to the effectiveness of acquired knowledge, which directly affects the quality of mining patterns. The algorithm should be selected according to the characteristics of data and the actual requirements of users [27]. After finishing the arrangements above, you can run the calculation of information mining. This stage is the most concerned by data mining investigators and specialists in related fields, which can be called data mining in the genuine sense.

2.3.3. Expression and Explanation of Results. Knowledge discovery mode in the stage of data mining can analyze and evaluate the extracted information according to the purpose of the end user's decision [28], while can also distinguish the valuable information and eliminate patterns that are redundant or irrelevant. For the mode that cannot meet the user's requirements, it is necessary to return to the previous stage, such as reselecting data and adopting methods of new data transition. Set new parameter values, or even change a mining algorithm.

3. Overall Design of System

3.1. Demand Analysis. In terms of physical education, teachers have to face the realistic problem of a huge workload at the stage of examination. With the increasing attention paid by the state to students' corporeity, how to establish a perfect performance assessment system and carry out more targeted teaching through the statistics and management of students' PE achievements over the years is an important issue for physical education. The users of the system are administrators, teachers, and students, while different roles correspond to different operation permissions and users need to log in with their personal account and password. The system provides users with different permissions according to personal account information and then completes the operation of corresponding permissions. There are many categories of sports test items, and the test methods, scores, and scoring methods are different. Therefore, it is necessary to set different scoring forms according to different items when calculating scores, and the total score of each item is 100 points. The addition, modification, and deletion of these test item categories need to be achieved by the system.

3.2. System Design. The design of the target system is based on data mining through detailed exchanges and discussions with related PE teachers in colleges. Aiming at various problems in the management of sports achievements, the design and development scheme of the sports assessment system is put forward to solve the problems faced in the current management of sports through the application of the target system, which frees the PE teacher from the busy work in the past and realizes the automation and informatization of the management of sports achievements. Figure 3 shows the overall diagram of sports achievement management.

From the figure above, it is known that there are three types of users that the target system faces, namely, PE teachers, students, and system administrators. The three types of users can perform different system operations. The system administrator has the greatest authority and can perform any function in the system. PE teachers can perform other functions except for system management. In contrast, students have the least corresponding permissions and can only perform functional operations about performance management.

The development of the system is based on the. NET three-layer structure divides the whole application into three layers, namely, presentation layer, business logic layers, and data access layers [29]. The presentation layer is a user-oriented application layer, which is responsible for completing the interaction with users. This layer usually uses the interface to complete the interaction by designing some controls on the interface [30]. It is only responsible for receiving access requests sent by users and feeding back the final results to users, and it does not need to be careful about the specific method to realize users' requests. The business layer is located between the presentation layer and the data access layer, which is the core link of the logic processing of the whole system, and is responsible for the logical calculation and processing of the user's request while receiving the data from the data access layer at the same time. The data layer works for gaining data and executing programs and feeding the processing results back to users. Figure 4 shows the architecture of the system.

4. Function Module Design of the System

The overall functional structure diagram of the system is shown in Figure 5.

It can be seen from the figure that the system consists of five functional modules, namely, test type management, test project management, score management, score analysis, and system management.

4.1. Management Test Type. Test type refers to items related to sports test, which is stipulated by the syllabus. Test type management includes operations related to test types, including adding test types, modifying test types, deleting test types, and setting weights. Figure 6 shows the functional block diagram of test type management.

(1) Increase test type: it means adding a new test type. During the process of adding, the system will verify the content added by the user, including whether it is blank or legal.

(2) Test type modification means to modify the existing sports test types and save the user's modified results to the corresponding type database.

(3) Test type deletion: delete the original test type in the database. In the process of deletion, the deletion object selected by the user will be judged whether there are test items under the test type. If there are any, the user will be prompted that the test type cannot be deleted, and the type can only be deleted if it is determined that there are no test items.

(4) Score weight setting: it refers to setting the relevant proportion of the score weight under each test type.

4.2. Test Project Management. Test projects refer to specific projects involved in sports tests, such as high jump, long jump, and basketball. Test projects management refers to the management of business related to test projects. Figure 7 shows the functional structure diagram of test project management.

(1) Increase test projects: it means adding new test projects. During the process of adding, the system will verify the contents added by users, including whether they are blank and legal.

(2) Test projects modification means relevant modification operations are carried out on the existing sports test projects, and the user's modified results are saved in the corresponding type database.

(3) Delete test projects: delete the original test projects in the database.

(4) Point weight setting: it refers to setting the relevant proportion of the score weight under each test project.

4.3. Performance Management. Performance management refers to the related management of students' sports performance, including the entry of performance, the modification of performance, the deletion of performance, the inquiry of performance, the export of performance, and the conversion of scoring system. Figure 8 shows the functional structure diagram of performance management.

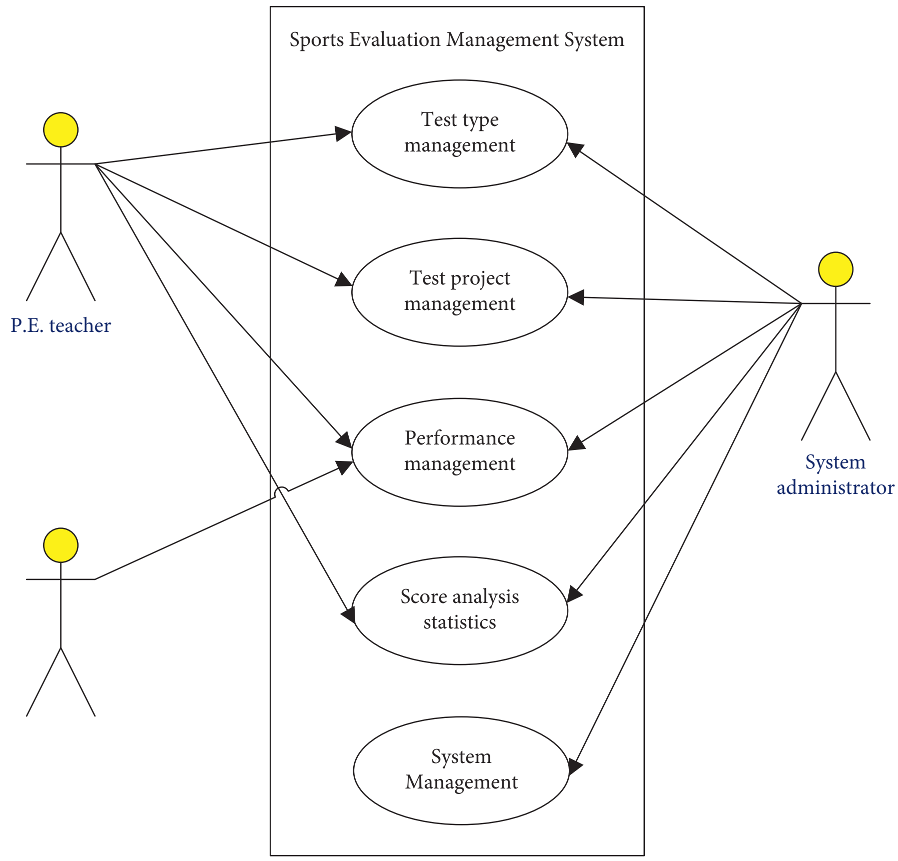

Figure 3: General use case diagram system.

(1) Input: it means that students' sports scores are entered into the score database of the system. In the process of score entry, the data entered by the user will be verified, including whether it is blank or legal. Only after confirming that both of them are satisfied will a new piece of information be inserted into the database to complete the entry.

(2) Modification: modify the original scores in the system and save the modified results into the score database of the system.

(3) Deletion: delete the original scores in the system and save the deleted results.

(4) Inquiry: by querying students' performance by entering specific query conditions, these conditions can include the student's student number, and the student's name or score range.

(5) Export: export the data related to students' sports achievements to Excel tables, which is convenient for statistics and decision-making.

(6) Conversion: it is converted into the corresponding points system according to students' scores.

4.4. Statistical Analysis of Achievements. Statistical analysis is to count the students' sports performance and analyze the statistical results using the algorithm of data mining. This is the core function of the target system. The functional structure diagram of the score analysis is given as shown in Figure 9.

(1) Score statistics: It means that students' sports performance is quantized to obtain the total score or average score. It also supports showing these statistical results in the form of charts or words, which is convenient for users to consult.

(2) Score analysis: It is the core part of the score analysis module, which refers to the analysis of students' scores using the algorithm of data mining.

4.5. System Management. System management refers to the management and maintenance of all the basic information of the target system. The main work includes the functions of user addition, user modification, user deletion, permission allocation, database backup, and database restoration. System management is the essential basic function module of every software. The following is the functional structure diagram of system management, as shown in Figure 10.

(1) User addition: it means adding users who enter the target system. The types of users targeted by the system include students, PE teachers, and system administrators.

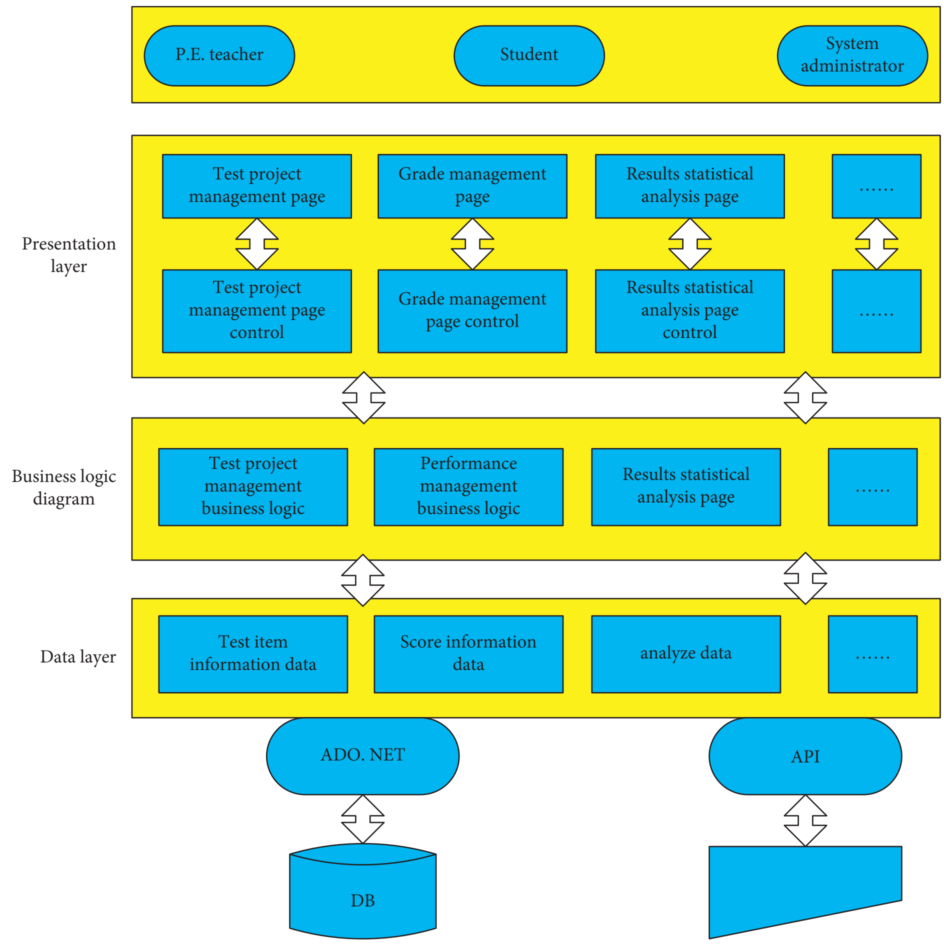

Figure 4: Overall technical architecture of the system.

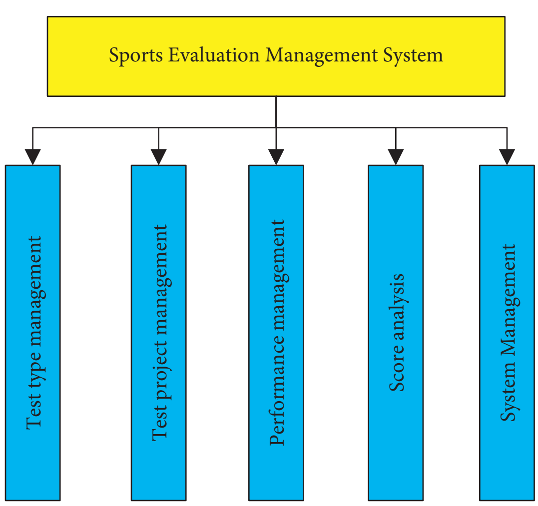

Figure 5: Overall functional structure of the system.

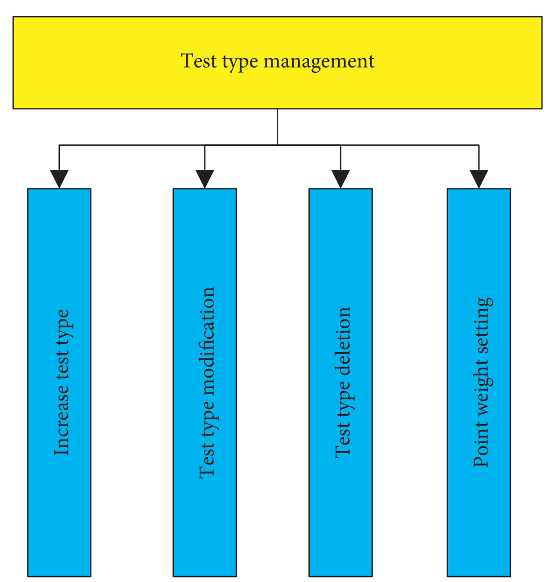

Figure 6: Functional structure diagram of test type management.

(2) User modification: it refers to the modification of basic information of users, including modification of users' password and modification of personal information of users.

(3) User deletion: it refers to the logout operation for information-related users who have entered the system.

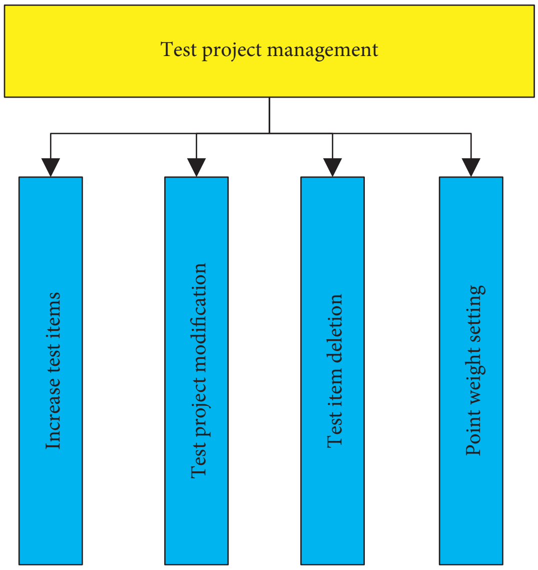

Figure 7: Functional structure diagram of test project management.

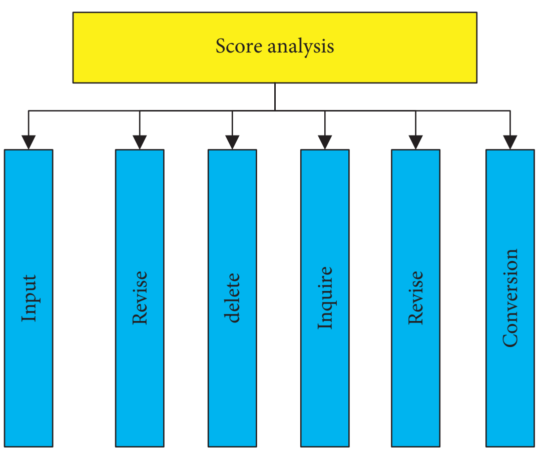

Figure 8: Functional structure diagram of performance management.

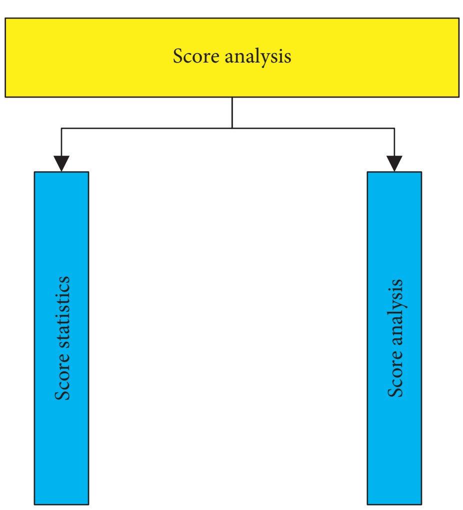

Figure 9: Functional structure diagram of score analysis.

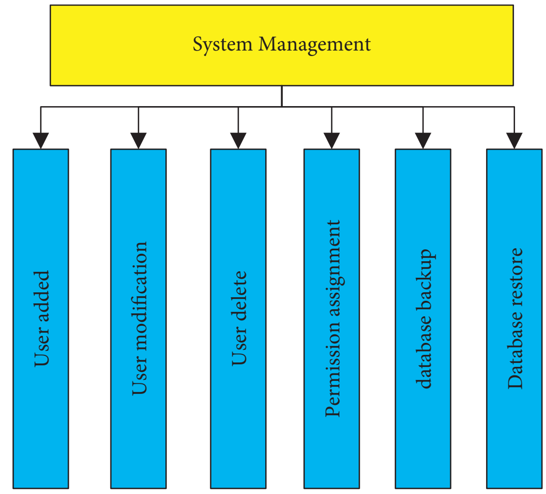

Figure 10: Function structure diagram of system management.

(4) Permission assignment: it allocates relevant permissions for users entering the system.

(5) Database backup: it is used to back up the database of the system.

(6) Database: it restores the database of the system.

5. Design of System Database

5.1. Design of Database System. According to the detailed analysis of the target system, the data table is designed here combined with the conceptual design and logical design of the system's database.

Table 1 shows the information table of users, which is mainly applied to store information related to the system, including ID, name, login Miyun, and type of users.

Table 2 shows the information table of students, which is mainly applied to store various information related to students, including name, ID, and login password of students.

Table 3 shows the table of test type, which is used to store various information related to test types, including test type name, type description, and weight.

Table 4 shows the table of test projects, which is mainly used to store various information related to test projects, including ID, name, type, description, and score weight of test projects.

Table 5 shows the table of test score, which is mainly applied to store the basic information related to students' test scores, including the test score number, test projects, student ID, and score.

Table 6 shows the table of students' achievement, which is used to store the basic information related to students' achievements, including grade ID, student ID, and total score.

Table 7 shows the conversion table of the points system, which is used to store the basic information needed for the conversion of the points system, including score ID, maximum score, minimum scores, and conversion name.

5.2. Application of ID3 Learning Algorithm. Data entropy, called normal data in the principle of data, is a normal worth

Table 1: Information table of user.

Field name	Data type (length)	Primary key	Null	Describe
Yong Hu ID	Int	Yes	No	User ID
Yong Hu Ming	varchar(20)	No	No	Username
Mi Ma	varchar(20)	No	Yes	Login password
Lei Xing	Bit	No	No	User type

Table 2: Information table of students.

Field name	Data type (length)	Primary key	Null	Describe
Xue Sheng ID	Int	Yes	No	ID
Xue Sheng XM	varchar(20)	No	No	Student name
Xue Hao	varchar(11)	No	No	Student ID
Mi Ma	varchar(20)	No	No	Login password

Table 3: Test type table.

Field name	Data type (length)	Primary key	Null	Describe
Ce Shi Lei Xing ID	Int	Yes	No	Test type ID
Lei Xing Ming Cheng	varchar(20)	No	No	Test type name
Lei Xing Miao Shu	Text	No	Yes	Test type description
Lei Xing Quan Zhong	Int	No	No	Test type weight

Table 4: Test item table.

Field name	Data type (length)	Primary key	Null	Describe
Ce Shi Xiang Mu ID	Int	Yes	No	Test project ID
Xiang Mu Ming Cheng	varchar(20)	No	No	Test item name
Ce Shi Lei Xing ID	Int	No	No	Belonging to the test type
Xiang Mu Miao Shu	Text	No	Yes	Test item description
Xiang Mu Quan Zhong	Int	No	No	Test item weight

used to quantify the communicated data. The data communicated in the source incorporates a set number of totally unrelated and together complete occasions, all of which appear with a certain probability, which is expressed by the mathematical formula: a group of events $x1$, $X1, \ldots, X_r$, which appear with a given probability $p(X1)$, $p(X_r)$, the mean value $H(X)$ is the information entropy, and it is equal to the mathematical expectation of the (self) information amount $I(X)$ of each event, namely,

$$\begin{aligned} H(X) &= -\sum_{r=1}^{r} p(Xi) I(Xi) \\ &= -\sum_{r=1}^{r} p(X_i) \log p(X_i). \end{aligned} \tag{1}$$

ID3 algorithm achieves the best classification in the algorithm according to the attribute of maximum information entropy and the principle conducive to the classification. The gain of information of an attribute will reduce the information entropy of the system, and the key operation of the ID3 algorithm is to calculate and compare the information of each attribute. It is needed to take a representative training sample as an example to introduce the decision tree node, which determines whether the samples are in the same category. By selecting the best classification attribute of the sample as the node attribute and dividing the samples, according to this node attribute, the maximum standard value is obtained. If samples are lacking in a branch, the sample types of the training cluster need to be compared.

6. Implementation of System

6.1. Types of Sports Test. Management of sports test types includes various functional modules: addition of test types, modification of test types, deletion of test types, and setting of weights. The database tables involved in these module tests mainly include test type tables, and the corresponding database program statements are Insert, Modify, and Delete. Among them, the program of test type deletion is shown in Figure 11.

6.2. Projects of Sports Test. The executives of sports test projects allude to the administration of data connected with sports test and its practical modules chiefly include the following: expansion of sports test projects, setting of weight, alteration, and cancellation of sports test projects. The tables of dataset engaged with the execution basically incorporate the data table of test projects. Some key codes of realization of functions are given as follows. First, the program gets the information entered by the user on the page. Among them, the procedure of added test projects is shown in Figure 12.

Table 5: Test score table.

Field name	Data type (length)	Primary key	Null	Describe
De Fen ID	Int	Yes	No	Score number
Ce Shi Xiang Mu ID	Int	No	No	Test items
Xue Hao	varchar(11)	No	No	Student ID
Fen Zhi	Int	No	No	Points

Table 6: Student achievement sheet.

Field name	Data type (length)	Primary key	Null	Describe
Cheng Ji ID	Int	Yes	No	Grade ID
Xue Hao	varchar(11)	No	No	Student ID
Zong Fen Zhi	Float	No	No	Total score

Table 7: Conversion table of the points system.

Field name	Data type (length)	Primary key	Null	Describe
Fen Zhi ID	Int	Yes	No	Point system ID
Fen Zhi Zui Xiao Zhi	Int	No	No	Minimum score
Fen Zhi Zui Da Zhi	Int	No	No	Maximum score
Ming Cheng	varchar(10)	No	No	name

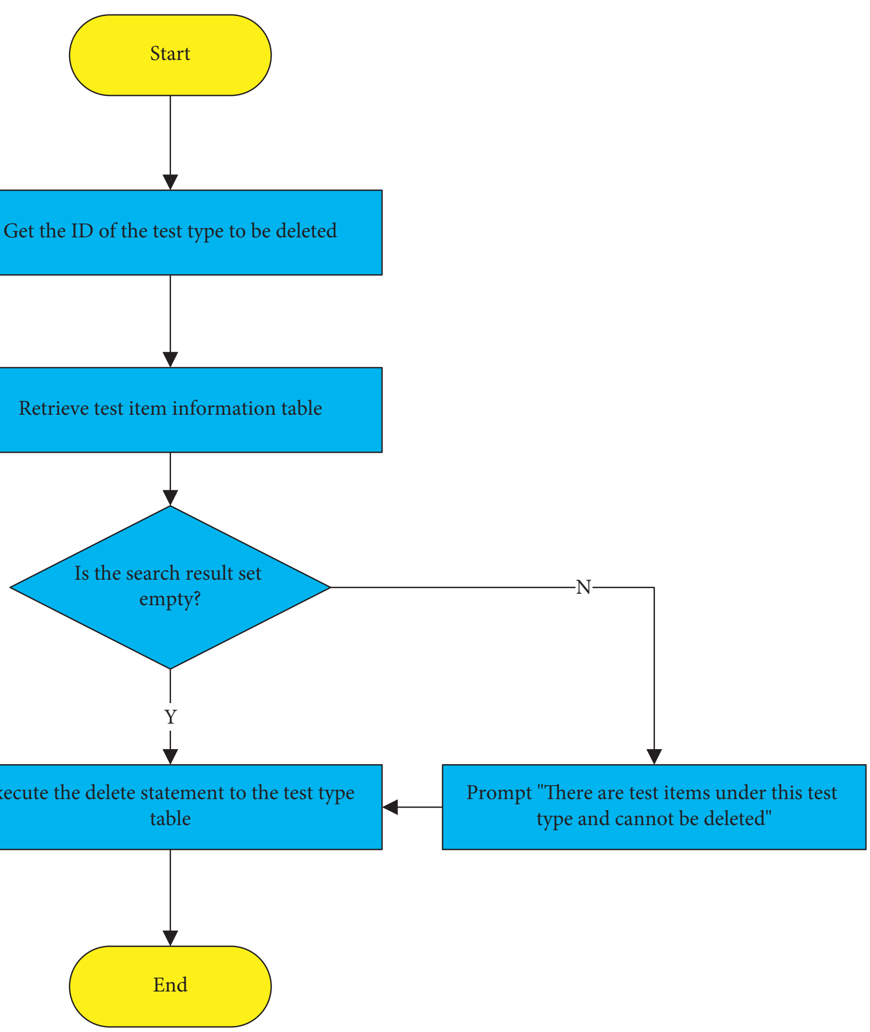

Figure 11: Program of test type deletion.

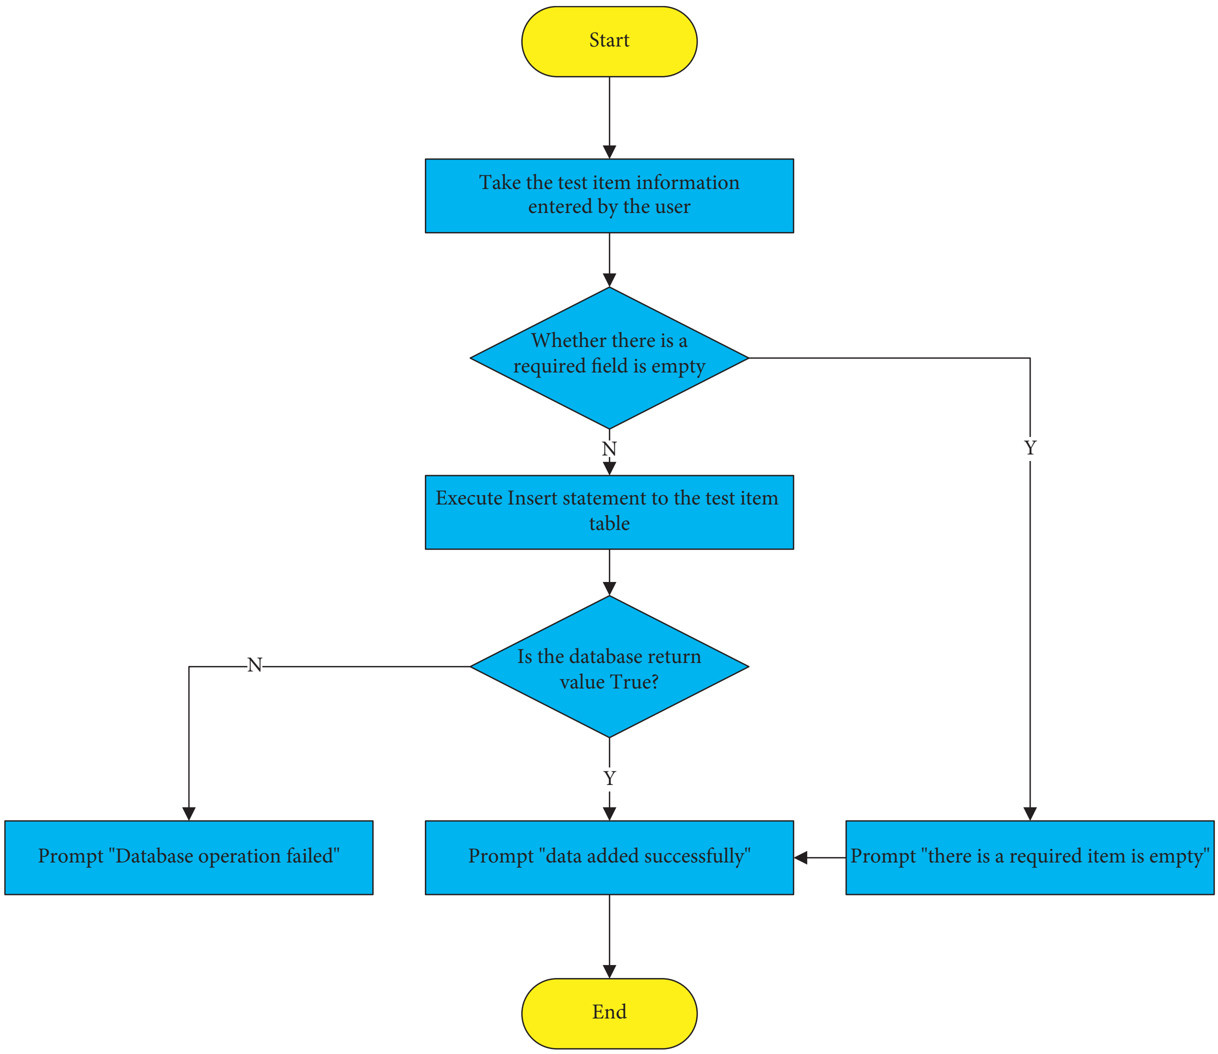

Figure 12: Procedure of added test projects.

6.3. Management of Performance. Management of performance refers to the management of information related to students' sports scores, which includes main functional modules: entry, modification, deletion, inquiry, export of scores, and conversion of point. In these modules, the core part is the entry and calculation of scores. In the process of entry, the tables of the database involved are information tables of scores, and the database tables indicated by calculation are information tables of scores and information tables of performance. Among them, the procedure of score entry is shown in Figure 13.

6.4. Problems and Solutions in the Process of System Testing. The problems and solutions in the process of testing the sports assessment system are as follows:

(1) After the system is installed, statistics of sports scores are made, but their download cannot be completed, and the system will not give a prompt of error. Solution: most of these problems are caused by the fact that office-related software is not installed in the system, which can be implemented after restarting according to the server. If it still cannot work, the permissions of components need to be modified.

(2) An error results in the termination of installation when IIS is registered and the database is coded. Solution: this situation usually occurs because the environment of NET is not installed, or the installed version does not match the version developed by the project; in addition, there is an error in the SQL. The current problems can be solved by improving these two aspects.

6.5. Evaluation of Teachers. After half a year's systematic maintenance, the PE evaluation management system based on data mining technology has been put into use, and it has been well received by PE teachers. Through this system, the workload of PE teachers is greatly reduced, and they are freed from the complicated work of processing data, which effectively improves efficiency, truly replaces manual labor with machines, and promotes the normalization of teaching

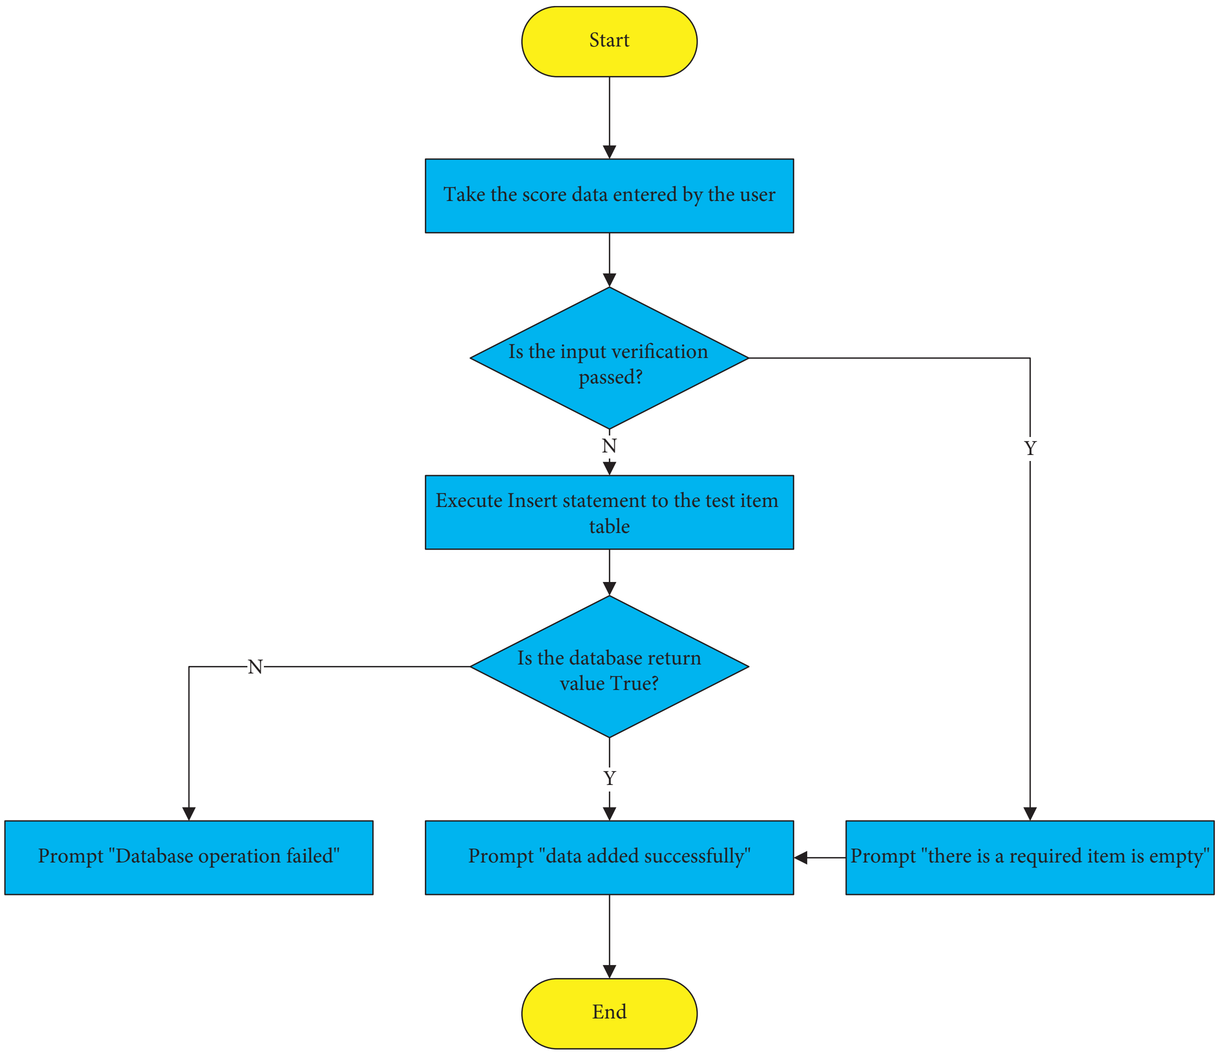

Figure 13: Procedure of score entry.

management through the application of sports management system based on data mining technology.

7. Conclusion

Advances in computer and network technology provide technical support for the information construction of colleges. On the basis of data mining, this article constructs a three-tier sports assessment system, completes the introduction of the system's functional modules and the design of the database, uses the ID3 algorithm to complete the data mining of the system, and finally completes the operation of each functional module. The results of the test show that the system runs stably, and the daily statistics and management of PE teachers' sports scores can be completed more easily through this system, which improves teachers' work efficiency, enables them to devote more energy to the improvement of PE teaching quality, and further enhances the level of automation and information management of physical education scores.

Data Availability

The dataset can be accessed upon request.

As the first incremental association mining algorithm, FUP can well solve the problem, but the algorithm also has the deficiencies to produce a large set of candidates and multiple iterating the database, leading to the algorithm's low execution efficiency when dealing with some large transactions with fast updates, such as book circulation data. This study proposes an improved FUP algorithm that takes transaction identifier (TID) in the database to scan the database only once, making the computation significantly less than the FUP algorithm. Through detecting the circulation data of a university library, the experimental results show that compared with the standard FUP algorithm and SFUA algorithm, with the increase of borrowing and record transactions, the improved FUP algorithm has significantly improved the operation efficiency, which can help the library to do a good job in book recommendation scientifically.

1. Introduction

Association mining is a main study direction of data mining. In the research of association mining algorithm, AIS [1], SETM [2], Apriori [3], DHP [4], and other algorithms have appeared successively. The above association mining algorithms that can only mine association rules from static databases [5] belong to static data mining algorithms. However, the actual situation is that it is often necessary to add a batch of new transactions to the original database transaction, or readjust the support degree and confidence threshold. In this case, a method needed to realize the updating problem of association mining. Rule of incremental association algorithm mainly deals with two kinds of problems: dynamic adjustment of threshold and updating of database. Concerning problem of dynamic threshold adjustment, the main representative algorithm is IUA [6] algorithm proposed by Feng Yucai et al, and related algorithms have also been proposed later. Reference [7] adopts the Can-tree sorted by the amount of data to improve the efficiency of frequent itemset mining in space and time. Reference [8] improves alarm prediction accuracy and model training efficiency through the alarm weight and communication prediction plan digging by weighted incremental association rule mining based on Can-tree. Reference [9] proposed a parallel incremental association rule mining algorithm based on information entropy and genetic algorithm to solve the problem of dynamically setting the support degree threshold. There are mainly FUP [10], FUP2 [11], and SFUA [12] algorithms for database updating problems. FUP is the first incremental association mining algorithm, which solves the problem of data update mining well, but it also has some shortcomings, such as generating a large number of candidate itemsets, traversing the database many times and so on. In view of the above shortcomings, scholars have improved this algorithm. Reference [13] uses the combination of strong frequent itemset connection and prepruning to improve the execution efficiency of the algorithm. Reference [14] proposed a method to update association rules efficiently based on attribute change. Reference [15] transforms the dataset into Boolean matrix to reduce the number of scans and storage of the database. Reference [16] combines inverted index technology with tree structure to solve the problems of low efficiency and high computational cost of incremental update mining algorithm.

In this study, an improved FUP algorithm is proposed. The algorithm uses the transaction identifier TID in the database to obtain frequent itemsets. It only needs to scan the database once, and then the candidate itemsets are obtained by connecting L_{K-1} and $L1$, so that the amount of calculation of the algorithm is significantly less than FUP. Through the detection of the circulation data of a university library, the experimental results show that compared with the standard FUP algorithm and SFUA algorithm, with the increase of borrowing record transactions, the improved FUP algorithm has significantly improved its operation efficiency, and can scientifically help the library do a good job in book recommendation.

2. Incremental Association Mining Algorithm

2.1. FUP Algorithm

2.1.1. The Core Idea of FUP Algorithm. Assume the original dataset dB, the new dataset dB and the updated dataset (DB∪db). Frequent itemset LDB in Dataset DB and support degree $\sup_{db}$. The support degree $\sup_{db}$ in new dataset db, minsup is the minimum support degree, and the core idea of FUP algorithm is [17] as follows:

(1) Frequent itemset L_{db} of the dataset db generated by Apriori algorithm, for any frequent itemset t, if $t \in L_{DB}$ and $t \in L_{db}$, then t will be the frequent itemset of the dataset (DB∪db).

(2) For any frequent itemset t, if $t \in L_{DB}$ and $t \notin L_{db}$, count the support degree $\sup_{db}$ of t in db by scanning the new dataset db, then according to the support degree supDB of the original dataset calculate support degree sup (DB∪db) of itemset t by the formula in the updated dataset. If $\sup_{(DB\cup db)}$>minsup, then itemset t is the frequent itemset of database set(DB∪db), otherwise is the infrequent itemset. The formula is: $\sup_{(DB\cup db} = (\sup_{DB}|DB| + \sup_{db} |db|/|DB| + |db|)$

(3) For any frequent itemset t, if $t \in L_{db}$ and $t \notin L_{DB}$, count the support degree $\sup_{DB}$ of t in DB by scanning the new dataset DB, then calculate itemset t according to the support degree $\sup_{db}$ in dataset (DB∪db), if $\sup_{(DB\cup db)} >$ minsup, t is the frequent itemset of database set(DB ∪ db), otherwise is the infrequent itemset.

2.1.2. Analysis of FUP Algorithm. FUP algorithm uses the frequent itemsets and support of the original dataset to generate a much smaller candidate itemset. When updating, it reduces the scanning of the original dataset as much as possible, so as to improve the efficiency of the algorithm. However, the algorithm also has obvious shortcomings [18]:

(1) The consumption of computing support is too large, and the database needs to be scanned many times, which is inefficient.

(2) Candidate itemsets are obtained by Apriori connection. With the increase of the number of items in the database, a large number of candidate itemsets will be generated, and the time complexity of the algorithm will rise sharply.

2.2. FUP2 Algorithm. FUP2 algorithm divides the updated database into ① datasets that remain unchanged after updating; ② additional datasets; and ③ deleted datasets. The algorithm adopts apriori_gen function and the L^1_{K-1} in frequent k-1 itemset of the updated dataset (DB ∪ db) generates a candidate k-itemset C_k, and C_k is a superset of L^1_{K-1}. Then, using the ^K_L in frequent k-itemset of the original dataset DB, the candidate itemset C_k is divided into the infrequent itemset and frequent itemset of the original dataset DB. What's more, the two itemsets are processed to finally obtain the frequent k-itemset of (DB∪db). Compared with FUP algorithm, FUP2 algorithm improves the operation efficiency, but it still uses Apriori algorithm when generating candidate itemsets, which likes FUP algorithm, it will produce too many candidate itemsets.

2.3. SFUA Algorithm. SFUA algorithm is an incremental association mining algorithm proposed by Chen Jinsong and others. The algorithm is mainly based on apriori_gen function in Apriori algorithm generating a collection of frequent itemsets db. Using the property "for itemset X, if $X \in$ LDB, and $X \in$ Ldb, there must be $X \in L$ (DB∪db)." The frequent itemset is divided into three disjoint parts:①a certain itemset is a frequent itemset in both dataset DB and db; ② an itemset is a frequent itemset in DB, while a infrequent itemset in db; ③ a certain itemset is a frequent itemset in db, but it is infrequent in DB

SFUA algorithm scans the dataset as follows: scanning the original transaction dataset DB only once; for the newly added dataset, db scanning $k+1$ times; the aggregate number of scanning is $|DB| + (k+1)|db|$. When the dataset is relative small, the efficiency of SFUA algorithm is truly high. However, when the newly added dataset is large, SFUA algorithm also has the problem of too many frequent itemsets.

3. Improved NFUP Algorithm Based on FUP Algorithm

3.1. Incremental Update Problem Analysis. The improved algorithm is based on the following theorems and properties [19], where $S(X)$ is a set consisting of identifiers, the number of elements in $S(X)$ is the support count of X, C_k is the candidate k-itemset, and Lk is the frequent k-itemset.

Theorem 1. *the necessary and sufficient condition for itemset X to becoming a frequent itemset is: SUP (DB∪db) (X)≥(|DB| + |db|)* minsup*

Theorem 2. *if the itemset X does not belong to the original frequent itemset, the necessary condition for X to become a frequent itemset is: SUPdb(X)≥|db|* minsup.*

Theorem 3. *$\forall C \in C_k$, S(C) can be obtained from two elements S(X) and S(Y) in S_{k-1}, and $S(C) = S(X \cap S(Y)$.*

Property 1. If itemset X is a frequent itemset in (DB∪db), then X is at least frequent in DB or db.

Property 2. If all candidate itemsets C_k can be generated by $L_{k-1} \infty L_{k-1}$ and there is $t \in$ Lk-1, the candidate itemset can also be generated by $L_{k-1} \infty L1$.

From Theorem 1, Theorem 2, and Property 1, combined with the support calculation formula, we can deduce SUPDB(t)+SUPdb(t)≥ (|DB| + |db|)*minsup, that is, to determine whether an itemset is a frequent itemset in the updated dataset, we need to compare whether$\mathrm{SUPDB}(t) + \mathrm{SUPdb}(t) \geq (|\mathrm{DB}| + |\mathrm{db}|)^* \mathrm{minsup}$ is true.

According to the above derivation formula and FUP algorithm, when adding a dataset db to an original dataset DB, the itemset has the following situations:

(1) If an itemset is a frequent itemset in both dataset DB and db, the itemset is also a frequent itemset in dataset(DB ∪ db).

(2) For any frequent itemset t, if there are one of the following two cases: ① $t \in L_{DB}$ and $t \notin L_{db}$② $t \in L_{db}$ and $t \notin L_{DB}$, if judging whether t is a frequent itemset in the dataset(DB∪db), it is necessary to compare the relationship between SUPDB(t)+SUPdb(t) and (|DB|+|db|)* minsup. If the former is bigger than the latter, it is a frequent itemset, otherwise it is a infrequent itemset.

(3) Moreover, t must also be a infrequent itemset in the updated dataset (DB∪db) if $t \notin L_{DB}$ and $t \notin L_{db}$. For cases (1) and (3), it is easy to determine whether they are frequent itemsets, so the improved algorithm focuses on case (2), and the problem is how to quic$_k$ly find frequent itemsets. From Property 2, it is obtained by connecting L_{k-1} and $L1$ when generating the candidate candidate set. The improved algorithm replaces the Apriori algorithm used in the original FUP algorithm to obtain the candidate item set for L K-1 self connection.

FUP algorithm mainly deals with the frequent itemsets of the database. In view of the shortcomings of this algorithm, this study proposes a method NFUP to obtain candidate itemsets by connecting L_{k-1} and $L1$. When generating frequent itemsets, it uses the transaction identifier TID in the database to obtain them. For the generated frequent itemsets, only the transaction identifier TID list and support degree need to be retained. The improved algorithm NFUP only needs to scan the original dataset and the new dataset once.

3.2. Execution Process of NFUP Minimum Support

(1) Scan the original dataset DB and the new dataset db respectively. The candidate item set of DB and db is C^1_{DB}, C^1_{db}, record the transaction identifier TID list corresponding to each item, and get the frequent 1-itemset of DB and db according to the minimum support, and mark them as L^1_{DB} and L^1_{db}.

(2) According to Theorem 3, calculate the support degree of db in DB. The support degreeof L^1_{db} in L^1_{DB} is the support degree of db in DB. According to the formula: $\mathrm{SUPDB}(t) + \mathrm{SUPdb}(t)$, calculate the support degree of L^1_{db} in (DB∪db). If $\mathrm{SUPDB}(t) + \mathrm{SUPdb}(t) \geq (|\mathrm{DB}| + |\mathrm{db}|)^* \mathrm{minsup}$ is true, it is the frequent itemset of (DB∪db), otherwise it is the infrequent itemset. In order to avoid repeating operations, L^{11}_{DB} obtained from the same items in L^1_{DB} and L^1_{db} that deleted from L^1_{DB}, and calculate the support degree of L^{11}_{DB} in db. If the support degree of L^{11}_{DB} in db is empty, it means that an item in DB has never appeared in db. Then continue to calculate the support degree of L^{11}_{DB} in (DB ∪ db). If it is bigger than $(|\mathrm{DB}| + |\mathrm{db}|)^* \mathrm{minsup}$, this item can be retained as a frequent itemset.

(3) Merge the frequent itemset of L^1_{db} in (DB ∪ db) and the frequent itemset of L^{11}_{DB} in (DB ∪ db) to obtain the frequent 1-itemset of $L^1_{(\mathrm{DB} \cup \mathrm{db})}$ in (DB∪db).

(4) $k > 1$, Calculate and itemsets of L^k_{DB} and L^k_{db}, obtain $L^1_{(\mathrm{DB} \cup \mathrm{db})}$ and respectively prune according to step (3), then obtain L^{12}_{DB} and L^{12}_{db}. Adopt improved Apriori_gen algorithm in L^{12}_{DB} and L^{12}_{db} to generate candidate itemset of L^{12}_{DB} and L^{12}_{db}. The idea of improvement followed by Property 2 shows that the candidate itemset C_k can also be generated by $L_{k-1} \infty L1$. The choice of L_{k-1} is related to k. when $k = 2$, it is actually $L1$ connecting $L1$, and $L1$ is the frequent one item set after pruning.

Continue to perform steps (1), (2) and (3) in the above process to obtain the frequent itemset k of (DB ∪ db) until the candidate itemset $k + 1$ of (DB ∪ db) is empty till the execution process ends.

3.3. NFUP Main Function Execution Function

(1) Build identifier Get_TID( ) function of 1 item collection

Get_ TID (database) function:
(1) $C_1 = \{$database collection$)\}$
(2) for all item $C \in C_1$ do $S(C) = c//S$ contains a set of identifiers, c is each item of $C1$
(3) end for
(4) for all $t \in$ Database do//an item in S
(5) $C_t = \mathrm{subset}(t, C_1)$
(6) for all $C \in C_t$ do $S(C) = S(C) \cup$ t.TID( )//build the identifier of 1-itemset to form 1 collection

(2) The process of generating candidate itemsets Apriori_gen( ) function

Apriori_CI( ) function:
(1) for all $l_{k-1} \in L_{k-1}$ do//l_{k-1} is one item of L_{k-1}
(2) for all $l_{k-1} \in L1$ do

(3) $l_{k-1} = l_{k-1} \infty l_1$
(4) $S(l_k) = S(l_{k-1}) \cap \cup S(l_1)$//generate k-itemsets
(5) Ct = subset(t, C_1)//gets a list of identifiers for the k-itemset

3.4. Case Analysis of NFUP. In order to better understand the process of finding frequent itemsets using NFUP algorithm, examples are listed for analysis. The original dataset DB is known, and the minimum support is 4. The specific information is shown in Table 1. Add a new dataset db with a minimum support of 2. The specific transaction data are shown in Table 2. The minimum support value of the updated dataset (DB ∪ db) is 6.

The process of mining frequent sets using the improved NFUP algorithm is shown in Figure 1.

Scan the original dataset DB and the new dataset db respectively to obtain the candidate item set. In Figure 1. ①, C_{DB}^1, C_{db}^1 are the candidate item sets of the original dataset and the new dataset respectively. Then the frequent itemsets L_{DB}^1, L_{db}^1 of DB and db are obtained according to the minimum support. Here, corresponding identifier and each item obtained from the improved algorithm Get_TID( ) function.

In Figure 1. ②, according to Theorem 3, the support degree of L_{db}^1 in DB is counted, and the support degree of db in (DB ∪ db) is calculated. The support degree of $\{I_1\}$ in DB is 3, and that in db is 4. According to the formula SUPDB(I_1) + SUPdb(I_1), 3 + 4>6 is calculated, so { I_1} is the frequent 1-itemset in (DB∪db). Similarly, $\{I_2\}$ is also the frequent item set in (DB∪db). $\{I_3\}$ and $\{I_5\}$ are infrequent itemsets via validating. To avoid repeating operations, delete the same items in L_{db}^1 and L_{DB}^1 from L_{DB}^1, and the remaining itemset is $\{I_4\}$. Count the support degree of { I_4} in the dataset (DB∪db). First calculate the support degree of $\{I_4\}$ in db. If $\{I_4\}$ does not appear in, the support count is 0, that is, the support degree of $\{I_4\}$ in L_{db}^1 is 0, the support degree of $\{I_4\}$ in L_{DB}^1 is 8, and 0 + 8 is bigger than the minimum support degree of 6, so it is determined that $\{I_4\}$ is the frequent itemset of (DB∪db). Merge and obtain the frequent 1-itemset $\{I_1, I_2, I_4\}$ of (DB∪db).

In Figure 1. (2), prune L_{DB}^1 and L_{db}^1 respectively according to the frequent 1-itemset of (DB∪db). Adopt the improved Apriori_gen algorithm to generate candidate itemsets, and then obtains two frequent itemsets C_{DB}^2 and C_{db}^2 . The same as the above calculation process, counte the L_{db}^2 in frequent 2- itemset of (DB∪db) and L_{DB}^2 in the frequent 2-itemset of (DB ∪ db). The obtained frequent 2-itemsets are: $\{\{I_1, I_4\},\{I_2,I_4\}\}$. Because L_{db}^2 in the frequent 2-itemset of (DB ∪ db) is empty, the frequent 3-itemset in (DB∪db) is empty, and all frequent itemsets in (DB ∪ db) are $\{I_1,I_2,I_4, \{I_1, I_4\},\{I_2,I_4\}\}$. It is consistent with the mining results of FUP algorithm.

4. Application of NFUP in Library Circulation Data

In order to test the feasibility and effectiveness of the improved incremental data association rule mining algorithm, library circulation data is used for detection. Test environment: 4G memory, CPU 2.50 ghz, window7 operating system, test software: WEKA.

Table 1: Dataset DB.

TID	Itemset
$T1$	I_1,I_2,I_4,I_5
$T2$	I_1,I_2,I_3,I_4
$T3$	I_1,I_2,I_4,I_5,I_6

$T4$	I_1,I_3,I_5,I_6
$T5$	I_1,I_2

4.1. Data Preprocessing. The mining data comes from the borrowing information of students from August 2017 to July 2019 exported from the management system of a university library. There are 110,326 records of the exported borrowing information. The core data in the borrowing information is shown in Table 3. Data cleaning, integration, selection and other processing work are carried out for borrowing information, and the processed data is 35,232 records. For the processed data, the book is classified by the retrievable number, and the classification number is A—Z, in which the classification number A—Z corresponds to 22 major categories in the Chinese library. The borrowing records are generalized to obtain the borrowing record transactions. The information in the transaction table is shown in Table 4.

4.2. Analysis of Association Rule Mining Results. Given the minimum support degree is 15%, the confidence is 40%, and 3,000 new data are added, the mining results are shown in Table 5.

From the mining results, 70.732% of the students who borrowed T-books borrowed F-books at the same time. 68.731% of the students who borrowed H-books and I-books simultaneously. The probability of H and I-books being borrowed at the same time is 34.413%, and the other rules are similar. According to the mining results, it can help university libraries establish a more reasonable collection layout, improve the utilization rate of library collection resources, and scientifically help libraries do a better job in book recommendation.

In order to verify the operation efficiency of the improved algorithm, a comparative experiment is carried out on FUP algorithm, SFUA algorithm and NFUP algorithm. Because FUP2 algorithm is equivalent to FUP algorithm

when the database is added, so it is not used for comparison. When the original dataset DB used in the experiment is 7,000, the new dataset db is 3,000, and the dataset of (DB∪db) increases from 10,000 to 30,000, the running time of the three algorithms is shown in Table 6, the comparison of running time is shown in Figure 2. The execution time is the execution time of the updated dataset (DB∪db) when all frequent itemsets in the original database are known. From Figure 2, with the increase of transaction data, the execution time of FUP algorithm, SFUA algorithm and NFUP algorithm gradually increases, but the execution time of NFUP algorithm is shorter than that of SFUA algorithm and FUP algorithm, which has main reasons as follows:

(1) The FUP algorithm needs to scan the original dataset and the newly added one for many times. The Hash table is used to store the candidate optionset. During mining, the Hash table needs to be searched, while the SFUA algorithm scans the original transaction dataset DB once; for the newly added dataset db scans $k+1$ times. NFUP algorithm only needs to traverse the database once to obtain the transaction identifier TID of each item, and get the frequent itemset according to the transaction identifier.

(2) NFUP algorithm obtains frequent itemsets by connecting L_{K-1} and $L1$, and prunes the frequent k-itemsets before generating candidate itemsets. The amount of computation and the number of candidate itemsets of the algorithm are significantly reduced. Compared with FUP algorithm and SFUA algorithm, this algorithm is more efficient.

5. Summary and Prospect

Incremental association mining algorithm FUP solves the problem of data updating, but the algorithm needs to traverse the database many times and spend a lot of efforts dealing with the candidate itemset with geometric growth. In this study, FUP is improved. The improved algorithm NFUP uses the transaction identifier TID in the database to obtain the frequent itemsets. It only needs to traverse the database once. The candidate itemsets are obtained by connecting L K-1 and L1, so that the amount of calculation of the algorithm is significantly less than FUP. The experimental results of borrowing data in the library management system show that compared with FUP algorithm and SFUA algorithm, with the increase of the amount of transaction data, the improved NFUP algorithm improves the operation efficiency and can efficaciously help the library do a good job in book recommendation. In the next research, we can focus on the borrowing relationship of a specific subcategory (such as category TP), dig out popular books, try to dig out the relationship between majors and book categories, find out the borrowing interests of students of different majors, and recommend books according to students' borrowing habits.

For the noisy industrial environment, the welded parts will have different types of defects in the weld area during the welding process, which need to be polished, and there are disadvantages such as low efficiency and high labor intensity when polishing manually; machine vision is used to automate the polishing and achieve continuous and efficient work. In this study, the Faster R-CNN object detection algorithm of two-stage is used to investigate the relationship between flops and the number of network parameters on the model by using a V-shaped welded thick plate as the research object and establishing the workpiece dataset with different lighting and angles, using six regional candidate networks for migration learning, comparing the convergence degree of different Batch and Mini-Batch on the model, and exploring the relationship between flops and the number of network parameters on the model. The optimal learning rate is selected for training to form a weld area object detection network based on the weld plate workpiece under few samples. The study shows that the VGG16 model is the best in weld seam area recognition with 91.68% average accuracy and 25.02 ms average detection time in the validation set, which can effectively identify weld seam areas in various industrial environments and provide location information for subsequent automatic grinding of robotic arms.

1. Introduction

The rapid development of welding has promoted the progress of related industries. The weld seam quality directly affects the structural use performance and the product life of the product [1]. Still, the weld seam, after welding, inevitably produces defects such as spatter, weld tumor, leakage, and porosity. Manual grinding of the weld area is required to eliminate welding defects, but there are disadvantages such as subjectivity and low efficiency. And the current welding is a large V-shaped welded thick plate; an automated weld area detection is needed to be introduced to find the location of the weld area [2]. At present, the detection of the weld area at home and abroad is mainly based on traditional and deep learning methods. Traditional image weld region extraction algorithm identifies to determine the weld seam location by constructing the critical points of the image and descriptor to the image to give feature information, such as ORB (Oriented FAST and Rotated BRIEF) [3], Image Hu moment invariant features [4], and AdaBoost weak learning [5]. Laser weld area detection and 3D laser reconstruction of the weld area are widely used in current research [6]. Such methods are extracted manually, and their poor generalization and low detection accuracy are unavoidable drawbacks.

Given weld seam forming results from the nonlinear formation of multiple welding parameters, convolutional neural networks (CNN) with nonlinear properties are also gradually applied to the welding industry [7], including object detection of weld seam areas. The mainstream object detection methods are mainly divided into one-stage detection algorithms represented by SSD and YOLO series based on regression analysis and two-stage detection algorithms defined by Faster R-CNN series based on candidate regions according to the detection process [8]. The former detection algorithm pursues more speed, while the latter also pursues more accuracy.

Although various object recognition methods have achieved significant results in workpiece recognition, the V-shaped weld plate workpiece samples belong to a small number of instances, which cannot meet the deep network training requirements, and there is a lack of weld seam region extraction algorithms under the few-sample weld plate workpiece. For V-shaped weld plate workpiece, such few-sample data contains very little labeled data, mainly based on the traditional classical mature object detection method, using migration learning few-sample learning strategy [9]; based on fine-tuned migration learning of the implementation of the whole system, large-scale dataset for learning the source domain model used the model parameters to initialize the object domain model, and later on, the small-scale workpiece dataset is used for fine-tuned recognition. For the accuracy of weld seam detection, the Faster R-CNN network in the two-stage model is applied as the object recognition framework. The fine-tuned migratory learning of the learning source domain is performed using the VGG16 network. It is also tested in the test set with an accuracy rate that meets the needs of industrial use.

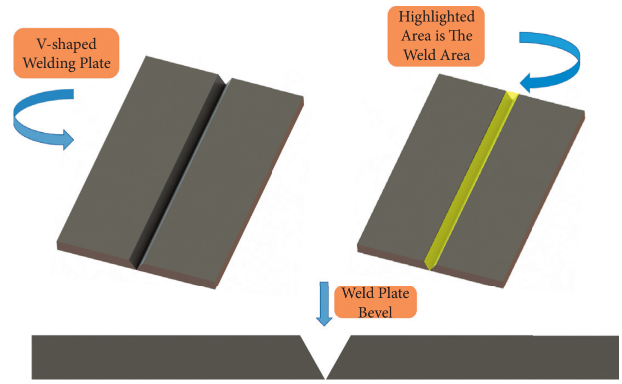

Figure 1: Diagram of the CAD model of the welded plate and the area of the weld.

2. Object Detection of Weld Seam with Few Samples

2.1. Creation of Weld Area Dataset. Migration learning of the network model is performed on the dataset ImageNet, and the Intel RealSense D435i RGB-D camera is used to capture the V-shaped weld plate workpiece with weld seam, and each view of the weld plate workpiece is shown in Figure 1. Using the eye-in-hand calibration strategy [10] to find the coordinate conversion relationship, as shown in Figure 2, the coordinates of the weld area are converted to the robot coordinates under the robot coordinates to realize the vision-based automated welding and grinding work [11].

Collect images of weld plate workpieces under backlight, normal light, and multiple angles, 1000 images in total. In order to improve the network feature learning and training speed, the image size is adjusted to 400×300 pixels. In order to learn the workpiece features at each angle and improve the network overfitting phenomenon [12], for high-frequency images under unbalanced lighting, different variance values and Gaussian filter noise with Gaussian kernel are added to them, and the data enhancement scheme of a random level, pretzel noise attack, arbitrary angle rotation, and random clipping is used to expand the dataset to 5000 samples [13] because the workpiece samples are few samples' data. Following the image data format of the neu-dataset (this is a dataset of steel plate surface curves produced by Northeastern University in China), the LabelIme annotation tool is used to export to XML, ensuring that each annotated border has only one weld feature. As shown in Figure 3, 80% of the images from the dataset were randomly selected as the training set, and 10% of the validation and test sets were divided, respectively.

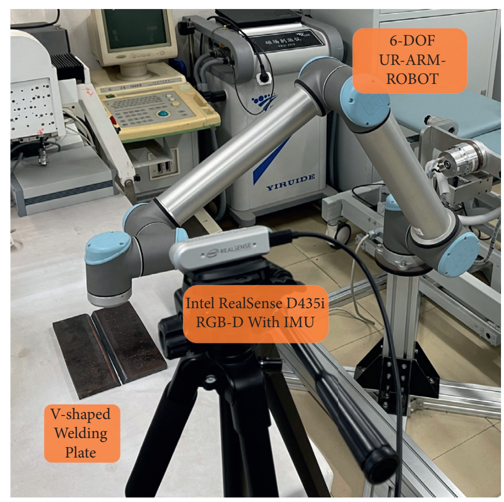

Figure 2: Diagram of welding plate, robot arm, and camera.

2.2. Migration Learning Model Building Based on Welded Plate Workpiece Dataset. The Faster R-CNN [14] in the two-stage model is used to build a workpiece-oriented object recognition network with fewer samples, using the pre-trained weights and bias information on the ImageNet dataset, freezing all parameters except the fully connected layer, and modifying the Softmax classifier to train the weld seam features of the weld plate workpiece. A simplified schematic of the network structure is shown in Figure 4.

The network model uses shared convolutional layers to extract weld region image conv features' map [15]. The network model uses a shared convolutional layer to extract the weld region image feature map, which is fed to the RPN (Region Proposal Networks) and the ROI (Region of Interest), respectively. The feature extraction layer consists of 13 convolutional layers, 13 ReLu activation layers, and four pooling layers; the RPN network determines whether the feature map belongs to the foreground or background by the Softmax classifier, where the RPN works as shown in Figure 5.

A 3×3 mask is used to slide the window motion on the feature map, and the position of the mask center corresponding to the original map is used as the center point (Figure 5(a)). Nine anchors with different scale aspect ratios are generated in the feature map (Figure 5(b)), and each anchor is assigned to the corresponding class label (positive label: foreground weld area and negative label: background area). The border regression algorithm obtains the weld area bounding box values and output to the ROI pooling layer for dimensionality reduction. The input of the ROI pooling layer is the feature map generated after the last convolution layer and the candidate region box are generated by the RPN layer,

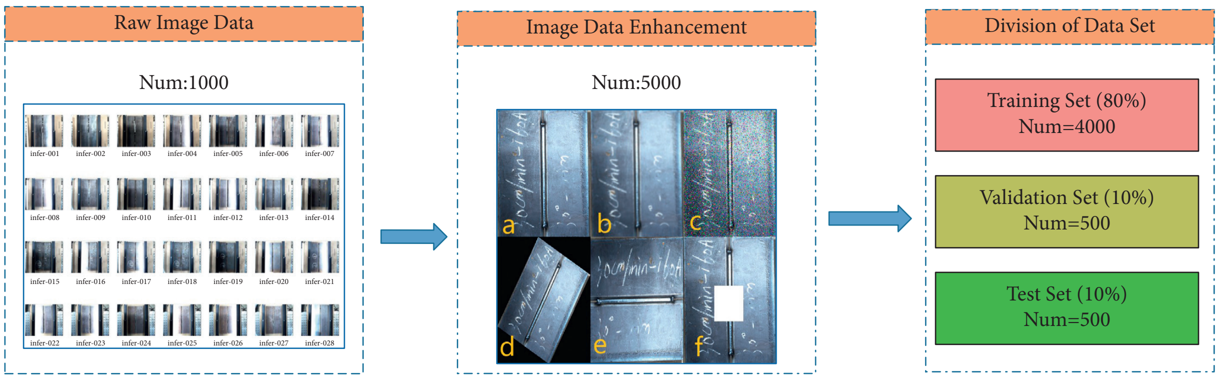

FIGURE 3: Image data enhancement: (a) original image, (b) Gaussian filtered image, (c) image with 'salt and pepper,' (d) image with random rotation, (e) image with random flap, and (f) image with random cut.

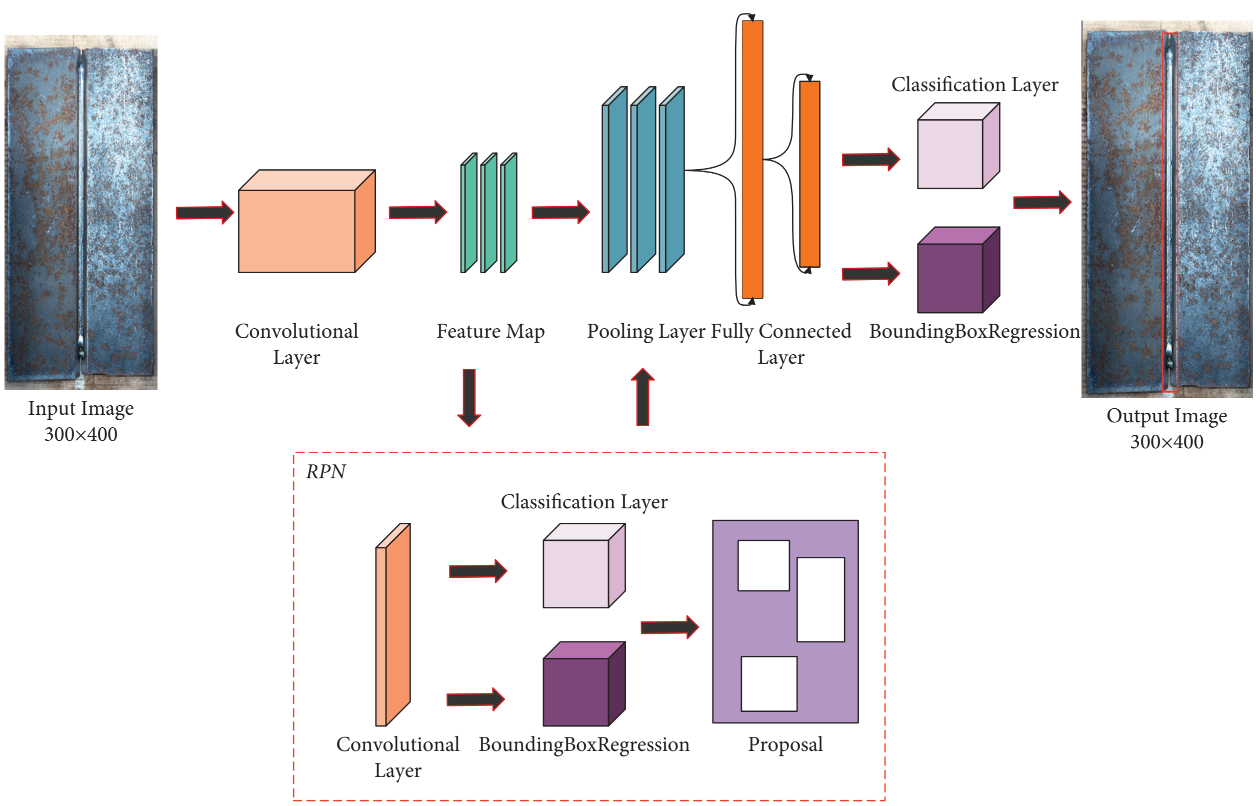

FIGURE 4: Schematic diagram of Faster R-CNN network structure.

and the final output is the ROI feature map. Finally, the fully connected layer and the Softmax classifier determine whether the candidate region is the weld region and output the exact location of the bounding box [16].

Six pretrained convolutional neural networks VGG16 [17], VGG19 [18], Googlenet [19], Resnet50 [20], Alexnet [21], and Lenet [22] on the neu-dataset are used as RPNs for migration learning so that the Faster R-CNN model first obtains the underlying feature weights of the images and then migrates the learning of these feature information to the task of weld region recognition, achieving the goal that the model can recognize accurate weld regions with a small number of artifacts.

Initial training was conducted using SGD (stochastic gradient descent) with learning rate set to 0.1, momentum factor set to 0.9, maximum Epochs set to 30, and dropout set to 0.1; the six feature region candidate networks were trained in turn, respectively. During the training process, the loss function L is as in equations (1), (2), and (3):

$$\mathbf{L}(\{\mathbf{p_i}\},\{\mathbf{u_i}\}) = \frac{1}{\mathbf{N_{cls}}}\sum_{\mathbf{i}}\mathbf{L_{cls}}(\mathbf{p_i},\mathbf{p_i^*}) + \lambda\frac{1}{\mathbf{N_{reg}}}\sum_{\mathbf{i}}\mathbf{p_i}, \tag{1}$$

$$\mathbf{L_{cls}}(\mathbf{p_i},\mathbf{p_i^*}) = -\log[\mathbf{p_i}\mathbf{p_i^*}] + (1-\mathbf{p_i})(1-\mathbf{p_i^*})], \tag{2}$$

$$\mathbf{L}_{reg}(\mathbf{t_i},\mathbf{t_i^*}) = \mathbf{R}(\mathbf{t_i}-\mathbf{t_i^*}), \tag{3}$$

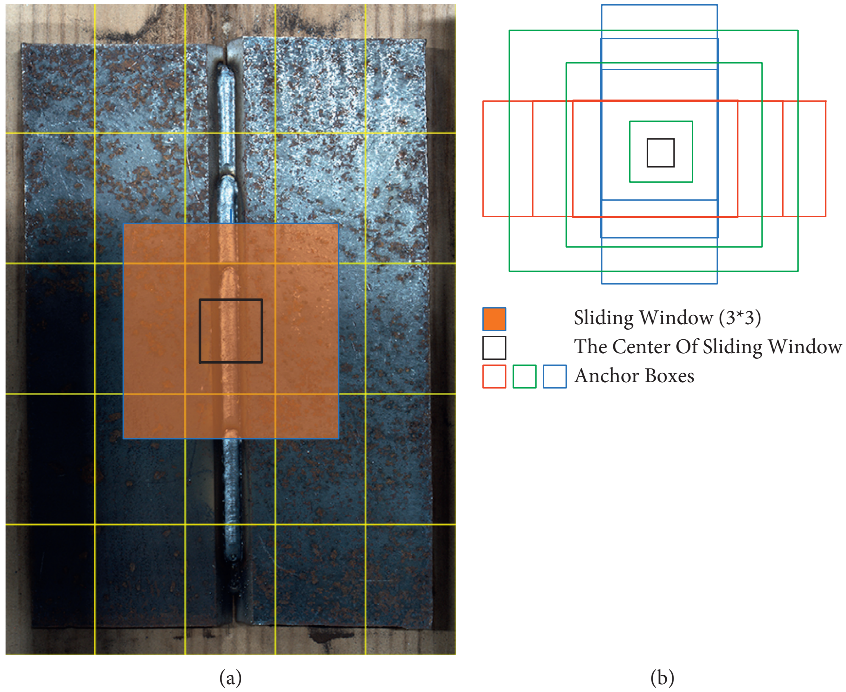

Figure 5: Sliding window diagram.

where $\mathbf{t_i} = (\mathbf{t_x}, \mathbf{t_y}, \mathbf{t_w}, \mathbf{t_h})$ is the coordinate value and bias of the bounding box, $\mathbf{t_i}^*$ denotes the predicted actual coordinate value and bias, $\mathbf{N_{cls}}$ is the number of classification samples, $\{\mathbf{P_i}\}$ and $\{\mathbf{u_i}\}$ are the output values, $\{\mathbf{P_i}\}$ denotes the predicted probability of the weld region, and $\mathbf{P_i}^*$ denotes the anchor point discriminant value, and when its value is 1, the anchor point is a positive label indicating identification to the weld region [23]; when its value is 0, it is a negative label indicating identification to the weld plate region. $\mathbf{L}_{\text{cls}}$ denotes the classification layer loss function, and $\mathbf{N}_{\text{reg}}$ denotes the number of regression samples. Since L1 loss has high noise immunity and insensitivity to numerical fluctuations compared with L2 loss, it can achieve better results in finding the border value of the target classification, so L1 loss is used, as shown in (1) [24]:

$$R = \text{smooth}_{L1}(x) = \begin{cases} 0.5\mathbf{x}^2 & |\mathbf{x}| < 1 \\ |\mathbf{x}| - 0.5 & \text{others} \end{cases}. \tag{4}$$

Iterative training and testing were performed on professional graphics workstations with the training and testing environments, as shown in Table 1.

2.3. Evaluation Method for the Performance of Weld Area Identification Models. Precision P (Precision), Recall R (ReCall), and Average Precision AP (Average Precision) [25] are used as evaluation metrics for object detection in the weld area to assess the degree of merit of the model. The calculation is shown in equations (5), (6), and (7):

$$P = \frac{TP}{TP + FP}, \tag{5}$$

$$R = \frac{TP}{TP + FN}, \tag{6}$$

$$AP = \int_0^1 P.R.\mathrm{d}R. \tag{7}$$

In (2), the larger the AP is, the better its recognition of weld regions is. TP is the number of correctly classified positive samples, FP is the number of incorrectly classified positive samples, and FN is the number of incorrectly classified negative samples. For each identified weld region, the identification score of the weld region is expressed as a confidence level. The precision-recall curves are plotted [26]. The precision responds to how accurately it predicts the positive samples, the recall responds to how well the classifier covers the positive samples, and the average precision is the integral of the precision-recall curve.

This study ensures that different candidate zone networks are tested and analyzed in a unified hardware-software environment to ensure a consistent FLOPS (Floating-Point Operations Per Second) [27]; the metric is used to measure to estimate the execution performance of the computing platform. The number of parameters of the RPN is only related to the network structure, and the memory occupation of the model is approximately four times the memory occupation of the number of parameters. The

Table 1: Hardware parameters and deep learning environment.

number of parameters [28] for the convolutional and fully connected layers is calculated as shown in equation (8), (9), and (10):

$$ParasConv = n \times (h \times w \times c + 1), \tag{8}$$

$$\text{ParasFull} = \text{Weight}_{\text{in}} \times \text{Weight}_{\text{out}}, \tag{9}$$

$$\text{ParasNum} = \sum_{1}^{i} \left(ParasConv_i + \text{ParasFull}_i \right), \tag{10}$$

where c is the number of input channels, n is the number of output channels, h is the height of the convolutional layer, and w is the width of the convolutional layer. The pooling layer does not need to calculate the number of parameters. A low number of parameters prevents the model from reaching the weld area features, making the model underfit. A high number of parameters will cause the model to occupy too much memory space, and the memory access cost (MAC) will increase. To measure the model complexity of the candidate area network, the number of floating-point operations, FlOPs, is introduced.

To compute FLOPs, this study assumes convolution is implemented as a sliding window [29] and that the nonlinearity function is computed free. For the specified convolution kernel, it is calculated as in equation (11).

$$\text{FLOP}s = 2HW\left(C_{\text{in}} K^2 + 1\right) C_{\text{out}}, \tag{11}$$

where H, W, and C_{in} are height, width, and number of channels of the output feature map, K is the kernel width (assumed to be symmetric), and C_{out} is the number of output channels [30]. For fully connected layer, it is calculated as shown in (7):

$$\text{FLOP}s = \left(2D_{\text{in}} - 1\right) D_{\text{out}}, \tag{12}$$

where D_{in} is the input dimensionality and D_{out} is the output dimensionality. The performance parameters of each RPN are shown in Table 2.

3. Result and Analysis

3.1. Recognition Results' Weld Areas by Different Feature Extraction Networks. This study uses a V-shaped welded steel plate with dimensions of 30.00 cm × 17.00 cm × 0.50 cm, a V-shaped opening angle of 45°, and a weld seam formed in the following welding parameters: the steel plate material is mild steel Q215, the welding method used is melt electrode gas metal arc welding (GMAW) and multilayer multipass welding, the shielding gas is argon, the welding current is 200 A, the welding wire diameter is 2 mm, and welding speed is 2 mm per second. By the recognition effect of the weld seam on the same V-shaped welding plate, the convolutional neural network with the best effect is selected as the RPN, and the model is fine-tuned on this basis for comparative analysis of the recognition of the weld seam in different work scenarios.

Ensuring consistent FLOPS, the network accuracy images and training loss images are plotted using the initial training parameters set in Section 2.2, using six different RPNs in the training and validation sets, respectively. The result is shown in Figure 5.

As shown in Figure 6, the statistical training results obtained by changing different RPNs in the Faster R-CNN model are shown in Table 3, where AP (%) - *T* is the average precision of the training set and AP (%) - V is the average precision of the validation set.

100, 200, 300, 400, and 500 different weld plate images are taken from the weld plate part test set as input images, and their average detection times are recorded to evaluate the operational efficiency of the algorithm (Figure 7).

Resnet50 is used as the RPN with the highest average accuracy in the training and validation sets, and the fraction of recognized weld areas is up to 94.34% (Figure 8(d)). The Resnet series network provides a shortcut connection mechanism, which ensures a reasonable recognition rate even if the network depth of Resnet50 is 50 layers and the number of layers.

The increase in the number of layers leads to flops 4GFLOPs. Resnet50 average detection time is 92.03 ms. Among them, when Alexnet is used as RPN, the flops are 727MFLOPs, and the average detection time consumes the shortest 18.02 ms because the number of convolutional layers is 5, the network learning effect is not as good as the deep network Figure 8(b), and its average recognition accuracy is 75.50% (Figure 8(a)). In the training process, Alexnet accuracy function and loss function gradually converge, and the loss function curve in the validation set fails to approximate the loss function curve in the training set, so the result weld candidate box has more rear view parts in the weld region candidate box (weld plate region). VGG19 can identify the weld area more completely (Figure 8(f)) with 20GFLOPs and 20,483,904 parameters, as shown in Table 2, resulting in a memory occupation of 548 M and a

AP (%) -T	91.55	85.34	94.34
AP (%) -V	86.45	70.05	84.5
RPN	Alexnet	Googlenet	LeNet
AP (%) -T	75.50	84.55	65.23
AP (%) -V	66.50	73.60	45.60

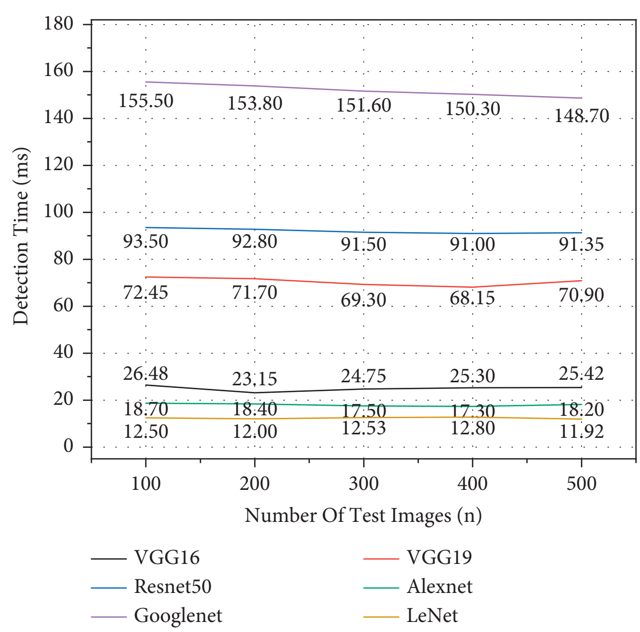

FIGURE 7: Runtime with different numbers of test sets.

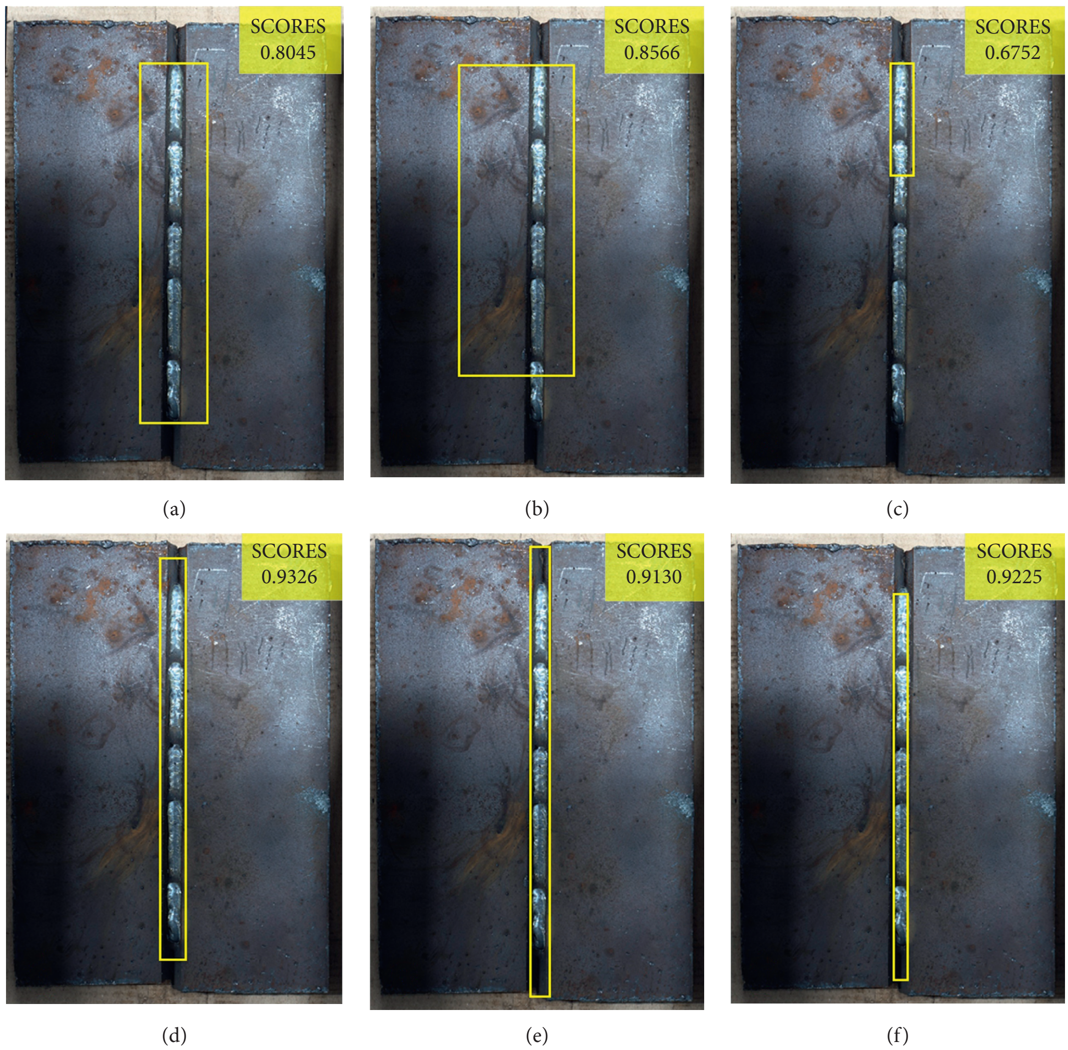

Figure 8: Recognition results of different RPN models for the same weld plate (comparison of six different RPNs using the same weld plate workpiece): (a) Alexnet, (b) Googlenet, (c) Lenet, (d) Resnet50, (e) VGG16, and (f) VGG19.

bloated model with a detection time of 70.50 ms. The worst performance is LeNet, which has the shortest average detection time, occupies 2.32 MFlops, and has the smallest number of parameters among the six networks.

Because its network layer is 7, it cannot learn the weld region's image features in-depth and is more suitable for dealing with scenarios requiring shallow network work and can only identify some features in the weld region under this study (Figure 8(c)).

The average accuracy of VGG16 is slightly lower than that of Resnet50 at 91.55%. Since VGG16 uses several consecutive 3x3 convolutional kernels instead of the larger convolutional kernels in Alexnet compared to AlexNet, for a given receptive field, the performance of the small convolutional kernels with stacking is better than that of the large convolutional kernels because the multilayer nonlinear layers can increase the network depth to ensure learning of more complex pat-terns, the flops' value of VGG16 is lower than that of VGG19 in the same series, and the number of parameters is increased to ensure the learning effect and reduce the memory occupied memory space. The average elapsed time is lower, only 25.02 ms, and the confidence level of the identified weld region is up to 91.30%, and the entire weld region is framed (Figure 8(e)). Therefore, the Faster R-CNN model based on the VGG16 candidate region network is selected as the model to identify the weld region.

3.2. Optimization of Models. As shown in the Result of VGG16 in Figure 5, the Faster R-CNN based on VGG16 for weld area recognition object detection network achieves 91.55% accuracy in the training set, and the accuracy in the validation set cannot converge to the same level as the test set. And in order to reduce the loss value to convergence in both training set and test set, different learning rates are chosen to be adjusted, and different numbers of Epochs are added, and Mini-Batch is more suitable for fewer sample data set models, so the optimization of the model is added on this basis. In order to make a comparison with the initial training parameters in Section 2.2, the size of the Mini-Batch is chosen to be 128. the time cost of training. As shown in Table 4.

Table 4: Mini-Batch in VGG16.

Epoch	Mini-Batch training accuracy (%)	Validation accuracy (%)	Mini-Batch training loss	Validation loss
1	38.52	45.85	1.36	1.28
5	79.20	55.98	0.76	0.95
10	88.10	64.50	0.51	0.84
15	90.56	78.64	0.45	0.80
20	92.35	82.65	0.34	0.76
25	93.48	83.62	0.31	0.71
30	93.85	85.62	0.28	0.69

Table 5: Accuracy results of training models with different numbers of Epoch and different learning rates.

Learning rate	Epochs: training accuracy (validation accuracy) (%)						
	30	35	40	45	50	55	60
0.1	89.57 (81.63)	91.18 (82.34)	93.88 (83.65)	92.03 (84.55)	92.86 (85.64)	92.01 (84.63)	91.61 (83.52)
0.01	93.85 (84.56)	94.10 (86.78)	94.33 (87.12)	94.85 (89.73)	95.17 (91.23)	94.01 (90.55)	93.51 (89.77)
0.001	94.56 (86.64)	94.84 (88.50)	95.25 (89.66)	95.36 (90.16)	95.66 (92.38)	93.83 (90.56)	92.84 (89.71)
0.0001	95.75 (89.31)	95.89 (89.65)	95.91 (91.68)	95.85 (92.36)	95.93 (92.45)	94.59 (91.63)	93.88 (91.09)
0.00001	94.79 (88.71)	94.97 (89.08)	95.48 (90.16)	95.12 (91.74)	95.25 (91.65)	94.77 (91.02)	93.87 (91.87)

The plasticity of the VGG16-based Faster-RCNN weld region detection model is verified by adjusting different Epoch and learning rates, and then, the optimal network model is obtained, and the results are shown in Table 5.

In Table 5, using VGG16 as RPN for migration learning at different learning rates, the model's accuracy gradually improves with increasing training times and starts to converge in both the training and validation sets. Reducing the learning rate of the network model can effectively improve the average accuracy of the overall model network at the same number of training sessions. Among them, when the learning rate is 0.1 and 0.01, the network converges very slowly, increasing the time to find the optimal value and not achieving optimal training accuracy. When the learning rate is 0.0001 and Epochs is 30, the accuracy of the network on top of the training set reaches 95.75%, and as Epochs keep increasing, the training accuracy keeps converging, but the growth is slow, and the average accuracy of 45 iterations is lower than before, and if we use continued iterative training, it will increase the algorithm is time complexity, but it does not bring noticeable improvement of training accuracy. When the learning rate is 0.00001, the effect is not as good as the learning rate of 0.0001 because the model hovers around the optimal value, does not converge, and appears to be overfitting. Each learning rate showed an overall decreasing trend after Epochs of 40, which was due to overfitting the network during training. Therefore, in this study, VGG16 is used as the RPN, and the Faster R-CNN with two-stage is trained on the weld plate workpiece dataset, keeping other parameters in Section 2.2 unchanged. The batch is changed to a Mini-Batch of size 128, and at a learning rate of 0.0001 and Epochs of 40 times, the 500 weld plates in the test set were used as the target for the Precision-Recall curve. The initial accuracy threshold was set to 0.8500 using a non-extreme suppression mechanism. The point of [0, 0.8500] was decremented in the Recall interval. The model determined the results more excellent than this threshold as positive samples and those less than this threshold as negative samples. As can be seen in Figure 9, as the entry is gradually reduced, more and more weld samples are predicted to be positive, and the curve reaches the (1, 0) coordinate point, indicating that the target detection model can identify the weld seam in the image data as a positive sample. In equation (7), the area enclosed by the curve and the coordinate perimeter is AP. As shown in Figure 9, the area surrounded by its X- and Y-axes occupies almost the entire coordinate axis area, indicating the strong recognition performance of the model.

As shown in Figure 10, the color is similar to that of the weld plate workpiece at different angles and working environments, but the network can also identify the weld area of both weld plate workpieces with a score above 90%. As shown in Figure 11, the complex industrial environment with different angles and each large field of view is used for recognition, and there are multiple weld parts in the image, the model network is able to recognize the complete weld area, and some smaller weld areas in the lower-left corner of the image can also be accurately recognized.

In Figure 12, the model is tested in this study by placing it in different working scenarios. Figures 12(a), 12(b) and 12(c) show the weld target detection recognition results at different angles. It can be seen that the recognition accuracy is almost always above 90% and is close to the training accuracy when trained on the training set. The material color in the background of the recognition scene is similar to that of the foreground weld plate, and the object detection network can still accurately frame the weld area's location. Figures 12(d), 12(e) and 12(f) show the effect of weld target detection with the influence of the side light source at a normal overhead angle, which can identify the weld area more completely and obtain an accuracy of about 92%. Figures 12(g), 12(h) and 12(i)

show the weld seam target detection results with laser interference and multiangle recognition. The target detection network can still frame the weld seam in a noisy environment, with a maximum recognition accuracy of 93.17% with laser and multiangle interference. The experimental results in Figure 12 show the robustness of this neural network model for the identification of weld areas in different working environments.

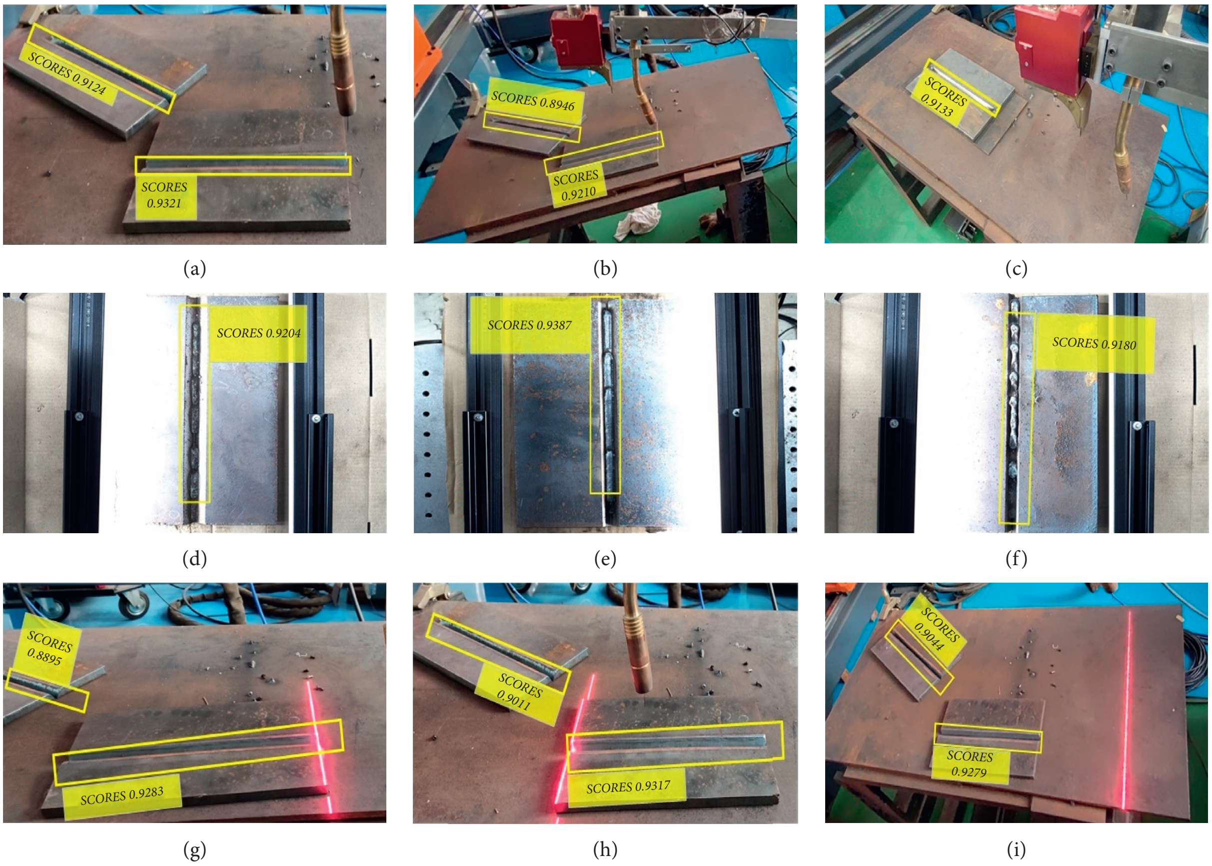

Figure 12: Multiangle and multienvironmental weld seam recognition effect.

4. Conclusion

The six networks LeNet, Resnet50, Googlenet, VGG16, VGG19, and Alexnet are selected as the RPN of the Faster R-CNN model for training using the migration learning method, and the recognition performance of the six Faster R-CNN models with migration learning is compared and analyzed, and the following conclusions can be drawn:

(1) Faster R-CNN based on VGG16 weld region detection effect is the best, when the model learning rate of 0.01 training times for 30 times, the model in the training set average accuracy of 91.55%, and the validation set accuracy of 86.45%. In the test set average detection time of 25.02 ms, in order to speed up the convergence of the network training process. In order to speed up the convergence of the network training process, the Batch is changed to Mini-Batch size set to 128, which can further improve the accuracy of the model in the training and validation sets, and the loss function convergence is reduced.

(2) When the learning rate is 0.0001, the accuracy decreases with the increase of Epochs in the training set, which is an overfitting phenomenon. After Epochs is 40, the model accuracy grows slowly to prevent the increase of time complexity; this study adopts the learning rate of 0.0001, Mini-Batch is 128, Epochs is 40 training parameters, and the identified network is applied to weld area recognition; as shown in figure, the recognition accuracy and breadth can meet the industrial requirements. The model is also able to accurately frame the weld seam in a mixture of multiplate conditions, multiangle welding conditions, and laser light source interference.

(3) From the point of view of real time, when the target detection model uses a VGG16 convolutional neural network as RPN, it can meet both the requirements of detection accuracy and detection time. The target detection model can achieve industrial recognition efficiency for weld area extraction in different environments, whether the recognition effect is under the ideal viewpoint or weld recognition effect under a complex environment. The industrial requirements for real time can be met.

Driven by the dual effects of artificial intelligence and accounting transformation, it has become one of the research hotspots of accounting intelligence in China to replace accountants with computers to make professional judgments and automatically evaluate accounting. On the basis of summarizing and analyzing the research status in the field of intelligent accounting, the realization path of intelligent accounting in water companies is put forward in this paper. By introducing the improved Apriori learning algorithm based on Boolean mapping matrix, intelligent data mining is carried out for evaluation of water accounting. With the help of the improved attribute inductive learning algorithm, the corresponding relationship between the original water consumption attribute and the water right transaction is mined and output. In addition, with the help of forward reasoning in inference engine technology, the computer intelligent data evaluation function is realized. Finally, the functional architecture of accounting system of the water company is designed, which provides reference for the development and application of intelligent accounting system, and explores a new path for the integration of accounting and intelligent algorithms.

1. Introduction

After more than 40 years of development, China has basically realized the automation of accounting books and statements processing, but the accounting personnel's professional judgment is always indispensable in the preparation of accounting vouchers, which leads to the stagnation of accounting automation in China. With the continuous development of artificial intelligence in the accounting industry, the research and development of intelligent accounting system with self-learning and the replacement of accountants by computers for professional judgment and automatic preparation of accounting vouchers have become the key research field of accounting [1]. The key to realize the intelligentization of accounting is to make the computer have the ability of autonomous learning, intelligent judgment, and reasoning in unsupervised mode. With the help of accounting rules automatically acquired by intelligent learning algorithm, it can analyze and judge economic business and compile accounting vouchers. Because the computer does not have the function of self-learning, and when the accounting rules change, the accounting voucher template needs to be changed manually, even if the financial robot based on RPA (Robotic Process Automation) technology is not intelligent accounting either. In essence, the financial robot is a computer based on predesigned fixed rules and processes [2] and a computer program that helps human beings to complete standardized work with fixed rules and high repeatability by simulating manual operation of computers.

Water enterprises belong to the water rights entity, which is the main body of water resources development and utilization. Water-related businesses include water storage, water treatment, water supply, and water trading [3]. Because of the various types of business, large scale and large water flow, water enterprises are representative in the process of realizing intelligent accounting. In water enterprises, establishing water accounting subjects, accounting water accounting business, formulating water accounting statements, expanding the application of existing water accounting framework of water rights entity to specific water users, and establishing corresponding accounting system can verify that the existing framework of water rights entity is the key of current research [4].

Therefore, in this paper, Apriori improved algorithm based on Boolean mapping matrix is used to automatically mine frequent item sets from accounting voucher database, and through attribute-oriented induction (AOI) algorithm, accounting rules are learned and extracted from the original water consumption database independently, forming accounting rule base, which enables the computer to have self-learning ability in unsupervised mode. Combined with the actual operation of water enterprises, the accounting of characteristic businesses such as sewage treatment, construction, and management of water delivery facilities is carried out. While promoting the fine management of water resources, the water accounting system is improved and the connotation of water accounting research is enriched and according to the original water consumption data and accounting rule base, with the help of inference engine technology, the computer has the function of automatically compiling accounting vouchers. Finally, the evaluation of accounting data will be realized, which will help accountants transform from accounting to management-assisted decision-making.

2. Basic Accounting Theory and Accounting Basis of the Water Company

2.1. Theoretical Framework. At present, there are two representative views on the definition of accounting in China's accounting theory circle, namely, information system theory and management theory [5]. From the perspective of information system theory, water resources accounting can be defined as follows: water resources accounting is based on the stock and flow of water resources, using monetary measurement units, and standardizing according to the requirements of specific accounting assumptions and accounting principles. By adopting the methods of modern accounting, resource economics, mathematics, and asset appraisal, the economic information system provides water resources information to users of water resources accounting information regularly through accounting and supervision [6]. According to the management activity theory, water accounting is a kind of management activity applied to water industry to reflect and control the process and results of water resources circulation caused by ecological circulation of water resources.

2.1.1. Accounting Objectives. Accounting objective is the highest level of accounting theoretical structure, which is the expression of subjective consciousness under certain social and economic environment. Only by correctly understanding the influence of these factors can we study accounting objective more deeply [7]:

(1) Ultimate objective: sustainable development is the theme of world development today. Water accounting is put forward under the condition that water resources are increasingly scarce and the sustainable development and survival of human beings are threatened. Water resources accounting should take sustainable development as the ultimate goal to promote people to rationally utilize water resources.

(2) General objectives: the general goal of water resources accounting is to make rational use of water resources accounting to obtain maximum social and economic benefits. Through the establishment of water resources value system, water resources information can be provided to promote the rational allocation and utilization of water resources. The establishment of water resources value system means that the law of value can be applied to allocate water resources by market [8]. The marketization of water resources (under certain intervention) will make the utilization of water resources more reasonable and scientific.

Water supply and demand are regulated separately. Water supply is ultimately determined by the "available water in the region" module, while the demand is mainly specified by the "water demand" module [9, 10]. This separation and linear structure of demand and supply is shown in Figure 1, in which the data connection from one module to another module is indicated by arrows. For example, different data exported from the module of "Water Availability in the Region" are directly transferred to the module of "Distribution of Emissions," "Water Allocation," "River Flow Calculation," and "Groundwater Flow" [11].

2.1.2. Accounting Hypothesis. Accounting hypothesis is to limit the scope and content of accounting and make logical inference according to the objective normal situation or trend of accounting phenomenon that has not been confirmed. Due to the economic characteristics of water resources, the basic assumptions of water resources accounting should include the following points besides general accounting hypothesis [12–15]:

(1) The assumption of sustainable development: although there are many uncertainties in the economic activities of accounting subjects, the normal procedures and methods of accounting and supervision should be based on the sustainable development of accounting subjects, especially in water resources accounting. Therefore, sustainable development is the hypothetical condition of water resources accounting, which is also the fundamental constraint for us to construct the water resources accounting theory and method system.

(2) Multiple units of measurement hypothesis: water resources accounting should be based on monetary measurement. Its accounting is to supervise enterprises in the whole water resources environment. Besides monetary measurement, physical quantity indicators and words can also be used to explain their social contributions or social losses, such as

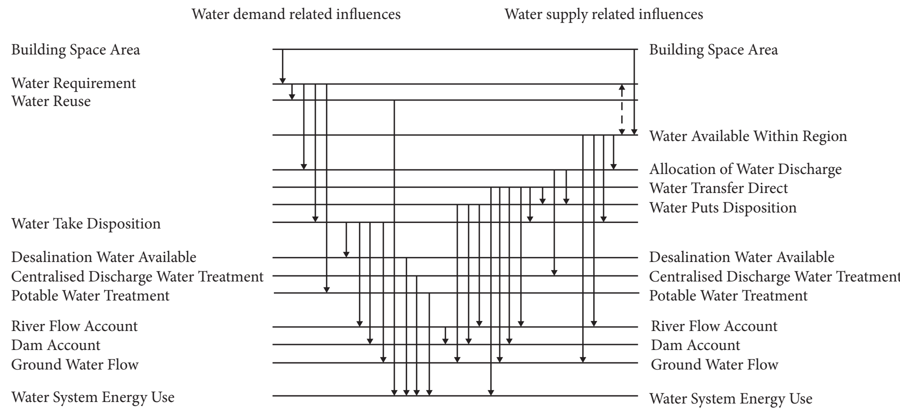

Figure 1: Module of water resources accounting.

biochemical oxygen demand, chemical oxygen content, suspended solids, and toxic substances in water pollution indicators.

(3) Multiple measurement attribute hypothesis: the assumption of multiple measurement attributes is also reflected in the fact that multiple measurement attributes should also be adopted within the monetary measurement form. Not only can historical cost, current cost, current market price, net realizable value, and future cash flow be used, but also new measurement attributes such as opportunity cost and substitution cost can be used in water resources accounting.

2.1.3. Accounting. Under the condition of clear water rights, the transformation quantity of microwater rights entity is accompanied by the changes of water quantity increase and decrease, such as water quantity acquisition or use, loss, and discharge, which is reflected in the fact that the increase or decrease of one water resources assets transformation movement is always closely related to the decrease or increase of another water resources assets transformation movement [16]. The accounting structure is shown in Figure 2.

Account setting of water resources accounting: the confirmation of water accounting elements can be based on traditional accounting element confirmation, which develops and broadens the concept connotation of traditional accounting element confirmation. The elements of water resources accounting include water resources assets, water resources liabilities, water owners' equity, water resources income, water resources expenses, and water resources profits [17]. According to the accounting elements of water resources, accounts such as water resources assets, water resources liabilities, water resources costs, water resources income, water resources profits, water resources capital, and water resources capital appreciation can be set up accordingly.

The account of water resources assets reflects the increase and decrease of water resources assets, and the account of accumulated consumption of water resources assets reflects the consumption of water resources assets [18]. "Water resources compensation payable" can be set for water resources liability accounts. The occurrence of water resources costs should be listed in the accounts of production cost, management cost, and manufacturing cost according to their different consumption and occurrence nature, and corresponding secondary accounts, such as water pollution control fee and water quality degradation fee, should be opened to reflect the various water resources costs incurred by microaccounting entities.

3. Realization of Intelligent Accounting

At present, there is a general consensus on the transformation of accounting from automation to intelligence under the background of artificial intelligence. However, most of the existing researches on intelligent accounting are focused on the impact of artificial intelligence on accounting industry and personnel, the assumption and prospect of intelligent accounting system architecture, etc. [19], and its development process is shown in Figure 3. Although some researches have studied the realization of intelligent accounting voucher preparation, the research process cannot get rid of accounting voucher template theory, accounting expert simulation theory, and assistant judgment of accountants, and most of the research results belong to the category of semiautomation or weak artificial intelligence. In addition, it is relatively rare to introduce artificial intelligence data mining algorithm into practice of water company, and it is even rarer to study the improvement and integration of machine learning intelligent algorithm and accounting information system. The results of developing practical intelligent accounting system with computer language platform are relatively few [20]. Although BP artificial neural network algorithm is theoretically introduced to explore the confirmation of accounting elements, due to the dynamic learning parameters of BP neural network and the instability of network output, the related research results cannot meet the basic requirements of accounting practice [21].

The intelligence of the intelligent accounting system is mainly reflected in the fact that the computer must have the ability of self-learning, knowledge updating, judgment

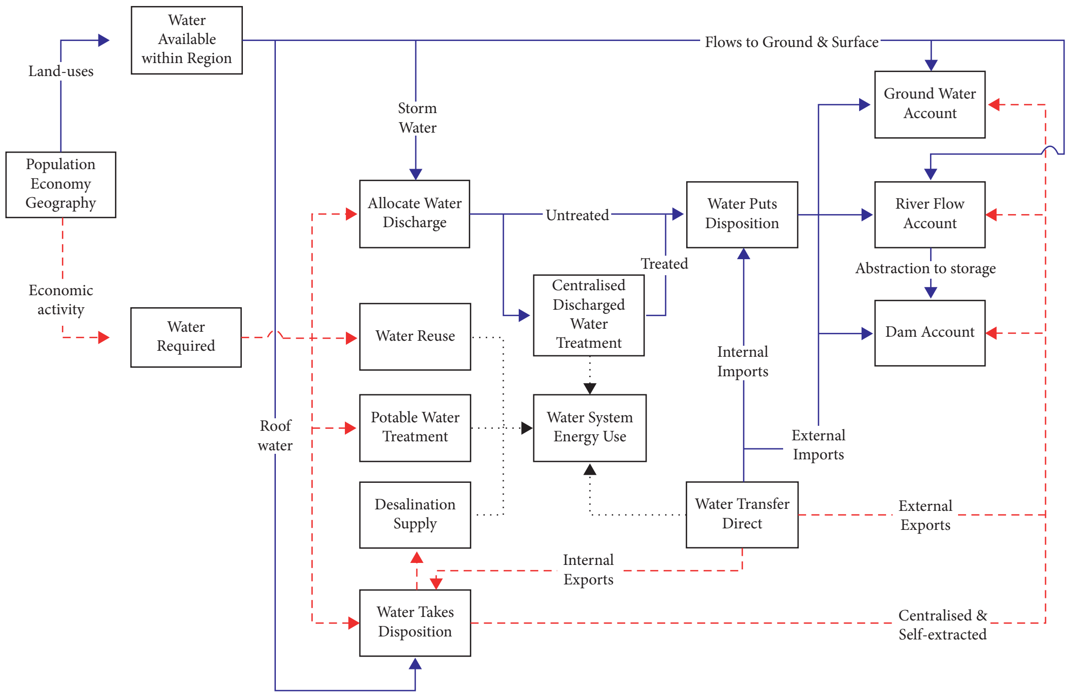

Figure 2: Structure of water resources accounting.

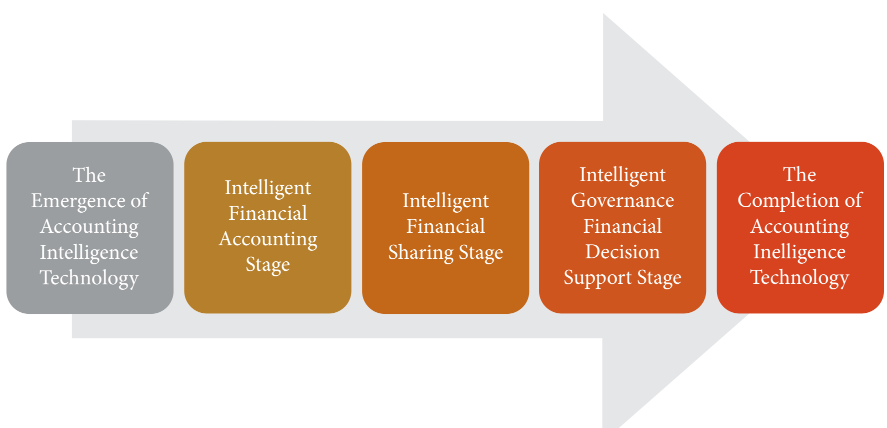

Figure 3: Development of intelligent accounting.

reasoning, and knowledge memory storage in unsupervised mode [22]. Therefore, the intelligent accounting system should have enough training samples for machine learning, on the one hand, and introduce intelligent algorithms for machine learning on the other hand, both of which are indispensable. At present, there are only accounting vouchers, account books, statements, and other related data in the mainstream accounting information system in China. The key information needed by machine learning intelligent algorithm is still blank. The core of accounting measurement is to determine the name, accounting direction, and accounting amount of the account. Different economic businesses have different impacts on accounting elements, and the combination of generated account and accounting rules will also have certain changes in different periods and different stages of the development [23].

The intelligent learning algorithm should be able to accurately mine and store the account combination rules and extract the corresponding relationship between the original voucher and the accounting voucher from the database (essentially, the corresponding relationship between the attributes and attribute values of the original voucher and the account name, accounting direction and accounting amount of the accounting voucher) [24]. In this way, the accounting system has intelligent attributes and can replace accountants to make professional judgments and automatically compile accounting vouchers, thus developing towards the direction that is shown in Figure 4.

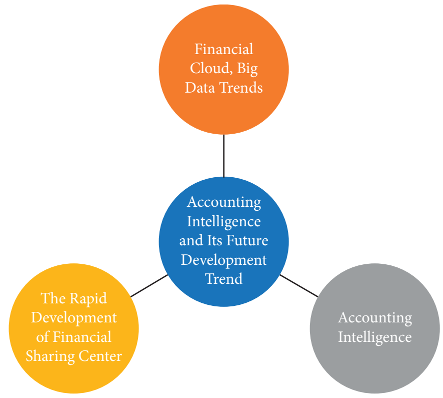

Figure 4: Accounting intelligence and its future development trend.

4. Accounting of the Water Company Based on Combination Algorithm

4.1. Improved Apriori Algorithm. The basic idea of Apriori algorithm is a machine learning intelligent algorithm based on frequency set theory [25], which mines frequent item sets through layer-by-layer search iteration method. Considering that Apriori algorithm will generate a large number of candidate sets in the iterative process, the intersection of some accounting accounts is empty in practice. Therefore, the iterative process of Apriori algorithm will generate a large number of invalid candidate sets. At the same time, Apriori algorithm needs to scan the database frequently to complete pruning and frequency statistics, which will greatly reduce the mining efficiency [26].

In view of the shortcomings of traditional Apriori algorithm, this paper proposes an improved Apriori algorithm based on Boolean mapping matrix, combining with combination rules of accounting account. The improvement ideas are as follows:

(1) Build a Boolean account combination matrix, in which the first column represents the number of transaction set W, the second to penultimate columns represent each item in item set *R*, and the last column is the total number of items in each transaction. Boolean mapping rule is as follows: if an item appears in transaction Ti, the matrix elements in the I-th row of Boolean account combination matrix and the column where the item is located are mapped to "1." Then map the matrix elements in the column where the item does not appear in row I to "0" and carry out vector inner product operation on the constructed Boolean account combination matrix. The improved Apriori algorithm can complete the required calculation and statistical work only by scanning the database once, and the algorithm efficiency is significantly improved.

(2) In view of the problem that the traditional Apriori algorithm will generate a large number of invalid candidate sets in the iterative process, this paper puts forward an improved strategy of building candidate sets based on the combination rule of accounting accounts: first, after the compound accounting entries are decomposed into simple accounting entries, all transactions in the set are of three types, namely, one-to-one, one-to-many, and many-to-one. According to the statistical rules of water consumption, when a one-to-many transaction candidate set is built, no more than two statistical combinations can appear in all candidate sets at the same time. Similarly, when a "many-to-one" transaction candidate set is built, no more than two combinations can appear in all candidate sets at the same time. The second is to investigate the correspondence between accounting accounts and make full use of the situation that the account portfolio is empty set to shield invalid candidate sets. Third, in the iterative process of the algorithm, if there is only one item in a transaction, the transaction should be deleted from the learning sample.

After the improved Apriori algorithm designed in this paper optimizes the construction of combined candidate set through the above three strategies, the invalid candidate set generated by the improved Apriori algorithm will be greatly reduced in the iterative process and the running efficiency of the algorithm has been significantly improved. The flow chart and pseudocode of Apriori improved algorithm is shown in Algorithm 1 based on Boolean mapping matrix.

4.2. AOI Algorithm Improvement. In order to explore the relationship between the original water consumption attributes, attribute values, and the combination of accounting accounts, AOI algorithm is introduced. On the basis of attribute compression of attribute values proposed by Hanetal [27], macrotuples are generated step by step and corresponding rules are output by upgrading the concept level of attributes:

(1) Build an original voucher attribute to extract all tuples related to frequent item sets from the original voucher database, take the original voucher name and attribute combination as column names, and make the attribute values corresponding to the combination as column values. In addition, the

Input:$Am\times n$, Minsup
for ($k=2$, Lk-1≠; k++)//Generating frequent k item sets from frequent k-1 item sets
begin
C_k = apriori_gen (Lk-1);//Call the apriori_gen function to generate Ck by Lk-1
For all transactions $T\in$ Ddo
begin
Ct = subset (Ck, t);//t contains the candidate set
For all candidates C ∈ CT
$m_i = M\ (,i_1)$ M $(,i_2)$//Calculate the vector inner product of the corresponding items in the candidate set, where i is the number of columns of matrix A.
qi = COUNT (m_i)//Statistics the summary of column i items
If qi < Minsup Then Delect, I//calculate to generate $A_{m,n-x}$ row intersection matrix $C_{m\times m\ m}$.
$k=k+1$
Go To Line3
L_k = {c ∈ Ct│c.q_i ≥ Minsup}//Output frequent itemset L
Output:LEND
apriori_gen
selectp.it_1,p.it_2,. . .,p.$it_{k-1}$from L_{k-1p},.L_{k-1q},
Wherep.it_1 = p.it_2,. . .,p.it_{k-2} = p.it_{k-2},p.it_{k-1}<p.it_{k-1};
For all itsets c ∈ Ck do//pruning step
If $c\notin L_{k-1}$or c ∈ Anti_B_R//If it does not belong to Lk-1 or violates the rules of correspondence between accounting direction and account
Then delete c from C_k//Delete c
End

ALGORITHM 1: Improved Apriori Algorithm.

original certificate attributes also include attributes and attribute value combinations newly added by the company for internal management.

(2) Count the number of attribute value types in each column. If the number of attribute value types is equal to 1, it means that the combination of the original voucher is positively correlated with the frequent item sets by 100%; at the same time, if the number of attribute value types is equal to the number of tuples, it means that the original voucher and attribute combination are not related to frequent item sets. Finally, if the attribute value type number is between 1 and tuple number, it means that the combination of the original voucher is related to frequent item sets to some extent, but the degree of their correlation is not high.

(3) Attribute-oriented generalization: for the case where the number of attribute value types is greater than 1, it is necessary to combine the attributes of the original voucher with the essence of economic business to improve the concept of the attributes of the original voucher. For some attributes in the original voucher that cannot be generalized, remove this column from the original voucher learning sample database.

(4) Specify the generalization threshold. Compress the attributes by setting the generalization threshold; that is, the progress and efficiency of attribute learning are controlled. For an attribute in the knowledge base table, if the number of types is greater than the specified generalization threshold, it should be further generalized. If the number of tuples of the generalized relationship is still greater than the generalization threshold specified by the user, the relationship should be generalized continuously until the set conditions are met and the algorithm is terminated. Otherwise, remove the attribute from the sample library.

(5) Rule verification: when the type number of the original voucher attribute combination is less than or equal to the set generalization threshold, extract all economic and business data from the accounting voucher database and verify the accounting rules. When all tuples related to the business in the accounting voucher database are true, the accounting rule can be output to the rule base. Otherwise, it is stored in the rule base to be verified, to provide reference for accountants, and AOI algorithm ends.

4.3. Improved Algorithm Based on Water Flow of the Water Company. 7 learning samples are extracted from the water resources flow database (Table 1), and let Minsup be 2. The learning process of the improved algorithm is as follows:

(1) According to the Boolean mapping principle [28], the data of water flow database is binarized, and the generated Boolean mapping matrix is shown in Table 2.

(2) Because the total count of F is less than Minsup threshold, five 1-item set items, A, B, C, D, and E, are formed after deleting F column from the matrix. T6

Table 1: Learning sample of water resources flow (unit: million cubic meters).

Order number	Item	Stock increase	Stock decrease
1	Water of productive use	60	0
2	Domestic water	15	0
3	Environmental water	0	27
4	Import	7	0
5	Export	0	6.3
6	Purchase	5	0
7	Other departments	0.7	3

Table 2: Boolean mapping matrix based on learning samples.

	Do the right	Not supply	Emission	Uncompensated use	Actual water	Others	Total
	A	B	C	D	E	F	
T_1	0	1	1	0	1	0	3
T_2	0	1	1	1	1	0	4
T_3	0	1	1	0	0	0	2
T_4	1	0	1	0	0	0	2
T_5	1	0	0	0	1	0	2
T_6	0	1	0	0	0	1	2
T_7	0	1	0	1	0	0	2
Total	2	5	4	2	3	1	

is deleted from the matrix because the subtotal of T6 transaction is less than 2.

(3) Adopt Apriori_gen function to connect A, B, C, D, and E and generate candidate set C2. As the learning samples are all "one-to-many" estimates, and both A and B belong to the rights of water entities, the AB combination is an empty set, which is directly shielded during the connection process. At the same time, A and D do not constitute a corresponding relationship, so the combination of A and D is an empty set, which should be directly excluded in the connection. The results of vector inner product in candidate set C2 and its corresponding column vector generated by the algorithm are shown in Table 3.

(4) The result of vector inner product calculation of candidate set C2 shows that only four combinations of BC, BD, BE, and CE meet Minsup threshold, so the algorithm adopts Apriori_gen function again, and according to four frequent 2-item sets, candidate set C3 is generated after connection. Table 4 shows the result of vector inner product calculation.

(5) Only BCE in candidate set C3 meets the Minsup threshold, so BCE is the frequent item set; that is, the combination of entity water quantity with the highest frequency leads to the termination of Apriori improved algorithm learning.

(6) Extract all the original voucher sample data related to BCE from the original voucher database, and AOI algorithm is selected to learn.

(7) After deleting the numerical variables (such as "Unused water-surface water –river" and "Unused water - surface water –reservoir") that have no influence on accounting rules in the original voucher attribute database, count the number of attribute values of original vouchers in each column where "Unused water-surface water" is 5 "Unused water consumption-groundwater" is 1; "Unused water-other water sources" is 2.

(8) Set the attribute learning threshold as 2, and generalize the attribute values with attribute types greater than 2 in the database, upgrading each attribute of "unused water-surface water" to "water resources" and upgrading the attribute of "unused water-groundwater" to "water entity." So the

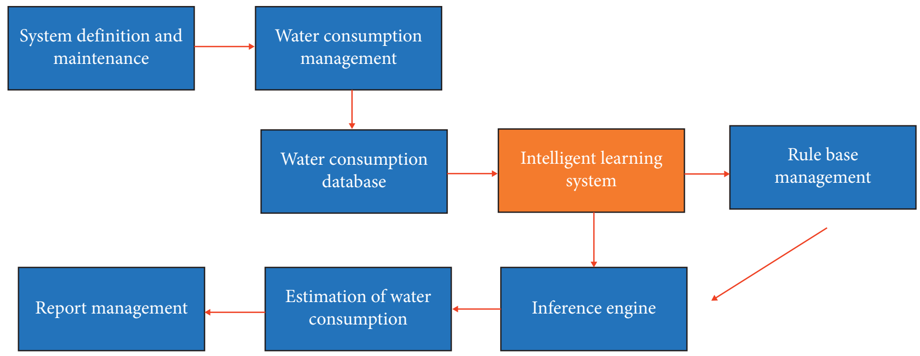

FIGURE 5: Architecture of the accounting information system.

attribute types in all columns are less than or equal to the set threshold.

(9) Extract all economic businesses in the water consumption database to verify the output rules and whether the accounting account combination in the corresponding accounting voucher is frequent item set BCE. If true, the rule is a strong rule that can be stored in the rule base, and the intelligent accounting algorithm is successfully learned. If false, the rule is weak and can be stored in the rule base to be verified.

5. Design of the Accounting System of Water Company Based on the Combination Model

According to the accounting practice process and the demand of intelligent accounting [29], the architecture of accounting information system of water company designed in this paper is shown in Figure 5, and the main functional modules are as follows:

(1) System definition and maintenance: this functional module mainly includes the basic work such as account initialization, accounting period definition, and personnel authority management. At the same time, the system also needs to collect and store a large amount of basic data such as personnel information, organization information, and water rights trading information, which lays the foundation for realizing computer intelligent judgment.

(2) The management of water consumption is an important part of intelligent accounting system which is different from ordinary accounting information system. A large amount of original voucher information needed for the learning and training of intelligent accounting system is collected and stored through this link. With the help of OCR text recognition technology and other intelligent data collection technologies, learning samples can be obtained efficiently and accurately for AOI algorithm [30].

(3) Intelligent learning system is the most important module in the intelligent accounting system, which mainly learns and extracts relevant rules from the database of original vouchers and accounting vouchers. First, preprocess learning sample data, including setting control parameters for intelligent learning of the system and creating Boolean mapping matrix according to the accounting voucher database. Second, mine association rules by calling Apriori's improved algorithm, and output frequent accounting account combination item sets to provide basic data for the original voucher attribute learning. Third, learn the attribute of original water consumption after extracting the learning sample data from the original voucher database. Finally, the inference engine automatically calculates and realizes the important function of automatically compiling accounting vouchers [31].

6. Conclusion

With the in-depth application of artificial intelligence technology in accounting field, accounting intelligence has become one of the hottest topics in the development of accounting industry at present. Focusing on the intellectualization of accounting, by taking computer intelligent judgment as the direction to replace professional judgment of accounting experts, this paper comprehensively applies improved Apriori algorithm and improved AOI algorithm based on Boolean mapping matrix. In addition, data mining is carried out on the relationship between the original water consumption attribute, attribute value, and water right transaction, and a water accounting rule base is formed. On this basis, the computer self-learning under unsupervised mode, intelligent judgment reasoning, and intelligent accounting of self-updating rule base are realized.

Excessive exercise can strengthen the body and make people happy, but it can also cause physical injury. To address this issue, this paper proposes the TFD-SE (Three-Frame Difference Spatiotemporal Entropy) algorithm and the LB (Label Propagation) algorithm, which are both based on SE (spatiotemporal entropy) and label technology. The TFD-SE algorithm calculates the difference image using the three-frame difference method, then calculates the SE of pixels in the difference image, and performs morphological filtering and threshold segmentation, allowing it to detect moving objects effectively. The significance value of unlabeled nodes in the image is calculated using the LB algorithm. In both qualitative and quantitative comparisons, the experimental results show that both algorithms outperform other classical algorithms in terms of detection performance.

1. Introduction

Fatigue is caused by a variety of factors. Fatigue can be classified into four different categories [1–3]: according to the first classification, fatigue is a transitional state between waking and sleeping with no clear distinction between the two; according to the second classification, fatigue is divided into psychological and physiological fatigue; the third type of fatigue is divided into four categories: psychological, pathological, mental, and physical fatigue; and the fourth classification is based on the most common clinical fatigue symptoms. Athletes and soldiers are two examples of occupations that require extensive sports training on a daily basis. Overtraining weakens the training effect while also increasing the risk of more serious side effects such as syncope, muscle injury, and even sudden death [4]. As a result, sports fatigue detection is critical for human safety. There are two parts to sports fatigue detection: sports data acquisition and data-driven recognition algorithm [5].

Aerobic exercise fatigue detection plays an important role in the fields of biological identification, biological monitoring, production, and breeding. In recent years, many methods have been put forward to solve this problem. Among them, the background subtraction method is one of the most commonly used detection methods [6, 7]. It subtracts the background frame from the current video frame and then selects a suitable threshold for binarization of the obtained image, so as to extract the moving target. Entropy is the representation of average information, which was first introduced in informatics. Knowledge about entropy has been widely used in the field of image segmentation [8, 9]. The edge-based method is considered more suitable for semantic video image segmentation. Because people are very sensitive to the edges of moving objects, the effect of extracting the edges of moving objects from the background largely depends on the preset threshold [10]. Because different image sequences contain different image components and their variable characteristics are obviously different, any preset fixed threshold value is not suitable for aerobic exercise fatigue detection. Affected by physical factors such as friction and slippage, the shape and position of the sensor will cause errors in the data acquisition process, which will reduce the accuracy of the recognition algorithm and fail to get satisfactory results.

To detect aerobic exercise fatigue, this paper uses a combination of SE (spatiotemporal entropy) and labeling technology. The moving target can be detected directly by subtracting the current frame image from the background to obtain the difference image and then calculating the SE of the difference image. This method uses entropy to reflect the strength of biological fatigue and, when combined with label technology, reduces the algorithm's calculation time. This algorithm has low computational complexity, strong parameter robustness, and a clear target and is an effective biological aerobic exercise fatigue detection method when compared to the traditional SE method.

2. Related Work

In recent years, research on human fatigue at home and abroad, especially the research on the influence of fatigue on fatigue, has been increasing year by year. In [11] by comparing with the data of healthy people, it is found that the symmetry of the two parameters and the linear relationship between them are quite different. Literature [12] proves that the muscle imbalance in the lateral and middle parts of the lower leg under fatigue is related to the lateral deviation on the floor of the dynamometer. In literature [13], through running on the vertical pressure plate, the impact speed and pressure are obtained. The results showed that the peak acceleration of the tibia and the acceleration of the shoe upper decreased significantly. Literature [14] studied the characteristic changes of HRV (heart rate variability) of the subjects when riding a power bicycle and found that with the deepening of exercise, the peak value of the high-frequency power of HRV gradually increased from 0.25 Hz to 0.6 Hz, which indicated that the main energy of HRV would gradually shift to the right during exercise. Literature [15] used HRV to study different types of fatigue in healthy people and achieved good results. Literature [16] studied the change in the power spectrum of surface EMG (electromyography) signals before and after fatigue under constant static load and found that the power spectrum after fatigue shifted to the left compared with the whole and peak value before fatigue. Literature [17] found that the one-dimensional EMG time series has chaotic characteristics. They calculated the information entropy of various EMG signals in the reconstructed two-dimensional phase space and analyzed the obtained results to determine the law between muscles and movements. In literature [18], using quantitative recursive analysis, it was found that the percentage of a deterministic segment of sEMG (surface electromyography signal) of biceps brachii continuously increased during exercise fatigue, and it was more sensitive than the change of median frequency MF (median frequency) with fatigue.

On the basis of SE, literature [19] proposes an algorithm for detecting human aerobic exercise fatigue. This method establishes a histogram to calculate the SE value of each pixel point and uses that value to determine whether the pixel point belongs to a moving target. An aerobic exercise fatigue detection algorithm based on entropy map and adaptive state label technology was proposed in the literature [20]. Literature [21] proposed a "center-surround" model, which was realized by using the spatial pyramid's local feature contrast of color, brightness, and direction. Despite the fact that the eye movement point prediction model is the origin of significance detection and has made significant progress, each of these methods has a flaw that will affect their performance in practice. To calculate saliency value, the literature [22] uses histogram information from the image luminance channel. For the first time, literature [23] introduced the saliency filter and used a high-dimensional Gaussian filter to fully express the contrast and saliency measurement standard. To detect salient targets, literature [24] fuses various prior information into conditional random fields. The contrast of the center surrounding the histogram, the spectral residual, and the color space distribution are among the prior data. Literature [25] integrates the appearance information alongside the spatial prior information to calculate the significance value of each pixel in the image one by one. These comparison-based methods are simple to use and calculate, but the results are not always ideal when dealing with complex backgrounds.

3. Research Method

3.1. SE-Based Aerobic Exercise Fatigue Detection. Fatigue is a kind of discomfort felt by human beings. It is a kind of feeling after a great deal of physical or mental work. It will reduce people's ability to finish work. When exercise fatigue occurs, the athlete's heart load will increase continuously, becoming more irritable and irritable than usual, muscle soreness and flexibility will decrease, and the necessary thinking ability in competitive sports such as judgment and reaction will also decrease [3]. Therefore, sports fatigue is a comprehensive physical and mental fatigue with mental, psychological, and physical strength.

As the human body's environment will change greatly during exercise, many physiological indexes of the human body will also change greatly. Among these indexes, which can be more related to the changing trend of human body fatigue, and how to select and calculate these indexes to better monitor and analyze human body exercise fatigue is still under in-depth study. In traditional sports fatigue assessments, the subjective (psychological) assessment method is often used to estimate the fatigue degree of the human body quickly, directly, and effectively. However, because sports fatigue is a complicated process, it lacks objectivity only through subjective evaluation, and it is difficult to analyze and evaluate it comprehensively and accurately.

State recognition has garnered a lot of interest as a new recognition technology. When people walk, the term "Li state" refers to the overall movement state of all body parts at any given time. The size of the step, the degree of body shaking, and the habit of exertion are all different aspects of walking posture. The purpose of state recognition is to determine a person's identity based on their distinctive walking posture. Walking is a movement in which both legs alternately push and cushion the ground. The body's acceleration changes over time during a period of walking. There will be turning points in the acceleration signal, such as maximum and minimum when the lower limb is initially grounded, buffered, and pedaled. Entropy is a measure of how much information is contained in a piece of data in information theory. When entropy is at its maximum, the amount of information obtained is at its greatest.

If a random experiment has N possible results or a random message has N possible values, and the probability of their occurrence is, respectively $p_1, p_2, \ldots, p_n$, then the information amount of these events, that is, entropy, is defined as

$$E = -\sum_{i=1}^{n} p_i \cdot \log p_i, \quad (i = 1, 2, \ldots, n). \tag{1}$$

Because entropy is a measure of information size, which indicates the degree of diversity of an event, entropy can be used to characterize the diversity of pixel states and then reflect the degree of motion intensity of pixel points.

An effective method of aerobic exercise fatigue detection must establish the corresponding relationship of moving targets along the time axis. At the same time, because moving targets not only have the temporal correlation of the moving areas but also have the correlation of spatial gray values, the 2D threshold is extended to detect meaningful aerobic exercise fatigue in the time domain.

In this paper, an aerobic exercise fatigue detection algorithm based on TFD-SE (three-frame difference spatial-temporal entropy) is proposed. The algorithm uses the three-frame difference method to get the difference image of video image sequence and uses the SE principle to detect aerobic exercise fatigue in the difference image. In the process of fatigue detection, first, divide the image sequence into 3×3 blocks and calculate the interframe contrast FCON and local variance LCON of the image sequence for each block.

The probability density distribution of each pixel in the video can be obtained by calculating its histogram. According to the distribution probability of a pixel on the time axis, and the distribution probability of the pixel in space is obtained by spatial coordinates, the sampling space shown in Figure 1 is established in this paper.

Interframe contrast indicates the continuity of pixel gray levels in the same position in different frames in time direction, defined as follows:

$$\mathrm{FCON}(m) = \sum_{x=0}^{2}\sum_{y=0}^{2}\left|I(x, y, t_n) - I(x, y, t_p)\right|^2, \tag{2}$$

in which $I(x, y, t_n)$ represents the gray value of the (x, y) position of the current block and $I(x, y, t_p)$ represents the gray value of the current (x, y) block position of the reference image.

The continuity of gray values of adjacent pixels in the same frame is represented by local variance, defined as follows:

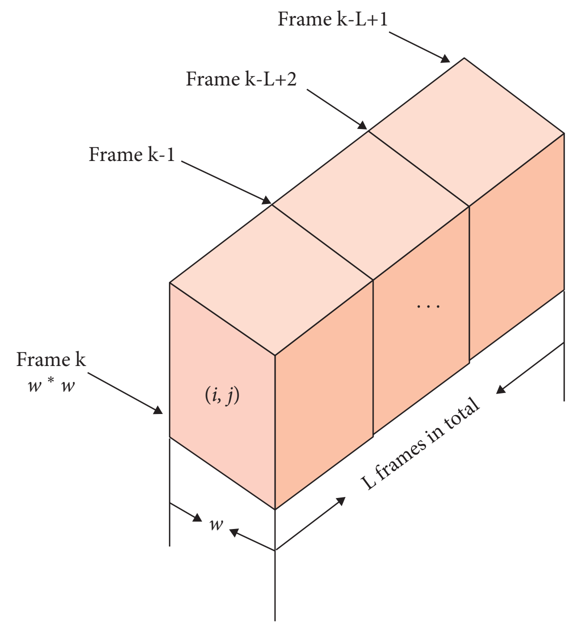

Figure 1: Two-dimensional histogram.

$$\mathrm{LCON}(m) = \sum_{x=0}^{2}\sum_{y=0}^{2}\left|I(x, y, t_n) - \mathrm{MEAN}(m)\right|^2, \tag{3}$$

where $\mathrm{MEAN}(m) = (1/9)\sum_{x=0}^{2}\sum_{y=0}^{2} I(x, y, t_n)$ is the average pixel gray value of the current block.

Calculating the histogram of an image yields the probability density distribution of each pixel. To calculate the histogram distribution of the pixel, a sliding window in time and space is used. The pixel's spatial variation and their variation over time are both represented in the sliding window.

After obtaining the histogram of each pixel, the probability density distribution of pixel (i, j) can be obtained by the following formula:

$$P_{i,j,q} = \frac{H_{i,j,q}}{N}, \tag{4}$$

where N is the sum of pixels in the rectangular window, that is, $N = L \times W \times W$. The probability density of each pixel can be obtained, and the entropy of each pixel can be calculated by (5) to obtain the SE image.

$$E_{i,j} = -\sum_{q=1}^{Q} P_{i,j,p}\log\left(P_{i,j,p}\right). \tag{5}$$

SE reflects the change of each pixel in the image in time and space. If the pixel belongs to the foreground target, $E_{i,j}$ is large, and if the pixel belongs to the background, $E_{i,j}$ is small. Therefore, it can be judged whether the pixel is the foreground target by taking a certain threshold of the entropy image.

The flow of the algorithm is shown in Figure 2.

To begin, edge extraction of video images is performed to obtain three consecutive frames of edge images, after which three frames of difference operations are performed on the

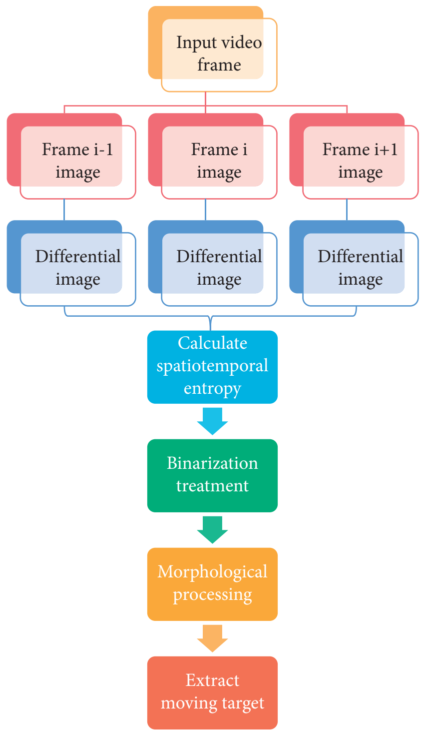

Figure 2: The flow of the algorithm.

three consecutive frames of edge images to obtain a difference image, a two-dimensional histogram of the difference image is established, the SE of the difference image is calculated, and finally, binarization and morphological processing complete the target extraction.

3.2. LB Aerobic Exercise Fatigue Detection. The existing methods of aerobic exercise fatigue detection are basically bottom-up data-driven, and the basic framework is to first define the measurement standards of saliency and then analyze the salient areas or basic pixel units in the image according to these standards, so as to detect the salient targets. These methods mainly use the feature information of salient targets to determine the measurement standard, or some methods detect salient targets according to the feature information of background areas.

In this paper, consider combining these two methods according to the different features information of the salient target and the background area and using the principle of LB (label propagation) to get the corresponding salient maps, respectively, and then fuse the salient maps through an improved Bayesian model to get the final detection result. Figure 3 is the algorithm flow chart of this paper.

The LB algorithm is a semisupervised learning algorithm in a graph model. Its basic idea is to use labeled nodes as label nodes and estimate the unlabeled node information based on the propagation mechanism of the graph model. When the iteration ends, the propagation probability distribution of similar nodes is often similar. The nodes with high similarity are classified into the same class, and then the LB process ends. People generally do not focus their visual attention on the edge of the image. The salient objects in the original image basically do not touch the edge of the image. Therefore, in this paper, the boundary node of the image is used as the seed node of background propagation, that is to say, the boundary node is used as the marked data to LB all other remaining nodes, so as to obtain the similarity measure between the remaining superpixels and the label superpixels, thus obtaining the saliency map based on the background prior information.

In order to meet the measure of significance, this paper needs to normalize the vector to the range of [0, 1]. Therefore, according to the propagation formula, the saliency map using background prior as label node can be calculated, and the saliency value $S_b(i)$ of superpixel node is defined as

$$S_b(i) = 1 - \overline{y}^*(i), \quad i = 1, 2, \ldots, N, \tag{6}$$

where i represents a superpixel node in the image and $\overline{y}^*$ represents a normalized vector. Because the background node is used as the label node in the LB process, the label value of the background area needs to be set to 1.

In most cases, good results can be obtained through the spread of background tags. However, in some images with complex background or low color contrast between foreground and background, the detection results obtained by background prior propagation are not ideal, and a large number of background areas are mistaken for significant targets.

Now, use the foreground target as a label node, so the label vector is known. According to the propagation formula, vector S is normalized to the range of [0, 1], and then the saliency map using the foreground prior information as the label node is obtained. Then the saliency value $S_f(i)$ of the superpixel node is defined as

$$S_f(i) = \overline{y}^*(i), \quad i = 1, 2, \ldots, N. \tag{7}$$

The object-like score is mapped to each pixel using the position relationship and the Gaussian kernel function. Finally, by adding and averaging each superpixel's object-like score, some superpixels with higher object-like scores are chosen as reliable foreground label nodes. This paper converts the saliency map from superpixel level to pixel level before Bayesian fusion for calculation accuracy, which increases computational complexity but yields better detection results.

The formula for calculating the saliency map of pixel level is as follows:

$$S(p) = \sum_{i=1}^{G} \frac{1}{Q_i} \exp\left(-\left(k_1 \left\| c_p - c_i \right\| + k_2 \left\| z_p - z_i \right\|\right)\right) S(r_i). \tag{8}$$

Among them, $S(r_i)$ represents the saliency map of superpixel level, c_p, c_i, z_p, z_i represent the color feature and coordinate vector of pixel p or superpixel area i, respectively, G represents the number of areas directly adjacent to super pixel area r_i, and Q_i represents the normalization parameter. k_1, k_2 are parameters that control color and position sensitivity.

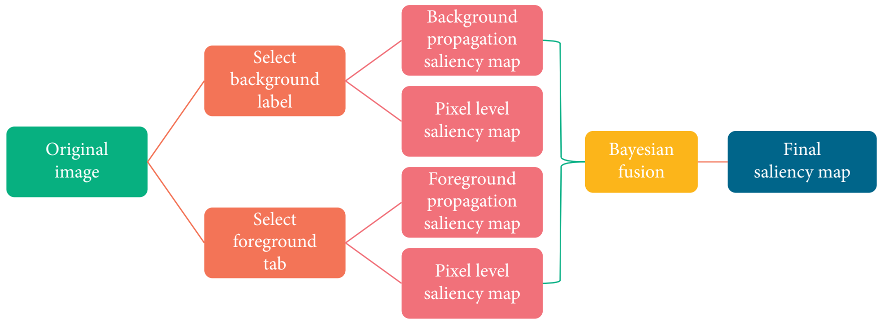

Figure 3: Algorithm flow of LB aerobic exercise fatigue detection.

In this paper, according to the foreground prior and background prior, errors will inevitably occur when selecting tag data, which will lead to inaccurate target detection after passing LB. However, use Bayesian fusion to combine the two propagation results, use the complementary relationship between background information and foreground information, improve the accuracy of the detection target through background LB, and effectively suppress the background area through foreground LB, and finally get the ideal detection effect.

4. Results Analysis and Discussion

Long-term aerobic exercise causes the body temperature to rise and the body heat to rise sharply. To keep the body from overheating, a lot of perspiration and heat dissipation is used to keep the body temperature balanced. The majority of the water lost through perspiration is water which comes primarily from plasma, intercellular fluid, and the intracellular fluid body. Dehydration will occur if water is not replenished in a timely manner, which will have a significant impact on exercise ability. When a person's water loss reaches 2% of their body weight, their working ability drops by 10% to 15%, and when it reaches 5% of their body weight, the athlete's sports ability drops by 10% to 30%.

In this section, the identification model for sports fatigue is constructed by the TFD-SE algorithm and its classification accuracy is tested. First, train the fatigue identification model with ECG (electrocardiogram) and EMG features, respectively, and check the accuracy, and then train and check with EMG feature fusion. Figures 4–6 are statistical results of the classification accuracy of the TFD-SE fatigue identification model constructed by three modes of EMG, ECG, and myocardial electrical feature fusion under a 50% cross-test.

Figure 6 shows that the recognition model trained on ECG and EMG features has a stable comprehensive classification performance and good recognition ability for three types of fatigue states. As a result, the TFD-SE recognition model trained with myocardial electrical feature fusion outperforms the TFD-SE recognition model trained with ECG and EMG features.

Skeletal muscles generate a lot of heat when they are worked hard for a long time. The body will increase heat dissipation to the external environment in order to maintain a constant body temperature. Heat can only be dissipated through perspiration,

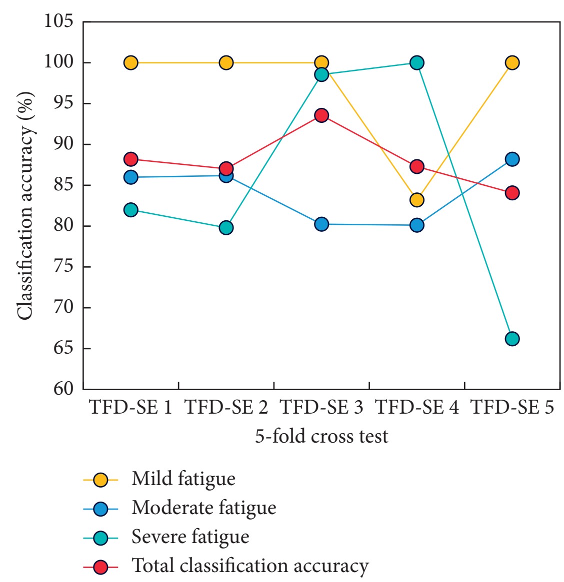

Figure 4: Statistics of classification accuracy of the TFD-SE classification model of EMG feature training under the 5-fold cross-test.

especially during high-temperature seasons when the environment temperature is higher than the body temperature. The body will sweat a lot at this time, and a lot of electrolytes will be lost through sweat, resulting in electrolyte disorder, abnormal neuromuscular excitability, muscle spasms, and decreased exercise capacity. To demonstrate the effectiveness and comparability of the fusion strategy in this section, the unweighted fusion strategy corresponding to the Chinese style in this section is used separately based on tracking with the same features within the framework of the algorithm in this section, and the tracking error is shown in Figure 7.

The time cost of this algorithm mainly focuses on the extraction of each feature and the calculation of similarity, which is directly related to the size of the target and the number of particles. The larger the target, the more particles are obtained and the more time is spent. Therefore, for larger targets, the calculation time can be reduced by sampling the target and reducing the resolution.

Correcting dehydration and providing energy soon after aerobic exercise can help you recover faster. The total amount of liquid and electrolytes lost during exercise should

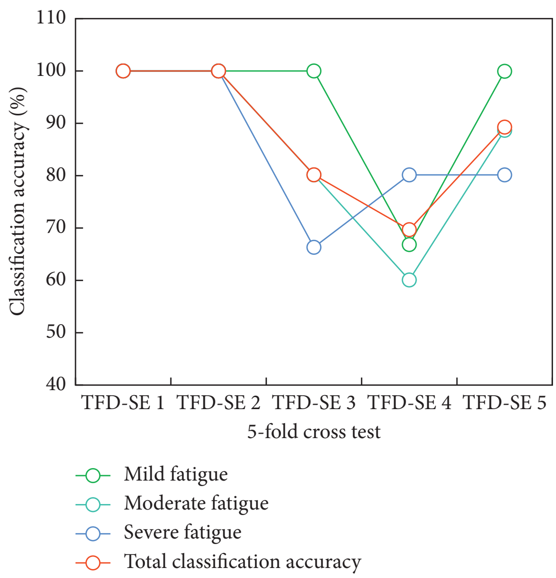

Figure 5: Classification accuracy statistics of the TFD-SE classification model of ECG feature training under 5-fold cross-test.

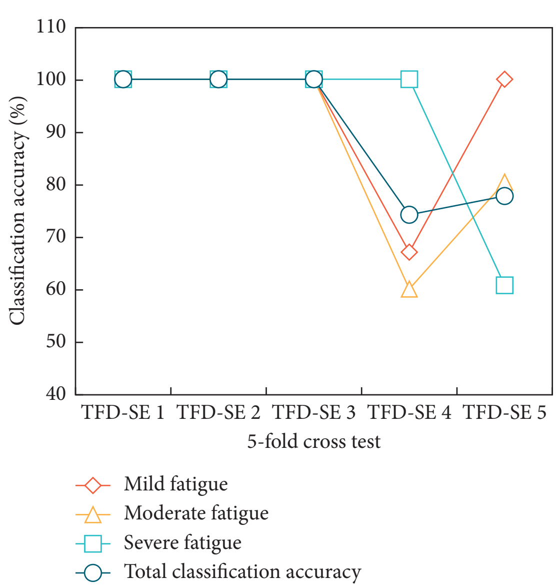

Figure 6: The classification accuracy statistics of the TFD-SE classification model of myocardial electrical feature fusion training under the 5-fold cross-test.

be recovered effectively. To obtain rapid hydration, it is best to consume a sugar-electrolyte beverage after exercise. The sugar content of the beverage can range from 5% to 10%, and the sodium salt content can range from 30 to 40 milligrams equivalent. Vitamin C is an important hydrogen donor in the biological oxidation process, so it is important for aerobic endurance exercise as well. It can speed up the oxidation-reduction reaction in the body, allowing the body to gain more energy and thus improve exercise performance. As a result, taking vitamins after exercise can help to alleviate fatigue symptoms and delay the onset of exercise-induced fatigue.

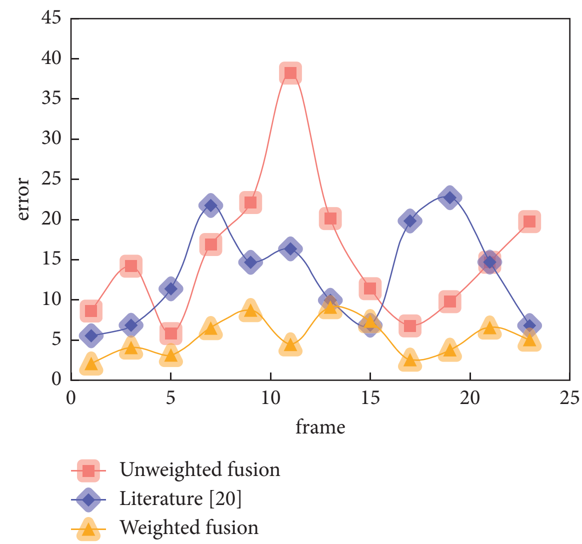

Figure 7: Comparison of error curves of tracking results with different fusion strategies.

In order to make this model more convincing in its aerobic exercise fatigue detection performance, compare it with other existing classic algorithms. In this paper, the F-measure value, recall rate, and AUC (area under the curve) value of these aerobic exercise fatigue detection algorithms will be evaluated on the ASD image database. The results are shown in Figures 8–10.

The accuracy-recall curves of different models are shown in Figure 8. The model in this paper can achieve an accuracy of 0.96 in most range of recall rate and is obviously superior to most detection models. The detection effect of literature [18] is close to that of this model, and the detection performance is slightly higher only in some parts with a low recall rate.

Many isolated small areas and gaps often appear in the binarized image, which will affect the extraction of moving objects. Therefore, the isolated small areas in the binarized image are removed by the image morphology method, and the small gaps are filled at the same time. In morphological processing of binary images, firstly, the isolated small areas are removed by the corrosion operation, and then the small gaps are filled by the expansion operation. On the one hand, it can eliminate noise, and on the other hand, it can smooth the image so that the moving target can be completely detected.

Figure 9 shows the average accuracy rate-recall rate and f-measure value of different models. It can be seen that the average accuracy and F-measure value of this method can reach 9.4 and 8.8, respectively, which is also better than other methods.

It has been established that when the human body participates in high-intensity sports, the strength is primarily maintained by an increase in the central nervous system impulse frequency [16], and the central nervous system constantly sends out high-frequency impulses during the movement. Due to the abrupt change in illumination, color and texture features lose their tracking performance when pedestrians pass through the illumination area. Despite the fact that edge features are less affected by illumination, they lose

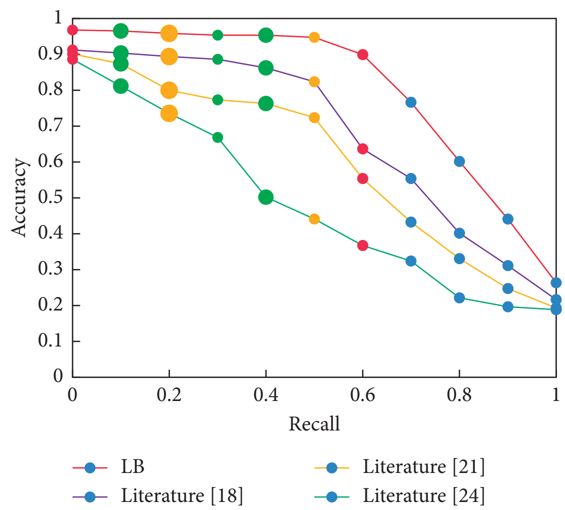

Figure 8: Accuracy-recall curve.

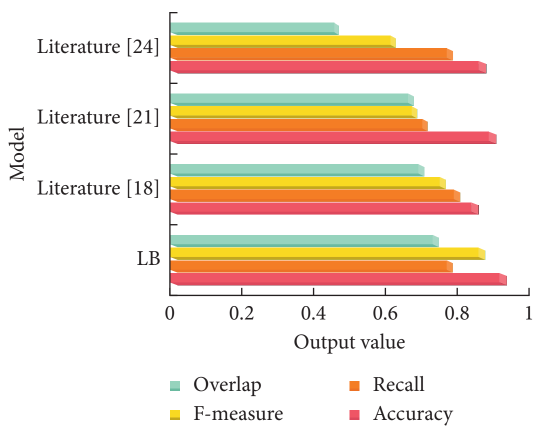

Figure 9: Average accuracy of different models-recall rate and F-measure value.

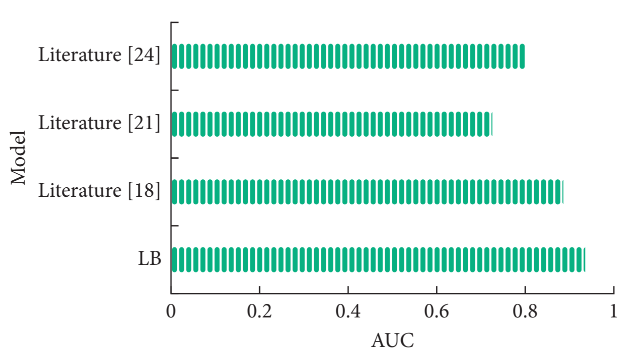

Figure 10: Comparison of AUC values of different models.

their effectiveness due to strong edge interference from object shadows in the illumination area, as the literature [21] shows.

Although the algorithm in this section is affected by the same influence, it also introduces the motion feature, which effectively distinguishes the moving pedestrian from the static background, allowing the tracking algorithm in this section to reliably track the target throughout the sequence.

The texture features are a good supplement when there is background interference. When the head rotates out of the plane, the color and texture features change abruptly, whereas the edge features can effectively capture the head's contour occlusion, which has not changed significantly. Many features are affected to varying degrees when the occlusion occurs due to the various positions and degrees of occlusion, but after fusion, the tracking effect remains stable and effective.

Figure 10 shows the comparison of the AUC values of different models. Aerobic exercise fatigue detection can be simply understood as a second-class classification problem, the purpose of which is to distinguish the prominent target from the background. The AUC value reflects the performance of this classification model. It can be seen from the figure that the AUC value of this model is slightly higher than those of other models and has reached 0.935.

It can be seen from the figure that highlights appear in some background areas. This is because there is no internal connection between the nodes in the background area of the image, which makes the detection algorithm unable to effectively distinguish the background area from the salient objects. After adding thegeodesic constraint, the connection between boundary areas is strengthened, and some obvious targets are not detected by using only one layer of neighbor nodes. This is because the neighbor nodes in the first layer did not make full use of the spatial information in the image, which led to missing some targets in aerobic exercise fatigue detection. However, if all the image nodes were regarded as neighbor's nodes, it would not only increase the amount of calculation, but also reduce the detection effect.

The results obtained by the LB formula have been able to detect remarkable targets well in this paper, using the characteristics of boundary prior and geodesic constraints. The background tag nodes are then hoof selected, and the contact boundary of obvious targets is minimized as much as possible, making the method more robust in this paper. Bayesian fusion takes advantage of the complementary relationship between background and foreground prior information to effectively suppress background noise while uniformly highlighting the prominent targets.

The results of the experiments show that applying the entropy principle in informatics to the field of biological aerobic exercise fatigue detection is feasible and effective, and that it effectively improves and solves the problems of irregular movement and slow detection speed of biological targets in fatigue detection, as well as corroborates the theoretical basis that entropy can reflect the strength of moving targets. This method has a low algorithm complexity, strong parameter robustness, and superior antinoise ability when compared to the traditional aerobic exercise fatigue detection method. It is a reliable biological method for detecting aerobic exercise fatigue that can be applied to biological identification, biological monitoring, and other fields.

5. Conclusion

The detection of aerobic exercise fatigue is investigated in this paper using SE and tag technology, which collects and processes human gait acceleration signals. The TFD-SE is used to propose a new algorithm for detecting aerobic exercise fatigue. The results of the experiments show that using entropy-related principles in informatics to detect aerobic exercise fatigue is feasible and effective. Saliency maps based on foreground information propagation and saliency maps based on background information propagation can both be obtained using the LB algorithm at the same time. The saliency map generated by this model can effectively suppress background noise and highlight saliency targets uniformly and accurately, as evidenced by comparisons of visual effect maps.

The relationship between EEG and exercise fatigue is only explored in a broad sense in this paper. In the future, more research and excavation will be done on this topic.

Venture capital firms are always faced with insufficient information and insufficient time when evaluating whether startups are worth investing in. This paper focuses on how to combine the public information of startups with the decision tree algorithm to assist investors in project screening. By extracting the public information of 1104 AI and big data companies from January 2016 to June 2017 and the financing progress in the following 18 months, this paper finds that: the six indicators of having a working background in well-known companies, being reported by well-known media, having patents and being invested by excellent institutions, working experience is highly related to this venture, and having well-known financing consultants can effectively help investors screen out projects that can obtain sustainable financing, that is, high potential projects. Considering the problem of data availability in the real world, combined with industry experience, this paper makes a more detailed variable mining for semistructured information, such as the team resume of start-ups, and selects a decision tree algorithm that is insensitive to missing values and has strong interpretability to amplify the value of fragmented information. Finally, by the improvement of the algorithm, a project screening model that can meet the needs of investment practice is designed, and the fusion mode of public information and private information is discussed, which has a more complete guiding significance for optimizing investment work.

1. Introduction

Venture capital is a form of investment that provides capital for start-ups with high growth potential in exchange for equity. Massive entrepreneurial projects and high investment costs pose a great challenge to fund managers. How to screen as many high-quality entrepreneurial companies in the market as possible under the condition of limited manpower and time, identify their development potential, and provide support is the first kind of problem faced by investors, i.e., time constraints. Another consensus is that there is a serious lack of information in the field of early investment. In the face of newly established companies, investors often cannot obtain hard data about the market, products, and finance, and they can only make decisions under imperfect information in combination with their own experience, industry estimates, and the judgment of the start-up team. In this process, which factors should be given a higher weight, and how to reduce the components of subjective assumptions and make decisions more rational are the second kind of problems faced by investors, i.e., information constraints.

Facing the problem of insufficient time and information, an intuitive solution is to let the machine assist people to collect and process more information, precipitate the decision-making knowledge in the way of algorithm, and rationalize the investment process. However, a series of questions, such as which channels, what information to extract, what indicators to refine, and what feedback to modify the model, need some definition to be effectively answered. Therefore, this paper extracts the link of early project screening from the whole process of investment activities and simplifies the problem as follows:

Assume that an investment institution has obtained the profile of an early-stage company disclosed in the venture capital media, including the endorsement information of relevant parties, such as "past investors," and the information of team characteristics, such as "profile of team members." Can this institution predict the company's potential to obtain the next round of financing based on the financing development of related companies in the same industry over the past period of time? Finally, decide if it is worth the time to research and follow up on the investment.

The two types of input required to answer this question have been extensively studied in academia.

In terms of team characteristics, the positive effects of industry-related experience [1, 2], entrepreneurial experience [1, 3, 4], and well-known company work background [5, 6] on the development of startups have been supported by most literature. However, studies on demographic factors are currently scarce. In the dimension of stakeholders, the endorsement of investment institutions [7, 8] and social capital [9, 10] are positive to the development of the company. The value of financing consultants, venture capital media, and other relevant parties has not been fully explored.

Therefore, this paper attempts to apply the research results of academia on venture capital decision-making and the influencing factors of startups to real investment activities, and based on semistructured public datasets, extract valuable traditional indicators from as many dimensions as possible and novel metrics to test its predictive power.

Therefore, this paper attempts to apply the research results of academia on venture capital decision-making and the influencing factors of startups to real investment activities, and based on semistructured public datasets, extract valuable traditional indicators from as many dimensions as possible and novel indicators to test its predictive effect.

2. Data Preparation

2.1. Data Sources and Extraction Methods. Since the potential of a startup is a latent variable, the effectiveness of the predictive model needs to be validated by explicit indicators. Therefore, this paper selects "whether to obtain the next round of financing," which is highly related to the company's potential, as a proxy variable to test the effect of "team capability signal" and "relevant party endorsement signal" in building a predictive model. Considering that companies that have never raised funding have less publicly available information, we target our research on startups that have raised at least one round of funding [11].

In practice, different industries have different investment analysis frameworks, and the timing and market enthusiasm have a significant impact on the difficulty of obtaining financing for entrepreneurial projects. Therefore, this paper, firstly, controls the industry and time window, and it selects all investment and financing events in the field of artificial intelligence and big data from January 2016 to December 2018, which is a total of 2527. The source of the data is Xinniu Data (https//:www.xiniudata.com), a third-party venture capital service platform, whose institutional account can provide data export function.

The normal financing rhythm for startups is to complete a new round of financing every 12–18 months. Based on this industry experience, this paper splits the dataset and selects all projects that have received early (round A and earlier) financing between January 2016 and June 2017. After the project, a total of 1104 independent companies entered the sample set. Whether these companies receive a new round of funding between July 2017 and December 2018 will be the predictor variable.

2.2. Data Field Description. The dataset collected in this paper contains 17 original fields: company name, industry field, one-sentence introduction, the current round of financing time, current round, the current round of financing amount, the current round of investor, company introduction, contact information, establishment time, region, company advantages, industry label, team members and introduction, activity performance, and business information [12]. After desensitizing the company name to the company ID, there are 4 remaining fields related to this modeling, all of which are semistructured or unstructured information.

By manually labeling the original dataset, we split the above four fields into the following two categories, with a total of 10 binary variables. See Table 1 for specific field extraction and processing.

The structured processing of information and the processing of missing values are explained as follows:

(1) Invested by excellent institutions (GoodInvestor): If the current round of investors includes excellent investment institutions, the variable is 1, otherwise, it is 0. The definition of an excellent institution is that more than 45% of the projects invested in 2015 have the next round of financing (this proportion is an empirical value and can be adjusted in practice). The information comes from the venture capital institution database of Enniu. If the investment institution does not disclose it, the variable is a missing value, marked with "?"

(2) Have well-known financing advisors (GoodFA): The variable is 1 if the company advantage contains "well-known FA"; otherwise, it is 0. The definition of well-known financing consultants by Enniu Data includes well-known financing consultants in the industry, such as Huaxing Capital and Xiaofan Table (this range can be dynamically adjusted in practice). There are no missing values for this item.

(3) Well-known media reports (GoodCoverage): The variable is 1 if the company advantage contains "famous media coverage," and 0 otherwise. The definition of this label by Enniu Data is that platforms, such as Pencil Road and Entrepreneurship, have an exclusive interview with the target company, rather than a simple financing news disclosure. In practice, this range can be dynamically adjusted. There are no missing values for this item.

Table 1: Field extraction and processing.

Field classification	Processed field name	Data Sources
Relevant party endorsement signal	Invested by excellent institutions	Investors in the current round
	Well-known financing advisors (FA)	Company advantage
	Well-known media reports	Company advantage
Team ability signal	Have patents	Company advantage + team members and profiles
	Working background in a well-known company	Team members and profiles
	Core members have a well-known university education background	Team members and profiles
	Core members have entrepreneurial experience	Team members and profiles
	The members have the same school or work experience	Team members and profiles
	The core team has diverse professional skills	Team members and profiles
	Previous work is highly relevant to this venture	Team members and profiles + company profile

(4) Have patents (Patent): The variable is 1 if the company or its members hold patents, otherwise 0. Among them, patents only refer to the company's invention patents, excluding trademarks, and so on. There are no missing values for this item.

(5) Working background in a well-known company (CompanyHalo): If the team members and their profiles mention well-known internet companies (Tencent, Baidu, Alibaba, JD, Xiaomi, Netease, 360, Sina, Google, etc.) or technology enterprises (Microsoft, IBM, Huawei, Lenovo, sap, Oracle, etc.), then the variable is 1, otherwise, it is 0. If the source field is missing, it is marked as "?"

(6) Core members have a well-known university education background (EduHalo): If the team members and the experience of famous universities in the world are mentioned in the profile, the variable is 1, otherwise, it is 0. If the source field is missing, it is marked as "?"

(7) Core members have entrepreneurial experience (StartupExps): If "continuous entrepreneurship" is mentioned in team members and profiles, the variable is 1, otherwise, it is 0. If the source field is missing, it is marked as "?"

(8) The members have the same school or work experience (CoworkExps): In the team members and profiles, it can be inferred that the core members have studied in the same university or the same company. Then, the variable is 1. If there is no obvious intersection in the main experience, it is 0. If the source field is missing or difficult to judge, it is marked as "?"

(9) The core team has diverse professional skills (DiverseExps): In the team members and profiles, the core members' experience covers at least two items in technology, product, management, marketing, and finance. Then, the variable is 1. If the background of core members is similar, then the variable is 0 (for example, CEO and CTO are from R & D background). If the source field is missing or difficult to judge, it is marked as "?"

(10) Previous work is highly relevant to this venture (WorkRelated): If the team members and the work background mentioned in the profile are highly correlated with the industry or business of the start-up company, the variable is 1, and if it is obviously irrelevant, it is 0. If the source field is missing or difficult to judge, it is marked as "?"

3. Research Design and Model Validation

To make a relatively independent judgment and comparison on the predictive value of the two types of signals, this paper, firstly, constructs two basic models using the endorsement signal of relevant parties and the team ability signal, respectively, and compares the Bayesian network and decision tree C4.5 and random forest. Then, the two kinds of signals are fused to build a comprehensive model to test the improvement of key indicators. Finally, considering the significant difference in the cost of "rejecting the true and accepting the false" in investment practice, this paper introduces a cost matrix to improve the recall rate of the model for high potential projects.

3.1. Basic Model 1: Based on Endorsement Signals of Related Parties. We, firstly, select the endorsement signals of three interested parties—invested by excellent institutions, well-known financing consultants, and well-known media reports—as the model input, and take whether we obtain the next round of financing within 18 months after the first disclosure of financing information as the classification label (yes is 1, no is 0). There are 1104 records in the complete dataset, of which 414 have the next round of financing (defined as a positive sample), accounting for 37.5%.

Under 10 10-fold cross-checks, the average performance of the Bayesian network, decision tree C4.5, and random forest algorithms was tested. The experimental environment is the open-source data mining software Weka, and the algorithm uses the default parameters. Considering the problem situation abstracted from investment practice and how to select a small proportion of samples that cover as many real positive samples as possible, we give the overall classification performance as a reference in Table 2 but focus

Table 2: Basic model 1: endorsement signals of related parties.

	Bayesian network	Decision tree C4.5	Random forest
Overall accuracy	64.2%	63.2%	61.6%
Overall recall	65.8%	64.8%	63.7%
The number of positive samples judged	210	281	256
The actual number of positive samples	123	153	135
Positive sample precision	58.7%	54.6%	52.5%
Positive sample recall	29.7%	36.9%	32.5%

Table 3: Basic model 2: team ability signal.

	Bayesian network	Decision tree C4.5	Random forest
Overall accuracy	68.3%	68.0%	68.2%
Overall recall	69.3%	68.9%	69.0%
The number of positive samples judged	286	249	237
The actual number of positive samples	180	160	154
Positive sample precision	63.0%	64.2%	65.0%
Positive sample recall	43.5%	38.6%	37.3%

on comparing the recall rate and accuracy rate of positive samples (i.e., continuous financing projects).

It can be seen from the above table that the Bayesian network is the model with the highest positive sample precision, and the decision tree C4.5 is the model with the highest positive sample recall rate.

Although the decision tree C4.5 model is slightly lower than the Bayesian network in accuracy, it predicts 30 projects that can get the next round of financing more than the latter on average (153 vs. 123), while only 71 additional projects need to be reviewed (281 vs. 210), which has significant value in practice. Because for investors, compared with the original 1,104 projects, the number of projects has been reduced to 281, which has significantly saved working time (corresponding to a 75% compression rate). 24% more project coverage is desirable in exchange for some additional project viewing time, and the recall of high-potential projects is a major consideration at this time.

In summary, decision tree C4.5 is the best performing model for this requirement.

3.2. Basic Model 2: Based on Team Ability Signal. In the basic model 2, we select seven founding team ability signals as the model input, including having patents, working background in well-known companies, core members having an educational background in well-known universities at home and abroad, core members having entrepreneurial experience, members having the same school or work experience, core teams having diversified professional skills, and previous work is highly related to this entrepreneurship. Then, repeat the aforementioned experimental process.

It can be seen from Table 3 that at this time, random forest is the model with the highest classification accuracy of positive samples, while the Bayesian network is the model with the highest recall rate of positive samples. The difference in precision is slightly lower than the difference in recall. In addition, compared with basic model 1, the three types of algorithms have improved in key indicators. Among them, the positive sample recall rate of the Bayesian network improved the most significantly (43.5% vs. 29.7%). The positive sample precision rate of the random forest algorithm improved the most significantly (65.0% vs. 52.5%).

A possible explanation is that, compared with the related party endorsement signal, the dimension of the team capability signal is richer, however, the proportion of missing values is also higher. Under the characteristics of this dataset, the Bayesian network can learn the rules existing in a small number of samples from the combination of indicators, and the pruned decision tree algorithm is more inclined to learn the negative samples with a higher proportion in the dataset. In the discrimination method, although the size of the selected samples is smaller (the compression rate is above 77%), the recall ability of positive samples is weak.

To sum up, in investment practice, if one encounters a situation with rich attributes but many missing values, the Bayesian network may be the better choice among the three.

3.3. Fusion Model. For base models 1 and 2, the sample compression and precision are acceptable in practice, however, the optimal model does not exceed 44% in terms of recall on positive samples. For investment institutions, the cost of omitting star projects is huge. Only when the recall rate of positive samples is high enough, the model has application value.

To this end, we tried to fuse the endorsement signal of related parties with fewer dimensions and the team capability signal with more dimensions as the model input and repeated the above modeling and testing process. The results are summarized in Table 4.

It can be seen from the above table that compared with the basic models 1 and 2, the three types of algorithms have a large proportion of the improvement in the recall rate of positive samples, and the value of the combination of the two types of indicators for improving the prediction effectiveness of the model has been verified. Among them, the Bayesian network has the best performance. The performance of decision tree C4.5 is in the middle, and the performance of random forest is second. Compared with model 2, the recall

Table 4: Fusion model.

	Bayesian network	Decision tree C4.5	Random forest
Overall accuracy	69.7%	67.6%	67.0%
Overall recall	70.5%	68.5%	67.9%
The number of positive samples judged	327	339	332
The actual number of positive samples	207	203	196
Positive sample precision	63.5%	59.7%	59.0%
Positive sample recall	50.1%	48.9%	47.4%

rate of positive samples for decision tree C4.5 is improved by 10 percentage points.

It is of great significance for investment practice. Take decision tree C4.5 as an example. Its practical meaning is as follows: after 1104 projects are screened by the model, 339 will be judged as possible for the next round of financing, of which 203 can indeed get the next round of financing. From the perspective of project coverage, if investors screen projects according to this method, they can cover 48.9% of high potential projects under 30.7% of the workload. From the perspective of time cost, investors can spend 59.7% of their working time on valuable projects, which is significantly improved compared with the positive sample rate of 37.5% when looking at projects at random.

However, it is worth noting that even under the optimal model, half of the high potential projects will not be screened out by the algorithm. By tracing back the characteristics of samples and their classification results, it can be inferred that there are three reasons, which are as follows:

(1) Incomplete information. For example, 72 positive samples lack team members' profiles and lack positive signals in the dimension of endorsement of related parties, which objectively limits the upper limit of the prediction ability of the model.

(2) The positive and negative proportions of the samples are uneven. The proportion of negative samples is 62.5%, which is 1.7 times that of positive samples, which makes the model with the goal of reducing the error rate more inclined to learn the discriminative method of negative samples, while the mining of positive samples is insufficient.

(3) There are unobserved influencing factors. Important factors affecting a company's ability to secure its next round of funding may not be limited to the 10 metrics used in the model.

4. Model Discussion and Extension

4.1. Factor Analysis and Rules Summary. This paper designs and validates a predictive model that can be used for early-stage project screening, but in investment practice, prediction results alone are not enough to support project screening. Investors need to understand the decision-making basis behind the model to confirm each other with their past investment experience, correct possible wrong judgments, or add new screening rules. At the same time, investors also need to know which factors contribute more to the prediction to consciously collect this information when contacting entrepreneurs or improve the information quality of these dimensions through other channels.

Considering the interpretability of the rules, this section selects the pruned decision tree C4.5 model as the analysis object, as shown in Figure 1.

As can be seen from the above figure, there are six indicators in the four layers of the decision tree, which are team capability signals (work background in well-known companies, patents, previous work experience is highly related to this venture) and relevant party endorsement signals (reported by well-known media, invested by excellent institutions and well-known financing consultants), three each. They are the most discriminative for judging whether a project can get the next round of financing [3].

There are also observable differences in the 0–1 distribution of these indicators in the whole sample and the positive sample, as shown in Table 5 for simplicity (the proportion of missing values is hidden). Except for "well-known financing consultants," the proportion of the remaining five indicators with a value of 1 in the positive sample is 12–19 percentage points higher than that in the whole sample.

Combined with the classification results output from Figure 1 and the decision tree model, the following four representative investment logics can be summarized from right to left:

(1) 76% of entrepreneurial teams with a working background in well-known companies can obtain the next round of financing (characteristics: strong team ability signal).

(2) 69% of the teams without working background of well-known companies but with well-known media reports and patents can obtain the next round of financing (characteristics: screened by stakeholders and strong technical ability of the team).

(3) 64% of the teams that have no working background in well-known companies and no well-known media reports but have been invested by excellent institutions and whose previous work is highly related to this entrepreneurship can obtain the next round of financing (characteristics: they have been screened by stakeholders and their team ability matches the entrepreneurship).

(4) 55% of the entrepreneurial teams without working background of well-known companies, well-known media reports, and investment by excellent institutions but endorsed by well-known financing consultants can obtain the next round of

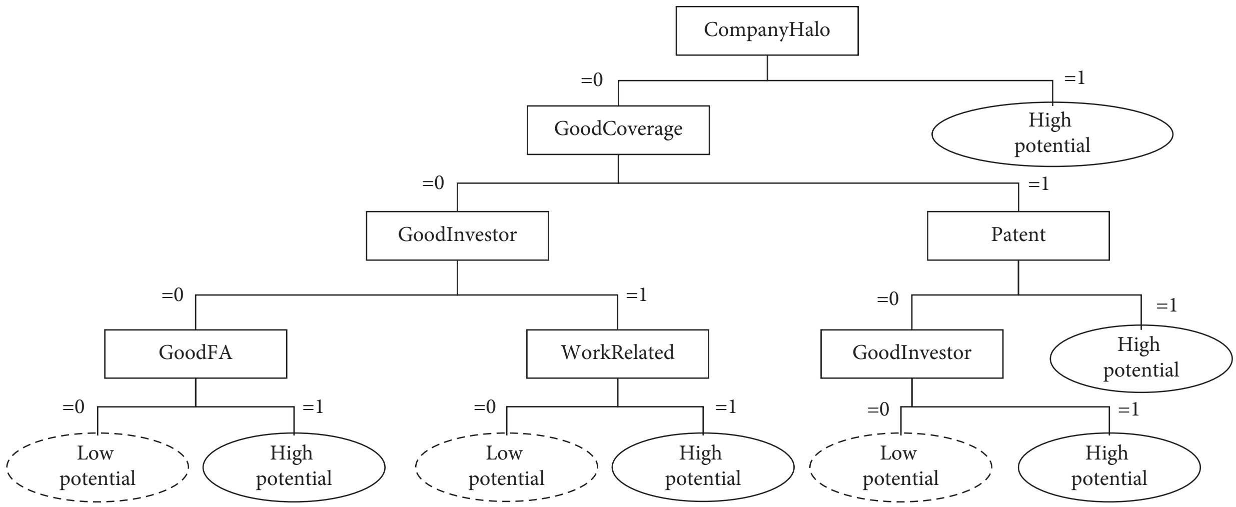

Figure 1: Visualization of decision tree rules (after pruning).

Table 5: 0–1 distribution difference of typical elements in all samples and positive samples.

Variable	All samples		Positive samples only	
	1	0	1	0
CompanyHalo	319 29%	785 71%	195 47%	219 53%
Patent	583 53%	521 47%	272 66%	142 34%
WorkRelated	474 43%	68 6%	257 62%	18 4%
GoodCoverage	272 25%	832 75%	155 37%	259 63%
GoodInvestor	222 20%	726 66%	132 32%	239 58%
GoodFA	134 12%	970 88%	71 17%	343 83%

financing. If the enterprise does not even have the signal of a well-known financing consultant, there is a 70% probability that it will not be able to obtain the next round of financing (feature: when it does not have the signal of team ability, the signal of stakeholders can play a certain screening role).

From the above typical rules, it can be found that the working background of well-known companies is the most differentiated signal. If it does not have this feature, it needs to have at least one of the ability signals of other teams and the endorsement signals of relevant parties to have a higher probability of obtaining the next round of financing.

The language to be converted into investment practice is as follows: if the team has outstanding highlights in its work history, it is worthy of investors' research and follow-up. If the team is average, it needs the investment of other excellent institutions or the information reported by well-known media to be considered.

4.2. Multiclassification Problem. The so-called multiclassification problem refers to using an empirical loss function to predict the classification results of different categories [13]. From start-up to listing, companies usually need to go through more than four rounds of financing (angel round, round A, round B, and pre-IPO round). However, companies that receive continuous financing in the early stage may not be able to go public or be acquired. For investment institutions, if an investment cannot be successfully exited, there will be no return on investment. Therefore, the more valuable the predictive model is to the investment institution, the more the predicted variable can be closer to the long-term potential of the company.

In this regard, an intuitive idea is as follows: after the first financing, companies that can obtain two or more rounds of financing have higher potential and value than companies that have only received one round of financing. In other words, we can classify start-ups into three categories based on the number of follow-up rounds a company has received after their initial funding round, which are as follows: low-value (no follow-on financing, recorded as L), medium value (1 follow-on round, recorded as class M), and high value (2 or more rounds of follow-up financing, recorded as class H).

It should be noted that this multiclassification problem has certain particularities: on the one hand, the three categories are not semantically independent but have a certain degree of progressive relationship. In terms of value, class L < class M < class H. On the other hand, from the perspective of investment practice, both M and H categories should be selected into the project library to be followed up, however, the H category deserves more attention. Therefore, the misclassification between class M and class H does not incur excessive costs.

The original decision tree C4.5 model can handle multiclassification problems but does not pay much attention to the above two problems. Therefore, this section, firstly, uses it as a reference model to measure the general classification effect of the algorithm and then discusses how to improve it.

Table 6: Three classification performance: based on decision tree C4.5 model.

	L	M	H
Sample frequency and proportion	690(62.5%)	294(26.6%)	120(10.9%)
Quantity determined as this category	931	134	39
Actual quantity of this category	627	45	13
Accuracy	67.3%	33.6%	33.3%
Recall	90.9%	15.3%	10.8%

Table 7: Confusion matrix: based on decision tree C4.5 model.

	Classified into L	Classified into M	Classified into H
L	627	52	11
M	234	45	15
H	70	37	13

In terms of datasets, this section follows all the projects that have received early financing from January 2016 to June 2017 in the artificial intelligence and big data industries, which is a total of 1104 projects. The independent variable is consistent with the training set. However, the predictor variable is changed to the number of subsequent financings, with a value of 0 representing no subsequent financing (type L), a value of 1 representing a subsequent round of financing (type M), and a value of 2 represents 2 or more follow-on financing rounds (Class H). Repeating the modeling process and 10-fold cross-checking, the classification performance of the three categories is shown in Tables 6 and 7.

It can be seen from the above table that the decision tree C4.5 algorithm is more biased toward negative samples with a higher proportion (i.e., samples that have not obtained subsequent financing). 84.3% (931/1104) of the samples were classified into the low-value L class, and the identification of medium-value (M-class) and high-value (H-class) samples was severely underidentified. Among the M and H classes, the algorithm also prefers to discriminate as the conservative M class (134 vs. 39). From the perspective of investment practice, this classification effect is not satisfactory.

4.3. Scalability Discussion. It is worth noting that the above models we designed and tested only consider the public information provided by third-party venture capital service institutions, however, in practice, investment institutions can also obtain private information from multiple channels, such as reading project business plans, communicate with founders, communicate with financing consultants, communicate with peers, communicate with colleagues with relevant experience, obtain third-party research data, etc.

The potential value of this private information is fourfold:

(1) Supplements the missing values of each indicator in the original model, and corrects the wrong labels.

(2) Adds new observations to the model to improve the predictive efficiency of the model.

(3) Provides more information about the research subjects (i.e., startups), such as funding amounts and valuations, to design proxy variables that are closer to the company's potential.

(4) Builds a closed loop between forecasts and observations earlier than the market, and iterates models earlier to improve forecasts and gain a competitive advantage.

Therefore, this section focuses on how to combine public information with private information to form a dynamically updated project screening mechanism. Figure 2 presents a conceptual framework considering practical feasibility.

As shown in the figure, after the public information about the project is obtained, it can be analyzed and processed through the following five steps:

(1) Clean and label the data. The dimensions of the labeling can include the ten dimensions proposed in this article, and it can also continue to expand with the enrichment of practical experience.

(2) For projects with relatively complete information, use decision trees or other machine learning algorithms to generate predictions and make corrections based on expert knowledge in investment institutions, thereby generating two sets—projects worthy of follow-up and projects that are not to be followed up for the time being.

(3) Projects that have not been followed up for the time being will enter the waiting pool together with projects with incomplete information before. After investors obtain more information about the team and projects, they will enter the data cleaning process for remarking.

(4) Projects worthy of follow-up and projects not to be followed up enter the observation pool together. Combined with the financing and development information obtained by investors through industry exchanges, projects are divided into four categories: TP (true positive) refers to projects that are determined by institutions to be worthy of follow-up and have real potential through follow-up observation, FP (false positive) refers to the project that the institution determines is worthy of follow-up, however, it is found

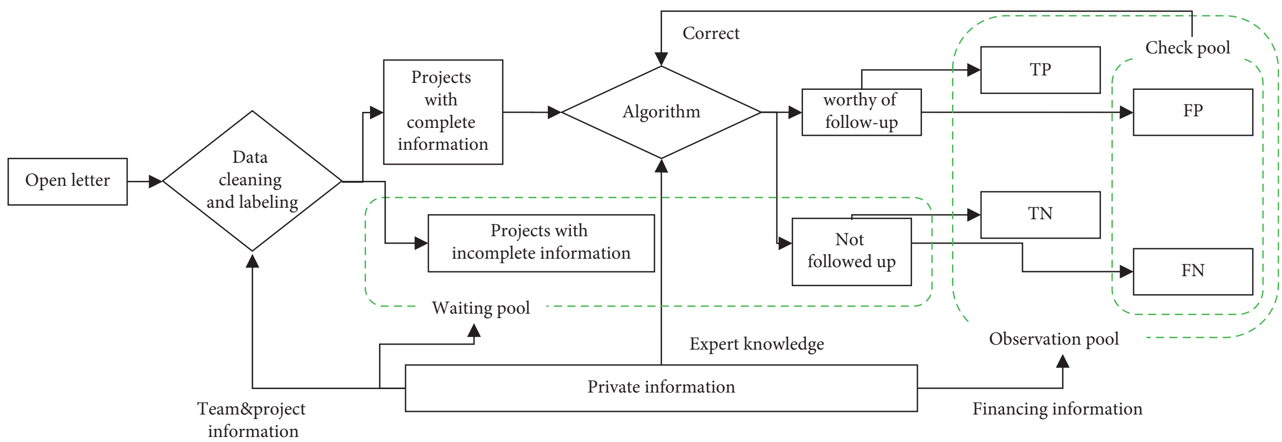

Figure 2: Project screening framework that integrates private information and public information.

that it has no development potential and sustainable financing ability, TN (true negative) refers to the project determined by the organization not to follow up temporarily and found to have no potential in the follow-up, and FN (false negative) refers to the project that the organization determines not to follow up temporarily but actually finds potential.

(5) The misclassified samples (i.e., FP and FN) are included in the check pool, and the dataset is used to modify the previous algorithm.

5. Conclusion

This paper mainly studies the application of the machine learning method represented by a decision tree in early entrepreneurial project screening. The research process is divided into four steps.

The first step is to establish a prediction model that can be used in investment practice. By processing the real investment and financing event data set in the field of artificial intelligence and big data, this paper extracts two kinds of signals, which are as follows: the endorsement of relevant parties and team ability, with a total of 10 indicators. After establishing the basic model based on the two types of indicators and verifying their prediction effectiveness, this paper combines all indicators to test whether the fusion model is significantly improved compared with the basic model. Then, considering that in practice, investors are more interested in projects that can continuously obtain financing (i.e., positive samples). This paper introduces a heuristic misclassification cost matrix to adjust the weight of the two types of samples and verifies how much the improved model can improve the recall rate of positive samples.

The second step is to interpret the law revealed by the model and to explore whether this law is still applicable over time and whether it can be applied to project screening in similar industries. The selected model is the decision tree C4.5 model with more interpretable rules. By interpreting the top-down judgment path of the decision tree, this paper extracts general rules for guiding project selection.

The third step is to extend the decision tree model from the binary classification scenario of positive and negative samples to the multiclassification scenario of project value segmentation to improve the usefulness of the model in investment practice.

Finally, in view of the private information available to investment institutions in reality, this paper discusses how to incorporate private information into an iterative analysis process based on the model constructed from public information to achieve a more accurate prediction of high-potential projects.

The implications of this paper for management are as follows:

(1) The value of the three team ability indicators, including working background in a well-known company, patents, and work experience, which are highly related to this entrepreneurship in predicting the potential of the company, has been supported by data. When communicating with entrepreneurs or conducting project surveys, investors deserve to verify the authenticity and basis of these indicators from more information sources. In addition, based on the working experience and the subsequent development performance of the company, a more accurate division basis can be established for the scope of well-known companies, the quality and quantity of patents, and the correlation between work experience and entrepreneurship to continuously improve the screening and judgment of projects.

(2) The optimal model and cost matrix settings are different for different classification objectives, and the same is true for different data dimensions. In practice, investors should fully consider their own classification needs and the availability of external data and then select the model with the best classification effect. In addition, in the context of not pursuing model interpretability, it is also an optional idea to introduce algorithms such as Bayesian network and random forest or use integrated learning

methods, such as Bagging and Boosting, to improve model prediction.

(3) On the issue of early project screening, the dimension of relevant party endorsement, which is less studied by the academic community, actually has a high signal value. It is also consistent with the basic common sense of the investment industry. These experiences should be incorporated into the construction of project screening mechanisms based on machine learning methods.

As one of the basic industries in China, the real estate industry contributes much to the national GDP every year and plays an important role in stimulating the economy. After years of development, the real estate industry has accumulated a large number of sales data, includes the data of customer and construction. However, the utilization of them is still in the stage of extensive collection and use, which is not sufficient for the accumulated data. Therefore, a precise marketing management system for real estate enterprises based on data mining technology is developed in this paper. Through big data mining, the target customers can be accurately subdivided and portraited, which realizes the matching and prediction of resources. On this basis, accurate marketing and promotion of multichannel collaboration are implemented, which realizes the innovation of real estate marketing mode in the era of big data.

1. Introduction

With the rapid development of information technology, the use of Internet+, 5G, cloud computing and mobile terminals has brought us into the era of big data [1]. Big data technology has become a hot topic at present that the arrival of big data era promotes the interaction between human beings and makes exchange of information more convenient, which also makes the Internet economy more closely linked, so that people can create wealth without leaving home [2–4]. “Big data” has penetrated into all walks of life, which subverts the operation thinking and marketing mode of many traditional industries. In this context, big data touches the nerves of the real estate industry, and real estate enterprises can accurately understand the demand of consumers, so as to formulate accurate marketing strategy [5].

As an emerging field, data mining has a wide range of application prospects, and has been widely used in all walks of life [6, 7]. The combination of real estate field and data mining technology is a topic that researchers are devoted to studying in recent years. It is meaningful to using data mining technology to research and analyze the application of big data in real estate marketing.

2. Overview of Data Mining Technology

Precision marketing is based on the collation and analysis of customer s’ data, which can accurately grasp the demand of customers, provide customers with appropriate products and marketing means, and realize the company’s interests. Data mining, including clustering analysis, discriminant analysis and factor analysis, is commonly used in practical technology [8].

2.1. Definition of Data Mining. Berry and Linoff [9] defined data mining as the process of exploring and analyzing large amounts of data in order to discover meaningful patterns and rules. A large number of data may be partly noise data or fuzzy data. The object of data mining can be a database, a file system, or any other data collection organized together.

The data set in the real estate database includes real estate sales data and feature data of real estate. By randomly extracting part of the data, and data conversion, analysis and other processing, we can find the key data that needed for the development of real estate sales strategy [10, 11].

Data mining is divided into directed one and non-oriented. The purpose of directed data mining is to interpret or classify a specific target domain. The purpose of non-directional data mining is to find out the pattern or similarity between batch data without preseting target domain or class.

2.2. Steps of Data Mining. The specific steps of data mining often take different steps or processes depending on the industry, technology itself and its situation. In addition, whether the data is complete or not and whether the professionals are skilled will also have an impact on the process. Therefore, the industry generally believes that the degree of systematization and standardization of data mining process, and there is a positive correlation with the value of the information. Usually, the main steps of data mining can be broken down into the following programs [12–14]:

(1) Understand the data and the source of the data
(2) Acquire relevant knowledge and technology
(3) Integrate and check data
(4) Remove erroneous or inconsistent data
(5) Establish models and assumptions
(6) Actual data mining work
(7) Test and verify the mining results
(8) Interpretation and application

The above steps show that there are a lot of related preparatory activities before the real implementation of data mining. While statistics show that data preprocessing takes more than 80% of the data mining work, including data filtering, format conversion, variable integration and data table linking [15–17] is shown in Figure 1.

2.3. Methods of Data Mining. The purpose of data mining is to mine valuable information. In order to realize data mining, we need to adopt certain methods, which is helpful to the better realization of data mining [18]. It can be completed by different methods and means, while users can choose the appropriate method according to their own needs. The following content describes several common methods:

2.3.1. Data Summary. The word "summary" is not difficult to understand literally, which is to use simple and concise sentences to summarize the more complex issues, so that people can understand the content of the exposition in a short time. In the same way, data summary is to concentrate the existing data in certain ways, such as through statistical methods such as sum and average, The calculation results of the data are reflected by charts. In addition, the common chart models are column chart and pie chart [19]. Data mining *i* is actually a process of data summary, but its research is more in-depth, which needs a more comprehensive summary of the data from a deep level and a wide angle. Generally, the data are analyzed, synthesized, abstracted and summarized in order from low level to high level, so as to find out some internal relations of these data, and judge the direction of future data development through these laws. According to the methods, it can be divided into multidimensional data analysis method and attribute oriented induction method.

2.3.2. Classification Mining. Classification mining refers to the classification of data in order to mine its potential value. It mainly classifies the data by mapping, so as to correctly classify the data to be processed. There are many ways to construct classifiers, while statistical method, machine learning method and decision tree method are commonly used [20, 21].

2.3.3. Cluster. Cluster refers to aggregate classification, that is, the data with the same characteristics are classified, aggregated and stored separately. In this way, the relationship between data is very clear, and the data belonging to the same category have the same or similar categories; on the contrary, data in different categories have different categories which is helpful to the later work. Statistical method and machine learning method [22] are commonly used in clustering methods.

3. Design of Precise Marketing Management System Based on Data Mining

3.1. Demand Analysis. The purpose of functional requirements analysis is to clarify the functional indicators of the real estate precise marketing management system, that is, the function points that the system should have. In the development of software, there are many tools used to describe users' requirements. This section will discuss them in detail through use case diagrams.

The overall use case of precision marketing management system is shown in Figure 2. The users of the target system mainly include enterprise leaders, market leaders, salesmen and system administrators. In addition, the business of the system can be roughly divided into real estate management, house management, building management, sales management, customer management, decision support and system management.

The real estate management mainly completes the maintenance of the basic information of the real estate, including the business of adding, deleting, modifying and querying the information of the real estate, and the users mainly include the person in charge of the market and the system administrator.

Building management mainly realizes the maintenance of building basic information, including the business of building information addition, building information deletion, building information modification, building information query and so on. The users involved include market leader and system administrator.

Housing management is the management of room information, which mainly maintains the specific information of the room, including the business of adding housing information, deleting housing information, modifying

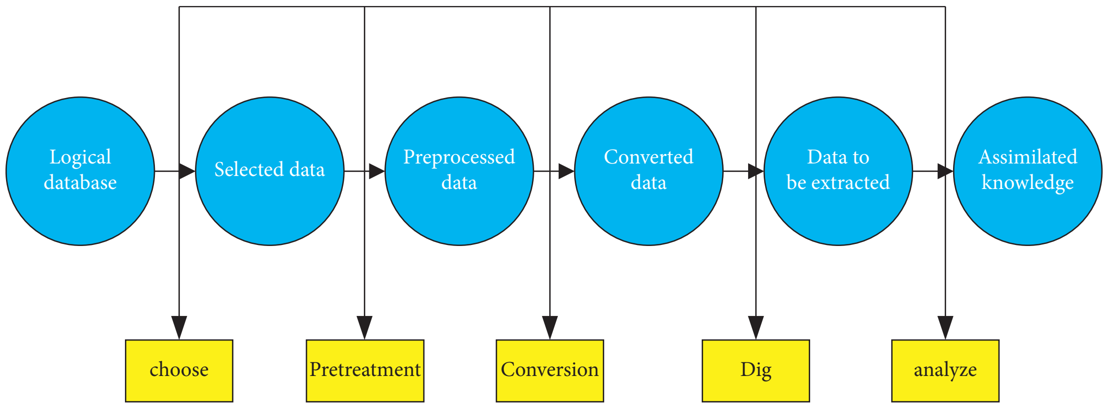

Figure 1: Basic process and main steps of data mining.

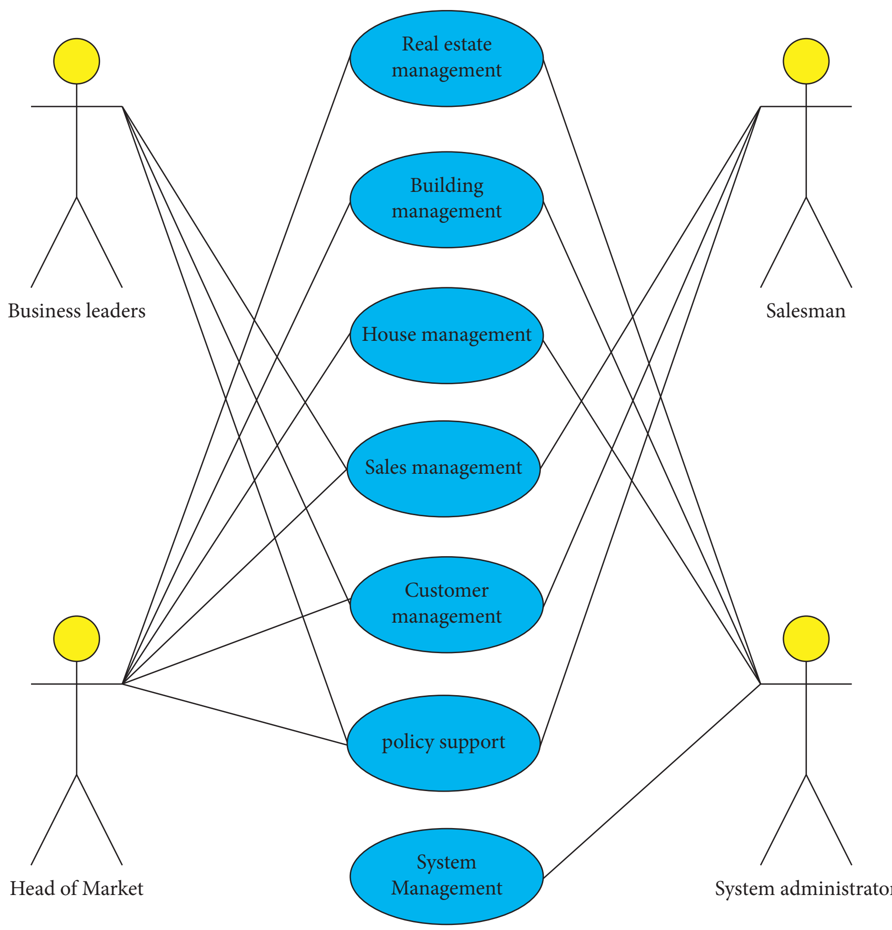

Figure 2: Overall diagram of system.

housing information, querying housing information, etc., and the users involved are market leaders and system administrators.

Sales management mainly maintains the basic information of real estate sales, including sales opportunity management, sales record management, sales performance management, etc., and the users involved are market leaders and salesmen.

Customer management includes customer information addition, customer information deletion, customer information modification, customer information query, etc. the user roles involved include enterprise leader, market leader and salesman. Among them, enterprise leader can only be responsible for customer information query.

Decision support includes sales forecasting, performance statistics, weekly and monthly performance reports. The users involved include enterprise leaders, market leaders and salesmen.

System management is mainly for system administrators, providing the maintenance of basic system information, including user management, data backup, data restore, permission setting, etc.

3.2. Overall Framework of System. In the overall design of the system, first of all, we need to design the overall framework of the system. The target system is mainly used for the daily sales management of real estate enterprises which mainly targets at the enterprise leaders, market leaders, salesmen and system administrators, and provides different services for diverse users. According to the actual *t* needs of the system, B/S mode is selected as the structure, which is a distributed application architecture based on Web. It can meet the needs of different types of users and is suitable for the development of precision marketing management system [23].

In the process of execution, it will give all the interaction between users to the browser side of the system, that is, the interface layer, and the business and data related operations are handed over to the web server to complete, so that the browser and the web server work together to complete the processing of requests. The architecture of precision marketing management system is shown in Figure 3.

3.2.1. Interface Layer. The interface layer is usually called user layer or application layer. The main function of this layer is to complete the interaction with users. On the one hand, it receives the request messages sent by users to the system, on the other hand, it feeds back the request results completed by the server to users for browsing. For users, this layer is the intuitive that their evaluation of the software will be directly reflected in the user's sense of operation on the interface layer. When a user sends out an access request, the interface layer will receive the request, and then send it to the business logic layer and data access layer. At the same time, the processing results will be fed back to the user's browser through HTML and displayed to the user.

3.2.2. Business Logic Layer. The business logic layer is responsible for executing the part that needs business logic judgment and processing in the user request which is located in the middle of the three layers. It is a bridge between the client and the database and it can be said that it is the core layer of the three layers, and its role is very important. When the interface layer receives the user's request, it will send the request of the logical processing part to the layer, which is responsible for executing it. At the same time, it will also send the request of data processing to the data access layer. In the three layers, the business logic layer has its own responsibilities from the top to the bottom. It also acts as a callee's identity, in this layer, involves a lot of business relations. Therefore, the business logic layer is the core part of the whole architecture.

3.2.3. Data Access Layer. Data access layer is also known as application data source layer. The main function of this layer is to complete the operation of database, including data call and data processing. Through the access layer, you can query, modify, delete and update database tables, and it will provide data call and execution related services for the middle layer. Because the operation of the system cannot be separated from the operation, and the database design of any system is relatively complex and takes up more resources, which makes the performance requirements of the database system higher, so the access mode of the database system should be optimized as much as possible, in order to improve the overall efficiency of the system.

3.2.4. Advantages of Three-Tier Architecture. The reason why the architecture design adopts the three-tier architecture mode is as follows:

(i) The three-tier partition makes the system more flexible, and realizes the maintainability and expansibility of the later functions and performance. Because of the independence of the three layers, it is easy to transplant the database

(ii) It accords with the design idea of "high cohesion, low coupling" in software engineering

(iii) The three layers are independent of each other, and the related functions are relatively clear, which facilitates the development of developers, effectively improves the efficiency of system development work, and shortens the cycle

3.3. Deployment and Functional Structure of System. The precision marketing management system based on Net environment is discussed in this paper, B/S mode is adopted for system structure, C# is used for foreground programming, SQL Server 2005 is used for backstage database, and ADO is applied between foreground and background Net connection to achieve interaction. For the system developed by B/S mode, the deployment can be divided into three parts: client, application server, and database server. The request submitted by the client will be sent to the application server for processing, and then through the operation of the database, the response to the user's request is realized. The deployment of the system is shown in Figure 4.

In the work of system design, the first is to design the overall architecture. When the overall architecture is determined, the design will have an overall direction. The next work is to design the function of the system, that is, to design some functions that the target system needs. This is the most concerned problem of users, which means, it can help users complete specific functions. The target system is applied in the real estate sales management. Therefore, in the demand analysis stage, the author talked with the staff related to sales management in depth, and defined the functional requirements of the system, which also laid a good foundation for the design of functional modules. The requirements of modular design are summarized as follows:

(1) In the process of module division, the system should be divided according to the hierarchy, that is, the system should be first divided from the overall perspective, and then the modules after division should be further divided, so that the final module can be realized in a certain way.

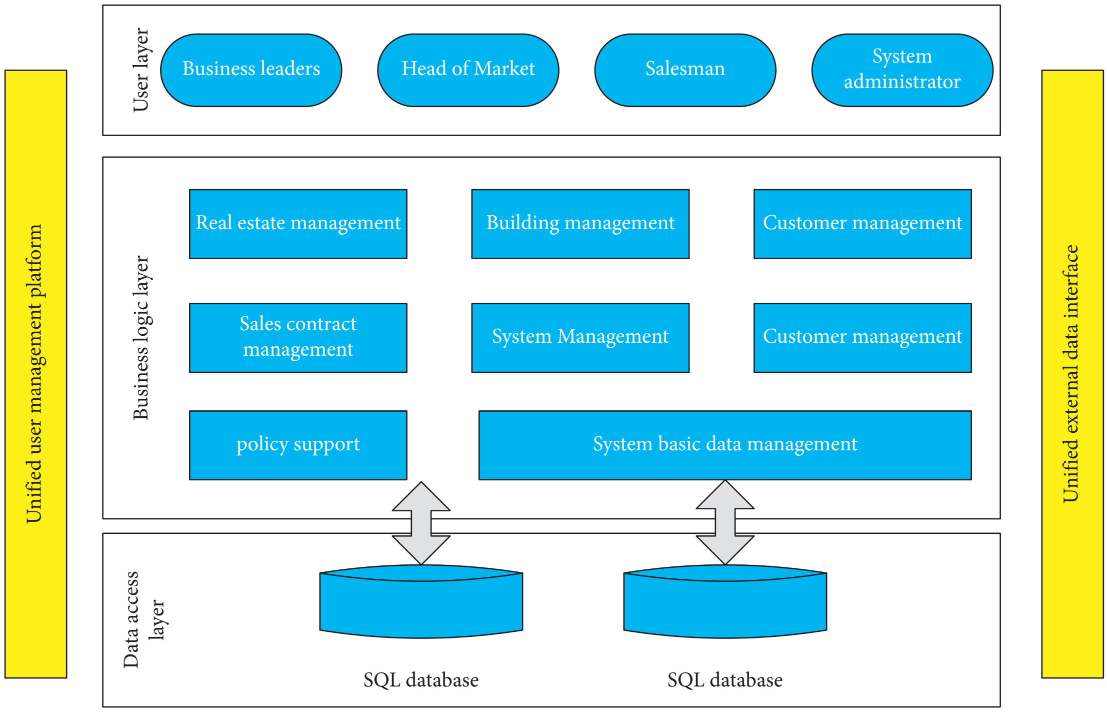

Figure 3: Architecture of system.

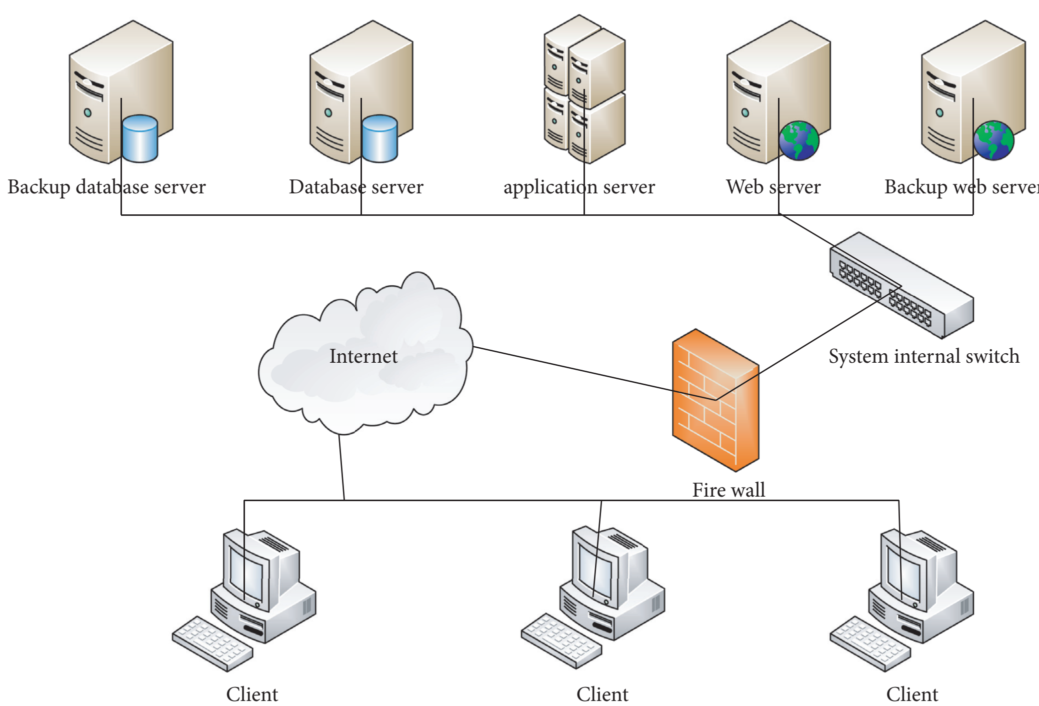

Figure 4: Operation and deployment of precision marketing management system.

(2) All the modules divided should be as independent as possible. In other words, there should be no association between these modules under special circumstances. Of course, this situation is not absolute, but should be avoided as far as possible.

(3) The relationship between the divided modules must be clear. The result of this is to facilitate the later maintenance of the system. When facing problems, the programmer can easily modify it and trace it.

After understanding the requirements of the system function module division, we can divide the function modules of the precise marketing management system. The relevant functional modules mainly include eight functional modules, including real estate management, building management, house management, sales management, customer management, users management, decision support and system management. The function module is shown in Figure 5.

(1) Real estate management: to manage all real estate

  (i) Information addition: add basic information of real estate
  (ii) Information query: query the basic information of the real estate according to the needs
  (iii) Information maintenance: to maintain and manage the basic information of real estate

(2) Building management: to manage the building information in each building of the enterprise

  (i) Information addition: add the building information, including the name, address, area and unit of the building
  (ii) Information query: query the basic information of the building according to the needs
  (iii) Information maintenance: include maintenance and management of related information

(3) Sales contract management: manage the sales contract information of the enterprise

  (i) Add sales contract: enter sales contract information into the system
  (ii) Sales contract maintenance: modify and delete the sales contract information
  (iii) Sales contract query: query sales contract information

(4) Customer management: manage all customers of the enterprise

  (i) Customer data entry: enter new customer information
  (ii) Customer information inquiry: according to the needs of customer information query operation
  (iii) Customer data maintenance: maintain and manage the customer's basic information and data

3.4. Design of Database. According to the process of concept design is the process of data entity design. Based on the previous analysis of the real estate precision marketing management system, part of the data entity design of the system is given below. The main entities of the system include user entity, house entity, building entity, room entity, customer entity, sales contract entity, etc.

The content of database logical design is based on the entities obtained from conceptual design, and transforms each entity into the actual data physical storage structure. This section gives the relevant data tables of the real estate precision marketing management system, and each data table includes the attribute description of each entity. The data tables of the target system include user information table, house type table, room information table, building information table, property information table, property sales information table, customer information table, sales contract table, etc.

The structure of user information table is shown in Table 1. The data table is used to store the basic user information of the system, including the fields of user ID, user name, user type, user real name, gender, age, etc., in which the user ID is the primary key.

The structure of the house type table is shown in Table 2. The data table is used to store the house type information of the room. While this fields included are mainly house type ID, house type name and description, in which the house type ID is the primary key.

The structure of the room is shown in Table 3. The data table is used to store the basic information of the room, mainly including room ID, building ID, floor, room number, house type ID, etc. among them, the room ID is the primary key, and the building ID and unit type ID are foreign keys.

The structure of the building type is shown in Table 4, which is used to store the building type information, including the fields of type ID, type name, type description, etc., in which the type ID is the primary key.

The structure of the building is shown in Table 5. The data table is used to store the basic information of the building. While the fields include building ID, Property ID, unit number, floor area, building type ID, etc. Among them, the building ID is the primary key, and the building ID and building type ID are foreign keys.

The structure of the real estate is shown in Table 6. The data table is used to store the basic information of the real estate. The fields mainly include the property name, developer, floor area, building area, etc., and the real estate ID is the primary key of the data table.

The structure of the real estate sales information table is shown in Table 7. The data table is used to store the sales of real estate. The main fields include sales ID, ID, ID, average price, and number of households sold. Among them, the sales ID is the primary key, and the real estate ID, building ID and room ID are all foreign keys.

The structure of the customer information is shown in Table 8. The data table is used to store the basic information of customers, including the fields of customer ID, customer name, contact number, age, occupation, etc., in which the customer ID is the primary key of the data table.

The structure of the sales contract table is shown in Table 9. The data table is used to store the sales contract information. The fields include sales contract ID, customer name, purchase time, purchase price, payment method, etc. among them, the sales contract ID is the primary key of the data table.

3.5. Design of Interface and Operation

3.5.1. Interface Design. The interface design mainly includes the definition of external interface and internal interface. The detailed design is shown in Table 10.

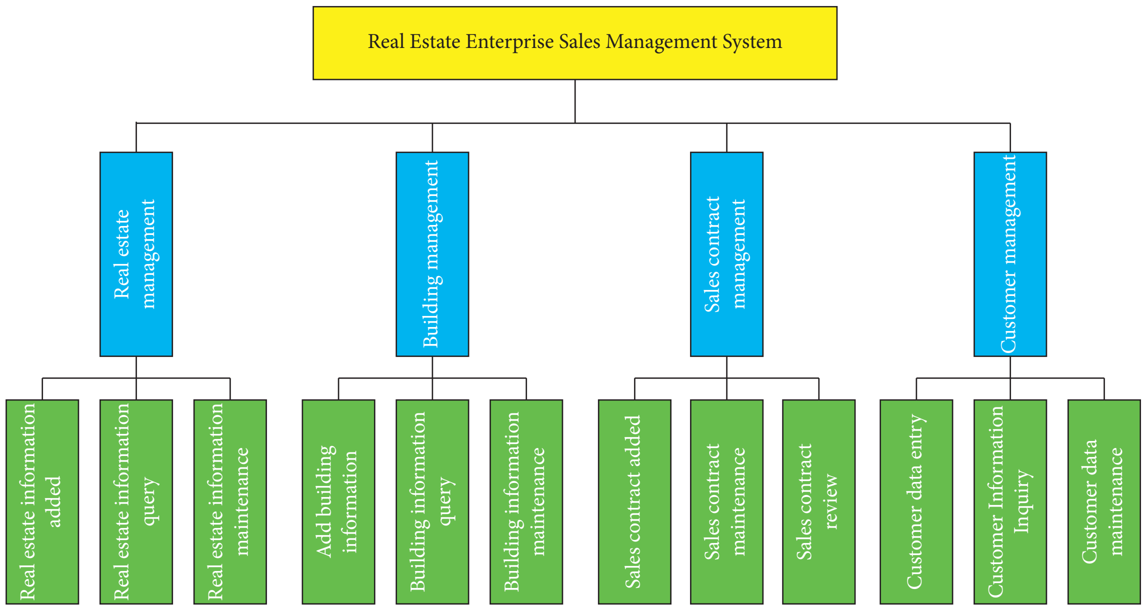

Figure 5: Division of systematic function module.

Table 1: Table of users' information.

Field name	Field type	Data length	Primary key/foreign key	Allow to be empty
User ID	Int	32	Primary key	No
Username	Varchar	20	No	No
User type	Varchar	10	No	No
User's real name	Varchar	50	No	Yes
Gender	Byte	1	No	Yes
Age	Int	11	No	Yes
User password	Varchar	50	No	No
E-mail	Varchar	50	No	Yes
Mobile phone	Varchar	20	No	Yes
User information remarks	Varchar	255	No	Yes
Last login time	Datetime	8	No	No
User's current state	Int	32	No	No

Table 2: House type.

Field name	Field type	Data length	Primary key/foreign key	Allow to be empty
Unit ID	Int	32	Primary key	No
House name	Nvarchar	50	No	No
House description	Nvarchar	50	No	Yes

Table 3: Room information table.

Field name	Field type	Data length	Primary key/foreign key	Allow to be empty
Room ID	Int	32	Primary key	No
Building ID	Int	32	Foreign key	No
Floor	Nvarchar	3	No	No
Room No	Nvarchar	50	No	No
Unit ID	Int	32	Foreign key	No
Use	Nvarchar	50	No	Yes
Area	Int	50	No	No
Construction area	Float	7	No	No
Starting price	Money	7	No	No
Highest price	Money	7	No	No
Average selling price	Money	7	No	No
Sales discount	Nvarchar	4	No	No
Selling price	Money	7	No	No
Balcony area	Float	7	No	No
Room orientation	Nvarchar	50	No	No
Decoration standard	Nvarchar	500	No	Yes

Table 4: Information of building types.

Field name	Field type	Data length	Primary key/foreign key	Allow to be empty
Type ID	Int	32	Primary key	No
Type name	Nvarchar	50	No	No
Type description	Nvarchar	50	No	Yes

Table 5: Information of building.

Field name	Field type	Data length	Primary key/foreign key	Allow to be empty
Building ID	Int	32	Primary key	No
Property ID	Int	32	Foreign key	No
unit number	Nvarchar	10	No	No
Area	Float	7	No	No
Construction area	Float	7	No	No
Building type ID	Int	32	Foreign key	No
Number of layers	Varchar	10	No	No
Number of garages	Int	32	No	No
Number of households per floor	Int	32	No	No
Consumer groups	Nvarchar	30	No	No
Remark	Text	250	No	Yes
Total houses	Int	32	No	Yes
Sold	Int	32	No	Yes
Unsold	Int	32	No	Yes

Table 6: Information of property.

Related procedures	Varchar	250	No	No
Delivery time	Datatime	8	No	No
Contract remarks	Text	250	No	Yes
Signing time	Datatime	8	No	No
Signatory	Varchar	20	No	No

3.5.2. Operation Design

(1) Combination of Running Modules. The system mainly takes a window as a module. Generally, a window completes a specific function. While the main window realizes the connection and combination of different functions between modules by opening another sub window. Each module is relatively independent, and the program has good portability. Moreover, the cooperation and data sharing between modules are realized by transferring the reference of data items.

(2) Operation Control. The user opens the system login window and enters the name and password. Then the system jumps to the corresponding background according to the user type corresponding to the name, so as to realize different operations with diverse permissions and roles.

(3) Running Time. The running time of each module should be controlled within 1–2 seconds (most of which is in response to the user's action). As the system adopts message driven mode, it will effectively improve the utilization of computer.

3.6. Algorithm of Decision Tree Construction and ID3 Learning

3.6.1. Decision Tree Construction Algorithm. The construction algorithm of decision tree can be completed by training set T, where $\mathrm{T} = \left\{\langle \mathrm{x}, \mathrm{C_j}\rangle\right\}$, and $\mathrm{x} = (\mathbf{a}_1, \mathbf{a}_2, \ldots, \mathbf{a}_\mathrm{n})$ is a training example, it has n attributes listed in the attribute table $(\mathrm{A}_1, \mathrm{A}_2, \ldots \mathrm{A_n})$ where a_i is the value of attribute A_i. $\mathrm{C_j} \in C = \{C_1, C_2, \ldots, C_\mathrm{m}\}$ is the classification result of X [24–26]. The algorithm is divided into the following steps:

Select the attribute AI from the attribute table as the classification attribute; If there are K_i values in attribute AI, T is divided into k_i subsets $T_1, \ldots, T_K$, where

$T_{\mathrm{ij}} = \{\langle x, C\rangle | \langle x, c\rangle\}| \in T$ and the attribute value a of X is the K_i value;

Delete the attribute AI from the attribute table

For each $T_{\mathrm{ij}}\,(1 \leqslant j \leqslant K_1)$, order $T = T_{\mathrm{ij}}$

If the property sheet is not empty, return (1), otherwise output

At present, the mature decision tree methods are ID3 and C45. Cart, SLIQ, etc.

Table 10: Definition of interface.

External interface	(1) User interface: it adopts windowing and menu design, and responds to hot keys during operation. (2) Hardware interface: printer (3) Software interface: connection to SQL server database through ADO.NET
Internal interface	By defining various classes and methods, the call and data communication with each functional module can be realized;

3.6.2. ID3 Learning Algorithm. Information entropy is called average information quantity in information theory, which is an average value used to measure the information transmitted, which includes a finite number of mutually exclusive and joint complete events. They all appear with a certain probability, which is represented by the mathematical formula [27]: a group of events $X_1, \cdots, X_r$ appears with a given probability $p(X_1), \cdots, p(X_r)$ while the mean value $H(x)$ is the information entropy, and its value is equal to the mathematical expectation of the (self) information quantity $I(x)$ of each event

$$\begin{aligned} H(X) &= -\sum_{r=1}^{r} p(Xi)I(Xi) \\ &= -\sum_{r=1}^{r} p(X_i)\log p(X_i). \end{aligned} \tag{1}$$

In the traditional ID3 algorithm, the information entropy is used as the standard of attributes selection, and the value of information entropy is obtained based on data calculation. Then it is selected by comparing the size of each information entropy, and the item corresponding to the information entropy is taken as the root node of the decision tree. After the example set is divided into subsets by using this attribute, the entropy value of the system is the minimum. It is expected that the average path of the nonleaf node to reach each descendant leaf node is the shortest, and the average depth of the decision tree generated is smaller [28]. In addition, it can be seen that the more fuzzy and disorderly the training case set is in target classification, the higher its entropy is, the clearer the training case set is in target classification, while the more ordered it is, and the lower its entropy is. ID3 algorithm is based on the principle of "the attribute with greater information gain is more beneficial to the classification of training cases". In each step of the algorithm, "the attribute in the table that can best classify the training case set" is selected. Moreover, the information gain of an attribute is the decrease of system entropy due to the use of this attribute to divide the sample, The key operation of ID3 algorithm is to calculate and compare the information of each attribute [29, 30].

The above detailed introduction of ID3 algorithm, in order to better achieve data mining, here will be the basic strategy of ID3 algorithm. The implementation of ID3 algorithm is as follows:

(1) Each node given in the training sample is taken as the root node of the decision tree to start the process of creating the decision tree.

(2) These root nodes are judged and analyzed. If they belong to the same class, they are set as leaf nodes, and the nodes set as leaf nodes are marked.

(3) For the samples that do not belong to the same class, the entropy based measure that called information gain is used as the heuristic information, and the best attribute that can be reclassified is selected from the heuristic information, which becomes the test or decision attribute of the node.

(4) Create a new branch for the new test property and divide new samples accordingly.

(5) The recursive method is used to create a decision tree for each sample. At this time, the attributes of its descendants can not be considered too much.

(6) The recursive process should be repeated until the following features appear:

(i) All the attributes represented by a node belong to the same category.

(ii) The attribute represented by the node does not have the feature of continuous partition.

(iii) If there are no samples under the branches of a tree, the classes in these training sets can be compared and analyzed, and the sample of the largest class's genus is set as the leaf node of the decision tree.

4. System Implementation and Testing

4.1. Implementation of Data Mining

4.1.1. Decision Tree Generation and ID3 Algorithm. The ID3 algorithm proposed by J. R. Quinlan is an earlier and most famous decision tree induction algorithm. Given a set of nonclass attributes C_1, C_2, ..., C_n, Category attribute C and record training set S, a decision tree can be constructed by ID3 algorithm. The ID3 algorithm of decision tree induction algorithm is described as follows [31].

//Returns a decision tree

Function ID3 (R: a nonclass attribute set, C: a Category attribute, s: a training set)

Begin

If s is null, a single node with the value of failure is returned; If s is composed of records whose values are the same category attribute values, and returns a single node with this value; If R is null, a single node is returned, whose value is the most frequent Category attribute value found in s record; The attribute with the maximum gain (D, s) value between attributes in R is assigned to d; Assign the value of attribute d to $\{d_j|J=1, 2, 3, \ldots, m\}$; The subsets of s composed of records corresponding to d_j corresponding to D are assigned to $\{s_j|1, 2, 3, \ldots, m\}$; Then return a tree whose root is marked D and its branch is marked $d1$, $d2$, $d3$, ..., d_m;

Then the following trees are constructed

ID3(R-{D}, C, S_1), ID3(R-{D}, C, S_2), . . ., ID3(R-{D}, C, S_m);

End ID3;

4.1.2. Application of Data Mining in Marketing Management. Combined with the previous analysis, this section analyzes the implementation of data mining with specific cases. Suppose that the following customer information exists in the database, as shown in Table 11.

(1) Step 1: transformation of data. According to the basic data of customer, the required data is transformed by generalization to higher-level concepts which are given as follows:

Data by age are shown in Table 12.

Statistics by income are shown in Table 13.

According to the statistics of purchase area, the statistics are shown in Table 14.

Statistics by marital status are shown in Table 15.

(2) The second step. Get the expected information and information gain. The key to construct a good decision tree is how to choose good logical judgment or attribute. It has been found that the smaller the tree is, the stronger the prediction ability is. To construct a decision tree as small as possible, the key is to choose the appropriate logical judgment or attribute. Information gain here is used to select attributes. The calculation formula of the degree is as follows

Among them, the data set is s, M is the classification number of S, CI is a certain classification label, PI is the probability that any sample belongs to CI, and S_i is the number of samples on classification CI.

(1) Entropy divided by a into subsets: A is an attribute with V different values;

(2) Information gain: Gain $(a) = I\ (s_1, s_2, \ldots, S_m) - E\ (A)$

The split attribute is obtained as follows:

For purchase area:

Info (purchase area) = 0.999215879

Age:

Expected information: info (age) = 0.965202313

Information gain: gain = 0.034013566

Gender:

Expected information: info (gender) = 0.999202348

Information gain: gain = 0.000013531

Occupation:

Expected information: Info = 0.717207246

Information gain: gain = 0.282008633

Marriage or not:

Expected information: Info = 0.958900714

Information gain: gain = 0.040315165

Revenue:

Table 11: Basic data of customer.

Numbering	Age	Gender	Profession	Marital status	Income	Area
1	35	Female	Doctor	Yes	8000	113.7
2	29	Female	Staff	No	4500	95.5
3	40	Male	Manager	Yes	7500	150.5

130	33	Female	Lawyer	Yes	8000	125.4

Table 12: Statistics of age.

Generation	Statistical data
Under 30	23
31–45 years old	60
46 years and older	8

Table 13: Statistics income.

Income range	Statistical data
Below 3000 yuan	20
3000 yuan-6000 yuan	59
6000 yuan or more	12

Table 14: Statistics of purchase area.

Purchase area	Statistical data
120.00 m2	47
120.00 m2 above	44

Table 15: Statistics of marital status.

Marital status	Statistical data
Married	77
Unmarried	12

Statistics by gender are shown in Table 16.

Table 16: Statistics of gender.

Gender	Statistical data
Male	66
Female	25

Statistics by occupation are shown in Table 17.

Expected information: Info = 0.710086325

Information gain: gain = 0.289129554

It can be seen that income has information gain in attributes, so it is selected as splitting attribute. Node n is marked with age and grows a branch for each attribute value. Then Yuanzu divided them according to this.

Step 3: generate decision tree and extract rules

According to the above data, a decision tree can be generated. The classification rules are extracted from the decision tree.

$R1$: if income = middle and occupation = professor then, purchase area = big;

Table 17: Statistics of profession.

Profession	Statistical data
Nurse	2
Manager	15
Professor	4
Teacher	17
Doctor	13
Entrepreneur	9
Lawyer	8
Staff	23

*R*2: if income = low and marriage = yes, then the purchase area = small;

*R*3: if income = high then house purchase area = big;

*R*4: if income = middle and occupation = doctor and age = senior then, purchase area = big;

*R*5: if income = middle and occupation = business owner then purchase area = big;

5. Conclusion

With the application of mobile Internet technology, 5G, cloud computing and other network technologies, enterprises have an increasing need for big data, especially in the real estate industry. The era of big data brings real estate marketing not only a challenge, but also an opportunity. Real estate enterprises must seize the business opportunity of big data, adjust their marketing mode in time, and promote the successful transformation and upgrading of real estate enterprises. Based on this background, this paper uses data mining technology to design a precise marketing management system for real estate. Its biggest advantage is to realize sales forecast through mining and analyzing customer data, which provides reference for sales personnel to formulate marketing strategies.

The relationship between parents' educational expectations and children's growth is a hot topic in family education. In this study, in-depth interviews are conducted with 30 elementary school students and their parents, and the interview data are analyzed by NVivo 12.0 qualitative software. Based on the data from NVivo 12.0, this study initially constructs a model of the relationship between parents' educational expectations and children's growth. This study consists of six parts, including introduction, literature review, research method and materials, results and discussion, and conclusions. The study finds that the educational expectations of elementary school students' parents include three main contents: their children's quality expectations, learning expectations, and life expectations; the differences in perceptions of educational expectations lead to differences in parents' behaviors, which in turn affects the children's growth; parents should maintain high expectations for their children when there is a deviation between children's growth and parents' expectations, and parents should not make a simple attribution to children and lower expectations; parental educational ways and teaching by words and deeds are the guarantees of parents' educational expectations and the conditions for promoting children's growth; national education policy is the fundamental guarantee to promote parents' educational expectations and children's growth. The research conclusions have different opinions on the content and cognition of parents' educational expectations and can provide a scientific basis for parents' family education guidance.

1. Introduction

The parental educational expectation is essentially the goal of family education and training [1]. Under the influence of the traditional cultural psychology of success and excellence, Chinese parents have always maintained high educational expectations for their children's academic performance. The relationship between parents' educational expectations and children's growth has always been a topic of concern in the academic world. At present, China attaches great importance to family education and has promulgated the "Family Education Promotion Law," which means that family education has risen from family affairs to state affairs. Family educators will have a critical role to play in the future in promoting children's healthy development from the perspective of family education. China has also implemented a "double reduction policy" to reduce the amount of homework and extracurricular training required of students. The policy has a big impact on family education and encourages educators and parents to think about what they are doing. Coupled with the fact that the number of parents with a higher education has increased significantly in the new era compared with the past, they often have their own ideas about how to raise their children. As a result of these influences, parents' educational expectations are bound to differ. A thorough examination of parents' educational expectations and their children's development is extremely useful.

2. Literature Review

Past scholars have studied the reasons, content, and effects of parents' educational expectations. Some researchers believe that high parental expectations for children's education come from examination-oriented education, employment pressure, interpersonal comparison psychology (Xining Wu), and parents' educational expectations. Chinese parents' high expectations come from traditional cultural psychology (Xiaowei Yang). Under the impact of the cultural psychology and reality of this kind of educational expectation, parents often give their children too high educational expectations and therefore put forward high learning requirements. When it comes to the content of parents' educational expectations, existing studies have focused on parents' expectations for their children's education and career (Dongmin Zhou). In recent years, scholars have paid attention to the educational expectations of the working class and disadvantaged groups. The educational expectations of the working class parents have highlighted the thinking path of studying hard, entering into a good university, finding a good job, and living a good life, reflecting the orientation of instrumental rationality and pragmatism (Heni Xiong). When talking about the role of parents' educational expectations, most researchers mentioned the Pygmalion effect; that is, the higher the expectations for the child, the better the child's performance (Gong Jing). Parents who convey positive "expectations" to their children will make them advance faster and develop better to stand out in the group (Yali Jiang). In addition, some researchers believe that parents' high educational expectations will cause them to spend a lot of time and energy on their children's academic work, resulting in a preference for intelligence over morality, which will also give children too much interference and deprive them of the space for self-exploration (Huilian Lin). Some scholars have pointed out that this kind of learning pressure imposed on children due to high educational expectations will harm the children. For example, Chen and Xiao believe that parents having too high expectations for their children in terms of learning will affect their children's physical and mental health [2].

Judging from the existing research, the research on the content of parents' educational expectations has more to stop in the "learning expectations." There is insufficient research on children's moral educational expectations, mental health expectations, and interpersonal communication expectations, especially expectation of moral education, because morality is the root of human beings, and the cultivation of children's moral education should be laid by family education [3]. The second is the intermediary variable of the relationship between parents' educational expectations and children's growth, that is, how parents' educational expectations can transform and promote children's growth. It is often limited to the variable research between parents' educational expectations and academic achievement. In addition, the research on the relationship between parents' educational expectations and children's growth is mostly speculative research rather than empirical research in terms of research methods. Although the impact of parents' educational expectations on children's growth has received attention, a review of the existing literature suggests that many questions remain poorly answered. The most representative questions are what the content of parents' educational expectations is, what impact these expectations have on children's growth, what the process of impact is, whether the results of the impact are different from the original educational expectations, what the new changes in parents' "educational expectations" are, and what the effects of these changes on their children are with the increasing importance parents attach to education and the promulgation and implementation of the national double reduction policy. Therefore, this study uses grounded theory methods to study the core content of parents' educational expectations and deeply analyzes the relationship between parents' educational expectations and children's development. It expands the field of research on parents' educational expectations, provides strategic guidance to enable parents to develop reasonable expectations for their children in family education, promotes a good parent-child relationship, and helps children grow up healthily.

3. Research Method and Materials

3.1. Research Method. This research adopts grounded theory to explore the theoretical model of the relationship between parents' educational expectations and children's growth to provide valuable theoretical guidance for parenting. In this study, all the data obtained from the interview are imported into the software for data processing. Grounded theory is not only a methodology, a way of thinking and studying social phenomena but also a research method, which is a procedure and technique for collecting and analyzing data. It requires researchers to maintain the mentality of generative theory at all times, adopt theoretical sampling standards, select research objects according to the needs of generative theory, systematically collect and analyze data, and discover, develop, and test theories from the data [4]. In other words, the grounded theory emphasizes generating theory from research data. This article uses open coding, axial coding, and selective coding on the research data obtained from the interview.

3.2. Research Data Collection. This study discusses the relationship between parents' educational expectations of elementary school students and children's growth, so the interviewees are elementary school students and their parents. The selection of interviewees is mainly based on the following considerations: (1) the grade and gender of the child. Face-to-face interviews are required for basic research, and upper elementary school students can express their ideas more clearly. To ensure maximum access to information, children in the fifth and sixth grades of elementary school are selected. Gender differences in the interviewees may result in the research questions presenting different content, so both boys and girls were selected as the interview sample. (2) The types of children's schools: the characteristics of children and parents varied from school to school. Therefore, the interview subjects are selected from three types of schools. One is suburban schools (some are essentially rural schools), the second is general schools in the city, and the third is high-quality schools in the city. (3) The gender of the parents: fathers and mothers also differ greatly in the education of their children. When interviewees were contacted, it was found that most of those interviewed were mothers, so the author purposely selected fathers for interviews. The details of the interviewees are as shown in Tables 1 and 2.

This interview focuses on research questions and conducts in-depth interviews with interviewees through a semi-structured interview. The interview outline is divided into two versions for parents and children. The parent interview covers the following topics: "What kind of person do you want your child to be?" "What are the aspects you pay attention to in the process of raising your child?" "Do you think you have high educational expectations for your child?" "What are the advantages and disadvantages of high expectations?" The interview with the child involves the following topics: "When do your parents usually praise you and what do they expect and demand from you?" "What your parents expect of you will put pressure on you?"

After finishing the interview recording, a manuscript of about 200,000 words was formed.

To ensure the reliability and validity of the research, this study adopted the principle of typicality and representativeness, interviewing children of different genders, school types, and grades, as well as parents of different genders, educational backgrounds, and occupations. An outline of the interview was laid out around the research questions, and two parents were selected for pre-interview. After the interview, the outline of the interview was adjusted appropriately. During the interview, the interviewer followed up with the interviewee in a timely manner if some of the issues were unclear. In addition, after the emergence of the core categories in this study, an independent new sample was used to test the theoretical saturation.

Table 1: Information of interviewees (students).

	Basic situation	Number	Percentage
Gender	Boy	10	33
	Girl	20	67
Grade	Five	14	47
	Six	16	53
Type of school	Urban high-quality school	10	33
	Suburban school	8	27
	Urban general school	12	40

	Teacher	4	13
	Enterprise	5	17
	Company	8	27
	Doctor	4	13
	Freelancers	4	13

3.3. Materials: Data Analysis and Model Construction

3.3.1. Open Coding. The first step of grounded theory is to carry out open coding (open coding), also known as first-level coding, which involves the researcher with an open mind, trying to suspend personal "bias," and carrying out all the information according to its state. The purpose of coding is to discover conceptual categories from data, name the categories, determine the dimensions and attributes of the categories, and then name and generalize the researched phenomena. NVivo 12.0 is used to analyze the interview data word by word; the parents' interview data formed 34 initial concepts and 19 categories. The children's interview data formed 21 initial concepts and nine categories, as shown in Tables 3 and 4.

3.3.2. Axial Coding. The main task of axial coding is to further discover and establish various connections between conceptual categories based on open coding. The parent interview data analysis yielded four main categories and seven subcategories and that of the child interview data yielded three main categories and four subcategories, as shown in Tables 5 and 6.

3.3.3. Selective Coding. Selective coding allows for further systematic treatment of inter-category associations, describes parents' educational expectations in a "storyline" format, and constructs models to represent the relationship between parents' educational expectations and child development during elementary school.

According to the categories derived from the coding, it is concluded in this study that the educational expectations of the elementary students' parents cover three main areas: quality expectations, learning expectations, and life expectations. Parents' educational expectations are closely related to children's growth. The cognition of "expectation" itself is particularly important. Children will regard their parents' educational expectations as an encouragement and a breakthrough in their abilities. However, whether parents adopt appropriate educational practices and teach by words determines whether children can grow up as their parents expect. At the same time, parents' educational expectations depend on the protection of national policies to truly promote children's growth, as shown in Figure 1.

3.3.4. Theoretical Saturation Test. About the theoretical saturation test, the original data from six in-depth interviews (three each for parents and children) are kept for the theoretical saturation test in this study. According to the three-level coding results, no new categories and relationships are found in the content of parents' educational expectations, cognition of expectations, and conditional guarantees. Therefore, it can be concluded that the relationship model between parents' educational

Table 3: Analysis of interview data of parents (open coding).

Excerpts of original data sentences	Initial concept	Category
Children have a correct outlook on life and values, to know how to respect others	A1 correct values	B1 guidance of values
Children cannot just pursue money, but do things useful to the country when they grow up	A2 being useful to the country	
No matter how brilliant the star is, it is packaged through some commercial means. It is through personal effort and talent that one can become a truly successful person	A5 work hard	B3 positive state
Self-discipline is more important in independent learning	A12 independence and consciousness	B7 self-discipline
The high expectations I have for my children sometimes put a lot of pressure on them, making myself and my family very anxious very often	A14 high expectations are prone to anxiety	B9 anxiety stress
Perhaps all parents have too high expectations for their children, which can cause some psychological pressure on the children	A15 high expectations bring pressure	
Double reduction is a good policy, which is beneficial to the physical and mental development of children	A24 political advantage	B13 national policy

Note. Due to the large number of coding contents, only the representative or special statements are selected as examples in this study.

Table 4: Analysis of children's interview data (partial).

Excerpts of original data sentences	Initial concept	Category
My mother seldom hits me but encourages me more	A1 positive encourage	B1 encourage education
Once I did not get good grades on the exam, my father encouraged me instead of blaming me. I felt a little sad because I did not try my best to learn; it was my problem	A2 self-reflection	
The high expectations my parents have for me are a great motivation. I don't want to live up to their expectations	A7 generate momentum	B4 transcend yourself
In some cases, my parents would let me try my best even though they knew I might not be able to do it. By trying, I did well every time, and things weren't that hard as I thought	A8 do your best	
My father doesn't ask me to study well; he wants me to stay happy and healthy by doing what I want to do in the future	A15 happiness and health	B7 life expectancy
Sometimes my teacher would give the parents some assignments, and my mother always did them very carefully	A20 work hard	B10 serious and self-disciplined
My mother insists on finishing her daily assignments, which greatly influences me	A21 stick to self-discipline	

Note. Due to the large number of coding contents, only the representative or special statements are selected as examples in this study.

expectations and children's growth is theoretically saturated.

4. Results and Discussion

4.1. The Educational Expectations of the Parents of Elementary School Students Are Not Limited to Learning, But Are More Concerned with the Intrinsic Value of the Children's Development. The existing research on parents' educational expectations focuses more on the parents' expectations for their children's studies and future careers. Therefore, some scholars believe that parents' educational expectations present too many external instrumental purposes, but lack attention to internal values [5]. Perhaps because the study population was elementary school, the educational expectations of parents in this study showed unique characteristics of this age group. The results of the interviews with parents and children indicated that parents' educational expectations consisted of three main areas, which are also apparent from the figure.

4.1.1. Quality Expectations. Family education involves many aspects, but the most important thing is character education, which is how to behave [6]. In other words, it is the primary task of family education and the most fundamental and effective function of family education [7]. After a grounded analysis, the interviewees' expectations of children's quality mainly include four major aspects: guidance of values (correct outlook on life and values, not self-centered), inner enrichment (with love in the heart, pursuing the inner), positive state (working hard), and positive qualities (honest and trustworthy, willing to help others, filial piety to the elders, take responsibility). From this, we can see that in terms of the quality requirements for children, in addition to the recognized traditional virtues, parents have good expectations of their children's internal and external conditions. Moreover, parents attach great importance to the cultivation of their children's values. As one interviewee said, children should become useful to the country when they grow up, rather than just pursuing money or their enjoyment, or simply pursuing their dreams and goals.

4.1.2. Learning Expectations. Chinese parents generally have high expectations for their children's education and hope they will have better academic achievements [8]. The parents of contemporary elementary school students present two characteristics in terms of learning expectations. First, there are two different perspectives on "learning" itself. The first view believes that learning is very important, and therefore, the expectations for children's academic performance are very high. If the children achieve the goals expected by their parents, they will be rewarded; otherwise, they will be punished.

However, the second view is that parents do not consider learning a core task in elementary school. As the interviewees put it: elementary school students should not bear the pressure of learning. The second notable feature is that parents pay more attention to children's learning quality, including internal learning motivation, self-discipline in learning, and good learning methods.

4.1.3. Life Expectations. The children interviewed stated that the most impressive sentence their parents have ever said is as follows: what is most important is not to study well, but to engage in what they want to do in the future, to do what they want to do well, and to live a happy and healthy life. It can be seen that happiness and health are parents' expectations for their children's entire life. Compared with the past research literature, this is a characteristic of the new era of parental expectations for children. In the past literature, parents' expectations of children mainly focused on learning. This may be related to parents' educational level and family education literacy. In particular, the recently promulgated "Family Education Promotion Law of the People's Republic of China" clarifies the importance of family education from a legal perspective, which stipulates that the state and society provide guidance, support, and services for family education. It can be predicted that the implementation of these policies will further play a positive role in changing parents' concept of family education.

4.2. There Are Differences in the Perceptions of Educational Expectations between Parents and Children. The educational expectation is of great value, which itself is the goal to be pursued. In pursuing the goal, there is a strong inner motivation to achieve it. The parents' educational expectations of their children will be transformed into the children's internal drive, which will enhance their self-confidence. In the research of this article, it is found that parents perceived two effects of educational expectations: generating anxiety and stress or prompting progress. Parents believed that if expectations were too high, both parents and children would experience anxiety and stress, but parents also believe that educational expectations allow their children to stimulate their potential and transcend their limits. Just as the interviewee said, if you have higher requirements for your children, they can at least make progress. If there is no requirement, they may stop or even regress.

In other words, parents believe that educational expectations have both positive and negative effects. However, analysis of the children's interview data revealed that children generally perceived their parents' high expectations as encouraging rather than stressful. The children's stress is partly because parents have used inappropriate educational ways, rather than deriving from high expectations. This may be related to the age of the children. They are all primary students and are unclear about their potential and future. Parents' high expectations for their children help them become a better version of themselves. This high expectation is a huge stimulus and encouragement to the children. As one child interviewed said, my parents knew that I probably could not do it, but they would let me try. I think I have to do it well because this is an encouragement and urge to me. I did my best every time and did well, and things were not that bad as I thought.

4.3. Parents' Educational Expectations as a Guarantee of Conditions That Promote Children's Growth: Educational Methods and Teaching by Words and Deeds. If a child's growth falls short of parents' educational expectations, some parents do not actively think about the reasons but lower their expectations [9]. This study also found that even if parents think about the reasons, they overly believe that their children have intellectual differences with others, thus creating a gap, instead of reflecting on their level of education, methods, and whether they teach by words. Education methods are generally divided into encouragement education and punishment education. Encouragement education refers to parents emphasizing the importance of efforts and not making unnecessary comparisons, which will help their children grow. Punishment education is mainly reflected in parents' emotional out-of-control and beating and scolding education, which creates psychological pressure on children. Psychological research shows that too much psychological pressure will affect the healthy growth of children. Teaching by words and deeds is the basic principle of family education [10]. In interviews with children, it is found that the most important thing affecting children is the attitude and spirit of parents when they do something. This attitude and spirit are the fundamental factors for children to grow up gradually.

4.4. The National Education Policy Can Better Help Parents View Their Educational Expectations Rationally. Educational anxiety will lead to quick-witted behavior in education, and parents' unreasonable educational expectation is an inevitable result of educational anxiety [11]. There are many reasons for educational anxiety, especially the unfairness of education. This problem needs to be solved by the national governance, and individuals are powerless to do anything about it. The newly issued Opinions on Further Reducing the Burden of Homework and Off-Campus Training for Compulsory Education Students (the "double reduction") is a national policy to return to the essence of education. In interviews, elementary school students' parents generally believe that double reduction is a good policy to reduce their educational anxiety. At the same time, it also promotes their new thinking in raising children and readjusts their educational expectations for their children. It can be seen that parents' educational expectations are significantly related to the national education policy.

5. Conclusions

5.1. Research Conclusions. Based on grounded theory, this study elucidates the educational expectations of parents of elementary school students through the analysis of the data from the interviews with elementary school students and their parents. In terms of the relationship between parents' educational expectations and children's growth, the following conclusions are finally drawn.

Firstly, the educational expectations of the parents of elementary school students mainly include three main contents, namely quality expectations, learning expectations, and life expectations for their children. That is to say, in addition to expectations for children's learning, parents of elementary school students today also have expectations in terms of quality and life expectations.

Secondly, different "cognitions" of educational expectations lead to differences in parents' behavior, which in turn affects children's growth. If parents believe that higher educational expectations are better, they tend to place high expectations on their children's education, which will stimulate their children's growth. Conversely, if they think that educational expectations are prone to stress and anxiety, they will lower expectations, and the child will naturally lower his or her self-expectations.

Thirdly, parents' educational methods and teaching by words and deeds are the guarantees of parents' educational expectations, which also promote children's growth. The deviation of children's growth from parents' educational expectations is not because of excessive parents' educational expectations. In fact, it is because parents use inappropriate educational methods to achieve their educational expectations, which leads to psychological pressure on children. This psychological pressure makes children tired of learning and rebellious.

Lastly, the national education policy is a fundamental guarantee for promoting the relationship between parents' educational expectations and children's growth. The research found that parents' educational expectations are closely related to the national education policy. To a certain extent, the national education policy provides parents with correct guidance for family education and also provides institutional guarantees, thus greatly affecting parents' educational expectations and making it possible for children to grow up healthily.

5.2. Theoretical Findings. Based on the grounded analysis of the content of parents' educational expectations, this study concludes that parents' educational expectations are not limited to academic expectations, but also include quality expectations and life expectations. This expands previous research studies that have been limited to academic expectations. In addition, previous studies have different views when exploring the relationship variables between parents' educational expectations and children's growth. Some researchers believe that parents' expectations need to be transformed into expectations that children identify with to promote children's growth [2]. This study believes that if parents use appropriate educational methods and teach by words and deeds by improving their literacy, parents' educational expectations will greatly contribute to children's growth. Therefore, the theoretical contribution of this study is to add new content for the relationship between parents' educational expectations and children's growth and provide a new research perspective [12].

5.3. Practical Enlightenment. According to the research of this study, we should pay attention to the following points in family education:

Firstly, parents should maintain high expectations for children. Parents' educational expectations are of great significance to their children. They are not only the driving force for children's growth but also the guide to stimulate their potential [13].

Secondly, parents should adopt a developmental mindset, rather than making a simple attribution and lowering expectations. When there is a gap between children's growth and parents' educational expectations, parents should think about whether to use encouragement education or stress education, whether to give children internal strength or increase emotional pressure, instead of making simple attributions and lowering expectations for the children [14].

Thirdly, parents should strengthen self-reflection. Parents need to improve their educational concepts, emotional management, behavior habits, life, and other qualities and consider whether they can influence their children by words and deeds.

5.4. Research Limitations and Future Research Directions. The relationship between parents' educational expectations [9] and children's growth is based on a small sample in this paper's model, and the sample is mostly from urban schools [15]. More research is needed to see whether this model applies to specific family groups. Second, children are perplexed by their parents' expectations, according to the in-depth interviews. Their parents, for example, expect them to contribute to the country, but the children have no idea how to do so. Parents generally expect their children to be self-disciplined when it comes to learning, but they also do not know how to raise their children in specific ways [16]. This phenomenon has not been explored in depth in this study. Finally, this study came to the important conclusion that national education policy has a significant impact on parents' educational expectations; however, what new relationship does this impact have with children's development? Due to the study's short length and duration, more research on this article is not possible. We will still be able to conduct in-depth research in the future.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The author does not have any possible conflicts of interest.

Acknowledgments

Throughout the writing of this study, the author has received a great deal of support and assistance. I would first like to thank Dr. Liu for teaching qualitative research course and insightful feedback that pushed me to sharpen my thinking and brought my work to a higher level. I would particularly like to acknowledge the 30 students interviewed and their parents for their wonderful collaboration and patient support. This study was supported by the following: Fund Project: Xi'an Academy of Social Sciences "Research on Parents' Family Education Competence under the Background of Double Reduction Policy" (2021ZDZT03).

Accurate and effective financial data analysis is very important for investors to avoid risks and formulate profitable investment strategies. Therefore, the analysis of financial data has important research significance. However, the financial market is a complex nonlinear dynamic system affected by many factors. It is very challenging to analyze the financial data according to the obtained information. Among them, stock selection is the most typical financial data mining problem. The core of stock selection is to design a systematic scoring mechanism to quantitatively score stocks so as to more intuitively reflect the investment value of stocks. The scoring mechanism is based on the assumption that stocks with higher scores have higher investment value and stocks with lower scores have lower investment value. The stock selection model proposed in this paper mainly includes two steps: stock prediction and stock scoring. First, construct stock predictors and use machine learning forecasting methods to predict the future price of each stock. Second, construct a stock scoring mechanism to evaluate each stock through the predictive factors and financial factors in the previous step. Finally, select high-scoring stocks and make equal-weight investments. This paper applies the model to the empirical study of the A-share market, verifies its feasibility and effectiveness, and makes a systematic comparison with other benchmark models.

1. Introduction

With the development of the market economy, the issuance and trading of stocks occurred, and both promoted the development of the market economy. In recent years, stocks have shown their tenacious vitality, and the stock market has gradually become an indispensable part of the entire financial industry, especially the securities industry. In order to develop the national economy better and faster, as my country continues to enter the deep water zone of reforms, the reforms in the financial sector are gradually deepening [1]. Predicting the development of stocks has always been the direction of research and exploration by scholars from all walks of life. Predicting the development of stocks is a branch of prediction. The premise is to use scientific methods and methods, and it is necessary to know the development laws of financial markets, understand economics, and fully grasp the law of development of the financial market and the current stage of development [2].

Faced with confusing, high-dimensional, and huge amounts of historical stock information, it is a reasonable and efficient way to analyze and process with the help of computers, which frees stock analysts from tedious work and concentrates on analyzing key issues [3]. The high-speed processing capability of the computer makes it possible to provide customers with more comprehensive and accurate forecasts in a short period of time. In addition, algorithms can provide insights into the forecasting problem from novel perspectives to achieve better forecasting results, which are beyond the reach of human analysis. Model algorithms such as machine learning and deep learning are suitable for the analysis of high-dimensional big data, and the use of computers to customize auxiliary software for stock forecasting for different service objects has become a research hotspot [4]. This paper will combine neural networks and support vector machines, two of the most widely used machine learning models, and propose improvements to provide novel solutions to problems such as model mixing and stock forecasting [5]. According to the existing stock analysis and prediction methods, the participation of the whole people can be maximized, and it is not necessary to have sufficient financial expertise to participate in stock investment. For research topics with special properties such as time series and high-dimensional stock historical data, many forecasting methods can be used for reference [6]. Therefore, the research topic of stock forecasting has very important significance from both theoretical and application perspectives and meets the current needs.

2. Preliminary Study

2.1. Problem Definition. The total data set $D=\{X, Y\}$ is composed of the input factor X and the real label Y corresponding to the input factor X, and the prediction result Y is obtained by using the model $F(\cdot)$ to predict the data set D. When designing a specific prediction scheme, the input factor X and label Y can be differentiated according to the prediction model $F(\cdot)$ and the purpose of prediction. Therefore, the input factor X can be time series data, text data, binary features, and so on, and the label Y can be a specific value, classification result, and so on.

Obviously, financial stock forecasting is a complex problem, which has the following five characteristics: (1) it is appropriate to use machine learning to analyze and predict financial stocks., and the input sources for stock prediction are huge, high-dimensional, and heterogeneous, and machine learning algorithms are particularly good at processing such data [7]; (2) indirect factors such as real-time data on the Internet and public sentiment will also affect the prediction results; (3) when considering numerical data as an input feature, the basic transaction data and the technical indicators calculated from the basic transaction data are huge and need to be selected, and in addition, the two features may affect each other; (4) each stock has its own specific development law, and the trained model algorithm is not necessarily applicable to the data sets of other stocks; and (5) for the prediction output, it can be divided into classification prediction and regression prediction according to the purpose of prediction. Classification and regression forecasts not only reflect trends and stock price forecasts but also provide new ideas for investment strategies and price reversal points [8].

2.2. BP Neural Network. The neural network model is currently the most widely used neural network. At the same time, the neural network has the ability to predict only after training and learning and can adapt to the prediction requirements, obtain the structure of learning knowledge, and map the nonlinearity to linear functions [9]. The main structure diagram and flowchart are shown in Figures 1 and 2.

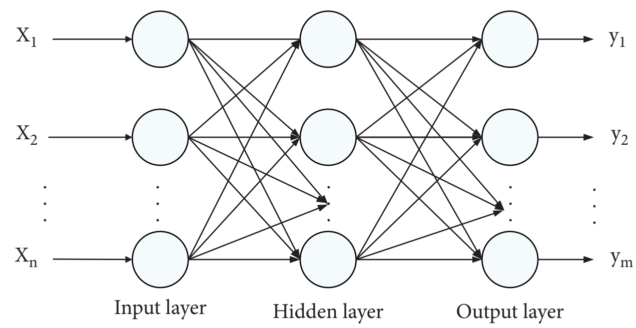

Figure 1: BP neural network structure diagram.

When the BP neural network predicts stocks, the time series $i\{X\}$ is regarded as the input value of the input layer, and a part of it is selected for training. The price $\{Y_i\}$ obtained from the training result is compared with the actual price and adjusted by feedback. After multiple iterations, the prediction model is obtained, and then the price of $a+b+c$ $(c \geq 1)$ at a certain time in the future is predicted. The nonlinear relationship of the price Y_{a+b+c} time series at the predicted time can be expressed by the following formula:

$$X_{a+b+c} = f\left(X_a, X_{a+1}, \ldots\ldots, X_{a+b}\right). \tag{1}$$

The fitting model f is obtained through the training set time series $X_a + X_b + \cdots + X_{a+b}$, and the unvalued value is predicted from this.

2.3. Support Vector Machine Regression. Support vector machine (SVM) was first proposed by Vapnik et al. [10] Based on the "structural risk minimization" criterion, the optimal hyperplane is constructed to separate the two types of samples to the greatest extent. Support vector machine regression (SVR) is an extension of SVM [11]. The basic principle of SVR is similar to SVM, but its purpose is different. It aims to construct an optimal classification plane to minimize the error of all samples from the classification plane [12].

There are n training samples, where x_i is the input variable and y_i is the output variable. SVR can be regarded as a quadratic programming problem, as shown in the following equation:

$$\begin{aligned} &\min \frac{1}{2}\|w\|^2, \\ &\text{subject to}\left\| y_i - \left(w \cdot x_i + b\right)\right\| < \varepsilon, \quad i = 1, \ldots, n, \end{aligned} \tag{2}$$

where ξ represents the boundary of the prediction error.

In order to ensure the generalization ability of the model, slack variables ξ_i and ξ_i^* are introduced to modify equation (2), namely,

$$\min \frac{1}{2}\|w\|^2 + C\sum_{i=1}^{n}\left(\xi_i + \xi_i^*\right), \tag{3}$$

$$\text{subject to}\begin{cases} y_i - w, x_i - b \leq \varepsilon + \xi_i, \\ w, x_i + b - y_i \leq \varepsilon + \xi_i^*, \\ \xi_i, \xi_i^* \geq 0, \end{cases} \tag{4}$$

where C is the penalty factor, which is the maximum tolerance error.

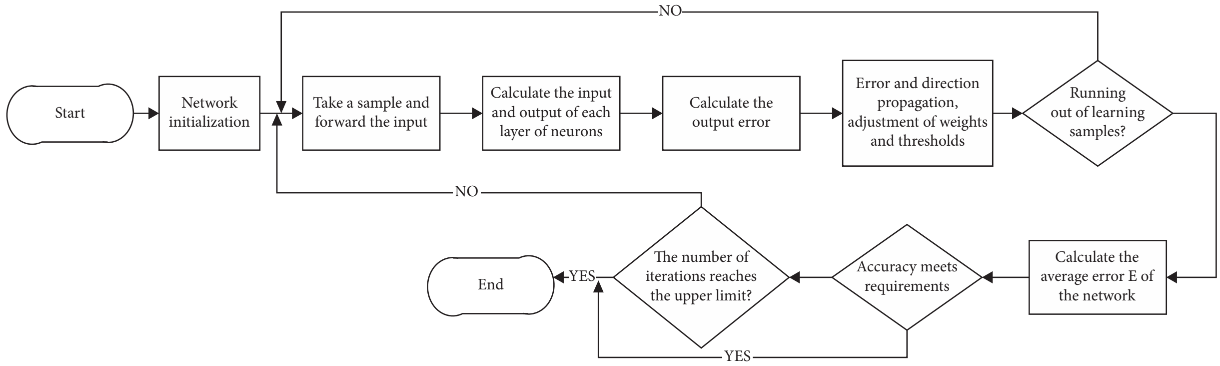

Figure 2: Flow chart of BP neural network implementation.

In order to solve equations (3) and (4), the Lagrange function is introduced and transformed into a dual problem as follows:

$$L = \frac{1}{2}\|w\|^2 + C\sum_{i=1}^{n}\left(\xi_i + \xi_i^*\right) - \sum_{i}^{n}\lambda_i\left(\varepsilon + \xi_i - y_i + w, x_i + b\right) - \sum_{i}^{n}\lambda_i^*\left(\varepsilon + \xi_i^* + y_i - w, x_i - b\right) - \sum_{i=1}^{n}\left(\eta_i\xi_i + \eta_i^*\xi_i^*\right), \in \eta_i, \eta_i^*, \xi_i, \xi_i^* \geq 0. \tag{5}$$

Solve the Lagrange equation and get the optimal solution w^* and b^* as follows:

$$\begin{aligned} w^* &= \sum_{i}^{n}\left(\lambda_i - \lambda_i^*\right)x_i, \\ b^* &= y_i - w^*, x_i - \varepsilon, 0 \leq \lambda_i \leq C, i = 1, \ldots, n, \\ b^* &= y_i - w^*, x_i + \varepsilon, 0 \leq \lambda_i^* \leq C, i = 1, \ldots, n. \end{aligned} \tag{6}$$

3. The Design of the Financial Stock Selection Model Based on Machine Learning Models

3.1. Stock Prediction Model Framework. The stock selection model proposed in this article mainly includes two steps: stock prediction (used to construct predictive factors) and stock scoring (used to evaluate stock value) [13–15]. The overall framework is shown in Figure 3.

3.2. Financial Stock Forecast and Scoring

3.2.1. Financial Stock Forecast. In order to construct predictors, we predict the returns of all stocks. In the period of t, use $z_{i,k,t}\,(k = 1, 2, \ldots, 17)$ transaction data to predict the stock price in period t+1 as follows [13]:

$$\widehat{P}_{i,t+1} = f\left(z_{i,1,t}, z_{i,2,t}, \ldots, z_{i,17,t}\right), \tag{7}$$

where $\widehat{P}_{i,t+1}$ is the predicted price of stock i in period $t+1$ and $z_{i,k,t}$ is the k-th transaction data of stock i in period t. A total of 17 trading factors are used to predict the future price of stocks. The 17 trading factors can be roughly divided into 4 categories. Volume and price factors include the previous day's closing price, trading volume, opening price, average price, closing price, lowest price, turnover, and highest price [14]. Valuation factors include P/B ratio, P/B ratio, P/E ratio, and P/S ratio [15]. Risk factors include ups and downs of yuan, ups and downs, and turnover rate. Scale factors include total market capitalization and total equity. The predicted stock price $\widehat{P}_{i,t+1}$ is transformed into the predicted stock return through equation (10):

$$\widehat{R}_{i,t+1} = \frac{\widehat{P}_{i,t+1} - P_{i,t}}{P_{i,t}}, \tag{8}$$

where $\widehat{R}_{i,1}$ represents the predicted return of stock i in the period. Furthermore, normalize $\widehat{R}_{i,t+1}$ to obtain $\widehat{Y}_{i,t+1}$, and the process is shown in equation (11). $\widehat{Y}_{i,t+1}$ will be used as a predictor for the stock scoring in the second step.

$$\widehat{Y}_{i,t+1} = \frac{\widehat{R}_{i,t+1} - \widehat{R}_{t+1}}{\widehat{D}_{t+1}}, \tag{9}$$

where $\bar{\widehat{R}}_i = \sum_{x\in 1}^{N}\widehat{R}_{i,t}/N$ is the average value of the predictor and $\widehat{D}_t = \sqrt{\sum_{i=1}^{X}(\widehat{R}_{i,t} - \bar{\widehat{R}}_t)^2/N}$ is the standard deviation of the predictor, where N is the number of stocks.

3.2.2. Financial Stock Scoring. In addition to predictive factors, financial factors $V_{i,j,r}\,(j = 1, \ldots, 12)$ have also been introduced into our stock selection model. These factors are widely used in existing stock selection models, and they usually reflect the company's operating conditions. For example, ROE usually reflects the company's profitability; debt to equity ratio (DE) usually reflects the company's bar ratio; current ratio (CR) usually reflects the company's liquidity; and inventory turnover rate (ITR) usually reflects the company's operating efficiency and operating income [16]. The growth rate OIG usually reflects the company's growth and so on. As with forecasted earnings, standardize them as follows [17]:

$$\frac{Y_{i,j,t} = V_{i,j,t} - \bar{V}_{j,t}}{D_{j,t}}, \tag{10}$$

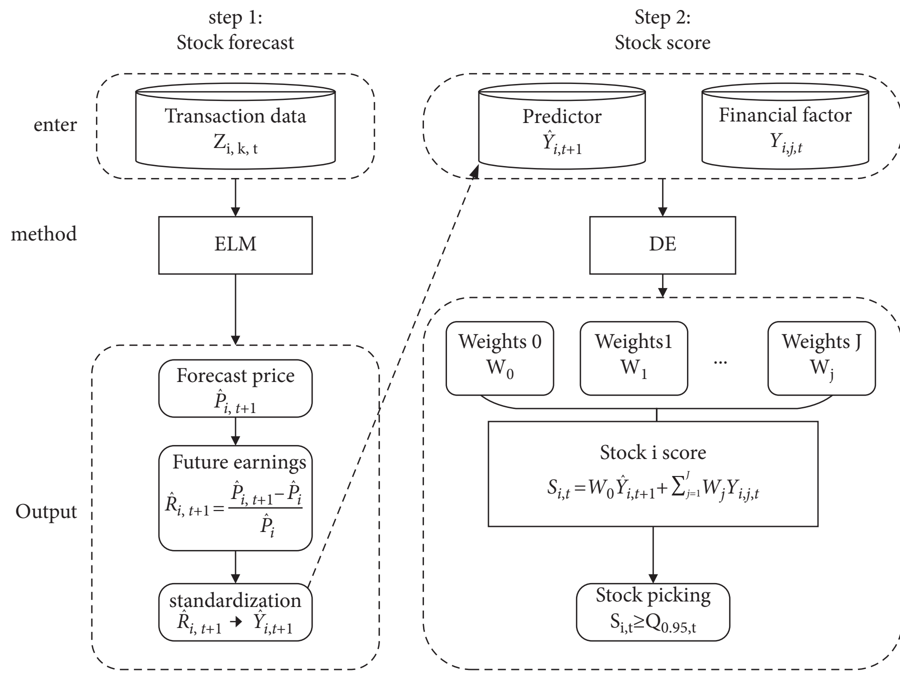

Figure 3: Framework diagram of the stock selection model.

where $\bar{V}_{j,t} = \sum_{i=1}^{N} V_{i,j,j}/N$ is the average value of financial factors and $D_{j,t} = \sqrt{\sum_{i=1}^{N} (V_{t,j,t} - \bar{V}_{j,t,})^2/N}$ is the standard deviation of the financial factor, where N is the number of stocks.

The stock's i score in the period of t, $s_{i,t}$, can be described as a linear combination of predictive factors and financial factors as follows:

$$s_{i,t} = W_0 \widehat{Y}_{i,t+1} + \sum_{j=1}^{J} W_j Y_{i,j,t}, \tag{11}$$

where W_0 represents the weight of the predictive factor, W_j represents the weight of the j financial factor, and $s_{i,t}$ represents the comprehensive score of the stock in the period.

Each stock is sorted according to its comprehensive score from high to low, denoting $r_{i,j} \in \{1, 2, \ldots, N\}$, if $s_{i,t} \geq s_{k,t}$, then $r_{i,1} \leq r_{k,}$ where $i, k \in \{1, 2, \ldots, N\}$ represents any two separate stocks. In each period, the top m stocks are selected for equal-weight investment. The portfolio returns are as follows:

$$\begin{aligned} \overline{R}_{t+1} &= \frac{1}{m} \sum_{r_{i,j}=1}^{m} R_{t+1}\left(r_{i,t}\right), \\ r_{i,t} &= 1, 2, \ldots, m, \end{aligned} \tag{12}$$

where m is the number of stocks that the investor hopes to choose and $R_{t+1}(r_{i,t})$ is the t return of the stocks selected during the period sorting in period $t+1$. R_{t+1} is the average return of stocks selected according to the model in $t+1$.

This research introduces Spread as the objective function (fitness function) of the model. The objective function (fitness function) is defined as the long-short portfolio return of the top stocks in the t period comprehensive score and the stocks after the m period comprehensive score.

$$\begin{aligned} \min_{w_j} F &= -\frac{1}{T} \sum_{t=1}^{T} \text{Spread}_t, \\ \text{Spread}_t &= \frac{\sum_{r_{i,t=1}}^{m} R_{t+1}\left(r_{i,t}\right) - \sum_{r_{i,t=N-m+1}}^{N} R_{t+1}\left(r_{i,t}\right)}{m}. \end{aligned} \tag{13}$$

3.3. Evaluation Indicator. Root mean square error (RMSE), mean absolute percentage error (MAPE), and directional statistics (D-STAT) are often used to evaluate the effectiveness of prediction models. This article also uses the above three indicators to evaluate the effectiveness of various prediction models in this article as follows [18]:

$$\begin{aligned} RMSE &= \sqrt{\frac{1}{N \cdot T'} \sum_{i=1}^{N} \sum_{l=1}^{\left(P_{i,t} - \widehat{P}_{i,t}\right)^2}}, \\ MAPE &= \frac{1}{N \cdot T'} \sum_{i=1}^{N} \sum_{t=1}^{T'} \left| \frac{P_{i,1} - \widehat{P}_{i,t}}{P_{i,t}} \right|, \\ Dstat &= \frac{1}{N \cdot T'} \sum_{i=1}^{N} \sum_{t=1}^{T'} a_{i,t}, \end{aligned} \tag{14}$$

where T is the number of test periods, N is the number of stocks, $P_{i,t}$ is the price of stock i in period t, $\widehat{P}_{i,t}$ is the predicted price of the stock, and when $(P_{i,t} - P_{i,t-1})(\widehat{P}_{i,t} - P_{i,t-1}) > 0$, $a_{i,t} = 1$; otherwise it is 0. In addition, the running time of the model is also an important indicator for evaluating the performance of the model. It will cover the entire time of the training period and the test period.

Choosing high-quality stocks for equal-weight investment means constructing an equal-weight investment portfolio. Portfolio income can most intuitively reflect the effectiveness of the stock selection model. The higher the portfolio return, the better the effect of the stock selection model. Therefore, this paper adopts the average return of all investment portfolios during the test period as one of the evaluation indicators of the stock selection model. In addition, portfolio risk is also a key concern. SharpeRatio is a commonly used indicator to describe portfolio risk. This article also uses SharpeRatio as one of the evaluation indicators of the stock selection model. The specific calculation formula is as follows [19]:

$$AR = \frac{1}{T'} \sum_{t=1}^{T'} \bar{R}_{t+1} \text{ , Sharpe Ratio} = \frac{E\left[\bar{R}_t - R_i^f\right]}{\sigma}. \tag{15}$$

where $\overline{R}_1$ is the average return of the portfolio in the t period, that is, the average value of the strategy return; R_i^f is the risk-free return in the t period; $E[\underline{R}_t - R_i^f]$ is the expectation; and σ is the portfolio volatility, that is, the strategy return.

3.4. Hyperparameter Setting. All parameters involved in the model and benchmark model proposed in this paper refer to previous studies, as shown in Table 1. Regardless of whether it is an optimization model or a prediction model, there are random variables or parameters, and different optimization values will be generated every time the model is run (the output result cannot be guaranteed to be the optimal result). Therefore, all models are run 30 times for each case, and their average value is used as the final output result.

4. Experimental Test and Result Comparison

4.1. Experimental Data Set. The trading volume and total market value of China's A-share market in the global financial market are increasing day by day, and its status is increasing day by day. Therefore, the A-share band field is selected as the experimental sample of this article. There are a total of 2,473 stocks as candidate stocks for the investment portfolio, which excludes financial industry stocks with different balance sheet structures and specially processed stocks ST that may be unstable. In the existing stock forecasting models, this chapter will introduce the acquisition, processing, and cleaning of data sources from two aspects of stock index data and text data. Among them, stock index data refers to data related to stock trading. The text data mainly consists of news data. The trading data used for stock forecasting and the financial data of stock scoring are all quarterly data, and they all come from the Wind database.

4.2. Benchmark Model Comparison. As shown in Table 2, this article introduces a variety of benchmark models, including different prediction models (marked as M1), different factorial designs (marked as M2), different optimization algorithms (marked as M3), and different fitness functions (marked as M4). Among them, M0 is the stock selection model proposed in this article. Next, we will introduce the construction methods of various benchmark models in detail.

In each benchmark method, in order to ensure the fairness of comparison, each type of benchmark model only changes its unique variable. For type M1, BP neural network (BPNN) and support vector machine regression (SVR) are two classic forecasting models, which are widely used in stock forecasting, investment portfolio, and stock selection research. Therefore, this article will introduce these two prediction models as the benchmark model. For type M2, the model proposed in this paper contains two types of factors, namely, basic factors and predictive factors, which are denoted as A0. Two new designs are now introduced as the benchmark model of this article. Design A1 means that only financial factors are considered but not predictive factors, and design A2 means that only predictive factors are considered but not financial factors. For type M3, the more popular intelligent optimization algorithm in the stock selection model is introduced as the benchmark model of this article, namely, genetic algorithm GA and particle swarm algorithm PSO. For type M4, in the stock selection model based on the intelligent optimization algorithm, four commonly used optimization objective functions (fitness functions) are used as the benchmark model of this article, namely, information coefficient (IC), equity (CR), long-short combination winning rate (IFHR), and absolute win rate (WIN).

$$IC = -\frac{1}{T} \sum_{t=1}^{T} \frac{\operatorname{cov}\left(r_{i,t,}, r'_{i,t}\right)}{\sqrt{\operatorname{var}\left(r_{i,t}\right)\operatorname{var}\left(r'_{i,t}\right)}},$$

$$CR = -\prod_{i=1}^{T}\left(1 + \bar{R}_{t+1}\right),$$

$$IFHR = -\frac{1}{T} \sum_{t=1}^{T} \left(\frac{\sum_{r_{i,t}=1}^{m} \operatorname{sgn}\left(R_{t+1}\left(r_{i,t}\right) - M_{t+1}\right)}{2m} - \frac{\sum_{r_{i,t}=N-m+1}^{N} \operatorname{sgn}\left(R_{t+1}\left(r_{i,t}\right) - M_{i+1}\right)}{2m} \right),$$

$$WIN = -\frac{1}{T} \sum_{t=1}^{T\sum\left(\bar{R}_{t+1}\right)} sgn, \tag{16}$$

where T is the number of training periods, $r_{i,t}$ is the ranking of stock i in the t-th period, $r_{i,t}$ is the stock's income ranking in $t+1$ period, $\operatorname{cov}(\cdot)$ is the covariance, $\operatorname{var}(\cdot)$ is the variance, m is to select the number of stocks, and $\overline{R}_{t+1}$ is the average return of the stock selection strategy in the $t+1$ period. It outputs 1 when it is $x > 0$; otherwise, it outputs 0. See Table 1 for benchmark model design.

Table 1: Parameter settings of this model and benchmark model.

Optimization	Parameter	Value	Method of prediction	Parameter	Value
	P	30		N	$0.1*N$_train
DE	Cr	0.5	ELM	TF	sig
	F	0.6		n	10
	P	50		ep	3,000
GA	cr	0.6	BPNN	lr	0.1
	mr	0.5		mc	0.4
	P	40		K	RBF
PSO	$c1 = c2$	1.495	SVR	r	$\{2^{-15}, 2^{-13}, \ldots, 2^{13}, \ldots, 2^{15}\}$
	wn	[0.4, 0.9]		C	$\{2^{-15}, 2^{-13}, \ldots, 2^{13}, \ldots, 2^{15}\}$

Note: γ and C are traversed from the grid of $\{2^{-15}, 2^{-13}, \ldots, 2^{13}, 2^{15}\}$ to obtain values. N_train is the number of training periods of the extreme learning machine. For other parameter descriptions, please refer to the description of symbols and abbreviations.

4.2.1. Comparison of Different Prediction Models (M1). When constructing predictors, this article uses the extreme learning machine ELM to predict stock prices. In order to prove the effectiveness of ELM in stock forecasting, two classic forecasting methods, BP neural network (BPNN) and support vector machine regression (SVR), are introduced as benchmark models. Table 3 shows the prediction results. Among them, Prob.(R1) is the probability that the stock selection model of this article will have a higher quarterly return than the quarterly earnings of R1; Prob.(R2) is the probability that the quarterly earnings of the stock selection model of this article will be higher than the quarterly earnings of R2; and Max. is the average value of the maximum return of the stock selection model of this article; Min. is the average value of the minimum return of the stock selection model of this article; and HitRate represents the probability of the model obtaining a positive return [20].

As shown in module A in Table 3, the stock selection model using ELM performs more prominently in AR, SharpeRatio, Prob.(R1), Prob.(R2), and HitRatio. At the same time, the SVR stock selection model has achieved a little advantage in Max. and Min. while the stock selection model of BPNN is at a disadvantage in any evaluation index. This shows that the predictive factors constructed by ELM can better assist stock selection decisions. In order to statistically prove that the stock selection model using ELM is significantly better than other benchmark models, this section tests each benchmark model. The process is as follows: first, the normality test is performed on each model, and the normality test is the prerequisite for the test. Second, construct a null hypothesis, H0: the AR of the stock selection model using ELM is significantly lower than other benchmark models. According to module B, all models pass the

Table 3: Comparison results of different forecasting methods in the stock selection model.

Model	ELM	BPNN	SVR
Module A: performance of stock-picking model			
AR	0.0998	0.0877	0.0799
SharpeRatio	0.4054	0.2997	0.3049
Max.	0.4199	0.4089	0.4278
Min.	−0.3178	−0.3203	−0.3049
Prob.(R1)	0.6554	0.4712	0.5083
Prob.(R2)	0.7831	0.7500	0.7521
HitRatio	0.7603	0.7580	0.5813
Module B: t test ($H0$: $AR_{ELM} \leq AR_{\text{Benchmark}}$)			
Positive test (p value)	0.3121	0.2014	0.4179
t-stat	NA	18.1433	13.2240
p value	NA	<0.0001	<0.0001
Module C: stock forecast			
Computing time	60.1222	16,100.2541	32,399.8999
D-STAT	0.5148	0.4997	0.4978
MAPE	0.2189	0.2578	0.4001
RMSE	18.9997	32.2359	44.8972
Module D: DM test (H0: the prediction result based on the benchmark model is better than the prediction result based on ELM)			
DM-STAT	NA	−17.2012	−5.001
p value	NA	<0.0001	<0.0001

normality test, and the values of all models are less than 5%. It shows that at the 95% confidence level, the stock selection model based on ELM is better than the benchmark model. This proves that the predictive factors constructed by ELM can better assist stock selection decision-making.

Module C shows the evaluation indicators of all forecasting methods. Obviously, the method of using ELM to predict stock prices crushes all benchmark models in computing time, directional accuracy D-STAT, prediction accuracy MAPE, and RMSE. In the research of this article, ELM has more prominent predictive abilities. Similarly, in order to statistically prove that the prediction results based on the extreme learning machine ELM are significantly better than other benchmark models, this section conducts the Diebold–Mariano test (DM test) on each benchmark model. The process is as follows: construct a null hypothesis, H0: the prediction result based on ELM is significantly lower than the prediction result based on the benchmark model. The DM test results are shown in module D in Table 3. All values are less than 5%, indicating that the prediction results based on ELM are better than the benchmark model at the 95% confidence level. This proves that ELM has a stronger predictive ability. It can be seen that the predictor based on ELM structure can better assist stock selection decision-making.

4.2.2. *Comparison of Different Factorial Designs (M3).*

The innovation of the stock selection model proposed in this paper is the use of predictive factors and financial factors to evaluate the value of stocks. The predictive factors contain the future information of the stock market, and the basic factors contain historical information of the stock. In order to prove the effectiveness of this innovative design, the proposed stock selection model A0 is compared with the benchmark model A1 and the benchmark model A2 (as shown in Table 4). Among them, the benchmark model A1 only uses basic factors, similar to the traditional stock selection model, for which refer to the research done by Huang, and the benchmark model A2 only uses predictive factors, for which refer to the research done by Huang and Quah.

Table 4 shows the relevant results. At the same time, the A0 stock selection model has achieved outstanding performance in AR, SharpeRatio, Min., and Prob.(R1). However, only the A1 stock selection model and the A2 stock selection model have no outstanding performance in the various evaluation indicators. In order to statistically prove that the stock selection model using A0 is significantly better than other benchmark models, this section tests each benchmark model. The process is as follows: first, the normality test is performed on each model, and the normality test is the prerequisite for the test. Secondly, construct a null hypothesis, H0: the average return AR of the stock selection model A0 using predictive factors and financial factors is significantly lower than other benchmark models. According to module B, all models pass the normality test, and the values of all models are less than 5%. It shows that under the 95% confidence level, the stock selection model A0 using predictive factors and financial factors is better than other benchmark models. This proves that adding predictive factors can better assist stock selection decisions, and financial factors are equally important.

Table 4: Comparison results of different factorial designs in the stock selection model.

Model	A0	A1	A2	R1	R2
Module A: model performance					
AR	0.1102	0.0765	0.0799	0.8403	0.0398
SharpeRatio	0.4010	0.2997	0.3012	0.2988	0.1798
Max.	0.4587	0.4099	0.4010	0.3789	0.3594
Min.	−0.2998	−0.3201	−0.3587	−0.3099	−0.3178
Prob.(R1)	0.6549	0.4378	0.5001	NA	0.0000
Prob.(R2)	0.8001	0.7603	0.7554	1.0000	NA
HitRatio	0.7602	0.7812	0.7399	0.7849	0.5645
Module B: t-test ($H0$: $AR_{DF} \leq AR_{\text{Benchmark}}$)					
Normality test (p value)	0.2998	0.0489	0.3379	NA	NA
t stat	NA	20.5879	14.1339	25.8999	57.0004
p value	NA	<0.0001	<0.0001	<0.0001	<0.0001

4.2.3. *Comparison of Different Optimization Algorithms (M3).*

In this paper, the differential evolution algorithm is used to optimize the weights of various factors. In order to prove the effectiveness of DE, the classic genetic algorithm GA and particle swarm algorithm PSO are set as the benchmark model. As shown in Table 5, during the training and testing period, the DE stock selection model used in this paper is superior in average return AR and SharpeRatio, which not only shows that DE algorithm can better assist stock selection decision-making but also shows that the algorithm can achieve the best performance. The optimized factor weights have stronger generalization ability than the benchmark model. In order to statistically prove that the stock selection model adopted is significantly better than other benchmark models, this section tests each benchmark model. The process is as follows: first, the normality test is performed on each model, and the normality test is the prerequisite for the test. Secondly, construct a null hypothesis, H0: the AR of the stock selection model using DE is significantly lower than other benchmark models. As shown in the module, all models passed the normality test, and the values of all models were less than 5%. It shows that under the 95% confidence level, the DE-based stock selection model is better than other benchmark models. Thus, it is statistically proved that the differential evolution algorithm can better assist the stock selection decision-making.

4.2.4. *Comparison of Different Fitness Functions (M4).*

In this paper, the Spread fitness function (old standard han number) is used to make stock selection decisions, and four different fitness functions such as IC, CR, IFHR, and WIN are now used as benchmark models. The results are shown in Table 6. The stock selection model using the Spread fitness function has outstanding performance in average return AR and Sharpe Ratio. The stock selection model using the Spread fitness function can better assist stock selection decisions. In

Table 5: Comparison results of different optimization algorithms in the stock selection model.

Model	Training set		Test set		t-test ($H0$: $AR_{DF} \leq AR_{\text{Benchmark}}$)		
	AR	SharpRatio	AR	SharpRatio	Normality test (p value)	t-stat	p value
DE	0.1201	0.1311	0.1078	0.3644	0.2988	NA	NA
PSO	0.1887	0.1088	0.1244	0.3577	0.4999	3.7994	0.0002
GA	0.1001	0.1022	0.1012	0.3578	0.1994	4.3829	<0.0001

Table 6: The comparison result of the fitness function in the stock selection model is the difference.

Model	Spread	IC	CR	IFHR	WIN
Module A: model performance					
AR	0.1109	0.0812	0.0899	0.1135	0.0898
SharpeRatio	0.3789	0.2978	0.3576	0.3477	0.3396
Module: inspection (H0: $AR_{\text{Sprear}} \leq AR_{\text{Benchmark}}$)					
Normality test (p value)	0.2997	0.3889	0.1299	0.3751	0.4999
t-stat	NA	18.4436	19.1324	3.1162	7.1124
p value	NA	<0.0001	<0.0001	0.0013	<0.0001

order to statistically prove that the stock selection model using Spread is significantly better than other benchmark models, this section tests each benchmark model. The process is as follows: First, the Han-state test is performed on each model, and the normality test is the prerequisite for the test. Second, construct a null hypothesis, H0: the average return AR of Spread's stock selection model is significantly lower than other benchmark models. According to the module, all models pass the normality test, and the values of all models are less than 5%. This shows that at the 95% confidence level, the stock selection model based on Spread is better than other benchmark models. Thus, it is statistically proved that the stock selection model using the Spread fitness function can better assist stock selection decision-making.

5. Conclusion

This paper uses two machine learning models, neural network and support vector machine, to predict stock prices and conduct empirical research on China's A-share market. The results show that the machine learning model adopted in this paper has obvious advantages in terms of ROI and model robustness. The returns of portfolios constructed using the stock selection model proposed in this paper are much higher than the average market performance (i.e., an equal-weighted portfolio of all stocks) and the China A-share index. Notably, in model optimization, predictors were given higher weights, suggesting that stock predictors play an important role in stock selection. This also supports the new idea that introducing stock predictors can improve stock selection decisions. Especially when comparing the designs of different factors, the stock selection model proposed in this paper has a significant advantage over the benchmark model A1 (considering only financial factors) and the benchmark model A2 (considering only predictive factors). This paper provides empirical experience and model design guidance for using machine learning for stock selection.

Academic Editor: Tongguang Ni

Of late, emerging algorithms such as machine learning have been increasingly used in shield tunneling construction management and control. This research article proposes a shield tunneling parameter matching model based on a support vector machine (SVM) and an improved particle swarm algorithm (PSO) to enhance the accuracy and reliability of shield tunneling parameter selection. First, the optimization performance of the algorithm is augmented by adjusting particle diversity. Simulation-based experiments are conducted to test the performance of the improved algorithm. The experimental results indicate that the improved algorithm has better accuracy. Meanwhile, the particle diversity adjustment strategy is given. Then, the SVM model to express the relationship between shield tunneling parameters and ground settlement is established and trained. Based on the obtained SVM model, the improved PSO is used to optimize the tunneling parameters. The results show that the shield tunneling parameter matching model based on SVM and improved PSO can obtain more accurate shield tunneling parameters and provides a more precise reference for selecting shield tunneling parameters.

1. Introduction

With the advancement of civil construction technology, large-scale projects such as tunnels have an increasing impact on the development of the large, medium, and small cities and have made extraordinary contributions to urban economic development. However, soil loss at the tunnel entrance, soil instability at the driving face, and subsidence of the shield are common problems in shield tunneling construction. Therefore, the selection of reasonable shield tunneling parameters plays a decisive role in the smooth progress of the project. The numerous factors involved in the shield tunneling process introduce many inconveniences to selecting shield tunneling parameters. Subsequently, the shield tunneling parameters are needed to optimize the system.

Recently, machine learning algorithms are adopted in several fields such as healthcare, business, agriculture, and social media [1–4]. In the Industry 4.0 era, the digital world has a huge amount of data such as cyber security data, mobile data, business data, healthcare data, and social media data. The knowledge of artificial intelligence (AI) and machine learning (ML) plays a key role to analyze these data for the design and development of smart and automated application. Recently, several machine learning algorithms are widely used in the field of civil engineering [5–14]. These approaches yield several prospects for the optimization of shield tunneling parameters. In addition, the works which are related to settlement prediction [15–17] using machine learning algorithms are proposed. Existing machine learning-based approaches for the optimization of shield tunneling parameters face several challenges.

The existing machine learning approaches which are based on shield tunneling parameter matching use neural networks [18], K-means [19], correlation-based algorithms [20], and Bayesian networks [21]. These algorithms are failed to improve the accuracy and choose the optimal shield tunneling parameters. To obtain shield tunneling parameters more quickly and accurately, the paper enhances the PSO algorithm optimization performance by improving the particle diversity. A specific strategy is proposed based on the simulation results of six classical functions. Combining

60 monitoring data points from Shanghai tunnel engineering, SVM is adopted to establish the relationship model between the surface subsidence and shield tunneling parameters. Then, based on the obtained SVM model, the improved PSO is applied to optimize the tunneling parameters.

The remaining section of the paper is structured as follows: Section 2 discusses about the state-of-the-art works related to shield tunneling parameter matching. The proposed works such as SVM-based shield tunneling parameter matching and PSO-based algorithm to enhance the accuracy and reliability of shield tunneling parameter selection are presented in Section 3. The performance verification of the PSO-based approach is briefed in Section 4. Section 5 details about shield tunneling parameter matching model based on SVM and improved PSO. An extensive case study which is pertaining to the shield tunneling parameter matching approach is elaborated in Section 6. Section 7 explained about discussion and conclusion which is associated with this research work.

2. Literature Review

Within the context of the rapid development of information technology, researchers have improved machine learning algorithms to varying degrees and gradually applied them in several fields [1–4]. Of late, intelligent algorithms are gradually being widely used in the field of civil engineering [5–8], providing an opportunity for the optimization of shield tunneling parameters. As one of the main tunnel construction methods [9–12], the shield method is a complex mechanical process of undisturbed soil damage and reshaping. Since the excavated soil is subjected to shear and extrusion of the cutter head and grouting pressure of shield tail soil, different degrees of settlement and deformation are inevitably caused. At the same time, Shanghai, Hangzhou, Wenzhou, and other coastal cities in China are primarily in soft soil areas with poor antideformation ability. The settlement has a significant impact on tunnel construction to varying degrees, causing heavy economic losses and threatening human life safety [13, 14]. Therefore, the shield construction settlement has become the main problem endangering the health of subway and highway tunnels.

In recent years, the major geotechnical problem of ground subsidence caused by shield construction has attracted the attention of many researchers. Chen et al. [15] combined actual engineering data to build a model. Comparing six machine learning algorithms with traditional multiple linear regression methods, this article discussed the potential and advantages of machine learning algorithms in settlement prediction. Scott et al. [16] optimized and enhanced the soil compressibility prediction model through the SVM algorithm. This work effectively tested the correlation performance between the compressibility index and the soil index characteristics in the settlement calculation.

Hu et al. [17] proposed an extended machine learning framework based on actual data to prove that the PSO-SVR method has the highest accuracy among the three proposed prediction algorithms. To significantly reduce the surface subsidence, the researcher has studied the shield tunneling parameters related to the surface subsidence to improve the tunnel construction level and protect human life safety.

Jing and Gang [18] established a neural network model between shield tunneling parameters and ground settlement and then optimized shield tunneling parameters through a genetic algorithm. Min and Jie [19] proposed the shield tunneling parameter analogy setting method (SAPAS). The combination of the K-means clustering algorithm and the empirical formula setting method improved the practical application effect of the empirical formula.

Tian and Ma [20] tried to use a multidimensional correlation algorithm to optimize the shield tunneling technology and established a parameter correlation model through the Apriori algorithm. Zeng et al. [21] proposed a parameter optimization method based on DBN and applied it to the tunnel project in Wuhan, China. In addition, Bo et al. [22] obtained the best tunneling parameters by utilizing onsite monitoring. These studies, however, have limitations in adjusting the neural network grid weight coefficient, which causes the model to fall into the local optimal. K-means clustering algorithm can only get the local optimal in the iteration, and Apriori algorithm I/O load is large, which will produce too many candidate-project sets and other problems.

3. Methodology

3.1. Particle Swarm Algorithm (PSO). PSO is a stochastic optimization algorithm proposed by Kennedy and Eberhart [23] to simulate biological activities in nature. As a branch of evolutionary computing, PSO has been applied to solve various engineering optimization problems. PSO is different from the genetic algorithm (GA) since GA uses bio-evolution mechanisms such as crossover and mutation operations. But PSO has no such operations. They follow the optimal particle to replace, and the PSO has fewer parameters and is easier to implement.

PSO algorithm mainly relies on two extreme values to update the speed and position. One is the overall optimal solution of all particles, called the global optimal solution $p_g = [g_1, g_2, \ldots g_n]$. The other is the optimal solution of the particle itself in the entire iterative history, called the individual optimal solution $p_i = [p_{i1}, p_{i2}, \ldots p_{\mathrm{in}}]$ where $i = 1, 2, \ldots, M$. The ith particle is denoted by $x_i = [x_{i1}, x_{i2}, \ldots x_{in}]$. The velocity of the ith particle is $v_i = [v_{i1}, v_{i2}, \ldots v_{in}]$.

The iterative formulas are mentioned as follows: the ith particle is expressed as

$$v_{i\,d} = \omega \times v_{i\,d} + c_1\gamma_1\left(p_{i\,d} - x_{i\,d}\right) + c_2\gamma_2\left(p_{g\,d} - x_{g\,d}\right), \quad (1)$$

$$x_{i\,d} = x_{i\,d} + v_{i\,d}, \quad (2)$$

where $p_{i\,d}$ is the individual optimal solution, $p_{g\,d}$ is the global optimal solution, ω is the inertia weight, c_1, c_2 are learning factors, and γ_1, γ_2 are random numbers in the range [0, 1].

To improve the performance of PSO, the inertia weight is adjusted according to the following formula [24]:

$$\omega_t = (\omega_{\max} - \omega_{\min} - \mathrm{d}_1)e^{1/\left[1+\left[\mathrm{d}_2 t/t_{\max}\right]\right]}, \quad (3)$$

where d_1 and d_2 are control factors, the purpose is to control ω between $\omega_{\max}$ and $\omega_{\min}$, $d_1 = 0.2$, $d_2 = 0.7$, $\omega_{\max} - \omega_{\min}$ takes 0.5, and $t_{\max}$ is the maximum number of iterations.

This article further mediates the diversity of particles in PSO to improve the performance of PSO. In each iteration, particles are eliminated according to the proportion of 1/2, 1/3, 1/4, 1/5, and 1/6 to analyze the performance changes of particles, and specific improvement strategies are proposed based on the analysis results.

3.2. Support Vector Machine (SVM). SVM is a supervised machine learning method that can be used for classification and regression problems [25]. The optimal decision functions are constructed by mapping input variables to a high-dimensional linear space based on the principle of structural risk minimization. The appropriate kernel function is helpful to reduce the increase of computational complexity caused by the mapping from low-dimensional space to high-dimensional space. The optimal solution is obtained by sample training. The regression function for SVM is as follows:

$$f(x) = u \times \varphi(x) + b, \quad (4)$$

where u is the weight vector, $\varphi(x)$ is the mapping function, and b is the bias term.

The goal of optimization is

$$\min_{w,b} \frac{1}{2}\omega^2, \quad (5)$$

where points located within the boundary should satisfy $|y_i - (\omega x_i + b)| \le \varepsilon$.

The introduction of nonnegative Lagrange multipliers α_j, α_j^*, η_j, η_j^* further transforms the problem into the following equation:

$$\begin{aligned}\mathscr{L}(\omega, b, \xi, \xi^*, \alpha, \alpha^*, \mu, \mu^*) = {} & \frac{1}{2}\omega^2 + C\sum_{i=1}^{N}(\xi_i + \xi_i^*) - \sum_{i=1}^{N}\mu_i\xi_i - \sum_{i=1}^{N}\mu_i^*\xi_i^* \\ & + \sum_{i=1}^{N}\alpha_i[f(x_i)i - y_i - \epsilon - \xi_i] \\ & + \sum_{i=1}^{N}\alpha_i^*[f(x_i)i - y_i - \epsilon - \xi_i^*],\end{aligned} \quad (6)$$

where C is the penalty factor and ξ_i and ξ_i^* are relaxation factors.

The equivalent duality problem is obtained as follows:

$$\begin{aligned}& \max_{\alpha,\alpha^*} \sum_{i=1}^{N}\left[y_i(\alpha_i^* - \alpha_i) - \int(\alpha_i^* + \alpha)\right] - \frac{1}{2}\sum_{i=1}^{N}\sum_{j=1}^{N}\left[(\alpha_i^* - \alpha_i)(x_i)^T(x_j)(\alpha_j^* - \alpha_j)\right], \\ & \text{s.t.} \quad \sum_{i=1}^{N}(\alpha_i^* - \alpha_i) = 0, \quad 0 \le \alpha_i,\ \alpha_i^* \le C.\end{aligned} \quad (7)$$

Restrictions are as follows:

$$\begin{cases} \alpha_i\alpha_i^* = 0, \quad \xi_i\xi_i^* = 0, \\ (C - \alpha_i)\xi_i = 0, \quad (C - \alpha_i^*)\xi_i^* = 0, \\ \alpha_i\left[f(x) - y - \int -\xi_i\right] = 0, \\ \alpha_i^*\left[y_i - f(x) - \int -\xi_i^*\right] = 0. \end{cases} \quad (8)$$

The bias term b is solved by the Caro required-Kuhn–Tucker condition and is presented as follows:

$$b = y^{(j)} - \sum_{i=1}^{n-k}(\alpha_i^* - \alpha_j)K(x^{(i)}, x^{(j)}) \pm \varepsilon. \quad (9)$$

The final SVM regression prediction model by using quadratic programming yields

$$f(\mathrm{X}) = \sum_{j=1}^{n-k}(\alpha_j^* - \alpha_j)K(x^{(j)}, x) + \overline{b}, \quad (10)$$

where $K(x^{(j)}, x)$ is the kernel function of the SVM.

The kernel functions commonly used in SVM are linear kernel function, polynomial kernel function, radial basis kernel function (RBF), and sigmoid kernel function. RBF kernel function has better convergence properties and is used in significant engineering prediction algorithms. Therefore, RBF is used as the kernel function for SVM models in the paper [26].

4. Improvement and Performance Verification of PSO

4.1. Improvement Method. In PSO, particles get different feasible solutions due to particles flying at different positions. That is, the diversity of viable solutions is called population diversity. Population diversity, also known as extensiveness and uniformity in PSO, is an important measure to evaluate the ability of PSO to search for feasible solutions. Therefore, to improve the population diversity, the paper explores the adjustment strategy of particle diversity by eliminating particles in the ratio of 1/2, 1/3, 1/4, 1/5, and 1/6 each iteration.

The specific experimental improvement strategy of this work is that the particles with smaller fitness values are eliminated in the ratio of 1/2, 1/3, 1/4, 1/5, and 1/6 according to their fitness values. Furthermore, the eliminated particles are generated by initialization. The individual optimal solutions and the global optimal solution are finally updated.

4.2. Validation of the Proposed Improved Algorithm. Experimental simulation analysis based on six benchmark functions is carried out to determine at what ratio the optimal value can be obtained. Table 1 shows the six benchmark functions.

The particle population size is 50, and the number of iterations is 200. The algorithm runs independently 15 times under each elimination ratio. The final results are shown in Tables 2–4.

Tables 1–3 show the optimal results obtained by the PSO with different elimination ratios. The minimum and average are visualized in Figures 1 and 2.

From the curves in Figures 1 and 2, F_1, F_2, and F_4 have higher searchability when the elimination ratio is 1/2. F_3, F_5, and F_6 are relatively close to each other regarding their searchability at each elimination ratio. The difference between each average value of the three benchmark functions F_3, F_5, and F_6 is tiny at each elimination ratio, indicating that the improved PSO has less influence on the stability. When the elimination ratio of F_2 and F_4 is 1/6, the average value is quite different from other elimination ratios. Moreover, it can be seen from the figure that there is a noticeable difference in the average value of F_2 under different elimination ratios, indicating the improved PSO algorithm has a significant impact on the stability of F_2. Except that the proportion is 1/6, the average value difference of F_4 under each elimination proportion is slight and significantly lower than other functions. This indicates that its stability is less affected by the improved PSO algorithm, and the optimization effect of the algorithm is better than other benchmark functions. According to the above analysis, it is clear from the figure that the elimination proportion of the three indicators in different functions is different, and the elimination proportion is not fixed and stable. The optimal value of each function has its own corresponding elimination proportion.

The iterations of six classical functions are shown in Figures 3 to 8. From Figure 3, the algorithm's corresponding elimination ratio of 1/2 is significantly more substantial than the other elimination ratios in the search for superiority before the 60th iteration. Between the 80th and 100th iterations, the searchability of each elimination ratio gradually approaches and starts to enter the local search phase. After the 160th iteration, each elimination ratio slowly converges and shows a clear distinction.

From Figure 4, the elimination ratio of 1/2 in two hundred iterations has better searchability than that under other elimination ratios. Except for the elimination ratio of 1/2, the function is not stable in the other elimination ratios before 100 iterations. After iterations, it gradually enters the local search phase. The searchability of each elimination ratio also slowly becomes an obvious distinction with a large gap, and finally, the function finds the optimal value in the case of an elimination ratio of 1/2.

From Figure 5, the iteration curve declines precipitously in the early stages and enters the local search phase more quickly. Before the 80th iteration, the function had the weakest search ability at an elimination ratio of 1/2. Since the 80th iteration, the searchability at the elimination ratio of 1/2 gradually increases and finally coincides with the iteration curve at the elimination ratio of 1/3. The elimination ratio that makes the function find the optimal value is 1/4. The function characteristics are similar to F_2.

From Figure 6, the iteration curve is clearly different from the other function curves. The function iteration curve as a whole decreases in a stepwise manner. At the same time, it can also be seen that the searchability at the elimination ratio of 1/4 is inferior before 50 iterations. After 50 iterations, its searchability shows a cliff-like growth. But after increasing to a certain level, there is no significant change between 60 and 160 iterations. Although it is further enhanced after the 160th iteration, it is still weaker than other elimination ratios in the end. As the elimination ratio is 1/2 for finding the optimal value, the function's ability to find the optimal value presents the characteristics of first being decisive, then weak, and then powerful. The algorithm gradually enters the convergence stage after 100 iterations and converges at the earliest when the elimination ratio is 1/6.

It can be seen from Figure 7 that the 1/4 elimination ratio has a significant advantage over other elimination ratios before the 70th iteration. In contrast, the functions under other elimination ratios show instability, weaker merit-seeking ability, and smaller gaps. At 80 iterations, the process gradually enters the local search phase under each elimination ratio. The iteration curve begins to converge as the searchability from different elimination ratios gradually stabilizes. The 1/4 elimination ratio that shows an absolute advantage in the first period gradually becomes inferior and finally overlaps with the 1/6 elimination ratio curve. While the 1/5 elimination ratio is inadequate in the first period, it shows a significant increase. This elimination ratio finally obtains the optimal value.

In Figure 8, the algorithm converges late, gradually converges after 120 iterations in each elimination ratio. The algorithm with an elimination ratio of 1/5 converges after 160 iterations. Before the 70th iteration, the elimination proportions did not show their respective advantages. In subsequent iterations, the searchability of the algorithm with an elimination ratio of 1/3 gradually increased and finally found the optimal value. The figure also shows that the merit-seeking ability is chronically inferior throughout the 200 iterations at a 1/4 elimination ratio.

Based on the above result analysis, through the overall analysis of the six benchmark functions and the independent study of each function, the six benchmark functions obtain the optimal solution. However, it is also found that different functions have their own most appropriate elimination ratios, so the min (1/2,1/3,1/4,1/5, and 1/6) strategy is adopted to solve realistic problems. If the same optimal value is obtained under different elimination ratios, the smaller elimination ratio is taken to improve the optimal solution's efficiency.

Table 1: Six benchmark functions used in simulation experiments.

Number	Benchmark function	Range of search	Dimension
1	$F_1 = \sum_{i=1}^{n} x_i^2$	[−10, 10]	20
2	$F_2 = \sum_{i=1}^{n} \lvert x_i \rvert^{i+1}$	[−10, 10]	20
3	$F_3 = \sum_{i=1}^{n} \lvert x \rvert_i + \prod_{i=1}^{n} \lvert x_i \rvert$	[−10, 10]	20
4	$F_4 = \sum_{i=1}^{30} i x_i^4 + \text{Gauss}(0,1)$	[−1.28, 1.28]	30
5	$F_5 = \sum_{i=1}^{n} x_i \sin(x_i) + 0.1 x_i$	[−10, 10]	20
6	$F_6 = 1/4000 \sum_{i=1}^{n} x_i^2 - \prod_{i=1}^{n} \cos + 1 (x_i/\sqrt{i}\ )$	[−200, 200]	20

5. Shield Tunneling Parameter Matching Model Based on SVM and Improved PSO

5.1. Determination of Shield Tunneling Parameters. According to scholars' studies on tunneling parameters [27–32], the following parameters are the main ones affecting shield tunneling construction.

5.1.1. Soil Lateral Pressure Coefficient. The soil lateral pressure coefficient affects the soil state. The soil lateral pressure coefficient needs to be dynamically adjusted to keep the front soil in a state of passive Earth pressure. It is influenced by the surface conditions ahead and above the excavation surface. When the surface settlement is large, the soil lateral pressure coefficient needs to be increased. However, the soil lateral pressure coefficient needs to be reduced while the surface uplift is considerable.

5.1.2. Advancing Speed. The shield advancement speed influences the soil settlement in front of the shield blade. When the propulsion speed is high, the soil in front of the cutter head is easily squeezed by the soil in the soil tank and the panel, causing the surface to bulge. However, the soil in front of the cutter head will have surface settlement due to insufficient pressure at a low propulsion speed.

5.1.3. Grouting Filling Rate. Synchronous grouting is indispensable in the tunnel construction method to fill the construction gap caused by the shield in real time. Because the slurry enters the surrounding soil, the building gap cannot be filled entirely. Whether the building gap is filled will also have a significant impact on the surface. Therefore, the grouting filling rate is closely related to the surface settlement.

5.1.4. Grouting Pressure. When the grouting pressure is too enormous, it will make the slurry flow too much into the surrounding soil, which will improve the grouting rate but not the filling rate of grouting and will have a counterproductive effect. On the contrary, when the grouting pressure is too small, it will not guarantee the slurry injection. The grouting pressure needs to meet a certain pressure to complete the construction gap generated by the shield construction. At the same time, the soil near the end of the shield is uplifted by the extrusion, leaving a certain amount for subsequent consolidation and settlement.

5.1.5. Stopping Time. The shield machine will stop tunneling due to many factors during construction. At this time, the stopping time will have an impact on the surface settlement. With the extension of stopping time, the surface settlement will increase significantly.

5.2. Model Establishment. In the shield tunneling parameter matching process, it is necessary to find a set of optimal parameters within the allowable range of parameters and, finally, achieve the minimum surface settlement. However, the relationship between each tunneling parameter is mutually constrained. Many tunneling parameters cannot be expressed in a simple functional relationship with each other. SVM has the unique advantage of reflecting the complex relationship between the parameters. Therefore, it can be used to establish the relationship model between shield tunneling parameters and surface settlement. Based on the actual engineering data samples, the SVM model is trained. And then, the shield tunneling parameters are optimized by the improved PSO. The specific steps are summarized as follows:

(1) Particle parameters initialization, setting population size, iteration number, learning factor in PSO, Initializing the velocity and position of the particles (shield tunneling parameters) in the PSO, setting the dimensionality and the range of particle positions according to the requirements of different problems, and calculating the particle fitness values.

(2) The particle velocity and position are updated according to equations (1) and (2), respectively. Equation (3) is used to calculate the Inertia weights. The updated particle fitness values are calculated, and the individual extremes and population extremes are updated.

(3) After the update is completed, the particle population is eliminated according to 1/2, 1/3, 1/4, 1/5, and 1/6 for particles with low fitness values. The eliminated particles are generated by re-initialization, and their fitness values are calculated. Individual extremes and population extremes for new particles are updated.

(4) Loop step 2, step 3 until the end of the iteration condition.

(5) The reciprocal of the immense fitness value is used as the final settlement optimization value. The obtained tunneling parameter values are used as a reference for final parameter adjustment in the later stage.

6. Case Study

6.1. Project Introduction. The Earth pressure balance shield machine, with a diameter of 14.27 m, is used for the Shanghai bund tunnel project. The tunnel's total length is 1098 m [33]. The project requires high environmental protection. There are many buildings and historical preservation buildings along the tunnel, which creates many difficulties for the construction and increases the technical difficulty. In terms of geological conditions, the location traversed by the shield machine has a sandy chalk layer and clayey chalk soil interspersed with a chalky clay layer, which is prone to collapse and sand flow during excavation. In the construction process, the minimum overburden thickness during shield advance is 8.52 m which belongs to shallow overburden shield construction. This project's shield diameter is 14.27 m, making it more difficult to control the infiltration prevention and shield axis of the cave door.

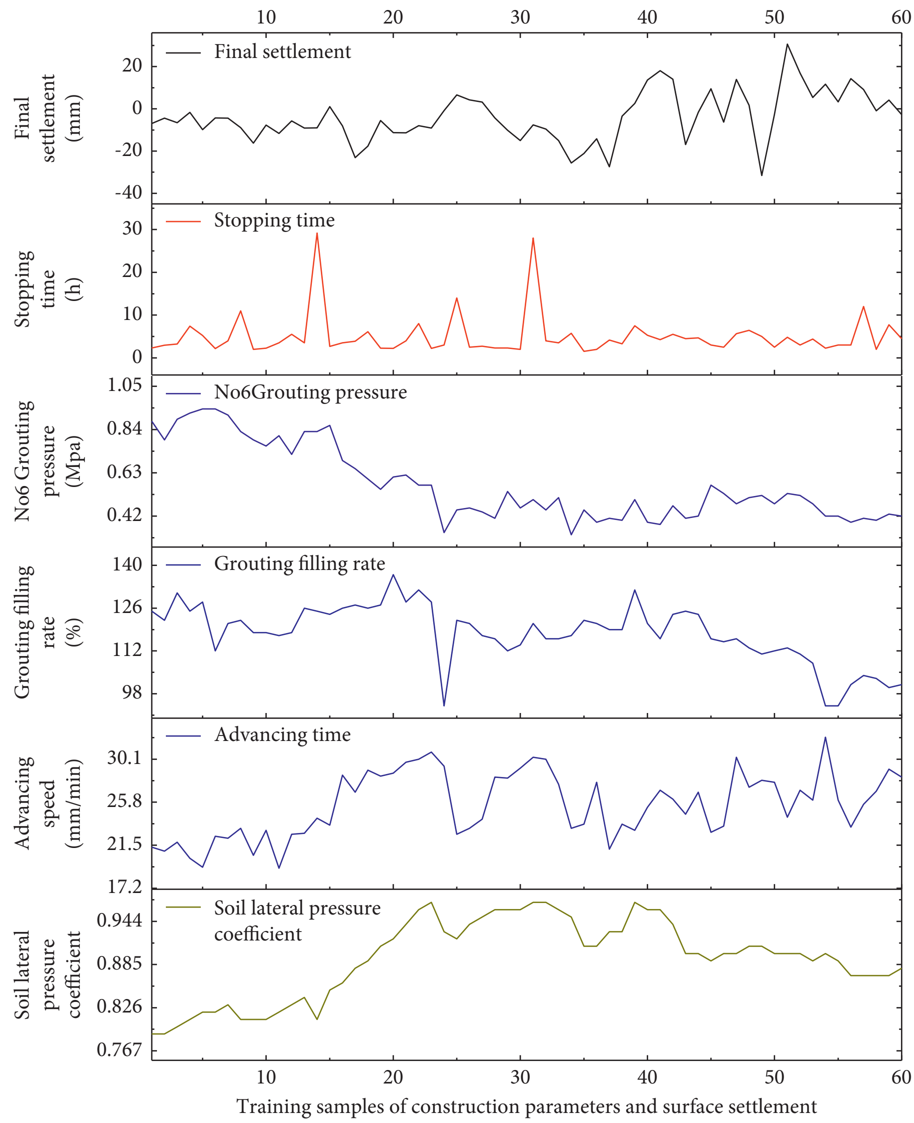

Figure 9: Training samples of construction parameters and surface settlement.

Because a shield machine with a large diameter is used, the usual experience of small diameter shield construction will not be applicable. The setting for the shield tunneling parameters will become more complex. It is necessary to take reasonable measures to set the critical shield tunneling parameters for maintaining the surrounding environment and reducing the impact on the surrounding environment and buildings along the route.

6.2. Optimization of Shield Tunneling Parameters. Sixty sets of monitoring points for the Shanghai Bund Tunnel Project are shown in Figure 9. These data are used to train the SVM model. Collection of real-time datasets in this machine learning task is challenging. So, we have chosen suitable machine learning algorithms which work better even in a small dataset. Support vector machines work better even in small samples [34, 35]. The parameters c and g in SVM were determined to be 18.5 and 2.1, respectively. It can be seen from Figure 10 that the training sample is consistent with the training output. The total error RMSE of the fitting system is 0.0844, indicating that there is good fitting. Combined with the test sample data in Table 5, the difference between the predicted and actual values is 11.8178% below 15%, proving that the model's prediction accuracy is based on SVM for the relationship between shield tunneling parameters and surface settlement is better.

The parameter value in PSO is set: population size is 50, the maximum number of iterations is 200, and the dimension is 5. The range settings for x_1, x_2, x_3, x_4, and x_5, which represent the soil lateral pressure coefficient, advancing speed, grouting filling rate, No6 grouting pressure, and stopping time, are [0, 2], [0, 50], [100, 200], [0, 1], and [0, 20], respectively. Optimization was conducted several times under each elimination ratio (1/2, 1/3, 1/4, 1/5, and 1/6) to obtain the minimum settlement value and corresponding optimal parameter. The fitness values were calculated based on the trained SVM model. Combining Table 6 with Figure 11, we know that under all elimination ratios, the minimum predicted value is 0 at the elimination ratios of 1/3, 1/4, 1/5, and 1/6. Five optimal

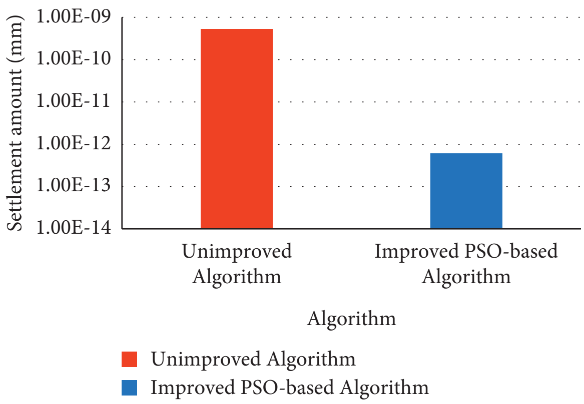

Figure 12: Comparative analysis of improved PSO-based algorithm and unimproved algorithm in terms of prediction of the settlement amount.

parameters are obtained as shown in Table 6, so 1/6 is taken as the elimination ratio for model prediction. Combining Tables 6 and 7, it can be seen that the improved algorithm with "elimination" can find smaller settlement values compared with the unimproved algorithm, which shows that the improved method proposed in this paper can find better settlement values and has certain research significance.

The main parameters considered in the model are soil lateral pressure coefficient, advancing speed, grouting filling rate, No6 grouting pressure, and stopping time. By combining SVM and PSO effectively, the model can obtain optimal parameter matching and the corresponding lowest settlement value. However, because the shield tunneling construction process is highly complex and involves many factors, the tunneling parameter value used in the final project needs to be further adjusted according to the optimized tunneling parameters. Therefore, the accuracy and reliability of the optimized tunneling parameters are essential. The method proposed in this study provides a more effective way for the selection of shield tunneling parameters.

In addition, an improved PSO-based algorithm is compared with an unimproved algorithm, and the settlement amount is recorded. The result is illustrated in Figure 12. It is clearly shown that an improved PSO-based algorithm has less settlement amount when compared to the unimproved algorithm.

7. Discussion and Conclusion

The paper first explores the strategy of adjusting particle diversity in PSO to improve the accuracy and reliability of shield tunneling parameter selection. Based on the analysis for simulation experiments, the particle diversity adjustment strategy is to take the optimal value of different elimination ratios. When the same optimal value is obtained under different elimination ratios, the smaller elimination ratio is used to improve the accuracy and efficiency of the optimal solution.

The SVM is applied to establish the nonlinear relationship between the shield tunneling parameter and the settlement value. Based on the Shanghai Bund Tunnel Project data, the SVM model is trained and tested. The result shows that the SVM model is a good fit and accurately describes the nonlinear relationship between each shield tunneling parameter and the final settlement. Finally, the improved PSO is used to optimize tunneling parameters. The improved PSO predicts that the amount of sedimentation will be close to zero. This is an ideal value. There are many other factors in practical engineering. The tunneling parameter value used in the final actual project needs to be further adjusted according to the optimized tunneling parameters. Therefore, the proposed match model in the paper can provide a better method for the selection of tunneling parameters in practical engineering.

Folk paper-cut art is one of the bright pearls, with a wide range of shapes and a long history, that serves as a model for modern visual communication design in China and encourages designers to think creatively. Integrating emotional elements into a design not only can elicit an emotional response from the viewer but also can make works created using traditional rational thinking more vivid, energetic, and touching. The main focus of this research is on the path and method of incorporating folk paper-cut emotion into visual communication design. The research status of various feature extraction methods and image recognition methods at home and abroad is examined in depth in this paper. For the recognition of distorted images that are not transformed by mathematics, some effective methods are proposed. They are used to recognize artistic images of paper-cut patterns because they can extract effective features that are not affected by translation, rotation, scale change, or small deformation. Experiments have shown that they have a positive impact. The use of folk paper-cut art in visual communication design not only improves the quality of design work but also generates new ideas for the transmission and development of other traditional Chinese cultures.

1. Introduction

As one of the traditional folk art forms in China, paper-cutting has been developing for more than 3,000 years. As one of the most distinctive art forms of folk culture, Chinese traditional paper-cut patterns, after historical baptism and deduction, have become an "image" cultural symbol with its unique artistic aesthetic concept and modeling means and are the visual carriers of Chinese traditional art, culture, and spirit [1]. Chinese modern experimental art and commercial culture design under the multicultural background have made a new interpretation of the "image" of folk paper-cut patterns through different contexts [2, 3].

The use of various forms of artistic expression, such as words, pictures, artistic modeling, and so on, to serve as information transmission and artistic promotion is referred to as visual communication design. The flatness, decoration, and cultural imagery of traditional paper-cut art are interpreted and designed through the visual communication design, which not only can give the visual communication design a strong expressive force but also can inherit and develop the paper-cut art [4–6]. The digital information age necessitates a mode of design thinking that is connected, integrated, systematic, and pluralistic, requiring us to recognize design problems from multiple perspectives and solve them using a holistic approach. Complementary perspectives and methods are one of the design methods that has piqued the author's interest and warrants further investigation [7]. Combining traditional folk paper-cutting with visual communication design and adding folk art to the foundation of modern design not only enriches the connotation of traditional culture but also adds an endless supply of new ideas to visual communication design.

With the blurring of traditional design boundaries and the visualization of emotional factors in design, the integration of emotion in visual communication design has become the decisive factor for the success or failure of design [8]. This paper combines wavelet analysis with other feature extraction methods. Wavelet analysis has the characteristics of multiresolution. If the features of images can be extracted based on wavelet multiresolution, the representation ability of feature vectors to images will be improved. By extracting

WM from the paper-cut pattern image, the multiscale features of the image can be obtained. The mean and standard deviation of different feature components are used to realize the feature selection of N-type patterns. Experiments show that this method can effectively remove noise interference and better identify paper-cut patterns with certain artistic exaggeration.

In this paper, the features and recognition methods of deformed images with nonstrict mathematical transformation are studied. The extracted features are not only geometrically invariant but also can recognize deformed images to some extent. In theory, the method of image recognition is broadened, and combined with the research of paper-cut art, it is applied to computer paper-cut, which lays a foundation for the realization of computer paper-cut.

2. Related Work

Although there were some new names for visual communication design more than ten years ago, it is now buried in the "visual age" and "visual culture." Literature [8] puts forward that visual communication design is a planned and effect-oriented design image generation and communication activity for people to achieve a certain purpose (such as information transmission, influence, promotion, and expression), that is, the design of the design image and its transmission mode. Literature [9–11] hold that visual communication design is a process in which designers transform ideas and concepts into visual symbols to convey information by visual symbols. Literature [12] holds that it includes the design of "visual communication design," graphic design, such as posters, photography, signs, fonts. Literature [13] holds that visual communication design refers to a design activity that uses modeling means and various visual media to convey information, mainly including the design and expression of visual information elements such as graphics, words, colors, images and aims to convey information accurately, quickly, and effectively. The design process mainly includes the generation of plans and ideas, translation and generation of visual images, and presentation and transmission of visual information. Literature [14] introduces the relationship between people and things in design and emphasizes how to grasp the design idea of starting from people's needs and returning to people when human beings enter the information age of audiovisual new sensibility from the age of reading and writing. Literature [15, 16] focus on the analysis of designers and audiences, discuss the differences between the psychological starting points of designers and audiences, and finally attribute the core concerns of visual design to the practicality of products and the emotional experience of audiences. Literature [17] has a more in-depth exposition on designer psychology, product experience, and experimental design of design psychology. Literature [18] reveals the general creative psychological activity law of art designers themselves in the creative process and guides and meets the psychological needs of consumers through design.

Template matching is the simplest method of image recognition, and it can be divided into two categories: rigid body shape matching and deformed template matching. Template matching is the process of comparing the template to the image to be recognized in order to find areas in the image that are the same or similar. Character recognition, face recognition, hand shape recognition, and other fields all use template recognition. Several finger outlines in the whole hand shape are extracted as templates in the literature [19], and the recognition rate is greatly improved by using the method of block matching and the function of direction angle. The Clifford convolution algorithm of template matching is used in literature [20] to improve the grid division of flow fields for a given flow field. Literature [21] proposes a fast template matching method that identifies the target by combining the central invariant moment with the template, aiming to overcome the drawbacks of large computation, rotation, and scale influence. The sample data from high-dimensional space were projected into one-dimensional space by literature [22] so that different samples were as far apart as possible, while similar samples were as close as possible. Literature [23] improved it by employing weighted or adaptive methods, resulting in a more accurate minimum distance method. Literature [24] investigated the graphic generation method for paper-cut patterns and used computer graphics technology to generate spline curves to construct paper-cut patterns, resulting in the creation of a computer paper-cut system based on patterns and the automation of the paper-cut system. Literature [25] is a breakthrough in the field of paper-cut pattern design, employing a genetic algorithm to generate a variety of paper-cut patterns in various styles.

3. Research Method

3.1. Convey the Emotional Integration of the Basic Elements of Folk Paper-Cutting in Visual Design. Folk paper-cut art, as a special form of artistic expression, has been loved by people in the process of its emergence and development, and working people pin their beautiful feelings on paper-cut. As a unique symbol, paper-cutting also has its unique use-value, conveying the faith of working people. Chinese traditional paper-cut art contains the aesthetic taste and modeling creation of working people. Working people pin their feelings on paper-cutting art and show their interest in life through different paper-cutting art forms. Visual communication design mainly analyzes and summarizes the images in paper-cut art and then displays them in the design works.

Traditional Chinese paper-cut art is primarily red with white accents, with simple red and white colors used to express paper-cut art. Paper-cut artistic modeling primarily expresses people's emotional experiences by combining reality and reality and incorporating images of everyday animals into paper-cut. Working people's lives are mostly represented by paper-cutting art. They can think creatively and express themselves exaggeratedly through various modeling patterns because they are not overly bound. This is similar to western artistic expression, and the works of art are romantic in nature. Direct graphical emotional expression and indirect graphical emotional expression are the two types of graphical emotional expression. The direct expression of graphic emotion is a realism built according to the original appearance of objective images, with a shape that is similar to the actual shape, reflecting true details and the typical essence of images. Indirect graphic forms are conceptual symbols created according to the prototype's concept and meaning, making it impossible for people to distinguish the original image and meaning. They are graphic forms with objective meaning derived from pure geometric concepts such as points, lines, planes, bodies, and their combinations or graphic forms with simple characteristics derived from them, and they are widely used in business, such as logo design.

Image motion is one of the most characteristic design factors, and it is also the fundamental difference from the traditional static visual communication design form. The way of movement can be divided into the movement of visual elements (images, characters, colors, lines, etc.) and the movement of design space areas (as shown in Figure 1).

For the movement with visual elements as the main body, it can generally be realized through image change, position change, and nature change. These methods draw lessons from the methods of visual communication design with printing as the carrier, but the difference is that in dynamic activities, more emphasis is placed on the process evolution and dynamic changes, rather than a single result. The visual elements can move in a two-dimensional plane or three-dimensional space.

Because there are so many different ways to express punctuality, different forms will have different emotional expressions. A larger point, for example, will give the impression of conciseness, simplicity, and lack of hierarchy. Small dots will be rich, gleaming, insignificant, and dispersed. There is a sense of detention and order. Dots are athletic, supple, and flawless. People will experience various emotions as a result of various combinations. The sum of point, line, and surface emotions creates modeling emotion. The incomplete shape gives people a sense of regret and sigh; complete shape gives people a sense of complete and complete emotional feeling. Virtual bodies give people a sense of emptiness and floating nothingness, while entities provide a real and credible sense of existence. People with a large shape experience a lot of depression, while those with a small shape experience a tight contraction. Geometry instills a sense of rigor in people, while freedom instills a sense of relaxation. Abstract modeling gives people a sense of science fiction transcendence and psychedelic mystery.

Decorative design is mainly for external image design of decorations, including external image and internal concept communication. Therefore, designers can deform the original patterns by exaggeration and pay attention to the use of paper-cut art concepts to enhance its cultural connotation to arouse consumers' consumption resonance. Therefore, in the decoration design, learn the exaggerated techniques of traditional paper-cutting art, update the design concept of visual communication, and improve the design level.

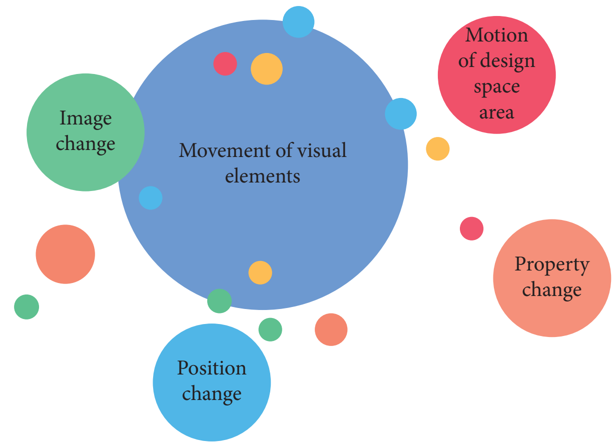

Figure 1: Analysis of motion mode of a dynamic image.

3.2. Research on Paper-Cut Pattern Recognition

3.2.1. Pattern Recognition Based on R-T and SVD. Paper-cut pattern pretreatment is an important link in pattern recognition and classification. The preprocessing of this paper includes background denoising, image graying, and binarization, as shown in Figure 2.

Compared with other crafts, paper-cutting materials and tools are the simplest, mainly composed of paper, scissors, carving knives, and so on. Because of the tools, paper-cutting has its own characteristics in artistic features. On the basis of its hollowed-out shape, there are two situations, that is, lines are connected or lines are broken. The paper-cutting has a simple and exaggerated aesthetic feeling. Simple modeling, clever and imaginative artistic conception, concise structure, and bright colors have become the important features of paper-cutting art.

The mathematician Radon studied the problem of finding the function along the integral value of a straight line or plane in two- and three-dimensional functions, which is called R-T (R-transformation) of Euler space. Nowadays, it has been widely used and played an important role in image recognition.

The radon transform of an N-dimensional function $f(x_1, x_2, \ldots, x_n)$ is defined as the integral value on the $n-1$-dimensional hyperplane. When $N = 2$, the radon transform of the function $f(x, y) \in L^2(D)$ on the plane refers to the integral of $f(x, y)$ along all possible straight lines, which is recorded as follows:

$$\begin{aligned} p(t,\theta) &= R(t,\theta)\{f(x,y)\} \\ &= \int\int_D f(x,y)\delta(t - x\cos\theta - y\sin\theta)\mathrm{d}x\mathrm{d}y, \end{aligned} \tag{1}$$

where $\theta \in [0, 2\pi]$, δ is the impact function, and D can be a circle or other plane area.

Let image $f(x, y)$ be $p(t, \theta)$ after radon transform, and continuous R-T definition is as follows:

$$R(\theta) = \int_{-\infty}^{\infty} p^2(t,\theta)\mathrm{d}t. \tag{2}$$

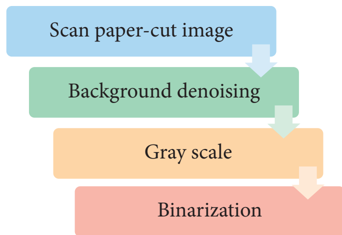

FIGURE 2: Paper-cut pattern.

That is, on the basis of radon transform, the integration of $p^2(t,\theta)$ along t can transform the two-dimensional information into one-dimensional.

Image scale change λ, R-T, there are

$$\int_{-\infty}^{\infty}\left(\frac{1}{\lambda}p(\lambda t,\theta)\right)^2 \mathrm{d}t \overset{\rho=\lambda t}{=} \frac{1}{\lambda^3}\int_{-\infty}^{\infty} p^2(p,\theta)\mathrm{d}\rho = \frac{1}{\lambda^3}R(\theta). \tag{3}$$

From the above properties, it can be known that the image after R-T is obviously invariant of translation. However, when the image is rotated, just like the radon transform, there will be a line shift phenomenon, but other things remain unchanged.

SVD (singular value decomposition) is an effective method to extract algebraic features of images. According to matrix theory, SVD is an important matrix decomposition method in linear algebra, and it has many excellent characteristics in describing the distribution characteristics of matrix data. In an image, any matrix can be decomposed into diagonal matrices by SVD.

The SVD theorem includes

$$\begin{aligned} AA^T u &= \lambda^2 u, \\ A^T A u &= \lambda^2 u. \end{aligned} \tag{4}$$

That is, it has the same singular value for A, A^T. Therefore, if the image matrix is transposed, the singular value feature will not change.

3.2.2. Pattern Recognition Algorithm Based on WM. Color is not only a composition element but also a dominant element, and it is also an important determinant of the emotion of design works. Only when you know the color can you use the right color to enhance the emotion of the design work. By skillfully using and controlling colors, you can strengthen your emotions in the direction you need.

The moment has been widely used in the field of image recognition, and its invariance of translation, rotation, and scaling can well represent the features of images. Paper-cut image has its unique characteristics, and its image is distorted and exaggerated. Paper-cut techniques can be divided into female cutting and male cutting, resulting in deformed patterns, which can lead to errors only by relying on intuitive features to identify. Most importantly, the image of paper-cut patterns is different from other images. Two similar patterns do not necessarily have strict mathematical transformation. They are the result of artistic exaggeration and deformation, and they are arbitrary.

In order to achieve the desired effect, follow the characteristics of WD (wavelength decomposition) to get the details of the pattern, and use the multiscale characteristics of WD to describe the changing characteristics of images on different scales, which is more suitable for image information processing.

Let $f(x,y)$ represent a continuous function, and the continuous standard moment of the image can be defined as follows:

$$m_{pq} = \iint x^p y^p f(x,y)\mathrm{d}x\mathrm{d}y. \tag{5}$$

By transforming the equation from rectangular coordinate system to polar coordinate system, the moment characteristic expression with rotation invariance can be obtained as follows:

$$F_{\mathrm{pq}} = \iint f(r,\theta)g_p(r)e^{jq\theta}r\mathrm{d}r\mathrm{d}\theta, \tag{6}$$

where $g_p(r)$ is the radial component of the transformation kernel and $e^{jq\theta}$ is the angular component of the transformation kernel. Order

$$S_q(r) = \int f(r,\theta)e^{jq\theta}\mathrm{d}\theta. \tag{7}$$

Further change the above formula into

$$F_{\mathrm{pq}} = \int S_q(r)g_p(r)\mathrm{d}r. \tag{8}$$

If $g_p(r)$ is a function of the local definition of the variable r, the difference between samples may be larger, and the noise will inevitably decrease so that the change areas of sample features are unlikely to overlap with each other, which is a key idea to extract invariant moments of appropriate order from images by using wavelet transform.

Here, the WM (wavelength moment) extracted by the above method is used as the feature vector of the paper-cut pattern. However, due to the high dimension of WM features extracted by different scale factors, selecting favorable features reasonably and effectively and reducing feature dimensions appropriately can eliminate redundancy, speed up operation, and improve classification efficiency.

There are w pattern classes to be distinguished, and each pattern class has one sample. Let the sample be s, where i is the i-th sample of pattern r and k is the k-th feature component of sample i; then the mean and standard deviation of the k th feature component of pattern r are as follows:

$$\begin{aligned} m_k^r &= \frac{1}{l}\sum_{k=1}^{n} X_k^r, \\ \delta_k^r &= \sqrt{\frac{1}{l}\sum_{k=1}^{n}\left(X_{ik}^r - X_k^r\right)}. \end{aligned} \tag{9}$$

For two kinds of samples, the larger the gap between the mean values of a certain one-dimensional feature component and the smaller the sum of variance, the better the separability of the component.

If China's modern visual art is to establish its own cultural identity in the international cultural exchange world, it must research and utilize its own country's traditional cultural resources while innovating and developing modern visual art and design. The significance of this issue has grown in recent years. As a result, the significance of this paper is to innovate the "image" of traditional folk paper-cut patterns using western theories, to inherit and express Chinese traditional culture in the most appropriate form, and to build Chinese contemporary visual art and design with local cultural connotation.

4. Results Analysis and Discussion

4.1. Experimental Results and Analysis of R-T and SVD Recognition. The artistic conception beauty of design works is the highest level of spiritual function and the highest requirement for visual design, which means that the environment has a specific atmosphere or profound artistic conception. The space mentioned here also has two meanings. The first one is the real space, that is, the real three-dimensional design and expression space. The second is the picture space, that is, the space of false two-dimensional plane design and expression. The visual communication design is more focused on the latter's space design.

The use of corresponding association to change unfamiliar to familiar, and to change the cognition, understanding, feeling, and experience of the other object to the theme to be expressed, is primarily used in the theme expression of visual communication design. The audience is more familiar with the other object than the theme to be expressed, making it easier for them to understand and accept it. People's imagination and creation can be used to enhance the theme's connotation. As a result, it is not advisable for China's modern visual art design to deliberately pursue national traditions in order to compensate for deficiencies or to westernize in order to accommodate international styles. Instead of sticking to certain appearances and styles, one of the best development directions is to learn from the expression of "image" in folk paper-cut patterns and create contemporary visual art with national cultural connotations.

R-T experiments are carried out on images with different geometric transformations of the same pattern, and the results are shown in Figure 3.

From this, the nature of R-T translation, scaling invariance, and rotation cycle motion can be seen clearly. Because the singular value of the matrix is independent of the position of rows and columns, the rotation variation can be eliminated according to this characteristic.

Design emotion and design thinking are the basic elements that any art category should possess. Emotion without proper thinking cannot constitute design, and thinking that cannot express emotion cannot be regarded as art either. In order to make visual design works have a profound artistic conception, from the creative point of view, it is necessary to see the situation and express feelings first and then express feelings, that is, entrust things to express feelings. From the perspective of appreciation, it means that the appreciator can be inspired, felt, edified, and even shocked by inspiration from the perceived spatial environment, which can arouse the resonance of thoughts and emotions, that is, feel the situation and feel the emotion suddenly.

The experimental results of noise resistance comparison between the two methods are shown in Figure 4. It can be seen that this algorithm is more robust than radon invariants and can well overcome the influence of noise.

The following shows that the algorithm in this paper is more effective in translation, rotation, scale invariance, and similar image recognition than the algorithm in reference [24]. The experimental results are shown in Figure 5.

The features obtained by using R-T and SVD are invariant, as shown in Figure 5, and the algorithm is simpler and more effective than radon moment invariants. R-T has a minor effect on the scale here, which is primarily due to some jaggies in the enlarged image. Visual communication design is based on artistic ideas and modeling characteristics, deconstructs folk paper-cut art expression skills again, and perfectly combines folk paper-cut with visual communication design, enriching the category of visual communication design. Visual communication design has evolved into a new form of personalized and traditional artistic expression in recent years.

The second group of experiments is feature extraction of similar images. Here, only some illustrations are listed to illustrate their singular value features, as shown in Figure 6.

It can be seen from Figure 6 that the invariant features constructed by radon are scattered, and the features in the same category differ greatly, so the method in reference [24] is not suitable for feature extraction of deformed images. The method of R-T and SVD is better.

Modern visual communication design is the reconstruction of graphics and images, and it is based on universal visual language to create a lot. Instead of sticking to the expression of objective images, the expression of ideas is usually carried out with the help of designers' subjective thinking mode, which will come from everyday life and all kinds of things.

In this paper, a large number of experiments have been carried out on seven kinds of patterns, which proves that this method can effectively extract invariant features. Due to the limitation of space, only four samples are listed for each of the following patterns, as shown in Figure 7.

From Figure 7, it can be seen that the characteristics of these seven modes are different, but they are relatively concentrated on the whole. In recognition training, those patterns that are too scattered can be removed, which is conducive to correct pattern classification. For patterns with complex deformation, there will be some cross-feature values.

Visual communication design should not only highly summarize the folk paper-cut art but also highly purify these artistic shapes, so as to find a concise and clear modeling image to embody in the visual communication design, thus

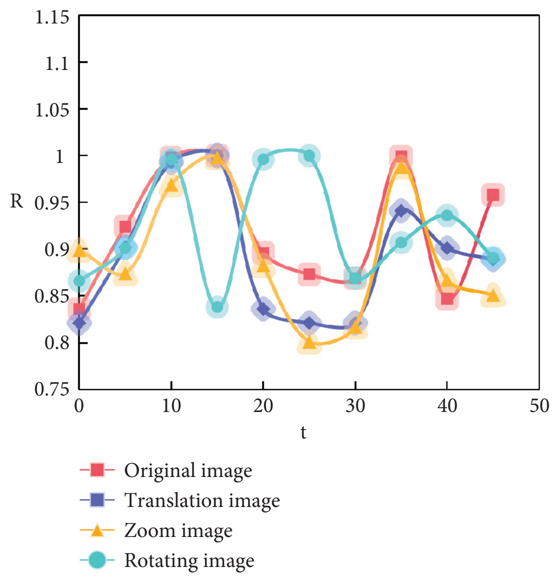

FIGURE 3: The results of geometric transformation and original graph R-T.

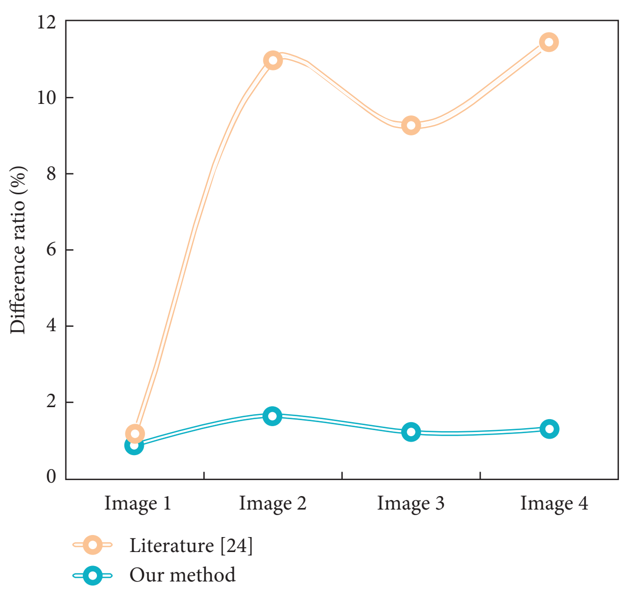

FIGURE 4: Comparison of noise resistance between two methods.

enhancing the artistic appeal. With the continuous development of science and technology, the performance field of visual communication design has also brought new changes, with more emphasis on the integration of traditional and modern elements.

4.2. Analysis of Pattern Recognition Results Based on WM. Visual communication design is not only the fullest beautification and decoration of artistic image but also the ideological expression of artistic creators. For example, the auspicious symbols in folk paper-cut art are applied to visual communication design, which shows the lofty idea of the happy life of the folk people and unique artistic skills. Visual communication design conveys realistic art and different kinds of artworks all present the public's thinking mode and aesthetic concept.

Sort each column from largest to smallest and set the threshold value to the average of the first three feature components. As the final feature vector, choose the feature component with a resolution greater than the threshold value. Despite the high resolution of some feature components, their feature values are small and have little impact on the Euclidean distance classifier. As a result, such feature vectors can be directly discarded to reduce redundancy and improve calculation speed. The identification result of WM is shown in Figure 8.

According to the above Figure 8, it can be seen that the WM method has a good recognition effect for different types of patterns. The high recognition rate of WM is mainly attributed to WM's grasp of details. The WM features extracted after image normalization are invariant to translation, scaling, and rotation of moment features. At the same time, the multiscale characteristics of WM features make WM invariants represent not only global features of images but also local features, so they can better represent the differences in image details and have a higher recognition rate when identifying similar objects.

The feature extraction method proposed in this paper is based on WD. Here, the feature extraction proposed in this paper is compared with other recognition methods, as shown in Figure 9.

According to Figure 9, it can be seen that among the above four feature extraction methods based on wavelet transform, WM has the highest recognition rate, mainly due to the multiscale characteristics of WM features, which makes WM invariants not only represent global features of images but also represent local features. However, its feature extraction process is cumbersome, and at the same time, it is complicated to select the extracted features.

The forms of folk paper-cutting collide with new energy and new technology in the development of modern design, absorbing the cultural characteristics of various styles and resulting in certain creations. It is reexhibited in a brand-new form through various expressions of visual communication design, resulting in folk art that not only meets the needs of the times but also retains its own distinctive characteristics. The paper-cut image is a very real modeling language with more prominent morphological features in traditional visual elements. Artists combine the ever-changing artistic images of folk paper-cutting with contemporary modeling languages and artistic forms to provide people with endless emotional experiences and a happy atmosphere. Each of us has a deep understanding of these symbolic languages and ideologies. After historical changes, people continue to love and recognize them, and they have become a popular artistic pursuit in the public's minds.

People process the inherent attributes of things, and with the symbolic connotation of art, folk paper-cutting uses a lot of decorative techniques of symbols, metaphors, and metonymies to convey emotions and conveys happy wishes. Modern designers use this expression to exert great creativity and imagination, expand the inherent space of design,

create more valuable artistic works, and form the inherent artistic language of folk local design.

5. Conclusion

Chinese traditional paper-cut art modeling has become increasingly popular as modern society has progressed. In the design process of artworks, people always incorporate patterns in paper-cut art. Paper-cut art can provide materials for designers to innovate when incorporated into modern visual communication works. These works of art can pique people's interests and help them communicate their charm more effectively. It is the key link between Chinese culture and world art, and the folk forms it contains are exactly what modern visual communication seeks. Today, with the rapid advancement of science and technology, the folk paper-cut art will be presented to the world with a brand-new creative technique, and the entire aesthetic form will be developed and can be extended and inherited for a long time, in order to preserve the folk art more completely. This paper also focuses on the method of feature extraction. The structural features of the target are represented by the features extracted in this paper, which are not affected by translation, rotation, or scale transformations and have good robustness. Experiments have shown that these techniques are effective.

The next step will be to develop a paper-cutting-friendly image segmentation algorithm. Image segmentation will divide and identify a complete paper-cut image into individual patterns in several pattern libraries, allowing complex patterns to be recognized.

Data Availability

The data used to support the findings of this study are included within the article.

Strain measurement technology plays an irreplaceable role in measuring the force change characteristics of mechanical components and monitoring important engineering structures. In structural health monitoring, dynamic stress and strain testing is the main way to determine its overall fatigue, and excessive stress will seriously affect the strength of the structure, causing the structure to deform or even break, which will affect the reliability of the experiment and the use of workpieces, so it is of great significance to carry out dynamic stress and strain tests on the structure. Resistance strain measurement technology is widely used in the civil engineering industry, but the principles of modern physics technology are unknown to many practitioners. Data fusion technology or information fusion technology is also called multisensor fusion technology. Using computer technology to automatically analyze and integrate the data processing process of the detection data from multiple sensors according to time sequence and certain criteria, it can complete the required decision-making and judgment.

1. Introduction

With the development of economy and technology and the progress of science and technology, more and more cars, airplanes, and ships are connected to people's daily life, and people have put forward higher requirements for their safety performance [1]. When the vehicle is running at various speeds and different road sections, the wheels are excited by the ground irregularly. This irregular random excitation causes irregular vibration of the body structure, that is, random vibration. In order to meet its safety requirements, it is an important way to conduct health monitoring to evaluate its structural safety performance. As a result, strain measurement technology emerged.

Large-scale machinery products are increasingly finding their way into a variety of fields as modern industry progresses. The strength of the product structure is very noticeable due to its large structure and important use occasions. In the research and implementation of modern engineering projects, strain measurement technology is an indispensable technology. It has a lot of potential for application and research. The strain value and its change law at various points on the structure are determined using the electrical measurement method, with a thorough understanding and grasp of the internal force distribution law and the stress situation of the body structure [2], as well as a finite element analysis and calculation of the structure. The strain value and change law at certain points on the structure are measured by the electrical measurement method in order to obtain the statistical characteristics of the stress and strain of the body structure, and the finite element analysis and body structure calculation are used to evaluate the strength of the body structure and propose a more reasonable solution. Structure must be improved. Large structures cannot be scaled up by small structures, and their strength cannot be increased linearly in proportion to the strength of small structures from a design standpoint. In addition, some special processing methods in the manufacture of large structures make large structures more effective in actual use. Intensity is full of variables [3]. After the structural strain signal output by the resistance strain gauge is amplified by the dynamic resistance strain gauge, the high-resistance output terminal is used to record the waveform of the tape drive, and the low-resistance output terminal is output to the light oscilloscope for waveform observation, monitoring, and selective recording. The electrical measurement method is a traditional method, which is widely used and the technology is very mature. Electrical measurement technology has developed rapidly due to its close integration with production practice. It has not only achieved high scientific and technological achievements in the research of theory, detection components, measurement and recording devices, test components, technology, and methods in harsh environments. Due to the large number of measurement points, long distances, and difficulty in loading, the requirements for the tester are high. There must be enough channels to meet the simultaneous measurement to avoid the trouble of repeated loading in the group test [4]. From the strain record waveform of the body structure, the time history is very arbitrary, and there is no repetitive phenomenon. However, when the overall analysis is performed using the methods of probability theory and statistical mechanics, there is a certain statistical regularity in the random process, which can be described by some statistical characteristic quantities and functions.

The painful lesson teaches us that the structure's safety performance not only affects project progress, but also puts people's safety in jeopardy, necessitating immediate structural health monitoring [5]. The accuracy of the strain value sampling is a key step that directly affects the analysis and calculation of the strength of the car body structure and whether you can draw the correct conclusion. Strain is an important metric for monitoring structural health. Strain is an important metric that reflects the structural integrity. The strain state is usually linked to a component's failure. To measure the strain on the structure's surface, the strain electrical measurement method employs a resistance strain gauge as a sensing element. From the 1930s to the present, it has evolved into a complete system. It is now a widely used method of strain measurement [6]. Because the structural damage caused by dynamic loading is often due to the dynamic pressure or strain on the structure exceeding the maximum value that the structure can withstand, regular evaluation of dynamic stress or strain is very important to effectively avoid dangerous accidents. In the strain measurement technology, the resistance strain method uses the generalized Hooke's law to find the stress by measuring the strain. The measurement accuracy is high, the sensitivity is good, and the method is simple. It has a wide range of applications and developments in the detection of building structures [7]. This article will introduce a single-chip microcomputer acquisition and processing system for dynamic (stress) and strain measurement of body structure strength. It has the characteristics of low cost, simple hardware structure, high accuracy, and reliability.

2. Related Work

Literature [8] conducted a dynamic stress test for local cracking in the cab of a new type of truck and analyzed the dynamic response of the measuring point in the time domain and frequency spectrum, pointing out the direction for cab structural improvement. The tangential wheel-rail force and lateral wheel-rail force of the power wheel axle of a 300 km/h high-speed EMU were identified using the different directions of strain gauges to be pasted and the way of forming electric bridges in [9], and a finite element model was built to obtain the load and strain relationship. The strain electrical measurement method is used in [10] to test the dynamic strain of the suspension frame under the conditions of general flat bottom, double-wheel crossing, and single-wheel crossing of the ditch, and it is combined with VC++ for data processing to obtain the stress condition and the stress when the wheel passes through the ditch. Literature [11] uses the ECAL/AMS-02 dynamic strain measurement system, a three-way resistance strain gauge, a temperature compensation sheet, and an extrapolation method to calculate the obtained strain results to obtain the maximum principal value of each point. Strain and principal stress testing have produced positive results, and strain testing technology has been improved and expanded. To reduce the impact of temperature variations on measurement results, [12] considers the impact of environmental temperature on the strain gauge in a variety of ways and employs the Huygens bridge circuit with a temperature compensation gauge to derive the expression for the heat output, which is the power output. The basic idea of the effective independence method proposed in [13] is to gradually fire off those degrees of freedom that contribute the least to the independence of the target parameters, so as to achieve the best spatial resolution of the target. Literature [14] proposed the use of perturbation analysis method to derive the relationship between sensor position and recognition error, so as to minimize the target recognition error obtained by the configured sensor network. Literature [15] developed a strain measuring instrument to solve the problem of strain measurement, which was subsequently put into production by Fairbanks and Ewing, which opened the curtain on the evolution and development of strain measuring instruments. Literature [16] combines the concept of Huston's design with the science and technology that keeps pace with the times and introduces a large number of advanced concepts into strain measurement. According to the connection state of the device and the object under test during the experiment, the strain measurement methods can be divided into contact strain measurement and noncontact strain measurement. Literature [17] embeds the optical fiber inside the composite material, resulting in a new type of optical fiber smart skin when combined with the distributed optical fiber strain measurement system. In [18] to calibrate the external parameters, the GRASP Laboratory at the University of Pennsylvania uses a straight line to represent the lane. Song Xuefeng et al. used the ground grid for calibration and introduced edge extraction in their paper [19]. In [20] image processing techniques such as the Hough transform and vanishing point detection were used to detect straight lines in both vertical and horizontal directions on the grid-like ground image, determine the position of the calibration point, and finally achieve rapid camera calibration. Li Qing et al. proposed a simple and practical three-line calibration method in [21]. This method only requires three parallel straight lines on flat ground and then determining the intersection of these three straight lines and the other three points in the image, either manually or automatically. Without a dedicated location, the camera's external parameters can be calibrated.

This article takes the single-chip microcomputer as the object, analyzes the structural strength dynamic strain measurement system, and explains its advantages. The system has a wide range of applications in the field of vehicle structural strength dynamic strain. Among them, the application of data fusion can reduce the impact of the uncertainty of each sensor and avoid the limitations of a single sensor. The fault diagnosis system of multisensor data fusion technology based on fuzzy mathematics and DS evidence theory is selected based on the decision-making layer and features. The layer-assisted method gives full play to the superiority of this algorithm.

3. Numerical Simulation

3.1. Displacement Mode Theory. In the dynamic analysis of the structure, the mode refers to the unique properties of the system structure. When a rod system such as a climbing dome is used for the analysis of the construction forming form, it is necessary to solve the mechanism displacement mode of the system. When the organization is singular, the eigenvalues of the submatrix of the control variable or the state variable in the overall balance matrix of the organization decrease, and the phenomenon of nonrow full rank occurs. During the service period of the structure, due to the influence of natural disasters, environmental loads, material aging, and other unfavorable factors, damage accumulation and resistance attenuation will occur [22]. Generally, accelerometers are often used to measure response in modal tests. Large errors may occur for light and small specimens due to the additional mass. Although the mass elimination technique can improve some accuracy, it is often not ideal. Traditional modal theory includes real modal theory and complex modal theory. It studies and describes the natural vibration characteristics of the system. Its essence is a coordinate transformation process. The displacement modal difference curve is shown in Figure 1.

Solving the dynamics equations of the structure into the sum of a series of single-degree-of-freedom dynamics equations brings great convenience to theoretical analysis or experimental research. In modern engineering, many structural systems are actually linked mechanisms, such as climbing dome, deployable structure, etc. In order to meet the needs of construction or use, it is usually necessary to obtain the movement trend of the mechanism in the current configuration. In the simulation, it is found that the existence of the mechanism's singular points makes the mechanism's movement uncertain. At the singular point, the phenomenon of "dead point" may occur, or bifurcation may occur, that is, the mechanism moves according to an undesigned motion path, and the problem of out-of-control movement occurs. This problem does not exist with the resistance wire, which is convenient to find the light weight and large bearing capacity. With the principal stress and principal strain, the transfer function measurement is as convenient as the acceleration method in identifying the displacement mode. This is undoubtedly very valuable for reducing test costs, improving test accuracy, and expanding the use of strain gauges. The real mode theory has a long history. It was developed from the undamped linear structural vibration conservative system and later applied to a variety of special structural vibration systems [23]. The orthogonal condition is its theoretical foundation. The mechanism displacement mode usually describes the movement trend of the mechanism system, and the movement trend of the mechanism system can be obtained by linear superposition of the mechanism displacement modes present in the current configuration of the mechanism system. The smallest nonzero singular value of the mechanism coordination matrix or balance matrix at the bifurcation point does not necessarily approach zero; that is, the number of mechanism displacement modes at the bifurcation point does not necessarily increase, whether it is a single-degree-of-freedom system or a multi-degree-of-freedom system.

Assuming that the linear mass $\overline{m}$ has nothing to do with the position x and the bending stiffness EI is related to the position x, the undamped free vibration equation is

$$\frac{2}{x^2} EI(x)^2 \frac{u(x,t)}{x^2} + \overline{m}^2 \frac{u(x,t)}{t^2} = 0. \quad (1)$$

According to the vibration theory, the solution of (1), that is, the free vibration displacement $u(x,t)$, can be expressed as the superposition of modes:

$$\mu(x,t) = a_{r=1}^{\circ} j_r(x) n_r(t), \quad (2)$$

where r is the mode order; $\phi_r(x)$ is the displacement mode; $n_r(t)$ is the displacement mode coordinate.

Substitute (2) into (1), and let

$$w_r^2 = -\frac{n_r^2(t)}{n_r(t)}. \quad (3)$$

Then the fourth-order differential form corresponding to the rth mode shape can be obtained:

$$j_r^{(4)}(x) = \frac{w_r^2 \overline{m}}{EI(x)} j_r(x) - \frac{2EI\varphi(x)}{EI(x)} j_r^{ii}(x) - \frac{EI^{ii}(x)}{EI(x)} j_r^2(x). \quad (4)$$

where w_r is a function of the generalized coordinates corresponding to the rth order.

If local damage occurs, the bending stiffness will also be reduced to a certain extent; that is, the stiffness distribution is no longer a constant, but a variable related to the position. The following functions are used here to describe the damage mode:

When injury occurs, $EI(x) = EI_0(1 - a\cos^2 t)$, where

$$(1-b)x_c < x < (1-b)x_c,$$
$$t = \frac{p}{2}\frac{x - x_c^n}{bx_c}. \quad (5)$$

When the structure is intact, $EI(x) = EI_0$, where

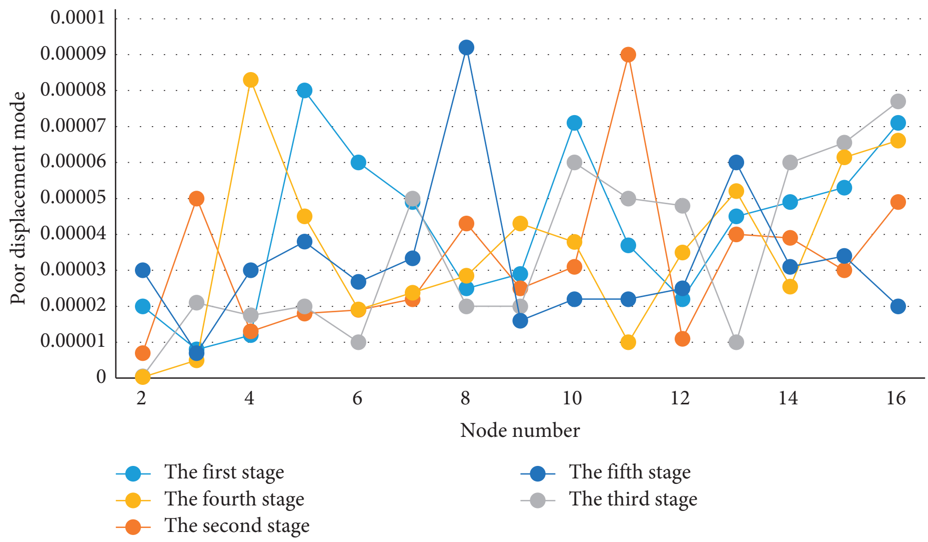

Figure 1: Displacement modal difference curve.

$$0\#x\,(1-b)x_c \text{ or } (1+b)x_c\#x\,L, \tag{6}$$

where EI_0 is the perfect bending stiffness; a, β, and n are the damage constants; L is the length; x_c is the center coordinate of the damage area.

The 4th derivative of the displacement mode cannot be measured directly in actual engineering structures, but it can be measured indirectly from the displacement mode; that is, the 4th derivative of the displacement mode can be calculated using the difference method based on the displacement mode. The following is how it was calculated:

$$j_{i,j}^{(4)}(x) = \frac{j_{i+2,j} - 4j_{i+1,j} + 6j_{i,j} - 4j_{i-1,j} + j_{i-2,j}}{l_i^4}, \tag{7}$$

where i is the node number, j is the modal order, and l_i is the length of the i unit.

Many studies on linear nonconservative nonclassical damped multi-degree-of-freedom systems have been conducted. The state space method, which has the advantage of solving the problem but the disadvantage of artificially increasing the unknown quantity, and the positional method are the two main methods. The common method of shape space has the disadvantage of not being able to solve the problem using orthogonal conditions. Under the current configuration, the mechanism displacement mode of the mechanism system is the left null space of the balance matrix of the mechanism [24]. The high-order coordination equation is always established for the non-self-stress modal mechanism, and the use of high-order coordination equations to solve the bifurcation motion path is no longer applicable. If the damage to the structure accumulates to a certain point and is not discovered and addressed in a timely manner, the damage will spread rapidly, resulting in the complete destruction of the structure. There are numerous benefits to using the strain admittance obtained from the application piece's side response as the parameter identification. On the specimen, it has no additional stiffness or quality influence. The strain gauge is small and inexpensive and can be used to measure multiple points. The measurement system is shown in Figure 2.

In general, the equivalent eigenvalue state equation of the motion equation of the linear structural vibration system can still be expressed by equation in form. Existing studies have used the singular value decomposition method (SVD method) to solve the mechanism displacement mode of the system. This method shows stable and efficient performance when the system contains few components and the balance matrix is small. To make the articulated rod system move, some nodes must be driven. The driven nodes are called driving nodes, and the rest are called driven nodes. The corresponding rods of the driving node and the driven node are called the driving rod and the driven rod, respectively. The mechanism system used in actual engineering often contains a large number of rods, and the balance matrix formed is huge and the element distribution is sparse. At this time, if the method described above is used to directly solve the mechanism displacement mode of the system, the calculation process will be slow.

3.2. Strain Mode Theory. The displacement mode is frequently obtained in modal analysis in many structural health monitoring systems today. The displacement modal analysis is frequently used when the structural deformation is analyzed, the internal force affects its change area, or there is a problem of stress concentration. It is impossible to obtain a good health monitoring effect [25]. The strain modal method's basic idea is that the vibration system's strain field can be expressed by superimposing appropriate characteristic strain fields in a certain proportion. The strain mode, like the displacement mode, reflects the structure's inherent characteristics. It is critical to analyze the stress state of the structure under dynamic load conditions when designing a structure dynamically. Strain is sensitive not only to local structural changes that affect the structure's strength and life, but also to the additional mass and rigidity caused by the

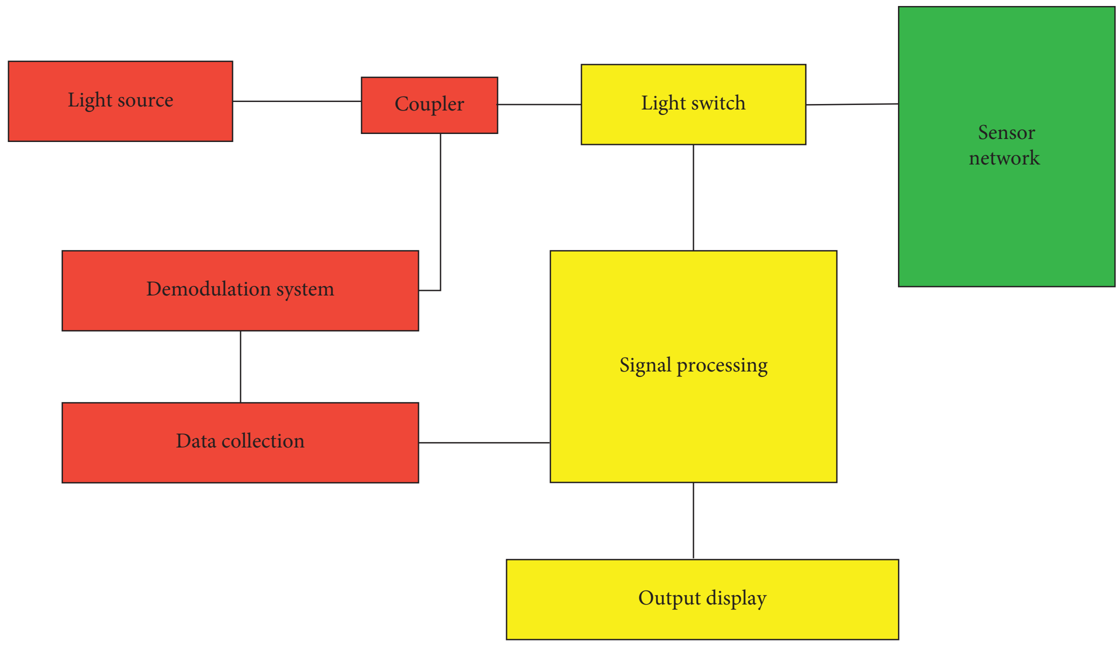

Figure 2: Block diagram of the measurement system.

resistance strain gauge sticking. Researchers are constantly exploring whether the strain response of the structure under the action of external force has a distribution law similar to the displacement response mode in order to effectively monitor the structure in all aspects. The physical significance of strain modal theory is obvious, but a more rigorous mathematical discourse has yet to emerge. The theory of strain modal is still being developed at this time. Curvature modal measurement is a method for indirectly detecting stress and strain that avoids the limitations of strain gauge measurement by using displacement measurement. The actual stress is determined by strain measurement. Strain modal testing technology has broad application prospects for structural damage identification research [26]. Traditional nondestructive testing techniques, such as ultrasonic method, shock echo method, acoustic emission, infrared method, and radar method, are all local damage diagnosis techniques, which require a priori knowledge of the damage site and are suitable for local detection, but in fact, it is very difficult to detect all parts of the structure. Compared with the displacement mode, the strain mode is another manifestation of the same energy balance state. It can be seen from the simulation results that the natural frequency and modal changes after damage are closely related to the location of the damage point. Establishing the calculation model of strain response directly will make the estimation of dynamic stress more accurate. The vibration diagnosis technology based on vibration theory is to analyze the natural frequency, damping, and modal vibration characteristics of the structure by testing the response of the structure under dynamic load and then to diagnose the location and degree of structural damage. There are two ways to make the inversion result unique: (1) add mathematical constraints; (2) add physical constraints. When the damage point is located at the mode node, the change of the natural frequency, mode, and mode difference of this order is extremely small. The function of the dynamic strain measurement system is shown in Figure 3.

This should be paid attention to when actually detecting damage. Strain is more sensitive to local structural changes (such as local small holes, cut grooves) that will have an important impact on the strength and life of the structure, while displacement responds slightly to this. Since the dynamic characteristics of the structure are only related to its inherent properties and reflect the overall behavior of the structure and have nothing to do with external conditions such as loads, the vibration diagnosis technology has the ability to diagnose global damage, which can make accurate safety assessments for the structure. The percentage of curvature mode change is much higher than that of displacement mode. Regardless of displacement mode or curvature mode, higher-order modes can better reflect the existence and location of damage than low-order modes. Direct modal analysis of strain response is more important for local stress or local damage. The problem of selecting the amount of damage identification, that is, deciding which parameters can be used as the basis for better identifying and calibrating the damage location and extent of the structure, is the first step in structural damage diagnosis. With more experience, the ability to identify and locate damage to a specific structure will improve steadily [27]. Obviously, if the measurement is repeated with an artificial neural network as the learning tool, we can design an intelligent structural fault diagnosis system with a self-evolving knowledge base. The low-order amplitude (generally inversely proportional to the square of its natural circular frequency) that can be excited by the same exciting force is much smaller than the high-order amplitude. Because the resistance strain gauge has a small mass, the additional stiffness caused by the paste is also small, making it ideal for measuring and analyzing thin and

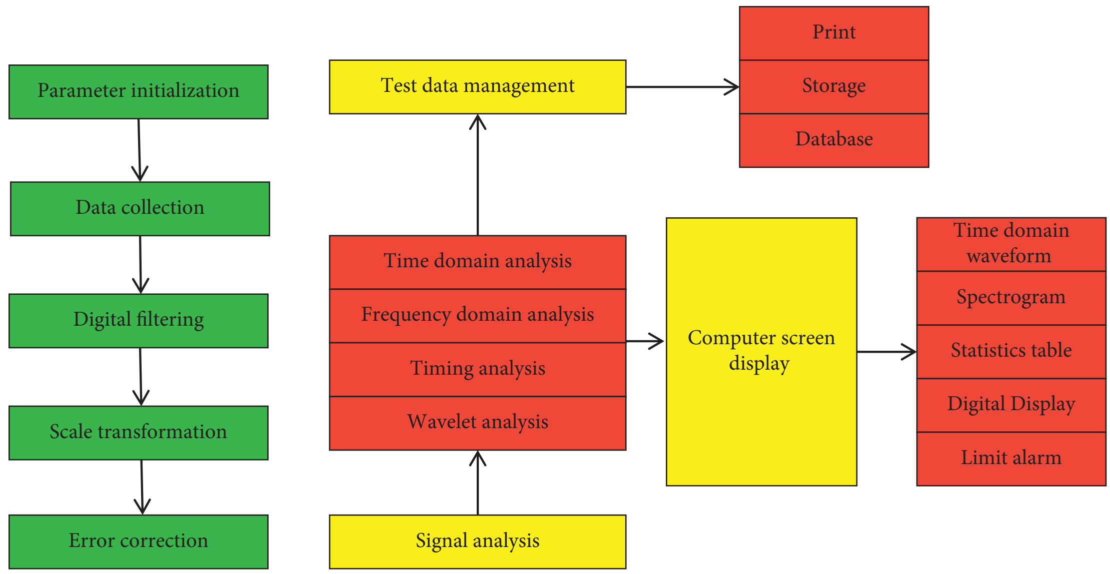

Figure 3: Functional block diagram of dynamic strain measurement system.

small structures. The amount of damage identification must change monotonously with the increase in the degree of damage to determine the degree of damage to the structure. As a result, some damage identification indicators will be produced by determining the location of the damage and calibrating the degree of damage. Limitations: Vibration characteristics are now a widely used and powerful diagnostic method for fault diagnosis and monitoring, but it primarily focuses on the diagnosis of mechanical equipment or mechanisms, component failures, and general engineering structures that bear or transmit loads. There has not been much research done.

3.3. Numerical Simulation. After knowing the displacement response mode of the fixed beam, in order to obtain the subsequent full-field dynamic strain, we must also know the strain response mode. According to the strain mode theory, the strain response mode can be obtained by direct deduction. Mode shape: In order to predict the safety state of the structural system during the dynamic response process, it is necessary to analyze the dynamic reliability of the structural system. The uncertainty of the actual structure's natural frequency will not guarantee the frequency tuning of the TMD. The cumulative energy that can reasonably explain the cumulative damage to the structure during vibration has become an important object of energy method research, but the pure cumulative energy spectrum can hardly reflect the tendency of vibration to damage the structure's impulse type. The anchor rod is usually analyzed as an axial rod unit with rough surface. However, in the joint slope reinforcement, it is more reasonable to consider the axial and lateral effects of the anchor rod due to the dislocation of the joint surface. The random factor method is used to analyze the dynamic characteristics and dynamic response of the random rigid frame structure. Starting from the frequency domain expression of the random response of the structure, using the algebraic synthesis method and the moment method to solve the numerical characteristics of random variables, the random parameter rigid frame structure is derived. The frequency tuning sensitivity of TMD is an important practical issue. The instantaneous input energy is related to the first destruction of the structure. In the joint slope engineering, due to the dislocation of the joint, the anchor rod will inevitably bear a certain lateral force, and its importance is no less than the axial force. Short-period structures are controlled by steady-state vibrations and are prone to cumulative damage and damage. For long-period structures, the total displacement is controlled by transient vibrations. In terms of values, the displacement generated by the transient vibration term is not only much larger than the resonance displacement, and the attenuation is very high. It is slow and is also affected by vibration. It is necessary to conduct a comprehensive analysis of the force of the anchor element in the joint slope, so that it can exert not only the axial force performance, but also the lateral force performance [28]. In transient vibration terms, the maximum displacement of the structure is more likely to exceed the damage standard, and the damage is often one-time and sudden. The numerical simulation method has the characteristics of low cost, short time, strong repeatability, and great flexibility. Especially for the qualitative study of the displacement field effect of huge rock mass structures, it is more unique. It can be discussed from the macro overall trend, with the changing law of the field effect of the rock mass. The above is of great significance to the design of structural control system in the future.

The use of modal analysis technology to analyze the dynamic characteristics of automobile structures is a mature technology that has been used by many units both at home and abroad. The dynamic stress-strain distribution of an automobile structure determines its fatigue damage. As a result, in recent years, the calculation or experimentation of the structure's dynamic strain field has gotten a lot of attention. The structure's experimental stress analysis is carried out under simulated conditions, an efficient method for determining static strength. The dynamic allowable stress of the structure is often calculated by dividing the static allowable stress of the structure by a chosen safety factor during the vehicle design stage. The results of the static experimental stress analysis are examined. The key to establishing the model is to simulate the nonlinearity of the moving boundary using the contact and target elements in order to achieve the lift-off of the tank bottom. The vehicle structure's use characteristics dictate that it is always subjected to dynamic random excitation of the road surface in actual use, and the dynamic allowable stress of the structure under dynamic load is much lower than the static allowable stress. Engineers work on building structures. We are more concerned about the distribution of stress and strain from the standpoint of strength and fatigue. The dynamic strain/stress field's basic idea is that the perturbed system's strain field can be superimposed and expressed in a proportion by an appropriate characteristic strain field. The so-called "strain mode" is the characteristic strain field. The dynamic strain of the structure is measured by the test-time. The procedure can take a long time. The original analog signal must be discretized sampling in order to perform effective signal processing. The dynamic strain of each measurement point of the frame structure is generally normally distributed due to the random nature of the road surface excitation. It is important to see if the maximum dynamic stress exceeds the allowable stress during the structure's strength check, as well as the strain distribution. It can be obtained through a differential deformation displacement operation. Alternatively, the strain distribution obtained by integration can be thought of as the deformation displacement. One row and one column of the strain transfer function matrix must be measured when building the dynamic strain response model of the structure, and both modal models contain the same modal parameters. The maximum stress value in each sample is a random variable that characterizes the maximum stress distribution at the measuring point because the sample is normally random.

4. Cantilever Beam Experiment Verification

4.1. Strain Electrical Measurement. Electrical strain measurement is a traditional method of measuring strain that is widely used and has a well-developed technology. Strain gauges are used as sensitive components in the strain electrical measurement method. It measures strain using the strain gauge's sensitive grid's strain resistance effect. During the actual measurement, the strain gauge is adhered to the test piece. Its benefits include high measurement accuracy and sensitivity, a wide measurement range, continuous measurement and recording, and long-distance measurement; it can also be easily integrated into a control system to automate the manufacturing process. The strain electrical measurement method is currently used to measure the longitudinal stress of the rail primarily in the United Kingdom, the United States, Japan, and other countries. The general procedure for measuring strain with a resistance strain gauge (strain gauge) is to paste or install the strain gauge on the surface of the component to be measured and then connect it to the measuring circuit (bridge or potentiometer circuit). The strain increases as the component is deformed. The chip's sensitive grid deforms as well, changing the resistance value. The damping coefficient test curve is shown in Figure 4.

The general resistance strain gauge is mainly composed of five parts: sensitive grid, adhesive, lead, base, and cover sheet. When measuring in a temperature-changing environment, measures must be taken to eliminate the influence of the heat output of the strain gauge in order to ensure the accuracy of the measurement. There are various measurement systems, which are directly related to the nature of the measured nonelectricity and the type of converter used. The overall design procedure of the system is shown as in Figure 5.

Commonly used converters can only convert a certain mechanical quantity into electricity. For example, strain gauges can only convert strain into resistance. In order to expand its measurement range, a mechanical converter is often added before the converter to change the required measurement. The mechanical quantity is converted into a mechanical quantity capable of driving the converter. The measured locked rail temperature is also relative to the locked rail temperature at the cleared temperature, and the longitudinal stress of the rail measured by the strain electrical measurement method is relative to the rail stress state after the strain sensor is cleared. The change in resistance value should be proportional to the component's surface. The signal generated by the strain gauge's resistance change is output by the measuring circuit. It is indicated or recorded by the indicating instrument or recording instrument after being amplified by the amplifier circuit. The sensitive grid is a monofilament or grid-like body made of metal wire or semiconductor material whose purpose is to convert changes in strain into changes in resistance. In an environment with large temperature changes, the self-compensation method uses a special treatment process or a method of connecting two materials with a resistance temperature coefficient in series to make a sensitive grid, so the heat output of this method is not high. A converter composed of certain elements or components can produce electrical effects under the action of nonelectricity, that is, converting nonelectricity into electricity. For example, the commonly used strain gauge is a kind of converter; it will produce the change of resistance under the action of strain and convert the amount of strain into the amount of resistance. Since the radius of the rounded corner of the connecting rod journal is relatively small, and the part covered by the sensitive grid of the same length is relatively large, the error of the strain electrical measurement is also larger than that at the rounded corner of the main journal, as shown in Figure 6.

Due to the influence of factors such as rain and snow, as well as other factors such as impact and vibration when the train passes by, higher requirements for the moisture-proof,

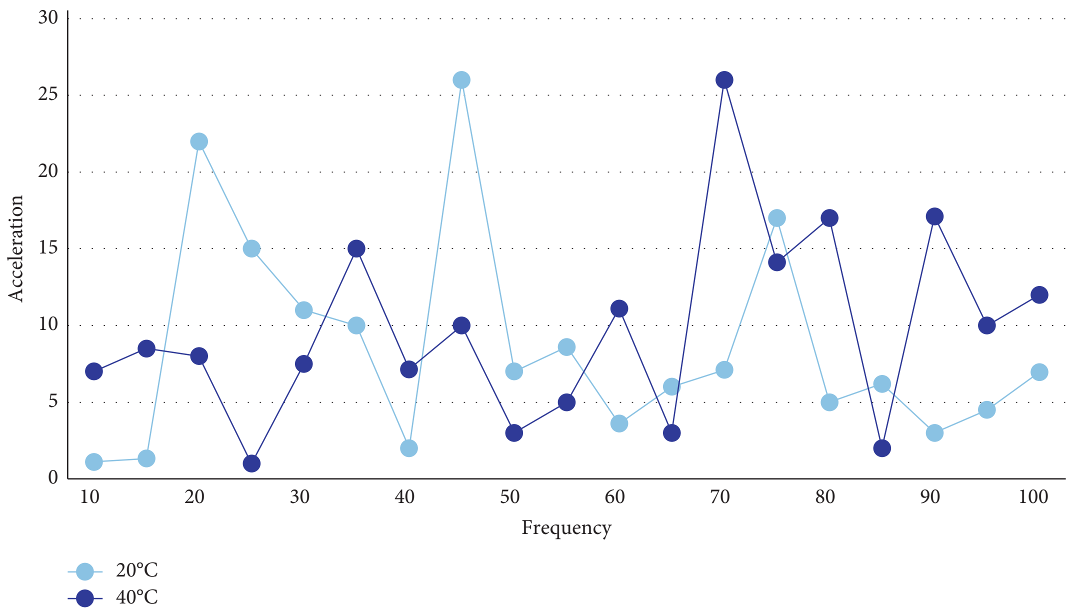

Figure 4: Damping coefficient test curve.

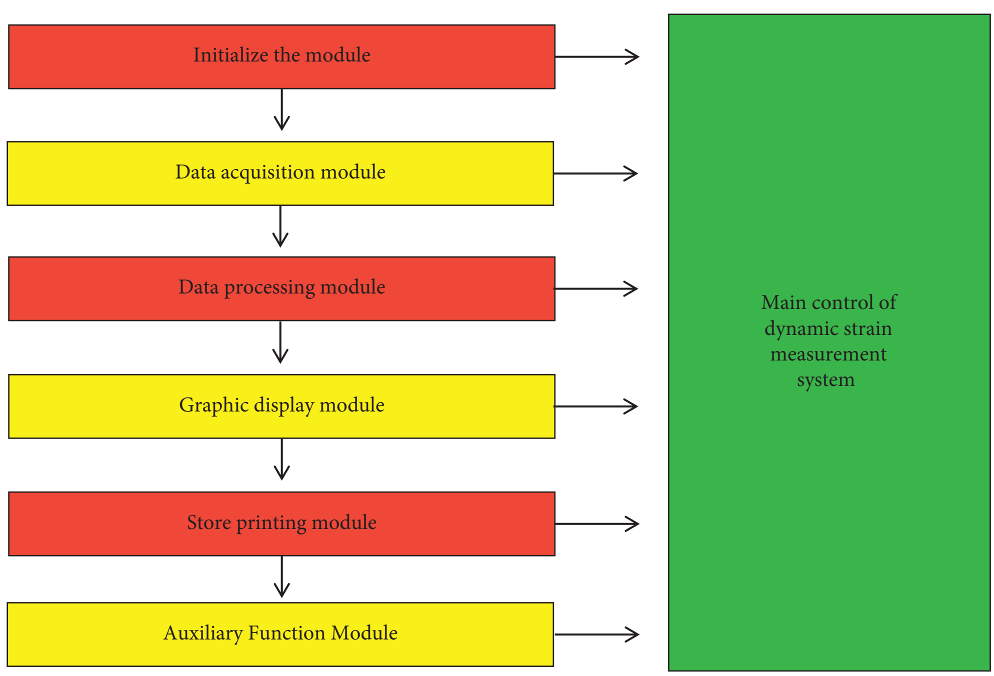

Figure 5: System overall design procedure.

antistripping, and long-term use performance of the sensor system are put forward on the seamless rail line in nature. The strain gauges' measuring points are chosen based on the results of the previous finite element method's simulation and calculation, and the strain gauges are deployed in the larger stress area and part of the abnormal stress area. The strain gauge's job is to convert changes in strain into changes in resistance, but it also has to convert the relative change in resistance into changes in voltage or current so that it can be measured by an electric measuring instrument. The thermal element method involves having the thermal element generate a signal that is of the same value and opposite sign as the strain gauge's heat output in order to cancel it out. This method necessitates the use of additional circuits, as well as a lengthy and time-consuming implementation process. The mechanical converter and the converter are commonly referred to as the sensor because they are assembled together, with load cell, acceleration sensor, and so on. The strain electrical measurement method must meet stringent requirements for longitudinal stress accuracy, applicability, and long-term online monitoring.

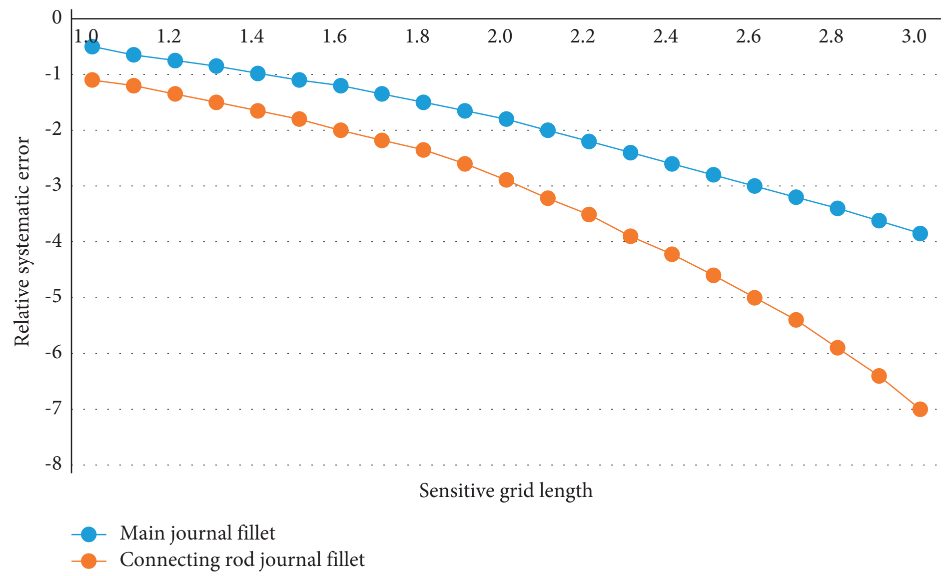

Figure 6: The influence of the length of the sensitive grid on the strain measurement error.

4.2. Experimental Design. In the test, one end of the cantilever beam is fixed on the experimental platform, and the other end is free, and the circular mark point is pasted on the side of the cantilever beam. The purpose is to use the binocular camera to capture the vibration image of the mark point and perform three-dimensional reconstruction, with vibration displacement of the mark point. In order to use the rectangular microcantilever to measure the fluid density, this paper adopts the mode superposition method according to the force balance principle to derive the theoretical relationship between the first-order resonance frequency and the fluid density of the rectangular microcantilever with one end fixed and the other free end, using ANSYS software. The resonance frequency of the microcantilever in different densities of n-heptane and isooctane is simulated and analyzed. Once the flexible member is excited, because of its tiny structural damping, the vibration of the flexible member will be difficult to stop in a short time, and the vibration of the flexible member will cause resonance, which will eventually affect the working accuracy and service life. The system performs sinusoidal sweep excitation on the specimen to obtain the response characteristics of the specimen and analyzes the data to obtain the coefficient of the structure specimen. In order to analyze the influence of different piezoelectric materials as the piezoelectric layer on the sensitivity of the piezoelectric microcantilever, piezoelectric ceramics and PZT-5H are used as the piezoelectric layer materials of the piezoelectric microcantilever, and piezoelectric analysis is carried out by ANSYS, as shown in Figure 7.

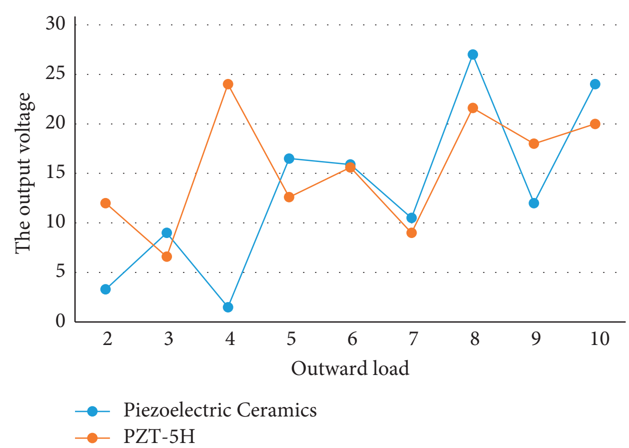

Figure 7: Output voltage when two piezoelectric materials are used as the piezoelectric layer.

Microcantilever is a typical movable microstructure device. Its length and width are generally in the micron rang, and the thickness is in the submicron range. According to different applications, it can be used such as monocrystalline silicon, polycrystalline silicon, silicon dioxide, aluminum, etc. It is made of three kinds of materials, because it has the characteristics of simple preparation process and strong ductility in the application field; it occupies an important position in the microelectromechanical system. By superimposing the vacuum mode of the microcantilever to replace the fluid-structure coupling mode of the microcantilever, the influence of the fluid on the microcantilever is converted into fluid dynamic pressure, and the vibration differential equation is solved by the orthogonality of the vacuum mode. The relationship between the resonance frequency of the cantilever beam and the fluid density is obtained. The general idea of the finite element method is to first divide a continuous area or object into finite elements (and these elements bear equivalent nodal loads) and then build an “element matrix” based on the relationship between the nodes of these elements to solve the problem. The external additional mass causes the natural frequency of the microcantilever to change, and the quality detection can be achieved by measuring the frequency shift of the microcantilever. Based on this principle, a micromass spectrometer can be made to detect the quality of single molecules and single cells and so on. In a natural law system, the total mechanical energy is conserved, so when the system is vibrating freely, potential energy and kinetic energy are converted mutually without energy loss, so that the system will maintain a constant amplitude structural vibration. Under normal pressure, the resonance frequency of the rectangular microcantilever in n-heptane and isooctane was measured experimentally, as shown in Figure 8.

Active control technology is the most effective way to reduce the vibration of a flexible structure. The piezoelectric sensor and actuator are integrated in the flexible cantilever beam, making it a smart structure, and the study of its vibration suppression characteristics will have practical significance for the active control of flexible beam vibration. The computer software sends a drive signal from the controller to the power amplifier, which amplifies the signal and drives the vibration exciter (vibration table) to move according to the required vibration control spectrum. The benefit of using the finite element method to simulate a micropiezoelectric cantilever is that it can discretize the object into a set of finite simple elements, which can then be used to simulate or approximate the original object, reducing a continuous problem to a discrete problem. Perform analysis to obtain the entire object's analysis structure. Thermal stress analysis, thermal structure analysis, thermoelectric analysis, thermal fluid analysis, magnetocaloric analysis, magnetic structure analysis, induction heating analysis, induction oscillation analysis, electromagnetic circuit analysis, and electrical structure analysis are just some of the multiphysics analyses available in ANSYS. The peak-to-peak output voltage of the vibration frequency (20Hz–200 Hz) is used, as well as the direct output of each cantilever beam piezoelectric slice and the connection modes of parallel and series. The maximum output voltage of each in parallel and series connection is compared. The test results are shown in Figure 9.

Regardless of whether the static mode or the dynamic mode is used for experimental research, a reference experiment is usually included, that is to say, a microcantilever with the same mechanical characteristics without surface functionalization is tested at the same time, and the difference between the two is compared. The signal gets the signal under test. Damping is definitely there and it is impossible to avoid. This will affect the conversion of mechanical energy, and the energy will slowly decay, so that the constant amplitude vibration cannot be maintained. This kind of mechanical vibration is called damped free vibration. Gray prediction is a prediction method that analyzes the dynamic behavior and operating trend of the object. It has the advantages of low model requirements, fewer online estimation parameters, convenient calculation, good comprehensive control effects, and strong robustness. It is currently in the field of industrial process control being widely used.

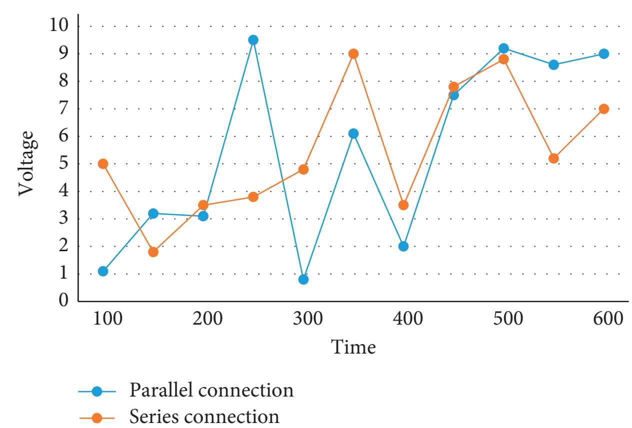

Figure 9: The relationship between output voltage and time.

4.3. Camera Calibration. Before performing the experiment, it is necessary to determine the two cameras for calibration, that is, to determine their internal and external parameters. The purpose of the camera calibration is to establish the relationship between the three-dimensional object point in the space and the two-dimensional image point of the pixel coordinate system, and the calibration result is directly related to the accuracy of the vision system. Internal and external parameter calibration are the two types of camera calibration. Fixed-focus lenses are used in all vehicle-mounted cameras, and their internal parameters do not change after one calibration. The calibration of external parameters is the only thing that needs to be considered. A one-dimensional calibration object with an infrared reflective marking ball installed at both ends and in the middle is made to solve the problem of camera calibration in the process of photoelectric detection of motion parameters. The effective focal length of the camera, the principal point of the optical center, and the lens distortion coefficient of the camera are among the internal parameters. External parameters are primarily the position transformation between the camera coordinate system and the world coordinate system, and these are the main parameters of each camera. The rotation matrix and the translation matrix are the two most important position transformation parameters between the two cameras. The camera obtains a two-dimensional image of the surface of the ground object, with the ultimate goal of obtaining the object's three-dimensional spatial information. As a result, research into how to solve three-dimensional spatial information of the ground object of interest in real time using the on-board 3D data acquisition system is required. The key content here is camera calibration. On the other hand, we investigate how to improve the accuracy of the solution model by optimizing it. The compensation algorithm can significantly improve the measurement accuracy of the vehicle's yaw angle and lateral displacement, as shown in Figure 10.

The feature point matching method uses a calibration board with special graphics to extract the three-dimensional points collected by the Lidar and the two-dimensional image points obtained by the corresponding camera, establish a constraint equation, and optimize the calculation of the camera pose. Its essence is the PNP (perspective n-point) question. When calibrating the camera, if too much nonlinear distortion is considered in the calculation process, it will lead to the introduction of too many nonlinear parameters in the calculation process, which will affect the calibration accuracy and cause other opposite effects. On the assumption that the road is flat, the following two situations will generally occur during the normal driving of the vehicle: local bumps on the road surface cause small bumps and vibrations in the vertical direction of the vehicle body. One-dimensional calibration object, a calibration method based on one-dimensional calibration object, has the advantages of low cost, being easy to move, and being suitable for on-site online calibration, and more importantly, it can solve the occlusion problem in multicamera occasions. The checkerboard calibration method uses a two-dimensional checkerboard as the calibration board and changes the position information between the calibration board and the camera by continuously rotating the calibration board. The relative orientation direct solution method entails expanding the coplanar equation and performing a linear transformation, then solving the relative orientation elements, and constructing a relative three-dimensional model. This method employs linear transformation; the solution is quick, but the outcome is not precise. The plane calibration template fits the straight line with Lidar points to find the intersection point and then manually marks the position of the characteristic points on the calibration board according to the scale to find the image coordinates. The primary goal of feature point extraction is to precisely determine the location of each feature point in the image so that it can be calibrated in the appropriate spatial coordinates. Reduce the relative solid model to a specific scale by incorporating it into the ground coordinate system. The relative solid model and the coordinate system's translation and rotation parameters, as well as the model scale factor, are solved in the on-board 3D data acquisition system camera pair calibration. A measuring device, independent of the front-view camera, was designed to accurately and quickly measure the vehicle's yaw angle and lateral deviation in order to verify the actual effect of the compensation algorithm in the driving of the vehicle.

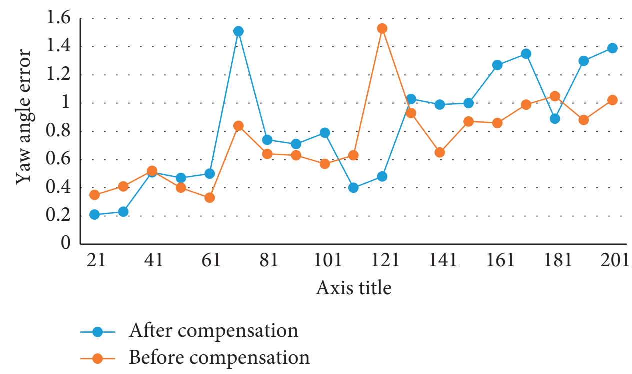

FIGURE 10: Actual measurement error of yaw angle.

5. Conclusions

Strain measurement is a traditional technology. Although the secondary instrument has new methods, such as automatic balance, computer postprocessing, etc., its essential things have not changed. The key to improving test accuracy is still this part of the instrument, namely, attaching strain gauges and soldering wires. The main features of the vehicle structure strength single-chip microcomputer data acquisition and processing system, as compared to the conventional test system, are greatly reduced test system cost, greatly improved measurement accuracy and detection speed, and diversified processing functions, and all of them can be obtained as soon as the test is completed. Collect information and test results. The measuring points for dynamic strain measurements of the car body structure's strength are chosen based on the results of static tests (static bending and static torsion), that is, the maximum stress value and location of the car's main components in a static state due to its own weight and load. The dynamic strain collector's intelligent and portable design will have a wide range of applications in the stress measurement of engineering structures such as dams, space shuttles, ship structures, and power generation equipment.

With the rapid development of new media technology, the demand for applied professional film and television talents in China's film and television industry is getting higher and higher, especially the comprehensive practical ability. In the Internet age, information technology has been widely used. It is integrated into people's lives with the unique characteristics of interaction and communication among all employees, and opens up a new mode of work, study and life with Internet as the medium. Under the new situation, all kinds of schools at all levels also make full and active use of the Internet for online teaching. In the past, the quality monitoring work focused on theoretical teaching. However, in the face of online and offline mixed practice teaching, there are bound to be many problems and deficiencies when using the theoretical teaching quality monitoring system. This paper mainly discusses the application of online and offline mixed tutorial mode in film and television literature course from the aspects of task-oriented teaching content, application of classroom teaching methods, diversification and dynamics of evaluation methods, etc., hoping to provide reference for college teachers who implement online and offline mixed teaching.

1. Introduction

Human society has entered the era of information society and knowledge economy at the end of the twentieth century. The mass media is credited with ushering in this era. Film and television are examples of rapidly evolving mass media in the twentieth century [1]. With the rapid advancement of new medium technology, the demand for application-oriented professional film and television talents in China's film and television industry is growing, particularly for those with a broad range of practical skills [2]. In the process of cultivating students, film and television majors must strengthen the cultivation of students' cognition and practical ability in addition to imparting basic theories [3]. As the most vigorous modern comprehensive art, film and television art is based on the development of sci & tech from birth to development. It is a new artistic flower open on the tree of modern sci & tech [4]. With the application of a series of high and new technologies such as Internet, digital technology, multimedia technology and interactive TV, the charm of film and television art is increasing day by day [5]. Compared with the traditional poetry, novel, prose and drama, film and television literature should be said to be a new literary style. People's understanding of film and television literature is not only inferior to the traditional literary style, but also inferior to the understanding of film and television art [6]. In the Internet age, information technology (IT) has been widely used. It integrates into people's life with its unique characteristics of full staff interaction and communication, and opens a new mode of work, study and life with the Internet as the media. Under the new situation, all kinds of schools at all levels also make full and active use of the Internet for online teaching [7].

Different from most tutorial modes dominated by online network teaching, hybrid teaching is not confined to a single teaching method, but through the combination of online digital education and offline classroom teaching, emphasizing student-centered and giving full play to the enthusiasm, initiative and creativity of students as learning subjects, It advocates using online educational resources and IT to promote curriculum teaching and improve learning effect [8, 9]. The core meaning of mixed teaching does not lie in the unique innovation of teaching means, but in whether the student-centered learning goal is realized. Therefore, all means that help to improve the learning effect can be used, which undoubtedly greatly expands the inclusiveness of mixed teaching [10]. At present, online and offline mixed teaching is a new tutorial mode, and practical teaching is in the stage of exploration and exploration [11]. In the past, the quality monitoring work focused on theoretical teaching, while in the face of online and offline mixed practical teaching links, there must be many problems and deficiencies in using the quality monitoring system of theoretical teaching [12]. This paper discusses the application of online and offline mixed tutorial mode in film and television literature courses, mainly from the aspects of task-based teaching content, the application of divided classroom teaching method, diversified and dynamic evaluation methods, hoping to provide reference for university teachers who implement online and offline mixed teaching.

Film and television literature is a relatively broad concept. It is the collective name and abbreviation of film literature and television literature. It is a new literary style with the prosperity of film and television art [13]. Film and television art has more audience groups than other arts, which is unmatched by any other art category, such as poetry, novel, drama, etc. the new era of film and television art has come [14]. Films, TV dramas and other film and television art works not only penetrate into human life style and change human concept and consciousness, but also give birth to a new cultural form such as film and television literature [15]. The student-centered hybrid tutorial model can effectively integrate all kinds of teaching resources and teaching forms into the classroom [16]. This rich and diverse teaching form is exactly what is urgently needed in the writing classroom aimed at stimulating students' enthusiasm and creativity [17]. The organic combination of online information-based teaching means and traditional classroom teaching can effectively make up for the poor interaction between teachers and students by using online teaching alone, and meet the needs of writing courses in simulating situations and inspiring emotional resonance. Based on the film and television literature course, this study explores the online and offline mixed tutorial mode, how to flexibly combine the online course with the traditional classroom, enhance students' knowledge application ability and integration ability, and provide new ideas and experience for the mathematics teaching reform in the classroom of universities.

2. Related work

Film and television literature is a relatively broad concept, the collective name and abbreviation of film literature and television literature, and a new literary style that appears with the prosperity of film and television art [18]. Literature [19] mentions that film and television literature is also an auditory art, and all descriptions of dialogue, monologue and narration should take into account the needs of pictures, with pictures as the main body of expression, and music, language and sound are all to expand and strengthen the expressive force of pictures. According to the literature [20], because film and television art is developed on the basis of photography, it is necessary to truly reproduce the object and its movement, so that it can approach life to the maximum extent in terms of expression form, and the screen image is not only visible but also realistic. Film and television literature, according to Literature [21], is a television art work that vividly reflects life, shapes characters, and expresses emotions through special screen modelling means, and imparts literary aesthetic taste to audiences. From the standpoint of the birth process of film and television literature, literature, as an artistic form, has become an organic part of a new type of literature as it has been absorbed and integrated, according to Literature [22]. Teachers should strive to meet the needs of curriculum reform, continue to learn, update their ideas, and improve their own cultural literacy, according to literature [23]. We should also study textbooks carefully and strengthen the inspiration and guidance provided to students in the cooperation and interaction of an equal dialogue with them. The mixed tutorial mode is introduced into the teaching of writing courses at universities in this paper, and it is sorted out and summarised after being combined with the actual teaching effect.

3. Connotation of online and offline mixed tutorial mode

As a kind of integrated tutorial mode, blended teaching is more flexible in learning methods. Through the online and offline hybrid tutorial mode, students can search relevant learning materials through the Internet anytime and anywhere, so as to learn in fragmented time [24]. And prepare or review according to the materials pushed by the teacher, so as to lay the foundation for the teacher's explanation of knowledge in class. Teachers and students strengthen the interaction and exchange of knowledge understanding in class, and can prepare relevant information for students to strengthen review and expansion after class. The purpose of hybrid teaching is to combine the advantages of traditional teaching methods with the advantages of network learning, so as to realize their complementary advantages and obtain better teaching results. From the perspective of teaching platform, the hybrid tutorial mode is mainly implemented based on MOOC (massive open online courses) platform and university network teaching platform. MOOC has the advantages of large scale, high efficiency, low cost, excellent teachers and flexible time, but there are still deficiencies in the depth of knowledge interaction. Although MOOC can preach and teach, it can not effectively solve doubts and achieve efficient and in-depth knowledge interaction.

Teachers cannot provide one-on-one personalised learning guidance to learners in the process of knowledge interaction between teaching and learning in the MOOC context, and learners find it difficult to conduct in-depth knowledge exchange. Knowledge interaction links like discussion are difficult to match. As a result, it is critical to supplement offline instruction to compensate for the shortcomings of online instruction. However, in order to achieve the effect of complementary advantages, online and offline teaching should be focused on each other, and the proportions should be appropriate and reasonable [25]. The mixed tutorial model's theoretical foundation is to create a relatively stable, systematic, and theoretical tutorial model around a specific theme in teaching activities, guided by specific teaching ideas. Students' learning enthusiasm can be mobilised through rich online learning resources and communication modes. At the same time, incorporating various offline activities into online courses can help to improve the teaching effect while also increasing students' interest in learning [26]. With the application of online and offline hybrid tutorial mode in Universities, it not only eliminates the limitations of traditional tutorial mode in time and space, but also makes teachers access to more high-quality demonstration curriculum resources, thus promoting the integration of teaching materials and lesson preparation methods. The learning process should be student-centered, and students must actively participate in the whole learning process. The second is that knowledge is the social construction agreed by individuals and others through consultation. Therefore, in the learning process, we should pay attention to the interactive learning method and change the current situation of students' passive acceptance of knowledge.

4. Significance of film and television literature teaching

4.1. Promoting Chinese Literature Education. In addition to strengthening the teaching of traditional poetry, novels, essays and dramatic literature styles, literature also needs to add fresh blood. For contemporary middle school students, film and television art should be said to be the most vital. It combines various artistic features such as literature, music, dance, art, sculpture, etc., coupled with computer synthesis and other scientific and technological means, whether it is dynamic, texture or sound effect, it is quite excellent. Appreciating film and television literature entails having a certain level of artistic achievement, a certain understanding of the aesthetic law of film and television art, and the appreciator's own life accumulation and experience, so that he can gain a deeper understanding of all aspects of film and television literature and, as a result, be psychologically happy. The film and television scripts themselves are based on literature or are closely related to it. A wide range of literary techniques for reflecting and expressing life, such as narrative techniques, structural styles, novel expression skills, lyricism in poems, and artistic conception in prose, all provide food for the creation of film and television literature. One of the best platforms for implementing comprehensive Chinese activities is through the teaching of film and television literature works. It can help students develop rich associations and imagination while reading, as well as connect with the works' image and artistic conception. It enables students to explore the works' rich connotation and deep meaning, as well as their own unique feelings and creative interpretations.

4.2. Improve students' cultural literacy. In the process of learning film and television literary works, students' listening, speaking, reading and writing abilities are improved, their aesthetic ability is constantly strengthened, and their artistic taste is gradually improved, which helps to cultivate students' practical ability and innovative spirit, and help to form students' good personality and sound personality. Therefore, the teaching of film and television literary works should be placed in an important position in literature education. Students should be instructed to read rich and excellent literary works, acquire necessary literary knowledge, cultivate and improve their literary literacy, and at the same time, incorporate ideological education into them to cultivate lofty ideals and ambitions. The education of literature development and achievements in common sense should rely on colorful literary styles such as poetry, prose, novel, drama, film and television literature, etc., and enter students' vision and thoughts, and a considerable part of the content will become their lifelong cultural wealth. Reading and appreciation of literary works is the focus and center of literary education, which includes reading and appreciation of ancient, modern and contemporary Chinese poems, essays, novels, dramas, film and television literary works and excellent foreign literary works, which is the main body of literary education. Students' understanding of the original novel and our explanation of the adapted film and television literature works can refer to each other, and the similarities and differences formed in the process can help students form their initial feelings and experience material accumulation of film and television literature works, thus leading them to re-recognize the shaping and deepening functions of film and television literature.

5. Present situation of mixed teaching of film and television literature

At present, when we teach film and television literature works, the way is extremely monotonous, which basically ignores the unique characteristics of film and television literature. Instead, we simply teach film and television literature works as general literature works, and more often analyze the writing and writing techniques from the perspective of language, resulting in that the unique appeal of film and television literature works has not been fully exerted, which can not really impress students and enhance the aesthetic ability of literature.

5.1. Simplification of film and television literature teaching content. At present, the outstanding problem in Chinese teaching is not the incorrect understanding of works, but the lack of full respect for students' subjectivity in the teaching process and the lack of more independent space for students. Teachers don't guide and encourage students to actively examine society and life with their own eyes, but always instill existing fixed answers into students, which is mandatory and oppressive. The film and television literature course in universities is different from other courses in content, which requires not only deep excavation of literary works based on writing background, historical environment, characters' personality, expression of emotions, etc., but also reasonable research and application of various theoretical knowledge that is convenient for exploring profound meaning. This kind of online and offline mixed teaching for literature will be difficult to achieve more rational application of teaching resources, which will make it difficult to display its value. Although students have a strong interest in film and television literature, most of the teachers, starting from the practical purpose of dealing with the examination, led the students to walk through the classroom in a superficial way. Students only remember what the examination contents need to be memorized, but they have little knowledge of film and television art and film and television literature, let alone deeply appreciate film and television literature works.

5.2. Poor teaching process design. The design of the teaching process determines not only the quality of the teaching effect, but also the quality of the teaching process organisation in the online and offline mixed tutorial mode. The works should have a three-dimensional sense and image, a broad thinking space, and promote thinking activities, rather than being limited to the words themselves. Furthermore, film and television literary works use a variety of expressive techniques. Fully digging and explaining can also help students gain a better understanding of other fields besides Chinese, as well as inspire them and provide them with a variety of writing opportunities. Students' self-study before class, teachers' deepening in class, and students' strengthening and consolidating after class are the three parts of the teaching process in the online and offline mixed tutorial mode. However, in online and offline mixed teaching, some teachers do not provide self-study materials prior to class and instead ask students to find relevant literature and author information on their own. Because of the big data mode presented by Internet platform information, students will encounter content deviations and misunderstandings in their interpretation of relevant literature materials or author information.

6. Construction of online and offline mixed tutoring mode for film and television literature class

6.1. Improve students' participation in autonomous learning. There are relatively few theoretical knowledge parts in film and television literature courses, and most of the understanding and appreciation methods used are common forms. In this regard, teachers can concentrate on teaching relevant theoretical knowledge according to its application categories. After students understand and master the basic ways of appreciating literary works, the follow-up teaching of literary works will be more targeted. Before class, the teacher's main task is to carefully analyze the learning situation, so as to choose reasonable teaching content and online teaching platform, and put forward certain requirements and effective suggestions for students' online learning content. At the same time, the teacher should make clear the learning objectives, learning priorities and learning difficulties of film and television literature course teaching through micro-class or PPT, so that students can actively, effectively and independently learn, and provide knowledge reserve for offline classroom teaching. Figure 1 is the dimension of effective learning environment of film and television literature and the path analysis model with learning effect.

Before class, teachers construct structured courses by designing curriculum guidance, unit knowledge tree and knowledge branch, setting exercises, discussion and inquiry topics before class, and establishing evaluation system. Teachers can arrange the task of watching movies in advance, so that students can have a preliminary understanding of the movies they want to learn, and set up simulation topics and examples related to movies by using teaching platforms such as rain class or cloud class class, so that students can learn by themselves first. Using modern IT to implement online and offline mixed teaching can not only effectively and rationally use time, but also remind and urge students to study tasks that need to be previewed before each class, and provide students with a broader learning path, thus helping to improve the teaching effect of film and television literature courses.

Teachers should deeply understand and combine students' individual characteristics, carefully select, design and prepare high-quality teaching and learning resources with different online difficulties according to the syllabus and teaching difficulties, so as to facilitate students' graded learning and help them to preliminarily understand and master knowledge content. Figure 2 shows the resource supply relationship of mixed teaching courses in universities.

Students are encouraged to explore and learn independently in class by using high-quality online curriculum resources or teacher-prepared video courses. Teachers use heuristic knowledge topics in class to guide students' independent thinking, discuss knowledge points, explain examples and exercises using the network platform, and analyse and calculate students' feedback questions that have been summarised before class. Simultaneously, combine different knowledge points, select application cases for teaching to enrich classroom content, and set up classroom tasks or group discussions to encourage students to engage in interactive communication, thus enlivening the classroom atmosphere. Students can use the mutual evaluation system set up in class to score and evaluate each other, enhancing students' sense of classroom integration.

6.2. Optimizing teaching process design. Optimizing the design of the teaching process can not only help students to strengthen their understanding of the literature knowledge they have learned, but also promote the teaching effect on the basis of enhancing students' interest in literature. First of all, in the pre-class self-study stage, teachers should give priority to searching and sorting out relevant literature knowledge, and tell students from which aspects to interpret the information of works. Teachers should have a purposeful dialogue between teachers and students in class according to the difficult points of students' feedback before class, and guide students at different levels individually to teach students in accordance with their aptitude. For students with

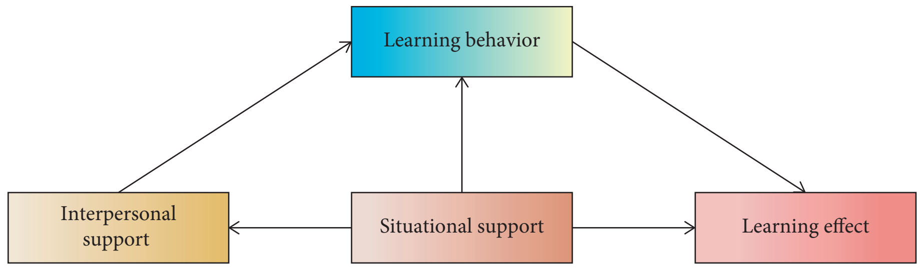

Figure 1: Path analysis model.

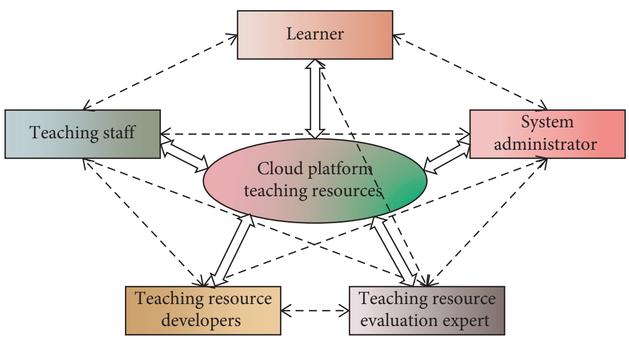

Figure 2: The supply relationship of mixed teaching curriculum resources.

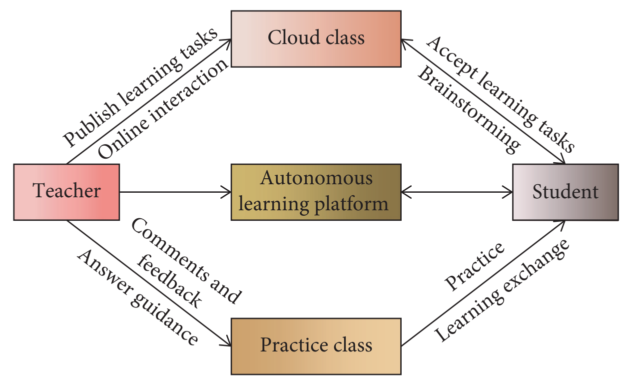

Figure 3: Mixed teaching implementation method.

good foundation and strong learning ability, teachers can assign some difficult learning tasks to expand their knowledge, and for students with poor foundation and weak learning ability, teachers can help them answer questions in class. In the class, teachers can selectively determine the content of lectures according to the movie watching tasks assigned before class, the feedback from the teaching platform to students' preview tasks before class, and the questions and discussions that students have made through the platform. The implementation method of mixed teaching is shown in Figure 3.

One of the great advantages of mixed tutorial mode is that it can provide students with a personalized learning space, so that learners can achieve completely independent personality learning. However, it is not easy to truly reflect this advantage, which requires systematic design of the whole network learning environment. The learning path components are shown in Figure 4.

Because students have a preliminary knowledge and understanding of the film before class, teachers should deepen and guide students' appreciation and understanding of the film in class. At the end of the course, teachers can use the last five minutes of the class to summarize and clarify the key points and difficulties in this class, so that the teaching effect can be guaranteed to the greatest extent. After class, teachers can arrange homework through online learning platform, the content can be about film appreciation or film appreciation, etc., so that students can extend and expand their knowledge about what they have learned about film appreciation. Students consolidate their knowledge and finish their homework, and then give feedback on their homework. After the first stage of listening and speaking teaching of film and television literature supported by mixed teaching method is completed, a stage test is required, and the test results are shown in Figure 5.

Teachers can reflect after class according to students' preview before class and the implementation of teaching in class, and both teachers and students can summarize from the perspective of teaching and learning. Online-offline mixed tutorial mode can enable teachers to adopt the most effective and direct teaching methods, carry out reform and exploration, and further improve students' learning status and teachers' teaching level. For example, Figures 6 and 7 is the survey result of students' satisfaction with online and offline mixed teaching of film and television literature course.

It is clear from Figure 6 and 7 that most students are satisfied with the multi-mixed tutorial mode. In addition to assigning homework of classroom teaching content, teachers can also introduce the frontiers of scientific research and provide practical application cases in combination with teaching knowledge points and teachers' own research direction, so as to help students broaden their horizons, stimulate their interest in learning and deepen their understanding of knowledge. Table 7 shows the statistics of students' evaluation on teachers' use of multimedia courseware in film and television literature teaching.

The premise of mixed tutorial mode is the Internet, which requires teachers to master the application of IT, which is the general trend in the teaching of film and television literature. Teachers should improve their IT level in actual teaching, fully and effectively integrate teaching resources of film and television literature with IT, innovate tutorial mode, change teaching environment and optimize classroom atmosphere. The independent explanatory power

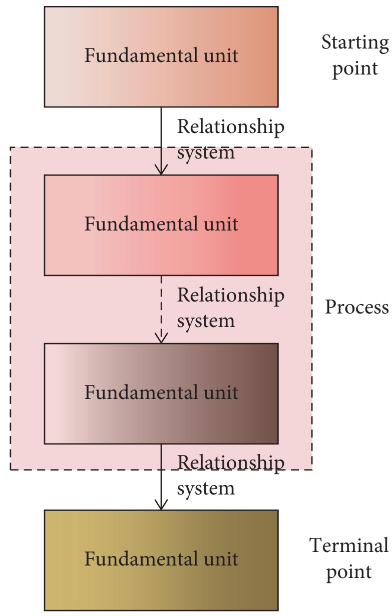

FIGURE 4: Elements of Learning Path.

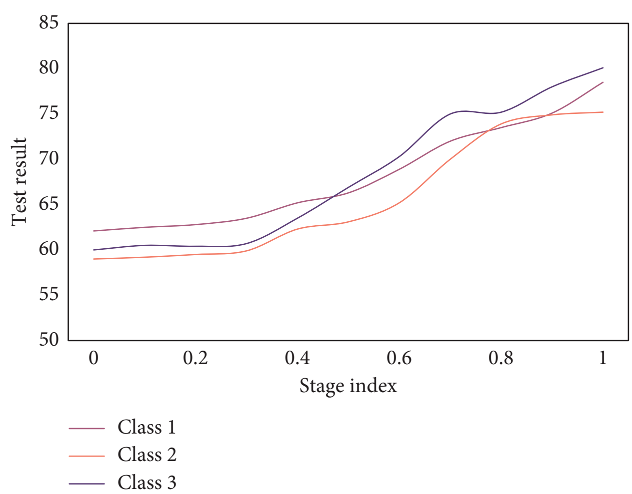

FIGURE 5: Comparison of stage test score data.

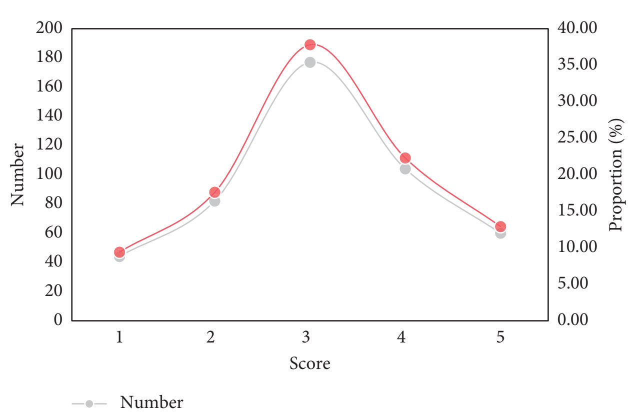

FIGURE 6: Survey statistics of students' satisfaction with online and offline mixed teaching.

data of the three dimensions of effective learning environment shows that both learning behavior and situational support have strong explanatory power to learning effect, as shown in Figure 8.

Most students take part in some exams related to professional skills while studying professional courses. The heavy learning tasks lead to the change of unsuitable teaching methods. Therefore, they have coping psychology for online learning, and can't finish online learning tasks assigned by teachers on time, quality and quantity. Therefore, schools should actively adjust teaching evaluation methods, emphasize the importance of process evaluation, arouse students' attention and attention, and then improve students' learning consciousness and enthusiasm. Students independently or in groups carefully complete the exercises, discussions and feedback after class, and freely put forward

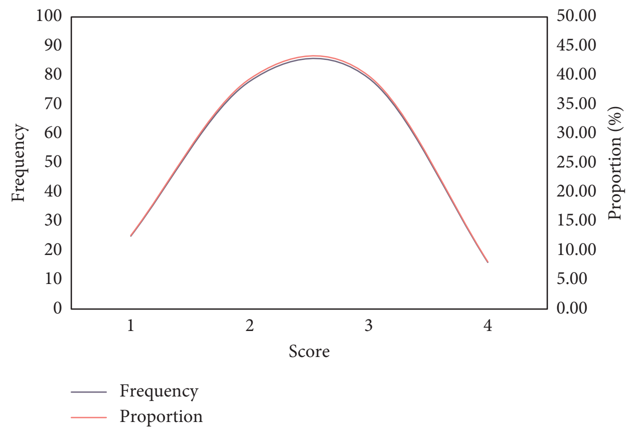

Figure 7: Students' evaluation of the effect of multimedia courseware.

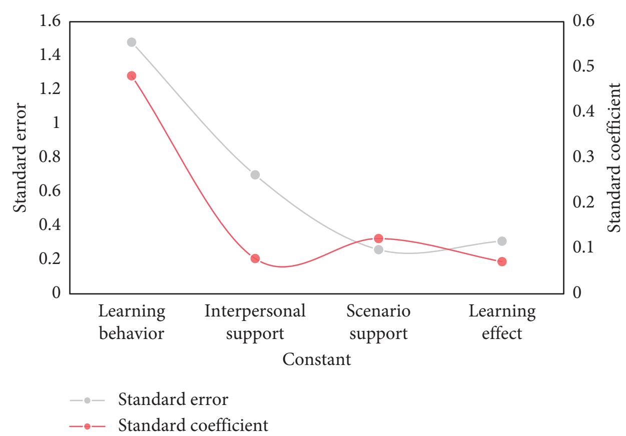

Figure 8: Effective learning environment construction corpus estimated results of learning effect.

their own opinions and suggestions on teaching design, teaching content and teaching videos through the teaching evaluation system, thus forming a good cycle between teachers' teaching and students' learning.

7. Conclusions

Film and television literature courses are different from general cultural courses. Today, with the emphasis on humanistic quality education, the methods and skills of film and television works appreciation can reflect students' thinking mode and aesthetic ability. Today, with the rapid development of the Internet, the film and television literature course is no longer a simple explanation of works and appreciation of contents. Through network information expansion, it can show students a more brilliant side of literary works. Strengthening the teaching of film and television literature works is the need of the development of the times and an important channel to improve students' cultural literacy. The appreciation of film and television literary works will provide a new growing point for the deepening of Chinese teaching reform. Online-offline mixed tutorial mode provides students with rich teaching resources and broad learning space, which enables students to change from passive learning to active learning. Students can watch videos independently before class, complete the preview work, and fully stimulate students' learning enthusiasm, thus contributing to the improvement of classroom teaching quality and teaching effect. With the development of the times, the teaching method based solely on lectures can no longer meet the needs of students. The online and offline mixed tutorial mode can improve the teaching quality, enhance the learning efficiency of students and promote their all-round development.

In the process of growth, apples' ripening, storage, transportation, and processing, the appearance and internal physiological characteristics will have some changes because of the effect of time and physical attributes. A series of problems, such as the false ripeness and putrefaction of fruit, will bring huge economic losses to fruit vendors and harm to consumers. In this paper, an odor recognition system has been designed for the fast evaluation of the freshness characteristics of apples, which is based on the freshness characteristics of Fuji apple. A series of apple-air mixture with equivalent model was established by studying the change of gas concentration during the growth and storage of apples. The continuous projection algorithm (Successive Projections Algorithm, SPA) is used to optimize the sensor array to solve the problems of collinearity and overlap and also to eliminate the abnormal and redundant sensors. ZigBee wireless sensor network is adopted to send data to host computer, and BP (Error Backpropagation) neural network algorithm optimized by SFLA (shuffled complex evolution, SCE + Particle Swarm Optimization, PSO) algorithm is used to recognize gas data, which greatly improves the training speed and precision of neural network. The experimental results show that the detection accuracy of the Fuji apples freshness is 98.67% and can quickly and comprehensively identify the freshness of apples.

1. Introduction

In 1961 Moncrieff, the first to complete the study of odor recognition technology, developed a mechanical odor detection device. In 1982, Persaud and Dodd proposed the concept of an electronic nose, which consisted of two main components: an odor sensor array and a pattern recognition system. The odor sensor is the core component of the electronic nose system. Because single odor sensor cannot evaluate the complex odor components of objects, the selective chemical sensor array is adopted. At present, the most commonly used sensors are metal oxide semiconductor sensors, metal semiconductor field effect transistor sensors, fast ion conductor sensors, optical odor sensors, and mass sensors. Among these sensors, the MOS (metal oxide semiconductor) sensor based on changes operates in its conductivity and resistance, which are caused by the measured redox between the odor and the odor sensing component. This is the most widely used sensor. Based on the data collected by the sensor array, simple and complex odors can be identified by an appropriate pattern recognition system.

Apple not only has sweet flavor, but also is rich in nutrition, which is a kind of high value fruit. According to the Food and Agriculture Organization of the United Nations, apple production worldwide exceeded 70 million tons in 2019. However, in the process of picking, processing, transportation, and storage, its appearance and internal physiological characteristics will be changed due to the problems of false maturation, mechanical damage, and fungal infection, which will bring huge economic losses. It is an important problem to detect the freshness of apple.

Italy's Natale et al. [1] examined the quality of harvested oranges and apples using odor recognition and found that the method could predict apples' defects. Brezmes et al. [2] used smell recognition to detect the ripeness of pear, apple, and peach, adopted neural network analysis to identify fruit samples, and also found that there is a close relationship between smell signal and fruit; the success rate is up to 92%. Although China starts late in the research of odor recognition technology, it has made great progress. In 1995, Pan and others first developed a system to detect smell of apples. The sensor array is used to collect the gas signal, then extracts the characteristic value from the signal curve, and uses the characteristic value as the input vector of pattern recognition. According to the results of signal processing by PCA (Principal Component Analysis), the good and bad apples can be identified, but there are overlapping parts. The research is mainly carried out under the condition of laboratory, and the classification level and the recognition efficiency need to be further improved. Hu et al. [3] used PEN2 electronic nose system to detect citrus fruits stored in different ways and time. The results showed that linear discriminant method was better than principal component analysis method in identifying citrus fruits stored in different time. The load analysis shows that 2, 7, and 9 sensors have great effect on citrus aroma. Electronic nose is expensive and cannot meet the requirements of large-scale applications. A 2017 study by Guo and Sun [4] found that ethylene release from apples is closely related to their ripeness. When ethylene release is less than $1\,\mathrm{mg} \cdot \mathrm{L}^{-1}$, the apples do not ripen; when ethylene release is greater than $1\,\mathrm{mg} \cdot \mathrm{L}^{-1}$, or less than $6\,\mathrm{mg} \cdot \mathrm{L}^{-1}$, the apples do ripen; when ethylene release is greater than $6\,\mathrm{mg} \cdot \mathrm{L}^{-1}$, the apples overripe. Because of the complex changes of the external environment, the concentration of single gas is not enough to judge the freshness characteristics accurately, but the research results of the concentration characteristics of ethylene gas are of great significance to freshness identification technology.

At present, the study of odor recognition technology in scientific research institutions is still in the laboratory stage, which is suitable for on-the-spot real-time detection and network remote monitoring. The key technologies such as gas sensing mechanism and pattern recognition algorithm still need to be further improved and modified. In this paper, a high-precision identification and matching algorithm is proposed to transmit detection data by wireless communication in the open environment, in which the self-made gas sensor array has a great price advantage over the finished electronic nose.

2. Related Work

2.1. Technical Principle. The odor recognition system consists of two parts: hardware system and software system. The software system is the host computer, mainly the pattern recognition module as well as the signal reprocessing unit. As a key part of converting gas signals into electrical signals, the gas detector has to be sensitive enough to identify and collect the mixture of gases produced by apples. The signal processing circuit preprocesses the signals collected by the sensors, such as filtering, amplifying, A/D conversion, etc. to reduce noise and signal errors. The obtained analog voltage signal is changed into a binary number that can be processed by a computer. The function of the signal reprocessing unit of the upper computer is to convert the binary signals collected by the computer into digital/analog signals and smoothen the signals. Finally, the signal recognition process is performed by the pattern recognition module to realize the quantitative and qualitative analysis of the measured gas. The basic workflow is shown in Figure 1.

As a core component of the odor recognition system, the performance of the gas detector directly determines the function of the odor recognition system. The gas detector is a key bridge for shifting gas signals into electrical signals, and when measuring the gas produced by the apples, the sensor adjusts the gas sample to filter out extraneous interference. The gas detector with good performance indicators can greatly improve the detection sensitivity of odor recognition systems. In an odor recognition system, the gas detector and its arrays must satisfy the following conditions:

(1) Gas detectors are able to identify different odors among the gas mixture, with strong gas detection generality, and also able to identify various odors at the molecular level

(2) When a gas sensor detects a kind of gas, the reaction to the gas odor molecule must be rapid and repeatable, without any "memory effect"

The smell of apples is another important indicator of their freshness. So far, more than 300 volatile compounds have been identified in apples, but only a small number of compounds can characterize the freshness of apples. In order to more accurately identify the changes of mixed gases during the process of apple deterioration, it is necessary for apple odor recognition system to be sensitive to distinguish the changes of different gases. The odor recognition system identifies the apple gas by the chemical reaction between the volatile gas mixture of apples to be measured and the sensitive material of gas sensor. So that the gas sensor generates resistance value, current, and other electrical signal changes to realize the acquisition from nonelectrical gas signal to the electrical signal. The collected electrical signals are transmitted to the host computer system, and after processing the signals, the characteristics of the apple odor signals are extracted. The changes of gas were identified by the system pattern recognition unit, and the results of freshness of apples were compared by the analysis system.

2.2. Technical Methods. Our research team has done a lot of relevant research work on odor recognition technology and completed the related system design, algorithm research, experimental data analysis, and so on. The system consists of host, ZigBee transmitter, ZigBee receiver, airtight box, and sensor array, as shown in Figure 2.

PC computer as the host is used as the controller of the experiment system and the memory of the experiment data, and the display can show the change of the gas concentration during the experiment. The ZigBee sensor array is used to collect gas concentration in the sealed box. The ZigBee transmitter sends gas concentration collected by sensor array to the ZigBee receiver; the computer processes the data and identifies the freshness. The system uses wireless sensor network nodes to realize data transmission. The use of wireless transmission technology increases the universality

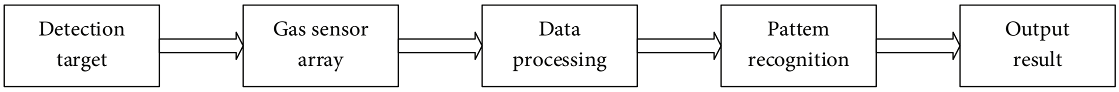

Figure 1: Odor recognition system flow.

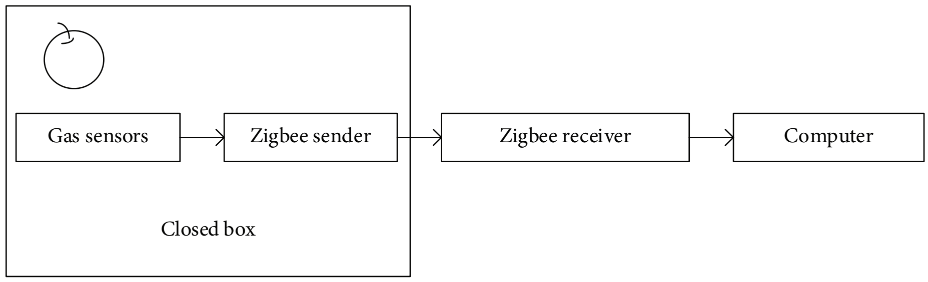

Figure 2: Composition of odor recognition system.

and convenience of the system. The airtight box has conductor grounding, used for shielding outside electromagnetic wave.

The types of sensors and performance indicators are shown in Table 1.

Because performance of gas sensor is affected by temperature and humidity, the experiment is carried out under the condition that the temperature and humidity are relatively stable. The gas collection steps are as follows:

(1) Put the gas sensor collection array into the sealed box, power up, and preheat

(2) The apple sample is placed in an airtight box, the gas is evenly diffused, and the smell emitted by apple to be measured reacts with the sensor array in the airtight box to produce an electric signal, and the data is collected and stored in the PC by ZigBee transmitter and receiver

(3) Preprocess the collected data and repeat the steps above by introducing clean air to restore the sensor to its original state after each measurement

For apples of different freshness, final response signal size is different. The CO2 concentration is measured among fresh, not-fresh, rotten, and severely rotten apples as shown in Figure 3.

From the graph, the concentration of carbon dioxide in apples increases with time, reaching a certain value, and freshness of apples is directly related to the concentration of carbon dioxide. Ranging from fresh, not stale, rotten to severely decayed, CO2 concentration is getting higher and higher. Other gases are collected and treated in a manner similar to carbon dioxide. In different test environments, the single gas concentration does not have unique identification characteristics, so it is necessary to collect data from other gas sensors and fuse the data to judge the freshness of apple.

2.3. Experimental and Data Processing Techniques. Sixteen apples were measured and the training data were normalized. According to the fresh characteristics of apples, the expected output vector of fresh apples is set as [1, 0, 0, 0]; the expected output vector of not-fresh apples is set as [0, 1, 0, 0]; and the expected output vector of rotten apples is set as [0,0,1,0]. The 16 apple charts are shown in Figure 4.

The original data collected by the sensor cannot be used directly for training and recognition because of great noise caused by the interference of the system itself and the external electromagnetic wave. Data preprocessing noise is used to extract the eigenvalue of the signals collected by the sensor array.

Firstly, the data collected by the sensor array are preprocessed, secondly, the eigenvalues are selected, and finally, BP neural network is used to identify the data. The construction of BP neural network determines the structure of BP neural network based on the characteristics of input and output data of the system. Because the input signal of gas eigenvalues has 15 dimensions and 3 types of apple fruit surface features are classified, the structure of BP neural network is 15-9-3. The training process of BP neural network includes the following steps:

(1) Network initialization

(2) Hidden layer output calculation

(3) Output computing in the output layer

(4) Error calculation

(5) Weight update

(6) Threshold update

(7) Determine whether the algorithm iteration is over, and if not, return to the hidden layer to output the calculation steps

In the process of identifying 16 groups of apples, recognition rate of apples can reach 93.75%, which shows that it is more accurate to identify degree of freshness of apples by using odor recognition combined with the ordinary matrix multiplication method in fuzzy comprehensive evaluation and can effectively identify degree of freshness of apples and categories. The identification result of number 11 in the experimental results is inconsistent with the actual freshness of apples. Due to data error caused by influence of external noise in the course of data collecting, the freshness of some apples cannot be correctly identified.

Table 1: Gas sensor array.

No.	Sensor model	Measured gas	Measuring range	Working voltage (V)
S1	MQ3	Ethanol	25–500 ppm	5.0
S2	MG811	Carbon dioxide	0–10000 ppm	6
S3	ME2-O2	Oxygen	0–25% vol	3.3
S4	ME3-C2H4	Ethylene	0–100 ppm	5.0

3. Fast Freshness Identification Technology

At present, the experimental method and algorithm research are mainly carried out in the laboratory condition, and gas concentration collection method in the closed environment, using the traditional BP neural network recognition technology, has the good effect. Therefore, feasibility of the odor recognition technology in the identification of apple freshness is verified. However, in the current information acquisition process, with the process of exhaust, sensor preheating, and acquisition information stability, the more complicated the procedure is, the longer the detection time is. The technology is still lacking field practicality. It is hoped that apple freshness can be identified quickly and related work such as experiment method, sensor array optimization, and algorithm optimization can be carried out on the basis of the research.

3.1. Experimental Apparatus. A gas sensor array is placed in a test vessel in a small container, put one apple at each time, and the gas emitted from the apple is detected at room temperature of 20°C and humidity of 50% Rh. The experimental equipment is shown in Figures 5 and 6. The odor recognition system is used to detect and analyze apples with different freshness.

A preheated sensor array is used to detect change of gas concentration in the process of apple aroma emission. In Figure 5, a battery powered wireless transmission module and a gas sensor array integrated circuit board are attached to the top of the glass bottle to capture apple smell. A wireless sending node is integrated into the circuit board of the sensor array, the apple test sample is placed on the test-bed, and the test bottle clasp after the sensor prediction is placed over the sample to collect all kinds of gases emitted by the sample. Figure 6 is another ZigBee wireless transmission node connected to the host computer, which receives the gas concentration data collected by the gas sensor array and saves it to the PC.

The steps are as follows:

(1) Establish a data acquisition platform and wireless transmission ZigBee network

(2) Preheat sensor array for 5 min according to the requirements of the sensor, and observe the data of the sensor collected by PC through serial port until it becomes stable, and then start the sample detection

(3) 300 groups of fresh, moderately rotten, and severely rotten apples are placed in the test box for 5 minutes in sequence, and the residual gases in the test box are removed by headspace method or drainage method between samples to ensure the consistency of the test environment and the accuracy of the sample data

(4) The collected 900 sets of data are classified and saved according to different freshness characteristics

3.2. Data Acquisition and Preprocessing. Among the odor recognition sensor arrays, the ethylene gas sensor is a ME3-C2H4 galvanic cell type sensor with an output current proportional to concentration, but a maximum output current is only 140 UA and a load voltage is 100 ohms, so it is necessary to enlarge original signal and control its output voltage in 0–3.3 V for follow-up processing. The ethylene concentration calculation formula is shown in the following formula in PPM.

$$P = \frac{83}{(2.207 - 0.608) * \left(V_{\text{out}} - 0.608\right)}. \quad (1)$$

In the open environment, the concentration of carbon dioxide, ethylene, ethanol, and oxygen in three kinds of apples is measured by gas identification system. Figure 7 shows the experimental results.

The original data collected by the sensor cannot be directly used for training and recognition because of interference of system itself, temperature sensitivity of sensor, and even interference of external electromagnetic wave. The data preprocessing process is to preprocess sensor array signal to extract eigenvalues. The process is as follows.

3.2.1. Data for Removing Singularities. The data of carbon dioxide, ethylene, ethanol, and oxygen concentration are obtained by eliminating singularity of original data of apples with different freshness.

3.2.2. Least Square Filtering. Because of interference of the system and temperature sensitivity of the sensor, the data are filtered by linear least square filter to remove noise and get a relatively smooth image.

3.2.3. Extraction of Eigenvalues. Take the first 60 seconds and every 5 seconds to take a data eigenvalue, multipoint eigenvalue extraction to do data training, then take the data filter processing. The results are shown in Figure 8.

As can be seen from the diagram, after preprocessing, concentration information of carbon dioxide, ethanol, and ethylene after 30 seconds is used as determining factor to determine freshness of apple based on stability of the sensor. The extracted data are trained and tested by extracting the eigenvalues.

The original data volume of gas sensor array is very large, dimension is correspondingly large, so complexity of classifier is also increasing; and it is easy to produce explosion. The performance of classifier can be improved by reducing dimension and improving extraction of eigenvalues. The extraction of sensor data eigenvalues is to transform the samples from high-dimensional space to low-dimensional space by mapping or transformation and extract main information which reflects essential attributes of target signal. The optimal value of BP neural network optimized by hybrid frog-leaping algorithm is used to train the network, which can accurately distinguish apples with different freshness.

3.3. Optimization of Sensor Array. In the process of odor recognition, sensor array is the key of information collection. Using reasonable gas sensor can not only improve recognition accuracy, but also improve collection efficiency. Continuous projection algorithm (SPA) is a forward variable selection method, which is used to solve classification problem. The purpose of SPA is to select a small set of variables with less redundancy and minimum collinearity, with elimination of redundant information in original matrix. The correlation contribution of each sensor to different freshness of apple is studied by PCA analysis. Figure 9 is a bar chart of the contribution rates. Figure 10 is a histogram comparison of RMSEP (Root-Mean-Square Error of Prediction).

As can be seen from the diagram, values of all sensors on PC1 are greater than 0.8, and the load coefficients of S2, S3, and S4 are very close, which means that these sensors have similar recognition functions and some overlapping information. Therefore, redundant sensors can be removed from the array. By retaining useful sensors and eliminating redundant ones, the sensor array platform of the system is reconfigured by using sensor array optimization SPA algorithm. Figure 10 shows RMSEP with different number of variables (number of sensors), in which three sensors (S1, S2, and S4) in the array are selected according to the relatively low RMSEP.

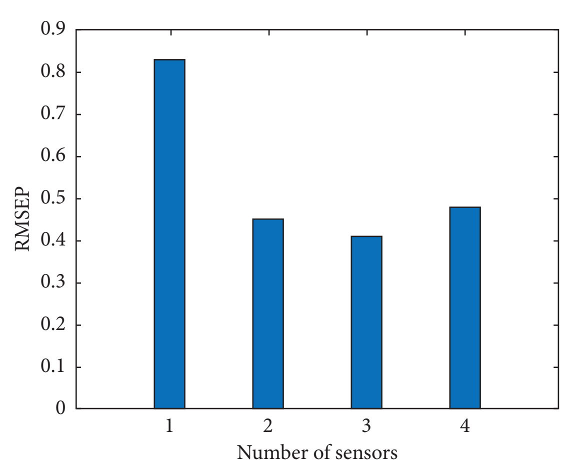

FIGURE 10: RMSEP values for different variables.

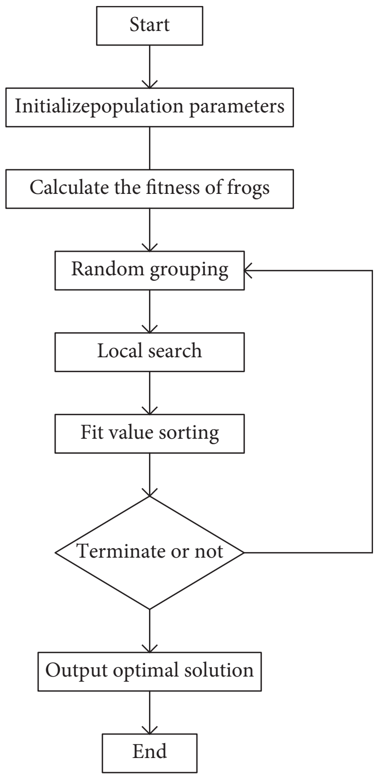

Figure 11: Flowchart of mixed leapfrog algorithm.

3.4. Hybrid Leapfrog Algorithm. Leapfrog algorithm (SFLA) is a heuristic group evolutionary algorithm with high computational performance and excellent global search ability. The flow of hybrid leapfrog algorithm is shown in Figure 11.

The algorithm works like this:

(1) Initialize the population information to determine the population size F, as shown in the following formula:

$$\mathrm{F} = \mathrm{m} * n. \quad (2)$$

Among them, m is for the number of subgroups, and n is for the number of frogs in each group.

(2) Compute fitness, the objective function value for each solution.

(3) According to descending order of fitness, write down location of the first best frog as the first global optimal solution. F frogs are assigned to m groups and each group has n frogs. Then start population optimization (local optimization). The positions of the best and worst frogs in the subpopulations are recorded as P_b and P_W, respectively. Trigonometric probability distribution is used to assign more weights to frogs with better fitness values and lower weights to frogs with worse fitness values. So the highest probability of a frog being selected as a subgroup is $P_1 = 2/(n+1)$, and the lowest probability is $P_1 = 2/n(n+1)$. Update position of the frog by optimizing the position of the worst frog in the subgroup in formulas (3) and (4).

$$D_S = \mathrm{rand}() * (P_b - P_W), \quad (3)$$

rand() is a random number of [0, 1].

$$\begin{aligned} D_S &= \min\{\mathrm{int}[\mathrm{rand}() * (P_b - P_W)], S_{\max}\} \\ &= \max\{\mathrm{int}[\mathrm{rand}() * (P_b - P_W)], -S_{\max}\}, \end{aligned} \quad (4)$$

$(-D_{\max} \le D_S \le D_{\max}) S_{\max}$ represents the maximum step allowed by an individual frog.

Replace the bad frog with the better frog, and if you do not get a better frog after the update, randomly generate a frog to replace P_W and return to the loop. The algorithm outputs the optimal solution and ends until the number of cycles or the stop condition is met.

3.5. Optimizing BP Neural Network. The structure of BP neural network is determined according to characteristics of input and output data of the system. Because the input signals of odor characteristics have 9 dimensions, there are 3 kinds of freshness characteristics to be classified. According to Kolmogorov's theorem, the range of hidden layer nodes is [4, 13], and the optimum number of hidden layers n is 10. So the structure of BP neural network is 9-10-3; that is, there are 9 nodes in input layer and 10 nodes in hidden layer; the output layer has three nodes.

After pretreatment, 900 groups of fresh degree characteristic signals are selected, from which 750 groups of data are randomly selected to train the network, and 150 groups of data are used to test the network classification ability. The expected output vector of fresh apple is set to [1, 0, 0]; the expected output vector of moderately rotten apple is set to [0, 1, 0]; the expected output vector of severely rotten apple is set to [0, 0, 1]. The training data are normalized according to the following formula:

$$X_n = \frac{x_n - x_{\min}}{x_{\max} - x_{\min}}. \quad (5)$$

The training error of BP neural network is shown in Figure 12, and the training error of optimized network is shown in Figure 13.

The unoptimized network reaches the minimum system error $4.21e^{-12}$ after 15 iterations, and the optimized network reaches the minimum system error $3.49e^{-10}$ after 12 iterations. The optimized network has fewer iterations than the unoptimized network, and the optimized algorithm is better than the original algorithm in training times and error.

Through 750 sets of data trained network, 150 sets of data are classified and 150 sets of sample data are randomly mixed to test accuracy and stability of the network. The results show that freshness of apples is divided into three grades; 148 out of 150 groups of test data could correctly identify the freshness of apple, and the classification accuracy is as high as 98.67%.

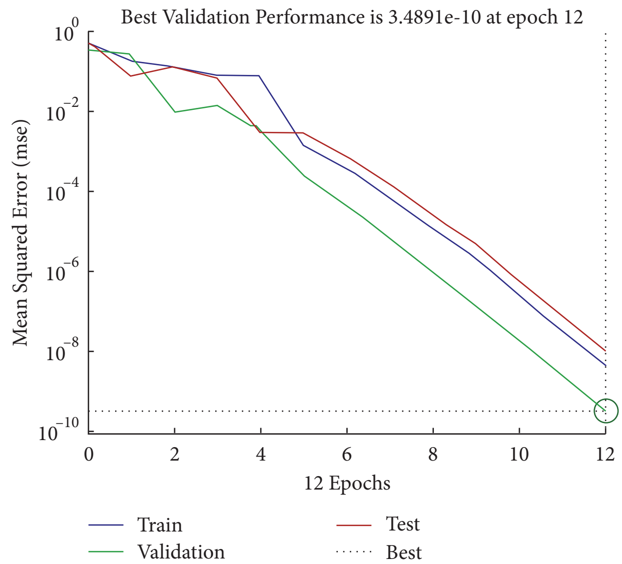

Figure 12: BP training error.

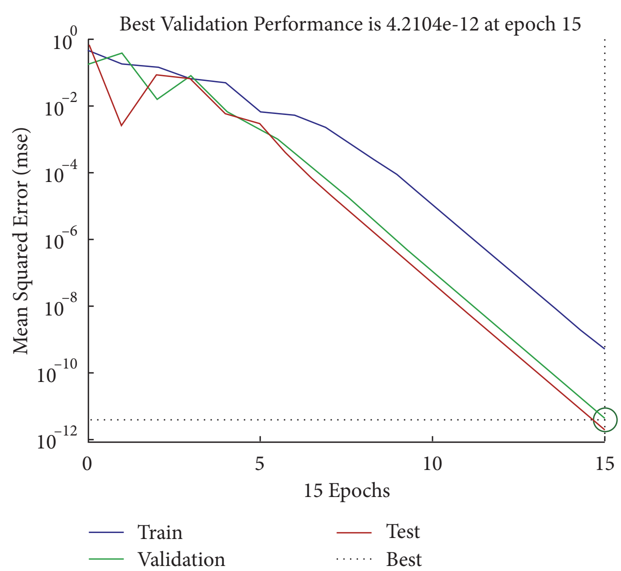

Figure 13: Optimizing BP training error.

4. Conclusion

In this paper, quick detection and analysis of apple freshness is completed by the optimization of odor recognition system, data preprocessing, sensor array, and BP neural network algorithm optimized by mixed frog leaping. The experimental results show that the algorithm has advantages of strong overall searching ability, fast training speed, and high recognition efficiency. The sensor array has reasonable composition and high accuracy and also can distinguish apples with different freshness. However, there are some limitations in the application of the system. To identify freshness of different kinds of fruits, it is necessary to pass a large number of experimental data, and the experimental testing time is slightly longer, and further optimization design is needed to realize the fast freshness detection of different kinds of fruits.

The importance of learning English is increasing as China's foreign exchanges become more frequent. China's independent colleges have been steadily growing in recent years, with the main school's main characteristic of cultivating applied talents, and teaching quality gradually improving. College English teaching is a practical application of college English education and instruction. The "sum of beliefs, recognized values, and technologies commonly accepted by the members of a specific community" is the world outlook and mode of behavior that a group of researchers engaged in a particular science adopts. Modern information technology has pervaded people's work and lives since the dawn of the information age, and it is now widely used in a variety of fields. Teachers' primary roles have shifted from disseminator of information, presenter of knowledge, transmitter of culture, and provider of correct answers in today's learning environment supported by modern information technology to promoter of learning, organizer of activities, student helper, and interactive collaborator. This paper obtains some information useful to the development of teaching work based on the data mining algorithm used in the mining practice of the educational administration information management system. This information is useful for improving teaching quality, implementing the talent development program more effectively, mastering student skill development, and teachers' teaching situations.

1. Introduction

With the increasingly frequent foreign exchanges in China, the importance of English learning is becoming more and more prominent. In recent years, China's independent colleges have developed continuously, with the main school running characteristics of cultivating applied talents, and the schooling quality has been gradually improved [1]. Since the 1990s, English schooling at college units in many Chinese universities have successively launched the schooling quality assurance system. Its main purpose is to improve schooling measures and promote the improvement of schooling quality through continuous schooling quality monitoring. English schooling at college is a specific application in the field of English schooling at college education and schooling [2]. In addition, teachers in independent colleges and universities have many courses and great teaching pressure. Many teachers do not have much energy to design an interesting, interactive and diverse English class. In addition, students are not easy to learn. As a result, many teachers teach according to the book, the teaching form is single, the content is boring, and cramming teaching, which finally make teachers become "lonely speakers" who entertain themselves on the podium.The world outlook and behavior mode that researchers engaged in a certain science follow together is "the sum of beliefs, recognized values and technologies accepted by members of a specific community" [3]. First, the data set is divided into training data set and test data set. First, the training data set is used to construct the model by analyzing the database tuples described by attributes. This stage is also a learning stage. The generated model is expressed in the form of classification rules, mathematical formulas, or decision trees. However, there are still many problems in English schooling at college in independent colleges: students' weak foundation, incorrect learning attitude, poor autonomous learning ability, serious shortage of teachers, unreasonable teacher structure, old and boring schooling mode, serious shortage of schooling hardware, and so on. The evaluation index of schooling quality is an important basis of schooling quality assurance system. The existing evaluation indicators mostly adopt the comprehensive evaluation method, and its index system is usually composed of multilevel indicators [4, 5].

Schools, as the output platform of future talents, should have this forward-looking vision as the universal development of modern information technology marks the rise of global economic integration, closer multilateral cooperation among countries, and continuous improvement of international exchanges. Traditional schooling activities usually only involve teachers, students, schooling materials, and other basic elements, but modern schooling also includes the element of "modern information technology" [6, 7]. This method of assessing educational quality is widely used and has produced some results. Traditional methods of evaluating educational quality, on the other hand, are not without flaws. Teachers' primary roles in the learning environment supported by modern information technology have shifted from information disseminators, presenters of knowledge, transmitters of culture, and providers of correct answers to promoters of learning, organizers of activities, student helpers, and interactive collaborators [8, 9]. This paper uses modern information technology to examine the educational quality of English schooling at the college level in order to serve as a model for future large-scale English schooling implementation at the college level. It is not only possible but also necessary to use modern information technology to assist English schooling in college, and it is an unavoidable requirement for developing innovative talents. English as a language subject has gotten a lot of attention in the process of using modern information technology to innovate traditional education [10, 11] because of its unique communication and practicality.

Assisted by modern information technology, higher vocational schooling can add advantages to traditional schooling, such as strong interaction, large amount of information, strong real-time, diverse media, and rich forms, which have a great positive impact on language learners' mastery of listening, speaking, reading, writing, and translation in English schooling at college and the cultivation of autonomous learning ability, At the same time, English schooling at college reform and English teachers are facing new challenges and opportunities [12]. In order to comprehensively, objectively, scientifically, and accurately evaluate the quality of English schooling at college based on modern information technology, the combination of formative evaluation and summative evaluation should be adopted, and the evaluation procedure should be standardized to ensure the reliability and validity of the evaluation [13]. Students cannot understand the charm of English, cannot have interest in English schooling at college quality, and cannot improve their English level. The data of teachers' teaching evaluation cover a wide range and has qualitative attributes, such as students' overall evaluation. There are also some quantitative attributes, which are relatively few, such as students' evaluation of teachers' teaching content. Data mining algorithm has good efficiency and effect in dealing with discrete data. Before data mining, data can be discretized in advance. Of course, data mining algorithm can also deal with continuous data. Teachers can carefully design and organize schooling through schooling software and network resources to truly play the leading role of teachers [14]. Different from audiovisual schooling means, the application of modern information technology characterized by multimedia and network requires teachers not only to master information application technology, such as word processing and operation skills, but also to learn to use some corresponding schooling software. Modern information technology assisted English schooling at college is a schooling method to cultivate students' comprehensive ability [1]. On the other hand, although multimedia schooling has changed in schooling form, it cannot be separated from the role of teachers' guidance.

2. Related Work

According to literature [15], when English schooling at college goes global, it will be localized, and localization of English schooling at college is an unavoidable result of globalization. According to literature [16] literature, the number of college students in China has risen sharply as a result of the continuous expansion of university enrollment, but English teachers are becoming increasingly tense, which has led to the continuous expansion of class size, with some colleges and universities having more than 100 students in a class. This will inevitably result in fewer language communication activities between teachers and students, resulting in a continued decline in schooling efficiency and quality in English classrooms. Data mining has been facing the application field of solving practical problems since it was proposed, according to literature [17], and its scope is very broad, involving almost all economic and social industries, including economic management, finance, insurance, electric power, astronomy, petrochemical, biology, geography, geology, and so on. According to literature [18], traditional English schooling at college is facing severe challenges due to the application of computer network technology and the development of English network resources. According to literature [19], it can be seen that the development of society promotes homogeneity on the one hand, and the school education theory and its elements are interconnected and further strengthened; on the other hand, the strengthening of localized knowledge and research makes foreign language education present heterogeneity and diversity, which is the interaction of globalization and localization of English education in the university paradigm. Literature [13] research shows that students' English learning materials are very rich, and their learning methods are increasingly diversified. Various English learning websites, audio materials, and multimedia software emerge one after another. Many English schooling at college textbooks are also equipped with CD-ROMs, such as new English schooling at college and new practical English. Literature [20] puts forward that from the perspective of the law of language schooling itself, each country and region has its own unique "localized" language schooling policy, schooling path, schooling approach and schooling method, and has its own unique local culture, language habits, thinking mode and the "migration" interference of mother tongue. Literature [21] through the big data analysis method, as a kind of human cognitive practice, school education activities have a complex interactive relationship among teachers, students, and content. Compared with "school education," teachers are the undertaker and subject of activities, and students are the object and object of teachers' work. Literature [22] studies show that in the face of the wave of globalization, especially the convergence of educational technology development, educational exchanges between the East and the West are also deepening. The globalization trend of foreign language schooling has become inevitable, which is mainly reflected in the diffusion and integration of schooling theories, the international sharing of educational resources, and the development of English schooling at college materials and schooling resources towards a more international trend. Literature [23] pointed out that the application and popularization of network technology are making China form a brand new network society. People's working methods and learning environment have undergone great changes, and it is entirely possible to realize "lifelong education" and "national learning."

Based on the data mining algorithm in modern information technology, this paper analyzes the quality of college English teaching, designs learning tasks, mobilizes learners' potential, provides scaffolding activities for learners, carries out data mining for learners, and gives guidance, feedback, and evaluation on the problems encountered in the learning process.

3. Construction of Algorithm Model for English Schooling at College Quality Analysis

3.1. Data Mining Principle and Algorithm. The data mining algorithm is a global and parallel search optimization algorithm. Students are the initiator and subject of activities, whereas schooling content is the object and object of activities, as opposed to "learning." The following are some of the meanings of this definition: Massive, real-time, and noisy data sources are required; what they uncover is knowledge that is relevant and interesting to users. And the knowledge that is discovered must be understandable, acceptable, and useable; finding universal knowledge is not required, but only supporting specific problems is. When solving optimization problems, data mining algorithms have the problem of searching for the best solution slowly, which is frequently accompanied by premature convergence. According to the advantages of randomness and stable tendency of cloud droplets in cloud model, conditional cloud generation algorithm and basic cloud generation algorithm are adopted to realize crossover and mutation operations, accelerate the search ability, keep the random search, and adaptively adjust the crossover and mutation probability to prevent falling into local optimum defects. The data mining algorithm adopts B/S structure (browser/server, browser/server mode), the server side stores applications and related databases, and customers access the server through the browser. The flow structure of data mining algorithm is shown in Figure 1.

For training sample set $\{(x_i, y_i)\}$, $i = 1, 2, \ldots, n$, $x_i \in R^n$, $y_i \in R$. Xi and Yi are the evaluation index of classroom schooling quality and the output value of classroom schooling quality respectively, which are fitted by the following formula

$$y = \omega^T \cdot x + b, \tag{1}$$

where ω is the weight vector and B is the offset.

According to the principle of structural risk minimization, the SVM regression model for solving the problem of (2) is

$$\min \frac{1}{2}\omega^T \omega + C \sum_{i=1}^{n} (\xi_i + \xi_i^*). \tag{2}$$

Constraints are

$$\begin{cases} y_i - \omega^T \cdot x_i - b \le \varepsilon + \xi_i, \\ \omega^T \cdot x_i + b - y_i \le \varepsilon + \xi_i^*, \\ \xi_i^* \ge 0, \xi_i \ge 0, \end{cases} \tag{3}$$

where c is the penalty parameter and ε is the fitting accuracy between the actual value and the regression function. Using duality theory, the (3) is transformed into a quadratic programming problem, namely

$$\begin{aligned} L(\omega, b, \xi, \alpha) &= \frac{1}{2}\omega^T \omega + C \sum_{i=1}^{n} (\xi_i + \xi_i^*) \\ &\quad + \sum_{i=1}^{n} \alpha_i \left(\omega^T \phi(x_i) - b + \xi_i - y_i\right), \end{aligned} \tag{4}$$

where α_i is Lagranse multiplier.

For the nonlinear classroom schooling quality evaluation problem, the classroom schooling quality training samples are mapped to the high-dimensional feature space through the nonlinear mapping function $\phi(\cdot)$, and the linear regression is carried out. The nonlinear SVR model is

$$y = \sum_{i=1}^{n} (\alpha_i^{\bullet} - \alpha_i) K(x_i, x) + b, \tag{5}$$

where K $(Xi,\ x)$ represents the kernel function.

Let Xi, $XJ \in u$ be described as $Xi = \{Xi, 1, Xi, 2, \ldots, Xi, m\}$, $XJ = \{XJ, 1, XJ, 2, \ldots, XJ, m\}$, then the difference measurement formula for simple matching between Xi and XJ is

$$d\left(x_i, x_j\right) = \sum_{l=1}^{m} \delta\left(x_{i,l}, x_{j,l}\right). \tag{6}$$

Among

$$\delta\left(x_{i,l}, x_{j,l}\right) = \begin{cases} 1, & x_{j,l} \ne x_{i,l}, \\ 0, & x_{j,l} = x_{i,l}. \end{cases} \tag{7}$$

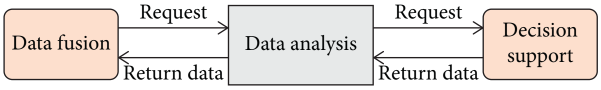

Figure 1: Flow chart of data mining algorithm.

Let $X = \{X1, X2,...,Xn\}$ be a group of data objects, where $X = (xi1, xi2,...,xim)$ represents a data object with m attribute values. Use "mode" to represent this set of data objects, and the mode of x is defined as $Q = (q_1, q_2, \ldots, q_m) \in U$ so that

$$D(X,Q) = \sum_{i=1}^{n} d(X_i, Q). \quad (8)$$

Get the minimum.

Data mining is a method that evolves over time. Data mining, on the other hand, is discovery-driven in that patterns are automatically extracted from data through a lot of searching work. Traditional data analysis methods generally give a hypothesis first and then pass the data verification, which is hypothesis-driven in a sense.

3.2. Analysis Model of English Schooling at College Quality Based on Data Mining Algorithm. Many studies have found that when solving a data mining algorithm, the speed of finding the best solution is slow, and that this is frequently accompanied by premature convergence. The conditional cloud generation algorithm and the basic data mining algorithm are used to realize crossover and mutation operations, accelerate optimization ability, and maintain the randomness of search, according to the randomness and stability tendency of the data mining algorithm. The crossover and mutation probabilities are adaptively adjusted to avoid falling into the defect of local optimization. Educational data mining and learning analysis are the two main directions of big data research in the field of education. Because many independent colleges and universities use the final English score and English schooling at College-4 pass rate of each semester to measure teachers' schooling level, most teachers focus on how to improve students' English schooling at College-4 pass rate and examination pass rate, ignoring English schooling itself. The relationship between educational data mining, learning analysis, and English schooling at college, pedagogy, and schooling quality is shown in Figure 2.

Data mining is an important means of data utilization under the background of big data, which refers to the process of extracting effective, novel, and potentially useful data from a large number of data and utilizing understandable knowledge, models and rules. The data mining algorithm is used to optimize the English schooling at College quality analysis model, and the optimization process is shown in Figure 3.

① Select the evaluation index of English classroom schooling quality.

② Collect the historical data of English classroom schooling quality evaluation, process the data, and eliminate some useless data.

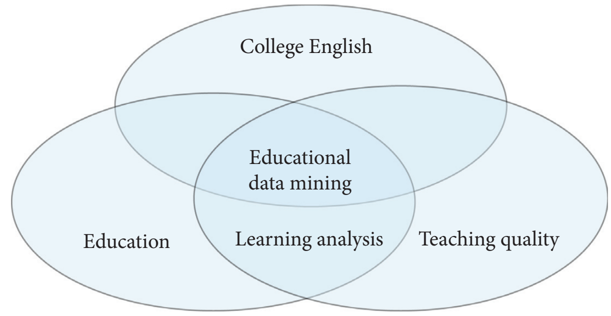

Figure 2: Major disciplines involved in data mining and schooling quality analysis of English schooling at College.

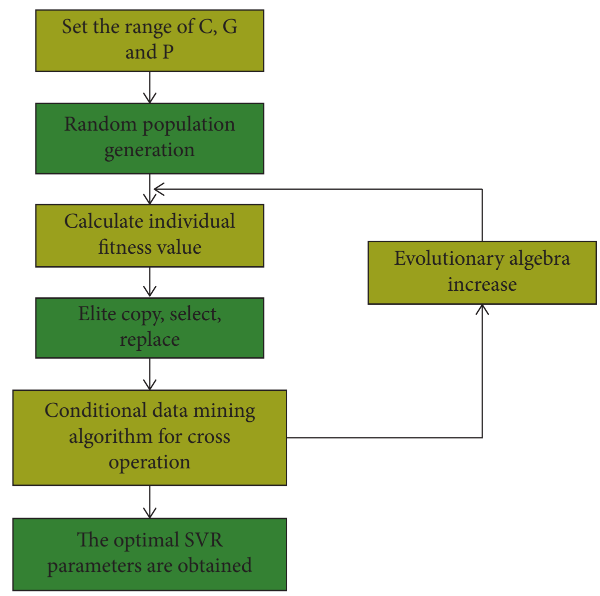

Figure 3: Optimization of English schooling at College quality analysis model based on data mining algorithm.

③ In order to speed up the learning of SVR, the evaluation index values of English schooling at College quality are normalized. The specific normalization formula is as follows:

$$x_i' = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}}, \quad (9)$$

where $x_{\max}$ and $x_{\min}$ represent the maximum and minimum values of each evaluation index, Xi and x'i. Represent the values before and after normalization, respectively.

After processing the data by formula, the range of all indicators is [0,1], which can improve the efficiency of the English schooling at College quality analysis model.

④ Divide the processed and normalized data into two parts: training sample set and test sample set. Input the training samples into SVR for training. In the training process, use data mining algorithm to optimize the English schooling at College quality analysis model.

⑤ Get the optimal parameters and learn the training samples again with the optimal parameters, so as to establish the optimal evaluation model of English classroom schooling quality.

⑥ Test the performance of the established optimal evaluation model of classroom schooling with test sample set, so as to realize the automatic evaluation of English classroom schooling quality.

4. Analysis and Application of English Schooling at College Quality Based on Modern Information Technology

4.1. Application of Data Mining in English Schooling at College Quality Analysis. English schooling at College inherits the benefits of schooling, the most notable of which is high schooling efficiency, which can help to alleviate China's shortage of high-quality talent and meet the needs of national modernization to some extent. As a college public English teacher, we should help students expand their English knowledge, broaden their horizons, and gain a more comprehensive understanding of the quality of English schooling and learning on the basis of a nine-year compulsory education. Data mining has been oriented to the application field to solve practical problems since its inception, and its scope is extremely broad, encompassing almost every industry in the economy and society, including economic management, finance, insurance, electric power, astronomy, and the petrochemical industry. Biology, geography, and geology are three fields of study. Schooling activities, as one of the human cognitive practice activities, have a complex interaction and relationship between teachers, students, and content. Compared with "schooling," teachers are the undertaker and subject of activities, while students are the object and object of teachers' work. Compared with "learning," students are the undertaker and subject of activities, and schooling content is the object and object of activities. However, because many independent colleges and universities take the final English score and English schooling at College-4 pass rate of each semester as the standard to measure teachers' schooling level, most teachers focus on how to improve students' English schooling at College-4 pass rate and examination pass rate, thus ignoring the schooling of English itself. Students cannot understand the charm of English, cannot have interest in English schooling at College quality, and cannot improve their English level. Domestic enterprises applying data mining are led by communication enterprises (China Mobile, China Unicom and China Telecom), and the depth and breadth of application are in a leading position. Domestic banks, insurance companies, and securities companies are also more willing to use data mining technology, which is consistent with the international trend. In the next few years, the application of data analysis in the financial field will definitely develop from traditional statistical analysis to large-scale data mining application.

Due to the large number of students, there are significant differences between students in basic English knowledge and language application ability in the analysis of English schooling at College quality, making it difficult for teachers to accurately grasp the "degree" of schooling requirements in the process of schooling quality analysis. The use of data mining technology by search engine companies is also in high demand. They must employ data mining algorithms to discover the structural and association relationships between web pages in order to better push web pages. In order to maximize commercial profit, major search engines must increase advertising revenue and analyze click stream data.

If schooling is conducted strictly according to schooling requirements, it will put a significant number of students with a weak foundation and lack of ability under psychological stress, causing them to experience excessive anxiety, tension, inferiority, disappointment, weariness, and other emotions. This group of students will eventually stop learning English at a college level. The majority of these students believe that their English learning is inadequate, and even worse, that they are tired of learning, believing that everything will be fine as long as they pass the final exam. Large class schooling of English at College quality still follows the traditional schooling mode, with the schooling goal of mastering language knowledge, the schooling content of words and sentences and discourse analysis, the schooling method of explanation and translation, and a limited ability and energy of teachers due to large class size, unsatisfactory schooling environment, obvious differences in students' levels, and limited ability and energy of teachers. Independent colleges and universities, on the other hand, have no shortage of studious students, and their attitude toward class is correct. Poor English foundation, low learning autonomy after class, quick success in learning English, and a strong purpose are some of their common issues. They want to pass the final exam and complete their English education at College-4, but they refuse to study hard and apply the teaching methods and skills.

4.2. Experimental Results and Analysis. Before the experiment, this paper trains the English schooling at College quality analysis model through 55 training sets. For each training composition, this paper should preprocess it, including segmentation, word segmentation, sentence segmentation, part of speech tagging and dependency parsing. In this paper, 5, 10, 15, ..., 55 English compositions were used for training, and a total of 20 models were trained. The performance of these 20 models was analyzed by using the above experimental evaluation criteria. The experimental results are shown in Figure 4. With the increase of the number of samples, the overall trend of accuracy, recall and F value also increases.

Secondly, through a group of comparative experiments, this paper tests the data mining algorithm and Soon's method on the same test set, and analyzes the advantages and disadvantages of this data mining algorithm. Our test set contains 30 English compositions written by Chinese students, of which there are 1420 entities in total.

The experimental results are shown in Figure 5. On the test set, son's model has accuracy, recall, and F values of

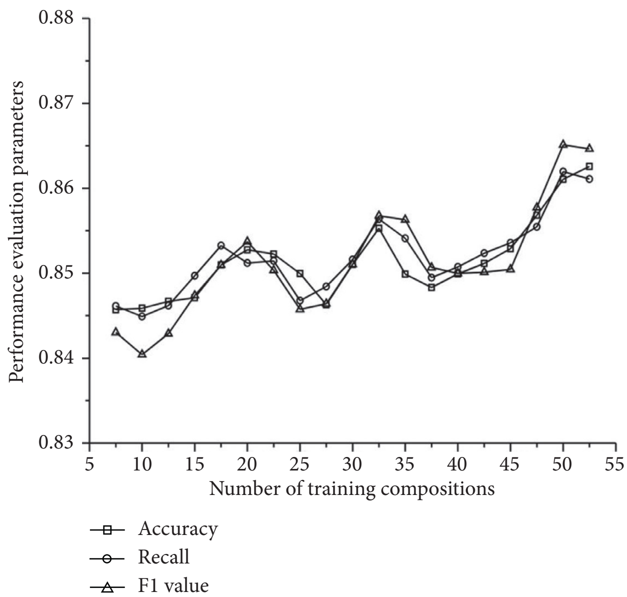

Figure 4: The change trend of accuracy, recall and F value with the increase of sample number.

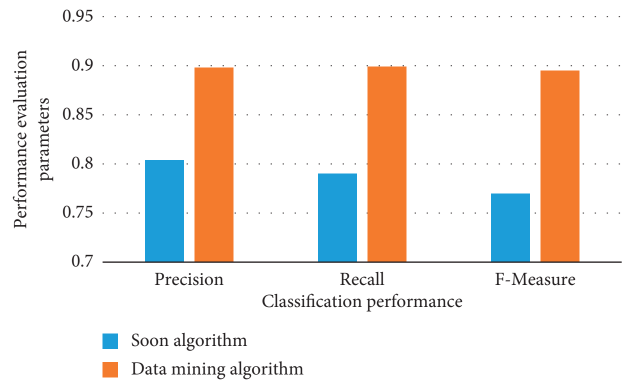

Figure 5: Performance comparison between data mining algorithm and Soon algorithm.

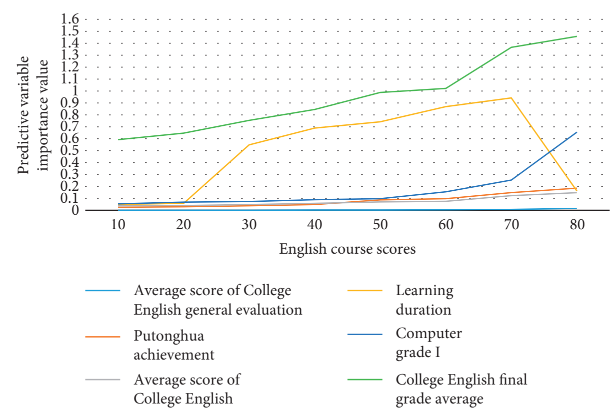

Figure 6: Importance value of each predictive variable.

0.804, 0.79, and 0.77, respectively, whereas the data mining algorithm model in this paper has accuracy, recall, and F values of 0.898, 0.899, and 0.895, which are all better than son's model. This also shows that selecting the right features and adding useful ones can help the data mining algorithm model perform better. Furthermore, the data mining algorithm model in this paper incorporates English schooling at College quality as an external knowledge source, allowing for the discovery of more co referential relationships of English schooling at College quality and an expansion of the co referential resolution range of the soon model.

Because Soon's method is a general method, that is to say, Soon's method may be effective in many fields, the performance of Soon's method on this test set is also better than that on MUC-6 and MUC-7 test sets. However, after feature extraction method optimization and feature design optimization, this data mining algorithm model has evolved into a more targeted co-reference resolution model in the application field, and it has more advantages in the field of English composition than Soon's model.

This study employs a data mining algorithm to construct a prediction model for English schooling at College-4 pass probability of English schooling at College quality analysis of our students by adding modeling attributes and adjusting model parameters in the data mining environment of SPSS modeler, based on students' basic information, English schooling at College quality analysis course scores, and various grade examination scores. By double-clicking on the prediction result node, you can see how important each attribute is. The importance value of each attribute is shown in Figure 6.

The most important factor in passing English schooling at College-4 prediction is "English schooling at College final grade average." The main reason is that the English schooling quality at College is similar to the requirements of English schooling at College-4, and the question types and questions are nearly identical. Both are written examinations that use answer cards to complete questions, according to the examination form. Both the students' knowledge level and examination mentality are taken into account. As a result, if the analysis of English schooling at College quality yields positive results, the likelihood of passing English schooling at College4 will naturally increase, as shown in Figure 7.

The pass rate and average score of English schooling at College 4 are higher for girls than for boys, according to the analysis of the data samples in the figure. The "learning duration" attribute indicates that the length of the learning period has an effect on whether students pass English schooling at College-4. The number of Public English schooling at College semesters for students in grades 2014, 2015, and 2016 is 4 semesters, 3 semesters, and 2 semesters, respectively, according to the school's training programs, and students are not permitted to apply for English schooling at College-4 in the first semester. The data show that during the first semester of an English schooling at College course, the number of English schooling at College-4 students can remain in the three digits, and that the number of English schooling at College-4 students drops sharply after the course, as shown in Figure 8.

It was discovered in a survey of college students' independent learning of English schooling at College quality analysis that "Only 42.5 percent of students can commit to

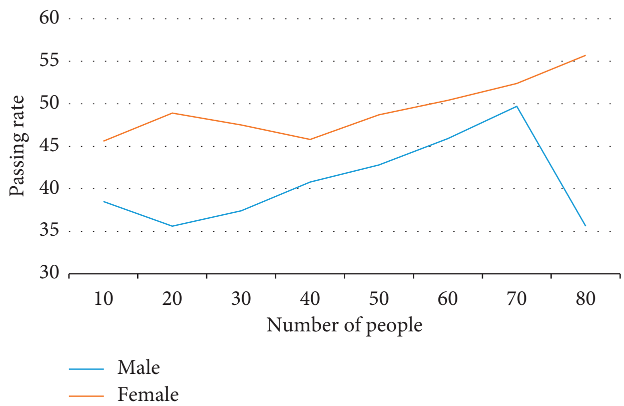

FIGURE 7: Pass rate of English schooling at College-4 for male and female students.

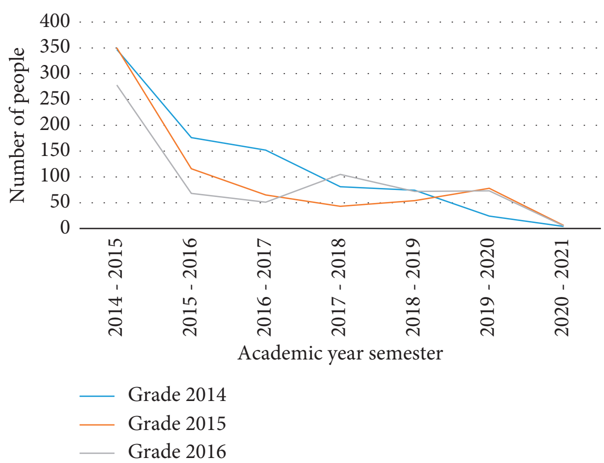

FIGURE 8: Statistics of the number of students passing English schooling at College-4 in each academic year and semester.

4–6 hours of study time per week, and less than 15% can commit to more than 7 hours of study time. Every day, students spend approximately half an hour studying English schooling at College quality analysis." We can see that during the 110 days from March 10th, 2020, to June 28th, 2020 (excluding May Day holiday), online class students spent an average of more than one hour per day on online self-learning, indicating that online English schooling at College quality analysis has played a positive role in stimulating students' learning motivation and enhancing students' self-learning ability, as shown in Figure 9.

At the end of the first semester of the online class, the average scores of each item were 15.5, 30.4, 10.3, 8.6, and 8, respectively, which were 1.2, 1.7, 1.2, 2.1, and 0.6 points higher than those of the non-online class. At the end of the second semester, the average scores of online classes were 16, 32.2, 12.2, 8, 8.6, respectively, which was 2.5, 2.6, 2, 1.6, 0.2 higher than that of non-online classes. The difference of scores shows that students in online classes have steadily improved their English learning scores under the network English schooling at College environment, and the speed of improvement is higher than that of non-online classes, as shown in Figure 10.

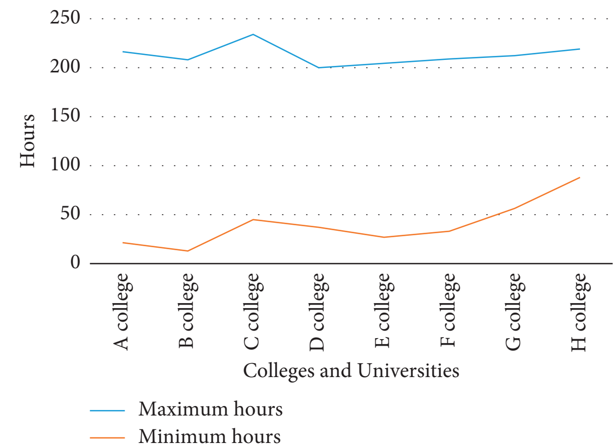

FIGURE 9: Statistics of autonomous learning hours of online English schooling at College for 2020 online class students.

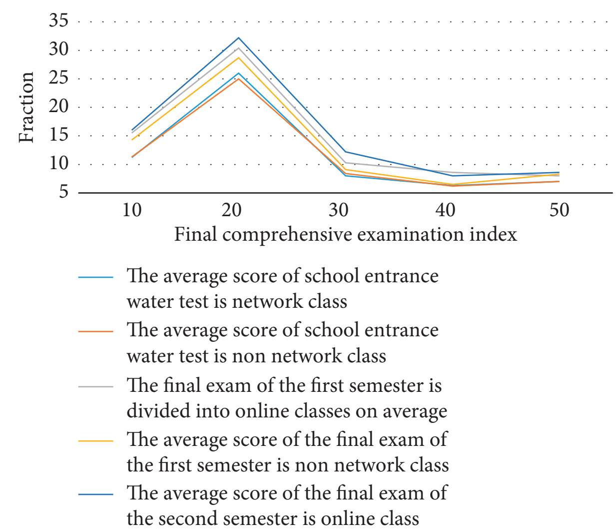

FIGURE 10: Comparison of scores of 2020 online class and non-online class.

5. Conclusions

In today's rapidly changing society and market, data mining technology provides us with methods and means that are unquestionably useful for making decisions. From the perspectives of the evaluation system, teaching mode, and teaching practice, this paper examines the role of network-based college English teaching mode in improving college English teaching quality. We have mastered the use principle of data mining algorithms and the realization of mining through research and practice and have implemented a data mining process using data mining tools. This allows us to gain a better understanding of data mining and lays a solid foundation for future research on the quality of college English teaching and data mining in our work. Educational data mining and analysis methods are becoming more common as educational data mining research advances, and the value of traditional educational data will be rediscovered. As a result, mining large amounts of traditional data is more likely to uncover deep-seated rules of college English development, teachers' teaching, and students' learning, among other things, which will aid in improving college English teaching quality analysis, improving teaching quality, and promoting students' learning.

Academic Editor: Tongguang Ni

The Chinese language is a nation's symbol, the accumulation of a country's magnificent culture, and the pearl precipitated in the long history's washing. The Chinese language is rich and complex, and there are still many topics and issues that merit repeated exchanges and discussions in academic circles. This study proposes a classification method of emotion polarity based on reliability analysis in order to identify the tendency of literary emotion in Chinese language. Support vector machine (SVM), class center, and KNN (K-nearest neighbor) are included in the combined classifier, which effectively improves the accuracy and efficiency of emotion polarity classification. A Chinese literary emotion analysis model based on the method of UKNNC (unbalanced K-nearest neighbor classification) is proposed at the same time by analysing the characteristics of text structure and emotion expression. The experimental results show that, when compared to traditional machine methods, the UKNNC method can analyse text sentiment in fine-grained and multilevel ways, while also improving the accuracy of Chinese literary sentiment analysis.

1. Introduction

The term "Chinese language and literature" specifically refers to a literary work that is created through Chinese editing and then communicated through Chinese works. The analysis of language application and artistic conception features in Chinese language and literature that follows is useful for improving human language expression ability and application. Using the content covered in Chinese language and literature can help students improve their language skills, improve communication with others, expand their thinking abilities, and better taste Chinese language and literature works. In essence, students can only grasp the applied context effectively if they have a broad understanding of Chinese language and literature, which helps to improve students' overall Chinese literacy.

Emotion analysis of Chinese language and literature refers to judging its emotion tendency by analysing and mining information such as emotions, positions, and opinions in the text [1]. It involves many fields such as data mining, information retrieval, and so on, and has a wide range of application value. Data level processing is very important for unbalanced classification [2, 3]. No matter whether the importance of samples is consistent in practical problems, data level processing will have a relatively positive impact on the final classification results. Traditional learning analysis techniques in the field of education frequently focus on analysing structured data but rarely consider unstructured data, making it difficult to accurately identify learners' attitudes, emotions, and psychological states [4, 5]. The support of classification methods is essential for successful classification of imbalanced data sets, and a good classification method is the key to success. When traditional classification methods are used to classify imbalanced data sets, however, test samples from a few classes are frequently misclassified into the majority of classes, making it easy to overlook a few classes and resulting in poor classification performance [6]. Because the complex distribution of unbalanced data is difficult to capture, current technology in this field still has many flaws. As a result, investigating an effective unbalanced data classification technology [7] is extremely important.

K-nearest neighbor (KNN) method has become one of the most famous algorithms in the field of pattern recognition [8–10] and statistics because of its simple algorithm, easy realization, no need to estimate parameters, and high classification accuracy, and it is also one of the earliest nonparametric algorithms applied to automatic text classification in machine learning [11, 12]. However, KNN method needs to store all the training sample data in the process of calculating the nearest neighbor of each sample to be tested, which leads to a large number of similarity calculations for classification and significantly increases the complexity of classification calculation with the increase of sample data set [13], thus reducing the classification efficiency. Based on this, this study puts forward a Chinese literary sentiment analysis model based on the method of unbalanced K-nearest neighbor classification (UKNNC) for learners' learning experience texts, which classifies the learning experience text information in multiple levels to improve the performance of learners' sentiment analysis and provide more effective support for teaching design and management.

Emotion analysis of Chinese literature belongs to the category of computational linguistics, which involves many research contents such as artificial intelligence, machine learning, information extraction, information retrieval, and data mining. It is closer to the goal of artificial intelligence than traditional technology, and has important research value in theory and application. Therefore, this study innovatively proposes an emotion analysis model of Chinese language literature based on UKNNC method. The difference between this method and the traditional voting strategy of combined classifiers lies in whether to vote on the categories of samples by multiclass classification by analysing the credibility of samples. Experiments show that the classification speed of this method is lower than that of SVM.

2. Related Work

As far as the nature of Chinese language is concerned, it involves a wide range of majors, but as a whole, liberal arts students are the main teaching objects, and some students do not study Chinese language and literature until they enter the university, which also reflects the charm of Chinese language and literature from the side, and makes the analysis of language application and artistic conception get corresponding attention and attention. Literature [14] puts forward Fisher discrimination rate that calculates the distance between positive and negative classes of each feature. The larger the distance, the easier it is to classify the data. Literature [15] puts forward the complexity measurement (CM) as the data set measurement index, and CM calculated the proportion of less than half of the samples in the nearest neighbors of the samples in the data set. The larger the CM, the larger is the cross between positive and negative samples. When IR is used as the data set evaluation index, there is no fixed value range of IR, but the CM range is 0–1, which makes it more comparable. Literature [16] holds that each sample has its neighbor distribution. When the sample is surrounded by samples of the same kind, the classification of the sample is simple, while when the sample is surrounded by samples of different kinds, the classification of the sample will be more difficult. In literature [17], the author used Naive Bayes and maximum entropy method to study the emotion classification of news and commentary corpus. Through experiments, it was found that the accuracy of binary value as feature weight was better. Literature [18] has studied the correlation between the extracted subject and the evaluation words of rhetoric. They introduce the relationship extraction into data mining, take the evaluation words and subjects co-occurring in the same sentence as candidate sets, and apply the maximum entropy model to extract the relationship with various features, such as words, parts of speech, semantics, and positions. The results show that degree adverbs can help improve the performance of subjective relation extraction.

In terms of classification method selection and design, it is primarily based on a thorough examination of the degree of influence of indexes (parameters, structures, and so on) of traditional methods on unbalanced data sets, with corresponding improvements to existing methods or the creation of new classification methods. The original training samples are primarily clustered or blocked in literature [19], and then representative training samples are selected to replace the original training samples. The literature [20] divides samples based on density. The KNN rule of distance weighting is based on the characteristics that the nearest neighbor points near the test sample contribute a lot to classification, whereas the opposite contribution is small, according to literature [21]. Literature [22, 23] proposes a generalised nearest neighbor classification method that assigns different weights to each dimension of classified data. The importance of boundary samples has been improved in the literature [24]. Literature [25] defines the representative function from two factors: the distance between two samples and the included angle and replacing the category attribute function with the defined function when calculating the weight by KNN method. In literature [26, 27], by summarizing the construction of praise and derogatory words, the table of influencing factors, the matching word list, and the clear word list in the field of electronic products, an evaluation system for electronic products was constructed, and the opinion mining of electronic products was realized, with the correct rate reaching 93%.

Emotion classification and extraction, as the basic research of emotion analysis, provide effective support for the application of emotion analysis, but there is still a big gap between the results of classification and extraction and the specific needs of users. Therefore, in order to narrow the gap with users' needs, the application research of emotion information becomes essential.

3. Research Method

This study examines the problem of Chinese literary emotion analysis, adopts the classification method of emotion polarity based on reliability analysis and the model of Chinese literary emotion analysis based on UKNNC method, and makes an in-depth study with various linguistic features, which greatly improves the effect of Chinese literary emotion analysis as a whole.

3.1. Traditional KNN. On the basis of the nearest neighbor method, the K-nearest neighbors (KNN) method was developed. It is one of the most widely used classification methods in the fields of data mining and machine learning, as well as the US Census Bureau's default data preprocessing method. It is now widely used in a variety of fields, including classification, clustering, and regression. This study will focus on how it can improve its classification.

Emotion tendency includes two categories: positive and negative. Therefore, emotion recognition can be regarded as two kinds of classification problems, namely, the recognition of positive and negative meanings. Based on this, KNN algorithm is used to identify the emotion of the text. The algorithm is a simple, effective, and nonparametric method, its essence is a predictive supervision algorithm, and its rules are data samples [28].

KNN's classification idea is very simple, that is, suppose that for a given sample $D = D(d_1, d_2, \ldots, d_l)$ to be classified (where l is the dimension of the sample), the computer trains the training data sets of known categories, finds out the k nearest neighbor samples most similar to D from these training data sets, and then classifies and votes D to determine its category.

Suppose the training set is

$$T = \{X, C\} = \{x_i, c_i\}_{i=1}^{n}, \quad x_i \in R^l. \tag{1}$$

Here, X is the training sample set, C is the category of training sample set, and test set is $S = \left\{x_j\right\}_{j=1}^{m}$.

The traditional KNN method mainly finds out the k training samples with the highest similarity with x_j from the training sample set X of known categories for each sample x_j to be tested:

$$M = \{X', C'\} = \{x_d, c_d\}_{d=1}^{k}, \quad M \in T. \tag{2}$$

The similarity of each sample x_i and x_j in the training sample set X is calculated as follows:

$$Sim = \left(x_i, x_j\right) = \frac{\sum_{t=1}^{n} w_{it} w_{jt}}{\sqrt{\sum_{t=1}^{n} w_{it}^2} \sqrt{\sum_{t=1}^{n} w_{jt}^2}}. \tag{3}$$

Here, w_{it}, w_{jt} represent the weight of the t-th feature item in samples x_i and x_j respectively, and the weight calculation formula of x_j belonging to class c_t is as follows:

$$W\left(x_j, c_t\right) = \sum_{x_i \in x_j} v\left(x_i, x_j\right) \phi\left(x_i, c_t\right). \tag{4}$$

Among them, $v(x_i, x_j)$ is the weight function of voting, generally taking 1 or $Sim = (x_i, x_j)$, and the ϕ function is as follows:

$$\phi\left(x_i, c_t\right) = \begin{cases} 1, & x_i \in c_t, \\ 0, & x_i \notin c_t. \end{cases} \tag{5}$$

x_j is classified into the category with the largest class weight W. Repeat this process to classify all samples to be tested. Finally, the classified category is classified with its real class label to measure the performance of this classification method.

The original KNN algorithm's classification principle is simple and straightforward to use, but there is no systematic consideration of the impact of sample data set imbalance on classification, that is, each selected nearest neighbor sample's representative degree to its class is treated the same. To solve this problem, an improved KNN algorithm is proposed in this study. This method primarily improves the algorithm in two areas: sample set imbalance between classes and sample set imbalance within classes.

3.2. Text Emotion Information Classification. The classification of text emotion information is primarily used to identify opinions, attitudes, preferences, and other related information expressed in natural language. Emotion classification research focuses on unstructured text information such as forums and blogs that come in a variety of formats and are written in a colloquial style. Emotion classification, unlike traditional topic-based text classification, focuses on subjective and objective classification, as well as emotion polarity classification. It is mainly divided into word-level emotion information classification, text-level emotion information classification, and sentence-level emotion information classification, depending on the granularity of the research.

Level-I sentiment information classification includes subjective and objective text classification and text sentiment polarity classification. The process is shown in Figure 1.

The mainstream method used in the classification of level-level emotion polarity is the classification method based on statistical learning. From the existing related research, it is found that the classification method based on statistics is also the most effective method to solve the classification of emotion polarity at present. In the existing research, scholars have tried to apply various statistical classification methods and linguistic features such as words and parts of speech to the study of emotion polarity classification, and achieved good results [29]. In order to further improve the classification accuracy, this study looks at two aspects: optimising the classification model and selecting effective features.

This study proposes a combined classifier method based on reliability analysis for optimising classification models. This study employs a method based on category attribute analysis for feature selection. Experiments show that the method used in this study can effectively improve classification accuracy without slowing down the classification process.

In the process of emotion polarity classification, through the analysis of emotion information, it is found that not all samples need to be discriminated by combined classifiers, and there is no obvious difference in the classification results of various single classifiers for samples that are easy to distinguish.

From Figure 2, we can see that the hollow circle and square respectively represent different types of sample points, and the circle and square which are far from the

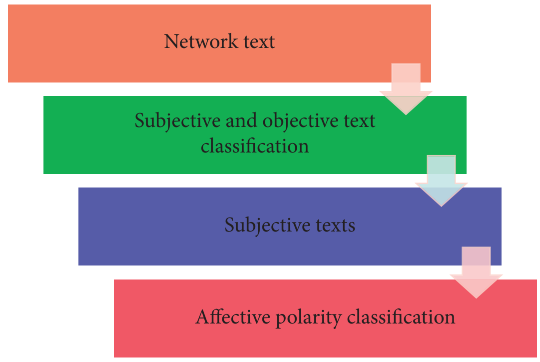

Figure 1: Emotion information classification process.

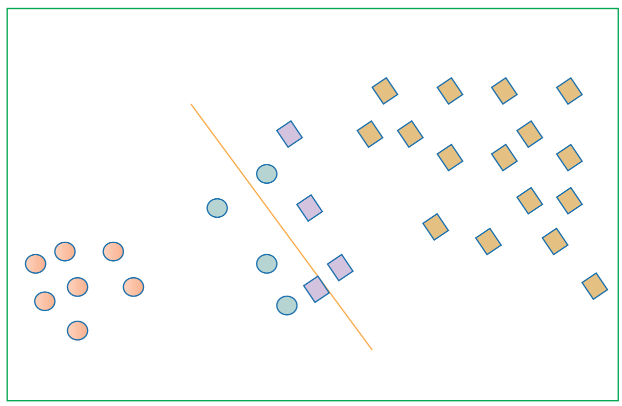

Figure 2: Schematic diagram of binary classification sample distribution.

classification hyperplane respectively represent samples with obvious classification characteristics.

Therefore, if we can find a way to determine which samples belong to easily distinguishable samples and which samples belong to indistinguishable samples, then we can treat the two types of samples with different methods and improve the accuracy and speed of classification. In this section, a classifier fusion strategy based on reliability analysis is proposed to solve the polarity classification problem of these samples.

Assuming that a confidence function $f(x)$ is determined according to the classification principle of the main classifier, and the discrimination threshold $\lambda\,(\lambda > 0)$ is set, if $f(x) > \lambda$ is used when the main classifier discriminates the samples, it is considered that the discrimination result of the main classifier has high confidence, and the result can be used as the final classification result of the samples.

Otherwise, the classification of the sample to be marked is determined by the method of voting together by the main and auxiliary classifiers. The discrimination process is shown in Figure 3.

We define the credibility function according to the distance between the test sample in the main classifier and the class center, as shown in the following formula:

$$f(x) = \frac{f_1}{f_2}, \tag{6}$$

where f_1 is the distance between the nearest class center and the test sample, and f_2 is the distance between the next nearest class center and the test sample.

It can be analysed that when the cosine similarity is used to calculate the distance between the sample and the class center, if $f_1 > f_2$, it means that the distance between the test sample and the nearest class center is relatively close, and the distance from the next nearest class center is relatively far, and this kind of sample is considered to be relatively easy to distinguish.

If $f_1 < f_2$, it means that the distance between the test sample and the nearest class center and the distance between the next nearest class center may be relatively close, and this kind of sample is considered not easy to distinguish.

In the classification problem, apart from the classifier used, the influence of feature selection on the classification results is also very important. The feature selection algorithm adopted in this chapter is a feature selection algorithm based on category attribute analysis [30], which has achieved good results in traditional text classification. The formal description of feature selection algorithm based on category attribute analysis is as follows:

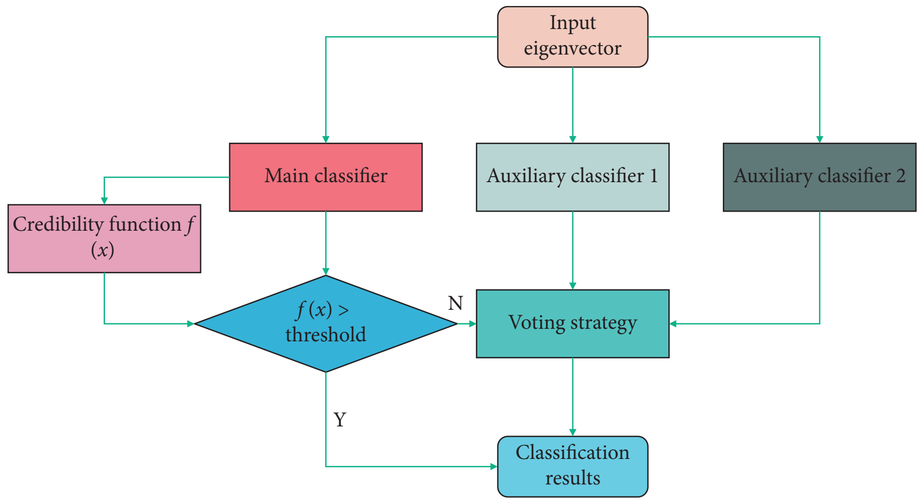

Figure 3: Discriminating process of combined classifier.

Let us assume that $X = (\omega_1, \omega_2, \ldots, \omega_n)$ represents a text, and $C_j = (X_1^j, X_2^j, \ldots, X_{n_i}^j)$ represents a text set with n_i texts and the category mark C_j, $j = 1, 2, \ldots, m$. The following formula represents the intraclass distribution law and interclass distribution law of feature ω_i in text class C_j.

Assuming that the word frequency of feature ω_i in C_j is T_{ij} and the document frequency is d_{ij}, the distribution within the class is as follows:

$$S\omega_{ij} = \frac{f\omega_{ij} \cdot \log\left(d\omega_{ij} + 1\right)}{\sqrt{\sum_{i=1}^{n} \left[f\omega_{ij} \cdot \log\left(d\omega_{ij} + 1\right)\right]^2}}. \tag{7}$$

Here, $f\omega_{ij} = T_{ij}/L_i$, L_i is the number of times ω_i appears in all categories; and $d\omega_{ij} = d_{ij}/D_i$, D_i is the number of all texts where ω_i appears.

Class distribution is recorded as follows:

$$B\omega_i = \left(S\omega_{i1}, S\omega_{i2}, \ldots, S\omega_{im}\right). \tag{8}$$

Generally, when the components of the distribution vector between classes differ greatly, the feature has a strong ability to distinguish between classes. When the components of the interclass distribution are similar or identical, the feature's ability to distinguish between classes will be very low, so the feature's resolution can be expressed as follows:

$$\mathrm{Im}p\left(\omega_i\right) = \sqrt{\frac{\sqrt{\sum_j \left(S\omega_{ij} - \bar{S}\omega_i\right)^2}}{\sum_j S\omega_{ij}}}. \tag{9}$$

In the above formula, $\bar{S}\omega_i = \sum_j S\omega_{ij}/m$.

From the above formula, we can find that the feature selection method based on category attribute analysis pays attention to the distribution of features within and between classes and quantitatively describes this distribution through variance mechanism. The features retained by the algorithm usually have obvious category attributes, so these features have strong representation ability to the corresponding categories, whereas those filtered out features have weak or zero representation ability.

3.3. An Analysis of Chinese Literary Emotion Based on UKNNC

The classification algorithm and the traditional oversampling algorithm are separate. To train the classifier, new samples are first generated and then added to the training set. The test results reflect the quality of samples after the classifier has been trained. However, the advantages of the oversampling algorithm in generating samples are not fully exploited in this framework, and the role of the samples generated in oversampling on the classifier cannot be guaranteed.

This study starts with the goal directly, draws on the idea of confrontation architecture, and proposes the concept of expected classifier, which refers to a new classifier trained by the current classifier under the update of synthesised samples, in order to accurately measure the quality of synthesised samples and judge whether samples can truly improve the performance of classifiers.

Assuming that the classifier used is a single-layer neural network, the influence of the new sample on the performance of the classifier is influenced by the update on the w, b of the classifier, that is, if the w, b calculated by the new sample are in the same direction as the calculation gradient of the original sample, they will reduce the loss function value of the original sample on the new network parameters, and the update of the parameters on the new sample is shown in the following formula:

$$\begin{aligned} w &= w - \eta \frac{\partial \mathrm{loss}}{\partial w}\left(x = x_{\mathrm{new}}\right), \\ b &= b - \eta \frac{\partial \mathrm{loss}}{\partial b}\left(x = x_{\mathrm{new}}\right). \end{aligned} \tag{10}$$

Let the classification cost function use cross entropy, which is defined in the following formula:

$$\begin{aligned}
\operatorname{loss}(y, \hat{y}) &= -\sum y \log \hat{y} + (1-y)\log(1-\hat{y}),\\
d\hat{y} &= -\frac{y}{\hat{y}} + \frac{1-y}{1-\hat{y}},\\
z &= w^T x + b,\\
\hat{y} &= s(z),\\
dz &= \hat{y}(1-\hat{y}) \times d\hat{y} = \hat{y} - y,\\
db &= dz = \hat{y} - y,\\
dw &= x dz = (\hat{y} - y)x.
\end{aligned} \tag{11}$$

The specific steps of the improved KNN classification are as follows:

Input: training sample set $T = \{X, C\} = \{(x_1, c_1), (x_2, c_2), \ldots, (x_l, c_l)\}$.

Among them, $c_i \in D\{c_1, c_2, \ldots, c_{|C|}\}$ is sample category, and $i = 1, 2, \ldots, l$, sample to be tested x_j.

Output: the class C to which the sample x_j to be tested belongs

(1) Standardization:

$$X_{\text{new}} = \frac{X - \min(X)}{\max(X) - \min(X)}. \tag{12}$$

(2) Calculate the class representation and sample representation of each class.

(3) Calculate the similarity of each sample x_i and x_j in the training sample set X.

(4) Calculate the weight $W(x_j, c_t)$ of the class to which the selected k samples belong, and assign x_j to the class with the largest weight.

(5) Repeat the above steps until all samples to be tested are classified.

UKNNC algorithm uses variational self-encoder as the $P(X)$ model for modeling in oversampling. When training the classifier, because incremental classifier is used, the modification direction of new sample to classifier can be calculated. When the expected classification result of classifier is poor, it means that the modification direction of new sample to classifier is wrong, so the parameters of generator are modified. The flow of UKNNC algorithm is shown in Figure 4.

4. Analysis and Discussion

4.1. Improved KNN Experimental Analysis. In the experiment, the traditional KNN method and the improved KNN method are used to experiment when the nearest neighbor parameter k takes different values, and the results are shown in Figure 5.

When the traditional KNN method is used to classify the experimental data set, the accuracy is the highest when the parameter $k = 50$, while when the improved KNN method is used, the parameter $k = 20$ is the best, so $k = 20$ is finally selected uniformly after comprehensive consideration.

When $k = 20$, the accuracy, recall, and comprehensive classification rate obtained by using the improved classification method on the above data set are shown in Figure 6.

It can be seen from Figure 6 that the improved KNN method proposed in this study has higher accuracy than the existing KNN method on data sets 3, 4, 5, 6, 7, and 8. Especially, on data sets 3, 4, and 8, the original 0 has been improved to a certain accuracy, but only on data set 9, the accuracy has not changed, which is mainly due to the fact that there are few such data sets and the degree of similarity with category 8 is too great.

To summarise, the improved KNN method proposed in this study adopts the idea of weighted calculation of nearest neighbor samples, aiming to solve the problem of equal weight treatment of nearest neighbor samples in the existing KNN method. As a result, each nearest neighbor sample has a specific weight, reducing the impact of unbalanced data sets on classification results and improving classification accuracy.

4.2. Analysis of Polarity Classification Results. In the experiment of Chinese language and literature emotion corpus, documents are represented by vector space model, feature selection algorithm based on category attribute analysis is used, term frequency-inverse document frequency (TF-IDF) value is used as feature item weight, and Chinese word segmentation system uses ICTCLAS3.0 of Chinese Academy of Sciences. The value of k in KNN method is 100.

Figure 7 shows the classification comparison results of the reliability analysis method at $\lambda = 2$, three single classifiers and voting method under the 50% cross-validation method. Among them, for the credibility analysis method, 44.83% of the texts need auxiliary classifiers to participate in voting decisions.

It can be seen from Figure 7 that among the three single classifiers, support vector machine (SVM) has the best classification effect, followed by the classification results of class center and KNN. The F value of reliability analysis is 1.7% higher than that of SVM, which is basically the same as that of voting method.

Chi-square significance test shows that the performance improvement of the method proposed in this study is statistically significant ($p < 0.05$) compared with other methods, which shows that the classification accuracy of the classification fusion strategy based on reliability analysis can exceed the results of SVM model under the condition of setting a reasonable threshold.

In addition, in order to verify the classification speed of reliability analysis method, the classification speed was tested on a computer with CPU frequency of 2.6 GHz and memory capacity of 3.8 GB. The average test result is shown in Figure 8.

Referring to the classification speed values of each single classifier obtained in Figure 8, we can see that the classification speed of the class center method is the fastest, and that

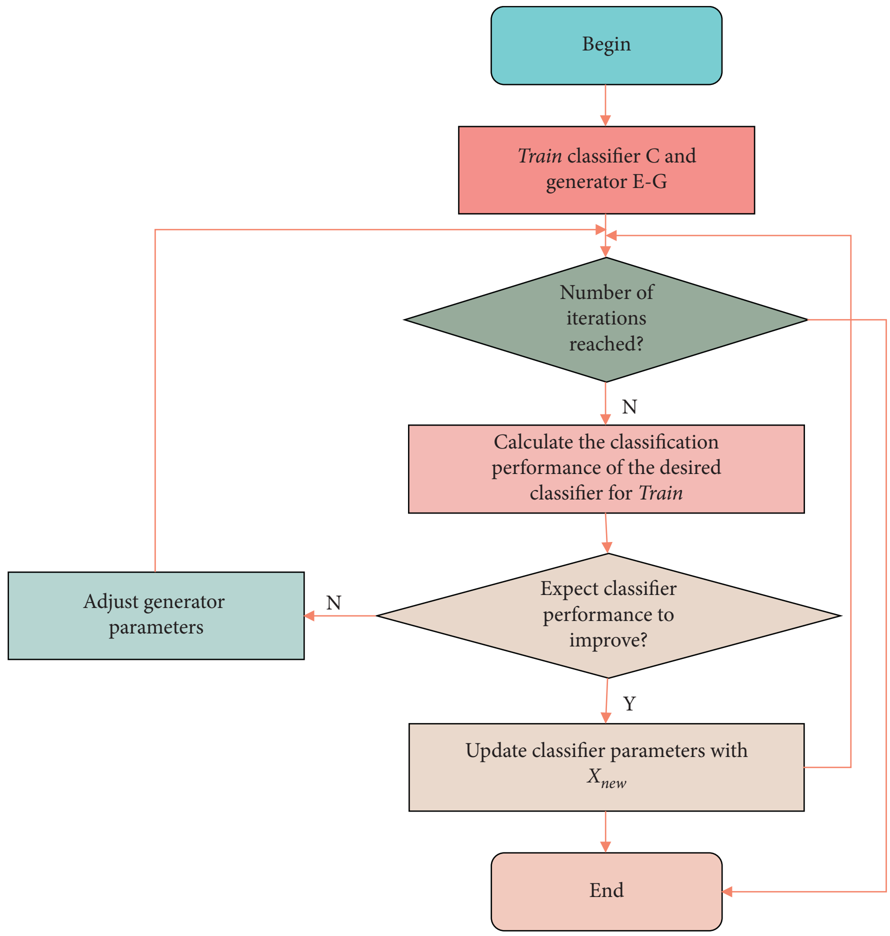

Figure 4: UKNNC algorithm flow chart.

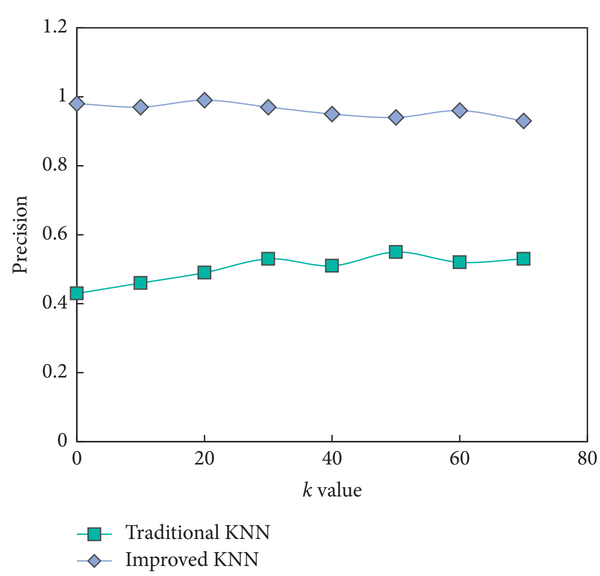

Figure 5: Experimental results of KNN precision before and after improvement.

of the SVM method is the slowest, while the speed of the credibility analysis method is obviously higher than that of SVM, which is between the class center and SVM.

Compared with the voting method, the speed of the credibility analysis method is obviously improved, which shows that the combined classification method based on credibility analysis has an obvious improvement effect compared with SVM and voting method in classification speed under the condition of setting a reasonable threshold.

In the evaluation, two groups of evaluation results of credibility analysis method and single classifier SVM are presented, respectively. The specific evaluation results are shown in Figure 9:

From the evaluation results, it can be seen that the results of reliability analysis method are lower than those of SVM on R-Accuracy and Acc_1000. The reason is that the evaluation does not provide training set, but the test set covers a wide range of fields, which leads to a great difference in the feature distribution between the test set and the training set.

The λ value obtained through the development set cannot well reflect the sample distribution characteristics of the test set, which may lead to the results of reliability analysis method being lower than SVM on some indicators.

To sum up, when the reasonable threshold λ is determined, the credibility analysis method can get better results than SVM method in classification speed and accuracy. At the same time, because the combination classification method based on credibility analysis can ensure faster

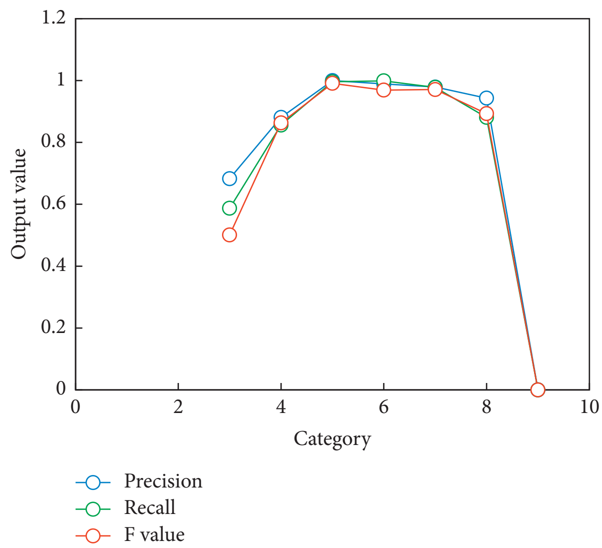

Figure 6: Experimental result comparison data set.

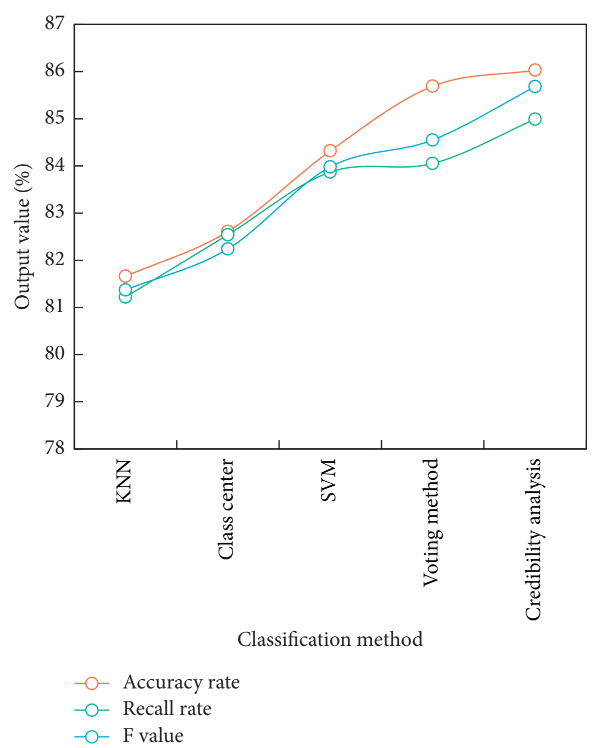

Figure 7: Emotion polarity classification result.

classification speed and better classification accuracy, it is more suitable for emotion classification of large-scale online texts.

4.3. Validity Verification of Unbalanced Classification Algorithm. In this section, in order to verify the rationality of the UKNNC algorithm, the classifier uses a single-layer neural network. The network architecture is consistent with that of the UKNNC algorithm, and it is consistent with the UKNNC algorithm in terms of training times and learning rate.

The VAEOS algorithm is used to generate a few samples that are added to the training set to directly train the LR classifier in order to compare the joint oversampling algorithm with the independent oversampling algorithm. To avoid randomness, the average of 10% cross validation is used in this section as a comparison between the joint oversampling algorithm and the independent oversampling algorithm.

Because it is necessary to make assumptions about the form of data distribution in an oversampling algorithm based on data distribution, this type of algorithm has higher requirements for the form of data distribution, as shown in Figure 10.

Ideally, the oversampling algorithm based on data distribution first reconstructs the probability distribution function of data and then conducts more intensive sampling according to the distribution function. The credibility of sampling results depends on the credibility of modeling. The improvement of classifier performance by the oversampling algorithm based on data distribution depends on whether the current sample meets the hypothesis. Therefore, in UKNNC, when there is no need to set the hypothesis of the true distribution form of samples, the modeling reliability of the algorithm for minority classes will increase, so the generated samples have higher reliability, which shows that the classification performance of minority classes is better.

Figure 11 shows the comparison of the classification performance of CGMOS in the case of Naive Bayes classifier and logistic regression classifier. From the experimental results, it can be seen that due to the different data characteristics, the experimental results are better than other frameworks on the data set that fits the classifier.

However, it synthesizes samples for Bayesian framework classifier, so the classification results on multiple data sets are similar to those of VAEOS algorithm on naive Bayes. All the results of UKNNC algorithm are better than those of VAEOS algorithm under LR classifier, which proves the effectiveness of UKNNC algorithm and joint oversampling algorithm.

Because the data sets in this study are all numerical values, the average classification value of Naive Bayes is slightly lower than LR. In order to obtain a better classification effect, firstly, the classifier should be selected according to the data characteristics; secondly, the oversampling algorithm has a higher probability to improve the classification effect. However, the joint oversampling algorithm based on the characteristics of the classifier has better promotion effect on the classification algorithm in its own framework.

After comparison, all the classification indexes are superior to the emotion classification results of other emotion dictionaries, which not only shows the effectiveness of introducing the expression dictionary to the analysis of Chinese literary emotion but also verifies the application value of the UKNNC method proposed in this study.

5. Conclusion

Chinese development has been shaped by thousands of years of precipitation, resulting in unique aesthetic characteristics that are extremely appealing. We should pay attention to the beauty of temperament when writing poetry. Music is frequently used in the creation of ancient poems. The beauty of images should be considered when describing lyricism. Different images are used to convey specific emotions, and the same images can convey joy and sorrow on multiple levels. The use of reliability analysis to classify emotion polarity is proposed. Experiments show that this voting method based on credibility analysis can outperform SVM in terms of classification accuracy, though its classification speed is slower than SVM's when the appropriate credibility threshold is selected. Simultaneously, a UKNNC-based emotion analysis model of Chinese language literature is proposed, with the emotions of each paragraph in the text obtained through the two-layer model. The experimental results show that, when compared to the traditional machine learning analysis method, the emotion analysis method proposed in this study significantly improves the accuracy of Chinese literary emotion recognition.

Currently, the expected classifier is calculated using synthetic samples and random gradient descent. There is still a lot of analysis and design work to be done on how to use a more accurate gradient descent method and how to avoid prematurely falling into a local optimum in order to stop training.

Received 9 January 2022; Revised 19 January 2022; Accepted 25 January 2022; Published 2 March 2022

Academic Editor: Tongguang Ni

The urgent need of high-quality mobile services and improved user experience has driven to develop high-capacity mobile network system. To achieve this goal, ultradense network (UDN) has been widely considered as one of the promising solutions that significantly expand the network capacity. However, as the communication resources and the number of links per unit area are extremely densified within UDN, efficient and high-quality scheduling and resource allocation for UDN become challenging. Even worse, the complex environment of UDN limits the direct adoption of traditional allocation schemes to UDN. In this manuscript, the author is going to propose an efficient resource allocation algorithm for UDN based on deep reinforcement learning. First, the author presents the resource allocation strategies in cellular network server based on double Q-learning. Then, the author optimizes the algorithm by pruning redundant model weights and making a tradeoff between computational complexity and performance to meet the requirements of low latency and limited computing costs. The experiment and simulation results show that the pruning algorithm effectively reduces 50% model parameters. The UDN allocation performance is still acceptable as the proposed algorithms save up to 50% complexity.

1. Introduction

The rapid growing need of high-quality mobile services and improved user experience has become a driving force for a high-performance mobile network. On the other hand, the improved efficiency and higher network performance enable emerging user experiences as well as novel applications, like the next-generation smart Industry 4.0 [1]. The need for connection speed and data traffic is both growing at an exponential rate. According to some reports [1, 2], the data rates are projected to increase by around ten times every five years. Moreover, trillions of mobile devices and sensors will be connected together across the world via wireless network. The upcoming Internet of Things (IoT) and future fifth-generation (5G) mobile networks will encounter a halt unless we can rapidly increase the capacity of current communication system. Therefore, a paradigm shift and enhancement in every aspect of current mobile network system are required to provide the immense amount of data traffic arising from high-resolution video applications [2]. In the next-generation communication system, many ideas and schemes are proposed to resolve the challenges imposed by the requirements of a lower network latency, higher peak data rates, more reliable connection stability, increased availability, and better user experiences.

The opportunities of 5G system have attracted great attention from academics, industries, and governments. Among the above-mentioned points, how to develop a high-performance network that offers massive capacity within a dense area becomes one of the major challenges. Ultradense network (UDN) is one of the promising solutions where the communication nodes and the number of links per unit area are extremely densified. Rather than focusing on the evolutionary improvements of previous generations in terms of spectral efficiency, the densification of network is able to bring about more significant overall system performance gain by dramatically increasing the network infrastructures [3]. The definition of UDN varies among different literature. Basically, UDN can be abstracted as a special type of network with very dense radio resources than current networks.

Specifically, UDN is equipped with tremendous amounts of base stations (BSs) with higher density, where the BS density reaches and even exceeds the user density. Besides, an UDN can also be modeled a network where the intersite wireless access points (APs) are separated by only a few meters.

However, UDN also faces several significant hurdles towards the way to constructing high-capability and high-efficiency mobile network. The factors causing the challenges include the dense radio resources, mobility, and interference between devices. Although the dense cellular networks can efficiently offload data traffic from traditional macro cellular networks, how to optimally allocate and schedule the available network resources affects the overall network performance and user experience. This makes the resource allocation algorithms of UDN a crucial part when design UDNs. Tremendous amounts of previous research works have studied the resource allocation policies in various perspectives, including UDN as well as heterogeneous network scenarios (HetNet) scenarios. The authors in [4] propose a novel UDN resource allocation algorithm that has low computational overhead. However, the resulting quality of resource allocation under fast changing and complex network environment is not satisfactory. To improve this shortcoming, deep reinforcement learning-based scheduling algorithms are presented in [5, 6]. But the limitations of these two algorithms lie in that they are still computationally intensive workloads, which are not suitable to be employed in UDNs with different sizes.

In this paper, we propose deep reinforcement learning-based resource allocation scheme to address the abovementioned challenges. Our algorithms can be efficiently applied to allocate UDN resources in the 5G scenario. The following parts summarize our contributions:

(i) We first model the mathematical model of resource allocation for UDN. Then the NP-hard nonconvex resource allocation problem in UDN is transformed into a form that can be solved by deep reinforcement algorithm.

(ii) A novel and efficient resource allocation algorithm based on deep reinforcement learning is proposed to achieve near-optimal resource allocation under different communication environments.

(iii) We also consider the efficient implementation problem of deep reinforcement learning-based resource allocation algorithm. The weight and model pruning schemes are utilized to train low-complexity models.

(iv) Compared to previous works, our work further considers the factors of computing power-constrained scenarios. The optimized (pruned) algorithms are able to perform energy-efficient resource allocation.

The rest of this paper is organized as follows. Section 2 introduces the system model and problem formulation for UDN resource allocation. Section 3 presents the proposed algorithms and optimization methods. Section 4 presents the simulation and experiment results. Section 5 concludes the whole paper.

2. System Model and Problem Formulation

To accurately model the resource allocation problem, we choose to use the ultradense networks of 5G downlink, as shown in Figure 1. In the following parts, we summarize the main points of this model according to [7]. In this case, a total of N small base stations (SBSs) will be randomly distributed within the area of one macro cell. In the center of the macro cell, one macro base station (MBS) is placed to process the incoming data and perform scheduling policies. Inside the MBS, a mobile edge computing (MEC) server is installed that is responsible for computing and allocating resources for the whole UDN.

Without loss of generality, we define the set of N SBSs as the form: $\mathcal{N} = [1, 2, \ldots, N]$. Many small user equipments (SUEs) will randomly present and move within each SBS. The arrival of users is considered as a random process. Moreover, the user arrival and departure are regarded independent. Hence, the arrival of each SUE to each micro cell is parameterized with a Poisson process and parameter λ_t. For each time slot, the probability that a total of n new SUEs will arrive in the micro cell, and this can be expressed as the following equation:

$$P(n) = \frac{(\lambda_t \tau)^n}{n!} e^{-\lambda_t \tau}, \tag{1}$$

where τ denotes the time period. The probability of SUEs that will leave the small cell can also be modeled as a Poisson process similar to equation (1) with a different parameter μ_t.

We denote the SUE set as $\mathcal{U}_n = [1, 2, \ldots, U_n] (n \in \mathcal{N})$. Outside the micro cell, there would be some macro user equipments (MUEs) that cannot be fully covered by SBS while can be reached by the center MBS. We define these MUEs as $\mathcal{U}_M = [1, 2, \ldots, U_M]$. Over time domain, a micro cell n has various numbers of SUEs at a time slot t. So we define the set of SUEs at time slot t of micro cell n as $U_n(t)$.

In reality, the identical network resources can be reused by multiple SBSs at a specific time slot, therefore the interference between SUEs and SBSs in other micro cells. In this work, we quantize this kind of interference as the signal to interference-plus-noise ratio (SINR) as follows:

$$SINR_{U_n(t)} = \frac{p_n g_n^m}{\sum_{i=1, i \neq n}^{N} x_n^m(t) p_n g_i^m(t) + \sigma^2}, \tag{2}$$

where p_n represents the assigned power to each associated SUE and g_n^m denotes the gain of channel from SBS within micro cell n to the SUE when the resource block (RB) m is reused by multiple UEs. We assume that the channel is an additive-white Gaussian noise (AWGN) channel so σ denotes the variance of AWGN noise. Finally, $x_n^m(t)$ is a Boolean variable indicating whether the RB is assigned to a specific UE. If $x_n^m(t) = 1$, it means that RB m is allocated. $x_n^m(t) = 1$ means RB m is not assigned to any SUE.

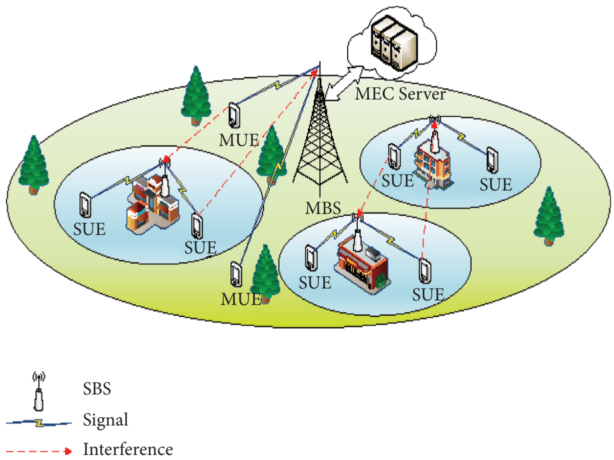

FIGURE 1: An illustration of ultradense network redrawn from [7].

Once we have the metric SINR for each SUE set $U_n(t)$, the summation of overall downlink throughput at a specific time slot t within the micro cell n could be computed based on the following equation:

$$TP_n(t) = \sum_{U_n \in \mathscr{U}_n} TP_{U_n}(t), \tag{3}$$

where $TP_{U_n}(t)$ can be shown as

$$TP_{U_n}(t) = B_m \times log_2\left(1 + SINR_{U_n(t)}\right), \tag{4}$$

where B_m is the bandwidth of the RB m, which is usually fixed for a given RB.

It is more meaningful to consider the total throughput for the whole UDN. Hence, we can calculate the total throughput based on the aforementioned $TP_n(t)$ as follows:

$$TP(t) = \sum_{n=1}^{\mathscr{N}} TP_{U_n}(t). \tag{5}$$

The UDN system not only requires high-speed network throughput but also needs to achieve some levels of efficiency. Apart from the total throughput for the UDN system, the other factors need to be considered are the spectral efficiency (SE) and energy efficiency (EE) for the system. Similar to [5], the SE is denoted as the ratio between the total throughput and the bandwidth of the given UDN at time slot t. In a similar pattern, the EE for this UDN is defined as the ratio between the total throughput and power dissipation at time t. The metrics SE and EE are summarized as follows:

$$\begin{cases} SE(t) = \dfrac{R(t)}{\sum_{i=1}^{M} B_i}, \\[2ex] EE(t) = \dfrac{R(t)}{p_M + \sum_{n=1}^{\mathscr{N}} \sum_{U_n \in \mathscr{U}_n} U_n(t) p_n}, \end{cases} \tag{6}$$

where p_M denotes the power consumption by macro cell network.

The goal of achieving optimal resource allocation for a given UDN is equivalent to maximizing the spectral efficiency SE as well as the energy efficiency EE at the same time. The conventional mobile system adopts various approaches to generate a good resource allocation policy. These algorithms include discrete optimization approaches, convex optimization methods, and other heuristic-based algorithms. However, the feasibility and performance of these previous algorithms heavily depend on the application scenarios. When the communication environment varies, a significant degradation in the quality of resource allocation is observed. Hence, we proposed a novel and efficient deep reinforcement learning algorithm in the following sections.

3. Proposed Efficient Resource Allocation Algorithms for UDN

3.1. Deep Reinforcement Learning. The resource allocation tasks for the UDN system can be regarded as a problem of searching the optimal control sequence that distribute the resource blocks within the UDN. However, the complex communication environment makes it difficult to accurately obtain the optimal allocation strategies that dissipate minimum energy while maintaining high spectral efficiency. To address this problem, similar to [5], we take the advantages of deep Q-learning algorithms [8]. Moreover, we also present optimization schemes to develop computationally efficient models with negligible performance loss.

As shown in Figure 2, for the case of UDN resource allocation task, the MEC server is regarded as an agent that interacts with the macro cell and micro cell environment. The goal of MEC server agent is to maximize the total reward between the first state and the final state. MEC server will make certain decisions that allocate the network resources based on the received data and information from different levels of cellular networks. After the decision is made based on the policy within the agent, the state of the UDN system will be changed and reach to various scenarios defined as state. As the decision (or actions) are taken, the agent receives positive or negative rewards.

Figure 3 depicts the overall diagram of our proposed deep reinforcement learning-based efficient resource allocation scheme for UDN. There are two parts in the depicted figure: training phase and inference phase. For the training phase, we use the system model in Section 2 to emulate the environment of UDN. Once the training phase has been completed, the trained model is optimized via network pruning algorithm to reduce the required model weights and computation complexity. In the following parts, we introduce the development steps of our algorithms in detail, including reward function design, action space design, and network model pruning.

3.1.1. Reward Function Design. The reward function design is a key factor that determines the final quality of resource allocation. This is because the reward function will guide the agent to take actions and make decisions. The actions will impact the state of UDN system. The reward design plays an important role in the task since it determines the quality of resource allocation and intelligence level of trained

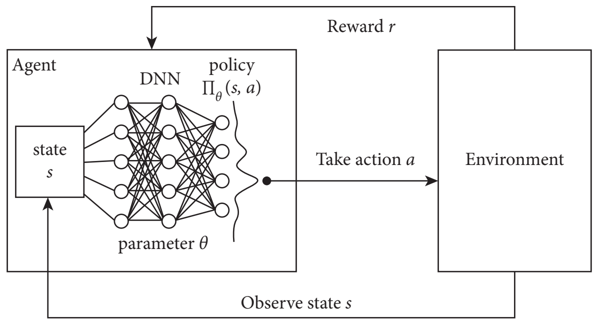

FIGURE 2: Overall diagram of deep reinforcement learning.

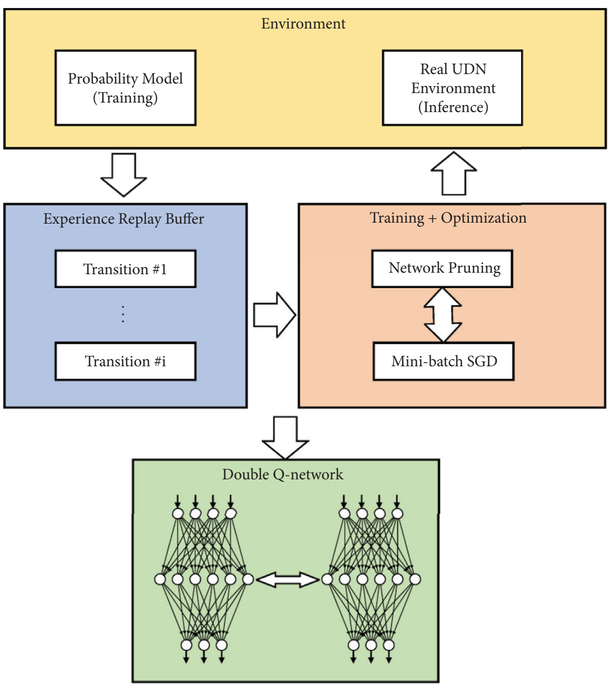

FIGURE 3: Proposed deep reinforcement learning-based efficient resource allocation scheme.

allocation algorithms. The key principle of designing reward function is that the reward should accurately reflect the goal of target application. Here, we adopt the two efficiency metrics, namely spectral efficient SE and energy efficiency EE in equation (6), as the reward function. We make minor modifications by summing these two metrics into one single reward with a weight ε. At a time slot t, the reward function is

$$r(t) = (1-\epsilon)SE(t) + \epsilon EE(t), \tag{7}$$

where the reward function considers both energy consumption and the spectral efficiency. It should be noted that the reward at time t is determined by the current state of network state. If we train the model properly, the agent is able to achieve the optimal reward by balancing the two aspects.

Achieving the optimal reward at time t as equation (7) is not enough since it is not guaranteed that the agent can achieve the global optimal goal. We hope the agent is able to maximize the total reward over a given period of time. In this case, the reward for single time step becomes a cumulative reward function through summing up the received reward at different time steps. The total reward that maximizes the reward between the initial and state becomes:

$$R_{total} = \sum_{t=1}^{T} \beta^t r(t), \tag{8}$$

where R_{total} is the sum of each reward the initial state to the end. In deep reinforcement learning, a discount factor $\beta \in [0, 1]$ is added to weight the different contributions of rewards in short term and long term. Small discount factor β reduces the importance of reward obtained from previous time steps. It is easy to understand that $\beta = 1$ means all the rewards are treated equally.

3.1.2. Action Space. The UDN state of next time step after the control signal is sent by MEC server can be considered to be only determined by the current network states, communication environment, and the resource allocation signals of the UDN. It is independent from the previous states. Hence, the resource allocation policy of UDN can be regarded as the Markov decision process (MDP). The large search space for the action sequence is significantly reduced under the assumption of MDP.

Considering the real realizability of simulation that accommodates real UDN system, we discretize the resource allocation signal of UDN system by a constant time interval. This is because the computing resources in MEC server are limited, thus unable to process data and make resource allocation with very high frequency. Therefore, we assume that the discrete control signal for RBs is in the following form:

$$A = [x_1(t), x_2(t), \ldots, x_T(t)], \tag{9}$$

where the time range of the control signals varies from time step 1 to time step T. It can be seen that the dimension of action space grows linearly as the time steps increases.

3.1.3. Model Updating and Training. Several tricks are used to make the iterative updating and training process more stable. According to [9], since the environment is usually complex, it is not realistic to store all of them into the Q table of traditional reinforcement learning. To alleviate this problem, deep Q-learning uses a deep neural network to estimate the Q-value function. Based on the Bellman equation, the Q-value updating equation is given as

$$\begin{aligned} Q(s_t, a_t) &\leftarrow Q(s_t, a_t) \\ &+ \alpha\left[R_{t+1} + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t)\right], \end{aligned} \tag{10}$$

where $Q(s_t, a_t)$ denotes the Q-value function associated to time step t while α represents the learning rate. Likewise, $Q(s_{t+1}, a)$ is the Q value associated to next time step after the MEC server is taking action a.

The weight of the neural network is initialized using random function. And we define the weight of neural network as w. The weights are updated in an iterative pattern through utilizing the mini-batch stochastic gradient descent (SGD) training algorithms. Specifically, the training of neural networks can be complete through updating the weights with the gradient with respect to the loss function. The updating procedure can be summarized as the following formula:

$$w_{k+1} = w_k - \alpha \cdot \mathbb{E}\Big[R_{t+1} + \gamma \max_a Q\left(s_{t+1}, a; w_k^-\right) \\ -Q\left(s_t, a_t; w_k\right)\Big] \times \nabla_{w_k} Q\left(s_t, a_t; w_k\right), \tag{11}$$

where the weights of target network at the kth iteration are called w_k^-. The weights w_k^- are set to be fixed during the training process and can only be updated using the Q-network weights w_k every C training iterations. The loss function we used in this paper is the mean squared error (MSE) between the target Q value and the output results of neural network.

The updating process in equation (11) for the target network and Q-network may experience some overestimating values of actions by the analysis in [9]. The reason behind this circumstance is that the mentioned scheme uses the same network to calculate both the predicted value and the target value. Hence, it leads to some divergence between the computed results. The overestimation problem hinders the resource allocation algorithms from choosing the good action in some UDN states. As a result, the overall performance of the resource allocation algorithms is negatively impacted. The negative effects arose from overestimating values can be reduced by using two different deep Q-network and target network [9]. In this case, the Q-value function is rewritten as follows:

$$Q\left(s_t, a_t\right) \leftarrow Q\left(s_t, a_t\right) + \alpha\left[R_{t+1} + \gamma Q'\left(s_{t+1}, a\right) - Q\left(s_t, a_t\right)\right], \tag{12}$$

where functions $Q'(\cdot)$ and $a = max_a Q(s_{t+1}, a)$ are used to estimate the expected Q-value by the selected action a that maximizes the value of the predicted Q-value network.

As introduced in [8], the training process for the agent will experience unstable circumstances if we just run the deep Q-learning algorithms on the state-action pairs as they occur during simulation. To equip the agent with some capabilities of memory, we introduce the experience replay buffer to store the transition of discovered data and occurred experience. The experience replay is used to reduce the correlation of observed samples, increasing the robustness of training process. As shown in Figure 3, the experience replay buffer stores the agent's experiences, including taken actions, states, and rewards over a certain time steps.

Exploration and exploitation are the two critical concepts for reinforcement learning. Exploration makes an agent improve the current knowledge about each action, while exploitation is able to select the most rewarded action by exploiting current action-value estimations. To balance the exploration and exploitation, ε-greedy policy is investigated to choose between exploration and exploitation randomly. It can be expressed by the following equation:

$$a_t = \begin{cases} a\, randoaction, with\, probability\, \epsilon, \\ \max_a Q(s, a), with\, probability\, 1 - \epsilon, \end{cases} \tag{13}$$

where the agent tends to select the action that maximizes the current Q-value with probability $1 - \varepsilon$. In contrast, the agent selects a random action with probability ϵ. In other words, the ϵ-greedy policy will let the agent explore most of the time. The larger ϵ value indicates that the control algorithm is more likely to choose a random movement. The value of ϵ cannot be too large since the large ϵ may deteriorate the overall performance. In the contrast, small ϵ value let the agent has a small chance to explore new experience, thus limiting the peak performance. In this paper, ϵ value is selected empirically based on the previous study.

3.2. Model Pruning. The training and inference of fully connected networks are computation-intensive and memory-intensive. Large amounts of computing and memory resources are required to perform the training and inference of deep neural network models. When the MEC server is equipped with limited computing chips, the computationally intensive workload of DNN will become the bottleneck, thus increasing the response time of resource allocation. These problems not only increase the implementation costs but also hinder the deployment of proposed resource allocation algorithms on some resource-constrained MEC servers. To solve this challenge, we use the model pruning methods in [10, 11], which are used to reduce the size of network models by removing redundant connections between fully connected layers.

There exists various types of network pruning algorithms to optimize the neural network structures. The deep compression in [10, 12, 13] is one of the promising methods to optimize sparse neural network architectures. The basic idea of deep compression is progressively searching and removing the redundant weights that have relatively small magnitudes. Figure 4 depicts the neuron connections of original and pruned fully connected layers. The original layer connection is dense and requires large excessive number of weights. Network pruning searches for the most representative and important connections for each layer. Then remove the trivial connections through setting the weights to zero, thereby effectively cutting the weights and reducing the model size as well as computational complexity. After applying the optimizations, the inference of neural network can be accelerated by several times without loss of performance. Meanwhile, the model size will shrink dramatically as large amounts of weights are pruned.

4. Simulation Results

4.1. Experiment Platform and Parameters. We perform simulations and experiments to verify the performance of proposed algorithms. The detailed configurations and process of simulation are given as follows. The proposed deep reinforcement learning algorithms are implemented using the state-of-the-art deep learning library, Pytorch. GPU is

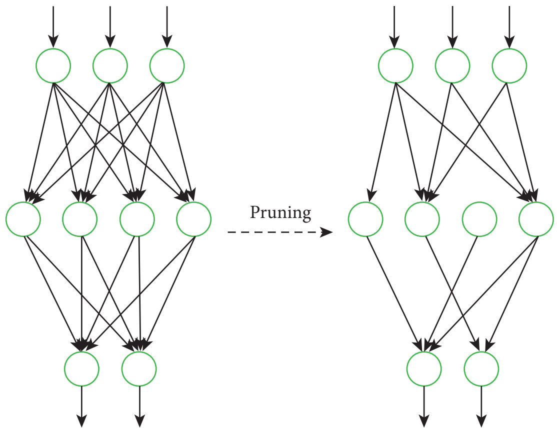

Figure 4: Weight pruning process for original deep neural network.

used to accelerate the training and inference process. The target network and deep Q-network both adopt a five-layer basic structure, where there are 64, 128, 256, 192, 96 neurons for each hidden layer.

During the training process, the mini-batch size is selected as 64 to stabilize the weight updating and achieve a smooth convergence process. The Adam optimizer [14] is used for achieving faster convergence. The input of trained resource allocation algorithm is the vector representing the network state of UDN. Suggested by [8], the probability of ϵ-greedy policy is chosen as 0.05. We create an experience replay memory with a buffer size of 3200. The weights of target network are copied every 5 training iterations. The discount factor of cumulative reward calculation is set to 0.96. The parameters of UDN are similar to those in [5]. The simulation parameters are summarized in Table 1.

Table 1: Summary of simulation parameters.

Parameter	Value
Total bandwidth	20 MHz
Number of RBs	80
Number of time slots	1000
Value of p_M	46 dBm
Batch size, B	64
Discount factor, γ	0.96
Experience replay buffer size, N	3200
Update frequency, C	5
ϵ-Greedy probability	0.05

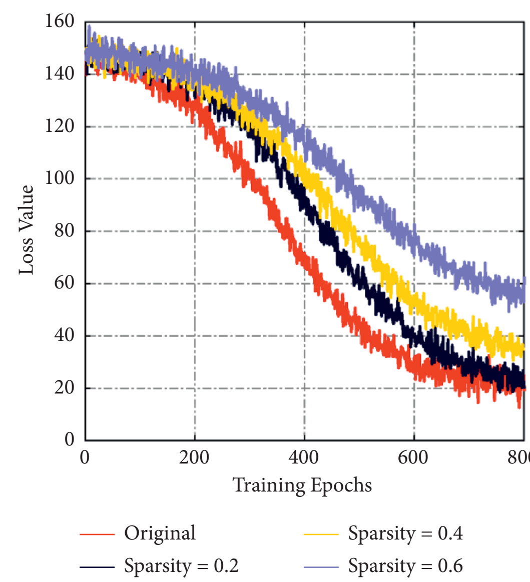

Figure 5: Loss value of DQN under different training epochs.

4.2. Simulation Results. We use the UDN system model to generate multiple training and testing data. We train various models under different weight sparsity constraints as in [10]. For each model, we train the associated model for at least 800 training epochs.

The average loss value of various DQN models for different training epochs is illustrated in Figure 5. As we can see, the loss values of all models decrease as the training epochs increase. The dense model achieves the fastest convergence. The sparse model with sparsity = 0.4 achieves comparable loss value as the dense model. This means that this sparse model is also able to yield promising performance while reducing the weight number and computational complexity by around 60%. The convergence process of model with 60% sparsity is much slower than other models. It can be inferred that the resulting performance is not acceptable.

We also test the yield system efficiency of propose resource allocation schemes under different number of SBSs. The number of SBS ranges from 6 to 18. The results are depicted in Figure 6. It can be seen that the spectral and energy efficiency gradually drops as the number of SBS is

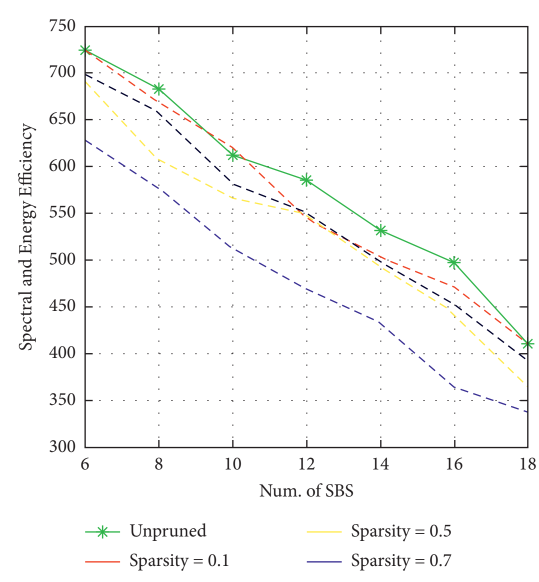

Figure 6: Spectral and energy efficiency under different numbers of SBS.

increasing for all models. We can see that the unpruned model obtains the highest system efficiency. The model with sparsity 50% is able to achieve about 90% efficiency compared to the unpruned baseline. Meanwhile, the total complexity to perform the resource allocation tasks is reduced by 50%. Hence, the weight and model pruning strategies provide a tradeoff between quality of resource allocation and algorithm complexity. For some MEC server that has limited computing resources or heavy workload, we can choose the resource allocation models with more sparsity to make the network resource scheduling more quickly and efficiently.

5. Conclusion

In this paper, we develop and propose the resource allocation algorithms for UDN based on deep reinforcement learning. First, we introduce the resource allocation strategies in MEC server based on double deep Q-learning. Then, to meet the requirements of low latency and limited cost, we optimize the algorithm by pruning redundant model weights and making a tradeoff between computational complexity and performance. The experiment and simulation results show the gain and effectiveness of proposed algorithms. Our proposed approach can be applied to UDN resource allocation in the 5G system, especially when the computing power is limited. The future work will focus on considering more impacting factors of UDN into this framework.

The exchange of literature and information resources between higher vocational colleges and cooperative enterprises is a win-win situation in which both parties benefit. Collaboration between schools and businesses is a significant departure from the traditional vocational education model, as well as an innovation in the talent training model, an important direction of higher vocational education reform, and the focal point for the formation of vocational education characteristics. Collaboration between schools and businesses is now not only an effective way for businesses to train a large number of applied technical talents, but also an effective way for vocational colleges to change their disciplinary structure. At the same time, collaboration between schools and businesses is critical to the advancement of vocational education. The focus of this article is on the publication of literature on the long-term mechanism of school-business collaboration, the field of research on the long-term mechanism of school-business collaboration, state laws and regulations on school-business collaboration, and academic opinions. The content, mode, problems to be solved, and importance of sharing document information resources in school-business collaboration are the main topics of this article. Vocational technical colleges and businesses should benefit from each other and maximize their respective advantages in school-business collaboration. One of the greatest advantages of higher vocational colleges is the abundance of literature and information resources. This article will raise a key question through a review of the literature: how can you establish an effective long-term mechanism for school-business collaboration? This theory has been enhanced by previous research in order to put the issue of school-business collaboration into practice and provide theoretical and practical guidance that will benefit the country, society, schools, and, most importantly, student employment.

1. Introduction

Vocational education cannot become vocational education in the true sense without the participation of enterprises. Only the close cooperation between schools and enterprises can fundamentally realize the authenticity of the training teaching environment, facilities and methods, the duality of students' roles, and the training of teachers, the dual-teacher nature, the mutual benefit of education funding (enterprise training funding-government investment funding), the security of systems and information, and so on. How to realize the sharing and optimal allocation of educational resources and achieve the goal of mutual assistance, mutual benefit, and win-win in school-business collaboration is a topic of common concern and discussion among all sectors of society [1]. School-business collaboration is an innovative model for schools and enterprises to cultivate and accept talents. In a practical sense, on the one hand, it can solve the employment problem of students and reduce employment pressure; on the other hand, this method can solve the problem of shortage of talents in enterprises. It can be seen that a successful school-business collaboration will undoubtedly become a win-win model for the development of schools, enterprises, individual students, and society.

The way of school-business collaboration is conducive to the adjustment of local economy, is conducive to the transformation of scientific and technological achievements into actual productivity, and is more conducive to driving the adjustment of local economy, thereby promoting the prosperity and development of local economy. Relatively speaking, in the process of school-business collaboration in running schools, the enterprise is the main body of the cooperation, and the enterprise pays more [2]. Accepting students for internships will add additional burden to the factory, also taking responsibility [3]. Higher vocational colleges are relatively in the secondary side and need to find companies everywhere to cooperate, seeking companies to receive student training and internships [4].

To some extent, the provision mode of information resource sharing can bridge this gap. Because higher vocational colleges are the primary parties and instructors in the sharing of literature and information resources, they can proactively provide literature and information services to businesses, assist businesses in developing joint information resources, and benefit businesses. More literature information resources are required for the development of related cooperative enterprises or the ability to accept more students [5]. For mutual benefit and mutual benefit, both schools and businesses can make full use of literature and information resources. Enterprises can save a portion of their manpower, material resources, and financial resources by reducing unnecessary document duplication. Both sides can benefit from each other, complement each other, and grow together, bringing the two parties' cooperation relationship closer together. Simultaneously, through information resource sharing and cooperation, all types of enterprise information can be fed back to higher vocational colleges in a timely manner, facilitating the adjustment of professional directions or enrollment plans, the organization of training projects, and the implementation of employment indicators for higher vocational colleges. Colleges and universities use an order-style approach to talent development [6].

In the school-business collaboration, the key point is how to establish a sharing mechanism between the school and the enterprise, so that both parties can make full use of the literature and information resources, communicate with each other, maintain a close relationship, and obtain what they need to achieve a win-win goal. System guarantee for the sharing of literature information resources in school-business collaboration [7] includes centering on the library of the higher vocational college, providing rules and regulations for the use of literature and information resources, rules and regulations for the use of school-enterprise network resources, funding and sharing system for information resource development and sharing, and the internal construction and development of libraries in higher vocational colleges., where the library should do a good job in the integration of document information resources and highlight key majors in accordance with the professional settings of the hospital. According to the needs of cooperative enterprises, production and R&D projects expand the collection of relevant professional and project literature and information, highlighting local characteristics [8].

2. Related Work

School-business collaboration plays an important role in improving the technological competitiveness of enterprises and expanding their technological resources. School-business collaboration has also accelerated the process of marketization of new technologies. Universities and enterprises at home and abroad are constantly conducting research and practice to explore better school-business collaboration models. Therefore, a key issue in the study of school-business collaboration is how to scientifically and effectively evaluate school-business collaboration projects.

According to [9], higher vocational colleges' financial investment is insufficient, and the conditions for running schools, particularly experimental training conditions, are relatively weak: The school-business collaboration mechanism is not perfect; the cooperation has not yet established a fixed base for industry-university-research cooperation; theoretical research on school-business collaboration in higher vocational education lags behind. According to [10], vocational education still has issues such as a lack of social recognition, a backward professional setting, and an unreasonable curriculum setting; key points and teaching difficulties are not prominent; and practical links are severely lacking. School-business collaboration, according to [11], is beneficial to resolving the supply and demand of talents between schools and businesses; it is beneficial to accurately positioning the goals of higher vocational education; it is beneficial to broadening the employment channels for students in higher vocational colleges; and it is beneficial to the formation of higher vocational colleges, the characteristics of a school principal. The difference is that [12] also suggested that collaborating between schools and businesses can significantly improve the conditions for running schools in higher vocational colleges. According to [13], school-business collaboration is also conducive to educational reform and talent training model reform; it is conducive to enterprise participation in the school talent training plan and process, as well as deepening the teaching reform; it is conducive to enterprises mobilizing their enthusiasm and initiative to run schools. In the course of running a school, we will make full use of the enterprise's human and material resources. Literature [14] based on the analysis of school-business collaboration model, guaranteed mechanism, monitoring, and evaluation mechanism and gave a set of evaluation index system for the quality of school-business collaboration. This achievement has important reference significance in enriching the theoretical system structure of higher education evaluation, improving the school-enterprise cooperative education and teaching quality evaluation system, and improving and ensuring the quality of education and teaching in schools. Literature [15] studied the research and practice of the school-business collaboration talent training model in higher vocational colleges. The development, change, and evaluation of the relationship between colleges and enterprises have gradually become the focus of researchers and the main concerns of practitioners. On the basis of the research of resource dependence theory, the effectiveness of cooperation between the two parties and the degree of resource dependence and difficulty establish a stable degree of influence. The relationship between the dependence structure of teaching management, analysis, and discussion shows that the impact of school-business collaboration is not only the relationship with teaching management, the degree of dependence on resources of the two parties' symbiosis, and the relationship with cooperation; the influencing factors are far greater than the degree of dependence on resources. Literature [16] aimed at the goal of talent training in higher vocational colleges, constructed a basic school-business collaboration teaching quality evaluation system with diversified subjects such as schools and enterprises (industry, employers), and demonstrated the diversified subjects and diversified subjects of teaching quality evaluation, with the choice of the evaluation method and the determination of diversified evaluation items. Literature [17] pointed out that the development of modern higher vocational education will inevitably promote cooperative education between schools and enterprises. Constructing a scientific and objective evaluation system for school-business collaboration will provide strong support and reference for the smooth development of school-business collaboration. Wang Ning put forward his own ideas on the construction of the evaluation system of school-business collaboration in higher vocational education.

For most companies, they do not evaluate success based on the financial benefits of cooperative research and development management or the number of research results. In order of importance, success is achieved by cooperation between companies that achieve the following goals: increase the understanding of new technologies and new technologies; provide employees with opportunities to acquire new knowledge; improve strategic thinking; obtain well-trained employees and knowledge of more access to property rights, improved corporate credibility, and better employee recruitment.

Literature [18] overviews the research in recent years; often it is the school's keen interest in school-business collaboration and the combination of work and learning that make the school-business collaboration a bottleneck. The primary issue is that collaboration begins only from the perspective of the school, ignoring the feelings of the enterprise, emphasizing the enterprise's public welfare and social duty, and ignoring the enterprise's needs. To break through this bottleneck, it is necessary to think about the composition of the performance evaluation index of the combination of work and study based on the perspective of corporate interests. Higher vocational education cultivates talents that directly benefit business and industry, while cooperative colleges and universities cultivate talents that directly or indirectly benefit business, allowing school-business collaboration to grow in depth and breadth and be long-lasting and smooth. China's higher vocational education has achieved "school-business collaboration, work-study integration," according to [19]. Although some progress has been made, a long-term operating mechanism and a complete system have yet to be established. In the implementation process, there are still some issues to be resolved in the use of the School-Business Collaboration Talent Training Model. It is difficult to overcome the traditional closed teaching quality monitoring system. We must improve teaching quality evaluation to adapt to the open system of higher vocational education talent training model of "school-business collaboration, work-study integration." There are also studies that use specific data as a basis for evaluating school-business collaboration through the creation of data models. For example, [20] shows that the overall level of cooperation between financial vocational schools and enterprises is relatively low, based on principal component analysis and empirical analysis of seven types of finance and economics on the performance of higher vocational school-business collaboration. There is a significant disparity between the two, as well as an imbalance; the success of school-business collaboration is dependent on the cooperation, process, and impact of school and enterprise resources. The two decisive factors are that we must place a high value on enterprise participation. As soon as possible, a multichannel and multidirectional exploration of school-business collaboration methods strengthen interschool cooperation and strengthen the radiation model and the leading role of key universities should be included in relevant local laws and regulations.

For the evaluation of the effect of school-business collaboration, two aspects are involved in the specific implementation process, namely, the establishment of the effect evaluation index system and the implementation of the effect evaluation. This article will discuss and determine the index system for evaluating the effectiveness of school-business collaboration projects through methods such as literature review, research, interviews, and specific school-business collaboration projects. Then the use of the evaluation index system should cover the effects of school-business collaboration projects in the tripartite of enterprises, universities, and the government.

3. Document Information Resource Sharing in School-Business Collaboration Forms Complementary Advantages

In the school-business collaboration, the advantage of the enterprise lies in the fact that the enterprise can provide students in higher vocational colleges with internship places, training, and employment opportunities. Enterprises have advantages in equipment resources. It can be used by students for practical operation. The enterprise has advantages in production technology and industry, and its personnel can guide students on-site, so that students can master certain skills. The company also provides job opportunities, so that some of the students can stay in for employment. The disadvantage is that companies mainly consider problems from economic benefits or are affected by economic operating cycles and are unwilling to invest funds in the construction of literature and information resources. Some enterprises are biased towards short-term behaviors, lack long-term benchmarks, and do not pay attention to the construction of literature and information resources at all. Enterprises lack professional management personnel of document information, which also affects the construction of document information resources [21].

Rich books and literature information resources, a certain amount of storage, and the formation of a library-centered literature information resource database are all advantages of higher vocational colleges. Have professional personnel who are involved in the collection and use of literature information and materials, as well as specific work experience. Take advantage of technical theoretical advantages in computer and network technology applications. Relevant professional teachers and skilled teachers are available. They have a certain theoretical and practical level of knowledge, a better understanding of the state of development of a particular industry and profession, and guiding advantages in certain professions and industries. The disadvantage of higher vocational colleges stems from the fact that college operation management differs from enterprise operation management. It is easy to cause information uncertainty because it does not fully comprehend the actual situation of enterprise literature information needs. Higher vocational colleges have strict school funding management and limited funds, making larger projects difficult. Figure 1 depicts the talent development model.

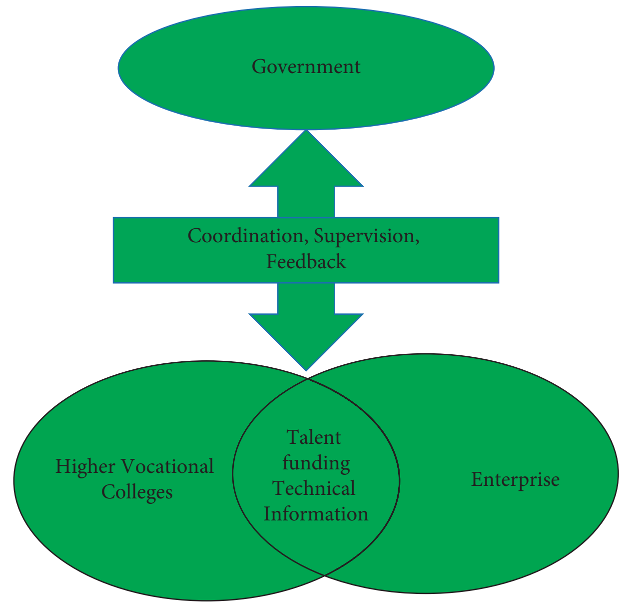

Figure 1: Talent training model.

In Figure 1, higher vocational colleges and enterprises share resources such as talents, technology, information, and funds. The government supervises and coordinates their cooperation and constantly makes adjustments based on their feedback information to ensure smooth cooperation.

Higher vocational education necessitates a close relationship between schools and businesses. Vocational schools collaborate with businesses and serve them in order to gain their support, assistance, and participation in order to expand their development space. In our country, there is currently a significant disconnect between higher vocational education and the business community. Enterprises are not overly enthusiastic about participating in higher vocational education. Disconnection between theoretical and practical teaching is a common problem in higher vocational colleges. The government must be involved in solving these issues. To realize the sharing of educational resources, Taiwan should follow the path of school-business collaboration and school-school cooperation in running schools and establish vocational education groups based on the principles of equality, voluntariness, mutual benefit, and common development. Form a school-business collaboration group school structure in which the school provides teaching management sites and basic theory teachers, while the enterprises provide equipment, technology, internship training bases, part-time teachers, and job opportunities.

4. Platform Design and Implementation

The school-business collaboration professional teaching system of information resource sharing highlights the benign interaction of the school-business collaboration behavior. It is a concise and quite operable theoretical framework of teaching structure. Compared with other teaching modes, it also consists of four elements: theoretical basis, functional goals, realization conditions, and activity procedures. Cultivate vocational technical personnel and high-quality laborers with dialectical materialist worldview, outlook on life and good professional ethics, and being capable of serving the front line of production. It is necessary to attach importance to the mastery of basic cultural and professional knowledge of students, but also to emphasize the cultivation of professional practical skills. At the same time, in accordance with the industrial characteristics of the cluster economy and the skill requirements of the industrial post group, vocational and technical personnel with intermediate and primary operating skills are trained. Make full use of the human, information, and material resources provided by modern enterprises and combine the characteristics of vocational education to conduct professional teaching. At the same time, it is necessary to achieve the necessary conditions for the benign interaction between the school and the enterprise in cooperation concepts, teaching training, and technology research and development. The details are shown in Figure 2.

The traditional teaching mode is frequently limited to the school's professional theory teaching in the activity procedure and rarely includes the teaching of corporate job group professional skills. The professional teaching model of information resource sharing for school-business collaboration includes not only the theoretical teaching of professional courses in the school, but also the teaching of professional skills and enterprise job skills training [22]. At the same time, the two parties' friendly interaction is the behavior that runs throughout the entire program. As one of the primary pillars of school-business collaboration, the school should fully implement the college's guidance on students' ideological behavior and the development of a sound personality and continuously improve its own school-running level with the help of industry and enterprise resources. Enterprises should actively participate in the process of educating people, extensively participating in all stages of student training, sharing resources, complementing

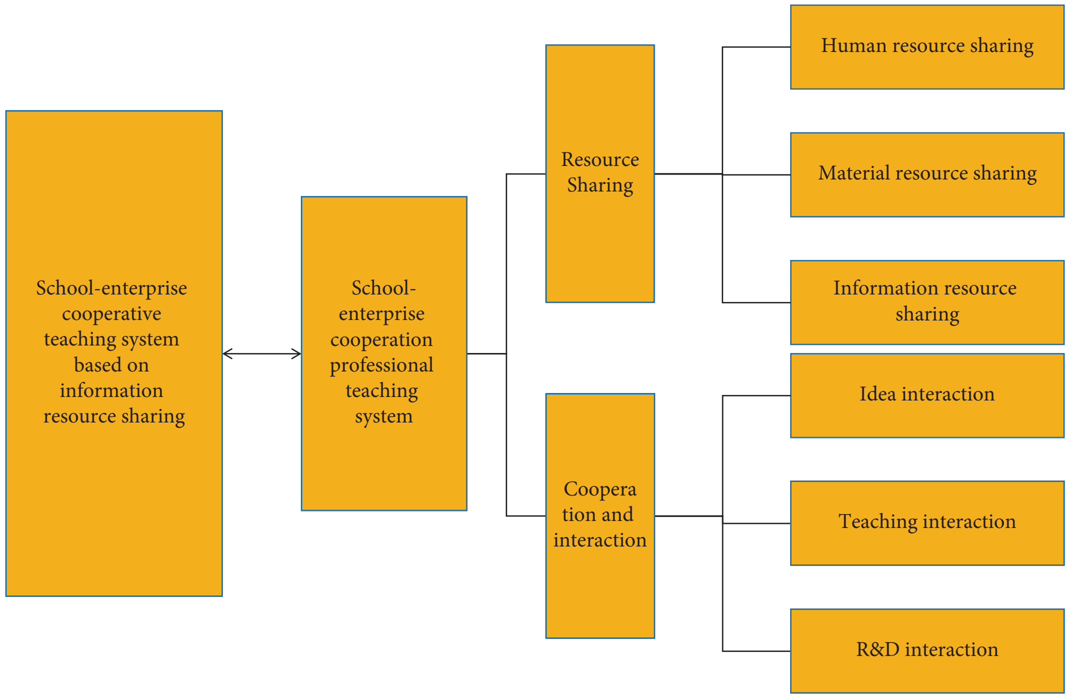

Figure 2: The basic framework of a school-business collaboration professional teaching system based on information resource sharing.

each other's advantages, educating people through science and technology, and technological innovation, achieving corporate profitability and social responsibility, as well as self-development and development, as another important subject of educating people. Industrial development has a high degree of coherence.

5. Research on the Importance of Factors Influencing Enterprise Innovation and Entrepreneurship Based on Information Resource Sharing

5.1. School Evaluation Index Selection. Higher vocational colleges can use the tangible assets of enterprises to provide students with internship places. The training goal of higher vocational education is that talents must have strong technical application ability and strong professional quality. This requires higher vocational education to pay special attention to practical teaching links. There are some experiences and contingency methods that cannot be taught in the classroom. It is possible to be sure of repeated training in a real live environment. Under the current situation where education investment is generally insufficient, it is difficult for schools to provide on-site environments, i.e., internships and training bases, and there is no need to set up a factory for each major as a training place for students. With the support of enterprises, vocational colleges can obtain experimental equipment funding or establish professional practice bases, improve teaching facilities or provide good conditions for practical training, and provide hardware guarantees for cultivating talents.

In order to understand the binary subclassification problem between class j and class k and maximize the boundary between the information resource sharing data, the soft-margin objective function is shown in (1) and (2).

$$\min \quad w_j w_k = \left\| w_j - w_k \right\| \frac{1}{2} + c \sum_{y_i \in \{j,k\}} \xi_i^{jk}, \tag{1}$$

$$y_i^{jk} f_{jk}(x_i) \geq 1 - \xi_i^{jk}. \tag{2}$$

Among them, $xi \in Rd$; ξ_i^{jk} is nonnegative slack variables used to deal with nonlinear data classification problems; assuming that there are a total of c attributes, then there are a total of $c(c-1)/2$ binary subclassification problems. An information resource sharing model is shown in formulas (3) and (4):

$$\min \quad w_j w_k = \frac{1}{2} \sum_{j=1}^{c-1} \sum_{k=j+1}^{c} \left\| w_j - w_k \right\|_2^2 + c \sum_{j=1}^{c-1} \sum_{k=j+1}^{c} \sum_{y_i \in |j,k|} \xi_i^{jk}, \tag{3}$$

$$y_i^{jk} f_{jk}(x_i) \geq 1 - \xi_i^{jk}. \tag{4}$$

When using model (2) to classify the samples, a voting mechanism is used; More categories Ij satisfy the relation. Finally, the predicted category of the sample will get the highest number of votes, as shown in formula (5).

$$\tilde{y}_i = \arg\max_j w_j^T x_i + b_i. \tag{5}$$

Table 1: Analysis results of factors affecting information resource sharing school-business collaboration.

	Dependency	Predictive correlation	Maximum sample dependence probability
Government policy support (GPS)	Higher	Higher	0.732
School entrepreneurship support (SES)	Higher	High	0.876
School's innovation support (SIS)	Higher	Higher	0.762
Enterprise's support for entrepreneurship (ESE)	High	Very high	0.951
Education (EDU)	Higher	Higher	0.769
Participation in the internship (PTI)	Middle	Lower	0.603
Individual ability (IAB)	High	High	0.944
Awareness of entrepreneurial risk (AER)	Higher	High	0.892
Entrepreneurial motivation (EMO)	Higher	Higher	0.824
Entrepreneurial determination (EDE)	Higher	Higher	0.798

In order to verify the effectiveness of the proposed model, the entrepreneurial data in [23, 24] is used as the data sample. The influencing factors considered for information resource sharing are shown in the first column of Table 1. There are five categories of influencing factors: low, low, medium, high, and high. The information resource sharing of model (2) is applied to the sample data, and the specific results are shown in Table 1.

The success of students' innovation and entrepreneurship depends heavily on the support of schools and enterprises to innovation and entrepreneurship. The experimental results in Figure 3 show that the model of school-business collaboration based on information resource sharing is conducive to promoting college students' innovation and entrepreneurship.

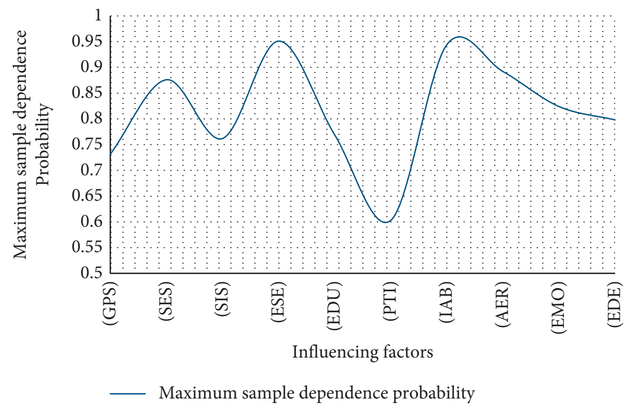

Figure 3: Analysis results of factors affecting information resource sharing school-business collaboration.

5.2. Selection of Enterprise Evaluation Index. The success of school-business collaboration projects for businesses is measured not only in terms of financial gains, but also in terms of scientific research and development progress. The ability to maintain a leading position in technology; the ability to increase training opportunities for corporate employees; the richness of human resource reserves; the improvement of the corporate reputation, and so on are all factors that influence the success of school-business collaboration for businesses. Students who stay in the company as part of the school-business collaboration project can save the company money on recruitment, training, and other costs by providing qualified employees who meet the company's needs directly. In summary, the following evaluation indicators were chosen for the school-business collaboration project: Corporate: corporate reputation, financial income, employee training, and student acceptance or recommendation for employment: work ability, professional characteristics, and competitiveness.

Construct a judgment matrix. For the indicators to be investigated in the target layer and the criterion layer, the average scores of the experts on the indicators are calculated to construct a matrix table. There are two calculation methods: geometric average method and standardized column average method. Calculate the consistency check coefficient C.R. and make a judgment:

$$C.R. = \frac{C.I.}{R.I.}. \tag{6}$$

When $C.R. < 0.1$, it is considered that the consistency of the judgment matrix is acceptable; when $C.R. > 0.1$, it is considered that the judgment matrix does not meet the consistency requirements, and the judgment matrix needs to be revised. The average random consistency index of the matrix is shown in Figure 4.

Calculate the weights between the criteria under the target layer. First, average the scores of the experts and the structure is shown in Table 2 and Figure 5.

Consistency check $C.I. = (\lambda\max - n/n - 1) = (5.195 - 5/5 - 1) = 0.5$. So the judgment matrix passed the one-time test.

5.3. Single-Level Evaluation of the Effects of School-Business Collaboration Projects. The overall effect of school-business collaboration projects is evaluated in this article using a fuzzy analytic hierarchy process. This evaluation method, which combines the two methods, can not only compare the important lines of the evaluation indicators of the school-business collaboration project, but also quantitatively reflect the overall effect of the school-business collaboration project, which improves the project's effect. Aspects can provide a more focused foundation. A judging group is chosen from among the project participants or benefiting personnel from schools, businesses, and governments in this paper. Based on the connotation of each evaluation index,

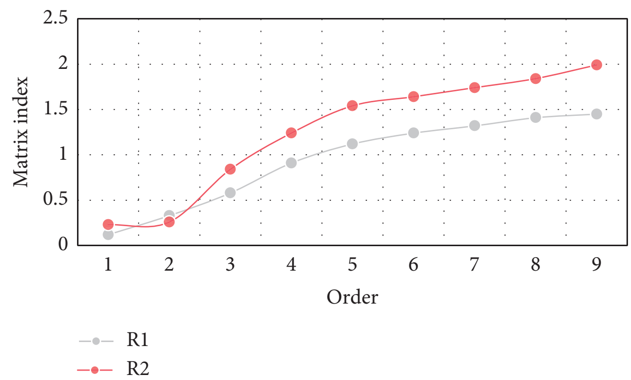

Figure 4: The average random consistency index of the matrix.

Table 2: The structure of the judgment matrix.

Level a	A1	A2	A3	A4	A5
B1	1	0.25	0.261	0.778	4.333
B2	4	1	1.833	5.667	7.333
B3	3.383	0.545	1	4	6
B4	1.286	0.176	0.25	1	3.667
B5	0.231	0.136	0.167	0.273	1

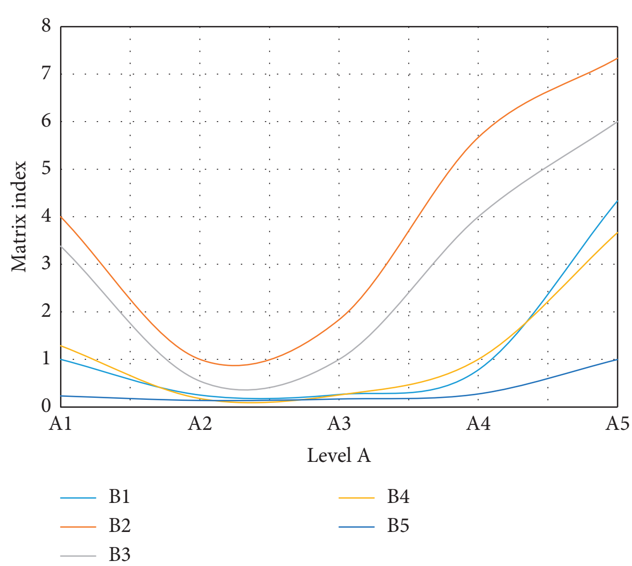

Figure 5: The structure of the judgment matrix.

the judging group will vote on a set of comments. Table 3 and Figure 6 are the statistical process for voting results.

After weighting the weights of each indicator at the scheme layer and the weight of each indicator at the criterion layer, the total ranking weight of each indicator at the scheme layer is obtained. The total ranking of the indicators at the scheme layer is as follows:

From Figure 7, Figure 8, Figure 9, Figure 10, and Figure 11, the fuzzy matrix between the school-business collaboration project effect A and the comment set v can be obtained from the single-level evaluation result of the school-business collaboration project effect. The effect of enterprise-enterprise cooperation projects is good, 22.5% of people think that the effect of school-business collaboration projects is average, and 9.4% of people think that the effect of school-business collaboration projects is very poor. During the operation of the project, the focus of both parties is mostly on strengthening the training of students through various means, in order to enhance students' professional ability and employment competitiveness. For the project itself, it is easier for this approach to obtain a more obvious effect. However, from the perspective of the development of the school, only through the school-business collaboration project to promote the improvement of the teacher's level

Table 3: Relationship between criterion level and program level.

Teacher improvement B1	Teacher training C11 Academic research promotion C12
Student training B2	Training cost C21 Curriculum effectiveness C22 Professional recognition C23 Core competence value-added C24 Graduation design quality C25
Student employment B3	Career planning awareness C31 Employment rate C32 Professional relevance C33 Occupational brother at coincidence degree C34 Value-added professionalism C35
Enterprise B4	Corporate reputation C41 Financial income C42 Staff training C43 Working ability C44 Professional characteristics and competitiveness C45
Government B5	Employment area C51 Income level C52 Current satisfaction C53 Non-unemployment rate C54

can the theoretical knowledge mastered by the teacher be better combined with the actual production, and the teacher with the "double-qualified" quality can be cultivated. The improvement of quality has cultivated more students with practical ability for schools and society and cultivated more employees with excellent professionalism for enterprises to promote the reform of teaching.

6. Conclusions

This article provides a three-tier school-business collaboration organization system to provide school-business collaboration organization guarantees to ensure the effective implementation of school-business collaboration; four school-business collaboration operating mechanisms provide school-business collaboration system guarantees to ensure efficient school-business collaboration. Operation: Three school-business collaboration groups are formed to provide school-business collaboration in running schools and to integrate high-quality resources for school-business collaboration. It established a hierarchical structure model with five dimensions of teacher improvement, student training, student employment, enterprise, and government as the criterion layer and selected 21 indicators covering the above five dimensions as the program layer and used the analytic hierarchy process to pass on the school. Experts from the three aspects of enterprise and government have calculated the weights of each indicator of the model. The weights are ranked from high to low for student training, student employment, teacher promotion, enterprise, and government.

The largest collection of transaction costs, such as manpower, financial resources, resources, and technology, is the common benefit of collaborative education for all parties involved in the collaboration. Only by actively undertaking their due obligations in collaborative education, actively fulfilling their responsibilities for educating people in various roles, and working closely together and committing to the cultivation of students can the coordinated development of the regional industrial economy, and ultimately the mutual benefit of multiple parties, be realized. The government should exercise its macrocontrol and supervision functions, provide policy support and social guidance for school-business collaboration, and create a system for third-party industry association evaluation. Mechanisms ensure coordinated efforts, with each party fulfilling its responsibilities, as well as multiparty interaction, in order to cultivate high-quality, compound, and practical talents that truly serve the development of regional industrial economies, as well as to achieve sound and rapid vocational education development. Only by resolving the incentive mechanism of school-business collaboration, that is, by paying attention to the short- and long-term interests of enterprises in the process of vocational education, can we attract enterprises to participate in school-business collaboration and form a stable school-business collaboration mechanism, establishing a long-term partnership between schools and businesses.

This article examines the positive effects of school-business collaboration in today's society by looking at the history of the collaboration and the mode of cooperation. Research is even more important. The government's role in school-business collaboration is frequently overlooked in current research. This article begins with a systematic assessment of the impact of school-business collaboration projects from the three perspectives of universities, businesses, and government and ends with an empirical analysis of the experience and shortcomings of school-business collaboration in order to provide school-business collaboration.

Academic Editor: Tongguang Ni

Cultivating students' autonomous learning abilities has become a research hotspot in CE (College English) reform, and the new CE autonomous learning teaching mode with students at the center also requires teachers to change traditional teaching ideas. The traditional teaching mode and teacher orientation have changed dramatically as a result of the new situation of CE teaching reform. The design and implementation of a CE data resource base based on a web database demonstrates that these technologies provide people with greater convenience and practicality. A GA (Genetic Algorithm) based on a QoS (Quality of Service) constraint is proposed on this basis. This algorithm can find a suitable resource node in the computing resources for each subtask that meets the constraint conditions and assign it to the corresponding task. Information-based education has become a powerful driving force for educational revolution, with computer technology and network information technology making English classroom teaching richer, more flexible in form, rich in content, and searchable in data.

1. Introduction

The traditional teaching model has been greatly impacted and challenged as CE teaching reform continues to progress. The reform entails gradually transitioning from a teacher-centered teaching mode of imparting language knowledge and skills to a student-centered teaching mode that emphasizes the development of students' practical language use ability and autonomy in learning. This necessitates a shift in teachers' responsibilities. CE teachers face an urgent problem: how to fully utilize students' initiative of autonomous learning and make better use of the autonomous learning mode to improve their English level. Outside of the classroom, students can learn English in a variety of ways, and the popularity of multimedia teaching in college classrooms has changed CE (College English) teachers' requirements and orientation [1, 2]. The design and implementation of a web-based CE data resource database, on the other hand, can not only realize the educational era's development but also promote network technology's development.

Make full use of social resources and use the "bringing in" method [3]. Good resources should be kept in the teaching resource pool, while outdated and obsolete resources should be discarded. The construction of a professional teaching resource pool should follow the education and teaching philosophy of "putting students' needs first and teachers second" and give full consideration to the characteristics and benefits of teaching resource pools [4]. Text, pictures, animation, and other forms of traditional learning resources can no longer meet the learning needs of learners. When streaming media technology is used to create a large number of audio and video resources, the teaching effect becomes more vivid and vivid [5, 6]. Teachers should play an important role in the learning process by guiding students' autonomous learning activities, assisting students in mastering the proper learning methods, adjusting their learning progress according to their current situation, and setting personalized learning goals. English teachers should also assist students in gathering a variety of learning materials, organizing and analyzing them on a regular basis, and finally assisting students in developing the ability to learn independently [7]. Multimedia web teaching is not only simple and quick, but can also improve teachers' teaching quality while also ensuring teachers' and students' access to resources is reliable. The use of multimedia network teaching can greatly aid teachers in improving teaching quality, allowing teachers to improve their own teaching level to some extent [8].

In the case of emphasizing multimedia teaching, instead of seriously studying the characteristics of multimedia teaching, just emphasize the convergence of forms, which leads to the phenomenon of full teaching in multimedia classroom. The teaching methods of some teachers are not standardized, and the main points are not highlighted. Teachers only demonstrate and read multimedia courseware in multimedia teaching so that students can copy their teaching materials. Multimedia instruction is information-rich, fast-paced, and ever-changing. Students believe that, in the process of multimedia teaching, they are unable to grasp key points and have a strong memory and that it is difficult to digest what is said in class and take notes. As a result, this paper develops and implements a web-based CE data resource database. The platform of the CE data resource database and the teaching resources in the CE data resource database are divided into two sections.

2. Related Work

According to [9, 10], despite the fact that the construction of digital resources has reached a pinnacle, the overall quality is not high, and quality resources are limited; particularly the supply and service based on digital resources are too rough and crazy. In the compulsory education stage, [11] proposes the creation of "synchronous courses for famous teachers," which provides primary and secondary school students with courses from all grades and disciplines in the form of online video, further enriching the supply of quality education resources. Reference [12] has created a multimedia education resource database system with significant communication value. Users of such a network platform of teaching resources can share all types of teaching materials without being constrained by time or geography, and it provides a convenient and quick platform for teaching. According to [13], an English curriculum requires students to cultivate their daily communicative activities in addition to having good language skills. According to [14], English teachers should not only teach students basic English skills, but also consider their psychological well-being and promote their physical and mental development. According to [15], the new teaching model can provide students with rich, vivid, and intuitive information, expand students' cognitive space, shorten students' cognitive process, create a communication bridge, and help students improve their language and cultural awareness.

People's network dreams are embodied in the cloud computing vision. To some extent, distributed computing and grid computing reflect the concept of cloud computing, that is, combining idle resources distributed across a network to provide powerful computing power [16]. Many researchers have tried to use the resource scheduling algorithm in a grid environment to see if resource scheduling in the cloud is possible. In a distributed environment such as a grid, for resource scheduling, [17] describes a task scheduling algorithm for grid computing based on GA (Genetic Algorithm), which aims to maximize resource utilization and throughput. Reference [18] examines existing cloud computing platform solutions and technologies, then designs and analyzes a job scheduling algorithm for virtualization platforms, and proposes a scheduling scheme based on the threshold dynamic scheduling model. In [19], in light of GA's flaws, an improved algorithm for optimizing scheduling is proposed, and GA with a double fitness function is considered to find nodes that reduce task scheduling's average and total times. The half-validity method, proposed in [20], is an improved method for maintaining the timing consistency of real-time data objects. The update period of real-time data objects is set to half the effective interval length of real-time data objects in this method. As a result, even in the worst-case scenario, this algorithm can guarantee the timing consistency of real-time data objects. To achieve better optimization of system resource use, it is also suggested in [21, 22] to delay the sampling time of update transactions as long as possible and use a dynamic periodic transaction deadline.

3. Method

3.1. Construction of CE Data Resources. Help students master various cognitive tools item by item and use them skillfully, so that they can successfully carry out autonomous learning and collaborative learning, according to the application requirements of various learning tools needed by universities to experience the information-based learning environment of English. Freshmen are given a week to experience the English autonomous learning system when they first start school. This model satisfies current national CE teaching reform requirements, particularly those related to teaching model reform; for example, "the reform of teaching model should cause English teaching to develop toward individualization, independent of time and place, and active learning."

The CE data resource database is designed to help people share resources and manage large amounts of data. Teaching resources refer to the most basic materials used in network teaching, such as graphics and images, audio and video, multimedia lesson plans, network courseware, and a test question bank. Because the platform is primarily used to implement streaming media resources, the development of resources is primarily focused on streaming media teaching resources. This platform can help teachers make better use of their teaching materials.

To begin, a large number of scattered network resources, teaching film, and television materials are collated by schools for many years, and school-based curriculum resources are collected and stored as video files with chapters as the unit, and each video file is divided into N segments according to the teaching needs, and corresponding text streams and HTML page indexes are inserted at each segmentation point to find or index the corresponding tex. The platform is divided into three parts: a streaming media producer, a server, and a client. A model diagram of an application platform is shown in Figure 1.

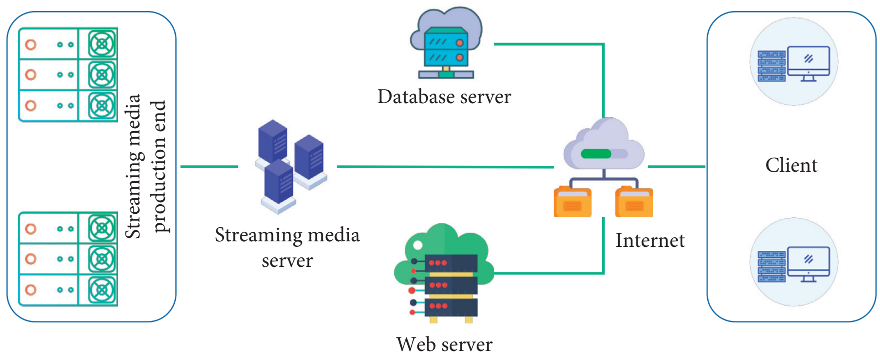

FIGURE 1: Model diagram of CE data resource pool.

The service interface subsystem provides external systems with interface services based on unified standards, such as the identity authentication interface and the resource metadata service interface. Metadata service interface includes metadata query, details browsing, behavior track, resource catalog, retrieval box docking, and other contents, which can meet the diversified resource application service needs of districts and schools. Figure 2 depicts the design of a specific functional structure.

The identity authentication interface and the metadata service class interface are both part of the service interface. Metadata service interface provides metadata query, details browsing, resource catalog, retrieval box docking, and other services. Identity authentication interface supports identity mutual trust among platforms based on joint authentication system. Metadata service interface provides metadata query, details browsing, resource catalog, retrieval box docking, and other services. A series of website security enhancements are being carried out in response to the characteristics of its Internet external service portal. The system patch is upgraded in time to strengthen the system security through vulnerability scanning and code auditing. Synchronous backup of the platform's core data is performed in the remote computer room to ensure that the remote computer room can carry web services if the main server room fails, and the digital resource sharing service platform's core services, such as web and exchange, can continue to operate.

Because each university offers a diverse range of disciplines and majors, the number of people who use it is naturally quite large, and each has its own set of needs, as well as different resources and materials. However, the web's educational resources system can meet such complex requirements, allowing for more open uploading, searching, and application of various teaching resources. With such a large resource pool, the system must meet specific storage capacity requirements, as well as stringent resource quality requirements. It is necessary to consider whether the resources are reliable and whether the system is in place.

Incorporate English teaching resources into the creation of digital English teaching materials, and gradually develop the school's own digital English teaching materials that are tailored to the needs of various grades, majors, and classes. Improve the usability of English textbooks and the rate at which they are used. From general English instruction to specialized English instruction, we have got you covered. As a result, incorporating high-quality teaching resources is critical. English teachers should integrate existing teaching resources with advanced teaching equipment, recognize the added value of teaching information, and adhere to strict teaching objectives. Teachers should have a thorough understanding of the meaning of digital technology, be able to use multimedia technology effectively in the classroom, and organically integrate the purpose and content of English instruction.

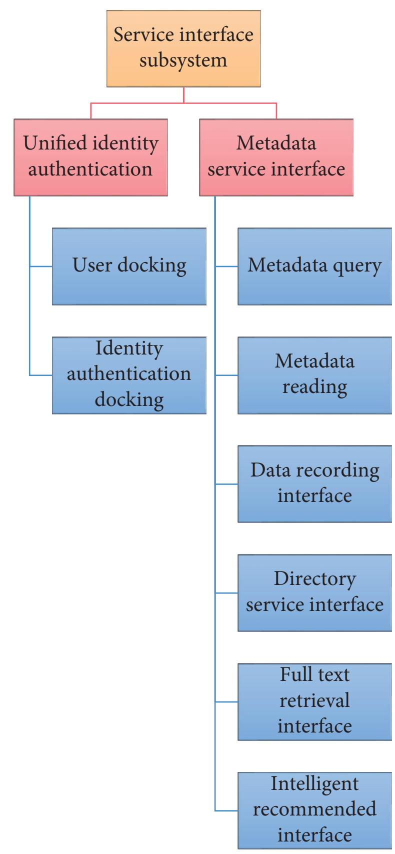

FIGURE 2: Service interface function structure.

3.2. Data Resource Optimization. Students are instructed, assisted, and encouraged to write "works" by their teachers. And the students are responsible for a large portion of the language input learning. Students learn in an autonomous learning center or over a local area network according to their own needs and levels, as determined by the teaching requirements and teachers' arrangements, embodying the principle of individualized instruction. Teachers can also recommend bibliographies and introduce network resources or Internet websites and assist students in developing the habit of self-study and increasing their self-assurance.

The units for task completion time, cost, and system load are all different. The fitness function is closely related to the comprehensive value of the weighted sum of these three indexes, so it is necessary to deal with the indexes so that there is no dimensional difference between them when designing the scheduling algorithm.

The actual value of the index and the evaluation value of the index are the two variables in a multiobjective comprehensive evaluation. There will be dimensional differences because each index has a different physical meaning. Resources in the cloud computing environment are dynamically heterogeneous, tasks are complex, and different types of tasks submitted by different users are also different. When designing GA, it is important to make assumptions about resource nodes and tasks and then base the algorithm's design on those assumptions, so that the algorithm can find a suitable allocation scheme for scheduling in a given environment.

Traditional network QoS (Quality of Service) usually refers to network speed, network reliability, and availability. QoS reflects consumers' satisfaction with the services provided. It is a comprehensive index. For example, QoS in the grid refers to the performance of a set of services, which determines the satisfaction of users with services. Research on QoS can be divided into three levels: application layer, system layer, and resource layer.

It expresses the objective function as the weighted sum of three-dimensional QoS objectives [23].

$$M(x) = \omega_1 * \text{time} + \omega_2 * \text{cost} + \omega_3 * \text{load}, \tag{1}$$

where $\omega_1 + \omega_2 + \omega_3 = 1$, $\omega_1, \omega_2, \omega_3$ refers to the weight coefficient of each index, *time* refers to the completion time, time refers to the cost, and load refers to the load.

Experimental tests show that the weight coefficient ratio of CPU (Central Processing Unit), memory, and bandwidth load is 4 : 3:15[48]. The penalty substitution iteration method is used to calculate the comprehensive load, and the specific formula is shown in formula (2).

$$\text{load} = 1 - \prod_{k=1}^{3} \left(1 - \text{load}_k\right)^{\omega_{Lk}}. \tag{2}$$

The overall goal of resource scheduling in this paper is to ensure system load while meeting users' QoS requirements, such as task time and cost. The three indicators are closely linked by comprehensive indicators. The smaller the values of these three indicators are, the more satisfactory the scheduling results can be for users, according to the problem analysis (Figure 3).

Suppose the population size is m, the fitness function value of individual i is f_i, and the probability of i being selected is flat P_i.

$$P_i = \frac{f_i}{\sum_{i=1}^{n} f}. \tag{3}$$

P_i represents the proportion of the fitness of individual i in the sum of all individual fitness in the population. The greater the fitness value of an individual, the greater the chance of being selected.

The execution time of the update transaction job is not fixed due to various factors that may affect the actual update of the transaction, but it often changes dynamically with the influence of the actual running environment of the system at the time, and this change is sometimes very significant and substantial. The purpose of this paper is to improve and supplement the shortcomings of the DS-FP (Deferring-Scheduling Fixed-Priority) method in the application of software/fixed real-time systems. The calculation time of updating transaction jobs obeys a certain probability density function distribution [24] after using the probability statistics method to design the system, ensuring that the results of job scheduling and transaction execution meet the system's performance requirements.

In DS-PS method, for $i < j$, suppose $T_i < T_j$, when any job $J_{i,j}$ of T_i is ready; the worst case is that all jobs with priority not lower than $J_{i,j}$ are also ready at the same time. If the sampling time $r_{i,j+1}$ of the next job $J_{i,j+1}$ of transaction job $J_{i,j}$ is delayed to $r_{i,j+1}$, then:

$$r'_{i,j+1} = d_{i,j+1} - R_{i,j+1}\left(r'_{i,j+1}, d_{i,j+1}\right), \tag{4}$$

where $R_{i,j+1}(r'_{i,j+1}, d_{i,j+1})$ is the response time of job $J_{i,j+1}$ in $[r'_{i,j+1}, d_{i,j+1})$. In this case, $J_{i,j+1}$ is allowed to have the following number of jobs ready at most in T_i within $[r'_{i,j+1}, d_{i,j+1})$ time period after sampling:

$$hp_i\left(d_{i,j+1} - r'_{i,j+1}\right) = \sum_{i'=1}^{i-1} \left\lceil \frac{d_{i,j+1} - r'_{i,j+1}}{P_{i'}} \right\rceil. \tag{5}$$

Within $[r'_{i,j+1}, d_{i,j+1})$ time, the execution time of all jobs with high priority $J_{i,j+1}$ in the system:

$$\Theta_i\left(r'_{i,j+1}, d_{i,j+1}\right) = \sum_{i'=1}^{m} \sum_{j=1}^{hp_{i'}(t)} C_{i',j}. \tag{6}$$

The formula (4) is as follows:

$$R_{i,j+1}\left(r'_{,j+1}, d_{i,j+1}\right) = \sum_{i'=1}^{m} \sum_{j=1}^{hp_{i'}(t)} C_{i',j} + C_{i,j+1}. \tag{7}$$

Therefore, DS-PS algorithm must obtain the delayed sampling time and absolute deadline of all high priority jobs before calculating $\Theta(r'_{i,j+1}, d_{i,j+1})$.

3.3. The Orientation Change of CE Teachers. The transformation and orientation of CE teachers' functions have become unavoidable, according to research on the

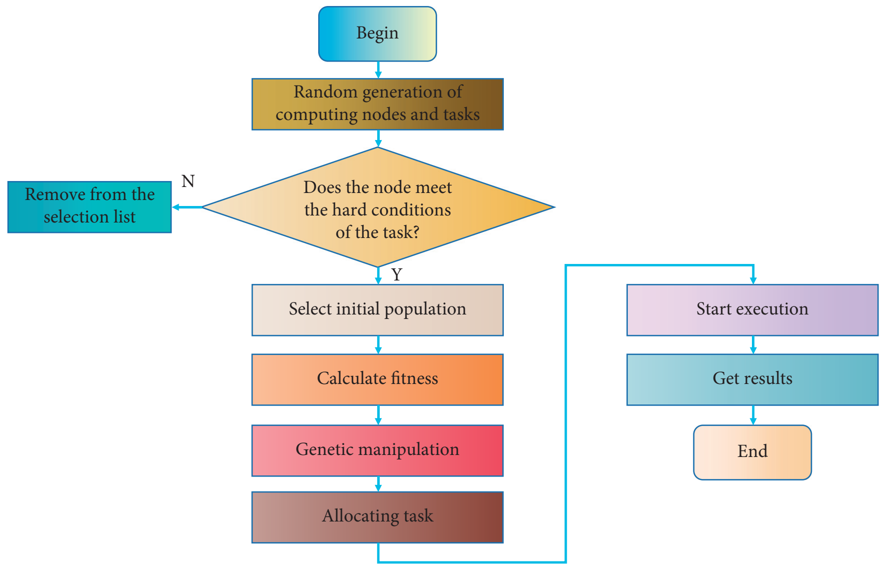

FIGURE 3: System diagram of resource evaluation model.

development status of CE teachers supported by digital technology.

Students actively collect and analyze relevant information and materials under the guidance of teachers, using multimedia and the Internet, and try to relate what they learn in the current learning content to what they already know. Effectively construct the meaning of the learned knowledge through the guidance of teachers and communication, discussion, and cooperation with learning partners, in order to improve our ability of information collection, information analysis, information processing, information innovation, and information expression, as well as cultivate our spirit of cooperation and innovation.

English teachers should use digital technology to create an active learning environment for their students. To achieve the best effect of English teaching, teachers should actively build a bond of trust in English teaching, release students' learning pressure, and eliminate their inferiority complex through two-way communication between teachers and students [7].

Teachers and students can use the Internet to ask and answer questions. This necessitates that teachers and students understand each other's teaching effect and that both sides work together to efficiently organize the teaching process in order to maximize the teaching effect. At the same time, students must understand their own learning effect after a period of study. The teacher's role at this time is also that of an evaluator, pointing out the students' accomplishments and advantages while also offering suggestions and guidance for their problems. Students will have a more accurate assessment of their learning situation if they are evaluated on time and in a reasonable manner. They will also be better prepared to learn in the future if they are evaluated on time and in a reasonable manner. The intrinsic motivation to motivate students to be positive is positive evaluation. Teachers should abandon traditional evaluation methods that primarily focused on test scores in favor of testing and evaluating students' learning performance and effect [9]. To ensure fairness and rationality in evaluation, teachers should conduct comprehensive evaluations on students, provide patient guidance and inspiration, and pay attention to the combination of personalized and process evaluations.

4. Results Analysis and Discussion

The more hands-on activities they participate in in the classroom, the better their hands-on ability, creativity, and sense of gain will improve. Teachers are proud of what they have accomplished. Under the information environment, there are two parts to the construction of CE digital teaching resources and teaching materials: English digital teaching resources construction and teaching materials construction.

In this experiment, the data involved are the attribute and number of cloud computing tasks, the attribute and number of resource nodes, the user's demand weight for time, cost, and load, the population size of GA, etc. Figure 4 shows the attribute values of 10 randomly generated tasks.

As an educator, even in the environment of students' autonomous learning, consider teaching issues from the perspective of pedagogy, and use nontechnical factors such as our emotions to urge students to learn better. At the same time, emphasize the psychological changes of students in the learning process, and solve their psychological problems in time. In addition, English teachers should strengthen their own research, be a researcher, keep up with the development of various ideological trends and new technologies, and apply the latest theories and technologies to teaching.

The results of simulation experiments show that the algorithm proposed in this paper is capable of selecting appropriate scheduling nodes for tasks based on users' needs and generating a satisfactory allocation scheme. The algorithm in [15] is compared to the algorithm in [19] in three ways: task completion time, cost, and the value of the

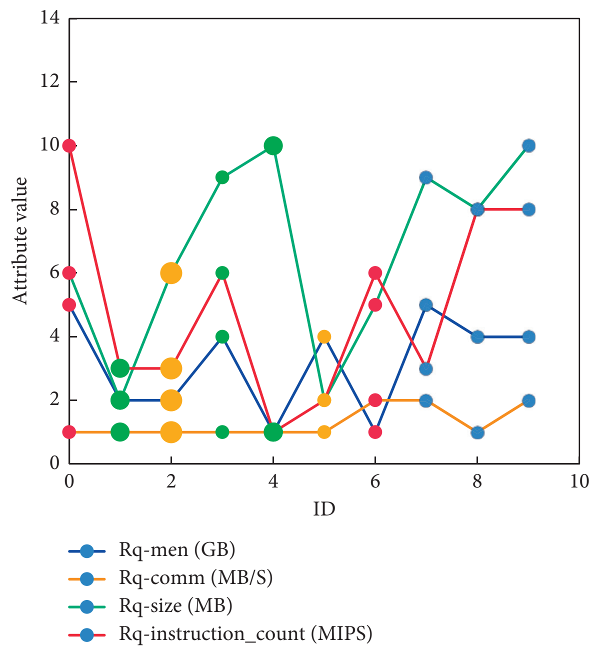

Figure 4: Task attribute value.

comprehensive objective function. The results shown in Figure 5 are the ones that were obtained.

Ninety percent of users of cloud computing want to get satisfactory service at the lowest possible cost. Analyzing from the constraint index of cost, the cost of the three algorithms will be higher and higher, but the cost of the algorithm in this paper is less than that of the algorithms in [15, 19].

In classroom teaching, teachers communicate with students mainly by asking questions. The learning process adopts the static teaching method, and students' learning thinking is limited, so they cannot learn independently, and it is difficult to communicate and exchange with English knowledge.

English teachers must improve their classroom knowledge, teaching activity design, student psychology, and teaching resource development, among other things. The teacher's role is similar to that of a traditional teacher in this regard. Teachers should plan and organize an entire stage of the teaching process, not just a single class, that is, in a macrosense, the organizer. This demonstrates that teachers should plan and organize the selection of students' learning materials, the formulation of students' learning objectives, the organization of the learning process, and the evaluation of learning effect based on the students' current situation. Figure 6 shows that as the number of tasks grows, the time required by the three scheduling algorithms grows. However, the algorithm in [19] takes less time to complete in total than the algorithm in this paper.

The objective function values of the two algorithms are very similar when the number of tasks is less than 40, but when the number of tasks exceeds 40, the objective function values obtained by the algorithm proposed in this paper are less than those obtained by the algorithms in [15] and [19]. As a result shown in Figure 7, in terms of overall performance, this algorithm outperforms the other two algorithms.

The system's load is an important consideration when allocating resources. Users can make the algorithm choose the best computing node for the task based on their own load weight coefficient setting through simulation experiments. The worth of a load will rise as well. Because the weight coefficients are set differently, the load values of the three algorithms will differ. The load calculation of the algorithm in [15], on the other hand, is based on a formula that ignores the needs of users. As a result, from a broad perspective, this algorithm can better meet various QoS requirements.

As shown in Figure 8, the real-time data object can guarantee the timing consistency requirement in this update transaction scheduling process, ensuring the system's overall performance. The first two methods can also guarantee 100 percent of the service quality requested by users and even improve the execution service quality above the service quality requested by users. When deterministic scheduling methods, such as those in [21] and [23], are applied in the software/fixed real-time system, it is shown that our previous strategy of reducing the schedulability of the system to ensure the correctness of the system performance is really harsh or pessimistic.

The network's all-around communication between teachers and students, as well as students and students, has reduced the psychological distance between them and increased the opportunities and scope of communication between them. Teachers can better understand the doubts, difficulties, and main problems that students face in learning by using statistical analysis of the types, times, and numbers of students' questions, which provides a realistic and effective way for personalized teaching. The CPU resource

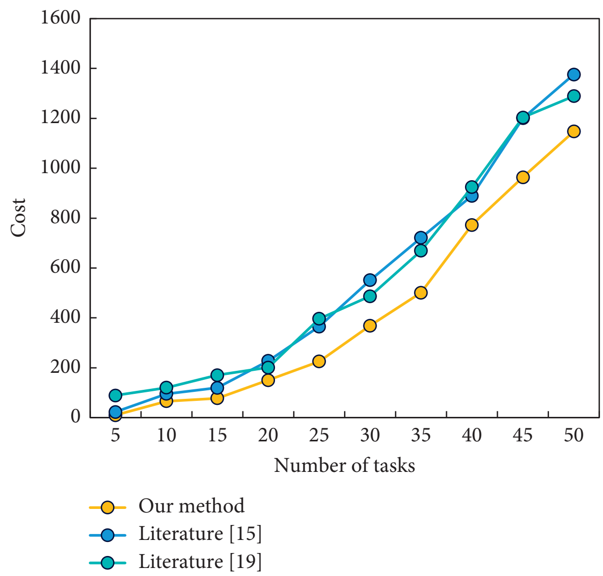

Figure 5: Cost comparison chart.

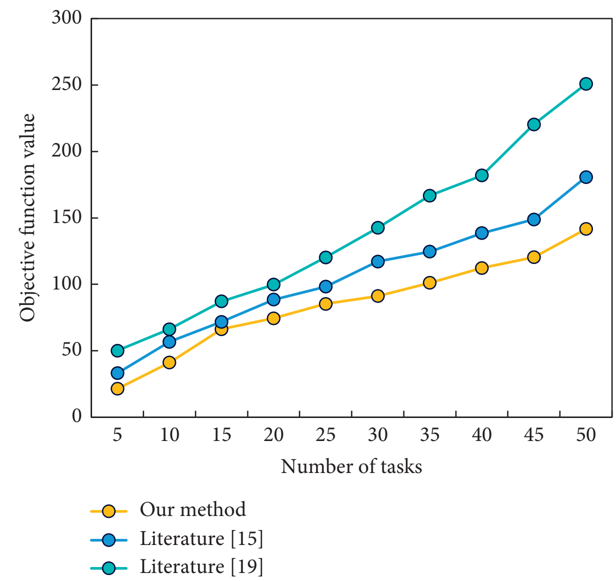

Figure 7: Comparison chart of objective function values.

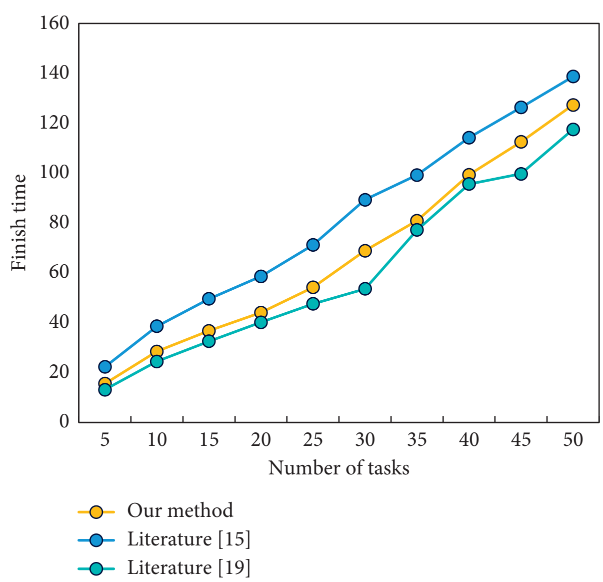

Figure 6: Comparison chart of completion time.

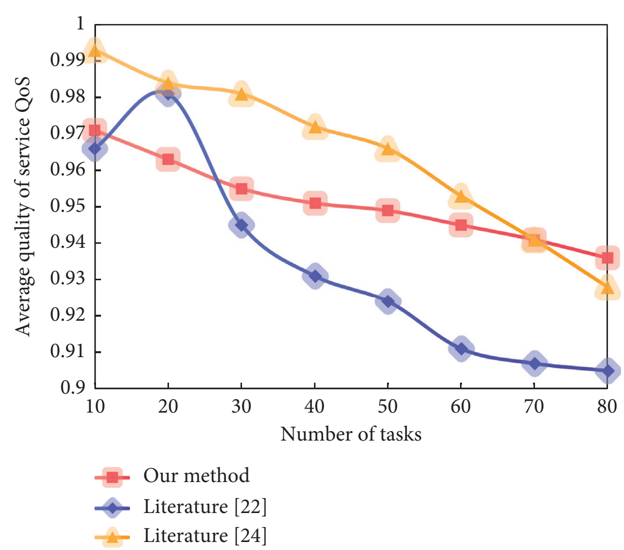

Figure 8: Comparison of the relationship between the average QoS of arrival of three methods and the number of transactions executed.

utilization rate of the three methods increases monotonically with the number of scheduled update transactions, as shown in Figure 9.

The main goal of DS-PS method is verified and realized (that is, while trying to delay the cycle of transaction operation, the calculation time of the operation is less than that in the worst case, thus reducing the utilization rate of CPU resources in the system).

Students-centered, teaching-centered programs improve students' overall performance, help them adapt to job demands, and help them better serve society, improving unified planning and design in the resource database building process, as well as integrating the resource application level. Teachers can use the platform of teaching resource pool to select the best teaching resources, design the most effective teaching process, achieve the best classroom teaching effect, meet the needs of students, and complete the teaching objectives.

The CPU resource utilization ratio of the method in [21] and the method in [23] when executing the scheduling update transaction under the condition that the QoS requested by users is different remains equal, as shown in Figure 10, because the system will still strictly require that the update transaction be executed to provide the service quality guarantee, even if the service quality requested by users is processed by these two methods.

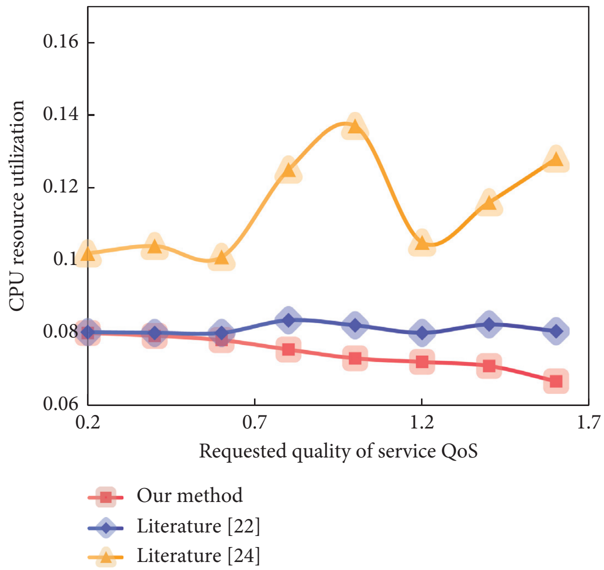

FIGURE 9: Comparison of the relationship between the number of transactions scheduled by three methods and the utilization rate of CPU resources.

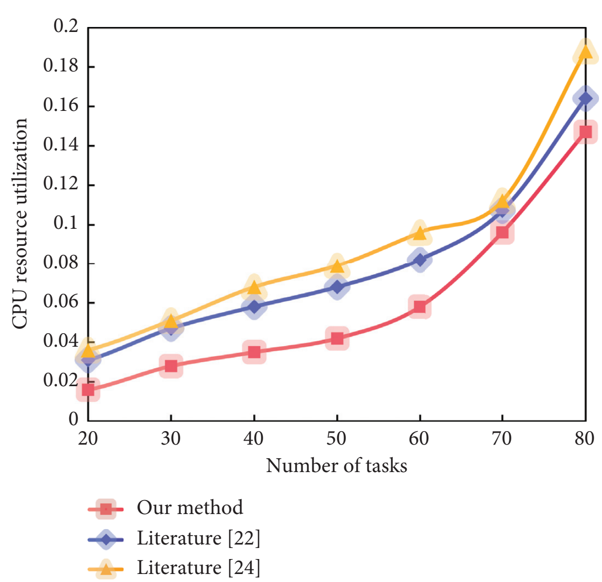

FIGURE 10: Comparison of three methods in relation between requested QoS and CPU resource utilization.

This also demonstrates that the DS-PS method can lower the quality of service of requests in exchange for increased system schedulability, making the DS-PS method more flexible in scheduling transaction job update operations and thus improving system performance.

Update resource management in the resource library on a regular basis, and improve resource construction management and application. Schools should use corresponding incentive mechanisms to ensure the long-term and dynamic construction process of resource pools in order to study the long-term mechanism of resource standardization and resource pool construction, acting as planners, organizers, guides, facilitators, designers, managers, supervisors, monitors, collaborators, and evaluators in the classroom to mediate students' learning process from teaching content, teaching methods, task setting and implementation, and other factors. This necessitates that teachers possess certain qualities, including knowledge of pedagogy, psychology, and other related topics, as well as the ability to use modern information technology, such as multimedia and network technology.

5. Conclusion

This research presents a relatively comprehensive construction scheme for a CE data resource base based on a web database, which allows users to upload, edit, download, read, and use teaching multimedia resources. GA is designed to solve the resource scheduling problem, and the objective function is obtained by integrating the three indexes of task completion time, cost, and load balance. The process of algorithm execution, preconditions, and assumptions, the unique environment of cloud computing, and the strategy selection of three types of genetic operations are all examined in this paper. In a cloud computing environment, a resource scheduling optimization strategy based on QoS constraints and GA is proposed. CE data resource pool can further integrate CE high-quality resources to achieve balanced supply, which has significant social benefits and plays an important role in expanding the coverage of CE high-quality education resources, promoting education equity, and improving the quality of school education and teaching.

Culture is an important feature that distinguishes human beings from animals. Human beings have created and developed various cultures and influenced people's psychology and behavior in different social forms. With the continuous improvement of China's international influence and cultural soft power, the number of foreign students studying in China is increasing year by year. In this paper, data mining is carried out on the data of international students, and the cross-cultural interaction model of international students is constructed. According to the characteristics of the research object, this paper explores the influence of cultural novelty and psychological capital on its cross-cultural adaptation in order to provide theoretical basis for the improvement of cross-cultural adaptation. It also promotes the better development of international students and the improvement of international exchange management in colleges and universities by providing some ideas for mental health education and management of international students. The importance of cultural study for international students in China is related not only to the development and improvement of foreign students' cognitive level of target culture, but also to the external communication of national cultural image.

1. Introduction

The trend of economic globalization not only brings closer economic and political exchanges between countries, but also brings more frequent educational exchanges and more developed educational services trade, resulting in the international study abroad fever [1]. International students will form their own understanding and cognition of Chinese image and culture while studying and living in China, and they will also bring their defined Chinese image back to their home country once their studies are completed [2]. International students in China can learn about foreign cultures and broaden their horizons by studying abroad, but coming from their home country to the host country also means dealing with cultural differences [3, 4]. In order to provide a comfortable learning and living environment for international students studying in China, the Ministry of Education and universities are constantly improving relevant procedures, education management systems, and professional training plans for international students studying in China, as well as allocating a large amount of funds to improve the hardware construction level of universities [5]. In this new era, data is no longer simply piled up and stored, and the ability to filter and utilize data is the criterion to judge whether a system can handle and load big data.

As messengers of cultural exchanges, international students lay human capital and cultural capital for bilateral coordinated development and further deepen international cooperation [6]. At present, there are millions of students studying abroad all over the world, and the number of international students has reached an unprecedented scale and leap-forward development. The process of cultural adaptation is also a complex process of resocialization or "secondary growth" [7]. The final academic and study quality of overseas students depends on the effectiveness of solving the adaptation problems in language, environment, eating habits, studies, and so on, and the effective adaptability has a great influence [8]. If the foreign students cannot effectively face the cultural impact of the host country, maladjustment will also damage their mental health, which to some extent means the failure of foreign students' families and national education investment [9]. The effect of foreign students' cultural learning not only is related to their cross-cultural life experience, but also affects the external communication effect of Chinese culture to a great extent [10]. Therefore, paying attention to the significance of foreign students' cultural study in China is not only conducive to the development and improvement of foreign students' cognitive level of target culture, but also related to the external communication of national cultural image. According to the characteristics of the research object, this paper explores the influence of cultural novelty and psychological capital on its cross-cultural adaptation and carries out data mining on the data of international students to build a cross-cultural interaction model for international students.

With the rapid development of international education in China, the country has risen to become the world's third largest destination country and Asia's largest. As a result, academic circles are paying more attention to research on international students in China [11]. International students' cross-cultural adaptation has become a source of concern. As a result, education administrators should prioritize learning how to effectively educate and manage international students, as well as improving their cross-cultural interaction [12]. Positive self-efficacy, a positive outlook on life, and tenacious willpower are all important factors in international students' cross-cultural adaptation activities in China [13]. As a result, educational institutions must provide timely, scientific, and comprehensive cultural adaptation counseling to international students in China, in order to improve the continuous release of collective internal pressure by international students in China and then to strengthen their individual psychological resilience. The degree of difference between the culture of the home country and the culture of the country of residence recognized by people living in other countries is referred to as cultural novelty [14]. Because of individual differences, everyone has different cultural understanding of the home country and the target country. Understanding cultural distance with cultural novelty can better reflect cultural differences from the individual level. In this study, a mixed research method combining qualitative and quantitative methods was adopted, and the research steps were planned according to the exploratory sequence design scheme. This paper probes into the influence of cultural novelty and psychological capital on their cross-cultural adaptation. Data mining is carried out on the data of international students, and the cross-cultural interaction model of international students is constructed. This paper analyzes the influence of gender, time in China, Chinese proficiency, and country on the use of cultural learning strategies by foreign students.

2. Related Work

The cross-cultural adaptation of international students in China is a material derived from the integration of individual international students and the external ecological environment, according to [15], which is based on the cross-cultural adaptation model from the perspective of psychological capital. From the perspective of psychological capital, [16] discusses the management of a cross-cultural adaptation model for Chinese students. Reference [17] examines cultural learning strategies that have not been thoroughly explored in the field of second language learning strategies from the perspective of cross-cultural communication. Reference [18] develops a survey tool to analyze the current situation of cultural learning strategies used by international students in China, as well as a classification system for cultural learning strategies for international students in China. In addition, it investigates the factors that influence cultural learning strategies. Reference [19] discusses and analyzes the factors influencing cross-cultural adaptation from the perspective of cross-cultural adaptation, using interview and questionnaire research methods. Reference [20] points out that individuals and groups in cross-cultural contact will adopt strategies for acculturation, and two important issues related to strategies are the preservation of the original culture or the contact and participation of the new culture. Reference [21] holds that the definition of "culture" is the conceptual basis for constructing the theoretical framework of cultural learning research. Without a reasonable definition and explanation of culture, it is difficult to scientifically define and substantively discuss the connotation, content, and purpose of cultural learning. Reference [22] points out that individuals and groups in cross-cultural contact will adopt strategies for acculturation, and two important issues related to strategies are the preservation of the original culture or the contact and participation of the new culture. In this paper, data mining [23] is carried out on the data of international students, and the cross-cultural interaction model of international students is constructed, thereby providing theoretical support for cross-cultural adaptation research, especially providing theoretical analysis and explanation for cross-cultural adaptation of international students with different cultural distances.

3. Analysis of Influencing Factors of Cross-Cultural Adaptation

Culture is an important feature that distinguishes people from animals. Human beings have created culture, which in turn influences individual psychology and behavior. When people move from one cultural situation to another, they show psychological uneasiness and behavioral discomfort due to the constraints of the original cultural elements, but culture is learnable and dynamic, and people also have initiative. Therefore, when people enter the second cultural situation, they will make adjustments to changes, that is, cross-cultural adaptation, which is embodied in psychological adjustment and the acquisition and application of the second cultural elements.

With the advent of the era of economic globalization, it has not only greatly promoted the development of Chinese economy and culture, but also brought the upsurge of studying abroad. As a bridge of cultural exchange, international students studying in China lay a good human foundation for the coordinated development between countries. It is the program written by culture and placed in people's mind in advance. These programs are the entirety of people's life style in a broad sense in a specific society. They are the one-benefit and collective spirit programs, which determine individual emotions [24], behaviors, and cognition [25]. However, different from computers, human beings as individuals are an open and active system. On the one hand, their behaviors are partially controlled by mental programs, but on the other hand, people may deviate from or modify this program by exerting their individual initiative, showing new ways of emotion, behavior, and cognition. With the increasing number of Chinese students studying in China, to some extent, it has effectively promoted the two-way development of national economy and traditional culture. However, there are still some adverse effects; that is, a large number of international students studying in China have a series of potential unstable factors, the most well-known performance of which is the problem of cultural adaptation.

The psychological adjustment that people make to their social environment is known as adaptation. Every stage of a person's life, including childhood, adolescence, middle age, old age, and death, involves psychological adjustment and change, which is the process of adjusting to one's social environment. Self-acceptance, self-enrichment, satisfaction, happiness, and other outcomes of adaptation can be seen. On the contrary, even physical and mental organizations are harmed and dysfunctional. The cultural distance between the two countries is an objective measure of their cultural similarities. Some people believe that psychological distance is caused by spatial geographical distance or cultural circle. Cross-cultural anxiety is almost a necessary stage for every international student, but it is difficult to manage and can even cause physical discomfort. For cross-cultural adaptation, cultivating international students' positive attitude toward life and optimistic quality is critical [26]. In practice, group counseling can be used to teach international students to form positive attribution styles, to use their own advantages to increase self-awareness, to enable international students to gain positive energy, and to use these forces to adapt to cross-cultural life, according to the explanatory style theory, expectation theory, and learned optimism theory.

Individuals can acquire and use their inner strength to improve themselves in a short time and overcome the obstacles of cross-cultural adaptation. Its flexibility, benefits, and investment characteristics make psychological capital become a more attractive way to adjust the level of cross-cultural adaptation. The influencing factors of cross-cultural adaptation are shown in Figure 1.

From the perspective of culture, cross-culture can be understood as cultural identity; that is, the attribution and acceptance of a particular culture by cross-cultural groups or individuals is a culture that crosses the boundaries of different countries and nationalities and has its specific value orientation. Cross-cultural adaptation is a complicated process. At present, there are many cross-cultural interaction models put forward by academic circles, and the research focuses on many explicit influencing factors. However, most models seem to regard cultural adaptation as passive behavior and develop many more negative concepts. We know from the investigation and research that international students have a high rate of mental illness at this time. International students' cross-cultural misadjustment not only has a negative impact on their personal development, but also has a negative impact on the overall social development and causes some intercountry contradictions. Cross-culture is a social phenomenon that emerges in the course of human history's continuous evolution and is unavoidable. The rise in social mobility and the cohabitation of different ethnic groups are the primary causes of this phenomenon. The cross-cultural phenomenon will become increasingly obvious as the globalization era progresses. In the collision and integration of different cultures, the essence of this phenomenon is to change traditional and existing cultures and to create new cultures.

4. Cross-Cultural Interaction Model of International Students Based on Big Data Analysis

At present, self-awareness and ability of international students in China are the main factors that affect cross-cultural adaptation. It mainly includes the self-learning experience, personal experience, physical function of foreign students in China, and the self-coping ability of the external living environment changes. The cross-cultural interaction model based on big data is a descriptive model, which is based on the understanding of the changing characteristics of cross-cultural adaptation and psychological capital. The three adaptations explore the emotional, behavioral, and academic state of international students from different analytical frameworks, as shown in Figure 2.

People's adaptation implies that people may change the social environment. It is possible for people to change the social environment, but it is more likely for people to change when they only have group strength. The energy for the state can be defined as

$$\begin{aligned}\Delta w_{jk} &= \eta \delta_k^o y_j = \eta\left(d_k - o_k\right)\left(1 - o_k\right) o_k y_j,\\ \Delta v_{ij} &= \eta \delta_j^y x_i = \left(\sum_{k=1}^{l} \delta_k^o w_{jk}\right)\left(1 - y_j\right) y_j x_i.\end{aligned} \tag{1}$$

Deep mining data, using radial basis function:

$$\begin{aligned}p(x, y) &= \frac{\sum x_1 y_1 - n\overline{xy}}{(n-1) s_x s y}\\ &= \frac{n\sum x_1 y_1 - \sum x_1 \sum y_1}{\sqrt{n\sum {x_1}^2 - \left(\sum x_1\right)^2}\sqrt{n\sum {y_1}^2 - \left(\sum y_1\right)^2}}.\end{aligned} \tag{2}$$

By polynomial kernel function:

$$T(x, y) = \frac{x \bullet y}{\|x\|^2 \times \|y\|^2} = \frac{\sum x_1 y_1}{\sqrt{\sum {x_1}^2}\sqrt{\sum {y_1}^2}}. \tag{3}$$

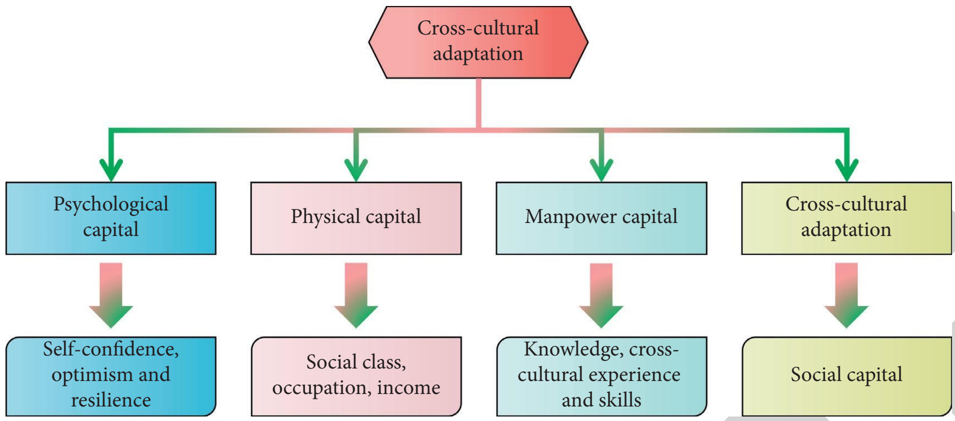

Figure 1: Influencing factors of cross-cultural adaptation.

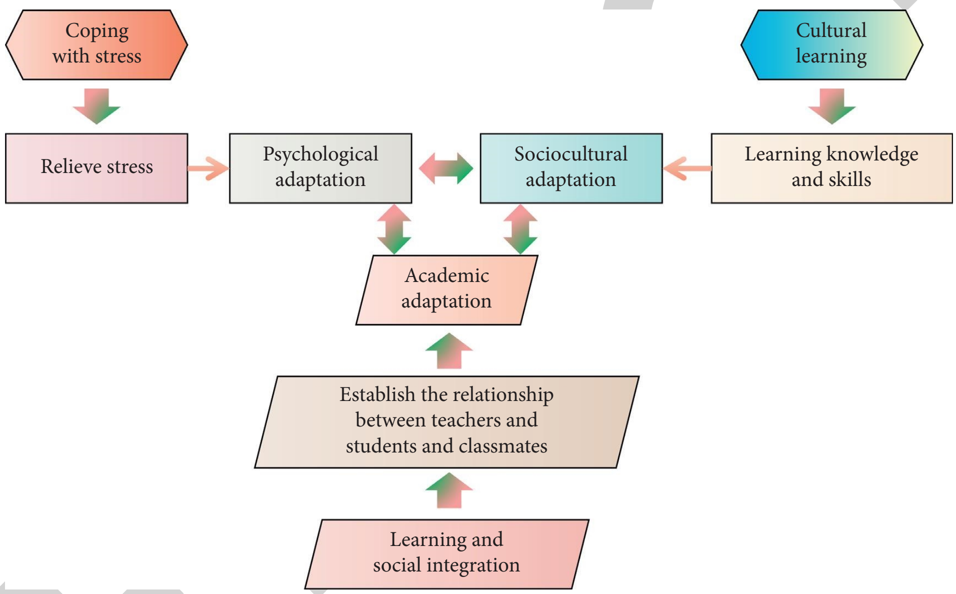

Figure 2: Structural model of students' cross-cultural adaptation.

When the parameters are fixed, it is simplified as follows:

$$d(x, y) = \sqrt{\left(\sum (x_1 - y_1)^2\right)}. \tag{4}$$

Positive psychological adaptation, from a cognitive standpoint, entails forming an objective and rational view of oneself and the host country group, as well as implementing integration strategies in cultural situation transformation. However, due to international students' limited residence time and the constraints of academic tasks, it is difficult to form an objective and rational viewpoint in a short period of time. For international students' cross-cultural adaptation, positive self-efficacy, an upbeat attitude, a sense of hope, and perseverance are essential factors. Conscious psychological capital exercises can help people better understand stress and increase their psychological resilience to it. The cross-cultural interaction model based on big data and psychological capital is shown in Figure 3.

The cognitive process is influenced not only by individual factors affecting international students, but also by the host society's overall attitude toward foreigners, i.e., openness and acceptance of foreigners. International students with a strong sense of hope will set attainable goals, plan specific and attainable paths to achieve those goals, dare to overcome obstacles, and carry out the plan, and it will be difficult to give up halfway due to external influences. As a result, a group intervention program tailored to international students can be designed to improve their hope quality and assist them in experiencing happiness while participating in cultural exchange. Because most international students in China are nondegree students with a short stay in China (more than half of the time spent in China by Wood Research Institute is less than a year), cognitive factors are not considered in the psychological adaptation results. It is critical for cross-cultural adaptation to cultivate international students' positive outlook on life and optimistic quality.

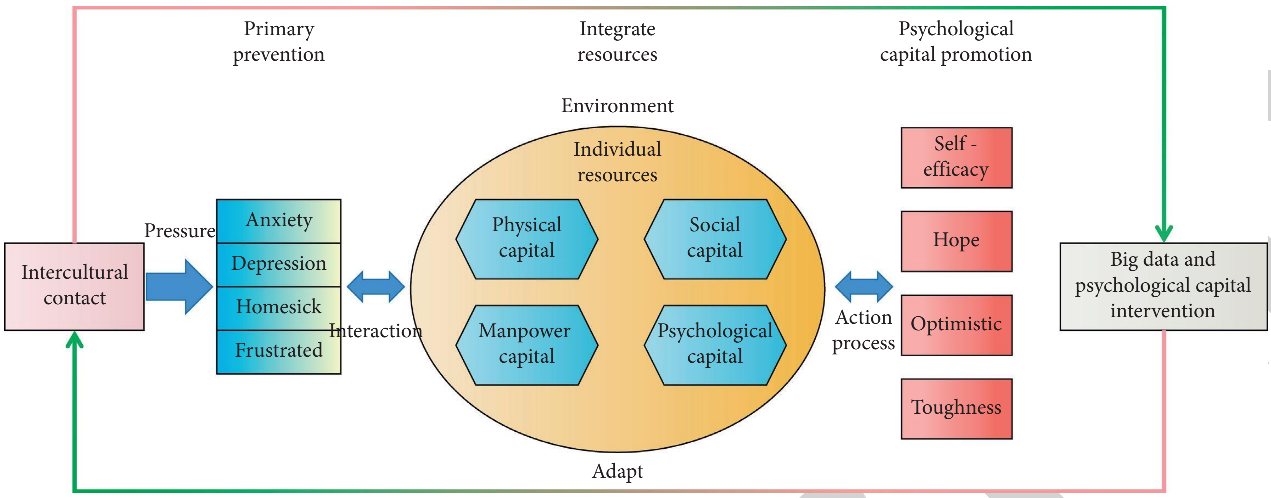

Figure 3: Cross-cultural interaction model.

Data preprocessing is a part of data mining in a broad sense. The data preprocessing work in this project is as follows. There are two relationships between the previous database fields: functional relationship and correlation relationship. An arbitrary n-dimensional to m-dimensional mapping can be accomplished with a three-layer neural network. The number of neurons in the hidden layer is $s = \sqrt{n + m} + a$, and n and m are the number of nodes in the input and output layers, respectively. The activation function of the neurons in the hidden layer is selected as the hyperbolic tangent function, and the function form is

$$f(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}. \tag{5}$$

The activation function of the output layer uses Sigmoid excitation function, which is in the form of

$$f(x) = \frac{1}{1 + e^{-x}}. \tag{6}$$

The induced local domain of a neuron J in the hidden layer is

$$v_j(p) = \sum_{i=1}^{n} w_{ij} x_i - \theta_j. \tag{7}$$

The induced local domain of a neuron K in the output layer is

$$v_k(p) = \sum_{j=1}^{s} w_{jk} v_j(p) - \theta_k, \tag{8}$$

where n and s are the number of neurons in the input layer and the hidden layer, respectively.

In practice, group counseling can be used to teach international students to form positive attribution styles, to use their own advantages to increase self-awareness, to enable international students to gain positive energy, and to use these forces to adapt to cross-cultural life, according to the explanatory style theory, expectation theory, and learned optimism theory. The self-identification of international students with Chinese traditional culture and their understanding of international cultural differences severely impedes their own development. In the process of self-cross-cultural adaptation, the material capital and social capital in the self-capital of foreign students in China have become an indispensable part of their self-growth. The mobilization of resilience mechanisms in the adaptation process will, to some extent, encourage international students in China to solve problems in the process of adaptation in a scientific and reasonable manner.

5. Result Analysis and Discussion

At present, a large number of experimental data prove that self-efficacy is closely related to external life situations. It is inevitable that foreign students in China will encounter some problems when they first come to China. At this time, the self-efficacy of foreign students in China begins to play a role. There are significant differences in the dimensions of daily life adaptation in three variables: gender, cross-cultural experience, and religious belief. It is more difficult for men who have cross-cultural adaptation and religious beliefs to adapt to daily culture, which shows that daily life adaptation is the most basic content for foreign students to contact with different cultures. Maybe men are less careful about trivial matters of daily life than women, and they are more likely to find it difficult to adapt to daily life. Cross-cultural experience also makes it easy for international students to constantly compare the differences of various cultures in the past, but it is even more difficult for them to let go to adapt to the new environment.

Specific intervention strategies to improve foreign students' self-efficacy include the following: during the actual enrollment process, the school should organize activities to help students better adapt to cross-cultural situations, so that foreign students in the class can continuously improve their self-efficacy while participating in activities, and provide them with a superior learning environment on campus. It is necessary to design role exchange activities between international students and Chinese students in the actual teaching activities, as well as to continue to increase the analysis of actual cases. We can effectively help international students fully experience the fun of learning by constantly stimulating their positive emotions and then comprehensively improving their actual survival and learning ability.

Hope is a positive psychological mechanism and a new field of positive psychology research that involves an individual's desire to achieve a specific goal. Hope influences not only an individual's life satisfaction, but also his or her coping style and ability to effectively overcome obstacles. In this way, hope affects an individual's difficult coping in a new cultural environment. Hope influences not only the degree of self-satisfaction of international students, but also their ability to overcome external challenges to some extent. We need to make mandatory intervention for foreign students who are having difficulties in China right away in order to effectively improve their self-efficacy and actual survival ability. International students with a strong sense of hope will set achievable goals, plan specific and feasible paths to achieve those goals, dare to overcome obstacles, and carry out the plan, and it is difficult to give up halfway due to external influences. Using this model to analyze various data of international students, we get the change curve of cultural novelty and social and cultural adaptation as shown in Figure 4. The curve of cultural novelty and depression is shown in Figure 5. The curve of psychological capital and social and cultural adaptation changes is shown in Figure 6.

As can be seen from the above figures, there is a significant positive correlation between cultural novelty and social and cultural adaptation. There is no significant correlation between cultural novelty and depression. Psychological capital is negatively correlated with social and cultural adaptation. The data analysis methods used in this study are mainly divided into qualitative data and quantitative data analysis methods. As far as the analytical perspective of qualitative research is concerned, on the one hand, this study emphasizes the interpretation perspective of data center and tries to abandon the unverified speculation held by itself, so as to prevent subjective and one-sided interpretation of interview materials. However, on the other hand, in order to ensure the breadth and depth of qualitative data analysis, it is necessary for researchers to obtain corresponding theoretical guidance on the methodology of data interpretation, which can not only make an overall description of the use of foreign students' cultural learning strategies, but also make a partial close-up of the influence and effectiveness of specific strategies. For the analysis of quantitative data, this study uses statistical software for processing. From the results of the study, we can see that cultural novelty sometimes has a positive relationship with cross-cultural adaptation, while sometimes it has a negative relationship. It shows that there is a variable that affects the direction and strength of the relationship between cultural novelty and cross-cultural adaptation. As far as this study is concerned, psychological capital can be considered as the moderating variable.

Education must provide multilevel learning tasks for international students, ranging from simple to complex, so

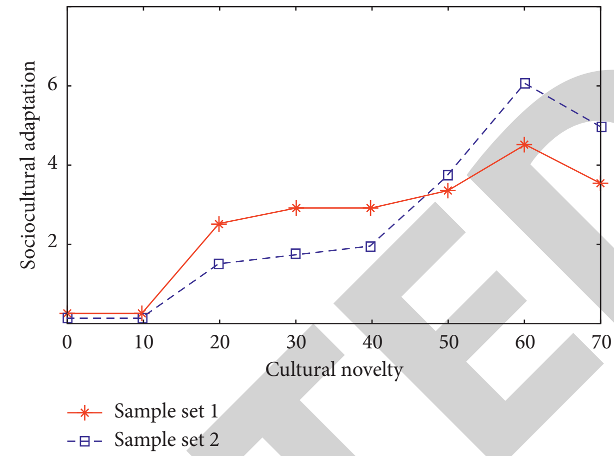

FIGURE 4: Changes of cultural novelty and social and cultural adaptation.

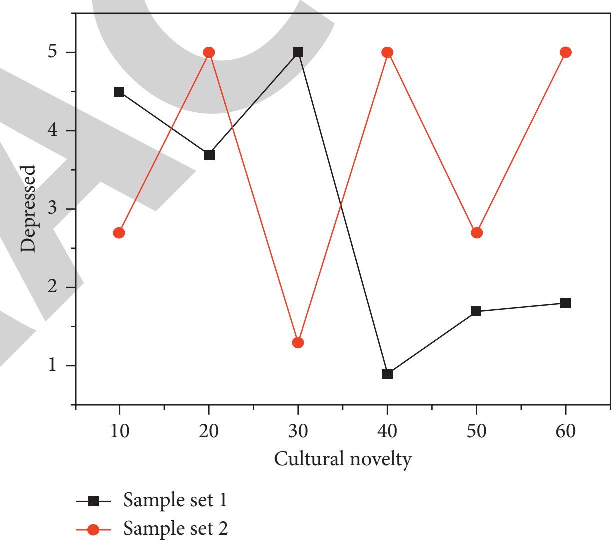

FIGURE 5: Cultural novelty and the result of depression change.

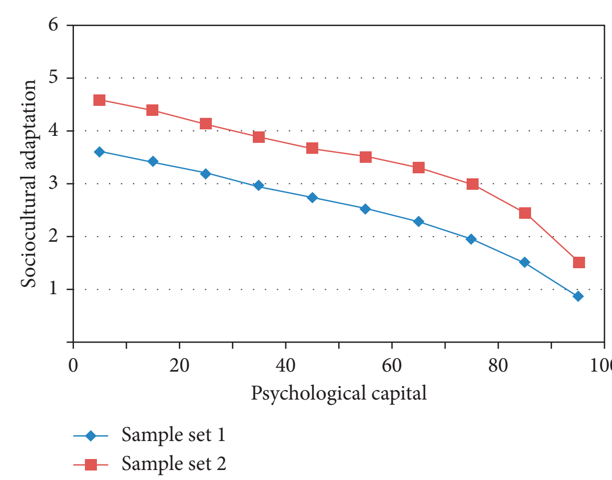

FIGURE 6: Psychological capital and social culture adapt to the changing results.

that students can continuously improve their ability to solve problems in a stable state, thereby fully stimulating international students' motivation and continuously improving related cultural adaptation functions. Individuals' sense of hope can be improved more effectively through group intervention, according to studies. As a result, a group intervention program tailored to international students can be developed to improve their hope quality and assist them in experiencing happiness through cultural exchange. It can specifically assist international students in setting short-term goals with small steps while also stimulating their path thinking and dynamic thinking, that is, increasing their cognitive belief in their ability to find the target path and increasing their motivation to move forward along the target path. This model is compared to an existing model to ensure that it performs as expected, as shown in Figure 7.

It can be seen that this method is faster than the existing methods in operation time and is superior to the existing methods on the whole. The method used in this paper is the principal component analysis of data. However, the first problem encountered in the process of data principal component analysis is how to analyze unknown types of data. Here, we use several numbers as dummy variables of the form. If there are only two categories of target data, such as gender data, we can simply set one category as 1 and the other categories as 0. However, some data items contain two or more variables. Therefore, using multiple dummy variables to analyze data is a solution, so it is necessary to build more variables with numbers to represent multiple data types. People with high self-efficacy handle things rationally and dare to accept challenges. Comparing this algorithm with other algorithms, the calculation error is shown in Figure 8.

It can be seen from Figure 8 that the other two algorithms have higher errors. On the whole, compared with the other two algorithms, this algorithm has smaller error and higher accuracy. The superiority of this method is further proved. The cultural distance perceived by graduate students is smaller, and the cultural distance perceived by foreign students with more friends is smaller. And the variables of age and length of stay in China are further found in back testing. The scores of cultural novelty of international students aged 18 are significantly higher than those of international students under 18; that is, they perceive that there is a small gap between the culture of the host country and that of the home country. It shows that, due to the increase of experience, the perception of cultural differences may be low. However, the international students who have been in China for the longest time have the smallest perceived cultural distance, reaching a statistically significant level. It can be seen that time is a factor that affects the cultural novelty of international students. With the familiarity with the environment, the strangeness of foreign students will gradually disappear. Exploratory factor analysis of the data, as a validity test, can also determine whether the strategy dimension divided by qualitative research can be supported in the data, and orthogonal rotation is carried out by principal component analysis and maximum variance rotation method.

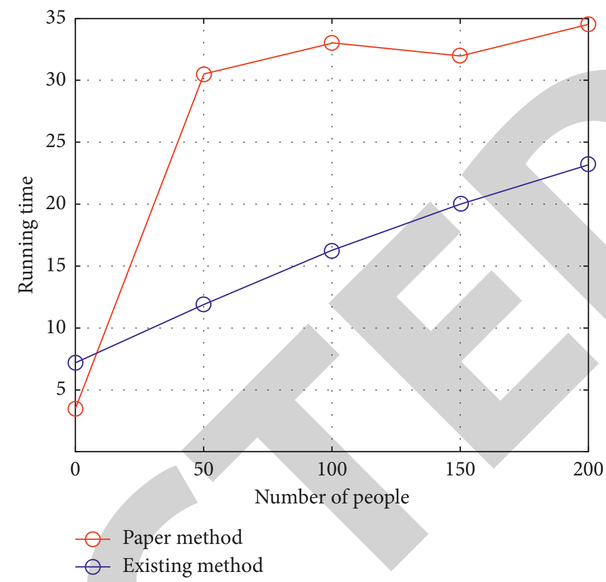

Figure 7: Comparison results of running time of two methods.

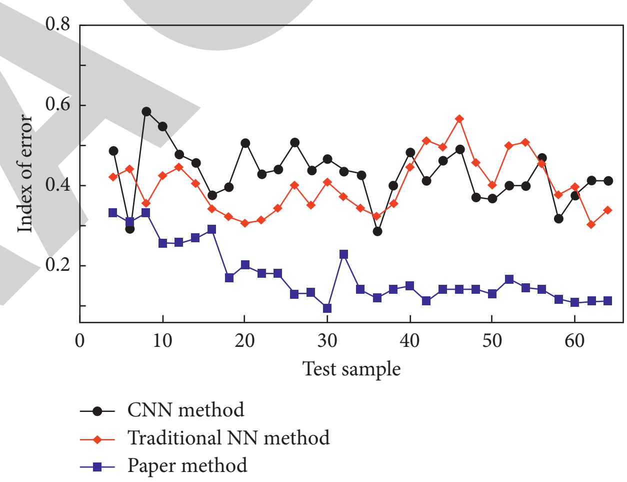

Figure 8: Comparison results of calculation errors of different methods.

A five-factor social and cultural adaptation scale can be obtained after exploratory factor analysis and confirmatory factor analysis. Cultural value adaptation, day-to-day life adaptation, pressure and risk adaptation, social interaction adaptation, and language skills are some of them. The validity and reliability of the data are both satisfactory. This paper uses a mixed research method to look at international students' cultural learning strategies in qualitative data and statistically explain how they are used in quantitative data. The mixed research method can not only broaden the types of data sources and increase the number of participants, but also investigate how foreign students in China use cultural strategies through various research paths, enhancing the credibility of the research findings.

6. Conclusions

This paper investigates the cross-cultural adaptation of international students in China at the individual level through a literature review, questionnaire survey, and statistical analysis that combines descriptive and inferential statistics. The main findings of the cross-cultural adaptation research of international students in China will be summarized on this basis, and effective strategies for optimizing international student management in colleges and universities will be discussed based on the findings and theories of this research. This paper investigates the impact of cultural novelty and psychological capital on cross-cultural adaptation and conducts data mining on international student data to develop a cross-cultural interaction model for international students, based on the characteristics of the research object. The state should refine the entrance examination standards for international students in China, improve the preparatory education system for international students in China, and improve the training mode for international students' education and management professionals, among other suggestions and countermeasures for cross-cultural adaptation guidance for international students in China. Colleges and universities in China should improve humanistic care and mental health education for international students, as well as innovate international student education and management methods. International students should focus on improving their personal willpower, continually strengthening their knowledge reserves and social practice abilities, gradually expanding their personal social circle, actively accepting Chinese culture, and striving to improve their Chinese learning and application ability.

Data Availability

The data used to support the findings of this study are included within the article.

In recent years, the cultural and creative industry has become an emerging industry that countries have vigorously supported and promoted in the new economic era. This article introduces the TRIZ innovation theory into the cultural and creative industry. As an innovative problem-solving theory, TRIZ has good practicability and operability. It seeks breakthroughs on the basis of original creative thinking and provides a scientific and efficient cultural creativity. Combining specific cases, analyze the innovative principles of TRIZ theory as the origin, stimulate creative methods that generate divergent thinking, aggregate thinking, and conversion thinking, and apply them to creative mechanisms and applications in cultural advertising creativity. The whole process is guided by rational principles to lead perceptual thinking, and concrete principles drive abstract imagination, exploring the source of thinking of the essence of cultural advertising creative design. This theory and its application mechanism have become a brand new thinking method and application attempt in the field of cultural advertising creativity.

1. Introduction

The term "cultural and creative industries" first appeared in the 1998 "British Creative Industries Path Document", emphasizing that individuals or teams use technology, creativity, and industrialization to develop, operate, and market industries with intellectual property rights. The main areas of this industry are computers, software, fashion design, advertising, architectural design, animation, music, radio, film and television, the Internet, mobile media, and so on. Our country also put forward the need to vigorously develop cultural and creative industries in the "Outline of the National Cultural Development Plan for the Eleventh Five-Year Plan Period" [1, 2]. At present, the main characteristics of the development of my country's cultural and creative industries are similar programs, products, and content, serious plagiarism in the industry, and insufficient innovation. The government proposed a change from "Made in China" to "Created in China". Since China's reform and opening up, developed countries such as the United States and Europe have taken advantage of intellectual property rights and brands to turn China into their manufacturing plants, paying cheap labor prices and earning high profits on their own, but they consume China's resources. Even at the cost of destroying the environment [3], China has become synonymous with "foundry". Chinese companies have insufficient R&D investment and very limited innovation capabilities. Although some companies have made considerable efforts, most of their products are plagiarism and follow suit. For example, Tencent is already a major Internet company, but the company's business philosophy still believes that "the ability to copy products must be regarded as the company's core competitiveness." Obviously, this society lacks an atmosphere and awareness of innovation. In the communications industry, it is very common for the United States to study Japan and Japan to study Korea. These phenomena are very common. Summarizing the development path of the "cultural and creative industries" in other developed countries, it is not difficult to find that the core of the healthy development of this industry is people, with emphasis on human creativity as the core factor. The information age emphasizes human wisdom, creativity, intellectual property rights, and human proactive factors. Only by giving full play to the active creative factors of people can we lead the development of society in the information age [4–7].

At present, the development of my country's cultural and creative industries can be roughly divided into three echelons. The order is the developed eastern region, the developing central region, and the underdeveloped western region. With the change of the international trend, all countries are actively turning their development vision to the cultural industry. This is an excellent opportunity to build a cultural China, enhance the influence of the world, and enhance the people's recognition of their own culture. China's major cities are also undergoing policy reform, industrial adjustment, and transformation.

The cultural creative industry is a collection of industries that commercialize cultural or natural and human resources with cultural factors through modern technology and creativity. The high-quality development of the cultural and creative industry is concentrated in catalyzing the creation of new business formats, cultivating new kinetic energy, and releasing new vitality, thereby enhancing the core competitiveness of the industry [8]. From the perspective of rapid economic growth to the high-quality stage, labor productivity and total factor productivity have achieved simultaneous increases, which will inevitably promote industrial quality changes, efficiency changes, and power changes. Compared with traditional industries, cultural and creative industries have certain cultural attributes, but also economic attributes such as high technological content, high degree of creativity, high added value, and high degree of integration. Therefore, promoting the high-quality development of cultural and creative industries has rich connotations [9].

The research on creative thinking has a long history, and the creative thinking methods involved are unknown. However, the existing creative thinking methods are more generalized and formalized and lack specific principles to generate creative origins. As an innovative problem-solving theory, TRIZ has good practicability and maneuverability. Try to combine the two, based on the TRIZ principle, seek a breakthrough on the basis of original creative thinking and provide a scientific and efficient cultural and creative industry integration technology. In addition, it provides an application basis for expanding the multifield development of TRIZ theory [10–14].

2. Creative Thinking Method

2.1. The Connotation of Creative Thinking Method. Creative thinking is the creative abstract summary and behavioral potential of the brain's essential attributes and internal connections of objective things. Creative thinking is specifically divided into divergent thinking, convergent thinking, and conversion thinking. Thinking method is the tool and means by which people realize the purpose of thinking through thinking activities. According to different scopes, it can be divided into general thinking methods, specific scientific common thinking methods, and different scientific unique thinking methods. The creative thinking method is a systematic thinking mode, which can be materialized mental activities and high-level expressions. It is a necessary ability to engage in creative thinking activities, and it is the basis of inspiration and behavioral navigation for the completion of creative design. The creative thinking method is constantly changing and evolving.

2.2. The Importance of Creative Thinking Methods. Creative thinking methods play an important role in the design of graphic advertising, enabling designers to give full play to their imagination and creativity, combining good design concepts and artistic skills, combining actual needs and integrating them into their works, thereby enhancing the meaning and communication value of graphic advertising design. Humanistic and artistic value: in the field of design, creative thinking methods are more important than design skills. Especially in today's era, computer software technology is widely used in the field of graphic design. First, the difference between design technologies has become smaller, and the second has prompted more people to chase and update software. The operation technique creates the so-called "designer" who has no ideas, creativity, and mechanical work. Print advertising design urgently needs scientific and creative thinking methods as theoretical guidance and applied to specific design practices. The creative thinking method is not to construct a perfect idealistic plan. Its value is to propose creative, clear, concise, efficient and operable best ideas for the work, thereby increasing the difference between the design and other works and avoiding uninspired ideas, the same while making the viewer experience fresh and intuitive [15].

3. Summary of TRIZ Theory

3.1. The Concept of TRIZ Theory. TRIZ is the abbreviation of English, and its meaning is the theory of solving invention problems. It originated in the Soviet Union. It was the Soviet Genrich Altshuller. After summing up tens of thousands of invention patents, he found that innovation is also regular. Follow his core ideas: first, he believes that no matter what product is a simple or complex system, his core technology must follow objective laws and models to gradually evolve and develop; second, he believes that the driving force for the development of things is due to the technology. Difficulties, conflicts, and contradictions are constantly being resolved; the third is to use as little resources and energy as possible to promote technological breakthroughs and development. The difference between TRIZ theory and traditional innovation methods is that it is a methodology, a summary of laws, and reveals the laws and methods of innovation [16, 17]. This theory has been proven to be correct. For example, the renewal of military systems, equipment, and products in the early Soviet Union was later used by famous companies in the United States, Japan, and other countries. It was discovered that TRIZ's method was used when innovating products. Able to effectively analyze the problem, find the bottleneck and crux of the problem, and quickly grasp the essential problem. It plays a very important role in helping R&D personnel research, break through the fixed thinking, adopt new thinking, summarize the law, and predict the future [18–20].

The most basic three theoretical bases are as follows: (1) in the process of solving problems, people will encounter many contradictions, and corresponding solutions to these contradictions will often appear; (2) there are few innovative ways to solve problems thoroughly, which researchers can learn and master; and (3) generally speaking, the most effective way to solve problems usually comes from some knowledge in other fields. After hundreds of years of development, TRIZ theory has been widely used all over the world.

3.2. The Relevance of TRIZ Theory and Cultural Creative Thinking. Through research, it is found that the research heat of TRIZ theory in innovation is rising. Up to now, TRIZ theory has been developed in many fields such as management science and social science. When people encounter problems that are difficult to solve, they can not only solve them with the knowledge of their own discipline but also use the knowledge of other disciplines to find some solutions in other fields. Therefore, the application of TRIZ theory to cultural and creative industry technology in this paper is consistent [21].

The TRIZ innovation principle is to use the principles and methods of scientific discovery to rationally analyze and thoroughly solve problems. It contains the common principles followed by human innovation and is the earliest, most basic, core, and most practical content of TRIZ theory. It is effective and easy to learn and master, as shown in Table 1.

3.3. TRIZ Innovation Principles and Traditional Creative Thinking Methods. Traditional creative thinking methods are divided into divergent thinking, convergent thinking, and conversion thinking. Divergent thinking is a thinking form in which the brain presents a multidimensional diffusion state. It is a thinking method to put forward abundant ideas and find various ways to solve specific problems from a thinking starting point and break away from traditional practices and create more possibilities. Convergent thinking refers to sublimating logical conclusions from existing representations and gathering broad thinking paths into a focus. It is a convergent thinking mode with scope, direction, and order. The transformation of thinking is to observe objects from different aspects and angles from the perspective of connection and development, to change a new perspective, to avoid stereotypical thinking, and then to get a comprehensive understanding of objects and perfect solutions.

In terms of suitability, logicality, and efficiency of combining TRIZ theory with traditional creative thinking methods, most of the existing creative thinking methods in the field of graphic design, their procedures, steps and measures are based on overcoming psychological barriers of creation to stimulate creative thinking. Its methods are highly abstract and generalized and tend to be formalized [22–24]. TRIZ reveals the inner laws and principles of creation. Compared with traditional creative thinking methods, it adopts scientific methods to boil down particularity problems into general problems of TRIZ and form solutions to problems. In terms of methods and processes of solving problems, TRIZ is faster, more accurate, and more efficient than traditional creative thinking methods. TRIZ is a controllable and effective method and powerful tool for generating innovative thinking from the original origin [25, 26].

Break the inertia, inertia and one-sidedness of thinking, and avoid the blindness and limitation of traditional creative process. TRIZ theory confirms that the basic principles of creativity exist objectively, and these principles can be sorted out and summarized into targeted design creativity theories, which can shorten the design creativity cycle and improve the success rate. To sum up, TRIZ can make up for the obvious deficiencies of the existing creative thinking methods, thus generating a more suitable creative method for design. The design lacks the guidance of innovation theory of rational dimension, while TRIZ can solve problems creatively in a scientific and rational way to achieve design innovation. In order to better grasp the entry point of TRIZ theory in creative thinking, it is necessary to define the TRIZ innovation principle and traditional creative thinking. Among them, TRIZ innovation principle focuses on analyzing the expression law of creative generation from microscopic angle. In contrast, traditional creative thinking focuses on the macro perspective to analyze the general rules of creativity in the process of operation. In the field of combining cultural and creative industries, in addition to the known traditional creative thinking methods, it is necessary to further explore the origin of thinking that can induce its generation. This topic tries to introduce TRIZ theory into the combined field of cultural and creative industry, focusing on the study of modern creative thinking methods based on TRIZ theory.

4. Advertising Culture Creative Industry Technology Based on TRIZ Theory

This article mainly introduces the combination principle, versatility principle, and reverse action principle of TRIZ innovation principle to stimulate divergent thinking, convergent thinking, and conversion thinking in traditional creative thinking and produce methods suitable for creative thinking in advertising. The whole process is guided by rational principles. Thinking, abstract imagination driven by concrete principles, seeks the origin of thinking of the essence of advertising creative design.

4.1. Methods of Using the Principle of Multifunctionality to Stimulate Divergent Thinking

(1) Principle of operation: The famous German philosopher Hegel once said that "creative thinking requires rich imagination". Divergent thinking is listed as the top creative thinking in design.

Table 1: 40 innovative principles of TRIZ theory.

Serial number	Principles of innovation	Specific description
1	Principle of segmentation	1. Divide the whole into independent small parts. 2. Divide the whole into parts that are easy to assemble and disassemble. 3. Improve the separability of the whole and realize the overall transformation
2	Combination principle	1. Spatial dimension, combining the same or similar objects. 2. Time dimension, combining the same or related operations
3	Principle of versatility	1. An object has multiple different functions. 2. Cut objects with unnecessary functions
4	Reverse action principle	1. Turn the object upside down or upside down. 2. Turn the object or the environment into motion and static motion.
...	...	...
40	Principles of composite materials	Replace homogeneous ingredients with composite ingredients

Figure 1: “One World” Figure.

Figure 2: “Symbiosis-building a green city with beautiful China”.

According to the multifunctional principle of TRIZ theory, the principle of using an object to have multiple different functions stimulates the emergence of divergent thinking. A subject has multiple interpretations and an object has multiple uses, which is an important manifestation of the principle of multifunctionality. At any time, place and environment, when objects are versatile, they can have more collaboration and value-added effects.

(2) Application examples: using TRIZ's multifunction principle of "one question with multiple solutions" and "one thing with multiple uses" triggers divergent thinking and produces print advertising creativity. In the creation of the series of print advertisements "One World" shown in Figure 1. The main image is not only the biological representatives of the ocean, land, and sky but also the continents of the world. It not only expresses the biological image but also symbolizes that we live in the same world. The peace and beauty of the world are the theme of our common home. One type of graphic represents multiple content, and the ultimate goal is to express more levels of meaning and connotation. Guided by the same principle, in the creation of the "Symbiosis" theme print advertisement design, as shown in Figure 2. The content of the promotion is to call for environmental protection. The hourglass is used as the main image to convey, indicating that as time passes, glaciers melt, sea level rises, and other issues. Although the current degree is not large, people's real life changes are not easy to detect, but as the time continues to accumulate small problems, they will eventually cause huge problems. The problem, the end point is determined to be a devastating burying of our living environment. The images arouse viewers' deep thoughts. We need to immediately cutoff the problem and pay attention to protecting the environment, otherwise the good life will slowly disappear. The hourglass is treated in a multifunctional way, and its image expresses the double standard of material and time. With the existence of problems and the aggravation of time, small problems will eventually become catastrophic catastrophes.

(3) Summary of experience: The design ideas that have never appeared in the creativity are minimal. The elements that everyone knows are superimposed and synthesized to produce a new image, and then express rich meanings, and they are superior in skills.

Creativity is by no means blindly pursuing the absurd or uncanny. Creativity that comes from the simple elements of life is often the most touching. Using divergent thinking to discover creative points from every bit of life is a corner that is easily overlooked in the creative thinking process. Ensuring the quality of divergent thinking is the basic guarantee for the apparent accumulation of daily knowledge and experience.

4.2. Methods of Using the Principle of Combination to Stimulate Convergent Thinking

(1) Operation principle: The combination principle of TRIZ is to combine the same objects in space or time or objects that complete similar operations. The deconstruction and reorganization of design elements and the introduction of new colors, new textures and new materials into old objects are all important means of the operation of the combination principle, and then the combination principle leads to the aggregation thinking. Such as the complete image split into a single visual elements and repeated distribution in the picture, using the same or similar approach to "processing" one by one, so that the main body repeated and set a certain order, adjust the size of specifications or color texture, the final effect is often able to produce creative and highly visual impact.

(2) Application example: Create print advertising works that promote traditional Chinese folk culture, as shown in Figure 3. First of all, it is planned to use the allusive but well-known positive vocabulary "Hundred Flowers" as the theme to describe culture or literature and use flower patterns as design elements to reorganize the main body in an orderly manner with changes in size, direction, and location. Second, the same noumenon elements are "processed", and the visual element floral cloth representing traditional folk culture is selected to adjust the color and texture of the main body. The shape of blooming flowers and traditional calico patterns imply the beautiful blooming of traditional Chinese folk culture. The finished effect image is full, the meaning is clear, and the visual impact is strong. Figure 4 shows the work "This Cycle," an advertisement for the protection of water resources, which uses clean water droplets and polluted water droplets. After changes in size, color, and texture, they are reorganized in order to form the image of Tai Chi. Tai Chi expresses the process of transformation of all things, and its ultimate goal is to hope that human activities conform to the great virtues and the laws of nature. The emphasis on design elements is gradual, the black and gray water pollution expands, and the blue clean water source decreases. With strong visual contrast, people are called to pay attention to the water cycle, stop water pollution, and keep water clean.

(3) Summary of experience: Convergent thinking uses the TRIZ combination principle as the creative origin in the creative thinking method of print advertising and re-deconstructs and reorganizes the same object into a new image by completing similar operations. Divergent thinking takes the TRIZ multifunctional principle as the origin of creativity and uses the principle of using one object to perform multiple different functions to stimulate new ideas. Convergent thinking and divergent thinking are the

Figure 3: “A Hundred Flowers” theme of traditional Chinese folk culture.

Figure 4: “So Circulation” to protect water resources and public welfare.

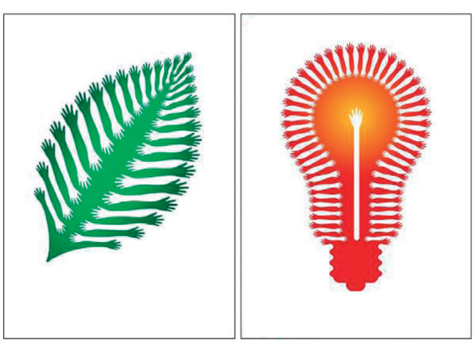

Figure 5: “Request and Rescue” “Utilization and Conservation” energy conservation and environmental protection theme.

Figure 6: Animal protection theme poster.

opposite of the thinking path. These two ways of thinking make a dialectical combination of the expansion and convergence of the creative thinking of print advertising.

4.3. Methods of Using the opposite Principle to Stimulate Conversion Thinking

(1) Operation principle: The opposite principle is a different conventional way to solve the problem and the way of thinking. The application of the opposite principle is to stimulate the transformation of the method of thinking, and the poster design is often simple and powerful, but also can lead viewers into deep thinking. Specific principles include (1) attribute conversion: swap objects with opposite attributes to produce a new image, such as size, speed, and weight; (2) positional and structural transformation: things are arranged in places where they should not appear to change the normal structure of things; (3) process transformation: reverse the natural law of development of things; and (4) theoretical transformation: convey profound meaning and arouse the audience’s resonance and reflection.

(2) Application example: The method of transforming thinking is generated through the opposite principle of TRIZ. The application in the design of graphic advertising can use the principle of the relationship between the positive and negative forms of the main image to cleverly connect the bottom of the picture to complete the composition. This achieves the balance between the visual and psychological spaces of the viewer. Using the same picture to complete the conversion of thinking is not only a conversion of visual thinking but also a conversion of abstract thinking, so that the viewer can get a complete interactive experience and comprehensive cognition. Use the opposite operation path to stimulate the transformation of thinking and create energy-saving and environmentally friendly posters. Take the works “Request and Rescue” and “Utilization and Saving” as examples, as shown in Figure 5, the author cleverly uses the opposite principle and uses the positive and negative patterns of the basic styling elements to convey the theme of the poster. The positive and negative patterns are interdependent and complement to each other. At the same time, it expresses the concepts of claiming, using and saving, and saving. The poster “Extinction” is shown in Figure 6. Using the same method, superimpose the shape of the hand and the pattern of endangered animals. The two sets of different works achieve the same effect, which first activates the viewer’s visual interest, and then promotes the viewer’s deep reflection.

(3) Summary of experience: The most extreme way of thinking in conversion thinking is reverse thinking, that is, thinking about problems from a completely opposite perspective. In the creative thinking of print

advertising, we must dare to go the other way and carry out in-depth exploration of the problem in the opposite direction, which can generate new ideas. Reverse thinking can overcome the solidified deadlock of fixed thinking and inertial thinking.

5. Conclusion

In recent years, the cultural and creative industry has become an emerging industry that countries have vigorously supported and promoted in the new economic era. This article introduces the TRIZ innovation theory into the cultural and creative industry, combined with specific cases, analyzes the creative methods of TRIZ theoretical innovation principles as the origin, stimulates the generation of divergent thinking, convergent thinking, and conversion thinking, and applies it to the creative mechanism and creativity in cultural advertising application. The whole process is guided by rational principles to lead perceptual thinking, and concrete principles drive abstract imagination, exploring the source of thinking of the essence of cultural advertising creative design. This theory and its application mechanism have become a brand new thinking method and application attempt in the field of cultural advertising creativity. Logical analysis verifies the feasibility of combining TRIZ theory with creative thinking. The article mainly introduces TRIZ's combination principle, versatility principle, reverse action principle and divergent thinking, aggregate thinking, and conversion thinking combination mode. The use of thinking in a large number of design practices may not be a simple one-way combination, but may appear in a complex and intersecting form. Therefore, there are still a lot of research vacancies in this topic. In the follow-up research, it should include a large amount of content such as the combination of TRIZ's innovation principle and thinking method and the choice of combination. This article introduces the TRIZ theory into the related fields of advertising creative thinking methods, only to provide a new research field and direction for the future.

As a "content industry" that reflects the national culture of a country, the development of the cultural innovation industry reflects the strength of a country's comprehensive national strength to a certain extent. The emergence of artificial intelligence, a new technology with trans-era significance, has changed the product content form, dissemination form, and consumption mode of the cultural innovation industry. With the continuous development and innovation of artificial intelligence technology, the cultural innovation industry is facing major changes. Therefore, we should constantly explore ways to realize the in-depth integration of artificial intelligence and culture, so that my country's excellent cultural industry can truly integrate into people's lives with the help of intelligent technology, so as to meet the spiritual and cultural needs of the public.

Community safety has become an important part of social public safety. The construction of a safe community focuses on the accumulation of community safety capabilities. This paper discusses the application of big data technology in community safety construction and the improvement of community safety promotion capabilities. We analyzed the sources and collection methods of community data, classified multisource heterogeneous community data, and constructed seven types of community data. We designed the conceptual structure and storage structure of the community database. On the basis of the construction of the community database, the architecture design of the big data platform for community security was launched. From the perspective of different user types, the functional requirements of the big data platform were analyzed. Combined with demand analysis, the overall architecture design of the community big data platform was carried out. On the basis of the overall architecture, the application architecture and technical architecture were designed in more detail, and the key technologies of the community big data platform were analyzed. Finally, it analyzes how to use the community big data platform to predict public security risks by constructing a CART regression tree model.

1. Introduction

For a long time, the changes in the natural environment and the destruction of man-made factors have intensified the deterioration of the ecological environment in western China, and the contradiction between the environment and development has become increasingly prominent [1]. To protect the ecological environment, while improving the production and living conditions of farmers and herdsmen in the region, starting in the 1990s, with vigorous promotion by the government, the ecological immigration project has been implemented on a large scale in western China [2]. The implementation of ecological migration has played a certain role in improving the local ecological environment and promoting regional economic development. However, for those farmers and herdsmen who voluntarily relocated or were forced, they were faced with both opportunities and challenges. In the process of constructing an immigrant community, there is always some dissatisfaction. At present, safety issues were the most important in the ecological immigrant community [3]. This article will discuss how to improve the safety management of the community and realize the goal of intelligent community management in combination with big data technology.

Yoko Shiraishi of Ritsumeikan University in Japan studied the safety of the elderly under the safe community movement [4]. After analyzing the data of six international safe communities in Japan, she found that the safe community movement has effectively improved community safety. The number of falls and other types of dangerous events has been reduced, which ultimately improves the quality of life of the elderly [5]. Cecilia studied the factors that promoted the sustainability of safe community projects. They believe that safety promotion is different from injury prevention that focuses on technical solutions. Safety promotion tries to influence people's attitudes; to better carry out the sustainable development of safe communities, information exchange is a necessary factor. The safe community needs to provide information to decision-makers, residents, and staff on a regular basis in order to incorporate the safety plan into their daily work; and the cooperation between the safe community and the media is an area that can be improved in the future [6]. Nordqvist et al. established a control group in the communities where safety interventions were carried out and ordinary communities and assessed the safety risk status of children in the two types of communities. The results showed that the risk of injury to children in communities that took safety interventions was significantly lower than that in the control group [6]. Chen and Adefila proposed a higher education participation model for "effective disaster prevention and mitigation education." Research shows the positive impact of college students participating in community "effective disaster prevention and mitigation education" through field trips and internships. In their analysis, they concluded that incorporating "effective disaster prevention and mitigation education" into higher education is beneficial to the community and students. Local higher education institutions should cooperate with local communities to maintain an impact on the sustainable development of society [7]. Barbosa et al. researched and tested and used a data service platform with complex authentication, authorization, logging, and auditing mechanisms. This platform is used to achieve safety assistance and comprehensive care for the elderly in the community. This is to establish a support service platform and a complex safety mechanism that effectively combines the safety management of the elderly in the community, but at the same time, it is also found that the platform still has potential for development in terms of data collection [8].

Today, the world has ushered in the era of "big data." Big data related technologies have become more mature and have been used in many fields. Many scholars study the application of big data in the field of public safety. Scholars design big data platforms, combine and mine urban big data, and then discover new ideas for social public safety governance. The society is also aware of the importance of big data to social development, and the government actively promotes the application and development of big data in various fields [9]. In summary, there are few studies on the application of big data platforms to the construction of community safety. Community security has become the foundation of social security, and big data is also playing an important role in more and more fields, and big data still has a lot of room for development. Therefore, the combination of big data and community security emergency management will be the focus of future research and trends.

2. Construction of Community Management Database

There are many types of data in the community, and there are also many data sources. The first step in establishing a community database is to collect community data, and the basis of collecting community data is to clarify the source of the data and what different types of community data can be collected from these sources. This section will analyze the source of community data.

2.1. Management Department and Organization Data System. The government departments that construct and manage the community have basic information and data in the community, including the basic information of community residents, infrastructure information in the community, construction information, greening information, and so on. The community information data of government departments is the most basic data of the community [10]. Although these data have a certain amount of data and involve many types of data, the content of the data is not detailed, and there is also the problem of timely data updating. The data system of the community property contains the basic information of the owner, the house information, and the information of the cleaning personnel, maintenance personnel, security personnel, and other staff in the community.

The community data in the community construction and management department data system can be used as the basic data of the community big data platform database. Starting from the needs of the platform, these basic data are filtered, cleaned, and stored. However, there are barriers to data sharing with management departments. The construction of community big data platforms must actively cooperate with multiple management organizations to seek data sharing and break the barriers between community data systems [11].

2.2. Equipment Collection Data. Detection and monitoring equipment installed in modern communities collect real-time data on changes in the community. The detection and monitoring equipment can collect the data of the infrastructure equipment in the community, the data of the community residents, the community environment data, and so on, with multiple data types, rich data structures, and the characteristics of real-time data update. The data collected by community detection equipment is an important source of real-time data in the community database. There are mainly the following forms of equipment collection data in the community:

2.2.1. Sensing Detection Equipment. Various sensing devices such as temperature sensors, infrared sensors, and water immersion sensors installed in the community collect dynamic data on the environment, infrastructure, and residents in the community [12]. The data collected by the detection equipment in the community has the characteristics of timely update, and the data reflects the real-time status of the detection object. The data collected by the detection equipment is a powerful support for the daily management of the community, the prediction and prevention of safety accidents, and the emergency decision-making of emergencies.

2.2.2. Video Surveillance Equipment. Video surveillance equipment collects dynamic video, image, and audio data of the movement of people in the community in real time. Face recognition camera collects facial image information of people entering and leaving the community. 3D oblique photography technology collects building house information and outputs 3D video data of community houses after modeling. The community data collected by video monitoring equipment is mainly semistructured and unstructured data. The data is visualized and more intuitive, and it can also realize real-time data collection.

2.2.3. Modern Technology Equipment Such as Drones and Robots. Modern drone technology combines detection equipment and video monitoring equipment to collect data in the community and combines the types and characteristics of data collected by the two types of equipment [13]. Robots patrol the community, collect road information, real-time information on the flow of people, and so on. The community information collected by modern technology equipment can be combined with the characteristics of data collected by multiple devices, including multiple data structures and data types.

2.3. Personnel Collecting Data. The data information collected manually by the community grid members supplement the data that the equipment cannot collect. There are more types of data collected manually, and the data is more detailed. Manual collection has great flexibility. It can check the conditions of equipment, buildings, and environment, communicate with residents, and collect unstructured text information in the community. Manually collected data is an important source of multisource heterogeneous data in community databases.

2.4. Community Safe Data Network. Store the previously data collected in seven types of databases. Data entities in different types of databases are closely linked. Start with a community entity as the center, connect with other data entities, and radiate to the surroundings in a "radiation type." Each data entity can be used as a center to connect other data entities with a radial model [14]. After continuous connection, the data in the community database will eventually form a community data network that is connected as a whole. Figure 1 shows a schematic diagram of the community data network, with residents of a certain community as the center, forming a part of the community data network. The figure shows an example of the data in the local community data network. The data takes people as the main unit and is expressed in a tree-like structure, which is then associated with related items, fire-fighting facilities, and so on.

The community data network makes the community data a whole. The data entity can be described from different angles. For example, the residents of a certain community can be the owner of a house, the owner of a vehicle, the owner of a pet, and the object collected by video information. Establish a "community data cube," that is, "multidimensional" data. Each data is related to different data from multiple angles. In practical applications, according to the type of accidents concerned, take a certain community data as the center, and extract the data related to the accident from the multidimensional associated data [15]. For example, in case of a fire in a household, taking the community resident data as the center, select the associated house data, family data, neighbor data, fire equipment data, sensor data, and so on, and extract and process these fire related data from the community data network, which is conducive to further data analysis and processing.

2.5. Design of Community Safety Database Structure. Community data comes from objective entities that exist in the community, and the community database is a collection of community data. The community database is essentially a study of objective entities in the community and reflects the existing connections between entities. However, the physical forms that exist in reality cannot directly enter the computer. They must be abstracted into data and stored in the computer before they can be recognized, analyzed, and processed by the computer. Conceptual structure design is the process of abstracting real entities into conceptual models [16]. The entity-relationship model (i.e. E-R model) is one of the most commonly used modeling methods for database conceptual models. This section will use the E-R model method to design the conceptual structure of the community database. The main components of the E-R model are entities, attributes, and connections. The specific representation methods are as follows.

(1) The entity is represented by a rectangle, and the entity name is inside the rectangle.

(2) The attribute is represented by an ellipse, and the attribute name is inside the elliptical box, and it is connected to the entity with an undirected edge.

(3) The connection between entities is represented by a diamond, and the connection name is inside the diamond box. The connected entities are connected by an undirected line, and the connection type is indicated on the undirected line. There are three types of contact, one-to-one contact (1:1), one-to-many contact (1:n), and many-to-many contact (m: n).

Taking a fire accident in a house in the community as an example, a fire accident occurs in a house. Multiple residents can live in this house. Multiple firefighting and first-aid equipment are used to participate in fire rescue work. The fire accident will have a harmful impact on residents. Part of the data conceptual model design of the community fire accident is shown in Figure 2. The E-R model diagram shows the conceptual structure and logical relationship of some data.

2.6. The Design of the Storage Structure of the Community Security Database. The community database is a relational database, and there is a logical connection between entity data. Design the data storage structure on the basis of the

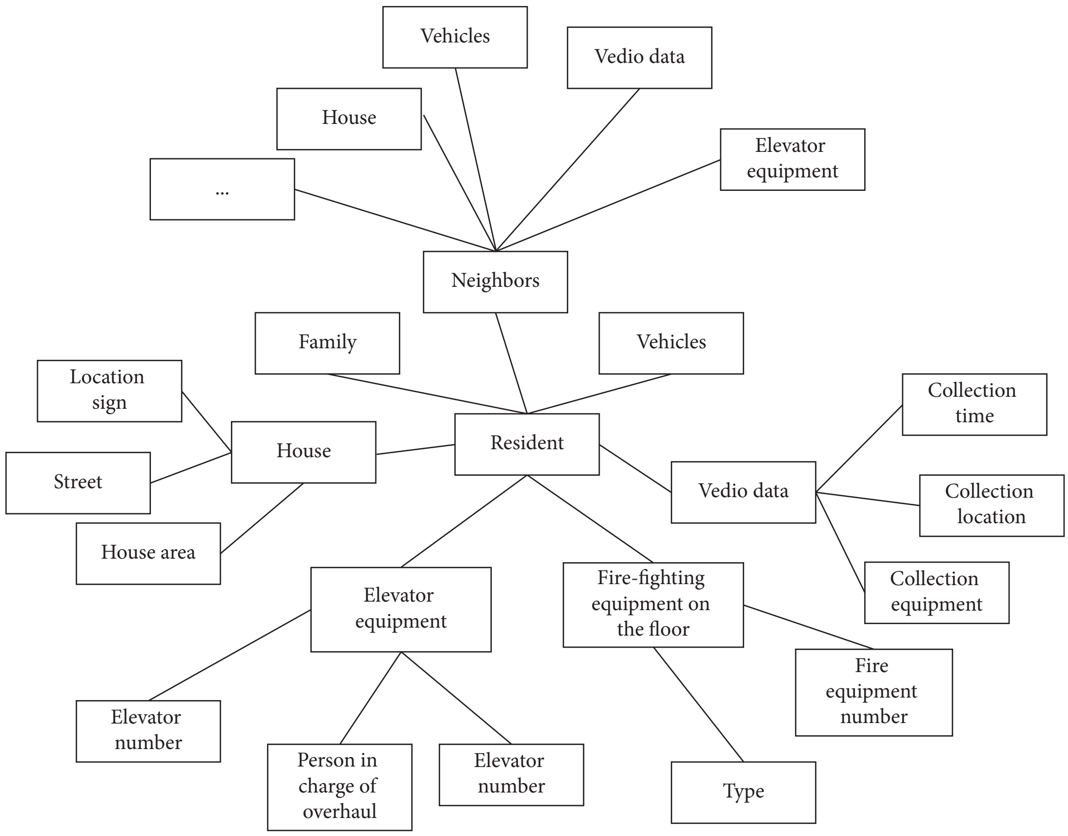

Figure 1: An example of a local community data network.

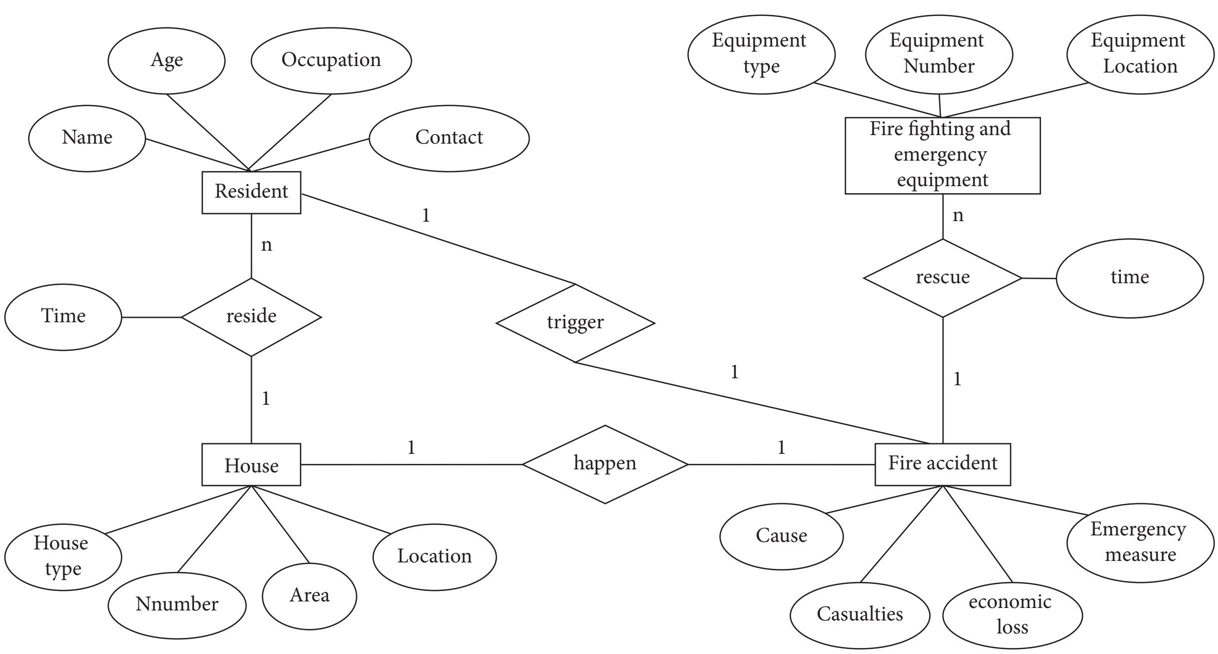

Figure 2: Community fire accident E-R diagram.

data conceptual structure model. Each community entity has a unique code that can identify it in the storage of the database. This code is the entity's identification attribute, such as resident code, house number, equipment number, and vehicle number. Establish the layer table, class table, and detailed attribute table of the community database [17].

The layer table corresponds to seven types of information at the database level, including the entity code, entity name, level information, level code, and other content of the level. The class table corresponds to this class code, entity code, and entity name. The detailed attribute table corresponds to the entity code, entity name, and attribute data of the entity. Take population data in the community as an example. The population data layer table contains the population data layer code. The three types of entity codes are permanent population code, temporary resident population code, and staff code; the permanent population category table contains permanent population code and permanent residents code, permanent resident name, and so on; the detailed attribute table of a resident contains detailed attribute information data, such as resident code, name, occupation, and contact information.

On the basis of the conceptual structure model of the database, the data are connected by a logical relationship. In the stored data table, the tables of each database layer establish a connection. The category code in the layer table is the same as the category code in the category table, and the category code in the category table is the same as the category code in the detailed attribute table, so that the layer table, the category table, and the detailed attribute table can be linked together. Through these connections, the query language of the database can be used to query and call relational data. The level definition of the data table is clear and simple. Different types of tables are connected by code relationships, and the connection path is concise, which improves the processing efficiency of query and call. Take the analysis of accidents in the community as an example. Data entities such as population data, building data, and infrastructure equipment data are all logically connected to the accident. Each entity level table, entity class table, and entity detailed attribute table are connected through entity codes to achieve multilevel data analysis and description of community accidents.

3. Community Big Data Platform Architecture Design

This part develops the architecture design of a community big data platform for community security. The community big data platform is built to realize the functions of community safety management, community risk analysis, and equipment and facility safety monitoring. The construction of the community big data platform facilitates the lives of community residents and the work of community managers, improves community safety capabilities, and reduces community safety risks. Starting from big data, modern technologies such as modern big data mining are used to build smart and safe communities. This part conducts research and analysis from requirements analysis, platform architecture design, and key technologies used.

3.1. Demand Analysis. This article divides the user types of the community big data platform into two categories, including general community residents and community manager users. Demand analysis is carried out separately according to user types.

Community residents' demands on the platform are mainly divided into the following points.

(1) *Basic Data Acquisition.* Residents can obtain public basic information through the data platform. Residents obtain public basic information through the output of the data platform, such as the safe operation and maintenance of infrastructure equipment; video surveillance in public areas; environmental conditions in the community; location and quantity of firefighting equipment. By obtaining this information, residents can master the daily safety situation of the community and quickly make favorable countermeasures in case of emergencies.

(2) *Receive Community Safety Notices.* The big data platform carries out risk analysis and risk assessment on the community through data analysis and mining. Community safety information is sent to residents through the platform. Residents understand community risks and learn safety knowledge through the platform. By receiving safety information, accidents can be effectively prevented.

(3) *Provide Hazard Information.* Residents who find dangerous situations in the community can reflect the situation to the data platform at the first time.

Community safety management is an important part of the management of community managers. Community managers have community safety management needs for the data platform. The main requirements are as follows.

(1) *Community Daily Safety Management.* Community managers obtain community facilities and equipment data, resident data, environmental data, monitoring data, sensor acquisition data, and so on through the platform to carry out daily safety management.

(2) *Community Risk Analysis.* The data platform carries out risk analysis and risk assessment on the community. Knowing the risks existing in the community, managers can timely investigate and manage the community risks, avoid accidents, and improve the safety level of the community.

(3) *Community Data Monitoring.* Through the data collected by sensing detection equipment and video monitoring equipment in the community, the manager can carry out daily monitoring on the facilities and equipment, buildings, and community environment in the community and track and monitor the suspicious people flowing in the community.

(4) *Community Emergency Management.* When an emergency occurs in the community, the manager uses the data platform for emergency management and takes emergency measures for the accident.

(5) *Analysis and Handling of Community Accidents.* After the occurrence of community accidents, process and analyze the accident data, absorb the accident experience, and improve the safety management level and accident emergency level.

3.2. Platform Architecture Design. Using the relevant technologies of big data, build a big data system for community safety, sort out and integrate the community data collected from multiple sources, and design the overall architecture of the community big data platform in this paper in combination with the functional requirements and technical elements of users for the community big data platform. Under the background of big data technology, from the perspective of users, facing community security, real-time processing community structured, semistructured, and unstructured data, so as to realize the data technology intelligence of community security management.

The community big data platform is generally divided into the following parts: data input layer, data storage layer, data processing layer, application access layer, and data output layer. The overall architecture is shown in Figure 3.

For community data collected from different sources, the platform extracts, transforms, and loads the data through ETL technology. After preprocessing the multisource heterogeneous data, the data is stored according to different categories. Hadoop system is used to analyze and process different types of data. According to the functional requirements of platform users, the community data is comprehensively and intelligently analyzed. The results of data analysis can be visually output by means of emergency management platform and mobile terminal.

3.3. Technical Architecture. The technical architecture of the big data platform is divided into five layers:

(1) *Data Collection Layer.* The data collected by various collection methods in the community are processed and imported through ETL technology.

(2) *Distributed Storage Computing Layer.* This layer mainly uses HDFS and other technologies for distributed storage of data, MapReduce, and hive and for distributed calculation and analysis of data, and zookeeper technology for distributed cooperation.

(3) *Interface Layer.* FTP, web service, R language interface, and other technologies will provide interfaces for data transmission.

(4) *Business Application Layer.* This layer will realize the main functional applications of the community big data platform, such as data query, data fusion, data analysis, data matching, and risk analysis.

(5) *Access Layer.* The data platform provides users with visual data output through different terminals, such as mobile terminal, web browsing, community integrated management platform, and so on.

3.4. Data Preprocessing. The multisource heterogeneous data collected by the community through various technical methods shall be preprocessed through ETL technology, such as data extraction, processing, conversion and loading, and the preprocessed data shall reach the data storage and computing layer. The ETL technical workflow is shown in Figure 4. After the system data is integrated with the collected data, data extraction and data cleaning are completed to obtain verification data. Datasets for different purposes are then stored in different locations after matching the dataset to the task.

3.4.1. Data Extraction. The first step of collecting community data is to extract data. The data extraction shall comprehensively determine the extraction rules by considering the data extraction frequency, data update frequency, and other contents based on meeting the needs of users. The data extraction of community data platform shall meet the extraction requirements of structured data, semistructured data, and unstructured data. The frequency of data extraction shall meet the actual needs of real-time updating of community data. The extraction method should include full extraction, incremental extraction, and so on.

3.4.2. Data Cleaning and Processing. The data extracted from different sources will also have problems such as data storage format, data integrity, classification, and import of data types, so it is necessary to carry out subsequent cleaning, conversion, and processing of the data.

Community database is a relational database, and community data has the characteristics of multisource and heterogeneous. Combined with the actual needs of the data platform, the data can be processed in two ways. There are structured community data in the management department data system. This kind of structured data can be processed by SQL statements. This method can be used to convert and process structured data clearly and efficiently. For semistructured and unstructured data, SQL cannot be processed. It needs to be processed in ETL engine to realize data type conversion, data cleaning, data matching query, and so on, according to functional and storage requirements and certain conversion rules.

In addition, due to the different data formats of different data, in order to keep the subsequent data interfaces consistent, the data needs to be aligned. The specific method is to keep different types of data in the same data type and use the long integer format for data storage.

3.4.3. Data Loading. Loading the extracted, cleaned, transformed, and processed community data into the storage computing layer is the last step of community data preprocessing. The formulation of data loading scheme needs to consider the loading efficiency on the basis of meeting the functional application needs of community platform users. Considering a large amount of historical data and real-time dynamic data collected by the community, the community data platform should realize batch data loading. A large amount of data should be loaded into different databases at the same time, and manual loading is supported.

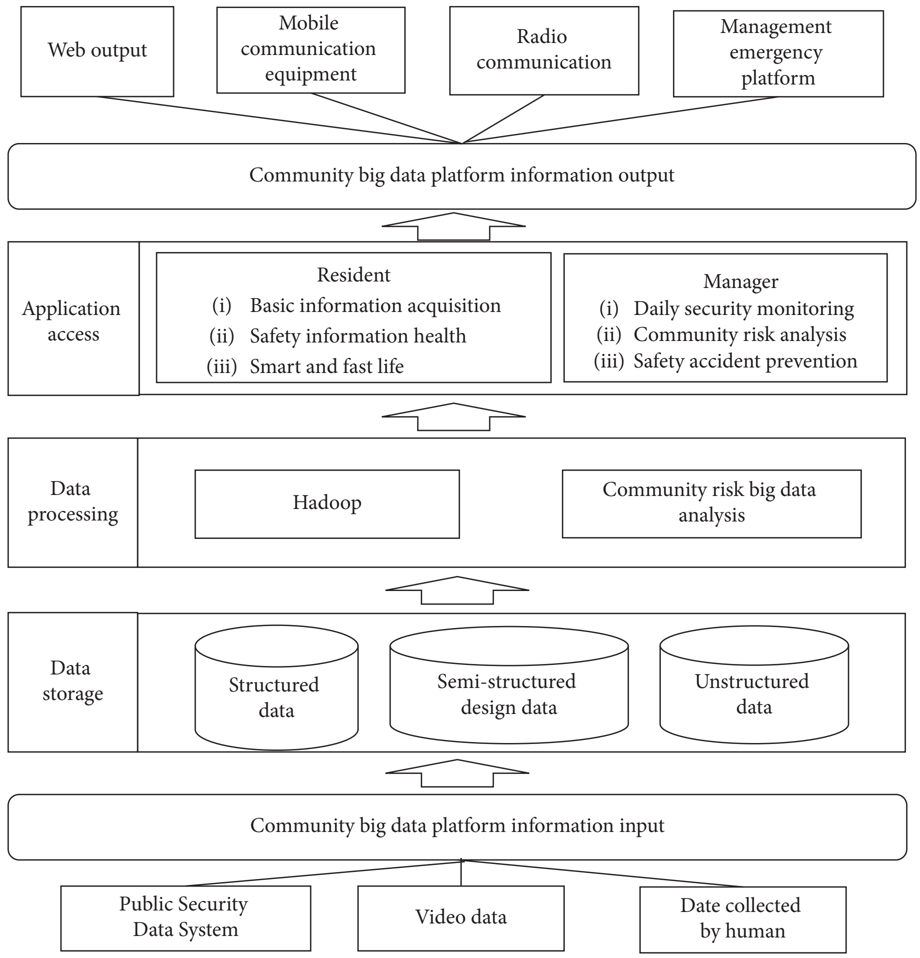

Figure 3: Overall architecture design of community big data platform.

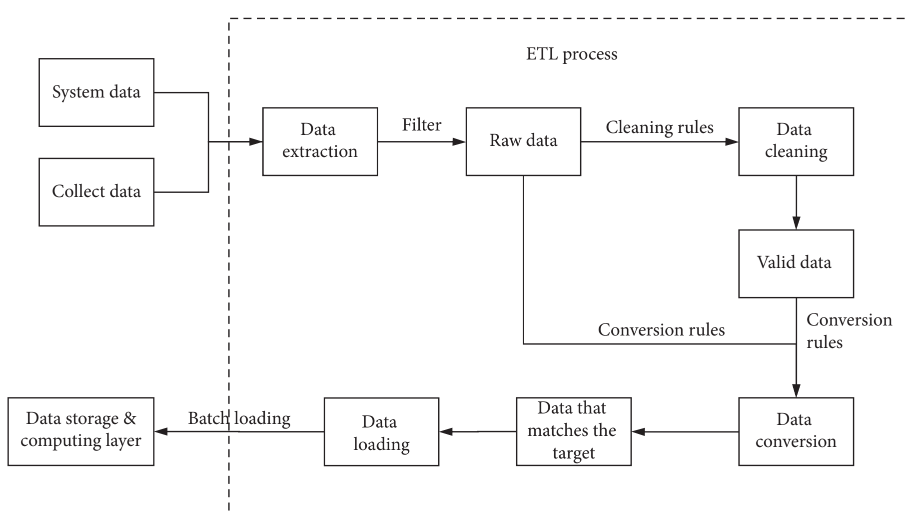

Figure 4: ETL work flowchart.

4. Risk Prediction Based on CART Regression Tree

4.1. CART Regression Tree Construction. When analyzing the factors related to community public security risks, it is found that the characteristic data is basically composed of four categories and a total of 21 attributes. The decision tree can more accurately find the relationship between attributes and classes, and when the relationship is found, it can be used to predict feature data of unknown categories. Therefore, this article chooses to use CART regression tree to build a single model. CART assumes that the decision tree is a binary tree, the values of internal node characteristics are "yes" and "no," the left branch is the branch with the value of "yes," and the right branch is the branch with the value of "no." Such a decision tree is equivalent to recursively bisecting each feature, dividing the input space, that is, the feature space into finite units, and determining the predicted probability distribution on these units, that is, the conditional probability distribution output under the given input conditions.

Since the prediction of future community security incidents based on various risk factors is a numerical prediction, the CART regression tree is used for prediction during the construction of the decision tree model. Figure 5 is the flowchart of the CART regression decision tree algorithm. In the process of model construction, the smallest MSE is selected as the dividing node of the feature data, and the average value of all sample data where the feature data falls into a certain node is used as the output value of the predicted value of community public security cases.

CART regression tree construction process is as follows:

(1) In order to predict the volume of community security cases and verify the accuracy of the model, first, all feature datasets are divided into training sets and test sets. Construct a regression tree training sample set. In the community public security risk data set S, $S = \{(X1, Y1), (X2, Y2), \ldots, (Xi, Yi), \ldots, (Xn, Yn)\}$, where (Xi, Yi) is a single sample in the sample, Xi is a vector constructed according to the data source introduced previously, and Yi is the output target value, which is the predicted volume of community security cases.

(2) Create a root node based on the community public security risk training data sample set constructed in step (1). When there is only one sample left, the node is returned as a leaf node, and when the sample sets corresponding to the root node are all of the same category, the node is also returned as a leaf node, and the predicted value is output.

(3) For each feature predicted by community public security cases, perform a division on the feature and calculate the corresponding segmentation index value. This study uses the mean square error as the segmentation node and first selects a feature data value in the community public security data as a cutting point, calculates the mean square error at this time, and then recursively calculates the mean square error of the remaining characteristic factors of community public security. After traversing all the eigenvalues, compare all the mean square errors, and find the eigenvalue when the mean square error is the smallest is the best cut point for this regression tree.

(4) According to the segmentation index value of the public security risk data in step (3), select the best feature segmentation attribute, and divide the community public security case sample set S into S1 and S2 sample subsets accordingly.

(5) For sample subset S1 and sample subset S2, repeat the process from step (2) to step (3) until the generated regression tree no longer produces new branches.

To prevent the CART regression tree from being divided too finely, it will have an overfitting effect on the noise data in the community public security data, and the CART regression tree is postpruned. If the noise data in the community public security data interferes too much, so that the model has overremembered the noise characteristics but ignores the real relationship between input and output, it must be solved by pruning. Moreover, only after pruning the CART regression tree can the prediction of the CART regression tree in this paper retain the most important community security feature attribute value division. This article divides the community public security case data set into a training set and a test set. A training set is used to form the learned CART regression tree, and a separate test set is used to evaluate the accuracy of the CART regression tree constructed in this article on subsequent data. Using the cost-complexity pruning strategy in postpruning, calculate the surface error rate gain value α of each nonleaf node in the decision tree, find the nonleaf node with the smallest α value, and perform pruning. The calculation formula of α is as follows:

$$\begin{aligned} \alpha &= \frac{R(a) - R(A_a)}{|N_{Aa}| - 1}, \\ R(a) &= r(a) \times p(a). \end{aligned} \tag{1}$$

Here, $|N_{Aa}|$ is the number of leaf nodes contained in the subtree species; $R(a)$ is the error cost when node a is pruned; $r(a)$ is the error rate of node a; $p(a)$ is the data on the error rate of the prediction model accounting for all data Proportion; $R(A_a)$ is the error cost of subtree A_a if the node is not pruned.

Finally, after the CART regression tree prediction model is trained, save the model, and use the CART regression tree prediction model to predict the community security case test dataset. By comparing the prediction value of community security cases predicted by the CART regression tree prediction model with the accuracy of the test set data, the prediction accuracy of the CART regression tree prediction model is calculated.

4.2. Analysis of Results. The feature engineering analysis of the original input data is carried out, and the correlation analysis method is used. It is obtained that the correlation

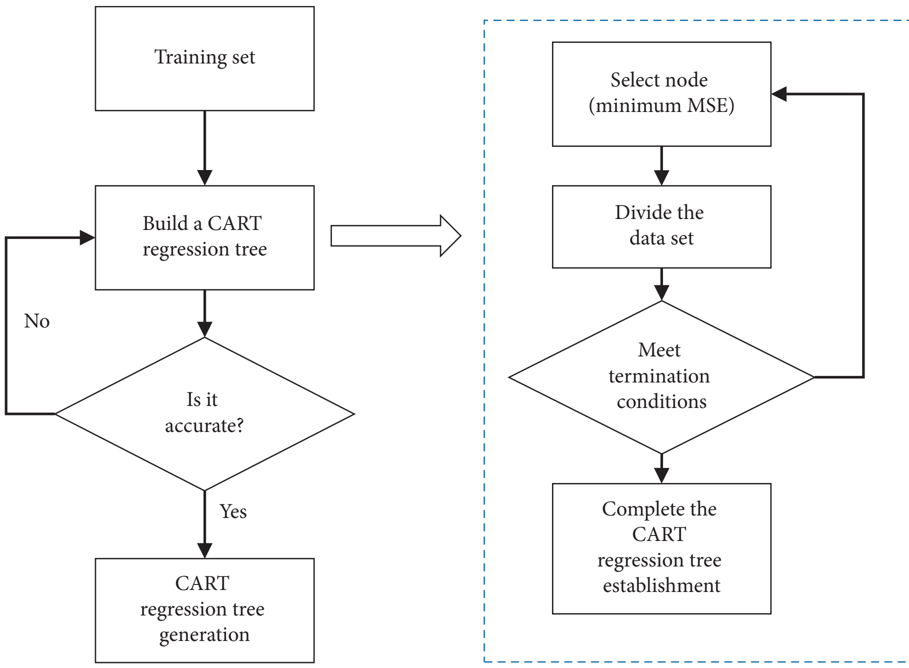

Figure 5: CART regression modeling framework diagram.

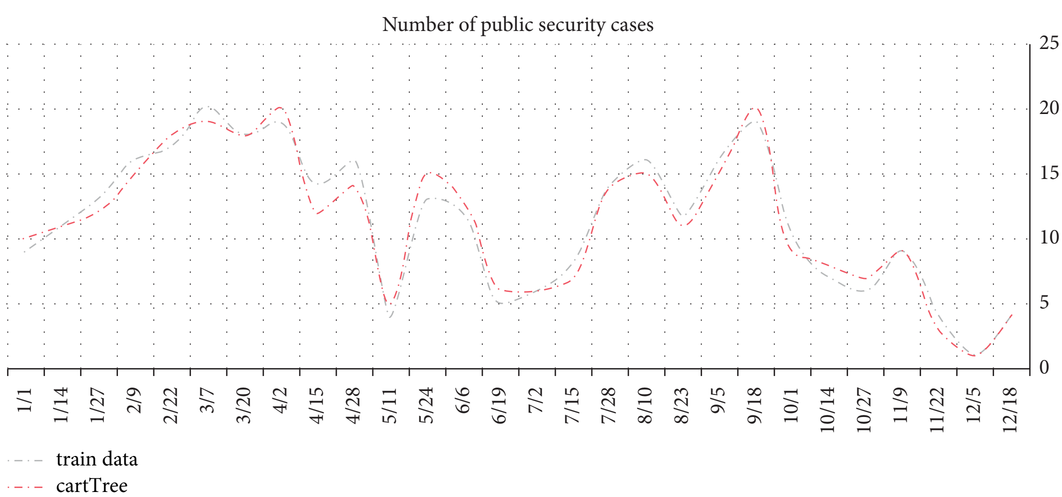

Figure 6: Comparison of cart regression tree model prediction results.

between the data was seven days ago and the target value is 0.978, and the correlation between the data was six days ago and the target value is 0.982. The data obtained seven days ago and the data obtained six days ago are strongly correlated with the target value. To enrich the amount of data, the first seven days of community security cases and the first six days of community security cases are taken as the input characteristics, and the maximum tree depth is 4 and the minimum leaf node is 5.

Figure 6 shows the comparison between the prediction results of CART regression tree prediction model on the test set and the actual observation values. The error between the test data and the predicted data is very small, which shows that the prediction model proposed in this paper is suitable, and also proves the feasibility and effectiveness of the method in this paper. The data takes one day as the granularity, the abscissa is the date, and the ordinate is the number of community security cases. The gray solid line is the actual number of community security cases collected every day in Z community of H City in 2019, and the red solid line is the prediction result of cart regression tree model. It can be seen from the figure that the trends of the gray solid line and the red solid line are basically the same. The two solid lines have two wave peaks and two wave troughs. From the beginning of a year to the first wave trough, the predicted value of the regression tree is much higher than the actual value, but the difference between the predicted value and the actual value after the first wave trough is very small. At the wave peak, the predicted value of the regression tree model is higher than the actual value. At the first trough, the trough value of the predicted value of the regression tree is higher than the actual value, and at the second trough, the predicted value of the regression tree model is lower than the actual value.

5. Conclusion

Facing community security, combined with big data technology, this paper analyzes studies and designs the relevant contents of community big data platform. This paper studies the origin and development of the concept theory of community in China. Using the method of questionnaire survey, this paper studies the relationship between factors such as community safety management and community residents' satisfaction with the community and analyzes residents' attitude towards providing personal data to noncommercial community big data platform. The classification of community database data types was studied, and the community database structure was designed. Based on the community database, this paper summarizes the functional requirements of the community big data platform, then designs the architecture of the community big data platform combined with Hadoop and other big data technologies, and analyzes and studies the key technologies in the platform. Finally, combined with the data in the database, the CART regression tree prediction model is constructed to predict the community public security risk, which provides convenience for the rational scheduling and allocation of community police resources in the future, and provides decision support for the prevention and control of community public security risk.

Rock masses existing in nature may experience closed internal stress under the action of geological structures. This closed internal stress makes the deformation of the rock mass incompatible, so classic continuum theory is not suitable for analyzing the stress and deformation of rock masses. In this study, a non-Euclidean model for rock masses was established based on differential geometry. By choosing the non-Euclidean parameter as the internal variable, a thermodynamic model was constructed. Then, numerical computation based on the non-Euclidean model was applied to a circular tunnel in a deep rock mass. The distribution of internal stress and the effects of rock parameters on the distribution of internal stress were analyzed. Through our research, we conclude that the stress field of the deep rock mass consists of classical stress and internal stress and that the internal stress shows a distinct wavy behavior. The radius of the fractured zone decreases with an increasing Young's modulus E and Poisson's ratio ν, but increases with increasing non-Euclidean parameter ξ.

1. Introduction

In classical continuum theories of rock mechanics, a rock is a continuous, simply connected body that undergoes deformation, and the deformation satisfies the equations of compatibility. The metric tensor for measuring the distances between material particles in the reference configuration is Euclidean. However, rock masses existing in nature may contain closed internal stress. The internal stress makes the deformation of the rock incompatible. Therefore, the classical continuum theory is not suitable for analyzing the incompatible deformation of rock masses [1–5]. It is necessary to introduce non-Euclidean space to describe the incompatible deformation, and differential geometry will be used to describe the closed internal stress.

The relationship between the continuum theory and mathematical theory of differential geometry has been studied by many researchers. Kondo [6] first recognized the relationship between dislocation theory and non-Riemannian theory. Later, Anthony [7] pointed out the relationship of differential geometry to disclinations. Then, Kroner [8] completed the underlying theory for defects and differential geometry, including dislocations and extra matter. These investigations established a relation between the parameters of non-Euclidean geometry and elastic strain, bend twist, and quasiplastic strain of defect theory [9]. The first non-Euclidean continuum model to describe the stress-field distribution around underground working was developed by Myanikov and Guzev [10]. A modification of this model was presented by Guzev and used to describe different rock phenomena, such as zonal disintegration and anomalous deformation of rock samples [11–15]. Investigations were also undertaken by other researchers, and a non-Euclidean continuum model was proposed to investigate the zonal disintegration phenomenon of surrounding rocks by Zhou and Qian [16–19]. These existing models assume that the undeformed body is in three-dimensional

Euclidean space. However, there is closed internal stress in the rock mass.

Suppose there is a flat plate in two dimensions. Due to uneven heating and mutual expansion, thermal stress will be generated, and the uneven temperature field causes internal stress in the plate. If we cut the whole plate into tiny elements and release each tiny element into its stress-free natural state, then the flat plate composed of various elements can no longer be in two-dimensional Euclidean space. However, if the flat plate is allowed to warp, it will bulge and become a curved surface. The plate is a two-dimensional Riemannian space immersed in three-dimensional Euclidean space R^3. According to this scenario, the undeformed rock mass with closed internal stress should be regarded as a manifold.

In this study, it is assumed that the undeformed rock mass with closed internal stress was a manifold. A non-Euclidean model of rock masses was established based on differential geometry. By choosing the non-Euclidean parameter as the internal variable, a thermodynamic model was constructed. Then, numerical computation based on the non-Euclidean model was applied to a circular tunnel in a deep rock mass. The distribution of internal stress and the effects of rock parameters on the distribution of internal stress were then analyzed.

2. Differential Geometry Method

The initial state of the rock is as a manifold. Moreover, the manifold is an imagined state of undeformed rock that occupies a compact and simply connected region. Consider a material point p in the undeformed body and an m-dimensional manifold M that is referred to as a configuration. We choose the configuration $p \in U \subset M$ at time $t = t0$ as a reference configuration, such that the subsequent deformation and motion of the current configuration are given by $q \in V \subset N$ at time $t = t$ with respect to the reference configuration [14] (Figure 1).

For any $p \in M$, there exists a neighborhood U of p, such that U is homeomorphic to an open set in R^m, i.e., the homeomorphism is φ_U: $U \longrightarrow \varphi_U(U)$.

$$X^i = \varphi_U(p)^i, \tag{1}$$

where X^i is the local coordinate of the point $p \in U$.

For any $q \in N$, there exists a neighborhood V of q, such that V is homeomorphic to an open set in R^n, i.e., the homeomorphism is ψ_V: $v \longrightarrow \psi_V(V)$.

$$x^i = \psi_V(q)^i, \tag{2}$$

where x^i is the local coordinate of the point $q \in V$.

The deformation of the body is a continuous map from the initial configuration smooth manifold M to the final configuration smooth manifold N. F: $M \longrightarrow N$. Compatible coordinate charts (U, φ_U) exist at points $p \in M$ and (V, ψ_V) at $f(p) \in N$, such that the map

$$\psi_V \circ F \circ \varphi_U^{-1}: \varphi_U(U) \longrightarrow \psi_V(V), \tag{3}$$

is C^∞ at the point $\varphi_U(p)$.

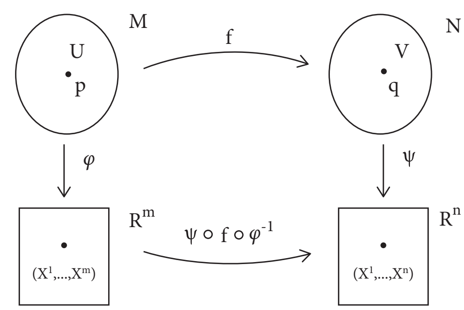

Figure 1: The initial configuration and final configuration. M is the manifold of the undeformed body. N is the manifold of the deformed body.

Moreover, smooth maps F between M and N induce linear maps between tangent spaces and between cotangent spaces. F: $M \longrightarrow N$, $p \in M$, and $q = F(p) \in V$. F_* is a linear map of the tangent space induced by F. We define the map F_*: $T_pM \longrightarrow T_qN$ as follows (Figure 2):

$$F_*(v)(f) = v(f \circ F), \quad \forall f \in C^\infty_{F(p)}. \tag{4}$$

The adjoint map of F_* is $F^*: T_p^*M \longrightarrow T_q^*N$ which is called the differential map induced by F.

$$F^*(df) = d(f \circ F), \quad df \in T_q^*N. \tag{5}$$

X^i and x^i are the local coordinates of points p and q. The deformation map F can be expressed near p by the functions

$$x^\alpha = F^\alpha\left(X^1, \ldots X^m\right), \quad 1 \le \alpha \le n. \tag{6}$$

The increment vector dx of point $q \in N$ in deformed body N belongs to cotangent space T_qN, and the increment dX of the corresponding point $X \in M$ in undeformed body M belongs to tangent space T_pM. They are related by the differential map F^*.

Thus, the action of F^* on the natural basis $\{dx^\alpha, 1 \le \alpha \le n\}$ is given by

$$\begin{aligned} F^*(\mathrm{d}x^\alpha) &= d(x^\alpha \circ \mathrm{F}) \\ &= \sum_1^m \left(\frac{\partial F^\alpha}{\partial X^i}\right) \mathrm{d}X^i. \end{aligned} \tag{7}$$

The matrix representation of F^* in the natural bases dx and dX is exactly the Jacobian matrix $(\partial F^\alpha/\partial X^i)_p$. This relates the infinitesimal line segment $dX \in M$ to the corresponding segment $dx \in N$.

Map F^* plays a role in the coordinate transformation from T_qN to T_pM. Since no material point vanishes, there is an inverse relation for F^*:

$$\mathrm{d}x = F^{*-1}(\mathrm{d}X), \tag{8}$$

where F^{*-1} is the deformation gradient.

A volume element dV in undeformed body M is related to the volume element dv in deformed body N through determinant J of the deformation gradient F by $dv = JdV$.

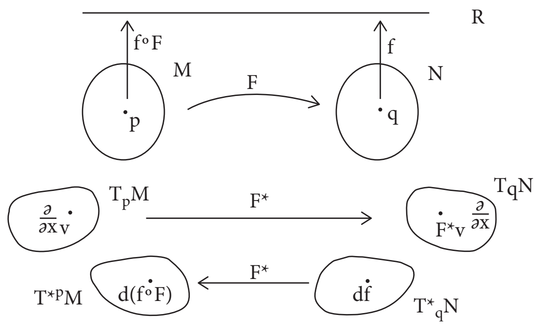

Figure 2: The tangent map and differential map. T_pM and T_qN are the tangent spaces. T_q^*(N) and T_p^*(M) are the cotangent spaces.

$$J = \det F = F^{*-1}F^{*-1}F^{*-1}, \tag{9}$$

where J is referred to as the Jacobian.

The deformed body N is a manifold with a topological structure and smooth structure. During deformation, some vectors act on it, such as body force and external force. They are vector bundles on N (Figure 3).

N is called the base space. π: $E \longrightarrow N$ is a smooth surjective map called a bundle projection, and $V = R^s$ is an s-dimensional vector space.

If there is no mass flux, the total mass of undeformed body M is conserved in deformed body N:

$$\int_M \rho_0 \mathrm{d}v_0 = \int_N \rho \mathrm{d}v, \tag{10}$$

where ρ_0 and ρ are the mass densities before and after deformation, respectively. The time differential form using Reynold's transport theorem gives the following mass conservation law:

$$\frac{\mathrm{d}\rho}{\mathrm{d}t} + \rho\nabla \cdot v = 0, \tag{11}$$

where v is a vector of the tangent bundle and ∇ is the gradient operator. The divergence makes a linear map div: $TM \longrightarrow C^\infty M$.

Newton's second law states that in an inertial frame, the rate of linear momentum is equal to the applied force. Here, by applying the second law to a continuum region, the linear momentum of the deformed body N is given by

$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \rho v \mathrm{d}v = \int_{\partial\Omega} t \mathrm{d}s + \int_\Omega \rho b \mathrm{d}v, \tag{12}$$

where t is an external force per unit area called the stress vector, which acts on the boundary $\partial\Omega$. It is a tensor of the tensor bundle $T_0^{\,1}(N)$, and the body force per unit volume b acting in volume N is a tensor of tensor bundle TN.

Substituting (12) into (13) yields the following:

$$\rho\frac{\mathrm{d}v}{\mathrm{d}t} = \mathrm{div}\sigma^T + \rho b, \tag{13}$$

where σ is called the Cauchy stress, which gives a transformation law that maps the unit outward n to the traction t acting on the surface by $t = \sigma^T n$. σ is a tensor of tensor bundle $T_0^{\,2}(N)$, and n is a tensor of tensor bundle $T_0^{\,1}(N)$.

Now, we need to measure the extent of deformation of an elemental length located at a material point. To do so, we should introduce a metric on the smooth manifold. If the metric is a smooth, nondegenerate positive symmetric second-order covariant tensor field, then the manifold is called a Riemannian manifold, and the metric is a Riemannian metric. We compare length $|dx|$ with its original length $|dX|$ by comparing the difference of both lengths as a squared measure:

$$|\mathrm{d}x|^2 - |\mathrm{d}X|^2 = g_{ij}\mathrm{d}x^i\mathrm{d}x^j - G_{\alpha\beta}\mathrm{d}X^\alpha\mathrm{d}X^\beta, \tag{14}$$

where g_{ij} is the metric tensor of manifold N, and $G_{\alpha\beta}$ is the metric tensor of manifold M.

Substituting the deformation gradient yields

$$\begin{aligned}|\mathrm{d}x|^2 - |\mathrm{d}X|^2 &= g_{ij}\mathrm{d}x^i\mathrm{d}x^j - G_{\alpha\beta}F_i^{*\,\alpha}F_j^{*\,\beta}\mathrm{d}x^i\mathrm{d}x^j \\ &= \left(g_{ij} - G_{\alpha\beta}F_i^{*\,\alpha}F_j^{*\,\beta}\right)\mathrm{d}x^i\mathrm{d}x^j.\end{aligned} \tag{15}$$

Then, the deformation measure can be written as

$$g_{ij} = 2\varepsilon_{ij} + G_{ij}. \tag{16}$$

This tensor ε is referred to as a strain tensor.

Furthermore, M and N are two smooth manifolds, and f: $M \longrightarrow N$ is a smooth map. If f is the immersion and h is a Riemannian metric, then

$$g = f^* h. \tag{17}$$

where g is the Riemannian metric of M. (17) indicates that the metric of manifold M can be induced by the differential map and the metric of manifold of N.

The Riemann tensor R of the initial configuration is a function:

$$R_{ijkl} = \frac{1}{2}\left(G_{ik,jl} + G_{il,jk} - G_{il,jk} - G_{jk,il}\right) + \widetilde{\Gamma}_{h.ik}\widetilde{\Gamma}^h_{jl} - \widetilde{\Gamma}_{h.il}\widetilde{\Gamma}^h_{jk}. \tag{18}$$

The Riemann tensor R of the current configuration is a function.

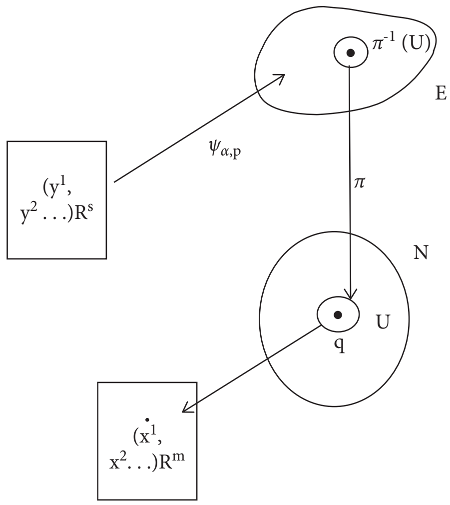

Figure 3: Vector bundles on the manifold. E and N are the smooth manifolds. E is a vector bundle on N.

$$R_{ijkl} = \frac{1}{2}\left(g_{ik,jl} + g_{il,jk} - g_{il,jk} - g_{jk,il}\right) + \Gamma_{h.ik}\Gamma^{h}_{jl} - \Gamma_{h.il}\Gamma^{h}_{jk}. \tag{19}$$

Substituting (18) and (16) into (19), equation (19) can be rewritten as

$$R_{ijkl} = \left(\varepsilon_{il,jk} + \varepsilon_{jk.il} - \varepsilon_{ik,jl} - \varepsilon_{jl,ik}\right). \tag{20}$$

During excavation in a deep rock mass, a circular tunnel is a typical plane strain problem. Thus, the Riemann tensor R can be obtained in a two-dimensional manifold as

$$R_{1212} = 2\frac{\partial^2 \epsilon_{12}}{\partial x^1 \partial x^2} - \frac{\partial^2 \varepsilon_{11}}{\partial x^2 \partial x^2} - \frac{\partial^2 \varepsilon_{22}}{\partial x^1 \partial x^1}. \tag{21}$$

The other component of R_{ijkl} is equal to 0. On the right of (21) is the compatible condition of classical mechanics. Due to the existence of closed internal stress, the deformation of rock masses is not compatible. Then, the tensor contraction of R_{ijkl} is a second-order tensor R_{ij}, and the components are

$$R_{ij} = \begin{vmatrix} \dfrac{R}{2} & 0 \\ 0 & \dfrac{R}{2} \end{vmatrix}, \tag{22}$$

where R is the tensor contraction of R_{ij}, and $R = 2R_{1212}$.

3. The Thermodynamics Model and Discussion

Classical thermodynamics provide valuable information that can assist in the solving of practical problems in many fields of science and engineering. The physical state of the system can be described by variables such as internal energy, entropy energy, and free energy. They are decided by independent parameters; these parameters are the internal variables. The choice of the internal variables is not unique. It can be decided by the level of the model, the nature of the thermodynamic system, and the accuracy of the system state. The independent parameters consist of external variables (the strain tensor, deformation gradient, and temperature) that can be observed and internal variables that relate to the material properties of the system.

In geotechnical engineering, the strain tensor ε, temperature T, and Riemann tensor R_{ij} can be chosen as external and internal variables. Now, we consider the deformation from the initial configuration to the final configuration, and this deformation is elastic. Thus, the Helmholtz free energy can be rewritten as

$$\dot{\Psi} = \frac{\partial \Psi}{\partial T}\dot{T} + \frac{\partial \Psi}{\partial \epsilon_{ij}}\dot{\varepsilon}_{ij} + \frac{\partial \Psi}{\partial R_{ij}}\dot{R}_{ij}. \tag{23}$$

According to the second law of thermodynamics, the Clausius–Duhem inequality will be

$$\rho\dot{T}\left(\frac{\partial \Psi}{\partial T} + s\right) + \rho\frac{\partial \Psi}{\partial \epsilon_{ij}}\dot{\varepsilon}_{ij} + \frac{\partial \Psi}{\partial R_{ij}}\dot{R}_{ij} - \sigma_{ij}\dot{\varepsilon}_{ij} + \frac{q}{T}\,\mathrm{div}, \quad T \le 0, \tag{24}$$

where ρ is the density of the body, s is the entropy, q is the heat flux, and σ_{ij} is the Cauchy stress tensor. The inequality above will be satisfied for any T, Q, h, and ε. Then, the following thermodynamic restrictions hold true:

$$\sigma_{ij} = \rho\frac{\partial \Psi}{\partial \epsilon_{ij}}, \tag{25}$$

$$\frac{\partial \Psi}{\partial R_{ij}}\dot{R}_{ij} + \frac{q}{T}\,\mathrm{div}, \quad T \le 0, \tag{26}$$

$$s = -\frac{\partial \Psi}{\partial T}. \tag{27}$$

Equation (25) indicates that the stress tensor is equal to the derived free energy, in accordance with classical elasticity theory.

Supposing that the rock material is isotropic at a constant temperature, we can extend the free energy to second order with

$$\Psi\left(\varepsilon_{ij}, R_{ij}\right) = \frac{\lambda\left(\varepsilon_{kk}\varepsilon_{kk}\right)}{2} + \mu\varepsilon_{ij}\varepsilon_{ij} + \frac{\nu\left(R_{ij}R_{ij}\right)}{2} + \xi\varepsilon_{ij}R_{ij}, \tag{28}$$

where λ and μ are Lame's constants, and ν and ξ are the parameters related to the internal structure of the rock. Substituting equation (28) into (25) gives

$$\sigma_{ij} = \lambda\varepsilon_{kk}\delta_{ij} + 2\mu\varepsilon_{ij} + \xi R_{ij}. \tag{29}$$

The underground rock experiences the effects of construction and heat, and the deformation will be incompatible and lead to a nonuniform stress field. A part of the stress will be lost by the tunnel excavation, but the residual will remain in the rock. In equation (29), for the initial undeformed body, the strain tensor is equal to zero. Then, the rock experiences an initial stress ξR_{ij}, which is the self-balancing stress closed in the rock. This value is related to the metamorphic and tectonic movement of rock. From a physical point of view, the existence of nonzero self-equilibrated stress fields in a continuous medium is due to the presence of structural defects in the material.

The stress can be regarded as the sum of classical stress Σ_{ij} and t_{ij}:

$$\sigma_{ij} = \Sigma_{ij} + t_{ij}. \tag{30}$$

According to the principles of thermodynamics with internal state variables, we define the force Q as

$$\begin{aligned} Q &= -\frac{\partial \Psi}{\partial R_{ij}} \\ &= \nu R_{ij} + \xi \varepsilon_{ij}, \end{aligned} \tag{31}$$

where Q is a generalized force conjugated to R, which is an internal variable that relates to the internal stress of the rock mass and contributes to the dissipation of energy.

Recall that equation (29) can be written as

$$\varepsilon_{ij} = \frac{1}{2\mu}\left(\sigma_{ij} - \lambda \varepsilon_{kk}\delta_{ij} - \xi R_{ij}\right). \tag{32}$$

For the deformation from the initial configuration to the final configuration, the equilibrium and boundary conditions are

$$\sigma_{ij,j} = 0. \tag{33}$$

Substituting (32) and (33) into (21), we obtain

$$R = \frac{2(\lambda + \mu)}{\mu(3\lambda + 2\mu)}\Delta\sigma_{kk} - \frac{\lambda + 2\mu}{2\mu(3\lambda + 2\mu)}k\Delta R. \tag{34}$$

Because the stress of the rock mass is self-balanced, $\Delta\sigma_{kk} = 0$. Equation (34) can be rewritten as

$$\Delta R + \omega R = 0, \tag{35}$$

where $\omega = 2\mu(3\lambda + 2\mu)/(\lambda + 2\mu)\xi$. Equation (44) is Poisson's equation, and the solution is

$$R = AJ_0(\sqrt{\omega}\rho) + BY_0(\sqrt{\omega}\rho), \tag{36}$$

where J_0 and Y_0 are the Bessel function and Neumann function, respectively. A and B are the parameters related to the structural defects of the material.

Considering a circular tunnel in the plane strain state, the total stress can be written as

$$\sigma_r = p_0\left(1 - \frac{r_0^2}{r^2}\right) + \xi AJ_0(\sqrt{\omega}\rho) + \xi BY_0(\sqrt{\omega}\rho), \tag{37}$$

$$\sigma_\varphi = p_0\left(1 + \frac{r_0^2}{r^2}\right) + \xi AJ_0(\sqrt{\omega}\rho) + \xi BY_0(\sqrt{\omega}\rho). \tag{38}$$

The rock mass experiences gravitational stress and internal stress before excavation. The construction of underground engineering projects breaks the stress balance, and so, the stress will redistribute. In the plane strain state, the shear stress of the internal stress dissipates with the deformation, but normal stress still exists in the rock mass and shows a periodic change with radius. If this stress reaches a critical value, the rock will break.

4. Analysis Based on Numerical Computations

4.1. The Distribution of Internal Stress around a Deep Tunnel. The model for numerical computation [20–23] was from Tangkou mine coal, Shandong Province, China. During the excavation of the tunnel, the completed roadway was damaged successively, and the surrounding rock was fractured violently. The material parameters used in the simulations were from a depth of 1028 m, including a uniaxial compressive strength of rock $\sigma_c = 35$ MPa, Young's modulus $E = 30$ GPa, and Poisson's ratio $\nu = 0.25$. The cross-section of the tunnel is approximately a circle, and the radius is $r_0 = 3$ m. The stress of the surrounding rock is equivalent in vertical and horizontal orientations, and the stress $p_0 = 23.4$ MPa.

Substituting these parameters into equations (37) and (38), we can obtain

$$\sigma_r = 23.4\left(1 - \frac{9}{r^2}\right) + \xi AJ_0(3\sqrt{\omega}) + \xi BY_0(3\sqrt{\omega}), \tag{39}$$

$$\sigma_\varphi = 23.4\left(1 + \frac{9}{r^2}\right) + \xi AJ_0(3\sqrt{\omega}) + \xi BY_0(3\sqrt{\omega}). \tag{40}$$

The parameter ξ is related to the internal stress of the rock mass and can be chosen by the radius of the fracture zone. According to geological observations, the fracture zone radius $r_c = 1.58\ r_0$; thus, we have the following boundary conditions for the function R:

$$R|_{r=r_0} = 0 \cdot \frac{dR}{dr}|_{r=r_c} = 0. \tag{41}$$

Substituting (36) into (41) gives

$$AJ_0(3\sqrt{\omega}) + BY_0(3\sqrt{\omega}) = 0, \tag{42}$$

$$\sqrt{\omega}\left[AJ_1(4.74\sqrt{\omega}) + BY_1(4.74\sqrt{\omega})\right] = 0. \tag{43}$$

By solving equations (42) and (43), $\omega = 7.18$ and $\xi = 5.57$ GPa can be obtained.

Meanwhile, fracture appears when the stresses in the rock mass reach a certain critical value. From a physical viewpoint, this means that it is necessary to use a force criterion, whose fulfillment in a selected region corresponds to the fracture zone. In this study, the Mises criterion is applied.

$$(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2 = 2\sigma_c^2. \tag{44}$$

Substituting (39) and (40) into (44), we obtain $A = 5.05 \times 10^{-3}$ and $B = 3.57 \times 10^{-3}$. Thus, the relation between the stress components and radius is shown in Figure 4. The distribution of hoop stress and radial stress shows a distinct wavy behavior. The range of fluctuation reflects the magnitude of internal stress and is related to in situ stress and rock behavior.

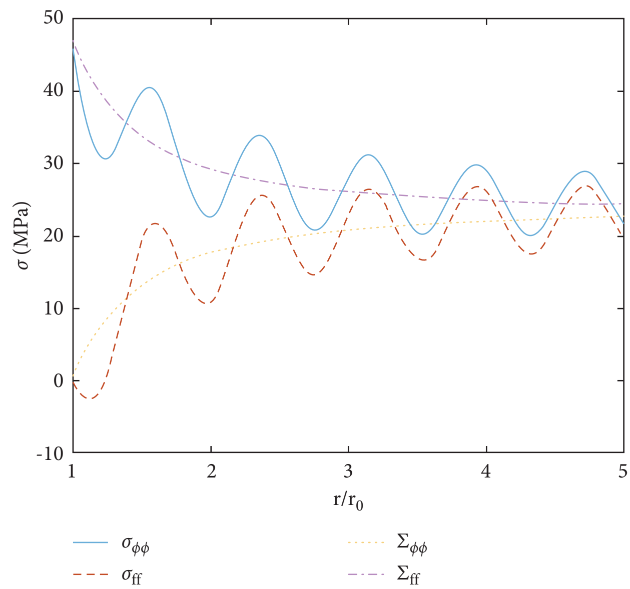

FIGURE 4: The distribution of stress with radius (r).

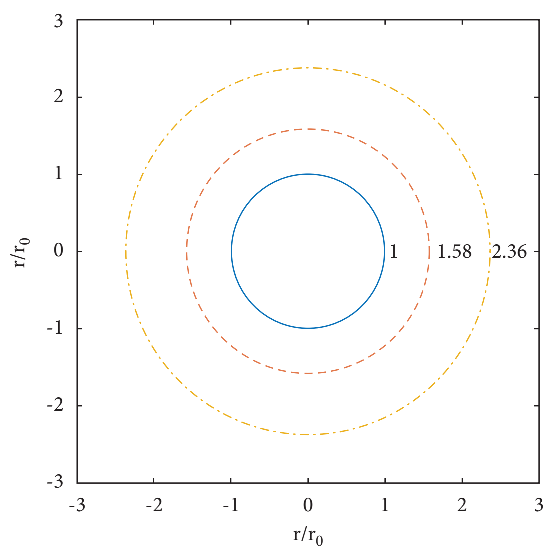

FIGURE 5: The site of crest zones from the computational model. Effects of rock parameters on the distribution of internal stress.

TABLE 1: Location of crest internal stress in the surrounding rock mass.

Location of crest stress (r/r_0)	Young's modulus E (GPa)			Poisson's ratio ν			Non-Euclidean parameter ξ (GPa)		
	27	30	33	0.2	0.25	0.3	5.01	5.57	6.13
First	1.69	1.58	1.47	1.63	1.58	1.46	1.43	1.58	1.67
Second	2.37	2.36	2.02	2.29	2.36	2.06	2.01	2.36	2.34

According to the prediction of the numerical computation, the second crest of the stress is located at 2.36 r_0, and the observation value is 1.58 r_0, as shown in Figure 5. The prediction value is 31% greater than the observation value because the fracture of the rock mass at $r = r_c$ is a region failure.

The fluctuation location and magnitude of the internal stress were influenced by the parameters of the rock mass, such as Young's modulus E, Poisson's ratio ν, and non-Euclidean parameter ξ, which affected the fracture zone of the surrounding rock of the tunnel, and the location of the crest stress is given in Table 1.

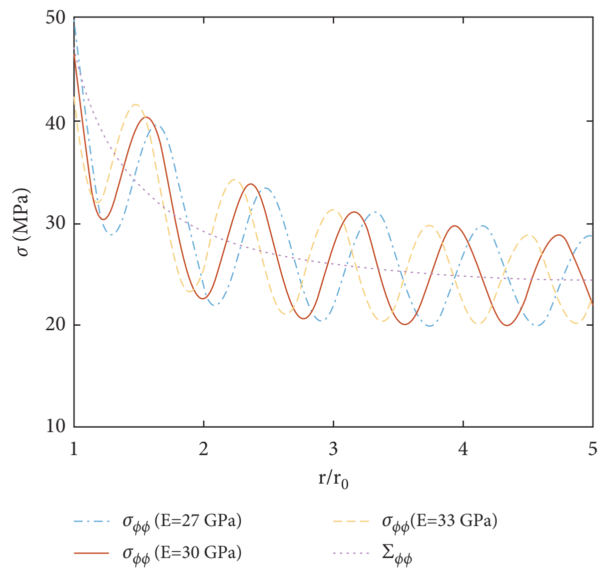

Figure 6: Effects of Young's modulus (E) on the distribution of hoop normal stress in surrounding rock mass.

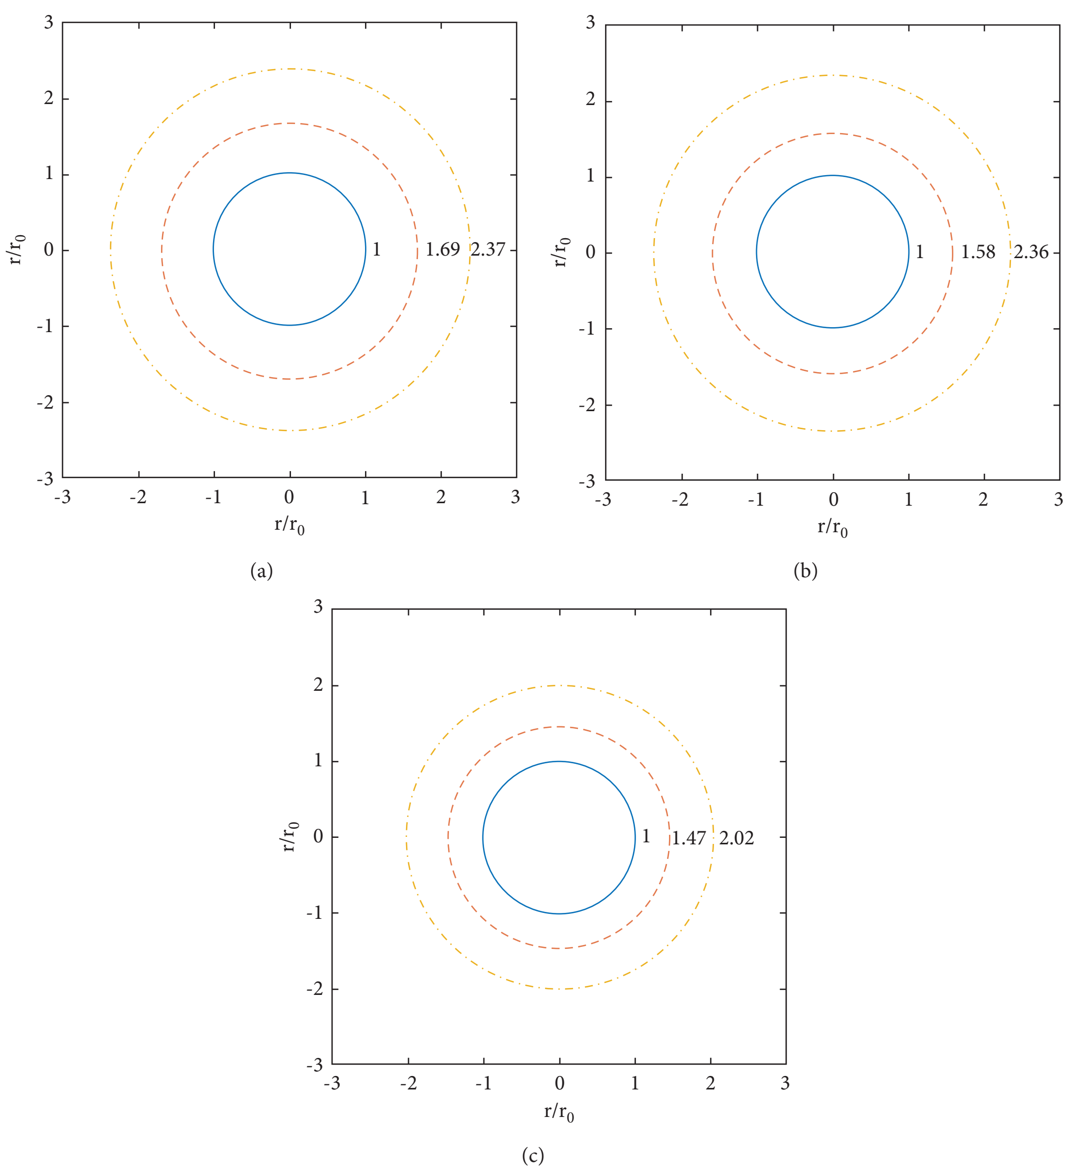

Figure 7: Location of crest internal stress in the surrounding rock mass with different Young's moduli. (a) $E = 27$ GPa. (b) $E = 30$ GPa. (c) $E = 33$ GPa.

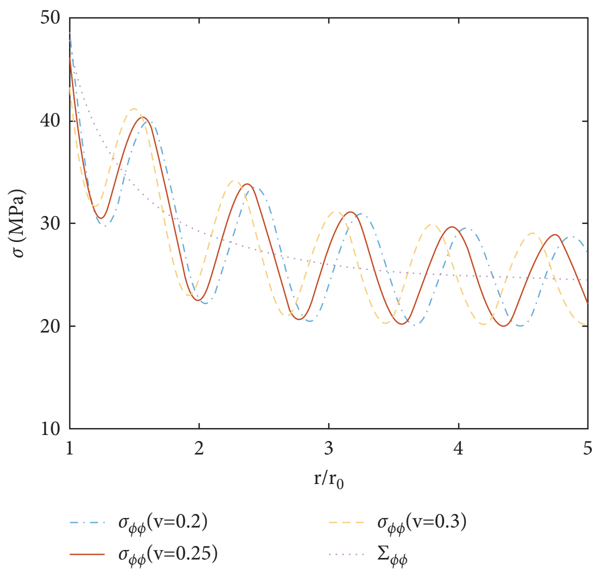

FIGURE 8: Effects of Poisson's ratio (v) on the distribution of hoop normal stress in the surrounding rock mass.

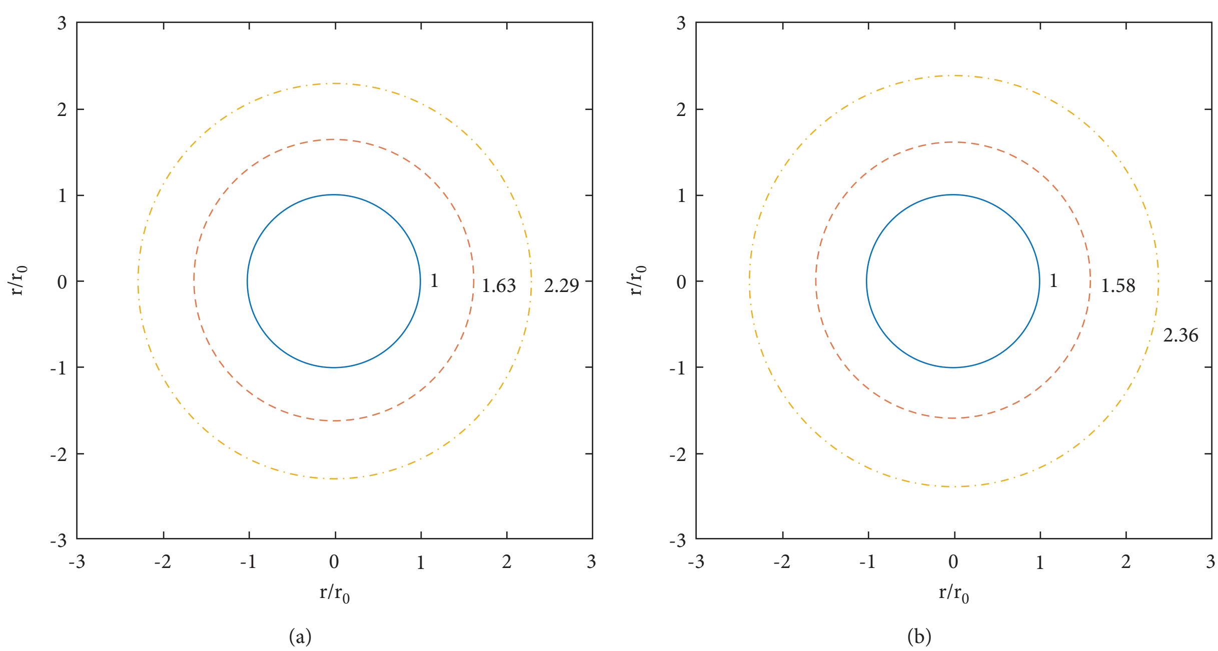

FIGURE 9: Continued.

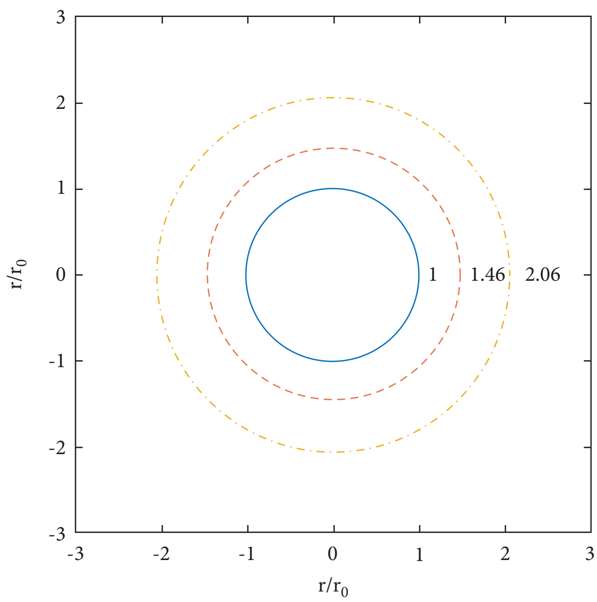

(c)

Figure 9: Location of crest internal stress in the surrounding rock mass with different Poisson's ratios. (a) $\nu = 0.2$. (b) $\nu = 0.25$. (c) $\nu = 0.3$.

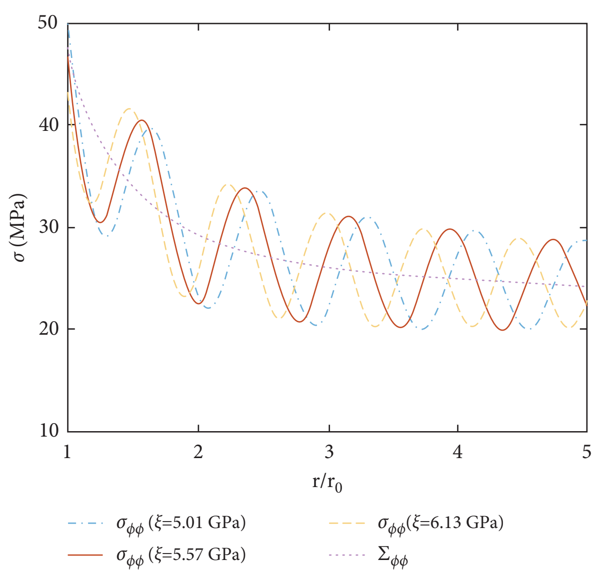

Figure 10: Effects of the non-Euclidean parameter ξ on the distribution of hoop normal stress in surrounding rock mass.

Figures 6 and 7 show the effects of Young's modulus E on the distribution of the internal stress crest in the surrounding rock mass around a deep circle tunnel. It can be observed that the radius of the internal stress crest decreases with an increase in Young's modulus E. These results indicate that the magnitude of internal stress and energy existing in the rock mass increases with Young's modulus. The larger Young's modulus is, the closer the fracture location is to the tunnel.

Figures 8 and 9 show the effects of Poisson's ratio ν on the distribution of the internal stress crest in the surrounding rock mass around a deep circle tunnel. The radius of fractured zones decreases with an increase in Poisson's ratio ν.

Figures 10 and 11 show the effects of the non-Euclidean parameter ξ on the distribution of the internal stress crest in the surrounding rock mass around a deep circle tunnel. It can be observed that the radius of

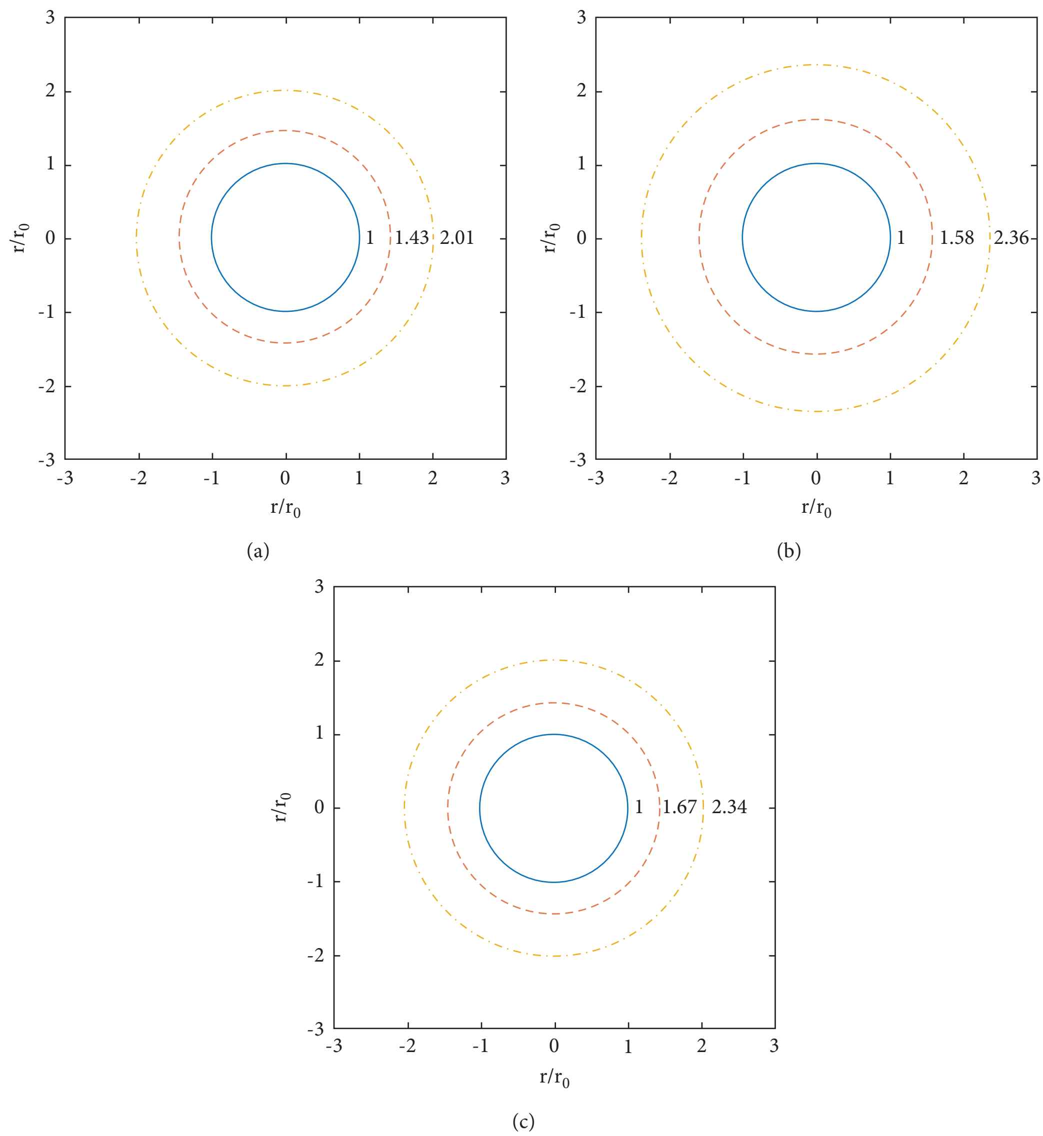

Figure 11: Location of the crest internal stress in surrounding rock mass with different non-Euclidean parameters. (a) $\xi = 5.01$ GPa. (b) $\xi = 5.57$ GPa. (c) $\xi = 6.13$ GPa.

fractured zones increases with an increase in the non-Euclidean parameter ξ.

5. Conclusions

(1) Because there is closed internal stress in the rock mass, the deformation of the rock mass is incompatible. The undeformed body is a manifold immersed in three-dimensional Euclidean space. The metric tensor of the space is the Riemannian metric g_{ij} instead of the Euclidean metric δ_{ij}. The deformation of the rock mass is a continuous map from the undeformed manifold M to the deformed manifold N. The incompatible deformation of the rock mass is related to the Riemannian curvature tensor R_{ijkl} of the manifold.

(2) The rock mass experiences gravitational stress and internal stress before excavation. The construction of underground engineering projects breaks the balance, and the stress will redistribute. In the plane strain state, the shear stress of the internal stress dissipates with the deformation, but normal stress still exists in the rock mass and shows a periodic change with radius. If this component reaches a critical value, the rock will break.

(3) For the rock mass with internal stress, with the increase of elastic modulus E, the peak value of hoop

stress decreases, and the position of peak stress is closer to the tunnel. It shows that the harder the rock mass is, the more severe the damage near the tunnel surface is. With the increase of Poisson's ratio v, the hoop stress of rock mass decreases, which indicates that the larger Poisson's ratio v is, the larger the deformation of rock mass under the same confining pressure, and more internal stress will be released. With an increase of non-Euclidean parameter ξ, the radius of the fractured zone decreases.

Finance is becoming more important in the national economy. Maintaining financial stability is critical not only for the financial industry's prosperity and development, but also for a country's political, economic, and social development. This paper will look at the mechanisms that cause systemic risk to develop and evolve, as well as how to measure systemic financial risk in multiple dimensions. To begin, create a system for evaluating financial risk in a systematic manner. Second, using the AHP and CRITIC methods to determine various indicators and market weights, create a systemic financial risk evaluation model based on the system dynamics model, and calculate the system from 2010 to 2019 comprehensive financial risk index. Finally, simulation research is conducted using the system dynamics model of systemic financial risk, and the simulation results are analyzed. The findings show that China's financial risk has been gradually increasing since 2016, with relatively small fluctuations in risk state.

1. Introduction

Systemic financial risks not only occur in financial markets, but also affect macroeconomic and social wealth, according to international social practice [1]. Financial globalization will, without a doubt, benefit China's financial industry. It has the potential to introduce more efficient and diverse funds, introduce international advanced management concepts and innovative thinking, and revitalize China's financial system. However, there are no benefits on either end, and financial globalization has numerous drawbacks [2, 3]. It may increase a country's economy's risk exposure and the financial system's vulnerability to external pressure, raising the possibility of systemic financial risks. Overall, the financial system's operation has a twofold impact on economic development [4]. It has the potential to boost economic growth while also increasing the likelihood and severity of systemic financial risks escalating into financial crises. As a result, systemic financial risk research is particularly important at this stage.

Studies have not designed scenarios for systematic financial risk early warning, but there are differences in systematic financial risk monitoring and early warning under different scenarios [5, 6]. In these studies, empirical research is the majority, while theoretical research is the minority. In empirical research, empirical research on fundamentals and trade channels is the majority, while relatively few focus on financial channels and expectations [7, 8]. Scholars in China have gradually focused their attention on financial contagion research, but due to a lack of data sources and theoretical mechanisms, the existing research results are mostly broad theoretical introductions, with little in the way of specific path analysis and empirical testing of financial risk contagion mechanisms [9–11]. The system dynamics model is used in this paper to investigate the systematic financial risk early warning mechanism of internal driving mechanism. The interaction of these influencing factors (the product interaction term in the econometric model) is used to identify the systematic financial risk on this basis.

A typical system model for the processing and analysis of highly nonlinear [12] and large-scale complex problems is [14] the system dynamics model [13]. We can simulate the real system and find the target problem's solution strategy by establishing a dynamic simulation model. The vast and multilevel structure of the financial ecosystem influences the structural change of systemic financial risk. Each level of risk in the systemic financial risk contains a large number of elements, which in turn make up the elements of the previous level of risk. Each level's elements are autonomous individuals who will have a diverse impact on the systemic financial risk associated with the activities. As a result, the systematic financial risk evaluation model in this paper is built using Vensim software and is based on the idea of a system dynamics model.

2. Related Work

Because systemic financial risk has such a large impact on a country's financial security and even global financial stability, it has piqued academic interest. Systemic financial risk, for example, is defined as the risk that the entire financial system will collapse or cease to function. This intuitive definition, on the other hand, is very unfavorable for measuring and analyzing systemic risk, particularly for the development of macroprudential supervision, which has drew scholars' attention. A comprehensive study on the measurement and early warning of systemic risk has been published in [15], but few scholars have looked at the overall study of systemic risk in China [16]. It was confirmed that there is a systemic risk spillover effect in listed commercial banks in China, especially during the crisis, by measuring the fluctuation of stock prices of 12 listed banks in China and constructing a quantile regression model. Literature [17, 18] further points out that there is a direct positive correlation between the size of banks and their risk contribution and negative externalities, and the magnitude and direction of risk spillover effects have an important influence on the stability of the financial system. Literature [19] holds that systemic financial risks will seriously damage the operational ability of the financial system, and it is difficult for the financial system to maintain stability. Its fragile characteristics will affect economic growth and social welfare and even threaten the whole financial system and macroeconomic stability. Literature [20] holds that systemic financial risk will lead to a wide range of financial service failures, resulting in partial or total losses of the financial system, and then the risk of serious impact on the real economy.

The structured method, which uses data from financial statements such as balance sheets of financial institutions to calculate the joint impact distribution of crises and then measures financial risks on that basis, is the most widely used of the major international financial risk measurement methods. Literature [21] uses quantile regression technology to calculate the systemic risk of the entire financial sector under the assumption of a single bank asset loss. According to [22], the financial stress index can measure the degree of potential risks faced by financial markets, making it the explained variable of the degree of systemic financial risks, while other leading indicators of financial risks are explained variables of systemic financial risks. Literature [23] assumes that systemic financial risk is a one-time occurrence. If Y is used to represent the crisis variable, it can only take the values 0 or 1, indicating that the crisis has not occurred or has occurred, respectively, and X is the above-mentioned crisis influencing factor. Literature [24] investigates past crisis events, identifies leading indicators of the crisis, and establishes a threshold for each indicator, which is determined using the "noise-signal ratio" method. The research method based on tail risk probability was used in [25]. It used the extreme value measurement method to estimate the tail risk of China's financial market and used it as the basis for measuring systemic risk. Literature [26] uses the RMB foreign exchange market pressure index to study the release process and effect of pressure, while [27] uses the vector autoregressive model of regional Markov matrix transfer to study the systemic risk of China's financial market and provides an early warning for future risks.

3. Research Method

3.1. Analysis of Influencing Factors of Systemic Financial Risk

3.1.1. Macroeconomic Operation Risk. A good macroeconomic environment is required for the effective operation of the financial markets. The financial market's effectiveness will be hampered as the macroeconomic operating environment deteriorates, resulting in unsustainable financial market stability and the emergence of systemic financial risks. The quality of a country's macroeconomic environment is influenced by the overall economic operation. The overall economic operation risk refers to the possibility that the economic operation deviates significantly from the equilibrium state. In practice, the degree of realization of macroeconomic development goals is often used to measure the overall economic operation risk. Therefore, the adjustment of industrial structure leads to the slowdown of economic growth, the difficulties of non-state-owned enterprises lead to the deterioration of employment environment, the internationalization of RMB aggravates the imbalance of international payments, and the inflation caused by high leverage will all have negative effects on the stability of financial order.

3.1.2. Financial Market Risk. On the one hand, financial market development can quickly and effectively guide the rational flow of funds and improve the efficiency of capital allocation; on the other hand, it has a pricing function, and financial market price fluctuation promotes financial innovation, increasing market volatility and bringing financial market risks while realizing risk dispersion and transfer. The stock market, credit bond market, and foreign exchange market are currently the most influential markets in China's financial market, and their risk characteristics are the most obvious. Although there has been no large-scale bond default in China's credit bond market in recent years, as the size of corporate credit bonds grows, the future debt repayment burden and pressure will grow, and the credit bond market's potential risks will intensify, posing systemic financial risks. The internationalization of the RMB, the opening of capital accounts, and the establishment of an offshore RMB market have brought the Chinese financial market and the international financial market closer together, and the risks of the international financial market have spread to the domestic financial market via a variety of channels. Therefore, financial market risk includes three dimensions: stock market risk, credit bond market risk, and foreign exchange market risk.

3.1.3. Financial Institution Risk. Financial institutions are an important part of the main body of financial ecology. Although financial innovation has given birth to diversified new financial institutions, at present, banks, securities, and insurance are still the most important financial institutions in China, and their risk levels and risk contagion among them play a vital role in the fluctuation of systemic financial risks. The risk contagion among financial institutions has contributed to the outbreak and spread of systemic financial risks. Therefore, financial institution risk is a collection of bank risk, securities risk, and insurance risk.

3.1.4. Risks of Nonfinancial Enterprises and Residents. The study of systemic financial risks should not be limited to financial institutions, financial market risks, or risk agglomeration and diffusion in the financial industry. To expand the research radius of systemic financial risks, we should pay close attention to all types of risk factors exposed in the development of nonfinancial enterprises and residents' consumption, as well as the transmission of risk factors to the financial industry.

3.2. Construction of Systematic Financial Risk Evaluation Index System. According to the definition and connotation of systemic financial risk, financial risk exists in different financial institutions or systems, so it is impossible to evaluate it by a simple method based on a single index data, but many factors must be considered. This paper selects the measurement index of systemic financial risk from four aspects: macroeconomic operation risk, financial market risk, financial institution risk, and financial enterprise and resident risk. The evaluation index is shown in Figure 1.

3.3. Construction of Systematic Financial Risk Evaluation Model Based on System Dynamics Model. The system dynamics model has obvious benefits when dealing with complex social system problems, particularly those that are nonlinear, are dynamic, and require low accuracy. The essence of the system dynamics model, from the standpoint of research thinking, is the concrete application of each theory in the research target field; from the standpoint of research, the system dynamics model is to bring various factors that affect the research objectives into the research framework and form a model for experiments.

3.3.1. Causality Diagram and Model Structure of Each Subsystem. To assess the systematic financial risk, we must first grasp its structure. Assume that the structural framework serves as the foundation for data classification and organization.

In this paper, the analysis of systemic financial risk is based on four primary risk indicators: macroeconomic operation risk, financial market risk, financial institution risk, and nonfinancial enterprise and resident risk. Therefore, this part is divided into four subsystems: macroeconomic risk subsystem, financial market risk subsystem, financial institution risk subsystem, and nonfinancial enterprise and resident risk subsystem to analyze the correlation among each subsystem (Figure 2).

3.3.2. Determination of All Levels of Weights of Systematic Financial Risk Evaluation Model from the Financial Perspective. Determining the reasonable index weight is very important to build a complete and scientific systematic financial risk evaluation model. At present, there are three main methods to determine the index weight:

(1) Subjective empowerment methods that are "function-driven" are highly dependent on experts' knowledge and experience, but the evaluation results can reflect the subjective preference of decision makers.
(2) The objective weighting method that is "difference-driven" determines weights by rigorous mathematical logic reasoning. Its main advantage is that it does not reflect the subjective color of decision makers but is based on the information characteristics of decision matrix.
(3) Integrated weighting method is present.

When comparing the first and second types of weighting methods, we can see that the objective weighting method relies on the system's mathematical and optimization theory, and it is extremely objective to deduce the weighting through rigorous mathematical deduction, but the weights obtained by this method are frequently contrary to the actual situation and difficult to explain, and this method is highly dependent on the selected model and data, and the weights obtained by different models are often quite different, lacking inheritance and order preservation. Although the outcome of the subjective weighting method is subjective and arbitrary, it is excellent in terms of explanation, inheritance, and maintaining order.

Therefore, this article also adopts the subjective and objective weighting method to ensure the reliability and authenticity of the weights: subjective weighting adopts the AHP (Analytic Hierarchy Process) method, and objective weighting chooses the CRITIC (Criteria Importance through Intercriteria Correlation) method.

Using AHP method, first of all, the relative importance of each factor to the target at the next higher level is assigned with 9-level Bipolar scale. For any target in the decision-making system, a judgment matrix is formed by pairwise

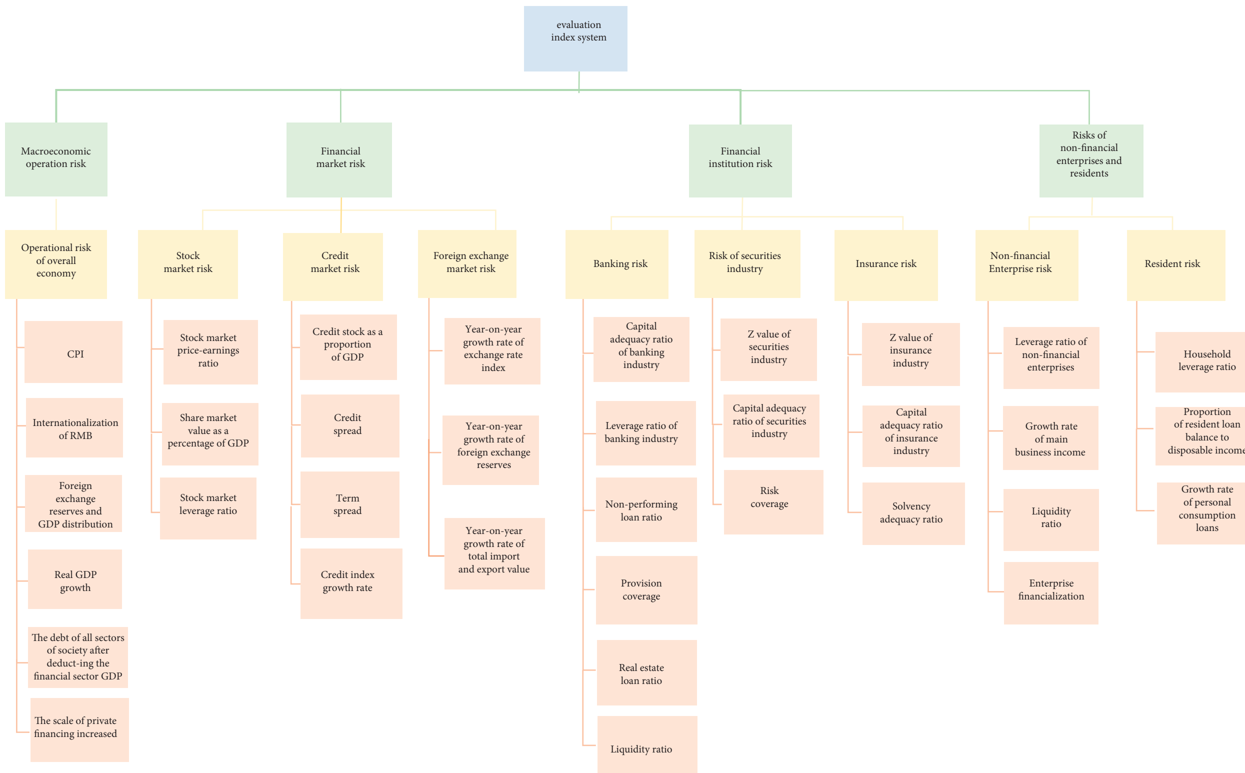

Figure 1: Systematic financial risk evaluation index system.

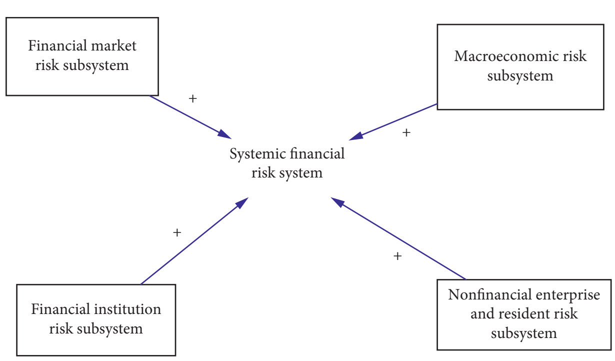

Figure 2: Structural diagram of systematic financial risk model.

judgment between the next level indicators. Take any first-level indicator A_i as an example, the corresponding number of second-level indicators is m, and b_{cd} is the importance ratio of the second-level indicators A_{ic} and A_{id} to A_i, then the judgment matrix expression is as follows, the importance meaning of b_{cd} value is as shown in Table 1, and $b_{cc} = b_{dd} = 1$.

$$c = (b_{cd})_{mm} = \left\{ \begin{array}{c} b_{11}\, b_{12} \ldots b_{1m} \\ b_{21}\, b_{22} \ldots b_{2m} \\ \ldots\ \ldots\ \ldots\ \ldots \\ b_{m1}\, b_{m1} \ldots b_{mm} \end{array} \right\}. \tag{1}$$

Secondly, the relative weight is calculated by the judgment matrix.

Step 1. calculate that product of elements in each row of the judgment matrix:

$$\mathrm{M}_c = \prod_{d=1}^{m} b_{cd} \quad c = 1, 2, \ldots, m. \tag{2}$$

Step 2. calculate the m-th root of M_c:

$$\omega_{ic} = \sqrt[m]{\mathrm{M}_c} \quad c = 1, 2, \ldots, m. \tag{3}$$

Step 3. carry out vector normalization on ω_{ic}:

$$\mathrm{W}_{ic} = \frac{\omega_{ic}}{\sum_{c=1}^{m} \omega_{ic}} \quad c = 1, 2, \ldots, m. \tag{4}$$

According to this method, $\mathrm{W}_{i1}, \mathrm{W}_{i2}, \mathrm{W}_{ic}, \ldots\ldots \mathrm{W}_{im}$ are the weight of each secondary index to its primary index A_i, and the subjective weight coefficient of each index is obtained by analogy.

In order to ensure the rationality and correctness of the obtained feature vector, consistency test should be carried

Table 1: Grade 9 Bipolar scale assignment table.

Scale	Meaning
1	c and d are equally important.
3	Compared with indicator d, indicator c is slightly more important.
5	Compared with indicator d, indicator c is more important.
7	Compared with indicator d, indicator c is particularly important.
9	Compared with indicator d, indicator c is extremely important.
2, 4, 6, 8	The intermediate value of the above adjacent judgment.
Reciprocal of the above scale	The importance ratio of c to d is b_{cd}, and then the importance ratio of d to c is $1/b_{cd}$.

out. When the test is passed, the feature vector can be used as the weight vector; otherwise, the judgment matrix should be reestablished or corrected.

Consistency test formula:

$$CR = \frac{CI}{RI}. \quad (5)$$

When $CR < 0.1$, it is considered that the consistency test of the judgment matrix has passed.

Among them,

$$CI = \frac{(\lambda_{\max} - n)}{(n-1)}. \quad (6)$$

$\lambda_{\max}$ is the largest characteristic root; RI is a random consistency index, and the values are shown in Table 2.

Diakoulaki (1995) proposed the CRITIC method, which uses contrast strength and conflict between evaluation indexes to determine the objective weight of evaluation indexes. Standard deviation is used to measure the intensity of the contrast between indicators, while the correlation coefficient is used to describe the conflict. CRITIC-based weighting indicators frequently have two distinguishing features: first, data fluctuation has a significant impact on the weighting; and second, data are frequently related. To assign objective weights to indexes, this paper employs the CRITIC method.

G is defined as the amount of information in the systematic financial risk evaluation system. Then, for any first-level index A_i, the information content of the corresponding c-th second-level index A_{ic} is

$$g_{ic} = \sigma_{ic} \sum_{d=1}^{m} (1 - r_{cd}), \quad c = 1, 2, 3 \ldots\ldots m, \quad (7)$$

where σ_{ic} is the standard deviation of A_{ic} and r_{cd} is the correlation coefficient between A_{ic}, A_{id}, so $\sum_{d=1}^{m} (1 - r_{cd})$ can represent the conflict between indicators.

The larger the g_{ic}, the more information it contains, and the higher the corresponding weight. Therefore, the objective weight φ_{ic} of g_{ic} is calculated as follows:

$$\varphi_{ic} = \frac{g_{ic}}{\sum_{c=1}^{m} g_{ic}} \quad c = 1, 2, 3 \ldots\ldots m. \quad (8)$$

According to this method, the objective weight coefficients of indicators at all levels are obtained.

The measurement of systemic financial risk index is, in the final analysis, the measurement of risk index in four aspects: financial market, financial institutions, nonfinancial enterprises and residents, and overall economy. At the same time, the overall level of systemic financial risk can be obtained by synthesizing according to their respective weight proportions.

4. Results Analysis and Discussion

4.1. Determination of Data Source and Initial Value of Model. Part of the original data and information in this model comes from reputable public databases like the China Statistical Yearbook and wind, while the rest comes from official websites like the IMF and the People's Bank of China. Because the most recent China Statistical Yearbook is the 2020 Yearbook, with data up to 2019, the evaluation period for systemic financial risk in this paper is 10 years, from 2010 to 2019.

As the table function value, take the growth of each three-level index from 2010 to 2019. Before using the model for evaluation, dimensionless treatment of the data of three-level indicators should be performed in order to make the data more comparable. According to formula (8), indicators with a positive correlation with secondary targets are positively dimensionless, whereas indicators with a negative correlation with secondary targets are inversely dimensionless (9).

$$x' = \frac{x - \min(x)}{\max(x) - \min(x)},$$
$$x' = \frac{\max(x) - x}{\max(x) - \min(x)}. \quad (9)$$

Take the weight of each index as the ratio constant of the model. The index weights of all levels in the model are weighted by AHP method with subjective weighting and CRITIC method with objective weighting, respectively.

4.2. Model Test Result Analysis

4.2.1. Consistency Test Result. Consistency test is carried out on the judgment matrix of indicators at all levels of systemic financial risk, and the test results are shown in Table 3.

From Table 3, it can be seen that the judgment matrices of decision-making objectives at all levels of systemic financial risk have passed the consistency test. AHP is effective in empowering.

Table 2: Numerical value of random consistency index *RI*.

Order	1	2	3	4	5	6	7	8	9	10
R.I.	0	0	0.58	0.9	1.12	1.24	1.32	1.41	1.45	1.49

Table 3: Consistency test result.

Index	Judgment matrix order	Maximum characteristic root $\lambda_{\max}$	Consistency index *CI*	Average random consistency index *RI*	Consistency index *CR*	Have you passed the consistency check?
Financial market risk	3	3.006	0.003	0.58	0.005	Pass
Financial institution risk	3	3	0	0.58	0	Pass
Nonfinancial enterprises and residents' risk	2	2	0	0	0	Pass
Overall economic risk	6	6.289	0.058	1.24	0.047	Pass
Stock market risk	3	3	0	0.58	0	Pass
Foreign exchange market risk	3	3.018	0.009	0.58	0.015	Pass
Credit market risk	4	4.088	0.029	0.9	0.032	Pass
Banking risk	6	6.11	0.022	1.24	0.018	Pass
Insurance risk	3	3.009	0.005	0.58	0.009	Pass
Risk of securities industry	3	3	0	0.58	0	Pass
Nonfinancial enterprise risk	4	4.072	0.018	0.9	0.020	Pass
Resident risk	3	3.014	0.007	0.58	0.012	Pass

4.2.2. Model Operation Inspection. The Vensim software includes a model checking tool that checks the model for mechanical errors in equations, variables, and dimensional units. Nonstructural and logical surface errors, such as unit mismatch at both ends of the equation and negative stock variables, are referred to as mechanical errors. The system of financial risk equations from the perspective of financial ecology has passed the mechanical error test, and the model can run as a result of testing and adjustments.

4.2.3. Model Authenticity Test. Comparing historical data with model simulation data, if the error between them is less than 10%, the model simulation value is considered to be valid, which is also called historical test. In this paper, four common indicators such as CPI, the growth rate of social financing scale, the share of stock market value in GDP, and the rate of nonperforming loans in the banking industry are selected as the test variables, and the test time is from 2010 to 2019. The inspection results are shown in Figures 3–6. The error between the model simulation value and historical data is less than 4%. The model has passed the authenticity test, and the model simulation is effective.

4.3. Analysis of the Evaluation Results of Systemic Financial Risk. We can construct an evaluation index describing China's systematic financial risk after determining the weight of the systematic financial risk evaluation index. We must not only grasp the state of financial risks as a whole, but also analyze the state of financial risks in each submarket in order to objectively and comprehensively assess China's systemic financial risks.

Systemic financial risks, structurally speaking, are ubiquitous and exist in various markets within the system, thus encompassing all aspects of systemic risks, in which submarkets are interconnected and form systemic financial risks. Overall, systemic financial risk is an evolving process, and the state of each stage will change as well, providing a description of the previous state as well as a hint of future development trends. As a result, an objective assessment of the state of systemic financial risk is required. Figures 7–12 depict the change trend of the systemic financial risk index.

First and foremost, based on the overall trend, other submarkets, in addition to financial institutions, are becoming increasingly risky. The pressure levels of macroeconomic operation risk, financial market risk, and nonfinancial enterprise and resident risk are all relatively close, and the risk trend is from low to high. The risks of nonfinancial enterprises and residents, as well as macroeconomic operation risks, are relatively stable in the early stages of the samples chosen in this paper, but they all show a one-way increasing trend in the later stages.

Second, from the standpoint of internal structure, each subrisk market's indexes are interconnected and collectively reflect systemic financial risks. We can see that financial institution risks are closely related to China's asset economy and that banks' credit business has always had a significant impact on China's stock market and has become a significant source of systemic financial risks, by analyzing the financial risk measurement results of financial institution risks. The risk of financial institutions has been fluctuating, and speculation is extremely dangerous. International hot money, influenced by the external market, has a constant impact on the domestic

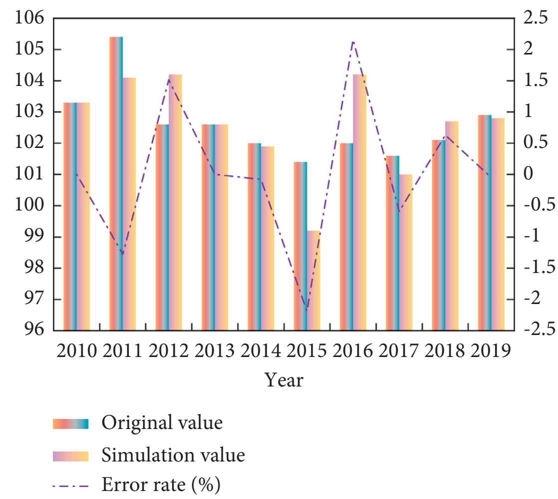

Figure 3: CPI authenticity test result.

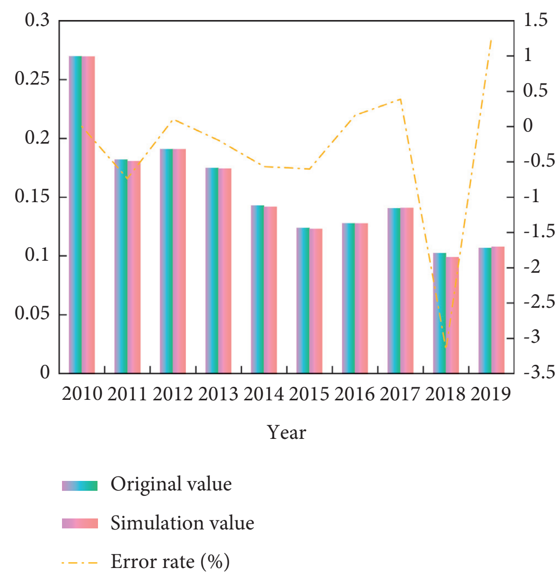

Figure 4: Truthfulness test results of social financing scale growth rate.

banking industry and stock market, and banks' rising financial risk drives the domestic stock market's rising financial pressure.

Then, from the perspective of fluctuation characteristics, there are significant differences in risk indices of each submarket. From 2010 to 2019, with the continuous promotion of interest rate marketization, the fierce competition among major banks increased the competition cost of small and medium-sized banks, and then the "money shortage" problem also highlighted the short-term liquidity problem faced by the banking system, which made the risk level of financial institutions improve in 2012. In terms of macroeconomic operational risk, the macroeconomic operational risk has increased to a certain extent. From these figures, it can be observed that the risk of nonfinancial enterprises and residents in China has been rising almost all the time from 2010 to 2019. On the whole, the financial risk fluctuation of financial institutions in China is not great.

5. Conclusions and Suggestions

5.1. Conclusion. This paper establishes China's systematic financial risk evaluation model, based on the system dynamics model, and selects four dimensions: financial market, financial institutions, nonfinancial enterprises and residents, and overall economy. As the foundation for the development of China's comprehensive financial risk index model AHP and CRITIC are chosen on this basis to determine the index weights of submarkets and the weights of each submarket, in order to synthesize and comprehensively reflect systemic financial risk and each market's risk index, which is used to describe its state. The following is the final conclusion:

(1) The level of systemic financial risk is always greater than 0, indicating that China's financial system as a whole is in a moderate financial risk state, as determined by the identification and analysis of China's systematic financial risk index.

(2) The systematic financial risk index from 2010 to 2019 is calculated using the CRITIC and AHP weighting methods. The findings show that financial institutions, financial markets, nonfinancial enterprises and residents, and macroeconomic operations, all play a role in China's financial risk index fluctuation. There are some systematic correlations, but there are also some differences between submarkets.

(3) There are significant differences in risk indices of each submarket in terms of fluctuation characteristics. The risk of macroeconomic operation increased to some extent between 2010 and 2019. In general, the financial risk fluctuation of Chinese financial institutions is not significant.

5.2. Policy Advice. Continue to encourage high-quality economic growth. Economic development of high quality is the only way to keep systemic financial risks at bay. We can only optimize the allocation of financial resources and resolve financial risks if we continue to promote high-quality economic growth.

Intensify the financial industry's "penetrating" supervision. "Penetrating" supervision is based on the principle that substance is more important than form, and it entails delving deeply into the true identity of financial market subjects behind financial activities, as well as identifying the transaction essence hidden beneath the formal cloak of complex financial products, in order to conduct targeted and deep supervision and adjustment of financial activities using effective supervision tools. "Penetrating" supervision can elucidate the logic of financial behavior, investigate the source of financial risks, and aid in the systematic prevention of financial harm.

Focus on nonfinancial enterprise risks, as well as preventing and controlling risks in resident departments. It is critical to limit the deviation from reality; reducing leverage is essential, and improving enterprise competitiveness is critical.

Physical education is a highly skilled education offered in colleges and universities. Teachers do not appear in front of inanimate machines as laborers, and they are not the same as gardeners who grow colorful trees, according to their essential characteristics. Their work is aimed at flesh-and-blood students who are sentimental, thoughtful, and engaged in critical thinking. As a result, schools should prioritize physical education and place a premium on emotional infiltration education, improve learning interest, improve teacher-student relationships, create a harmonious teaching environment, and improve teaching quality; it has a significant impact on an individual's entire life. The modern educational process places a premium on the transmission of rational knowledge while overlooking the accumulation of emotional experience. The cultivation and development of emotional feeling ability, emotional expression, and expression ability receive less attention than the training and improvement of language, concept, logic, and reasoning abilities. Emotion feature clustering is used to propose an emotion recognition method in this study. This method generates extended features for classification by constructing a co-occurrence matrix based on the co-occurrence relationship of emotion features and then by applying the spectral clustering method. The binary value of whether emotional features of emotional education in college physical education appear in a particular cluster is then expressed as a feature and extended to the original training feature set, alleviating the problem of sparse features.

1. Introduction

In contemporary universities, there will be such a situation, that is, students who are active in the playground will be stronger than those who lack physical exercise, which has to cause concern in schools. Physical education in colleges and universities is a highly skilled education. Its essential characteristics determine that teachers do not appear in front of inanimate machines as laborers and are different from gardeners who cultivate colorful trees. Their work targets young students who are full of flesh and blood, sentient, thoughtful, and active in thinking. This determines that schools should play a leading role in physical education and attach importance to and implement emotional infiltration education [1]. According to modern psychology theory, the factors that affect students' learning include not only their intelligence factors but also non-intelligence factors such as emotion and will. This non-intelligence factor can lay a good psychological foundation for a person's socialization and meet his psychological needs [2]. In the past, physical education in colleges and universities mainly focused on competitive minority sports, but now our requirements should develop into popular sports of art and ecological sports so that sports can become a necessity for people to survive. Therefore, in college physical education, physical education teachers should add emotional education instead of simply teaching physical education [3], improve interest in learning, harmonize the relationship between teachers and students, form a harmonious teaching atmosphere, and improve teaching quality, which even has an important influence on his whole life. The modern educational process emphasizes the imparting of rational knowledge and neglects the accumulation of emotional experience. Emphasis is placed on the training and improvement of language, concept, logic, and reasoning ability but less on the training and development of emotional feeling ability, emotional expression, and expression ability [4, 5]. This educational model ignores people's emotional characteristics, cannot meet people's different emotional needs, cannot stimulate and regulate people's emotional mechanism, and cannot say it has a profound impact on people's emotional aspects.

The method of emotion recognition proposed in this study is based on emotion feature clustering. This method generates extended features for classification by constructing a co-occurrence matrix based on the co-occurrence relationship of emotion features and then by using the spectral clustering method. Because the training dataset for the learning method of emotional feature clustering is small, there may be an emotional education situation in college physical education where the features in the test dataset do not appear in the training dataset, resulting in unsatisfactory classification results [6, 7]. To put it another way, the sparsity of this feature distribution has an impact on emotion classification accuracy. To complete the final emotion classification, the two classifiers collaborate. The method proposed in this study is based on the following basic assumption: in college physical education with similar emotional tendencies, emotional words of emotional education have a high probability of appearance in consumer comments with similar emotional tendencies; these "similar" emotional features can then be clustered based on their co-occurrence relationship in comments [8, 9]. The goal of image retrieval based on emotional semantics is to investigate the emotional analysis of emotional education features in college physical education, to describe and extract these features in a way that is appropriate for people's psychological reactions to the features, and to cluster the emotional features [10].

The emotion recognition algorithm based on emotion feature clustering is based on an observation: words or phrases of emotional education in college physical education with the same emotional tendency are more likely to appear in the same product comments [11, 12]. For example, in general, the probability of "very good" and "perfect" appearing in the same comment with a favorable emotional tendency is higher than that of "very poor" and "perfect" appearing in a comment together [13]. By using the emotional characteristics of emotional education in college physical education with unlabeled emotional category data to cluster the emotional characteristics, the number of available clusters is limited [14]. Then, at this time, the binary value of whether the emotional features of emotional education in college physical education appear in a certain cluster is expressed as a feature and extended to the original training feature set, which can alleviate the problem of sparse features. Emotion recognition algorithm does not depend on the specific mathematical description, has good global complex combination optimization ability, and has penetrated into many fields, such as coloring problem, vehicle route planning problem, and so on [15].

2. Related Work

Literature [16] puts forward that in college physical education, emotional educators enthusiastically carry out educational activities, induce and stimulate the positive emotion and positive attitude of the educatees in the process of education, make them in the best state of psychology, and regard the emotional cultivation of the educatees as one of the objectives of education. In literature [17] through the big data analysis method, in college physical education teaching, if physical education teachers can grasp students' inner feelings and use their own cultivation to adjust students' psychological trends and inner needs, they will shorten the psychological distance with students, produce a good classroom atmosphere, and achieve the desired teaching effect. Literature [18] shows that in order to implement emotional education in college physical education, teachers are required to invest in teaching with positive and full enthusiasm and good personal image; second, we should be good at using various methods and means to induce, motivate, and coordinate students' emotions. Literature [19] proposed that foreign research on text emotion recognition began in the 1990s. In text emotion analysis, researchers found two very interesting phenomena: first, emotional words with opposite tendencies generally do not appear together; second, emotional words with the same tendency often appear at the same time. In literature [20] through the big data analysis method, the professional norms of physical education teachers are highly intuitive, and their words, deeds, and emotions are very easy to have an impact on students. Literature [21] shows that the biggest feature of physical education teaching is to pay attention to physical activities. Physical education teachers' treatment methods and means of various classroom behaviors reflect their own educational wit and professional cultivation. Literature [22] puts forward that the semantic inclination of each sentence in the text can be obtained by weight first calculation method, emotional education is discussed on the combination of emotional words in college physical education, and the concept of the headword is put forward to calculate the inclination of words, which lays a foundation for more complicated emotional analysis of the text. In literature [23] through the big data analysis method, physical education teachers in colleges and universities should make full use of the advantages of disciplines in emotional education, pay attention to active and healthy emotional communication with students, win the respect and cooperation of students, and obtain the best educational effect. Literature [24] shows that the grades of praise and disapproval in college physical education can be divided into three categories (positive emotion, negative emotion, and neutral emotion) by star rating index, and the polarity classification of emotional education in comment text is completed by using the experimental algorithm using three classification methods, among which the method of the support-vector machine gets higher accuracy. Literature [25] puts forward a method of semantic correlation field based on two semantic tendencies of emotional word dictionary as the calculation basis of emotion classification.

Emotional education in college physical education is investigated in this study. Based on an emotional feature clustering algorithm, words or phrases with similar emotional connotations are more likely to appear in the same product review. In general, the likelihood of "very good" and "perfect" appearing in the same comment with a commendatory emotional tendency is higher than the likelihood of "very poor" and "perfect" appearing in the same comment with a disparaging emotional tendency. This study believes that if we can cluster these emotional characteristics based on their co-occurrence relationship, it will be beneficial to emotional education in college physical education.

3. Emotion Recognition Algorithm and Model Based on Emotion Feature Clustering

The emotion recognition algorithm of emotion feature clustering needs to label the data manually, which may require a lot of manpower and time. This is the most difficult and challenging work in the emotion recognition algorithm system. This study uses emotion feature clustering college physical education as the research object and considers the influence of different weights of interested and non-interested regions of emotional education on feature extraction. However, how to make users interactively select eigenvalues and set the weight of eigenvalues is a problem worthy of discussion. The emotion classification method of emotion recognition algorithm based on emotion feature clustering only needs to manually label a small amount of training data and then uses a large number of data without labeling the categories of emotion to train the learner, so as to classify consumer comments of unknown categories of emotion. This study selects 600 pictures in emotional education in college physical education as the original dataset, that is, the research object. The emotion analysis steps of analyzing emotion feature clustering are shown in Figure 1.

There is only a small amount of training data in the training dataset of emotion analysis of emotion recognition algorithm, so it may happen that the features in the test dataset do not appear in the training dataset, which may lead to unsatisfactory classification results. That is to say, the sparsity of feature distribution will affect the accuracy of emotion analysis. Emotional feature clustering based on the partition is the most widely used clustering. Its purpose is to divide the dataset into several subsets, that is, given a dataset with n tuples or records, k groups are constructed, and each group represents a cluster (for a given k, we can give an initial grouping method and then change the grouping through repeated iterations, so that the grouping scheme after each improvement is better than the previous one). This study describes the basic block diagram of the emotion recognition algorithm with divided emotion features, in which there are various methods in the first three steps, and different emotion recognition algorithms with divided emotion features can be obtained through combination, as shown in Figure 2.

The partition method is to divide n objects in set u into a given K subset so that the object similarity in the same set is high, while the object similarity in different sets is low. The definition of similarity is the key to division. Generally, it defines the objective function in the form of a formula and uses the heuristic method to minimize the value of the objective function.

$$J = \frac{1}{N} \sum_{K=1}^{K} \sum_{n=1}^{N} u_{nk} d^2 \left(\bar{x}_k - x_n\right), \tag{1}$$

where j is the sum of the mean square deviations of all objects in the set U and the corresponding cluster centers, xn is a data object in the space representing the objects, and x_k is the mean value of the cluster C_k. The formula of clustering standard aims to make the obtained clusters have the following characteristics: each cluster itself is as compact as possible, and each cluster is separated as much as possible.

The basic idea of emotion analysis based on emotion feature clustering and emotion recognition algorithm is briefly introduced: data are regarded as emotion analysis with different attributes, and the cluster center is the "emotion source" that emotion analysis is looking for, so the data clustering process can be regarded as the process of emotion analysis looking for emotion. It is assumed that the data object is $x = \{\text{xi} \mid \text{xi} = (\text{xi1, xi2, ..., xim}), I = 1,2,3, \ldots, n\}$. First, the algorithm is initialized. The pheromone $\tau(\text{O}) = 0$ of each path is set to O, and the parameters such as cluster radius R, statistical error ε, and representative object M are set. The weighted Euclidean distance dij between objects Xi and Xj is calculated, and the pheromones on each route are calculated as follows:

$$\tau_{ij}(t) = \left\{ \begin{pmatrix} 1, d_{ij} \leq r \\ 0, d_{ij} > r \end{pmatrix} \right. . \tag{2}$$

The probability formula for merging objects Xi into XJ is as follows:

$$P_{ij} = \frac{\tau^a ij(t) \eta^\beta ij(t)}{\sum_{s \subset S} \tau^a sj(t) \eta^\beta ij(t)}, \tag{3}$$

where $S = \{x_s | d_{sj} \leq R,\ s = 1,\ 2,\ \ldots,\ J,\ j+1, \ldots,\ n\}$. If PIJ (T) is greater than the threshold P_0, X_i is merged into the domain of X_J. Among the above clustering methods, the representative object m has a great impact on the operation efficiency and clustering results, and there are many selection methods of representative objects. Different methods can be tried according to the situation to avoid the algorithm falling into local optimization. Although the number of clusters does not need to be given in advance, the scale of clustering is limited because the cluster radius is preset.

The cluster centers of these two clusters are calculated according to the following formula, where n_1 is the number of samples in cluster A1 and n2 is the number of samples in cluster A2.

$$\bar{A} = \frac{1}{n_1} \sum_{k=1}^{n_1} X_k \left(X_k \in A_i\right) (i = 1, 2). \tag{4}$$

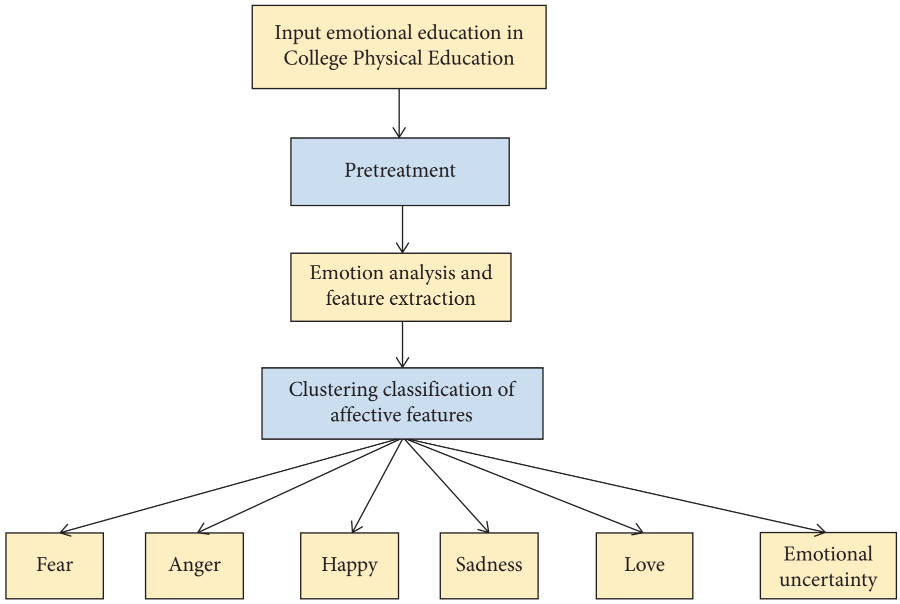

Figure 1: Flowchart of emotion feature clustering emotion recognition algorithm.

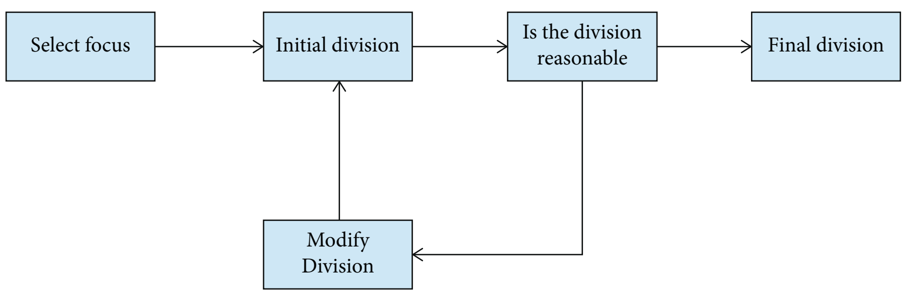

Figure 2: Framework of emotion recognition algorithm for emotion feature clustering.

After clustering, the distance between any two adjacent classes is calculated according to the clustering center of each class. If the distance between classes is less than the threshold value ε, the two categories are merged and the cluster center is updated at the same time. The distance between two classes is defined as the distance between the nearest two samples X and Y in two classes s and V.

$$d(S, V) = \min(d(x, y), x \in S, y \in V). \tag{5}$$

If we use emotion feature clustering in unlabeled emotion category data to cluster emotion features, the number of available clusters of emotion recognition algorithms is limited. The presence of an emotion feature cluster in the cluster of an emotion recognition algorithm is then expressed as a feature and extended to the original training feature set, alleviating the problem of feature sparseness.

Emotional feature clustering is a model that considers the probability relationship between physical and emotional education before and after college. It depicts the text's word sequence relationship. As a result, it is widely used in a variety of emotional recognition problems, including text word segmentation, automatic input, part of speech tagging, machine translation, and so on. In simple terms, the emotion feature clustering emotion recognition algorithm model counts the likelihood of a sentence or word sequence.

$$P(W_1, W_2, \ldots W_K), \tag{6}$$

where W represents each word, and k represents the length of the word sequence. We borrow the knowledge of the conditional probability of probability theory.

$$P(W_1, W_2, \ldots, W_K) = P(W_1)P(W_2|W_1)\ldots P(W_K|W_1, W_2, \ldots, W_{K-1}). \tag{7}$$

But if the length of k is too long, the word sequence modeling needs a very complicated model. Therefore, in engineering implementation, an approximation is often needed. Common methods include the n-gram model, maximum entropy model, conditional random field model, neural network model, and so on.

Affective feature clustering is one of the most used statistical affective feature clustering affective recognition algorithm models. The n-gram model is also known as the n-1-order Markov model. It is based on Markov's conditional hypothesis, that is, the probability of the current word is only related to the probability of the previous n-1 word.

$$P(W_K|W_1, W_2, \ldots, W_{K-1}) \approx P(W_K|W_{K-N+1}, \ldots, W_{K-1}). \tag{8}$$

Therefore, the probability of word sequence is approximately

$$P(W_1, W_2, \ldots, W_K) \approx \prod_{l=1}^{K} P(W_1|W_{l-n+1}, \ldots, W_{l-1}). \tag{9}$$

When the value of n is 1, 2, and 3, the corresponding emotion feature clustering emotion recognition algorithm models are called unigram, bigram, and trigram models, respectively. With the increase in grammar order, the model is more complex, so it is necessary to select the appropriate order in a specific application. The parameter estimation of the n-gram model generally uses maximum likelihood estimation (MLE).

$$P(W_l|W_{L-N+1}, \ldots, W_{l-1}) = \frac{\mathrm{Cont}(W_{l-n+1}, \ldots, W_1)}{\mathrm{Count}(W_{L-n+1}, \ldots, W_{l-1})}. \tag{10}$$

4. Application of Emotional Education in College Physical Education Based on Characteristic Clustering to Development

4.1. Emotional Education in College Physical Education Based on Emotional Feature Clustering. The emotion recognition algorithm of feature clustering is the sensory experience and reaction of people to emotional education in college physical education and the psychological stress state caused by the stimulation of external things to people's brains. Generally speaking, emotions include positive and negative, and each of them may contain rich content. In many cases, they are connected, and the community is now in people's reactions to external things. Physical education teachers and students are two sources of emotional analysis in physical education teaching. The greatest feature of physical education is to attach importance to physical activities, and the ways and means of dealing with various classroom behaviors by physical education teachers reflect their own educational wit and professional accomplishment. In the process of physical education, infiltrating the necessary emotional education can help college students learn respect, tolerance, friendliness, and self-confidence, cultivate collectivism and perseverance, and contribute to the formation of college students' good personalities. Any sport can show the strength, speed, dexterity, and vitality of human body and show the beauty of form and soul. Infiltration of emotion recognition education in physical education can help college students understand and appreciate this beauty, broaden their aesthetic vision, and promote their esthetic pursuit, thus forming a good esthetic taste. The emotion recognition algorithm of feature clustering is applied to emotional education in physical education in colleges and universities. Combined with the research results of modern educational information technology, volleyball teaching theory and methods and other aspects of emotion recognition algorithm, theoretical analysis, and experimental research are carried out in order to solve the one-sidedness of conventional teaching to cultivate students and further explore the influence of this emotion analysis on students' learning interest and academic achievement. Physical education teaching in colleges and universities is mostly in a relaxed environment, and many routine sports events are included in the teaching content, which broadens the vision of college students' sports knowledge, enriches their spare-time activities, and is conducive to stimulating and cultivating college students' emotional analysis of novelty, happiness, and satisfaction.

Physical education teaching characteristics determine that college students can gain a wide range of emotional analysis experience. For example, students will feel satisfied and happy after learning and mastering the fundamentals of sports movements; tension will arise during sports tests and competitive competitions; if you pass the test without difficulty or achieve good results in the competition, you will feel happy; and so on. Physical education teachers' professional norms are highly intuitive, and their words, actions, and emotions have a significant impact on their students. Individuals and classes receive physical education together in the process of physical education in colleges and universities, and physical activities necessitate competition. They often require mutual encouragement and assistance when competing as a team. They must learn to observe, unite, and love one another. It is simple to improve college students' collective reputation and friendship among peers, which is conducive to the development of a harmonious teacher-student and classmate relationship. The sports psychology, sports skills, and acceptance ability of students in college physical education differ. As educators, they should treat each student with respect and understanding, set different goals for them, use different methods and means to promote their progress, and encourage them to build confidence. As a result, physical education teachers should make full use of the subject's advantages in emotional education, pay special attention to positive and healthy emotional analysis, communication, and communication with students, earn students' respect and cooperation, and achieve the best educational effect possible. "Rational education" is the polar opposite of emotional learning.

This kind of education does not include emotional analysis into the feasible means of education. The emotional identification algorithm in emotional feature clustering regards the goal of knowledge imparting as the central position of emotional education, which is manifested in the indifference, distortion, and obstruction of students' emotional needs in the process of emotional education, the lack of normal emotional analysis and communication between teachers and students, the lack of vitality in emotional education activities, the inflexible form of emotional education, and the lack of initiative and interest of students. In the practice of physical education teaching in colleges and universities, college students need to bear certain sports load and overcome different degrees of difficulties. In this

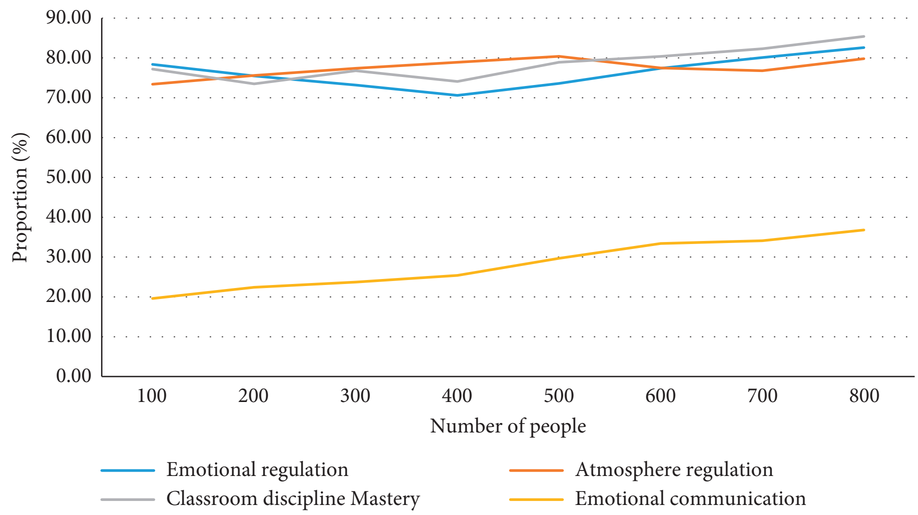

Figure 3: Proportion chart of emotional communication in college physical education.

process, college students can realize their own values and get different degrees of satisfaction, which will effectively enhance students' collective sense of honor. In college physical education teaching, we should not only cultivate students' action skills but also organize practice methods and logical thinking ability. It is also necessary to train students to have good learning psychological quality, personality quality, and esthetic quality, which are all indispensable and important components in professional emotion teaching. However, in the traditional teaching quality, action technology occupies the absolute center, and the factors of ability training are not given due attention, which has caused various defects and set up many obstacles to the implementation of quality education. Students have all kinds of emotional analysis experiences in their studies. Teachers must go deep into them and communicate with them in order to implement teaching more accurately. This is the emotional communication function of emotional education in physical education. As an activity requiring collective participation, the physical education class's teaching nature determines that students need to help and cooperate with each other in the course of class. During training, students are both practitioners and protectors of classmates, which can effectively cultivate students' sense of responsibility and obligation. A person's emotional experience is closely related to his life attitude, mental state, work efficiency, and intellectual potential, and it is an important part of his intelligence, personality, and thinking development. Emotion clustering is the driving force of the emotion recognition algorithm to catalyze college students' cognitive understanding, promote their moral level, and motivate students to make progress.

4.2. Analysis of Experimental Results. Physical education teachers should make full use of the advantages of the subject in emotional education, pay attention to positive and healthy emotional analysis, communication, and communication with students, win students' respect and cooperation, and obtain the best educational effect. The author conducted a questionnaire survey on the classroom behavior and influence of PE teachers on 600 college students of 2019 and 2020 in a university and made a statistical analysis, as shown in Figure 3.

One of them is emotional communication. Nearly 80% of students think that teachers do not communicate with them emotionally, there is emotional distance between teachers and students, and students stay away from teachers, which directly affect the teaching effect. Students have all kinds of emotional experiences in their studies. Teachers must go deep into them and communicate with them in order to implement teaching more accurately. This is the emotional communication function of emotional education in physical education, as shown in Figures 4–6.

Figure 4 shows that after the experiment, the experimental and control classes' interest in physical education emotional education showed significant differences, indicating that incorporating emotional teaching theory into the professional course of physical education emotional education in colleges and universities can improve students' interest in physical education. The reason for this is that applying emotional analysis teaching theory to professional physical education courses in colleges and universities meets students' direct physical education needs and stimulates their desire for sports. Students' direct sports needs refer to a desire to learn about or participate in a sport because it interests them. Figure 5 shows that the experimental and control classes significantly improved their technical evaluation results after the experiment when compared to the control class, and the difference is significant. It demonstrates that using emotional education theory in physical education classes is more conducive to mastering technical skills and improving the teaching effect of emotional analysis in physical education classes than traditional classes.

As can be seen from the statistical results in Figure 6, there is no significant difference between the students in the experimental class and the control class after the experiment. This shows that emotional teaching and conventional teaching methods in volleyball major courses in colleges and

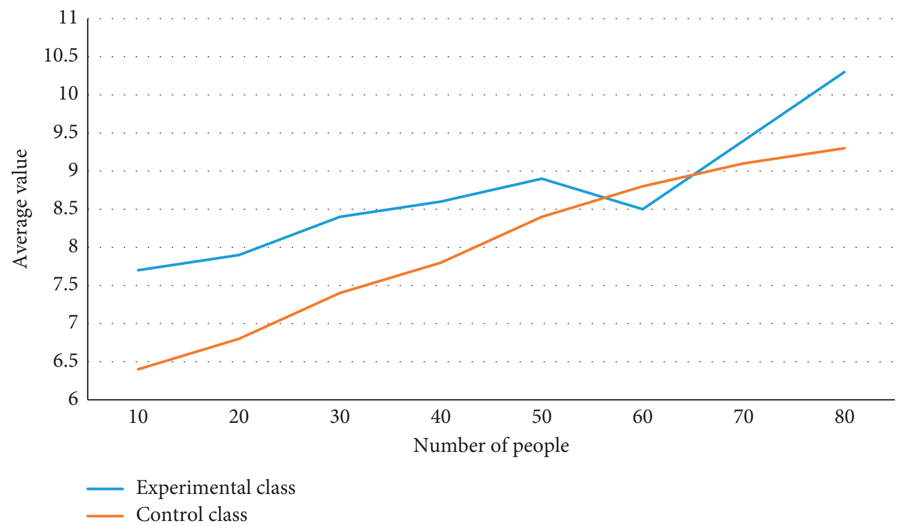

Figure 4: Comparison and analysis of comprehensive technical evaluation of emotional education technology in physical education (volleyball players).

Figure 6: Comparison and analysis of comprehensive technical evaluation of emotional education technology in physical education (sprinters).

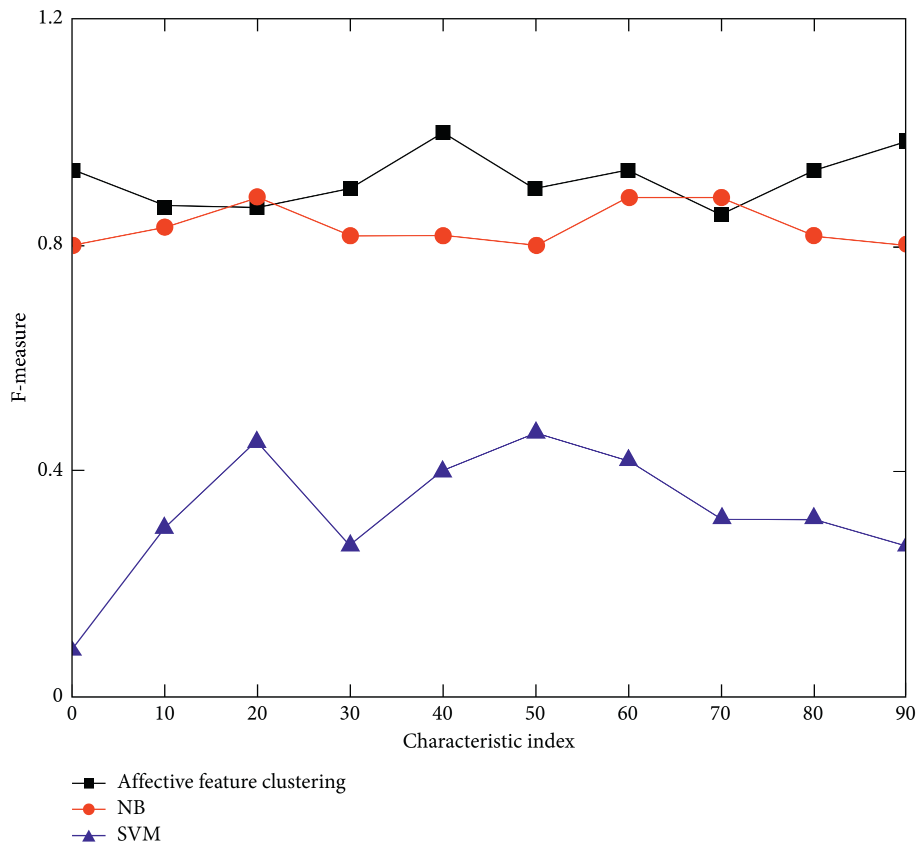

FIGURE 7: Recognition effect after emotional feature clustering (volleyball corpus).

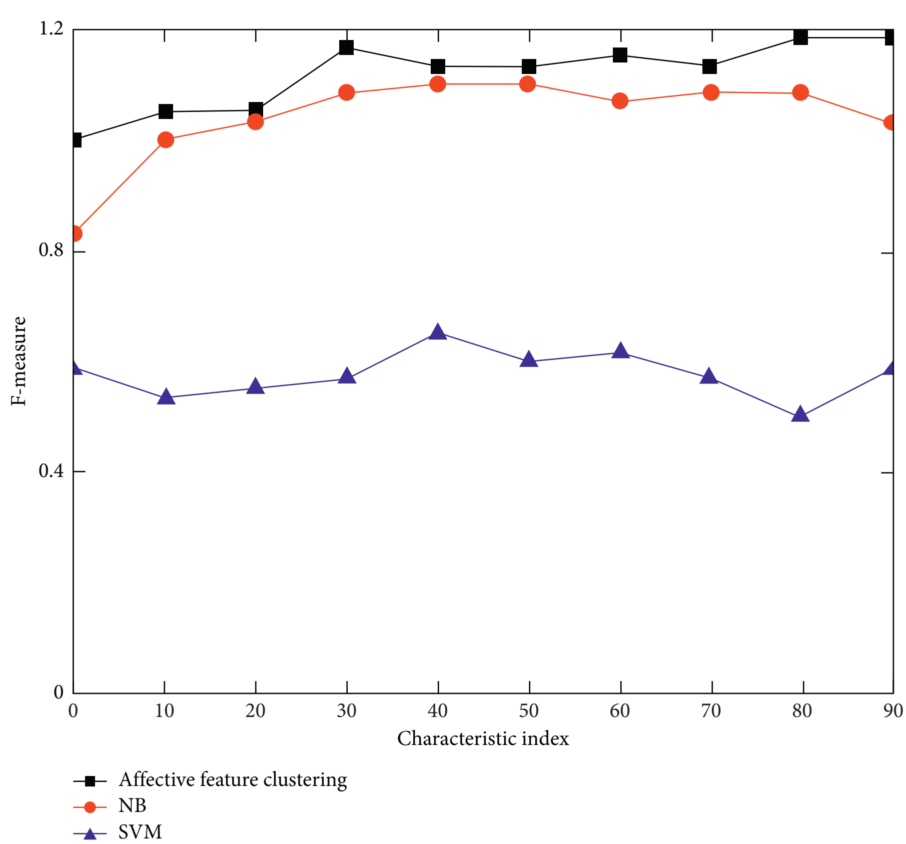

FIGURE 8: Recognition effect after emotional feature clustering (basketball corpus).

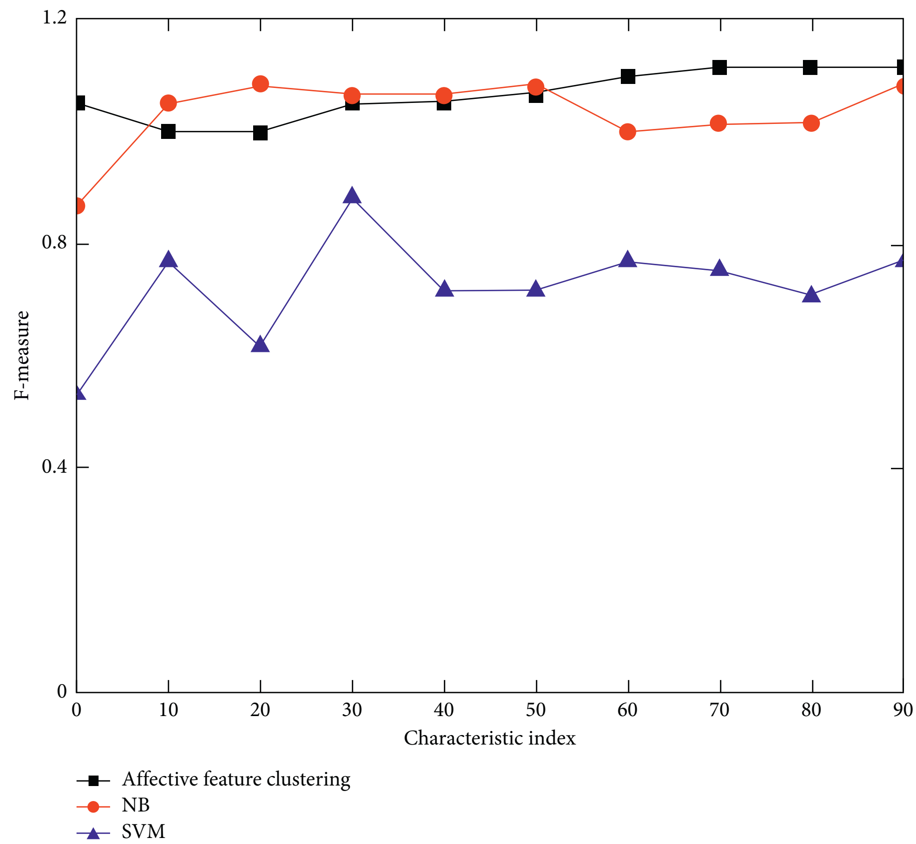

Figure 9: Recognition effect after emotional feature clustering (sprint corpus).

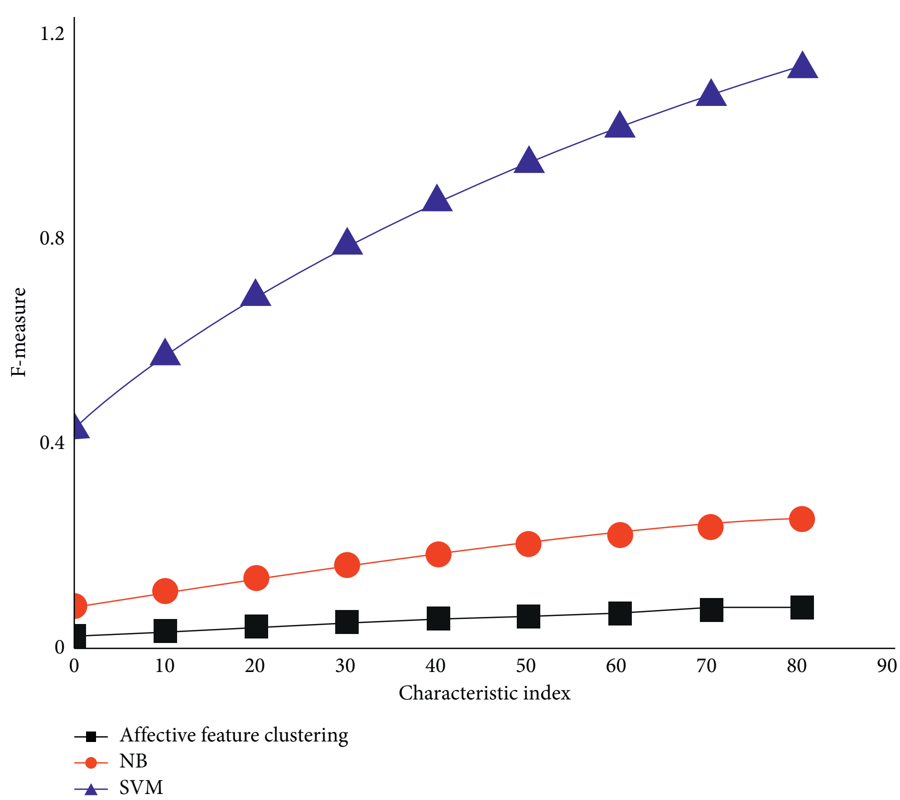

Figure 10: Recognition effect after emotional feature clustering (table tennis corpus).

universities have improved students' achievement to a certain extent. Compared with conventional teaching, emotional teaching does not significantly improve students' achievement in reaching the standard because the formation of motor skills is a long-term systematic and scientific learning and training process, and the level of students' achievement in reaching the standard is related to training time and training level. After we get the word vector, we use the similar characteristics of emotional feature clustering in emotional education in college physical education. We first use the emotional recognition method to divide all words into 500 categories, then use various labels to replace the corresponding words, and then classify the text emotional analysis. About 30% of the data are used as test data and the rest as training data. The classification results are shown in Figures 7–10.

Experimental results show that SVM still has a good classification performance. In the emotional education of physical education, the mixed feature classification of ternary grammar and TFIDF has the best effect. However, compared with the recognition rate in chapter 3, the overall recognition rate of text sentiment analysis using sentiment feature clustering results has declined. By analyzing the reasons, the biggest problem is that although Word2Vec quantifies the word direction and has good clustering characteristics, the use of clustering brings side effects of classification results: the fewer categories of emotional education in physical education in clustering will lead to the less accurate differentiation of features, for example, two words with far distance in the same category of emotional education in physical education may have more differences in meaning. Experiments have verified our conjecture, and our emotion recognition algorithm that expands the clustering category of emotional features will improve the success rate of emotional education in physical education. An extreme idea is that when each word is divided into a separate category, the classification results will be consistent with those in Section 3, that is, Word2Vec. Although the recognition rate of emotional education in physical education is not better, it also proves that the language model features and SVM classification method have higher recognition rates, and the network structure of emotional feature clustering also inspires us to use a neural network.

5. Conclusions

To summarize, physical education teaching characteristics determine that college students can gain a variety of emotional analysis experiences. For example, students will feel satisfied and happy after learning and mastering the fundamentals of sports movements; tension will arise during sports tests and competitive competitions; if you pass the test smoothly or achieve good results in the competition, you will feel happy; and so on. We focus on the implementation of formative evaluation in emotional teaching evaluation so that problems in the teaching process are brought to the attention of teachers and students right away, problems in teaching are remedied quickly, and students' learning errors are reduced. This study investigates emotional education in the context of college physical education. Based on emotional feature clustering, this study proposes improved methods for text features and classification algorithms using the original structure model. Before each clustering, the emotion recognition algorithm uses emotion feature clustering to calculate the two points with the smallest similarity as the starting cluster center. After clustering, the distance between each class is calculated, and the two classes with the shortest distance between them are combined. The goal of knowledge transfer is placed at the center of emotional education by the emotion recognition algorithm in emotion feature clustering. There is a dearth of standard emotion analysis and communication between teachers and students. Emotional education activities are devoid of vitality. Students lack initiative and interest as a result of the rigid nature of emotional education.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that there are no conflicts of interest.

The research on identifying college students' psychological crises can assist college administrators in better understanding of students' psychological changes and planning of intervention measures ahead of time to ensure college students' mental health. When confronted with unexpected events or major setbacks and difficulties, people experience psychological crises, which they can neither avoid nor solve using their own resources and stress methods. This paper proposes a method of college students' psychological crisis identification based on data mining technology to solve the problems that exist in the process of identifying psychological crises in college students and to improve the correct rate of identifying psychological crises in college students. In comparison to other technologies, data mining can uncover the link between students' psychological problems and their basic information, as well as the main causes of psychological problems, using statistical data.

1. Introduction

Psychological crisis refers to the serious psychological imbalance that individuals can neither avoid nor use their own resources and stress methods to solve when encountering unexpected events or major setbacks and difficulties [1]. Because of the differences in cultural background, family background, educational experience, individual development period, and personal experience, the situation of psychological crisis is not absolute. At the same time, each person's individual crisis varies with the change of time, place, event, and situation, and university students' psychological crisis identification has its own characteristics. When Hopfield fails to meet the objective function's requirements, the penalty function structure can be used to control the objective function of identifying psychological crises among university students, greatly reducing error rates and making network maintenance easier. As a result, current research is concentrating on the identification of university students' PCS. In the field of mental health education, incorporating big data technology into the identification of students' psychological crises, collecting and analyzing data from university students' daily lives at school, and improving the timeliness and accuracy of psychological crisis identification have become a new topic for psychological crisis identification workers in the information age. Every crisis has its particularity, and every crisis is unique and different [2, 3]. When we grasp and analyze the overall situation and start with the nature of the psychological crisis, we can still divide the crisis into three categories: first, developmental crisis, which is also called adaptive crisis or maturity crisis. It refers to the abnormal stress reaction caused by the sudden change of environment or self-physiology in the process of individual growth and development. Second, the situational crisis [4] refers to a situation in which individuals are unable to predict or control rare or unexpected extraordinary events. The key difference between a situational crisis and other crises is that the extraordinary events that trigger the crisis are unpredictable or difficult for university students to control, such as a parent's divorce, violent aggression, or strong interpersonal conflicts [5]. At this time, domestic research on PCS identification has been thoroughly examined from early warning to prevention to intervention, yielding some promising findings. However, most of the studies focus on the explicit crisis, such as what kind of external performance the PCS identification will have, with less attention paid to the implicit crisis [6].

In order to solve the problems existing in the process of university students' psychological crisis identification and improve the correct rate of university students' psychological crisis identification, this paper proposes a method of university students' psychological crisis identification based on DM technology. DM is a technology of data management, analysis, and processing, and a key step of knowledge discovery. The main applications of this method are correlation analysis, classification [7, 8], clustering, prediction time series model [9], and deviation analysis. However, the system designed by the system dynamics method is subjective in data classification, and the causal relationship is obscure and difficult to explain. The mental health analysis system designed by other weighted fuzzy logic theories [10] only stays at the data operation and management level such as data acquisition, statistics, query, and report, and the utilization efficiency of data is not high. The basic process of DM, a large number of DM, according to the definition of management, the preprocessed data get a reliable format, which is convenient for the mining wizard to process the data, and then enter the mining kernel to get the pattern set, which can express and explain the comprehensive knowledge base that users can understand and use after the pattern filtering of the mining manager.

The basic process of DM is as follows: a large number of raw data are extracted after data preprocessing according to the mining manager's data definition to obtain data in a correct and reliable format that is easy to process by the mining wizard, and then entered the mining kernel to obtain a pattern set that is expressed and explained, and then filtered by the mining manager to obtain a knowledge base that is easy for users to understand and generalize. They can organize the structure of a neural network according to the specific problems of university students' PCS identification, and they can effectively fit the changing characteristics of university students' PCS [11, 12]. Despite the fact that prevention, early warning, and intervention mechanisms for the psychological crisis have been established, extreme crisis events that appear to occur "for no apparent reason" continue to occur frequently. Because some crises are complex, difficult to identify, and difficult to detect, they can only have serious consequences if they are not addressed quickly and effectively [13, 14]. This paper examines the unique challenges of identifying psychological crises in university students and collects signals of psychological crisis detection in university students using specialized equipment [15].

2. Related Work

According to literature [16], university students' psychological crisis is universal, with complex symptoms and no quick fix, and it is the driving force for university students' growth and change, including the duality of danger and opportunity, as well as having time-specific characteristics. According to literature [17], using the big data analysis method and the ID decision tree algorithm, a data classification mining system model of university students' psychological problems was created. The system mined association rules using the Apriori algorithm. The main factors affecting psychological problems and their relationships were discovered through data testing. According to literature [18] and research, school, family, and societal losses have resulted from students' vicious wounding or self-injury incidents caused by the psychological crisis. As a result, establishing an effective early warning system for psychological crises among university students is essential for effectively preventing crisis events. According to literature [19], university students' psychological crises are characterized by unexpected events, relief from helplessness, pain, and potentially dangerous consequences. Literature [20] proposes a psychological classifier model based on artificial neural networks and fuzzy mathematics theory and uses training samples to build the model using the MATLAB neural network toolbox, resulting in more accurate classification results. According to literature [21], research shows that differences in the characteristics, forms, and stressors of university students' psychological crises categorize them into different types. The network structure of a mental health prediction system model based on the BP neural network algorithm was established using the artificial neural network toolbox in MATLAB, according to literature [22], in order to predict the mental health of university students. According to literature [23], through the method of big data analysis, the psychological crisis of university students is mainly attributed to four aspects: the crisis caused by physiological and psychological contradictions; crisis caused by interpersonal tension; psychological crisis caused by the market economy and employment pressure; crisis caused by sexual physiology maturity and sexual psychology imperfection. According to literature [24], research shows that the diagnosis experience of domestic and foreign psychologists is introduced into the expert system of mental disorder diagnosis through the expert system of the artificial neural network, so that the system can detect and diagnose students' mental health in all aspects, which provides convenience for improving the function of mental health education for university students. Literature [25] puts forward that the BP neural network algorithm is applied to university students' psychological disorder identification, and combined with "artificial intelligence" to establish a model, which can be used by university students to realize online self-diagnosis of psychological disorder categories, thus reducing the workload of some mental health managers and reducing the working pressure of college psychological counseling institutions.

Based on DM, this paper studies the identification of university students' PCS, and some achievements have been made in the application research of DM technology in psychological crisis prevention. The feasibility and effectiveness of DM technology in analyzing and predicting students' mental state, evaluating students' mental health, pattern recognition of psychological diagnosis, and early warning of psychological crisis have been proved. The application of DM in the classification technology model, psychological obstacle identification model, and psychological condition prediction network model of psychological crisis prevention has also achieved relevant research results.

3. Principle and Basic Steps of DM Technology

3.1. Principle and Algorithm of DM. DM is a process of extracting potential and useful information and knowledge from a large number of incomplete, fuzzy, noisy, and random data. The extracted knowledge is expressed as rules, concepts, laws, patterns, and so on. In the process of identifying university students' PCS, it is a crucial step to collect university students' PCS signals first. At present, sensors are mainly used to collect university students' PCS signals. The decomposition scale of wavelet transform is determined, and multiscale decomposed the original university students' PCS identification signal to separate the noise from the useful university students' PCS identification signal, which will correspond to different wavelet coefficients. Therefore, this paper uses laser sensors to collect students' PCS signals, which can reduce the cost of collecting PCS signals. The basic process of DM is as follows: a large number of raw data are extracted after data preprocessing according to the mining manager's data definition to obtain data in a correct and reliable format that is easy to process by the mining wizard and then the mining kernel is entered to obtain a pattern set that is expressed and explained and then filtered by the mining manager to obtain a knowledge base that is easy to understand and generalize. The DM model is shown in Figure 1.

DM is an instance-based inductive classification algorithm. For a given data set, this algorithm can create a decision tree model and extract intuitive and simple knowledge of classification rules. To begin, each of the classification measure data set's attribute values is classified and chooses the root node. Take, for example, a university's psychological management system. Some problems that are relatively unseen can only be revealed in a high-stress environment. There will be one-sided problems in the process of evaluating an individual's psychological state if we cannot realize dynamic data management and track and record the data of students at school. This traditional static data management method clearly lags behind students' psychological change processes, reducing the precision and timeliness of psychological crisis intervention. There are four modules in the current psychological management system: student/teacher service, psychological counselor module, parent module, and administrator module. To obtain the target DM set, raw data must be processed. Based on the above mining algorithms, the structure of the psychological crisis system based on three DM methods is shown in Figure 2.

Let the original university students' PCS signal.

$$y(n) = s(n) + n(n), \tag{1}$$

where $s(n)$ represents a useful signal of PCS of the university student.

Let $\psi(t) \in L2(R)$, whose Fourier transform is $\psi'(\omega)$, and the mother wavelet of wavelet transform is defined as

$$C_\psi = \frac{\int_R |\psi'(\omega)|^2}{|\omega| d\omega \ < \infty}. \tag{2}$$

$\psi\ (t)$ is expanded and translated to obtain

$$\psi_{a,b}(t) = \frac{1}{\sqrt{|a|\psi(t - b/a)}}. \tag{3}$$

The calculation formula of the wavelet coefficient is

$$\omega_{j,k} = \int_{-\infty}^{+\infty} y(n)\psi_{a,b}(n)\mathrm{d}t = \langle f, \psi_{a,b}\rangle. \tag{4}$$

The hard threshold method can be described as

$$T_h\left(\omega_{j,k}, \delta\right) = \begin{cases} \omega_{j,k}, & \left|\omega_{j,k}\right| \geq \delta \\ 0, & \left|\omega_{j,k}\right| < \delta \end{cases}. \tag{5}$$

The function $\varphi\ (xk)$ introduces to process the signal data xk of university students' psychological crisis so that it can meet the following conditions:

$$\sum_{k=1}^{N} \Phi\left(x_k\right) = 0. \tag{6}$$

The covariance matrix $c\ \varphi$ of the training data set of university students' PCS is calculated as follows:

$$C_\Phi = \frac{1}{N}\sum_{i=1}^{N} \Phi\left(x_i\right)\Phi^T\left(x_i\right), \tag{7}$$

and

$$\lambda_v = C_\Phi v. \tag{8}$$

3.2. Basic Steps of DM. The implementation steps of DM vary with different application environments, and there are differences for different problems and requirements. Each subtechnology of DM also has its own applicable characteristics and application steps. Complete steps of DM are as follows:

① Understand the data and data sources

② Obtain relevant knowledge and technology

③ Integrate and check data

④ Remove erroneous or inconsistent data

⑤ Establish models and assumptions

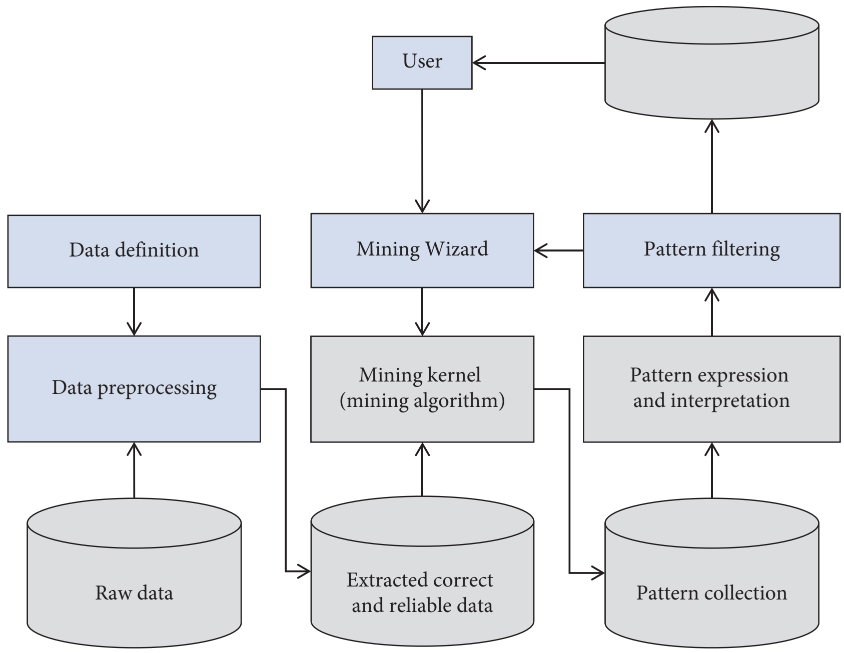

Figure 1: A model of DM.

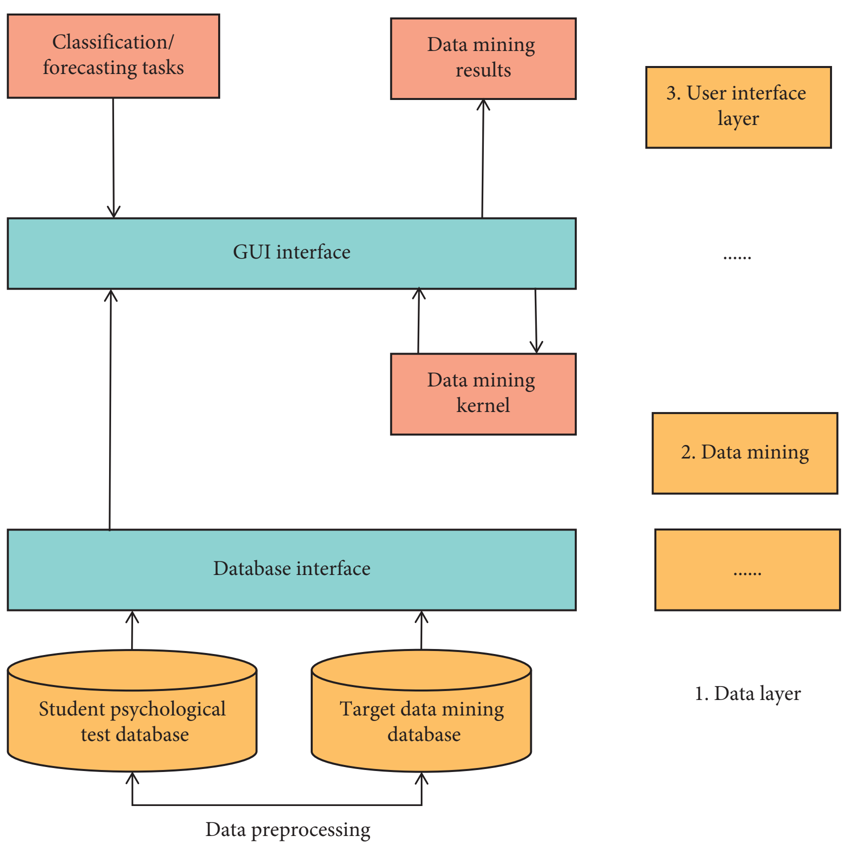

Figure 2: Structure diagram of the psychological crisis prevention system based on several DM algorithms.

⑥ Actual DM work
⑦ Test and verify the mining results
⑧ Interpretation and application

This paper examines the specific problems of identifying university students' psychological crises and collects the signals of identifying university students' psychological crises using specialized equipment. The wavelet transform's decomposition scale is determined, and then, multiscale decomposed the original university students' PCS identification signal to separate the noise from the useful university students' PCS identification signal, which will correspond to different wavelet coefficients. The performance of the identification model of university students' PCS is verified using test samples, and the identification results of university students' PCS are output. To summarize, Figure 3 depicts the process of identifying university students' PCS based on DM.

The single support vector machine (SVM) method for identifying university students' PCS directly extracts features from university students' PCS without denoising. This method is called SVM for short. The advantages of using neural network algorithm to optimize computer network connection are obvious. First, it effectively improves the connection efficiency of the computer network and makes the network run faster. Second, it effectively reduces the problem of increasing capital investment caused by optimizing computer network connection and maximizes the efficiency of capital utilization; that is, it can get the best optimization effect with the least capital. Traditional intervention did not fully tap the hidden value of student behavior data, which led to the related information being in a state of deep sleep. Only through big data mining and scientific utilization, and effective integration of unrelated and scattered data, can the accuracy of intervention be fully improved. After the analysis of big data students' psychological problems is completed, only by giving feedback to counselors and other psychological staff can the data value be further developed. Technologies such as economics, statistics, computer science, and applied mathematics are commonly used to make use of big data resources. However, psychological workers and managers rarely have such majors, which means that technical personnel are unsure how to intervene in a crisis, and psychological educators are unaware of big data technology's application methods. Students' psychological counseling, Internet access, and loan information, on the other hand, will be subject to privacy protection. More attention from the relevant personnel is required to determine whether this type of data is leaked or not, and whether it can be directly used, among other things.

4. Research and Implementation of University Students' PCS Identification

4.1. Identification of University Students' PCS Based on DM. The DM model based on the comprehensive CART decision tree, BP artificial neural network, and pattern recognition, which learn from each other's strengths, is embedded into the current school psychological management system to realize the psychological crisis prevention system. The complex averaging operation is transformed into functional regular operation, which greatly saves the calculation time of university students' PCS identification and realizes better interaction of network information data. Any behavior has a precursor. At present, students' psychological information processing ability is poor, and the sources are relatively few. Therefore, there is a lack of use-value, which leads to the lack of validity of the data held by counselors and affects their ability of judgment and analysis. Big data have the function of data mining, which can deeply mine and analyze massive data, and effectively predict the development law of things based on it, thus improving the prediction accuracy. Big data analysis can find the rules behind a large amount of data by studying students' external behavior and judge and predict students' behavior patterns and psychological state from all aspects of study and life. To integrate all kinds of data from various channels, it is necessary for the school work leading group to take the lead in establishing a data collection platform for psychological crisis intervention. The collection platform integrates and analyzes the data of various departments, timely provides valuable information for school psychological intervention workers, counselors, class teachers, and other student workers, and improves the predictability, accuracy, and effectiveness of psychological crisis intervention. RBF neural network is a method to identify the PCS of university students. Wavelet analysis is used to denoise the PCS signal of university students, and the characteristics of PCS of university students are extracted from the denoised signal, but RBF neural network is used as the modeling method. The teacher service module provides four submodules of student basic information data management, student measurement management, measurement data management, and other management. Therefore, we can introduce big data technology into the intervention process of university students' psychological crisis. By collecting and processing information such as academic performance, course selection, living conditions, family conditions, interpersonal relationships, and network activity, we can dig and analyze students' psychological state, so as to improve the predictability of students' psychological crisis and give targeted solutions.

As an example, the university's psychological management system is considered. Student/teacher service module, psychological counselor module, parent module, and administrator module are the four modules of the existing psychological management system. Student basic information data management, student measurement management, measurement data management, and other management are the four submodules of the teacher service module. Teachers can filter, query, sort, modify, print, and delete data in the measurement results management module. Researchers collect data on university students' mental health status using clinical scales, psychological investigations, daily outpatient services, and other methods, but the results are rarely shared with counselors, class teachers, and other student workers in the traditional mode of psychological crisis. Furthermore, aside from the aforementioned methods of obtaining psychological data, psychological workers may find it difficult to obtain data from other departments, or they may be unable to mine and process data efficiently. Some students will beautify and cover up problems from a quality standpoint. Furthermore, the information gathered in this manner is primarily stored in a static format, making it difficult to track students' development effectively. Furthermore, college students' psychology is insufficiently

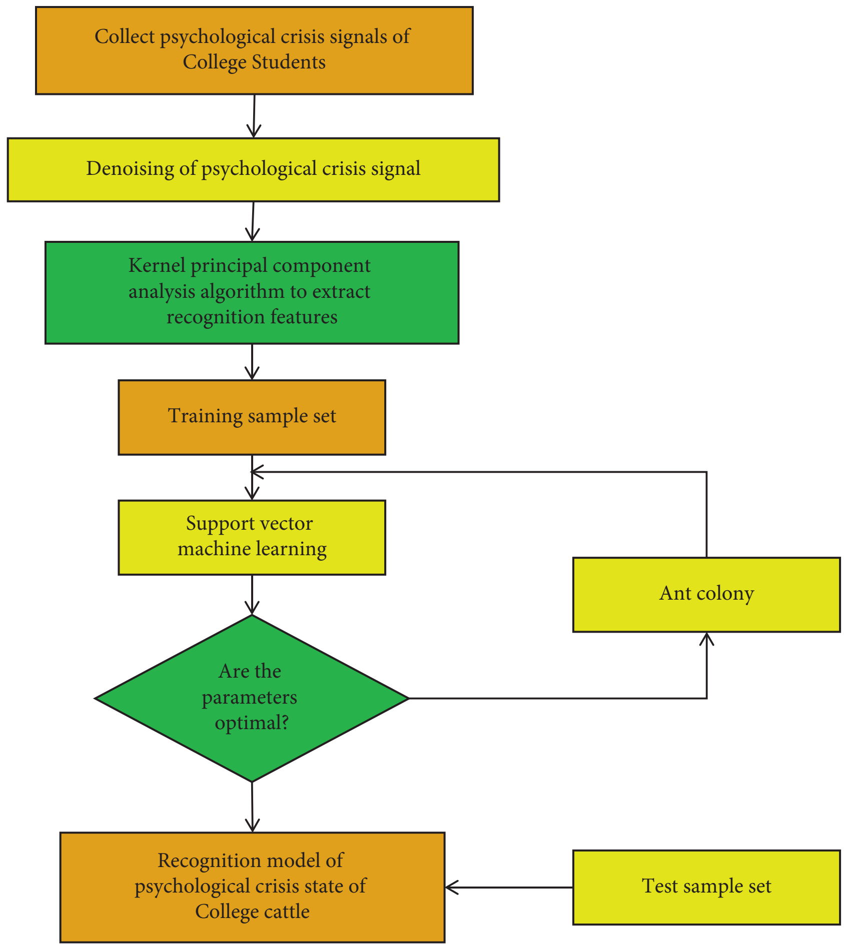

Figure 3: Process of identifying university students' PCS by DM.

mature. The psychological state will fluctuate as a result of unexpected events and environmental changes in a complicated social environment. The complex averaging operation is transformed into a functional regular operation, greatly reducing the calculation time for university students' PCS identification and allowing for better network information data interaction. Finally, a model is added to the neural network algorithm to fill in the gaps. When Hopfield fails to meet the objective function's requirements, the penalty function structure can be used to control the objective function of identifying psychological crises among university students, lowering the error rate, and making network maintenance easier. Furthermore, aside from the aforementioned methods of obtaining psychological data, psychological workers may find it difficult to obtain data from other departments, or they may be unable to mine and process data efficiently.

In the process of university students' growth, we should always give them the correct education. In the process of crisis, we should provide more help and attention to university students, provide multifaceted and multiangle social support, and guide university students to actively deal with a hidden psychological crisis. The data of students in school are distributed in various departments of the school, such as the number of students failing courses, elective courses, and punishment in the Academic Affairs Office. In the student office, students participate in social practice and competitions. Psychological investigation, consultation room, and clinical scale are all available at the psychological center. Tuition payments and student loans are handled by the finance department. Students' access to dorms, campus network usage, and other logistics are all part of the logistics package. An effective educational countermeasure system is conducive to effectively preventing university students' hidden psychological crises, timely detecting and intervening, assisting university students in smoothly navigating the crisis, enhancing their ability to resist the crisis, while also being conducive to family and school stability and the harmonious development of society. The university students' psychological crisis status is determined using the school's student psychological management system, and the information is stored in the psychological census database. By analyzing the psychological test data of university students' psychological crisis status identification in the screening data, which stores the original data of student information, psychological work evaluates students' psychological status.

4.2. Experimental Results and Analysis. In order to reflect the fairness of the experimental results of university students' PCS identification and increase the persuasion of the results, three experiments were carried out, respectively, and three methods were selected, including Rb, and the DM algorithm is used in this study. 10 experiments were conducted for each method and were selected for each experiment and analyzed by using the university students' PCS recognition. Error recognition rate and rejection rate are shown in Figures 4–6, respectively.

The correct rate, misidentification rate, and rejection rate of university students' PCS recognition by support vector machine are 85.12 percent, 8.35 percent, and 7.8 percent, respectively, as shown in Figures 4–6. The recognition effect of university students' PCS is not satisfactory. This is due to the high amount of noise in university students' PCS signals. This method ignores noise and, to some extent, interferes with feature extraction, increasing the error rate of university students' PCS recognition. The correct rate, misidentification rate, and recognition effect of university students' PCS are not the best, with 84.67 percent, 8.27 percent, and 6.56 percent, respectively. This is because, despite the fact that this method processes the signal of a university student's PCS with noise, it removes the noise interference. Teachers can use the measurement result management module to filter, query, sort, edit, print, and delete data. The correct rate, misidentification DM algorithm, and correct rate, respectively, are 94.62 percent, 3.45 percent, and 2.53 percent. The correct rate of the DM algorithm is increased by 10.39 percent and 9.65 percent, respectively, when compared to the correct rate of the DM algorithm. To ensure operational efficiency, clear division of labor, clear objectives, and complete functions, the team must continue to promote the development of an intervention system. The information system must also be standardized. There are currently no laws or regulations governing the collection, storage, mining, or use of big data technology. Data collection and use are harmed to some extent, and no clear workflow and requirements for implementation have been established. This is because this method first preprocesses university students' PCS signals and then extracts better recognition DM technology to fit the changing characteristics of university students' PCS, resulting in a better university students' PCS recognition model, reducing university students' PCS recognition based on neural network, and verifying the superiority of the DM algorithm.

In the traditional mode of psychological crisis, researchers collect data of university students' mental health status through clinical scale, psychological investigation, daily outpatient service, etc., and the results are often not shared with counselors, class teachers, and other student workers. It mainly includes the training time and test of university students' PCS identification. In order to reflect the fairness of the experimental results of university students' PCS identification, three methods were used to carry out four experiments for comparison, and each method used was selected for each experiment for simulation test. The sample data distribution university students' PCS identification is shown in Figures 7–10.

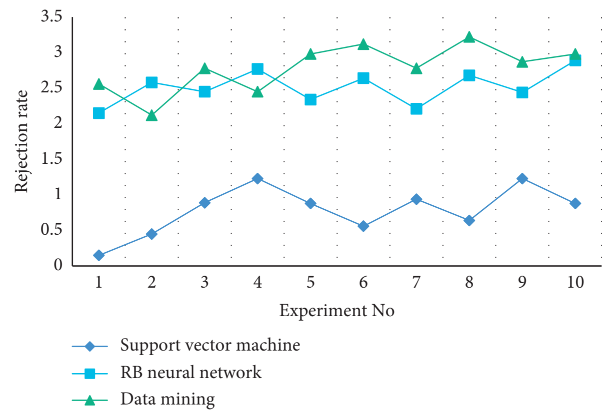

Figure 4: Rejection rate of university students' psychological crises by different methods (Experiment 1).

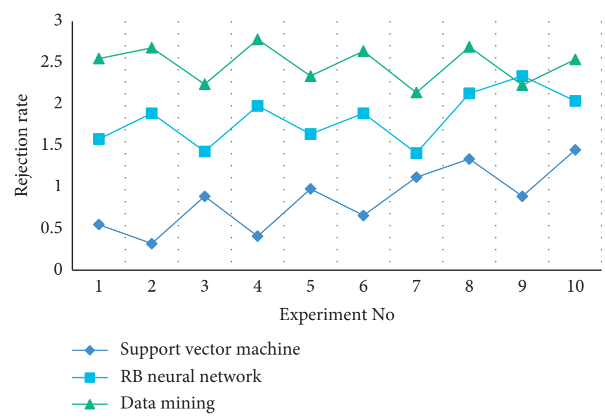

Figure 5: Rejection rate of university students' psychological crises by different methods (Experiment 2).

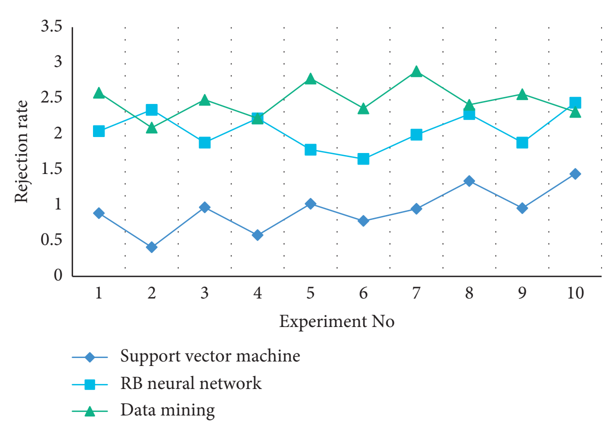

Figure 6: Rejection rate of university students' psychological crises by different methods (Experiment 3).

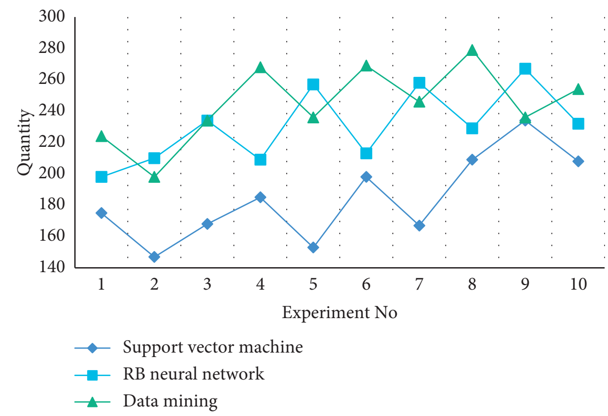

FIGURE 9: Distribution of sample data in the simulation experiment of university students' PCS identification (Experiment 3).

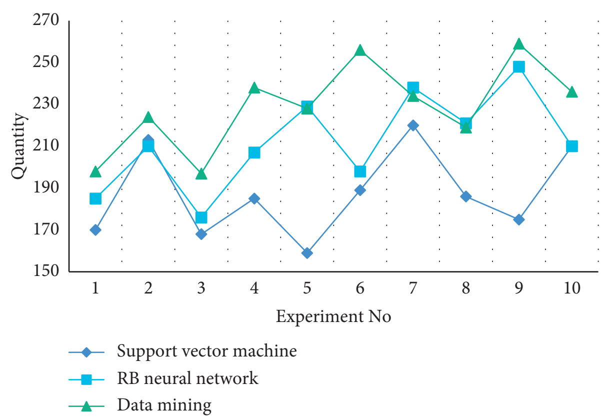

FIGURE 8: Distribution of sample data in the simulation experiment of university students' PCS identification (Experiment 2).

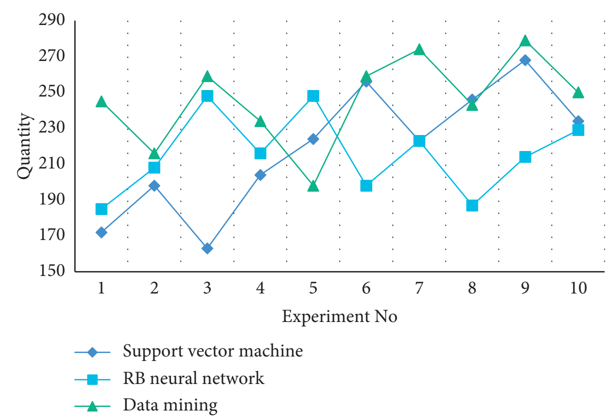

FIGURE 10: Sample data distribution diagram of university students' PCS identification simulation experiment.

The experimental results from Figure 7 to Figure 10 show that the average modeling time of university students' psychological crisis identification based on the DM algorithm is 18.03s, the network is 86.5s, and 38.47s, respectively. Psychological scale is widely used as a standardized work to evaluate the mental health level of university students, primarily for the investigation and research of university students' mental health. The general survey of newly enrolled students' mental health aims to identify students with psychological problems and assess the mental health of university students. The scale, as a test of students' psychological states, has a direct impact on students, and the scale's compilers are educators who use the scale to form relationships with students. Data on university students are primarily gathered in various school departments. Relevant leaders should pay enough attention to the cooperation between different departments and the data application management system in order to effectively retrieve, apply, and mine data in different departments. Schools should form a big data collection system working group that includes the security department, the school hospital, school leaders, the student affairs office, and the mental health department. Although the scale weavers considered students' characteristics to some extent in the past, they still regarded students as objects that could be used and transformed, and their inner world could be tested according to the contents of the test scale, influenced by the traditional educational concept. In reality, students' inner worlds are complex, and everyone receives different guidance information from the outside world. This has an impact on the scale's test results, and it makes it difficult to predict and screen out more problematic students. As a result, the DM algorithm reduces the modeling time for university student PCS identification, increases the speed of PCS identification for university students, and has a higher practical application value.

5. Conclusions

College students who have self-respect are more likely to accept themselves, accept their own flaws, and appreciate their own advantages, rather than feeling inferior and suppressing themselves because of their own flaws. This paper proposes a method of college students' psychological crisis identification based on data mining technology in order to achieve ideal results in psychological crisis identification. We can combine big data and optimize it through strategies such as building data feedback platform, optimizing management system, and building data collection system, in light of the shortcomings of the traditional intervention system, such as full sharing of data mining algorithms, insufficient dynamic management of data information, and inability to fully mine data. The simulation results of college students' psychological crisis state identification show that this method is a high-accuracy, short-modeling-time method of identifying college students' psychological crisis states, and the identification results can provide important information for college students' psychological managers. The information is kept in a database called the psychological census. Psychological work assesses students' mental health by examining psychological test data from college students' psychological crisis state identification in the screening data, which contains the original student data.

Data Availability

In this study, we employ the active noise control (ANC) method to eliminate the low-frequency part of the noise generated by the rotation of the axial fan in heating, ventilation, and air-conditioning (HVAC) pipelines. Because the traditional variable step size least mean square (VSS-LMS) algorithm has poor tracking performance, we propose a variable step size filtered-X least mean square (FXLMS) algorithm based on the arctangent function to improve the adaptive filtering method of the convergence speed and noise cancellation effect. The step size of the proposed algorithm can be adjusted according to the error. When the error signal is significant, a larger step can be obtained, and when the error is small, the step size smoothness of the algorithm can be optimized. Compared with the traditional VSS-LMS algorithm, the convergence speed of the proposed algorithm is increased by 29%, the noise reduction effect is enhanced by 19%, and the mean square error (MSE) is reduced by 23% (0.0084). In addition, we developed a hardware experimental platform based on noise characteristics. In the noise reduction test using a GB/T 5836.2-06 standard PVC pipeline, the system reduced the noise by 12–17 dB.

1. Introduction

Noise has become one of the three significant pollutants that cannot be ignored globally due to the development of modern industry and the constant improvement of people's desires for a higher quality of life. In heating, ventilation, and air-conditioning (HVAC) systems [1], the noise generated during using compressors and axial flow fans is transmitted indoors through air pipelines, severely affecting people's production and life [2]. National laws and regulations have become more stringent regarding noise control requirements that affect public health. Research on various methods of reducing pipeline noise is significant for residential buildings, shopping malls, office buildings, factory workshops, and other comprehensive places greatly affected by noise [3]. Traditional noise control techniques adopt porous material sound absorption or baffle sound insulation to reduce pipe noise. Sound absorption and insulation only reduce mid and high-frequency noise but not low-frequency noise [4]. Active noise control (ANC) technology can be widely used in noisy environments because of its effectiveness in low-frequency noise control.

In 1980, Morgan [5] proposed the filtered-X least mean square (FXLMS) method based on the least mean square (LMS) algorithm. In 2015, Ardekani et al. [6] modified the instantaneous gradient estimate by introducing the secondary path (SP) model to employ the FXLMS algorithm in ANC systems. In 2015, Zhou et al. [7] proposed a novel variable step size strategy for adaptive filtering algorithms, which depends on the sigmoid variable step size LMS (SVS-LMS) algorithm. Because the change in step size is not smooth enough, the algorithm generates larger MSEs. In 2016, Wang et al. [8] proposed a sigmoid function called the antiinterference variable step size LMS (AVSS-LMS) adaptive filtering algorithm. In 2019, Salman et al. [9] proposed adding l_0 or l_1-norm penalty term to the cost function of the traditional LMS algorithm. Salman used the arctangent and sign functions to constrain weights in the iterative process of the filter weights to increase the sparsity of the LMS algorithm and further improve its convergence in impulse noise environments. In 2020, Bershad et al. [10] developed a new variable step size NLMS based on switched piecewise functions. Although the convergence speed is improved using the characteristics of each stage, at the beginning of the iteration, the algorithm still needs to set a fixed step size, which reduces the weakening effect of the sensor and environmental noise on the convergence performance of the algorithm. The improved method can reduce the steady-state error of convergence, but the improvement of convergence speed is limited. Since Salman's method is implemented by adding a penalty to the cost function, the adjustment of weights is delayed, and the penalty function is independent of the size of the error. Although the improved method is highly stable, the convergence effect is not ideal.

In this study, we suggested an optimized step change strategy for the VSS-LMS algorithm based on the ideas and research methodologies of Wang et al. [8], Salman et al. [9], and Bershad et al. [10]. We propose a variable step size FXLMS algorithm based on the arctangent function. The improved algorithm uses an inverse tangent function to link the error to the step size for the complex transformation rule of the step size in the VSS algorithm, and the transformed step size will find the optimum within a stable convergence range and does not require any new information for prediction. This optimization process is fully autonomous and does not require any perceived intervention, and the noise in the pipeline can be judged adaptively and effectively eliminated. The optimized convergence speed allows the system to adapt faster to changes in the external environment. Better robustness indicates that the active noise reduction system using this algorithm can be applied in a more complex environment, making the method more widely applicable to noise reduction in HAVC pipelines. The proposed algorithm improves the convergence speed of ANC and ensures the ANC system's stability. The simulation proceeds such that the convergence speed of the algorithm can be increased by 29% compared with that of the Wang et al. [8], Salman et al. [9], and Bershad et al. [10]. VSS-LMS algorithms and the noise cancellation effect of at least 12 dB can be achieved in the ANC experiment of HVAC pipelines. Simulations and experimental investigations show that using the proposed algorithm for the low-frequency part of the noise generated by the axial fan in the pipeline has a better effect.

The rest of this study is organized as follows: Section 2 introduces the HVAC-ANC system and experimental setup employed; Section 3 presents the traditional FXLMS algorithm and analyzes the step change strategy of the VSS-LMS algorithm; Section 4 introduces the improved algorithm, and Section 5 examines the axial fan noise characteristics in HVAC pipeline; Section 6 presents the algorithm simulation and experimental results; Section 7 presents the conclusion of the study.

2. HVAC-ANC System

2.1. HVAC System. People's concerns about the health threats of $PM_{2.5}$, $PM_{1.0}$, and other particulate pollutants, allergens, formaldehyde, total volatile organic compounds (TVOCs), household odors, and gaseous contaminants in the surrounding air driving forces for developing indoor air treatment and purification markets. An HVAC system is a technology for home environment amenities [11, 12]. The HVAC system provides thermal comfort and acceptable indoor air quality, including room temperature control, oxygen supplementation, and moisture removal. Figure 1 shows an HVAC system mainly composed of axial fans, HVAC pipelines, air filters, heating, and cooling units.

There are many noise sources in the pipeline, but their noise characteristics also have certain similarities because different systems have similar structures [13]. We analyze the main noise sources in the axial fan of an HVAC system, and some useful information can be provided for the design of an ANC system. Figure 2 shows the feedforward ANC system in an air pipeline. The reference microphone collects the noise sound wave $P1$, and the controller outputs a control signal to the secondary speaker to generate an antinoise sound wave $P2$. Then, the error microphone receives the synthesized sound waves $P1$ and $P2$ and feeds them back to the controller. From the combined sound energy density, when the phase difference between $P1$ and $P2$ is 180°, the combined sound energy density is the smallest. When the amplitudes of the sound waves $P1$ and $P2$ are equal, the energy of the sound wave reaching the error microphone is zero, achieving the purpose of active noise reduction.

2.2. Simulation and Experimental Setup. MATLAB 2019 and COMSOL Multiphysics 5.5 are used to simulate the algorithm. The input signal is Gaussian white noise plus sinusoidal at the frequency of 50 Hz. The sample number is set as n, and the expected signal is a single frequency sinusoidal signal, as shown in Figure 3. Five comparison algorithms, including the proposed, fixed step size FXLMS, piecewise LMS, AVSS-LMS, and Salman algorithm, are used for comparison. The simulation experiment compares the convergence speed, MSE, and noise cancellation effect of the five algorithms. It is obvious from Figure 3 that the proposed algorithm can eliminate the random noise loaded in the sinusoidal signal, and the recovered signal has a good effect.

The experimental computer platform is shown in Figure 4. A polyvinyl chloride (PVC) pipeline following GB/T5836.2-06 standard was used in the experiment. The pipe is $820\,mm \times 110\,mm \times 110\,mm$ in size, and the size of the tee connection is 110 mm. The test system uses a Yamaha-UR44 sound card, two Superlux-ECM999 standard acoustic measurement microphones, and two Philips monitor speakers. We use one monitoring speaker placed at the end of the pipe to generate test noise and the other speaker placed at the pipe tee to generate the cancellation sound waves. The reference microphone is located near the noise source during the test, and the error microphone is located behind the cancellation speaker. The position of the microphone will have a certain impact on the noise cancellation effect. It can have a good effect only after the Gaussian white noise is used for modeling. In practical use, once the modeling is completed, the position between the microphone and the speaker cannot change; otherwise, the system will be unstable.

3. Active Noise Control Methods

3.1. Fixed Step Size FXLMS Algorithm. The FXLMS algorithm modifies the error gradient estimation; hence, it is always used in pipeline ANC systems. Figure 5 shows a block diagram of the ANC system based on the FXLMS algorithm for air pipeline.

We can see in Figure 5 that $\mathbf{d}(n)$ denotes the desired signal, $\mathbf{x}(n)$ denotes the input signal, $\mathbf{u}(n)$ denotes the output signal, $\mathbf{e}(n)$ denotes the error between $\mathbf{y}(n)$ and $\mathbf{d}(n)$, and $\mathbf{w}(z)$ denotes the weight coefficient of the filter. The FXLMS algorithm employs the Wiener filter [14]. The Wiener filter is a linear optimal discrete filter. By calculating the autocorrelation matrix $R = E[\mathbf{u}(n)\mathbf{u}^H(n)]$ and cross-correlation matrix $p = E[\mathbf{u}(n)\mathbf{d} * (n)]$, the filter with the smallest MSE can be obtained [15]. In order to obtain the optimal tap weight, the cost function is set as follows:

$$\begin{aligned}\xi = E\left[d^2(n)\right] - w^T E[x(n)d(n)] - E\left[d(n)x^T(n)\right]w \\ + w^T E\left[x(n)x^T(n)\right]w.\end{aligned} \tag{1}$$

The steps of the FXLMS algorithm are summarized as follows:

(a) The reference and error microphones collect the reference input signal $\mathbf{x}(n)$ and error signal $\mathbf{e}(n)$, respectively

(b) The output signal $\mathbf{u}(n)$ of the FIR filter with a length of M is calculated, and the output signal $\mathbf{u}(n)$ drives the cancellation loudspeaker.

$$u(n) = \sum_{i=0}^{M-1} w_i(n)x(n-i). \tag{2}$$

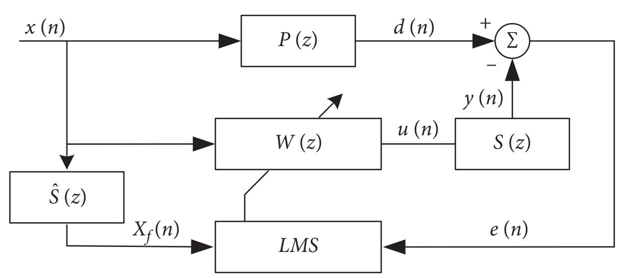

Figure 5: Feedforward FXLMS algorithm for an air pipeline.

(c) The filtered-X signal $\mathbf{x}_f(n)$ is calculated as the input signal of the LMS algorithm, where $\hat{s}_i(n)$ is the i^{th} impulse response coefficient of the SP $\hat{S}(z)$ model at time n.

$$x_f(n) = \sum_{i=0}^{M-1} \hat{s}_i(n)x(n-i). \tag{3}$$

(d) The iteration is repeated until the cost function $J(n)$ is minimized. Formula (5) indicates that the gradient of the cost function is obtained, and formula (6) indicates that the tap of the filter is optimized in the opposite direction of the gradient.

$$J(n) = |e(n)|^2 \approx \left(d(n) - \sum_{i=0}^{M-1} \hat{s}_i(n)u(n-i)\right)^2, \tag{4}$$

$$\nabla J_i(n) = \frac{\partial J(n)}{\partial w_i}, \tag{5}$$

$$w_i(n+1) = w_i(n) - \frac{1}{2}\mu\nabla J_i(n). \quad (6)$$

(e) Using formula (6) to renew the weight coefficients of the LMS algorithm adaptive filter iteratively,

$$W(n+1) = W(n) - 2\mu\mathbf{e}(n)\mathbf{x_f}(n), \quad (7)$$

where μ is the set convergence step size, and $e(n)$ is the error signal at the first iteration $e(0) = 0$. The step is fixed in the original LMS algorithm [16]. However, the inherent limitation of the fixed μ needs an adjustment between fast convergence rate and limited misalignment. The step size range is expressed as the following formula to maintain the stability of the FXLMS algorithm.

$$0 < \mu < \frac{2}{\sum_{i=0}^{M-1}\left(x_f(n-i)\right)^2}. \quad (8)$$

The FXLMS algorithm corrects the error gradient of the LMS algorithm by adding the estimated value of the SP, so that the LMS algorithm can converge stably.

The steps of SP modeling are summarized as follows:

(a) A white noise signal is set up by the white Gaussian-noise generator used as the input $S(z)$ to drive the cancellation loudspeaker, which is also used as the input signal $\widehat{S}(z)$ and the reference input signal of the LMS algorithm

(b) The error microphone collects the output signal of the cancellation loudspeaker as $y(n)$

(c) The output signal $\widehat{y}(n)$ of the SP estimation model $\widehat{S}(z)$ is calculated as

$$\widehat{y}(n) = \sum_{i=0}^{M-1}\widehat{s}_i(n)u(n-i). \quad (9)$$

(d) The output variation between the actual path signal $y(n)$ and estimated path model $\widehat{y}(n)$ is calculated as

$$e(n) = y(n) - \widehat{y}(n). \quad (10)$$

(e) The LMS algorithm updates the SP model of the adaptive filter as follows

$$s_i(n+1) = s_i(n) + \mu e(n)\mu(n-i), \quad i = 0, 1, 2, \ldots, M-1. \quad (11)$$

(f) The above process is repeated until the error signal $e(n) \approx 0$, and the coefficient of $\widehat{S}(z)$ for the FXLMS algorithm is stored.

3.2. Variable Step Size LMS Algorithm. The VSS adaptive filtering algorithm uses a variable step factor $\mu(n)$. Changing the step factor can increase the convergence speed of the adaptive algorithm and reduce MSE. At the beginning of the algorithm or when $J(n)$ is large, a larger step size factor $\mu(n)$ is used to speed up the convergence. When the convergence phase or $J(n)$ is small, a smaller step factor is used to reduce MSE [17].

The AVSS-LMS algorithm based on the sigmoid function proposed by Wang et al. [8] is a very classic VSS-LMS algorithm, and its step size factor $\mu(n)$ is given as

$$\mu(n) = b\left(\frac{1}{1+\exp(-aE|e(n-1)e(n)|)} - 0.5\right). \quad (12)$$

The parameter a is used to handle the steepness of the sigmoid function and b handles the value range of function. In this case, formula (7) can be expressed as

$$W(n+1) = W(n) - 2\mu(n)x_f(n). \quad (13)$$

Compared with the step size μ of the FXLMS algorithm, the iterative step size $\mu(n)$ of the AVSS-LMS algorithm is variable. The initial stage of the algorithm convergence $\mu(n)$ has a high rate, implying a high convergence speed. In the stable stage, $\mu(n)$ takes a smaller value. When b is 0.02, 0.01, or 0.005 and a is 5, 2, 1, or 0.5, the step size of the AVSS-LMS algorithm varies with the error.

Figure 6 shows the step size change strategy of the AVSS-LMS algorithm. The AVSS-LMS algorithm solves the problem that the stability and convergence speed always contradict each other. However, the step size of the AVSS-LMS change is not smooth enough when the error is limited, and the maximum step size of the function is limited by this problem. Here, the arctangent function is used to transform the error nonlinearly. The proposed algorithm can obtain a larger step size in the introductory stage. When it is close to stability, the step size changes smoothly to obtain rapid convergence speed and limited MSE.

4. Improved Algorithm Using the Arctangent Function

Although the principles of VSS-LMS algorithms are different, they all employ the basic adjustment strategy [18–21]. Mostly, VSS-LMS algorithms use a larger step size in the introductory moment of the iteration or when the error is large to increase the convergence rate. In the stable phase of the algorithm or when the error is limited [22], a limited step size factor is used to reduce MSE. This adjustment strategy is also employed here by introducing the arctangent function to construct the nonlinear accord between the error function and step size. The improved method adds three adjustable parameters for different noises. The improved step change coefficient is given as

$$\mu(n) = b\left(\frac{3}{\left(1+\exp\ (-a|\arctan(e(n))|)^c\right)} - 1\right), \quad (14)$$

where $\mu(n)$ represents the step value obtained when the error at the time n is $e(n)$, and a, b, and c are the user-defined parameters and constants. The arctangent function is used for three reasons; it is nonlinear, bounded, and continuous. These three points can ensure the convergence and stability of the function.

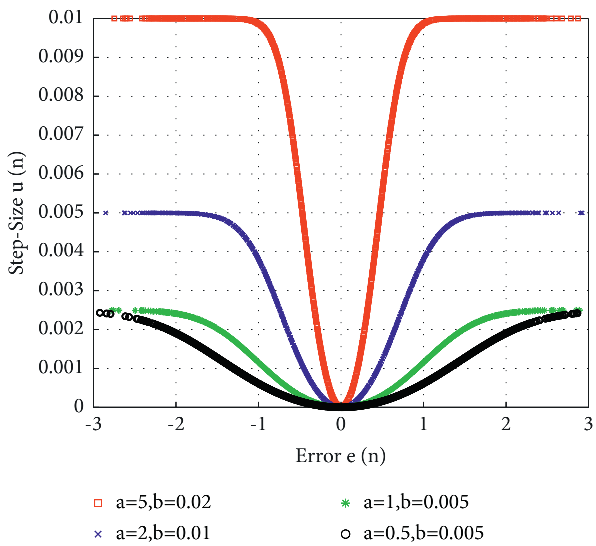

FIGURE 6: Variation of the step size of the AVSS-LMS algorithm with error.

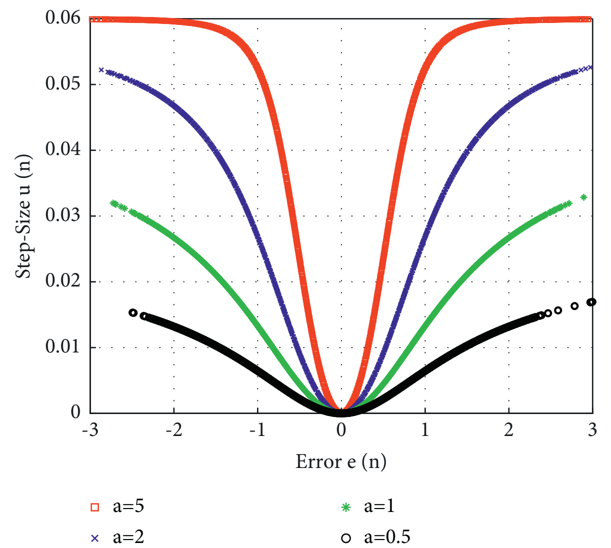

FIGURE 7: Variation of the step size of the proposed algorithm with a.

4.1. Effect of Step Size on the Algorithm. We conclude from formula (15) that increasing the step size factor can reduce the learning time and converge a little time. However, the small step length will boost the number of iterations [23], thus reducing the convergence acceleration of the algorithm.

$$\tau_{mse,\min} \approx \frac{1}{2\mu(n)\lambda_{\min}}, \tag{15}$$

where $\tau_{mse,\min}$ represents the smallest eigenvalue of the autocorrelation matrix of the input signal and $\lambda_{\min}$ represents the minimum MSE that can be obtained by the algorithm. Therefore, to solve the problem of the stability and convergence speed always contradicting each other [24] when the fixed step size adaptive filtering algorithm is tested to the active control of pipeline noise, the strategy of changing the step size is employed. Formula (16) shows that the steady-state error is directly proportional to the step size. As the step size increases, the steady-state error increases [25].

$$\varepsilon = \frac{\mu(n)}{2}\sum_{k=1}^{M}\lambda_k, \tag{16}$$

where λ_k is the eigenvalue of the autocorrelation matrix $\mathbf{u}(n)$. Formulas (15) and (16) show a contradictory relationship between the convergence rate and stability.

4.2. Effect of Parameter a on the Algorithm. Parameters b and c are fixed to investigate the effects of parameter a and step size μ of the proposed algorithm. When $b = 0.03$, $c = 2$, and $a = 5$, 2, 1, and 0.5 (Figure 7), the step size μ of the improved algorithm varies with the error $e(n)$. With an increase in a, the step variation curve gradually becomes steep. It means that a larger parameter a can make the algorithm more sensitive to error, but when a increases to a certain extent, the maximum step size of the algorithm will not continue to increase.

Figure 8 shows that as a gradually increases, the convergence speed increases rapidly. The convergence speed of the algorithm is influenced by a. As the value of a increases, the convergence speed becomes brisker, simultaneous bottom becomes sharper, and MSE increases accordingly. We can see from formula (16) that this is caused by the increase of step size. Therefore, blindly increasing parameter a is not a good strategy to improve the algorithm. It can be seen from Figure 8 that when $a > 2$, the increase in the convergence speed of the algorithm is not so obvious, so the value of parameter a cannot be set too large.

4.3. Effect of Parameter b on the Algorithm. The influence of parameter b on the step size μ of the improved algorithm is studied by fixing the parameters a and c. When the parameters $a = 1$, $c = 2$, and $b = 0.005$, 0.01, 0.03, and 0.1, the step size varies with the error, as shown in Figure 9. Parameter b directly affects the maximum step size of the algorithm. As b increases, the upper limit of the maximum step size increases, but very high values of b may increase the MSE.

As shown in Figure 10, at a smaller b, the convergence acceleration of the algorithm is greatly reduced. Therefore, to ensure the high convergence acceleration, stable convergence of the algorithm b should be adjusted according to the stable convergence conditions shown in the following formula:

$$0 < \mu < \frac{2}{\sum_{i=0}^{M-1}\left(x_f(n-i)\right)^2}. \tag{17}$$

The algorithm will not converge when the variable step size exceeds the upper limit. Therefore, the reciprocal of the input signal power is usually used to determine the upper limit of the step size.

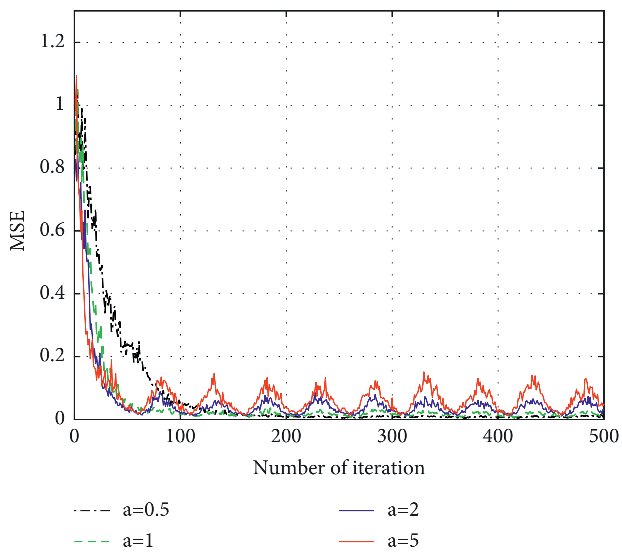

Figure 8: MSE of the proposed algorithm at different a.

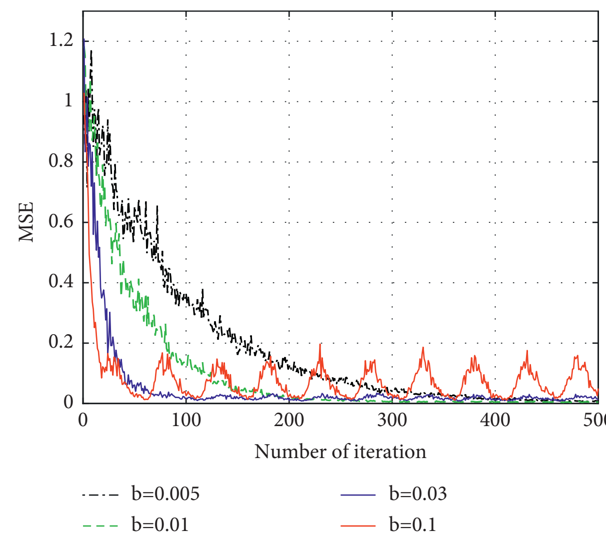

Figure 10: MSE of the proposed algorithm at different b.

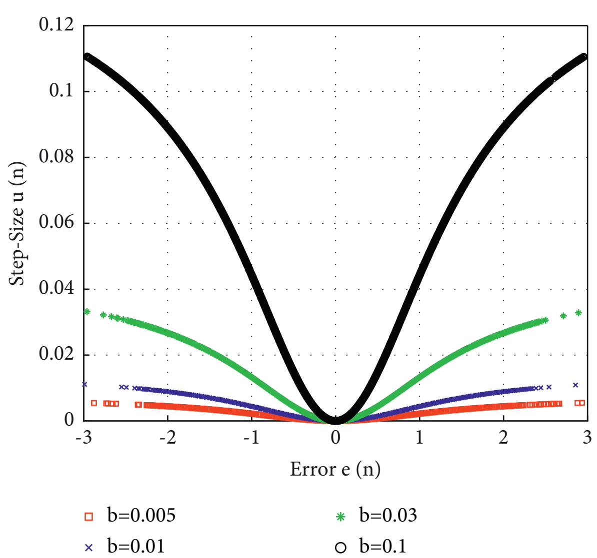

Figure 9: Variation of the step size of the proposed algorithm with b.

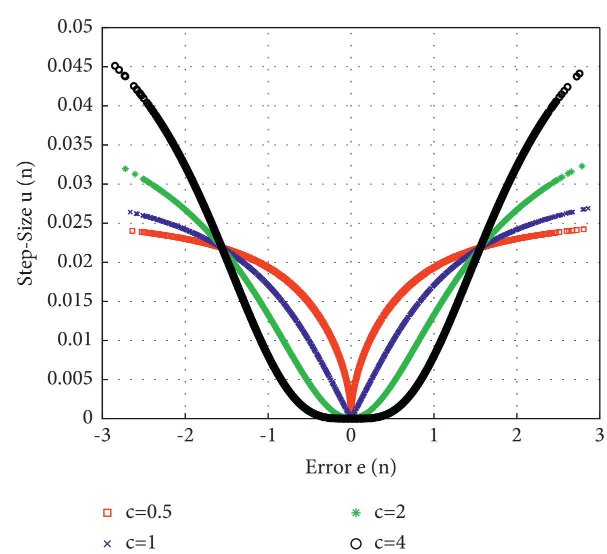

Figure 11: Variation of the step size of the proposed algorithm with c.

4.4. Effect of Parameter c on the Algorithm. The influence of c on the algorithm is studied by fixing a and c. When a, b, and c are 0.5, 1, 2, and 4, the step size varies with the error, as shown in Figure 11, and we can see that c directly affects the smoothness of the bottom of the function; the larger the value of c, the smoother bottom of the function. Without affecting the steady-state error, increasing the value of c increases the convergence speed of the algorithm to a certain extent without affecting the stability of the function. Since the value a directly affects the way of a step change, according to the variable step strategy, the value c should be greater than 1. Because exponential growth directly increases the amount of calculation (Figure 12), the convergence speed of the algorithm is not significantly increased only by adjusting the value of c. Therefore, the value of c needs to be adjusted after adjusting that of a and b.

4.5. Robustness of the Algorithm. Random noise has a severe impact on the stability of the adaptive algorithm [26]. A random addition is needed for a robust solution for the adaptive filter due to the inevitable noise in the environment, such as measurement noise and environmental modeling errors [27]. Therefore, it is necessary to introduce a random additive interference signal $v(n)$. The expected signal $d(n)$ is expressed as

$$d(n) = w_o^H(n)u(n) + v(n), \tag{18}$$

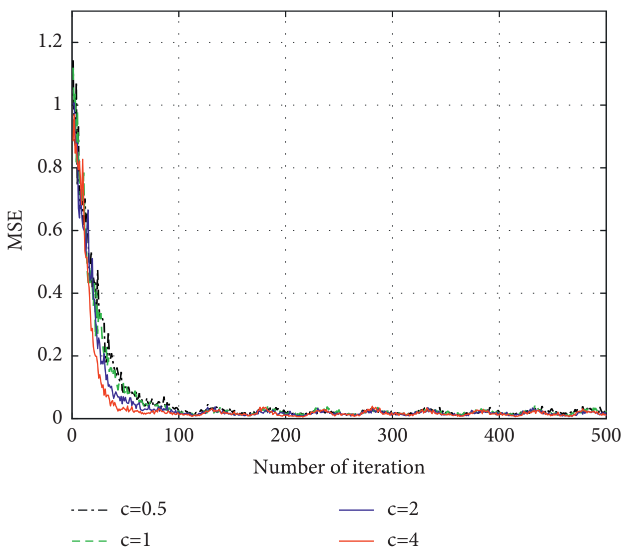

FIGURE 12: MSE of the proposed algorithm at different c.

where $w_o(n)$ is the optimal tap weight vector of the Wiener filter. However, because the environment of the system is unknown, suppose that $w_o(n)$ is estimated as $w(n)$, the expected signal can also be expressed by formula (25).

$$d(n) = w(n)u(n) + e(n). \tag{19}$$

Since the recursive estimation of $w(n)$ is strictly causal, in the adaptation cycle n, updating $w(n-1)$ to $w(n)$ depends only on the current input vector $u(n)$, and the weighted error vector $\widetilde{w}(n)$ can be defined as

$$\widetilde{w}(n) = w_o(n) - w(n). \tag{20}$$

As the measurable error signal relevant to the weighted error vector $w(n)$, the error without interference is given by

$$\begin{aligned}\xi_u(n) &= e(n) - v(n)\\ &= \left[w_o(n) - w(n)\right]^H u(n)\\ &= \widetilde{w}(n)u(n),\end{aligned} \tag{21}$$

where $v(n)$ is the random additive interference signal, $e(n)$ is the error signal, and the cause of $\xi_u(n)$ can be known from formula (20) as the deviation between the optimal solution $w_o(n)$ of the Wiener filter and the actual filter $w(n)$.

We calculate the arbitrary estimator H^{∞}, and it is necessary to calculate the worst-case energy gain from the interference [28] to the noninterference estimation error in formula (21). To obtain the bounds of the energy gain, we can obtain the following formula from the Cauchy-Schwartz theorem.

$$[\widetilde{w}(n)u(n)]^2 \le \|\widetilde{w}(n)\|^2\|u(n)\|^2. \tag{22}$$

Therefore, by taking formula (21) squared at both ends and based on the inequality shown in formula (22), the following conclusions can be drawn:

$$\left|\xi_u(n)\right|^2 \le \|\widetilde{w}(n)\|^2\|u(n)\|^2. \tag{23}$$

Add interference $v(n)$ to the right of formula (23), and since $\mu(n)$ is always positive and less than 1, we can obtain the inequality shown in formula.

$$\left|\xi_n(n)\right|^2 \le \mu^{-1}(n)\|\widetilde{w}(n)\|^2 + |v(n)|^2. \tag{24}$$

When the algorithm converges, it is necessary to ensure that $\widetilde{w}(n+1) \le \widetilde{w}(n)$, so the inequality shown in formula (25) can be derived from formula (24):

$$\mu^{-1}(n)\|\widetilde{w}(n+1)\|^2 + \left|\xi_\mu(n)\right|^2 \le \mu^{-1}(n)\|\widetilde{w}(n)\|^2 + |v(n)|^2. \tag{25}$$

Since the estimated value of the tap $\widetilde{w}(n)$ is monotonically decreasing, we can obtain the inequality shown in the following formula:

$$\mu^{-1}(n)\|\widetilde{w}(n)\|^2 + \sum_{n=0}^{N}\left|\xi_u(n)\right|^2 \le \mu^{-1}(n)\|\widetilde{w}(0)\|^2 + \sum_{n=0}^{N}|v(n)|^2. \tag{26}$$

If formula (23) is brought into formula (26), there must be an inequality shown in formula (27), which shows that the proposed method will have good robustness when the following conditions are met.

$$\sum_{n=0}^{N}\left|\xi_u(n)\right|^2 \le \mu^{-1}\|\widetilde{w}(0)\|^2 + \sum_{n=0}^{N}|v(n)|^2. \tag{27}$$

The right side of formula (27) can be divided to the left, and the symbol γ^2 represents the maximum energy gain.

$$\gamma^2(\mu(n)) = \underset{w,v\in H^2}{SUP}\frac{\sum_{n=0}^{N}\left|\xi_u(n)\right|^2}{\mu^{-1}\|\widetilde{w}(0)\|^2 + \sum_{n=0}^{N}|v(n)|^2}, \tag{28}$$

where superscript 2 represents the second norm, and sup means the supermum upper bound. Assuming the specific interference sequence is $v(n) = -\xi_u(n)$, so formula (28) can be expressed as

$$\gamma^2(\mu(n)) = \frac{\sum_{n=0}^{N}\left|\xi_u(n)\right|^2}{\mu^{-1}\|\widetilde{w}(0)\|^2 + \sum_{n=0}^{N}\left|\xi_u(n)\right|^2}. \tag{29}$$

Therefore, when the power of the input signal $u(n)$ is limited, it is $\lim_{N\to\infty}\sum_{n=0}^{N}\|u(n)\|^2 < \infty$. For any given normal number Δ, a parameter vector $w(n)$, and an integer N, formula (21) can be expressed as

$$\begin{aligned}\sum_{n=0}^{N}\left|\xi_u(n)\right|^2 &= \sum_{n=0}^{N}\left|\left(w_o(n) - w(n)\right)^H u(n)\right|^2\\ &\ge \frac{1}{\Delta\mu(n)}\left\|w_o(n) - w(0)\right\|^2\\ &= \frac{1}{\Delta\mu}\|\widetilde{w}(0)\|^2.\end{aligned} \tag{30}$$

By eliminating the common term of formula (29) and keeping the bounds of γ^2, we can get the result

$$\frac{1}{1+\Delta} \leq \gamma^2 \leq 1. \tag{31}$$

Formula (31) shows that as the constant Δ tends to 0, the maximum energy of the improved algorithm will never exceed 1. Therefore, the proposed algorithm is H^{∞} optimal, and the system has good stability [29].

5. Characteristics of Pipeline Noise

There are many noise sources in a pipeline. However, due to the similarity in the structure of different systems, their noise characteristics are also similar [30]. The rotating noise is the main source of pipeline noise, and its fundamental frequency can be determined by the number of fan blades and motor velocity [31, 32]. The noise produced by the axial flow fan is more than 25 dB (Table 1). Here, we use the POPULA-JD100 axial fan (Figure 13).

The noise generated by the axial fan can be calculated using the following formulas [33]:

$$\mathrm{PWL} = 56\lg V + 10\lg\left(p_s c_m^{0.6} LZ\right) - 15.23, \tag{32}$$

$$V = 2\pi r\left(\frac{n}{60}\right), \tag{33}$$

$$p_s = p_i + p_d, \tag{34}$$

$$\begin{aligned}\mathrm{SPL} = {} & 56\lg V + 10\lg\left(p_s c_m^{0.6} \mathrm{LZ}\right) - 15.23 \\ & - 20\lg(4\pi\ d) + 10.99.\end{aligned} \tag{35}$$

The static pressure $p_i = 101325\,(\mathrm{Pa})$, dynamic pressure $p_d = 274\,(\mathrm{Pa})$, motor speed $n = 2450\,(\mathrm{rpm})$, average width of the fan blade $C_m = 0.015\,(\mathrm{m})$, leaf height $L = 0.020\,(\mathrm{m})$, and the number of leaves $Z = 10$. d is the measured distance, and the constant number 15.23 is the empirical value. The simulation is performed according to formula (35). The noise of the axial fan is mainly produced by monopole, dipole, and quadrupole noise sources [34]. Monopole noise is mainly caused by a change in the gas volume [35], dipole noise by the fluctuation of the static pressure on the impeller surface, and quadrupole noise by viscous stress radiation [36]. Due to the low air velocity of the JD100 axial flow fan, the monopole noise source can be ignored, and in the case of a low Mach number, the quadrupole noise source can be ignored. Therefore, the aerodynamic noise of the JD100 axial fan is mainly a dipole noise source. Axial flow fans produce different noises under different working conditions, and their frequency, sound pressure, and speed are not linear. According to formula (35), the sound pressure spectrum distribution of JD100 axial flow fan at different distances from 0 to 2500 rpm is studied. Figure 14 shows that the fundamental frequency and harmonics of the aerodynamic noise generated by the JD100 axial flow fan gradually increase with speed. The maximum frequency of noise is obtained at a speed of 2500 rpm. The main frequency of the rotating noise is below 4 kHz, which indicates medium and low-frequency noise. It is difficult to reduce this part of noise using the passive noise reduction method. Figure 15 shows that the higher the fan speed [37], the closer the measurement distance and the greater the noise obtained. At 2500 rpm, the noise generated by the JD100 axial flow fan is not less than 30 dB when the distance is 1 m.

Noise mainly propagates through the pipe, and the shape, size, and wall material of the pipe affect sound wave propagation in the pipe [38]. To analyze this problem, first, a cylindrical coordinate system $O - r - \varphi - z$ is established for a circular pipe, as shown in Figure 16, assuming that noise is generated at z = 0 of the tube and the other end is infinitely extended. The wall of the pipe is assumed to be rigid. The acoustic field in the pipe varies in the range $r \in [0, a]$, $\varphi \in [0, 2\pi]$, and $z \in [0, \infty]$.

Assuming the relationship between the generator's sound pressure and time is simple and harmonic, the sound pressure can be expressed as

$$\begin{aligned} & p(x, y, z, t) = p(x, y, z)e^{j\omega t}, \\ & \nabla^2 p(x, y, z) + k^2 p(x, y, z) = 0, \\ & \nabla^2 = \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2}{\partial \varphi^2} + \frac{\partial^2}{\partial z^2}, \end{aligned} \tag{36}$$

where ∇^2 is the Laplacian of the three-dimensional cylindrical coordinate system, k is the number of waves, and c is the sound speed [39]. Then, the sound field in the rigid-walled cylindrical waveguide under excitation of the non-axisymmetric sound source is given by

$$\begin{aligned} p(r, \varphi, z, t) = {} & e^{j\omega t}\sum_n\sum_m A_{nm}J_n\left(\frac{\beta_{nm}}{a}r\right)\cdot\ \cos(n\varphi + \varphi_n) \\ & e^{-j\sqrt{k^2-(\beta_{nm}/a)^2}z}, \end{aligned} \tag{37}$$

where A_{nm} is the constant determined by the boundary conditions, n and m are the circumferential and radial modal numbers, respectively, a is the radius of the pipe, and $J_n(x)$ is the first Bessel function. The value of β_{nm} can be obtained from Table 2.

On the cross-section of a circular tube, the normal mode wave of order (n, m) determined at different values of β_{nm} would result in different acoustic characteristics [40]. The sound pressure in a pipe is the superposition of the sound pressure components of each model. From formula (39), we can obtain an important property of sound wave propagation in a circular tube, that is, the existence of cutoff frequency n, as

$$\sqrt{k^2 - \left(\frac{\beta_{nm}}{a}\right)^2} < 0, \tag{38}$$

$$f_{\mathrm{cutoff}} \geq \frac{\beta_{mn}}{2\pi a}c, \tag{39}$$

$$c = \sqrt{YRT}, \tag{40}$$

Table 1: Axial fan performance parameter table.

Model (no.)	Data parameter			
	Power (W)	Air volume (m^3/h)	Pressure (Pa)	Noise (dB)
JD100	28/25	200/150	180/130	30/25

$m=5$	6.415	13.987	13.987	17.313	20.576	23.804

where ϒ is the specific heat ratio (for air ϒ = 1.4), T is the thermodynamic temperature of the gas in K, and R is the gas constant (usually $R = 287\,\mathrm{J(kg \cdot K)}$). If there is no pressure change during a specific use, only the temperature is usually considered. In the pipeline, the sound wave frequency is smaller than the cutoff frequency that can propagate by formula (39), and the sound wave frequency larger than the cutoff frequency will decay exponentially. The noise higher than the cutoff frequency does not need ANC [41]. The frequency of the pipeline is a result of the superposition of multiple groups of β_{nm} values that can be obtained from Table 2. In the finite element analysis of the pipeline [42], white noise is used to excite the simulation model, and the simulation model has the attenuation effect of excitation sound waves at different frequencies (350–3600 Hz), as shown in Figure 17.

The simulation of the sound wave transmission aspect of the pipeline shows that, for the HVAC-ANC system, high-frequency noise generated by the axial fan is quickly attenuated in the pipeline. Therefore, the ANC system can only handle frequencies below 4 kHz at the end of the pipeline. Low-frequency noise can reduce the acquisition bandwidth of ADC [43], reduce the number of iterations of the ANC system, and improve the noise cancellation effect of the algorithm.

6. Experimental Results and Discussion

The proposed algorithm is compared with the fixed step size FXLMS, piecewise LMS, AVSS-LMS, and Salman algorithms in the simulation. Table 3 provides the parameter setting. The test input signal is composed of Gaussian white noise and sinusoidal signal. The system has 10000 iterations, and the signal noise ratio (SNR) is 20 dB.

Figure 18 shows the step sizes of the five algorithms very differently according to the error signal size variation trend. The proposed algorithm can obtain the maximum step size when the error is large. According to formula (15), the larger the step size, the higher the convergence speed of the algorithm. Therefore, the algorithm is characterized by high convergence speed when the error signal is large, and the step size obtained from the piecewise LMS algorithm occurs second. When the error signal is small, the step change of the proposed algorithm is smoother than that of the AVSS-LMS and piecewise LMS algorithms. Formula (16) shows that the steady-state error obtained with a smaller step size becomes smaller as it approaches stability. Therefore, compared with the AVSS-LMS and piecewise LMS algorithms, the proposed method has less MSE. Formula (30) shows that the proposed method has a high convergence speed and reduced MSE. It also has good antiinterference ability and can converge stably.

Figure 19 shows that the five algorithms can converge and filter out the noise, but their convergence speed and MSE are different; the speed and MSE of the proposed algorithm are better than those of the other four algorithms. Figure 19 shows that, among other algorithms, the performance of the piecewise LMS algorithm is closest to the convergence performance of the proposed algorithm. The proposed and piecewise LMS algorithms have good theoretical tracking performance on noise, but the piecewise points of the piecewise LMS algorithm affect the results of the algorithm. In order to improve the performance of the piecewise LMS algorithm, much time and energy are needed

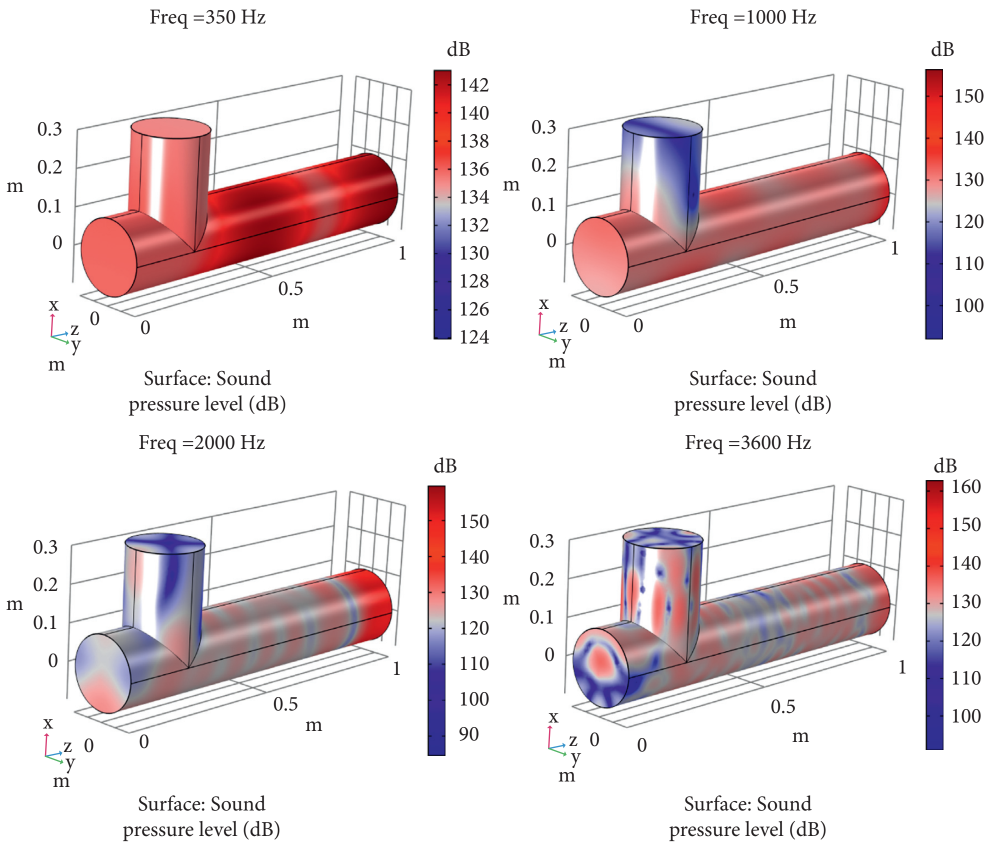

Figure 17: Sound wave transmission simulation in a PVC pipeline.

Table 3: Simulation parameters for the proposed algorithm and other algorithm.

Algorithm	Variable step	Parameter
AVSS-LMS	$\mu(n) = b(1/1 + \exp(-aE\|e(n-1)e(n)\|) - 0.5)$	$a = 0.97, b = 0.03$
Fixed step FXLMS	μ	$\mu = 0.01$
Piecewise LMS	$\begin{cases} \mu = k,\ 0 \le n \le \text{sample length}/5 \\ \mu(n) = b(1 - \exp(-a * \|e^2(n)\|)), 0.001 < \|e^2(n)\| \le 0.01 \\ \mu(n) = b(-1 + \sec(a * \|e(n)\|)),\ 0 \le \|e^2(n)\| \le 0.001 \end{cases}$	$k = 0.03,\ a = 0.97,\ b = 0.03$
Salman	$\mu(n) = \lambda(\operatorname{sgn}(w(n))/(1 + b\|w(n)\| + b^2\|w(n)\|^2))$	$\lambda = 0.02, a = 0.97, b = 0.03$
Proposed	$\mu(n) = b(3/(1 + \exp\ (-a\|\arctan(e(n))\|)^c) - 1)$	$a = 0.97, b = 0.03, c = 4$

to fine-tune the parameters. Considering MSE, the Salman algorithm has a low MSE after stability. The proposed method can have MSE as low as that of the Salman algorithm, but its convergence speed is much higher than that of other algorithms. Notably, the MSE of the proposed algorithm shows a further downward trend.

Table 3 provides that the Salman algorithm is also a variable step size algorithm, but Figure 18 shows that the variable step size strategy of the Salman algorithm is not causally related to the error signal. The Salman algorithm uses a penalty weight to adjust the step size. It makes the weight lag, so it does not have a large step at the beginning of iterations. Its convergence speed is much lower than the AVSS-LMS and piecewise LMS algorithms (Figure 19). However, it can obtain smaller MSE than the AVSS-LMS and piecewise LMS algorithms when the number of iterations increases and it converges stably. The Salman algorithm can obtain the same noise cancellation effect as the proposed algorithm when it is employed in the processing of HVAC pipeline noise. Still, its ability to track abrupt noise is not as strong as that of the proposed algorithm.

ANC-OFF in Figure 20 is the noise collected by the microphone at the outlet of the PVC pipe, and it can be seen that part of the noise generated by the axial fan, part of the rotating noise has a frequency, which can be deduced from formula (32), while the other part belongs to the random noise, and this part of the noise belongs to the more difficult to eliminate. From ANC-ON shown in Figure 20, it can be seen that the signal amplitude of the noise at the outlet of the PVC pipe can be reduced by about 17 dB after a very short time, indicating that the proposed method has a practical effect of noise reduction. It can also be seen from the

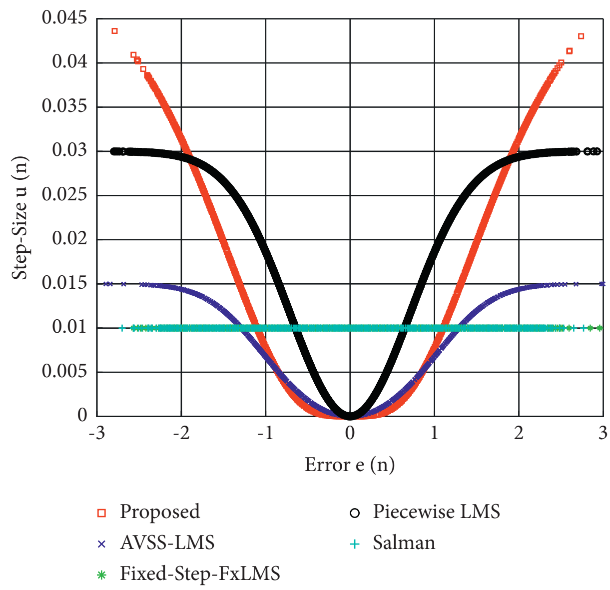

Figure 18: Comparison of step size of five noise reduction methods.

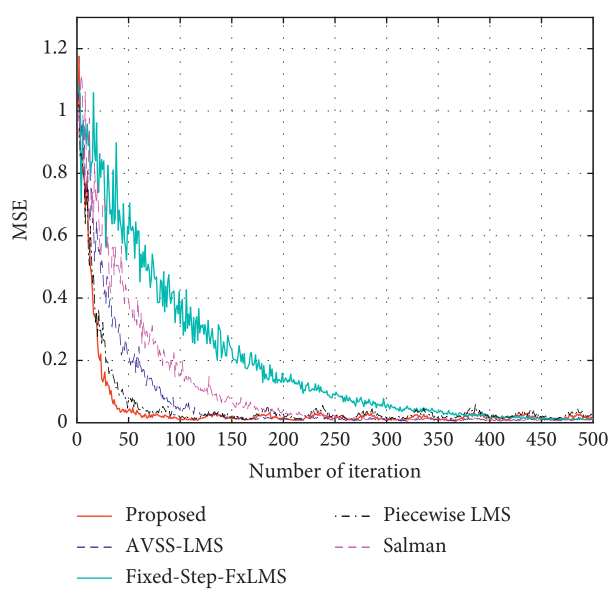

Figure 19: Comparison of MSE of five noise reduction methods.

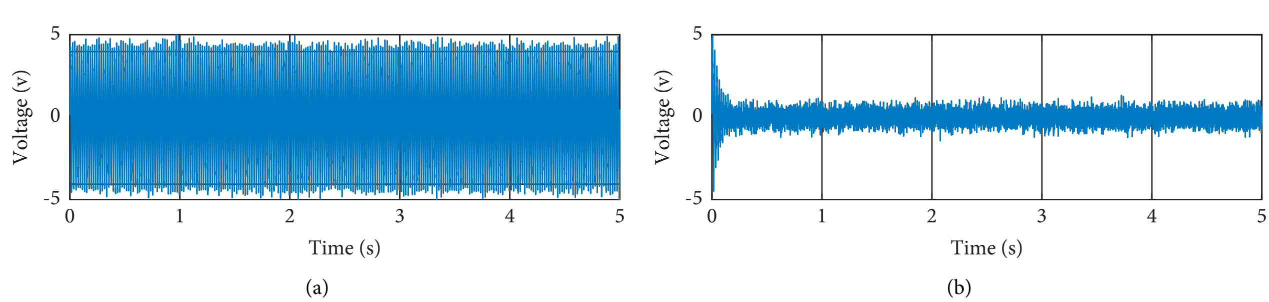

Figure 20: Comparison of (a) ANC-OFF and (b) ANC-ON.

Table 4: Performance comparison.

Method	Comparison parameters			
	Maximum step size	Number of iterations	Noise cancellation effect (dB)	Convergence time (ms)
Proposed	0.042	41	17.2	4.05
AVSS-LMS	0.015	70	16.0	5.91
Salman	0.01	220	15.5	18.21
FXLMS	0.01	413	14.3	22.3
Piecewise	0.03	55	14.9	4.25

experimental results that the improved method has a more satisfactory effect on the regular noise cancellation, while there is still some room for improvement for random noise.

In Table 4, we compare the maximum step size that can be achieved by the five algorithms, the number of iterations when $MSE \leq 0.1$, and the noise cancellation effect when applied to pipelines. The test environment for the five algorithms is consistent with the test signal. The proposed, AVSS-LMS, piecewise, fixed-step FXLMS, and Salman algorithms take 0.9901, 0.9438, 0.7719, 0.5406, and 0.8281 s, respectively, to perform 10000 iterations. In Table 4, the convergence time is the product of the average single-step iteration time and the number of iterations. Although the total time for the proposed algorithm to complete $n = 10{,}000$ iterations is the longest, it takes only a few iterations to converge, so the time for the proposed algorithm that converges to $MSE \leq 0.1$ is shorter than that of the other four algorithms. It can be seen that the maximum step size that can be obtained by the proposed method is larger compared to the other four algorithms, and therefore, the number of iterations is relatively less. In addition, the comparison in Table 4 also provides that the improved method can reduce more noise than the remaining four methods, and AVSS-LMS also has a better noise cancellation effect. The piecewise method is influenced by the segmentation strategy, and the segmentation points need to be retested after the usage environment has changed.

The proposed algorithm can quickly eliminate noise in pipelines. It has good tracking performance for rotation noise. The piecewise LMS algorithm can also converge rapidly for pipeline noise, and at the beginning of the iteration, it can achieve convergence performance close to that of the proposed algorithm (Figure 18). However, Figure 19 shows that MSE of the piecewise LMS algorithm is significantly higher than that of the proposed algorithm at a stable state, which is attributed to the nonsmooth change in the step size of the piecewise LMS algorithm at a steady condition.

Based on these results, compared with the other four algorithms, the proposed algorithm has a better suppression effect on rotation noise generated by the axial fan in HVAC pipelines. The algorithm uses the arctangent function to nonlinear the error signal and step size. In the effective noise reduction area, the random noise can be reduced by 12–17 dB, and the noise is reduced by about 83%–92%. Experiments and simulations show that the proposed algorithm has advantages in terms of convergence speed, steady-state error, and noise cancellation effect, and its comprehensive performance is better than that of the other four algorithms.

7. Conclusion

This study proposes a new variable step size FXLMS algorithm for ANC systems in HVAC pipelines. We present a variable step size FXLMS method based on the arctangent function based on in-depth evaluations of Neil, Wang, and Salman's step size modification strategies. The algorithm uses the boundedness and continuity of the arctangent function to nonlinearly transform the error signal, so that the step size can be adjusted following the change in the error signal, compared with the mainstream ANC algorithms that significantly improved convergence speed. It reduces the noise generated by the axial flow fan in HVAC systems and has a good noise cancellation effect. The proposed algorithm has an excellent response on standard PVC pipelines, but the algorithm may not converge for nonstandard pipelines due to the mismatch of the air pipeline SP. As a result, the algorithm may not converge when used for nonstandard PVC pipelines. A further research task in the future is to investigate how to provide a more accurate SP model for the algorithm, so that our proposed algorithm can be easily used in various types of HVAC systems.

Abbreviations

ANC: Active noise control
HVAC: Heating, ventilation, and air-conditioning
VSS-LMS: Variable step size least mean square
FXLMS: Filtered-X least mean square
MSE: Mean square error
SP: Secondary path
SVS-LMS: Sigmoid variable step size LMS
AVSS-LMS: Antiinterference variable step size LMS
TVOCs: Total volatile organic compounds
PVC: Polyvinyl chloride
SNR: Signal noise ratio.

Academic Editor: Tongguang Ni

This article compares the characteristics and advantages of flipped sports classrooms with other disciplines and traditional sports classrooms, and analyzes the characteristics and advantages of flipped sports classrooms, using the method of experimental comparison and comparative analysis to sort out the characteristics of Flipped classes in the application of teaching practice. Adjusting the teaching process and structure, with sports skill teaching as the main line, can create conditions for the deepening and expansion of PE. Students are the main body in a flipped class, which confirms the teaching concept. With the advent of the Internet era, students can access the information network at any time and from any location to gain PE knowledge. To meet students' learning needs, teachers must interact with them more and grasp teaching feedback more quickly. To sort out and research flipped classroom teaching in physical education, compare the use of flipped classroom teaching in physical education to traditional PE teaching over time, and demonstrate that flipped classroom teaching in physical education should be based on sports skills teaching and the teaching process. Making the necessary adjustments can help students learn in a positive environment. Then it examines two levels of technology and operation implementation in order to provide theoretical support for Flipped classroom teaching and improve student learning efficiency.

1. Introduction

Due to the ever-increasing use of the Internet, the educational model has undergone significant changes [1]. Flipped classrooms are becoming more common as the Internet era progresses. Using information technology in the classroom can help improve teaching efficiency and promote educational reform. Physical education (PE) is an important part of college and university education, as it promotes students' physical and mental health. The use of Flipped classes in college and university PE can be beneficial [2, 3].

Physical education (PE) classes are becoming more templated in today's colleges and universities [4]. PE teachers plan all of their lessons meticulously, no matter where they are in the process. Students are doing teacher-directed preparation activities, learning physical skills, and not having enough room in their PE class for self-expression. [5] Inflexible and mechanical, with no room for play. If things keep going this way, things will only get worse. PE teachers use this teaching model to instill physical skills, create various training activities to help students improve their sports skills, and exaggerate students' athletic abilities [6]. This teaching model fails to effectively cultivate students' athletic and humanistic qualities, which has a negative impact on their personal development [7].

Teachers must test the theory in the real world to ensure that flipped sports classrooms are as effective as they claim to be. It is hoped that this study will encourage the use of flipped classroom teaching methods in physical education, thereby speeding up the reform of the subject [8].

2. Related Work

As a result of its widespread use in the classroom, it has evolved into a new teaching method that is in opposition to traditional teaching theories. Is it possible to describe a flipped class?

The Flipped Class education model was created by Jonathan Berman and Aaron Sams, two chemistry teachers at Rocky Mountain Woodland Park High School in Colorado, USA [9].

Flipped classes, according to the literature [10], are a method for increasing interactive and individualized contact time between teachers and students; they are a personalised teaching environment in which students can receive individualized education. The teacher is no longer the dictator on the podium, but the instructor of the students' learning; the teaching content is saved, and students can review it at any time based on their own circumstances; the teacher is no longer the dictator on the podium, but the instructor of the students' learning; the teaching content is saved, and students can review it at any time based on their own circumstances. It's a teaching method that combines direct explanation with constructivist learning to prevent students from falling behind in class.

Literature [11] believes that the role of teachers and students in traditional classroom teaching has been rearranged as a result of the Flipped Class, and that classroom time is better utilized by reversing the knowledge transfer and internalization arrangements.

To complete the knowledge transfer and enter the stage of knowledge internalization in a Flipped classroom, the literature [12] believes that knowledge transfer before class must exceed the teaching effect of teacher instillation. Students will not be able to do their best outside of the classroom if they do not do their best in class. To put it another way, the success of a lesson can be measured by the extent to which the students' prior learning has influenced the teacher's teaching in a traditional classroom and the students have fully internalized the course's content.

According to literature [13], students learn independently before class using teacher-created materials, then participate in teacher-student interaction activities and complete exercises in the classroom. [14].

According to literature [14], flipped classes involve teachers creating instructional videos that students watch at home or outside of class before returning to class to share their learning outcomes and experiences face-to-face.

The flipped classroom teaching model is a traditional teaching model in which students complete homework assignments at home, allowing them to learn at their own pace and in their own time, and the classroom becomes a place where teachers and students interact, promoting knowledge internalization through strategies such as solving doubts. [15] Literature.

According to Literature [16], flipped classrooms are located in an information-rich environment. Teachers use instructional videos as a primary mode of instruction for their students. Students watch and learn from videos before class. For both students and teachers, classes are a time for teaching and learning. Active communication and other forms of engagement are incorporated into a new approach to teaching and learning.

According to literature [17], a flipped class is an educational method that improves knowledge transfer and ability to retain it. As a result, he thinks Flipped Class should be renamed Flipped Teaching, because the relationship between teachers and students has fundamentally changed.

To summarize, this article's definition of flipped class is: Using information technology and network resource management as a platform, the teacher provides learning for students in class by creating teaching videos that allow students to complete knowledge learning before class and achieve the desired results. Exchange opportunities, assist students in internalizing knowledge, and create a new type of teaching model for students to become true masters of learning.

3. Analysis of the Characteristics of Flipped Class

3.1. Teaching Presupposition from Rigid Presupposition to Flexible Presupposition. The concept of Flipped class has more characteristics than the traditional classroom teaching mode, and it is also derived from the traditional classroom concept, and its characteristics are more prominent than the former [18].

In traditional classroom teaching, teachers have always held a dominant position in education, and students have always been in a passive learning state. In the Flipped Class Teaching model, the role attribute of classroom teaching is reversed. In the classroom, the student takes on the role of protagonist, while the teacher takes on the role of organizer.

Teachers in traditional classrooms have a tendency to meticulously design the curriculum, step by step, and gradually advance the pre-set mode [19]. The interlocking instructional design will not be able to move forward as long as the teacher decides what students are allowed to express. As a result, students are frequently given teachers' teaching tasks, and students lose more autonomy and critical thinking skills, as well as their enthusiasm for the classroom.

3.2. The Teaching Process Is Reversed from First Teaching and Then Learning to First Learning and Then Teaching. Teachers have traditionally imparted new knowledge to students in the classroom, while students work to retain it outside of class time. Internalization, on the other hand, is more challenging for students. The flipped classroom model can be fully integrated into student learning when used in the classroom. The use of a flipped classroom causes traditional teaching methods to be disrupted. It goes from teaching first and then educating to learning first and then educating, as shown in Figure 1.

Students use the network platform's resources to gain a basic understanding and knowledge of new information during their free time. Rather than teaching new information, the teacher uses class time to guide and explore students' previous learning problems. Internalization can then be enhanced, allowing students to gradually master higher-level knowledge [20].

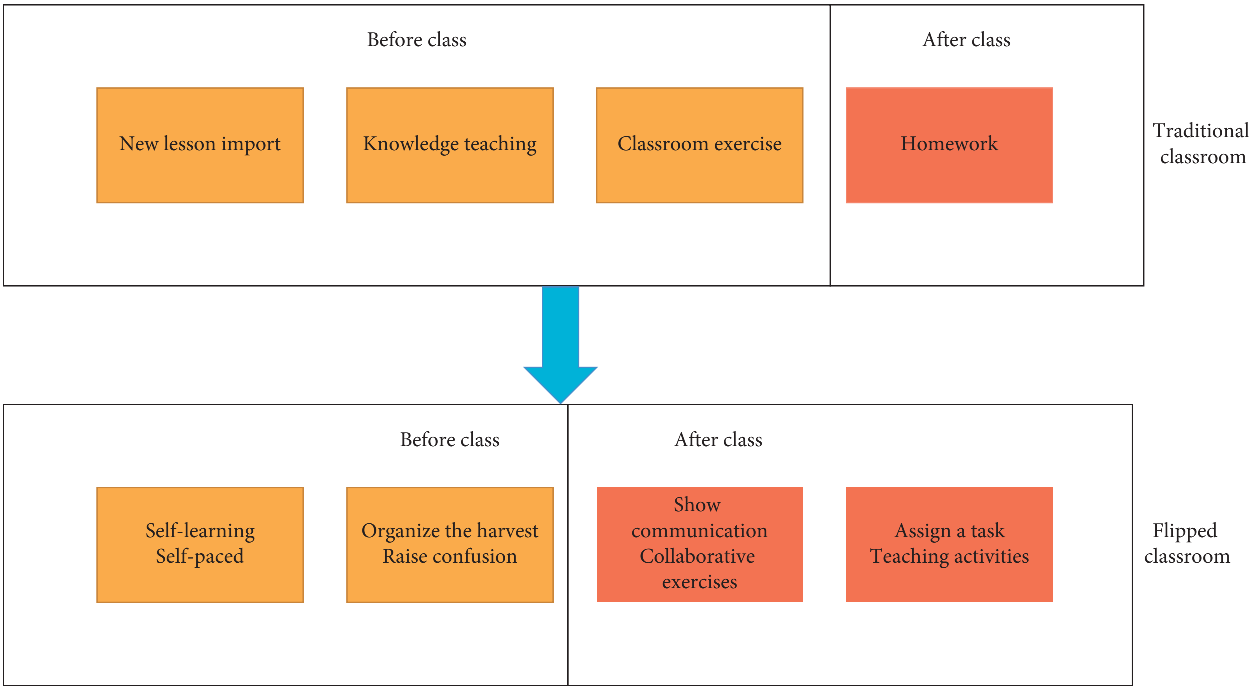

Figure 1: Process flip from traditional teaching to Flipped class.

3.3. Students' Learning Mentality Changes from Passive Acceptance to Active Exploration. In a traditional classroom, the teacher's lecture hall is the classroom. The students' task is to learn one line passively. Listening to the lesson and taking notes has become a routine for the students, and it is easy for them to lose interest in learning classroom knowledge. Flipped classrooms, as opposed to traditional classrooms, allow students to learn more actively, internalize concepts in class, and integrate them into their own cognitive structure. Students in the Flipped class spend more time in class discussing their own problems, interests, depth, value, and other issues in groups and with teachers, enhancing the value of classroom teaching and enabling each student to meet their own needs and increase interest, thereby enhancing the significance of Flipped class education in many ways.

4. Necessary Conditions for the Implementation of Flipped Class

4.1. Schools Must Have a Supporting Environment for Flipped Class. It is clear that information technology [21, 22] plays a critical role in implementing Flipped classes in the classroom; without it, Flipped classes will not be implemented. To some extent, information technology advancement is a precondition for using Flipped classes, and Flipped classes can only be presented with the help of highly developed information technology. As a result, since its inception in the nineteenth century, the Flipped class has only evolved [23]. This flipped teaching mode allows for self-study outside of class and classroom teaching after class. Technology is inextricably linked to any link, such as video production and transmission of teaching content, students watching video learning, and teacher-to-student individual communication. It is impossible to comprehend the situation and teach students according to their abilities without the use of information technology. A large classroom with cutting-edge technology is required for this flipped teaching mode.

The above-mentioned large environment of advanced information technology consists primarily of two major systems: hardware and software. Figure 2 depicts the four aspects of the hardware system:

4.2. The Overall Design of the School Curriculum. Flipped class implementation necessitates a thorough review of all courses offered at the school; otherwise, a slew of unfavorable implementation issues will arise. If each teacher makes partial or overall changes to the curriculum based on his or her own preferences, it will result in duplication of teaching content. Missed classes, subject confusion, and lengthy homework assignments after class are just a few of the issues. To avoid conflicts between courses, subjects, and time, general rules for overall design should be followed before implementing Flipped classes [24].

4.3. School Teachers' Teaching Ability Requirements. Before implementing a Flipped classroom, it is critical to address the issue of teachers' ability to use technology. Teachers in Flipped Classrooms should receive technical training from their schools. Teachers are the only ones who have truly mastered the use of information technology in education. With the help of network platforms, flipped classrooms can be implemented more efficiently [25].

Teachers' abilities are improving, so flipped classrooms cannot be ignored. To meet this demand, teachers of

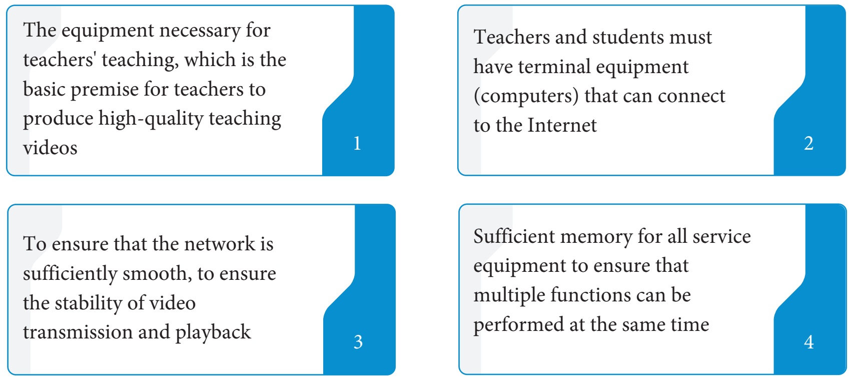

Figure 2: The Flipped class hardware system covers four aspects.

physical education (PE) must meet higher standards. Because it differs so much from other academic disciplines, physical education (PE) instruction can be difficult to implement. Because there are so many students, PE teachers find it difficult to know when to use Flipped classes. PE teachers can make an informed decision based on their ability to manage a PE classroom and their extensive teaching experience. As a result, schools should focus on cultivating PE teachers' ability to teach in a variety of modes, including traditional indoor and outdoor teaching, as well as the Flipped classroom. Each method of instruction has its own set of benefits and drawbacks. They do not have a positive or negative aspect to them. Appropriate or inappropriate is the only way to tell them apart. In order to achieve the best learning effect, PE teachers should adjust measures to local conditions and time, according to specific teaching content, and the actual situation of students chooses the best teaching mode [26].

5. Feasibility Analysis of Sports Flipped Class Teaching Based on Sports Skill Learning

5.1. Acknowledgement of the Help of Flipped Class for Sports Learning. In a flipped class, students move from a traditional templated classroom to an autonomous-mutual aid classroom based on motor skills [27]. During this transition, students must move from passively imitating actions and passively following instructions to active learning [28]. As a result of the transformation of inquiry, communication, and learning, students must have the ability and awareness to learn sports skills independently, actively participate in teaching, and effectively interact with teachers. Through questionnaires, seminars, and other means, this paper investigates the role of sports skills on students' learning and independent learning of sports in six elective PE classes in a college class to assist in the teaching of sports skills, a total of 377 students, 195 boys and 182 girls. The state of one's motor skills is examined.

Sports skills can benefit students in the form of self-paced learning before class, repeated observation after class to consolidate technical movements, and new ideas in movement arrangement in class. Figure 3 shows how students can learn sports skills by using open feedback.

As the Internet era and new learning methods have emerged, students' desire for sports resources has grown. Learning nowadays takes place outside of the classroom. When students have access to high-quality sports skills resources, they are more enthusiastic about sports. Learning physical education necessitates the acquisition of a wide range of abilities.

5.2. Investigation on the Flipped Class Consciousness of Autonomous Learning PE. The questionnaire survey is shown in Figure 4:

189 students prefer to study before class, especially if the number of views increases the day before class. After class, 135 students are still choosing to review. The majority of these students, according to interviews, are accustomed to the teacher's intuitive teaching in class, imitate the teacher, and spend less time reviewing after class. 57 students combined pre-class and post-class review. There are students who enjoy the course in particular, as well as students who lack coordination. Only a small percentage of students who prepare before class have poor self-study quality, according to survey and interview findings. Furthermore, many students continue to rely on their teachers' classroom instruction and do not take the initiative to do pre-class video learning, resulting in them remaining in class. Teachers and students are unable to communicate effectively with one another.

5.3. The Teaching Concept of PE Teachers Needs to be Updated. Thanks to technological advancements, PE reform in colleges and universities has gotten a big boost. Some PE teachers, who are eager to try out new ideas and methods, have embraced the use of information technology in PE. While this is a step forward, some PE teachers in traditional colleges and universities are still stuck teaching and improving sports skills as a coaching method. The teacher-student relationship is marked by an unwillingness to study students' learning methods in depth and a lack of understanding of PE reform, rather than focusing on the development and improvement of students' self-directed learning abilities. The lack of themes and limited communication channels are to blame. It's common to focus on the students'

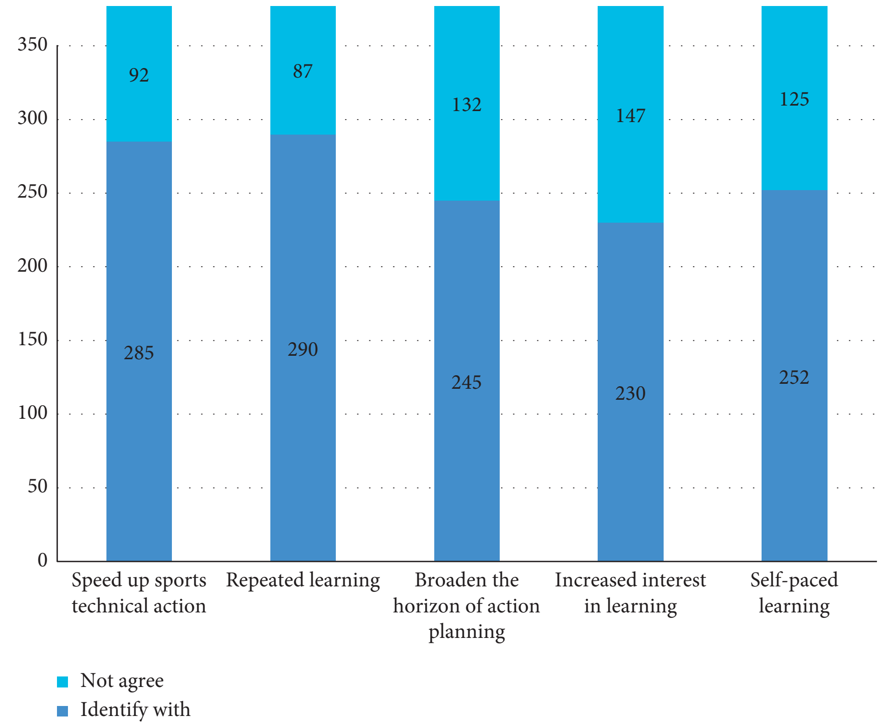

Figure 3: Statistics of Flipped classs for learning aids.

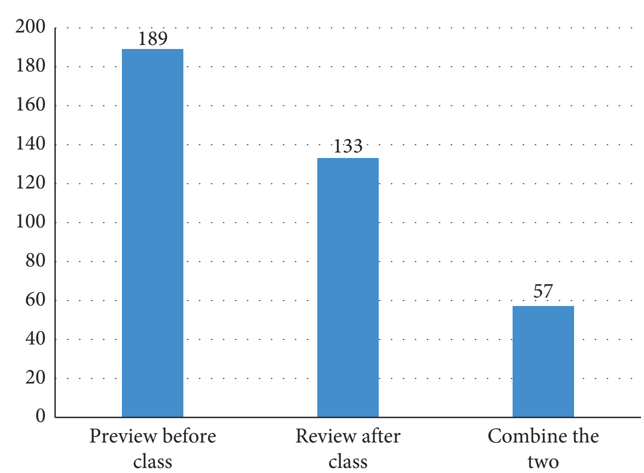

Figure 4: Survey statistics of self-learning sports Flipped class.

outcomes rather than their progress when evaluating their learning.

These sports departments have incorporated modern artificial intelligence [29–31] into their educational resources, making sports-related information more accessible to students, teachers, and the general public. In the field of physical education, the number of master's and doctoral students has steadily increased, as has the academic credentials of PE teachers hired by universities. In a flipped classroom, traditional PE is not taught. It has the potential to energize classrooms, motivate students to participate in sports, and improve the quality of classroom instruction, in addition to increasing student motivation and engagement in physical activity. In order to rely on the promotion of PE, college PE teachers must actively learn and implement the theories of Flipped Classrooms, as well as continually reflect on classroom issues and improve classroom teaching quality. Students' overall development and well-being.

For today's students, mobile phones can be the most direct means of instruction. Students can now access a wealth of sports-related information and video resources via their mobile phones and the Internet, and physical education teachers can use these tools to provide students with self-paced, self-guided learning opportunities. It's all about resource sharing. PE instructors who believe in the practical and interactive nature of the curriculum and are unconcerned about the integration of technology into college PE courses are still in the minority. Flipped PE classes are difficult to develop because it is difficult for PE teachers who are used to a more traditional model of teaching to embrace the use of technology in their classrooms.

6. Analysis on the Effectiveness of Sports Flipped Class Teaching Based on Motor Skill Learning

What is the most effective method for teaching sports skills? To be an effective sports skill teacher, you must first understand what type of instruction is most effective. The term "effective" is used when students make specific progress or development after receiving instruction. To put it another way, the only way to tell if a teacher is effective is to look at their students' progress. Even if it is extremely difficult, teaching is ineffective or inefficient if the student does not want to learn or does not benefit greatly from it. Teachers use their own desire to learn as a starting point to pique students' interest in learning.

When it comes to classroom teaching and sports skill instruction, there are a lot of moving parts. This article uses University A and University B as examples. In A college PE, flipped classes are used, while in B college PE, traditional classes are used. There are 120 target classes, and no significant differences in physical fitness exist between them.

6.1. Comparative Analysis of Student Practice Density. Students in a flipped classroom learn sports knowledge and action methods through the use of micro-videos. In the micro-class learning stage, students begin to learn and practice knowledge and movement. As a result of this, students will be able to learn more about sports and movement methods, free up more time for students to practice activities, and increase the amount of effective practice time that they have available to them. The number of students practicing in the classroom increases. Flipped and traditional classrooms are compared in Table 1 by student practice density.

A reasonable range is shown in Table 1 for the practice density of the two pieces of information. Flipped Class A and traditional classrooms have very different student practice densities. Students in Flipped Class A have a higher practice density than students in traditional classrooms; however, students in Flipped Class B have a lower practice density than students in traditional classrooms. The experimental results show that A outperforms B in terms of autonomous learning ability. Open-motor skills are also more effectively taught using the Flipped Classroom model. A higher density of practice was achieved in traditional lessons as a result of teachers' use of course design methods that were more open to adopting the new curriculum concept than other teachers.

6.2. Comparative Analysis of Students' Practice Intensity. While physical exercise is the primary method for students to improve their overall physical fitness, they are also given more time for exercise, but with a limited amount of time to achieve an appropriate level of exertion. Students in both a traditional classroom and a flipped classroom work hard (heart rate) Table 2 shows the results of the comparative analysis.

Except for the squatting start, there are significant differences in exercise intensity between the Flipped classroom and the traditional classroom. When compared to traditional PE classes, Flipped PE classes require significantly more physical effort.

A passing class in basketball is shown in Figure 5 as an example of a rational analysis of exercise intensity.

The Flipped class's heart rates range from 120 to 150 beats per minute, which is between medium and low intensity and meets the basic requirements of warm-up activities, as evidenced by the gradual increase in heart rate over the first 12 minutes (preparatory activity). In the second half of the 15–36 minute part of the basic requirement, there are two peaks of 192 times/min and 204 times/min, but the duration is short, reflecting the quality exercises in the second half. It's undeniable. The heart rate gradually rises during the first 12 minutes of traditional classroom (preparatory activity), and it is between 126 and 144 beats per minute, which is medium to low intensity. It's finished as part of the warm-up. 15–30 minutes at 150 beats per minute in the first half, then 174 beats per minute in the second half. Despite this, the summit has yet to fall below its peak elevation. As evidenced by the rapid decline in intensity toward the end of the 33–40 minute period, the second half of the quality training arrangement lacked high-intensity quality training. Because the traditional classroom exercise load intensity is lower, students' physical fitness improves significantly when taught in a Flipped classroom.

6.3. Contrastive Analysis of Students' Mastery of Motor Skills. What impact will the flipped classroom have on motor skill acquisition? As shown in Table 3 of this article, two groups of experts, A and B, observe the students' on-the-spot mastery of motor skills and then grade them using a scale.

Micro-classes in the classroom teaching process and the organizational effects of the classroom are one of the most important factors that determine the level of skill mastery, especially for team Learning content with a lot of collaborative elements, as shown in a flipped class with strong team cooperation.

Unlike traditional teaching, flipped class teaching generates enthusiasm for sports participation, a reasonable amount of physical activity, and effective motor skill learning. Students' physical health and fitness have improved as a result of the Flipped classroom. In flipped classrooms, students are more encouraged to express themselves than in traditional classrooms. Through goal-led and task-driven micro-class and classroom learning, students are encouraged to actively participate in learning activities, deepen their autonomy, cooperation, and inquiry, and effectively change how they learn. Thanks to the flipped classroom, teaching methods are fundamentally altered, teachers create student-centered activities, and the concept of teaching for learning is realized. The ability to innovate has been significantly enhanced.

Table 1: Comparison of student practice density between Flipped class and traditional classroom.

Subject	Flipped class		Traditional classroom		t	P
	n1	Proportion/%	n2	Proportion/%		
Basketball pass	46	75	45	51	2.367	<0.05
Squat start	49	79	47	39	3.966	<0.01
4 × 50 m Relay	40	72	42	60	1.178	>0.05
Aerobics	44	73	43	59	1.342	>0.05

Table 2: Comparative analysis of student practice intensity between Flipped classs and traditional classrooms.

Subject	Flipped class		Traditional classroom		t	P
	Average heart rate X1	S1	Average heart rate X2	S2		
Basketball pass	135.31	19.01	126.50	18.85	2.427	<0.01
Squat start	123.63	17.11	119.56	16.32	1.284	>0.05
4 × 50 m Relay	145.51	30.24	130.53	23.52	2.992	<0.01
Aerobics	138.12	27.35	125.51	19.25	2.492	<0.01

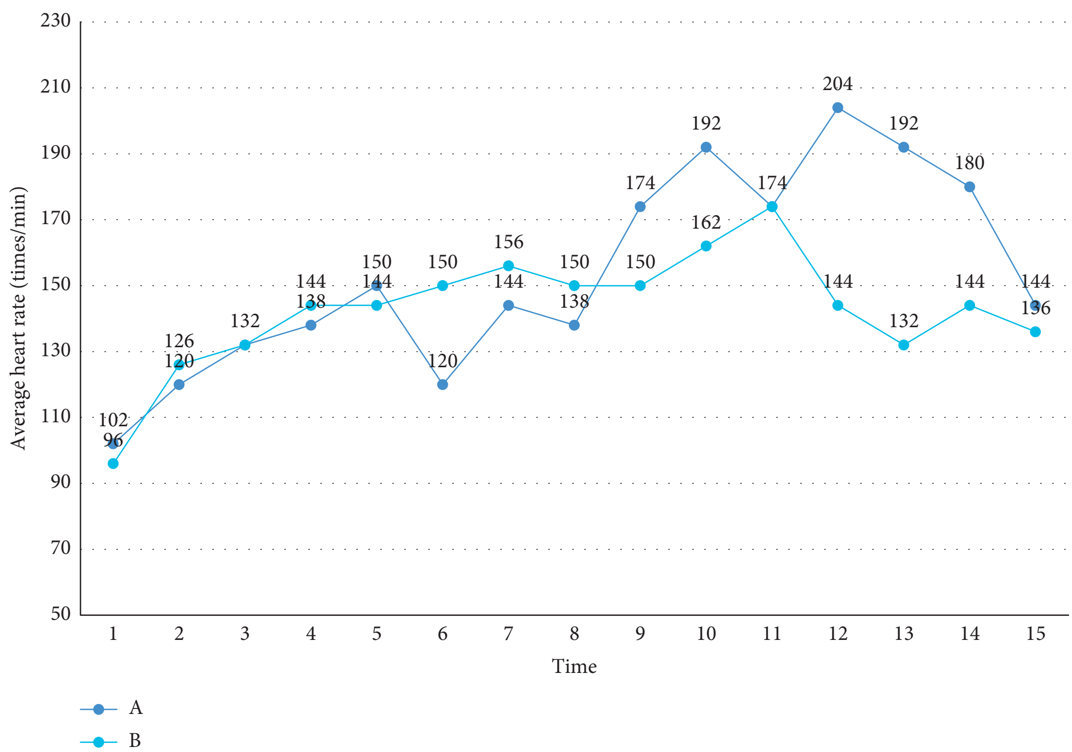

Figure 5: Comparison of heart rate curves between Basketball pass Flipped class and traditional classroom.

Table 3: Comparative analysis of students' motor skills mastery in Flipped classs and traditional classrooms.

Subject	Flipped class Average mastery score	Traditional classroom Average mastery score	t	P
Basketball pass	92	62	3.420	<0.01
Squat start	86	74	1.517	>0.05
4 × 50 m Relay	88	74	4.456	<0.01
Aerobics	53	51	0.259	>0.05

7. Conclusions

The popularity of flipped classroom teaching has grown as a result of the widespread use of multimedia technology. In order to stay on schedule, the college PE curriculum must be flipped to compensate for the information, content, and conceptual gaps. Maintain a steady pace with your field's current trends. The introduction of the flipped classroom teaching concept, which can serve as a supplement to, promotion of, and challenge to traditional university PE classroom teaching, could greatly benefit my country's colleges and universities. Some of the advantages of this method of teaching in college PE classrooms include a panoramic view of the content of PE courses, the development of sports interests and hobbies, and the establishment of good physical exercise habits. Traditional teaching methods and concepts have been reshaped by flipped classrooms for many teachers. Students and teachers are able to interact more frequently in a flipped classroom, resulting in a better value and emotional system for the students. In order to achieve a comprehensive assessment of students, we should evaluate their learning outcomes as well as their learning process using a comprehensive, multi-angle, and three-dimensional evaluation method.

Traditional teaching models influence Flipped class instruction; the network teaching environment is imperfect; there is a lack of relevant theoretical research and practical experience in sports practice Flipped classes; teachers lack production teaching resources and the ability to use micro-video; and students lack self-learning abilities.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The author does not have any possible conflicts of interest.

In view of the shortcomings of the traditional architectural design mode, such as high rework rate in the construction process and lack of collaborative design and intelligent information processing, a green building energy-saving design method based on BIM technology was proposed. Based on the comparative analysis of traditional computer-aided building design and BIM green building technology, the overall scheme of energy-saving design was constructed from the aspects of green building design principle, design preparation, and design concept. This paper expounded the connotation of energy-saving design elements from the aspects of modeling software selection, envelope energy-saving design, and lighting energy-saving design. Accordingly, the characteristics and process of building energy efficiency analysis based on BIM were proposed. Finally, the energy-saving effect evaluation method of green building based on BIM was given, and an example showed that the energy-saving design method of green building based on BIM proposed in this paper had good feasibility and effectiveness. The method proposed in this paper can provide a certain theoretical basis and application support for the application of BIM technology in the field of green building.

1. Introduction

Since the end of the last century, most developed countries have been deeply exploring green buildings and their applications and have successively issued some different evaluation standards based on the reality of various countries, which has accelerated the development of green buildings in the world to a great extent [1–3]. With the continuous development of green building field, BIM technology has been widely used in western developed countries. Relevant personnel in other countries have also conducted relevant in-depth research on BIM theoretical and technical system and its practical application and made great progress. Some scholars can realize the simulation of building energy-saving design and its effect by combining a three-dimensional building model with energy consumption analysis.

In recent years, with the promotion of BIM software, such as Revit series of Autodesk company and ArchiCAD of graph iSOFT company, it has been well applied in the field of green building [4, 5]. Applying BIM technology to the design of construction projects can not only predict and find the deficiencies in the design but also avoid the additional consumption in the actual construction process [6–8]. For example, the effective integration of building a 3D model and structural model with the Revit structure can promote the information exchange and collaborative work of construction project participants.

The application of BIM technology is conducive to the completion of various design, construction, and later maintenance of construction projects, which not only promotes the renewal of architectural design methods but also improves work efficiency [9, 10]. With the global energy crisis, energy shortage, and the continuous deterioration of the natural environment in recent years, how to use BIM technology to carry out energy-saving design of green buildings and scientifically evaluate the energy-saving effect has become a concern of relevant scholars. However, there are still some deficiencies in the application of BIM technology in green buildings, such as insufficient design accuracy and unscientific intelligent processing method. Therefore, how to improve green building design based on BIM technology is one of the urgent problems to be solved in the field of green buildings.

2. Related Works

Developed countries are the first to use BIM technology and have applied it to the whole process of construction projects. With the deepening of the concept of building energy conservation, the research and application of green building are also developing. Technology provides strong support for promoting the development of the construction field [11–13]. The adopted building information model can visually reproduce the real scene of the building and its stages from different dimensions, which fundamentally overcomes the shortcomings of the traditional building model. The core software of BIM can parameterize the building model and predict or simulate various situations that may occur in the building process through various information contained in the model. The collaborative operation between BIM building information model and other types of energy-saving analysis software can scientifically evaluate the design effect of green buildings.

Using the traditional computer-aided design mode, due to the decentralized management of various departments and the inconvenient communication of information, it is difficult to realize the collaborative requirements of all parties in the construction project. The green building based on BIM technology not only maintains information interaction but also can use the collaborative work platform to carry out effective information interaction and integrated management for all personnel involved in the construction [14, 15]. It provides important technical support for the collaborative development of the construction industry and other fields. The comparison between traditional computer-aided building method and BIM green building technology is shown in Table 1.

The core of BIM can not only use BIM technology to optimize various architectural designs but also optimize the cooperation mode of partners in different stages of the construction process to effectively save the comprehensive cost of the building and reduce the energy consumption of the building. In addition, BIM technology is used to simulate building energy consumption. Based on the analysis of the simulation results, the building design scheme is continuously optimized, the best scheme is selected, and the resource utilization rate is also improved.

BIM technology has changed the design mode in the sense of traditional architecture. BIM building model can not only visualize space facilities but also extract relevant data and information by using the model, which is conducive to the design, construction, and maintenance of green building projects and can meet the communication and decision-making of construction projects by participants in different stages [16, 17]. In addition, the data platform provided by BIM can provide information support for effectively formulating various construction-related work plans such as construction cost plan, material use plan, and personnel scheduling plan to avoid risks, reduce costs, and improve efficiency during the implementation of construction projects.

The traditional architectural drawing cannot integrate information, and it is difficult to communicate during construction. Because the drawings and information of traditional building models are generally not related to each other, model modification is not only time-consuming but also prone to errors, which is difficult to provide substantive help for the construction industry building model that can predict the real situation after the completion of the building through information interaction, and BIM data center can provide various data for different stages and provide relevant services after the completion of the building. Participants in different stages of project implementation can update information synchronously without checking architectural design and construction drawings. As shown in Figure 1, the comparison results between the traditional building model and the BIM building model are shown.

3. Overall Scheme of Energy-Saving Design

3.1. Principles of Green Building Design. In the whole process of green building, energy-saving design not only is related to architectural features but also considers natural environmental factors and the relationship between the external environment and architectural features. Therefore, green building design needs certain principles.

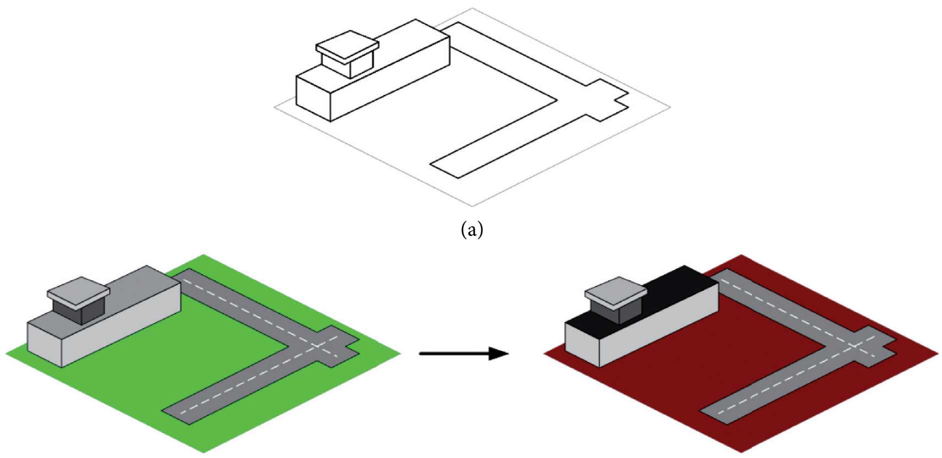
(1) We should adhere to the principles of sustainable development and people-oriented. In order to meet the needs of long-term and stable development, green buildings should be able to coordinate the problems of sustainable development such as resource consumption, environmental pollution, and resource conservation. Because the building energy-saving design is to better transform human living space, on the premise of ensuring that it does not affect the health of residents, the construction equipment and materials should be used reasonably when implementing green buildings.

(2) The energy-saving design of green buildings should comply with the comfort of living and the rationality of technology. When implementing green buildings, we should not only consider the spatial structure needs of residents for housing buildings but also make full use of the solar energy, wind energy, and other resource conditions provided by external nature according to the technical standards. Good energy-saving design can provide residents with good indoor temperature, humidity, and other environmental conditions.

(3) Based on the principle of saving resources and energy, the environmental differences in different regions should be considered in the energy-saving design of green buildings. Combined with the characteristics of external natural environment,

Table 1: Comparison between traditional computer-aided architectural design and BIM green building technology.

Item	Traditional architectural design	BIM green building technology
Work cycle	Design phase	Entire cycle
Design dimension	Two-dimensional design	Space design above 3D
Working mode	Independent operation	Collaborative work
Design effect display	Plan drawing	Visual model



(a)

(b)

Figure 1: Comparison between traditional building model and BIM building model.

regional characteristics, and people's social life customs, green buildings should not only conform to the local construction style but also make full use of local resources and environment.

3.2. Preliminary Design Preparation. Since the effect of the energy-saving design is an important part of green building evaluation, whether energy is effectively saved and utilized is an important reference standard, and it is very important to promote the application of BIM in green buildings. In order to ensure the normal implementation of green buildings, the BIM model is generally used to analyze the natural light radiation and distribution outside the building, establish a feasible solar energy utilization scheme, and realize the full utilization of solar energy resources by green buildings.

At the same time, according to the analysis results of indoor natural lighting based on the BIM model, make full use of external lighting to reduce the energy consumption of indoor lighting. In addition, in the selection and use of energy-saving materials, according to the functional requirements of public buildings and the technical rationality requirements of architectural design, BIM technology should be used to detect the electromechanical pipe network to avoid some problems caused by the unreasonable design of electromechanical pipe network. Finally, in terms of indoor environment and structural thermal performance test, the parameters of peripheral structure and thermal function are used as the input parameters of the BIM building model, and the required parameters are calculated through relevant software to ensure that the green building can meet the national standards. If the design or implementation of the construction project does not meet the requirements of relevant national green building standards, it is necessary to reanalyze and calculate the building energy consumption.

3.3. Conceptual Design. In the energy-saving design of green buildings, it is usually transformed into a description that can be implemented according to the construction needs or ideas of residents. Therefore, the relevant design documents are the basis for the implementation of energy-saving of green buildings. When evaluating the results of green building, it is necessary to integrate the relevant building information in the design stage to obtain accurate and detailed energy-saving design information of green building and then import the relevant information into the BIM platform database to provide shared data for all participants in the implementation process [14].

The whole process of implementing green building requires cooperation and collaborative design in different professional fields, and the BIM model can provide a better information management platform for collaborative operation. Because the BIM model includes various detailed information about green building concept, it can provide a basis and support for the simulation and analysis of green building energy efficiency. In addition, the parameterization and modularization of the BIM model can provide accurate information feedback for the later energy-saving design effect. The specific implementation route of BIM-based green building energy efficiency design is shown in Figure 2.

4. Key Points of Energy-Saving Design

4.1. Modeling Software Selection. Green building has been widely used with the development of BIM software technology. Choosing an appropriate BIM software is very important for green building energy-saving designers [18]. A building model is established by using BIM technology. On this basis, the energy conservation of green buildings is designed, the energy consumption is simulated and analyzed, and the technical route of building energy conservation simulation design is formulated according to the simulation analysis results.

In recent years, designers have mostly used Ecotec, Energy Plus, and other types of simulation analysis software to design green buildings and analyze the model simulation results, which has achieved good results. For example, Ecotec software has the characteristics of simple operation and specific analysis. It can optimize relevant parameters according to different architectural design models, providing an effective guarantee for specific implementation. At present, most designers combine the relevant simulation software provided by different BIM model software with Ecotec simulation software, then analyze the data of architectural design models in different stages according to the simulation software in BIM model software, and optimize the energy conservation and emission reduction scheme by using the analysis and design simulation results.

4.2. Enclosure Energy-Saving Design. The roof department of green building needs to be designed with comprehensive consideration of energy-saving factors. At present, the common roof shapes are mainly designed in the styles of high flat roof, slope flat roof, and various streamlined flat roofs. In terms of energy conservation and thermal performance design, it is usually necessary to consider the use of decorative materials, slope design, and thermal insulation layer to achieve good thermal insulation effects in summer and winter.

As the main part of the building, the goal of exterior wall energy conservation is to ensure the appropriate indoor temperature, avoid the impact of external high temperature, and reduce the adverse impact of indoor and outdoor temperature difference. The materials used for energy-saving exterior walls are usually composite building wall raw materials with good energy-saving effects, such as waterproof clay solid brick and centralized thermal insulation wall. As an important part of green buildings, windows are mainly used for ventilation, daylighting, and thermal insulation, which have a great impact on the energy consumption of the whole building to a certain extent. Therefore, the window design should not only meet the residential needs of users but also meet the requirements for building energy conservation.

The latest BIM design method can generally meet the needs of heat insulation and energy conservation of high-rise buildings and their auxiliary enclosure facilities. For example, using the BIM building model, different wall and roof building materials can be selected, and relevant parameters can be set to optimize the energy-saving construction scheme.

4.3. Sunshine Energy-Saving Design. How to design the sunshine conditions not only is the key to the energy-saving design of green buildings but also can affect the daylighting effect in the building. Effective use of lighting energy-saving technology can reduce artificial energy consumption. In terms of natural lighting design, it is necessary to make full use of the reflected light generated by external sunlight to supplement indoor lighting, reduce the energy consumption required for indoor artificial lighting, and meet the lighting conditions required for building residence and life.

According to the national laws and policies on the green building industry, when using the Revit architecture model to simulate buildings, you can import the lighting software Ecotec to simulate and comprehensively analyze the indoor lighting, sunshine, and daylighting of buildings. According to the analysis results, you can adjust the structure of the building model or update relevant parameters for the redesign.

According to the technical standards for green building design, the average daylighting coefficient of bedrooms in buildings is related to sunshine conditions. Generally, the average daylighting coefficient of the bedroom is 4.7%. The better the sunshine conditions, the greater the daylighting coefficient. The daylighting coefficient of indoor halls, kitchens, toilets, and other places is generally 1% [18, 19]. Due to the distance from the windows, it is generally difficult for these rooms to obtain a better sunshine environment. In the energy-saving design of green buildings, we should not only meet the standard of indoor daylighting coefficient but also meet the requirements of indoor energy conservation and environmental protection.

5. Analysis Method of Building Energy Efficiency Based on BIM

5.1. Characteristics of Building Energy Efficiency Analysis Based on BIM. In the past, there were many problems in building energy consumption analysis due to the limitation of technical conditions. The traditional building energy consumption analysis is mainly carried out in the construction process. The architectural design drawing cannot be changed, even if the problems found through energy consumption analysis cannot be reworked, resulting in a waste of human and material resources. Therefore, using the building model to analyze the energy consumption in the design stage and obtain the optimal design scheme can effectively improve the later construction efficiency and reduce the construction cost. The traditional energy consumption analysis method usually only analyzes a single factor without comprehensively considering the influence relationship between relevant factors, which makes this energy-saving scheme lack economy and practicability. For example, in the past, only the high-temperature performance of the building envelope was analyzed, or a single lighting

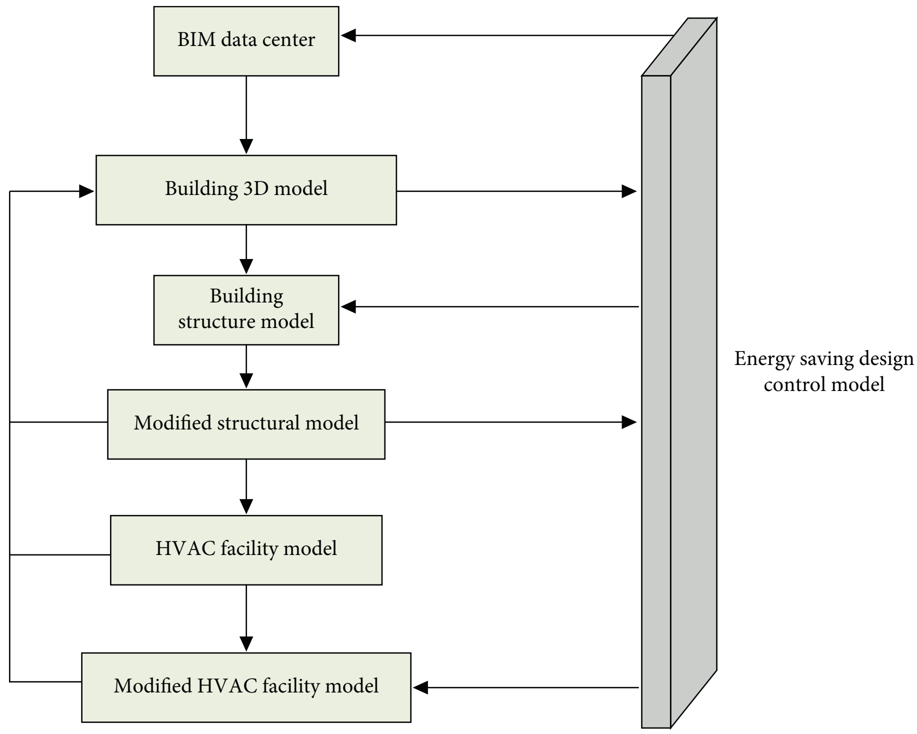


Figure 2: Information transmission process of green building energy efficiency design.

system and HVAC equipment were replaced to realize energy-saving transformation [20].

BIM technology is applied to process and analyze the data, the built building model is used to integrate and analyze the relevant information, external environment, and required parameters, and the building energy consumption is simulated and analyzed by running relevant programs. The building model based on BIM technology can realize the interaction between modeling software and energy consumption simulation software. Because building energy consumption involves the whole and part of the building and needs to be analyzed by using the knowledge of different professional fields, the interaction between different software must be used to help analysts continuously improve the modalism. Technology can realize the collaborative work between parametric modeling and energy consumption analysis, which is not only conducive to the scientific analysis and evaluation of energy-saving design effect but also conducive to the integration and sharing of information in the whole life cycle of the project so as to ensure the management to communicate and manage all departments below. In addition, through comprehensive energy consumption analysis, the building model based on BIM technology can not only analyze individual factors but also evaluate the overall performance of the building and the comprehensive effect of various factors. Thus, it can comprehensively grasp the situation of building energy consumption and provide decision support for various departments.

5.2. Building Energy Efficiency Analysis Process. In recent years, with the rapid development of BIM technology, it is more and more convenient to simulate and analyze building energy consumption, and the application of BIM energy consumption analysis software can comprehensively consider a variety of factors related to building projects in the construction process, such as building energy consumption and indoor energy consumption dynamic analysis. BIM energy consumption simulation software generally adopts Ecotec to design and analyze the energy consumption of specific building projects, and its main process is shown in Figure 3.

Usually, the first mock exam is required for different stages of construction projects. Because the design of a single model is mainly limited to a certain stage, in order to complete the whole construction project, the information of each stage must be integrated and processed. Among them, the interactive operation of each monomer model can not only effectively save the transmission time of information but also avoid various problems due to the required professional differences.

The building model based on BIM mainly contains the overall information of the construction project. Using BIM technology to simulate and analyze the energy consumption can not only export the effective information to the analysis software and complete the relevant analysis but also reduce the repeated work between different stages and improve the work efficiency.

Transfer the information contained in the BIM core building model to the relevant energy consumption analysis software, return the analysis results obtained by the energy consumption analysis software to the building model, and then continuously improve the energy-saving design effect by dynamically adjusting the model parameters. The specific information transfer process is shown in Figure 4.

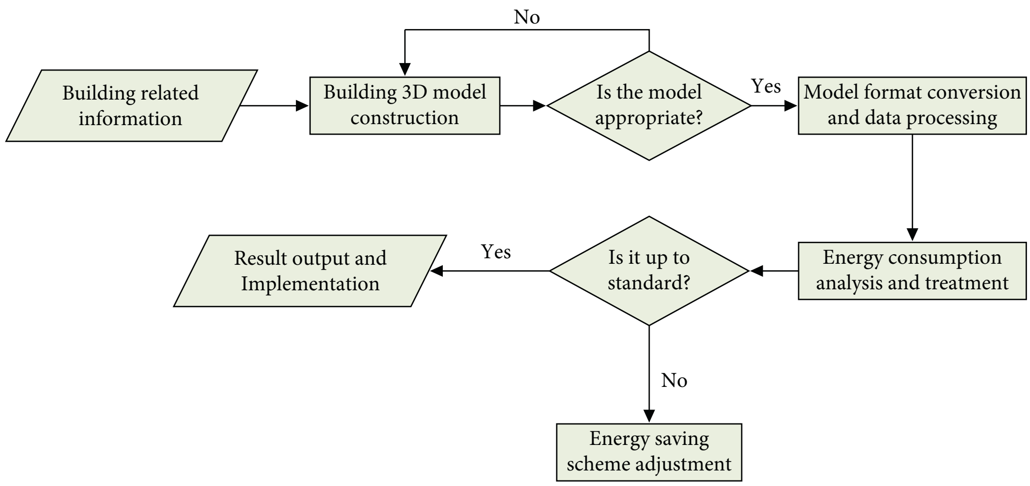

Figure 3: Energy consumption analysis method based on BIM.

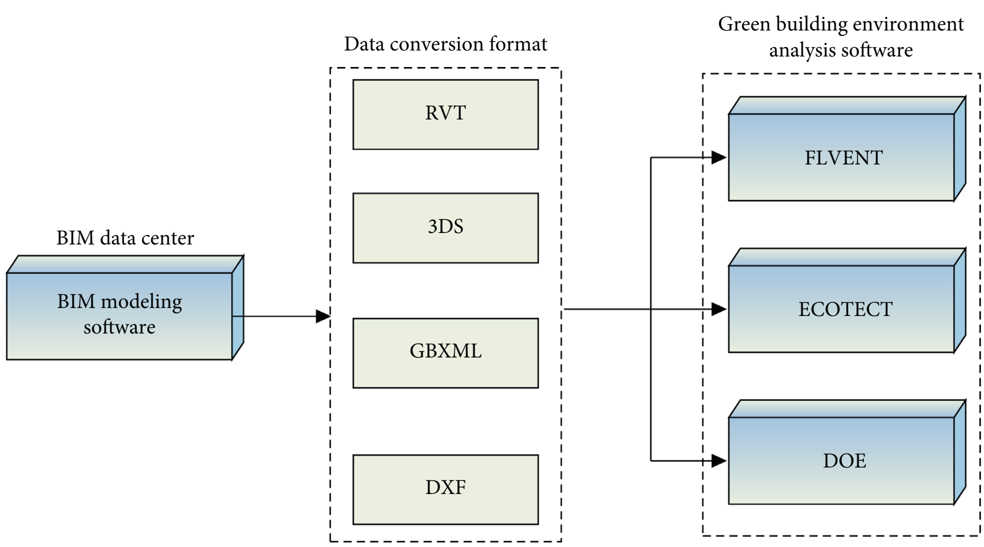

Figure 4: Interaction between BIM core software and building environment analysis software.

6. Energy-Saving Effect Evaluation of Green Buildings Based on BIM

6.1. Construction of Evaluation Index System. The energy consumption analysis software based on BIM technology mainly uses the building model in the design stage to simulate and analyze the energy-saving effect in the construction and use stages. Therefore, it is necessary to establish a relevant evaluation index system to evaluate the energy-saving effect of green buildings. The establishment of green building energy efficiency evaluation index is to promote construction project departments during the construction period; according to the local natural conditions, under the premise of ensuring the safety of the building, effectively improve energy utilization and reduce unnecessary losses caused by construction rework. The evaluation system should not only be the evaluation basis of building energy-saving effect but also provide guidance for guiding green building energy-saving design. Through the evaluation and analysis of the building energy efficiency effect of the evaluation system, the working process of each department of the construction project can be tracked, and the problems existing in the construction project can be summarized and analyzed.

Generally, a good evaluation system needs to follow certain principles. The first is to scientifically evaluate the energy-saving effect of green buildings through qualitative and quantitative analysis methods. Secondly, the evaluation indicators are adjustable and can be adjusted appropriately according to specific construction projects. In addition, it can simplify the index analysis and calculation process so that the evaluation process not only is easy to operate but also gives play to the practicability of the evaluation system.

Based on the evaluation standards of green building energy efficiency at home and abroad, the relevant reports output by green building energy consumption simulation analysis software can basically meet the standards of energy-saving design. Therefore, the simulation results of energy consumption analysis software can be used as the basis for energy-saving effect evaluation. According to the different aspects involved in the energy-saving design of green buildings, the energy-saving evaluation index system of green buildings is established, as shown in Table 2.

6.2. Evaluation Model of Energy-Saving Effect of Green Building. Using the established green building energy efficiency evaluation index system, comprehensively consider the different importance of indicators at all levels in the evaluation system, and calculate the weight value of corresponding indicators. The weight calculation method can consider the principles of subjectivity and objectivity.

According to the objectives, criteria, and specific design scheme of energy-saving design, the hierarchical structure model of the energy-saving effect evaluation index system can be established, as shown in Figure 5.

Based on the above energy-saving evaluation hierarchy model, in order to obtain the weight of each evaluation index, it is necessary to construct a relevant judgment matrix, as shown in the following equation:

$$B = \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1m} \\ b_{21} & b_{22} & \cdots & b_{2m} \\ \vdots & \vdots & \vdots & \vdots \\ b_{m1} & b_{m2} & \cdots & b_{mm} \end{bmatrix}. \tag{1}$$

The numbers 1, 2, $\cdots$, 10 are usually used to represent the relative importance of each element in the judgment matrix. Then, according to the evaluation experts, the importance of each index is compared, and the corresponding scores are given to form a judgment matrix.

Then calculate the weight of each index. The specific calculation formula is as follows:

$$\begin{aligned} a_i &= \sqrt{\prod_{j=1}^{m} b_{ij}}, \\ \overline{a_i} &= \frac{a_i}{\sum_{i=1}^{m} a_i}, \\ u &= \sum_{i=1}^{m} \frac{\sum_{j=1}^{m} b_{ij}\overline{a_i}}{m\overline{a_i}} (i = 1, 2, \cdots, m), \end{aligned} \tag{2}$$

where $\overline{a_i}$ represents each component value of the judgment matrix.

$$\begin{aligned} c &= \frac{u - m}{m - 1}, \\ cq &= \frac{c}{q}, \end{aligned} \tag{3}$$

where c denotes the consistency index of judgment matrix, q represents the random consistency index, and cq means the revised consistency ratio.

The random consistency index values are shown in Table 3.

Table 2: Evaluation system of green building energy efficiency design effect and index relationship at all levels.

Item	Primary index	Secondary index
1	Energy-saving design	Feasibility of design scheme Quality of external protection structure Energy consumption
2	Energy consumption	Lighting condition Energy utilization External environmental conditions
3	Daylighting condition	Indoor lighting condition Light transmittance of external window
4	Ventilation condition	Indoor ventilation Indoor air quality Outdoor ventilation

When $cq < 0.1$, it indicates that the judgment matrix has a good consistency. Otherwise, the consistency requirements can be achieved by continuously adjusting the element values of the judgment matrix.

After the establishment of an energy-saving evaluation index system, the qualitative indexes generally need to be treated quantitatively. Therefore, by setting the grade level of each evaluation index and then according to the different levels of these indexes in the evaluation index system or the importance of corresponding projects, they are divided into five grades: excellent, good, medium, qualified, and poor. The above five different grades can be represented by integers 10, 9, 8, 7, and 6 in turn.

The scores of each index are obtained by expert scoring, and the energy-saving effect evaluation sample matrix is established according to the scoring results. For example, suppose that the number of experts participating in the scoring is z, x primary evaluation indicators are scored by experts in turn, and each primary evaluation indicator has y secondary evaluation indicators; then the final energy-saving effect evaluation sample matrix can be expressed as

$$S = \begin{bmatrix} s_{111} & s_{112} & \cdots & s_{11z} \\ s_{121} & s_{122} & \cdots & s_{12z} \\ \vdots & \vdots & \vdots & \vdots \\ s_{xy1} & s_{xy2} & \cdots & s_{xyz} \end{bmatrix}. \tag{4}$$

6.3. Application of Evaluation Model in Engineering Cases. According to the design technical scheme formulated by the Architectural Design Institute, a three-dimensional model of green building is created. Then, based on the BIM platform, different professionals and departments can work together. Figure 6 shows the three-dimensional building model, which includes the building structure model, and Figure 7 represents the electromechanical comprehensive models of building water supply and drainage system, HVAC facilities, and weak current made by different professionals.

Based on the BIM data platform and by importing the building model into the energy consumption analysis software, relevant analysis reports can be generated.

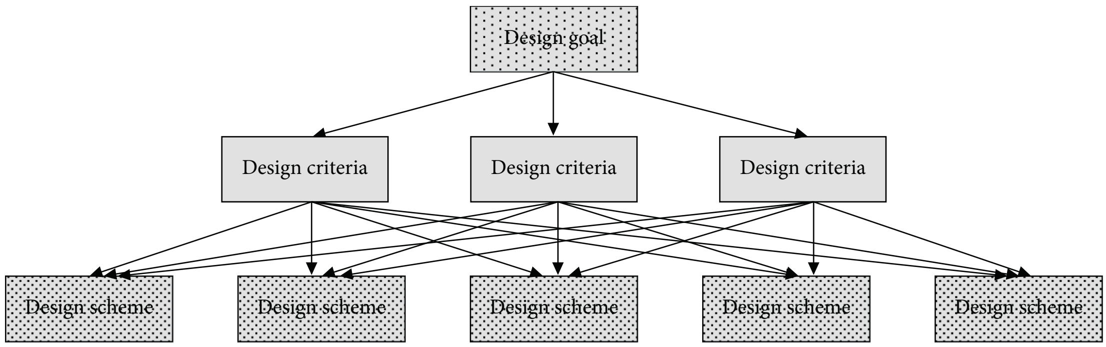

Figure 5: Energy-saving design evaluation hierarchy.

Table 3: Random consistency index values corresponding to different dimensions in the judgment matrix.

Matrix dimension	1	2	3	4	5	6	7	8	9	10
Q	0.01	0.02	0.36	0.54	0.82	1.15	1.27	1.32	1.41	1.49

Figure 6: Three-dimensional building structure model.

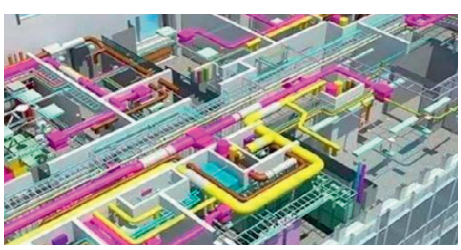

Figure 7: Electromechanical comprehensive model of building water supply and drainage system.

According to the analysis report and the evaluation index system of energy-saving effect of green buildings, the judgment matrix is constructed by using the primary index energy-saving design scheme B_1, energy consumption B_2, daylighting condition B_3, and ventilation condition B_4. The primary index judgment matrix of energy-saving evaluation system is shown in Table 4.

$\overline{a} = (0.136, 0.247, 0.315, 0.063)$ can be calculated from the judgment matrix. According to the consistency test formula, the maximum eigenvalue $u = 4.13$ and $cq = 0.014 < 0.1$. Through the consistency test, the weight values of each primary index are obtained, as shown in Table 5.

Then, each secondary index under each primary index can be compared in turn to determine the judgment matrix of its layer. For example, by judging and comparing various factors under the primary index of energy-saving design, the corresponding judgment matrix is obtained, as shown in Table 6.

Table 4: Primary index judgment matrix of energy-saving evaluation system.

B	B_1	B_2	B_3	B_4
B_1	1	0.5	0.8	1.5
B_2	1.5	1	2.5	3
B_3	0.5	0.5	1	2.5
B_4	0.8	0.5	1.5	1

Table 5: Primary index weight value of energy-saving evaluation index system.

Primary index	Weight value
Energy-saving design	0.136
Energy consumption	0.247
Daylighting condition	0.315
Ventilation condition	0.063

According to the judgment matrix, the corresponding $\overline{a}_1 = (0.124, 0.216, 0.473)$ can be calculated. Through the consistency test, $cq = 0.008 < 0.1$, meeting the requirements. After the consistency test, the weight values of each secondary index under the primary index are obtained, as shown in Table 7.

Similarly, the same method can be used to obtain the judgment matrix formed by comparing the elements under other primary indicators. At the same time, the corresponding weight can be obtained according to the judgment matrix. Finally, all different index weights of the green building energy-saving effect evaluation index layer can be calculated, as shown in Table 8.

Therefore, the corresponding scoring matrix can be constructed by using formula (4) and combined with the index weights at all levels of the energy-saving design effect evaluation system in Table 8.

Table 6: Energy-saving evaluation index system secondary index judgment matrix.

B_1	B_{11}	B_{12}	B_{13}
B_{11}	1	0.8	0.6
B_{12}	2.5	1	0.5
B_{13}	3	2	1

Table 7: Secondary index weight value of energy-saving evaluation index system.

Secondary index	Weight value
Feasibility of design scheme	0.124
Quality of external protection structure	0.216
Energy consumption	0.473

Table 8: Weight of indexes at all levels of energy-saving design effect evaluation system.

Primary index	Weight value	Secondary index	Weight value
Energy-saving design	0.136	Feasibility of design scheme	0.124
		Quality of external protection structure	0.216
		Energy consumption	0.473
Energy consumption	0.247	Lighting condition	0.103
		Energy utilization	0.185
		External environmental conditions	0.327
Daylighting condition	0.315	Indoor lighting condition	0.162
		Light transmittance of external window	0.538
Ventilation condition	0.063	Indoor ventilation	0.178
		Indoor air quality	0.349
		Outdoor ventilation	0.426

According to the grade classification of energy-saving effect evaluation of green buildings, it can be divided into five categories: excellent, good, medium, qualified, and poor, which is represented by integers 10, 9, 8, 7, and 6. According to the energy-saving evaluation method proposed in this paper, the comprehensive evaluation result M of energy-saving effect of green buildings is calculated as follows:

$$M = \begin{pmatrix} 0.21 & 0.17 & 0.35 & 0.23 & 0.13 \end{pmatrix} \cdot \begin{pmatrix} 10 \\ 9 \\ 8 \\ 7 \\ 6 \end{pmatrix}. \tag{5}$$

The comprehensive evaluation value of the energy-saving effect of the building project is 8.82, which is between good and medium, indicating that the energy-saving effect of the green building model reaches the expected goal.

7. Conclusion

As an important development direction of the modern construction industry, green building was inseparable from the wide application of BIM technology. This paper made full use of BIM technology, which had the function of integrating building information model and its simulation. From the perspective of reducing building energy consumption and maintaining the sustainable development of the ecological environment, this paper studied the energy-saving design method of green buildings based on BIM technology. This paper systematically expounded the design principles and design concepts of green buildings and gave the overall scheme of energy-saving design of green buildings. This paper deeply studied the energy-saving design elements of green buildings, which should be considered from the aspects of modeling software selection, envelope energy-saving design, and lighting energy-saving design and put forward the energy-saving analysis method of green buildings based on BIM. In addition, this paper also put forward the energy-saving effect evaluation method of green buildings based on BIM from the aspects of the design of energy-saving effect evaluation index system and the energy-saving effect evaluation model of green buildings. An example further verified that the energy-saving design method proposed in this paper had certain guiding significance for the field of green buildings [18]. The energy-saving design of green buildings based on BIM technology proposed in this paper can not only provide a reference for the in-depth research of BIM technology but also provide technical support for the wide application in the field of green buildings.

The openness of modern network intelligent education provides a broader learning space for Chinese language learners. People pay more and more attention to network learning, and network intelligent teaching platforms are constantly emerging under this background. Intelligence is one of the most important characteristics of ITS. However, the current network teaching system is far from enough in the intellectualization of teaching content, form, and process. In order to improve the intelligence level of ITS, this paper studies the use of DL network with strong self-learning ability to build ITS. From the point of view of teaching students in accordance with their aptitude and accurately reflecting students' learning state and characteristics, this paper analyzes the influencing factors in students' learning process, puts forward factors such as students' learning style and learning habits into the construction of a student model, and designs the student model. The future trend of ITS is predicted, and it is pointed out that this field with attractive development prospect is worthy of further research and design.

1. Introduction

In the network environment, Chinese language teaching workers need to reexamine the traditional communication media and teaching mode from the perspective of teaching practice, change ideas and roles, order the disordered oral Chinese teaching resources, and organically integrate modern information means with traditional language teaching means [1]. Teachers should be good at using network resources to design the learning process, and use the network to obtain each student's learning information to regulate the learning process. Artistic Intelligence (AI), computer science, pedagogy, psychology, and behavioral science are all involved in the development of intelligent computer-assisted instruction systems [2]. The ultimate goal of the study is for the computer system to take on the relevant responsibilities of education and teaching, i.e., to endow the computer system with intelligence so that it can partially replace teachers in order to achieve the best teaching [3]. The openness of modern network education unquestionably expands the learning space available for Chinese language instruction. People are becoming more interested in network learning, and network teaching platforms are continuing to emerge as a result. However, managers and teachers find it difficult to obtain dynamic learning information from network learners due to the increasingly complex particularity and temporal and spatial separation of the network education environment [4]. This results in a simple reproduction of the book content of resources and one-sided pursuit of quantity and scale in the push mode of teaching resources [5]. With a diverse group of online learners and a large number of them, determining how to collect reliable learning status information and provide personalized learning services has become a pressing issue [3].

With the development of multimedia technology and network technology, building a new Chinese language model that breaks the tradition and is not limited by region and time is an important issue that needs to be solved urgently [6]. In order to improve teaching efficiency and better train talents, people have been constantly exploring and trying to use new technologies and methods to improve teaching and learning methods and means [7]. At the same time, we hope to teach students according to their aptitude and carry out differentiated education according to students' different learning foundation, learning ability, and other characteristics [8]. However, due to a lack of teacher resources and teaching efficiency requirements, it has been impossible to teach each student according to their aptitude. The Intelligent Teaching System (ITS) proposal makes it possible to accomplish this goal. By creating an open teaching environment, modern education based on the Internet overcomes the time and space constraints of traditional education [9]. It is critical for effectively utilizing the resource advantages of various existing education systems, realizing rational resource allocation, and developing education. It also offers a viable solution to the problem [10]. This paper proposes and establishes an intelligent Chinese language network teaching system model to address the shortcomings of the existing network teaching system.

Intelligent teaching is an important development direction of computer-aided teaching. It is an open interactive teaching formed by using computer to simulate the teaching thinking process of teaching experts and taking students as the center and computer as the medium [11]. Based on modern educational theory, intelligent teaching introduces the latest achievements of AI, psychology, cognitive science, and other disciplines into computer-aided teaching, seeks the mode of learning cognition by studying the characteristics and process of human learning thinking, and enables students to obtain knowledge through personalized adaptive learning, so as to achieve the purpose of real individualized teaching [12]. The research on intelligent computer-assisted instruction system in China started relatively late. The research work started is mainly concentrated in a few universities and research institutions intermittently, most of them are systems for research and demonstration, and few systems have been strictly evaluated [13]. With the rapid development of intelligent computer-assisted instruction system, it will play a positive role in promoting China's education reform. This paper constructs a Chinese language teaching system model based on deep learning (DL). Based on the analysis of the serious defects of adaptability and personalization in the current online learning system, and on the basis of development practice, this paper discusses how to extract parameters such as behavior data and performance information of online learners by using key technologies such as fuzzy evaluation algorithm and Neural Network (NN) in ITS.

2. Related Work

According to literature [14], language teaching workers in a networked environment must reexamine traditional communication media and teaching modes from the perspective of teaching practice, change ideas and roles, and realize the ordering of disordered Chinese teaching resources. Reference [15] obtains a framework and design pattern that can quickly construct a college English teaching system with clear structure and reliable performance through research on the modeling of college English teaching system using UML modeling language. The current network teaching platform, according to literature [16], has a wide range of learning contents, and each platform only focuses on cultivating students' abilities in some aspects, rather than cultivating all-round abilities of listening, speaking, reading, and writing. Literature [17] seamlessly blends modern information technology with traditional language teaching methods. According to the literature [18], teachers should be skilled at using network resources to design the learning process and obtaining each student's learning information to regulate the learning process. According to the literature [19], the student model is at the heart of ITS individualized teaching and is responsible for the systematic representation of students' knowledge level, cognitive ability, learning motivation, learning style, learning history change, and other data. According to literature [20], these issues in the current Chinese language network teaching platform must be addressed immediately, and it is critical to develop a comprehensive, interactive, personalized, and feedback Chinese language teaching platform. According to literature [21], the main function of a network teaching platform is to display students' characteristics and attitudes and to provide a foundation for the realization of intelligent teaching objectives, teaching contents, and teaching strategies. Literature [22] proposed that educational objectives should include cognitive ability, motor skills, and emotion, in which the objectives of cognitive ability are divided into six levels according to the complexity of intellectual activities. Literature [23] studies the modeling of network college English teaching system based on UML. Through in-depth research, the framework and modeling diagram of online college English teaching system are designed. Literature [5] proposes that the student model is formed according to the interaction and response history between the students and the system, which can be dynamically modified according to students' learning situation, and the system can carry out individualized teaching through the student model. In view of the shortcomings of the existing teaching system, literature [24] proposed an intelligent network teaching system model. Based on previous studies and the current situation of Chinese language network teaching system, this paper constructs a Chinese language teaching system model based on DL. It also classifies students' learning characteristics and provides different teaching strategies and teaching contents according to different characteristics. The model can dynamically establish a personalized learning environment according to the characteristics of students and can truly realize individualized teaching.

3. Methodology

3.1. Theoretical Basis of ITS Construction. The concept of DL is derived from the research of Artificial Neural Network. A multilayer perceptron with multiple hidden layers is a DL structure. DL combines low-level features to form a more abstract high-level representation attribute category or feature to discover distributed feature representations of data. The motivation for studying DL is to establish a NN that simulates the human brain's analysis and learning. It mimics the mechanism of the human brain to interpret data, such as images, sounds, and texts. DL is a general term for a type of pattern analysis method. In terms of specific research content, it mainly involves three types of methods: Convolutional Neural Network, self-encoding NN based on multilayer neurons, and deep confidence network [25]. NN has strong learning ability; that is, the main characteristics of training samples can be abstracted through training, so it has strong fault tolerance and memory association ability, can process information in parallel, and therefore has a faster information processing speed. Applying NN to ITS can effectively improve the system's intelligence, adaptability, and response speed.

The combination of computer-aided education and AI, as well as the use of AI in teaching, is referred to as ITS. The intersection of AI, cognitive science, educational theory, and other disciplines produces it. It can be used as an adaptive learning support system to provide individualized instruction, knowledge, and guidance to students with various needs and characteristics. ITS looks for the mode of learning cognition by studying the thinking characteristics and process of human learning. Simultaneously, it aims for personalized teaching; determining students' personal teaching methods and contents based on psychological characteristics, cognitive level, existing knowledge base, cognitive structure, learning habits, learning style, and motivation; and selecting appropriate teaching strategies, in order to provide students with learning contents and progress that are consistent with their learning characteristics. Students develop their abilities as well as their knowledge through personalized and adaptive learning [26]. ITS is a new method and a new way to realize the modernization of teaching means, as it can fully exploit students' enthusiasm, can assist students in developing their intelligence and ability, and is a new method and a new way to help students develop their intelligence and ability. Expert model, student model, teacher model, and intelligent man-machine interface are the four main components of a typical ITS. The basic structure of ITS is shown in Figure 1.

The student model is one of the core components of ITS intelligence, and ITS can use it to implement personalized teaching for learners. A student model is a data structure that depicts the cognitive characteristics of learners. On the one hand, it keeps track of the learner's name, gender, number, and other basic information; on the other hand, it accurately reflects the learner's knowledge level, learning ability, psychological state, and other factors. The model of students changes dynamically in response to interactions between the students and the system, as well as the learning situation, and serves as the foundation for the system's determination of teaching strategies and resources. The expert model is used to represent relevant knowledge in the teaching field, as well as problem-solving knowledge that experts can use to solve related problems [27]. As for the teacher model, its primary responsibility is to choose appropriate teaching materials and present them to students in appropriate formats, while adhering to certain teaching principles. The key to this module's operation is knowing how to organize the teaching content, or how to teach. The Intelligent interface serves as the system's and users' interactive interface, providing intelligent multimedia knowledge input, user information and behavior acquisition, and knowledge output for other modules. Natural language processing, knowledge base maintenance, student model initialization, teacher model adaptive adjustment, and other functions are all part of the ITS intelligent man-machine interface.

Student model is a data structure representing learners' cognitive state, and it is the basis of ITS intelligent teaching. The dynamic structure of the student model shows the formation and relationship of the four components of the ITS in the learning process, as well as their roles in teaching decision. It can be seen that the student model is a dynamic structure, which tracks students' learning activities. By analyzing students' learning behaviors, it records and adjusts the information describing students' personalized characteristics, such as their knowledge structure, learning ability, and learning habits, so as to draw new teaching strategies. Among them, the decision-making mechanism is in the central position, and its functions are maintenance of relevant databases, generation of decisions, resolution of decision conflicts, etc. The dynamic structure of the student model is shown in Figure 2.

At present, there is a lot of research on ITS, including some student models, but these student models generally have some problems such as lack of intelligence. Student model is the most difficult part of ITS design at present, and it is also a hot issue in ITS research. Therefore, constructing a suitable student model is the focus of ITS construction. The model should be able to timely and correctly reflect the essential characteristics and state of students' learning behavior; that is, it reflects students' mastery and understanding of a certain learning content, learning style, habits and learning ability contained in learning behavior, etc. At present, students' models are generally classified into covering model, differential model, deviation model, and cognitive model.

In the covering model, the domain knowledge that students want to learn and its constraint relation are represented as a directed knowledge structure diagram, the learning state of students is regarded as the subgraph of this diagram, and the learning process is regarded as the approximation process of the subgraph to the original diagram. The system based on this model can get the defects of students' knowledge structure according to the comparison between the domain knowledge structure diagram and the students' knowledge state diagram, so as to recommend the contents to be learned to students. The deviation model records the deviations of the students' problem-solving path from the expert path. These deviations describe some deficiencies of students in this knowledge point and can give specific remedial measures according to the types of deviations. The cognitive model reflects the differences in cognitive ability and cognitive structure of each individual learner. By analyzing the cognitive differences of students, we can understand their initial learning ability and

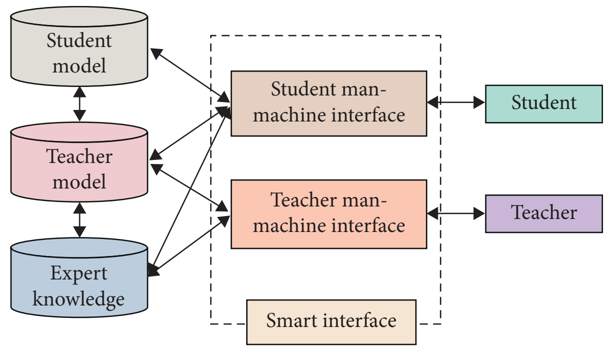

Figure 1: Basic structure of ITS.

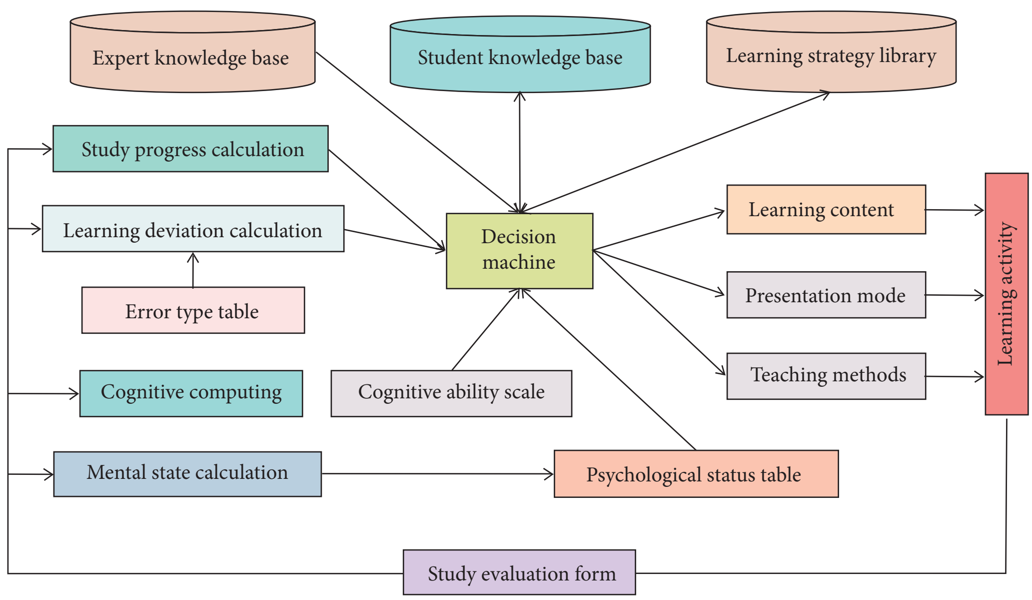

Figure 2: Dynamic structure of student model.

knowledge structure. The purpose of analyzing students' cognitive ability and cognitive structure is to formulate effective teaching strategies for specific teaching tasks. The differential model divides learners' knowledge into two parts: the pre-grant and the knowledge beyond the pre-grant, which is further expanded than the covering model, but its essence is the covering model.

3.2. Construction of Intelligent Teaching System. Based on the idea of intelligent teaching, the architecture of intelligent network teaching system is designed as three-tier B/S structure: user interaction layer, teaching application layer, and database server layer. The user interaction layer includes the interaction interfaces of students, teachers, and system administrators and realizes the interaction between the system and users through browsers. The student interaction interface is the individualized teaching content and learning interface provided by the system for different learners. Students log in to the system first and then participate in the pre-assessment test voluntarily, so that the system can get a preliminary understanding of students' knowledge level, cognitive ability, learning style, favorite learning strategies and so on. In the follow-up study, the system will select the learning contents in the teaching knowledge base that are suitable for students' characteristics and actual level according to the students' learning history, interaction with the system, and performance in the system diagnostic test and dynamically organize students' learning by the teaching strategies in the teaching model. During the learning process, the system dynamically generates the teaching process according to the student model.

Students can choose, judge, and deal with a large amount of knowledge using an intelligent reasoning mechanism in the intelligent teaching assistant system, which makes the learning content more targeted and improves the learning effect. The foundation of all development is system analysis, which is an important stage of software engineering. In the stage of system analysis, an accurate understanding of the system requirements and the internal operating mechanism of the system is helpful in accurately grasping the system requirements, so that the specific content of software development can be correctly determined. To fully understand the users' requirements for the system, we should complete the work of determining the content of system requirements, determining all involved elements, and establishing corresponding models for the current problems to be solved through system analysis.

After learning a knowledge point, students first consolidate their knowledge through corresponding exercises and then assess their cognitive ability through tests. The test questions of each knowledge point include three types: single-choice questions, judgment questions, and fill-in-the-blank questions. Each question can test at least one of the above six cognitive abilities. When students test, if they answer a question correctly, the cognitive ability of one or more items corresponding to the question will be 1; if they answer the question incorrectly, it will be −1; and if they do not answer it, it will be 0. After the students finish the questions of a certain question type, they can calculate each cognitive ability of the students in this question type as follows:

$$r_i = \frac{n_{ij}(1)}{n_{ij}(1) + n_{ij}(-1)}, \quad i = 1, 2, \ldots 6. \tag{1}$$

Among them, $1 \le j \le n$, where n is the number of test questions of this question type. $n_{ij}(1)$ is the number of times the i-th cognitive ability is answered correctly in this question-type test. $n_{ij}(-1)$ is the number of wrong answers to the i-th cognitive ability in this question-type test.

Suppose the test question types for each knowledge point include multiple choice questions, true or false questions, and fill-in-the-blank questions. According to (1), the cognitive abilities of each question type are calculated to form the cognitive ability evaluation of all question types. The matrix is as follows:

$$R = \begin{bmatrix} r_{11}, r_{12} \ldots r_{16} \\ r_{21}, r_{22} \ldots r_{26} \\ r_{31}, r_{32} \ldots r_{36} \end{bmatrix}. \tag{2}$$

Among them, $r_{11} \sim r_{16}$ represent the evaluation values of the six cognitive abilities of single-choice questions. $r_{21} \sim r_{26}$ represent the evaluation values of the six cognitive abilities of true and false questions. $r_{31} \sim r_{36}$ represent the evaluation values of the six cognitive abilities of the fill-in-the-blank question.

Knowledge base, as a crucial component of an intelligent teaching assistant system, primarily provides a guiding, adaptive, open, and operable framework, as well as service facilities. It also provides a standardized knowledge input organization for various disciplines' knowledge, as well as other teaching resources that are organized and managed in accordance with it. This will allow users to create their own knowledge system, providing a solid foundation for the development and integration of all types of knowledge applications. In addition, the core knowledge in the teaching field will be decomposed into interrelated knowledge points, forming a knowledge tree, with a visual and operational knowledge tree editing interface that makes it easy for teachers to input teaching knowledge into the knowledge base.

The whole processing process of NN is a quantitative process for students' participation in a course. The system divides the degree of participation into three levels: positive, general, and negative. The input of NN includes n variables such as the evaluation value of the three levels of participation, discussion, resources, learning progress, and the frequency of browsing the course web page. The degree of students' participation in the course is selected as the output node, which actually completes a nonlinear mapping from n-dimensional space to one-dimensional space.

$$\begin{aligned} F_{bp}&: X \longrightarrow Y, \\ X &= \{X_1, X_2, X_3, X_4, \ldots, X_n\}, \\ Y &= \{Y\}, \end{aligned} \tag{3}$$

where X_1, X_2, X_3 represent the evaluation values of 3 levels of participation. $X_4, \ldots, Xn$ express the discussion situation, resource situation, etc. Y represents the degree of student participation in the course.

Learning evaluation table records the learning results of each knowledge point in the unit after each test, which is the basis for adjusting students' knowledge table and error type table, calculating cognitive ability, and then forming teaching strategies. The module of the expert decision-making mechanism can be regarded as the inference engine in the intelligent teaching assistant system. Generally, it adopts the method of combining two levels of reasoning, that is, reasoning based on semantic network and reasoning based on production rules. Among them, reasoning based on semantic network is used to determine the teaching content, while reasoning based on production rules is used to determine the teaching strategy. Different from rule-based reasoning, case-based reasoning is regarded as reasoning based on previous experience. Therefore, in some intelligent teaching assistant systems, case-based reasoning is adopted.

The calculation of cognitive ability is to solve the problem of quantitative evaluation and measurement of cognitive ability. According to the different methods of evaluation and measurement of cognitive ability, there can be different methods to determine the cognitive ability of students. Define the weights of various question types: $W = (W_1, W_2, W_3)$. The weight of a single-choice question is as follows:

$$W_1 = \frac{\omega_1}{(\omega_1 + \omega_2 + \omega_3)}. \tag{4}$$

The weight of the true or false question is as follows:

$$W_2 = \frac{\omega_2}{(\omega_1 + \omega_2 + \omega_3)}. \tag{5}$$

The weight of the fill-in-the-blank question is as follows:

$$\begin{aligned} W_3 &= \frac{\omega_3}{(\omega_1 + \omega_2 + \omega_3)}, \\ W_1, W_2, W_3 &= 1. \end{aligned} \tag{6}$$

Among them, $\omega_1, \omega_2, \omega_3$ are, respectively, the evaluation value of the average answer of each question type of a number of students after the test (the W_1, W_2, W_3 value is given by an expert at the beginning and can be dynamically adjusted after a certain number of student tests).

Use (2) and weight W to calculate the final evaluation results of various cognitive abilities:

$$\begin{aligned} E &= R \bullet W \\ &= (E_1, E_2, E_3, E_4, E_5, E_6). \end{aligned} \tag{7}$$

Calculate the comprehensive cognitive ability of students after learning this knowledge point:

$$S = \sum_{i=1}^{6} E_i \times M_i. \tag{8}$$

Among them, $M_i\,(i = 1, 2, \ldots 6)$ is the weight of a certain cognitive ability (the weights of the six cognitive abilities are given by experts). This is a model of the cognitive abilities of students. The learning strategy library keeps track of the learning strategies for each knowledge point acquired through decision in the next round of learning. The next round of learning may consist of relearning a portion of the knowledge from the previous unit or learning a new unit. Determine the learning content, knowledge presentation, teaching methods, and test question generation, among other strategies. In fact, the intelligent interface module is a component that allows the system and users to interact. It not only allows students to input and register their information, but also allows them to communicate with the system. Natural language processing, internal processing of man-machine dialogue, systematic knowledge base maintenance, initialization of student model, adaptive teacher model adjustment, and other technologies are examples of related technologies. This module provides an excellent setting for using negotiation, debate, conversation, and other teaching methods.

The student knowledge base describes and records students' learning progress and level, as well as the types of mistakes made by students in each knowledge point. "Mastery degree" means the students' mastery degree of this knowledge point, and the system can set a threshold. If the knowledge points with test scores higher than the threshold are considered as mastered, the system will no longer arrange learning. Below the threshold, the system will arrange to continue learning. In the vicinity of the threshold, it will prompt students to choose whether to continue to strengthen their knowledge. The "error number" indicates the types of errors made by students in testing this knowledge point. The system can get the corresponding error description information and learning tips from the error type table and provide them to students for targeted learning.

4. Results Analysis and Discussion

The cognitive model is an essential component of the student model. People have been studying the human cognitive process for many years. Although some progress has been made, because the human cognitive process is such a complex problem, establishing an ideal student cognitive model at this stage is only an ideal. We must first solve the problem of how to represent cognitive ability in order to determine students' cognitive ability. Students have a variety of preferences. Two preferences are taken into account in this design: knowledge teaching and knowledge presentation. The teaching method of knowledge refers to how students prefer to be educated, and the presentation of knowledge refers to the media in which learning content is presented. We can use graphics to individually represent the data in the model. This is a line chart with coordinates: time, degree of participation, and variable value of cognitive ability, as shown in Figure 3. It has the advantage of being able to intuitively reflect the changing trend of students' related data for teachers to analyze and choose from.

Considering that the student model is mainly used to reflect the dynamic characteristics of students in the learning process, it can provide personalized teaching services for learners. Therefore, we use graphics to represent the data in the model hierarchically. Under the condition of different combinations of participation degree and cognitive ability, the system can automatically choose teaching strategies as a guiding graph. Its advantage is that various teaching resources can be placed in nine areas, analyzed, and selected. The system can provide a brand-new resource service mode of customized service, instant service, and active service for students in different regions, and teachers can also adopt different teaching strategies for students in different regions. The time domain waveform of data distribution obtained by DL algorithm is shown in Figure 4.

It is necessary to consider the cultivation and improvement of students' knowledge memory, classification, induction, and deduction abilities in the ITS student model, as well as reminding students to use deep learning. Thus, the corresponding teacher model can adjust the learning content and teaching methods, while giving suggestions on learning methods, rather than simply letting students learn a certain part of the content again; compare and analyze the questions answered by students; find out the reasons; especially analyze and diagnose the causes of errors; and feed them back to the corresponding teacher model. If the students scored well on the basic knowledge portion of the test but poorly on the comprehensive application test, the students may engage in shallow learning, and the teaching system should provide reminders and suggestions on learning methods, so that the effect of ITS teaching students in accordance with their aptitude can be better reflected. We have experimented on the practicability of the Chinese language intelligent education system, and the distribution of students' scores before and after use is shown in Figure 5.

The experimental results show that most students think that the system can effectively promote students' Chinese language learning, especially their learning cognitive ability. The teaching methods are divided into seven types: focusing on details, detailed description, general description, examples, brief description, prompt, and review. Students can choose a teaching method according to their own characteristics at the beginning of school hours, and the teaching module dynamically adjusts the teaching method during the

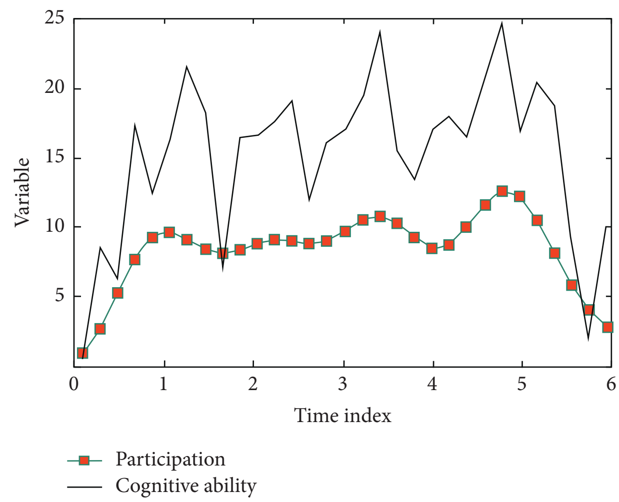

Figure 3: Student model line chart.

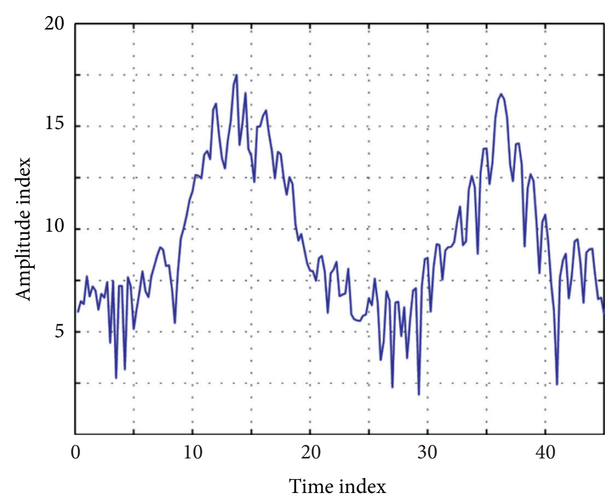

Figure 4: Time domain waveform diagram of data distribution.

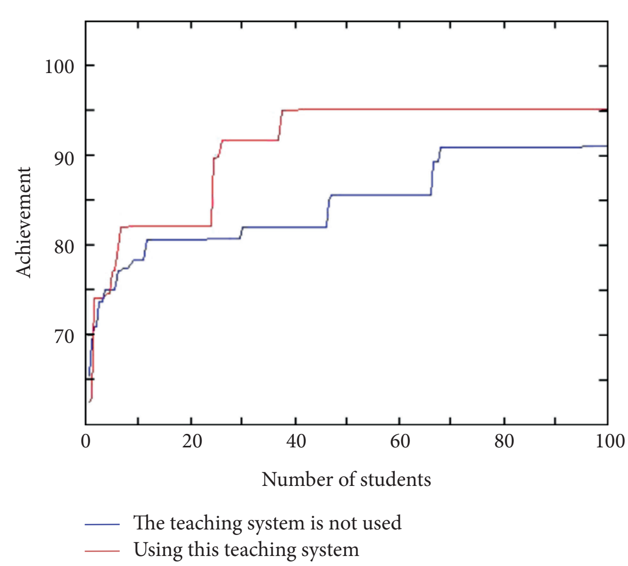

Figure 5: Comparison of student achievement distribution.

learning process. Teaching strategies are used to adjust the teaching content according to the student model in the teaching process. This strategy library has designed three teaching strategies. ① Continue to learn this knowledge point. ② Learn the prerequisite knowledge points for learning this knowledge point. ③ Learn the subsequent knowledge points of this knowledge point. In this experiment, 100 students were selected to use and score the original teaching system and this teaching system. The score data of the original teaching system and this teaching system are shown in Figure 6.

Students' study habits, their age, the correct knowledge they have and the degree to which they have mastered it, their study history, and their personality characteristics, among other things, should all be taken into account when designing the student model. Students' learning behavior in the student model includes total time, time spent learning a specific content, and time spent solving a specific problem. The accuracy rate drops to varying degrees, accompanied by a slight fluctuation, and the classification effect decreases as the feature dimension of Chinese language education increases. The relationship between the dimension of deep learning features obtained from two groups of experiments on the same batch of samples and the discrimination results is shown in Figure 7.

In the process of learning, students may be dissatisfied with or afraid of a certain course because they always make mistakes in doing the questions, thus taking a negative attitude to do or not do it. The system will repeat it according to students' performance until they learn, and students will become more and more bored, which makes the teaching effect not good. After adding students' emotions, the system can help students overcome this psychological state by appropriate means when students are in a bad state. Experiments are carried out on the data obtained in this paper, and the change trend of the target value with the number of iterations is shown in Figure 8.

NN modifies the connection weights of the network structure through adaptive algorithm, so that the network approaches the expected input-output relationship, can automatically adjust the parameters according to the changes of input data, and can optimize the system to better reflect the learning characteristics of students. The number of input level nodes is 5. The output layer is designed according to the students' learning state and characteristics to be expressed. At present, the set output includes the mastery of a certain learning content, learning methods, and learning habits. The number of hidden layers is set as needed. The model realizes the interaction between the users and the system, and it is the interface of two-way activities of teaching and learning, including student interaction interface, teacher interaction interface, and administrator interaction interface; at the same time, it includes the design of interfaces among the models. The model mainly uses web to express and communicate the content. Because of the untimely feedback of online learners' learning information, which is common in Chinese language teaching systems, it is difficult for teachers and managers to actively acquire the learning status of online learners. The intelligent network teaching system based on DL is designed and implemented in this section. The system uses NN and other technologies to analyze, mine, and establish student models in a shared environment of network "teaching and learning" with curriculum as the focal point. The basic teaching strategies used in the teaching process are determined based on the individual needs of students, and they are provided with a brand-new resource service mode of customized service, instant service, and active service.

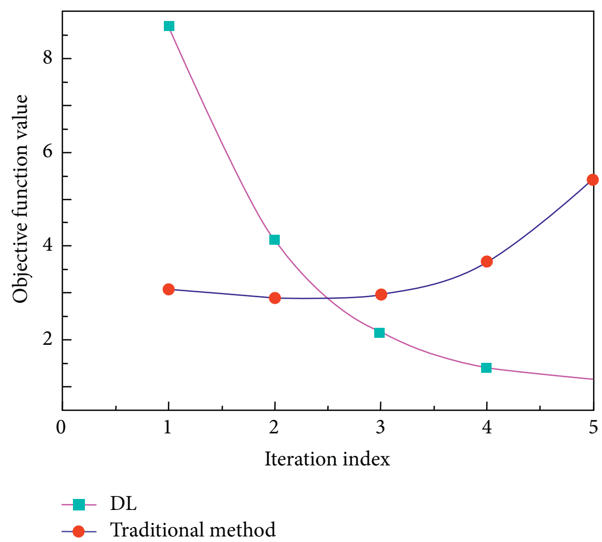

FIGURE 8: Trend of target value with iteration times.

5. Conclusions

In the information age, all things, environment, and information that can be used to achieve the goal of education and teaching can be regarded as educational resources. Therefore, in the process of Chinese language teaching, those that can be used to create Chinese language learning environment can be regarded as teaching resources. In today's educational reform environment, the intelligent teaching assistant system will play an increasingly important role. At present, there are not many achievements in this field in China, and even fewer systems can really be put into teaching practice. This field with attractive development prospects deserves our further study and discussion. Because the learning process and the factors affecting learning are very complicated, it is necessary to further study the factors affecting learning; the description, recording, and evaluation methods of learning activities; and the complex relationship between learning objectives, students' characteristics, teaching strategies, and learning effects and build a more scientific student model. In this paper, object-oriented modeling, teacher model, student model, and background support model are created in the system. It has solved the problems that the current development system is not fully functional and cannot realize personalized and interactive Chinese language teaching. The Chinese language teaching system model based on DL designed in this paper can adjust itself according to students' learning behavior; judge students' learning level, ability, learning style, and other student status and characteristics; and provide necessary information for teaching modules and expert modules, so that it can provide personalized learning resources and environment for students. At the same time, it is of great practical significance to improve the intelligence of ITS and teach students in accordance with their aptitude.

The interaction with the public and the coordinated change with the environment are more important in public environmental art sculpture. To be more accessible to the public, public environmental art sculptures should be integrated with the environment and interact with the public. Paying close attention to the scale and volume design of sculpture is one of the elements that embody and express the connotation of works, as well as one of the objects that sculpture, as a member of environmental elements, must study and analyze thoroughly. Based on this, this paper investigates the relationship between sculpture and environment in public environmental art through an examination of space environment characteristics, with the goal of creating a public space environment in which public art sculpture, the environment, and people are all in sync. The improved AFSA (artificial fish swarms algorithm) model is used to optimize the landscape ecological pattern. The landscape index can be predicted and analyzed more accurately using a dynamic model of landscape pattern from remote sensing and a geographic information system. Experiments show that this algorithm's prediction accuracy has significantly improved, providing a solid foundation for landscape ecological management and planning.

1. Introduction

Sculpture is a very important link in urban development and an important part of environmental art. Because of the influence of the location and other factors, sculptures placed outdoors show certain permanent characteristics, so it is very important to properly handle the relationship between sculptures and the environment. As a part of the development of mainstream art, this creative form tries to break the historical gap between life and art [1]. Sculptors can use any medium including clay, stone, sound, light, and sound to create environmental sculptures. There is an inevitable connection between public art sculpture and the space environment. Sculpture must be structurally coordinated with the surrounding environment, and the coordination between the designed works and the space of public culture should also be considered [2, 3]. Only in this way can the public environment art sculpture and the environment promote each other, create a tacit atmosphere for each other, and then increase the charm of the whole space.

Sculpture can refine the cultural information in the environment's main body, allowing for the creation of a matching scheme of theme, content, and even formal structure, resulting in a harmonious and interdependent relationship between them [4]. Thus, art sculpture in the public environment belongs to the urban public form, is an art created and designed for a specific urban environment, is an artistic practice that occurs and unfolds in public places or public spaces, and maintains a mutually complementary and benign interactive relationship with other environmental elements, resulting in an integrated and organically unified overall urban environment [5, 6]. However, many public art sculptures have lost their aesthetic value due to a variety of factors. Instead of becoming beautiful scenery, they have polluted the environment and have become unfamiliar or even trash in urban areas. As a result, public environmental art sculpture in the cultural area should be capable of enhancing the environment and space atmosphere of the entire cultural area, and good sculpture works can evoke memories of not only the sculpture works themselves, but also the entire cultural area [7]. It is, however, also the most easily overlooked location. The integration with the surrounding environmental space, which is the display of integrated environmental space, is the goal of public environmental art sculpture. People need art sculptures in the public environment to enrich their lives, and sculpture is the best carrier for displaying the atmosphere of cultural areas.

Environment includes human environment and material environment [8], which is not only the bearing space of public environmental art sculpture, but also the living space of citizens [9]. The art sculpture in public environment with proper location, vivid image, and reasonable scale is an important landscape element of urban space environment, which can play the role of unified coordination and guidance of landscape [10]. In the end, contemporary public space art sculpture is an artistic expression form in the urban space environment, which is an important part of the urban space environment and has an impact on it. Whatever the theme, type, or form of the sculpture, it must adapt to the functions and characteristics of the surrounding space environment, as well as properly reflect those characteristics, in order to render and contrast the urban space environment, adjust the urban color, and enhance the visual feeling of public beauty [11]. Sculpture places a greater emphasis on public interaction and coordinated changes in the environment. It differs in content from previous environmental sculptures that emphasized theme and memorial, but it makes reasonable conception and design to create a space that interacts and coordinates with the public and the environment, based on the artist's imagination and various factors of environmental space.

2. Related Work

The research and creation of foreign public environmental art sculptures are very mature, the supporting facilities for sculptures in cities are perfect, and the developed countries in Europe and America are the most developed areas of public environmental art sculptures in the world. In major cities in Europe and America, there are almost all familiar sculptures as important urban cultural landscapes. Literature [12] holds that public environmental art sculpture is a kind of public sculpture art form that relies on outdoor public space in urban public space and can be appreciated by the general public. Whether it is western "environmental sculpture" or what Chinese scholars call "public environmental art sculpture," its foothold is the interaction between the social function of sculpture and the public, and its main content is to integrate the media of public environmental art sculpture into the daily life of the general public and serve the general public. Literature [13] holds that an excellent public sculpture often becomes the symbol of a city's public culture. However, due to the different places where sculptures are set and the different human environment, the public responsibilities of artistic sculptures are also different. Literature [14] holds that in terms of expression techniques and forms, outdoor sculpture should not only coordinate with the architectural appearance, but also play a role in enriching the active environment and space atmosphere. Literature [15] holds that urban space is a space composed of entities and a stage for people's daily life. It can exist between buildings, a street, a downtown area, even the whole city, or a larger urban space. Literature [16] holds that the restriction of space environment on public environment art sculpture is mainly manifested in two aspects, namely, the setting location and control elements of public environment art sculpture. Literature [17] holds that human factors are the comprehensive embodiment of emotional forms, environmental atmosphere, decorative effects, spatial feelings, and other aspects in environmental space, and finally, the human environment of urban environmental space is formed through these aspects.

The ecological pattern of a landscape is an important aspect of landscape ecology. Landscape ecological pattern analysis and evaluation can provide a solid foundation for landscape ecological management and planning, and it is the key to successful landscape ecological planning [18]. Various nonlinear data processing technologies are used to predict various landscape indexes based on the landscape pattern dynamic model of RS (remote sensing) and GIS (geographic information system) and landscape ecology as the theoretical basis. The surface is reconstructed from an undirected point set using a distance field isosurface extraction algorithm proposed in [19]. Because this nonlinear algorithm includes a complicated normal consistency check and isosurface extraction process, the model reconstruction process takes a long time. The surface is reconstructed using a noisy directed point set as input in the literature [20], but the reconstructed result still contains noise. Literature [21] uses a Voronoi diagram to decompose the scanned data before using Delaunay triangulation to reconstruct the mesh model. This method can accurately fit the scanned data point set, but ideal reconstruction results for noisy models and sharp features are difficult to achieve. To solve this problem, literature [22] proposed a user-assisted reconstruction algorithm. He requested that users place restrictions in areas that are unstable or imperfect, whether inside or outside. Literature [23] used distributed memory parallel processing to speed up the reconstruction of Poisson's surface, resulting in a good speedup ratio and little loss in reconstruction results. For a large number of point cloud data, literature [24] proposes a 3D surface reconstruction method based on principal component analysis. The three-dimensional surface of the pipeline is reconstructed using the principal component analysis method, and its accuracy is effectively improved, meeting the accuracy requirements of engineering survey. This reconstruction method, on the other hand, is appropriate for first-order surface continuity of the measured object.

3. Research Method

3.1. Research on the Interactive Relationship between Public Environmental Art Sculpture and Environment. Sculpture is a form of art that exists in a specific location. The combined visual and psychological effects of sculpture with the indoor and outdoor environment demonstrate the mutual penetration and integration of artistic and scientific functions. As a result, the sculpture must be appropriate for the environment, meaning that its volume, shape, and material must conform to the specific environment and space in order to produce the desired effects. Depending on the specific purpose of sculpture creation, the desired effect can be harmonious or antagonistic. Sculpture, in its role as art, provides a finishing touch to the outdoor environment, enhancing people's visual experience. The limitations in the process of sculpture creation are greater for indoor sculpture than for outdoor sculpture. Indoor sculptures are limited by regional functions, such as commercial, office, and residential areas, in addition to being suitable for lighting. Sculptures are differentiated by their regional functions.

The interaction of emotional communication of public environmental art sculpture is mainly carried out among three elements, namely, the subject, the object, and the interactive media, namely, the self-emotion of the designer of public environmental art sculpture, the attitude toward sculpture, the understanding of materials and the presentation of design ideas, etc. That is, the appreciators and acceptors of the public environmental art sculpture of the object, these audiences are bound to add their own feelings to the public environmental art sculpture and feel the creator's feelings; that is, the media public environment art sculpture itself, the public environment art sculpture is like a symbol, which conveys the designer's subject emotion to the audience object, and is the interactive medium and link between the subject and object.

The foundation of the 3D urban landscape model is the D-Digital City Information System. One of its key features is that it can manage terrain structure (digital elevation model), terrain texture (digital orthophoto scene), 3D artificial building structure information, and artificial building texture information. Furthermore, the system includes 3D urban model visualization technology, which employs virtual reality to represent transmission stereo models or virtual stereo models on a screen. The data model of 3D digital city is shown in Figure 1:

In different environments, sculpture gives people different visual feelings and different psychological experiences. Designers are required to pay attention to the interaction between sculpture and natural environment, coordination, and unity. Only when sculpture works become the carrier of nature, can they bring permanent artistic vitality to sculpture works, specifically when creating environmental sculptures, taking the characteristics of the natural environment as a starting point, and enriching the essence and connotation of sculptures by using relevant elements in the environment, so as to achieve the expected design effect.

The scale and form of environmental sculpture must be appropriate for the location of the sculpture, be consistent with the behavior and psychological activities of people in that location, and attempt to establish some sort of connection with the general public. The sculpture's form and theme are related to the public's behavior and psychology, resulting in a relaxed and interesting atmosphere. The ability to grasp the scale is a direct expression of the designer's own design thinking and design ability in the design of public environmental art sculpture. It may reflect the designer's intuitive understanding and grasp of the designed space. People can usually judge scale instinctively, so in a space with an inappropriate scale design, people will make incorrect judgments about the space itself and the size of objects in the space, lowering the environment's appeal. A good use of scale, on the other hand, can make a space feel beautiful.

In the design of public environment art sculpture, it is necessary to pay attention to the spatial relationship of various elements in the urban environment, grasp the hierarchy and identifiability of space, and make people feel comfortable physically and psychologically when they move in outdoor space, thus improving the utilization quality of space.

Excellent public environment art sculpture can stimulate people's aesthetic taste and artistic yearning, attract many citizens and tourists to watch and play, then condense the indispensable popularity of space places, and create a lively atmosphere. Therefore, clearly establish sculpture as a new concept of cultural image, and it can start from two aspects; first of all, improve the artist's cultural accomplishment, so that the artist can clearly realize that the sculpture and skills are full of cultural spirit. Secondly, realize that sculpture has various themes and different functions. Whether they are monuments of historical figures or portraits of important figures, they all have cultural meanings and are carriers of culture. Therefore, people should not underestimate the cultural significance of urban landscape sculpture. It often has an imperceptible cultural character, which exerts a subtle influence on people and becomes an indispensable connotation in social culture.

3.2. Layout Planning of Artistic Sculptures in Public Environment Based on the Analysis of Spatial Environment Characteristics. Different working processes for dynamic analysis of landscape ecological pattern depend on the objects, scales, and objectives, but the basic processes are as follows: objective determination, information collection, model establishment, preliminary scheme, scheme evaluation, planning formation, and management. The creation of models and the optimization of schemes are the most important aspects of ecological planning. Starting with the behavior of constructing a single fish and progressing through the local optimization of each individual in the fish school, AFSA (artificial fish swarms algorithm) imitates the foraging, clustering, and rear-end chasing behavior of fish. Obtain the global optimum.

The improved AFSA idea is adaptive to the environment during the searching process of artificial fish, such as foraging, clustering, and rear-end collision. Its purpose is to speed up the convergence speed and improve the accuracy of the algorithm. In this paper, the variable step size method is adopted, and the artificial fish adjusts the moving step size

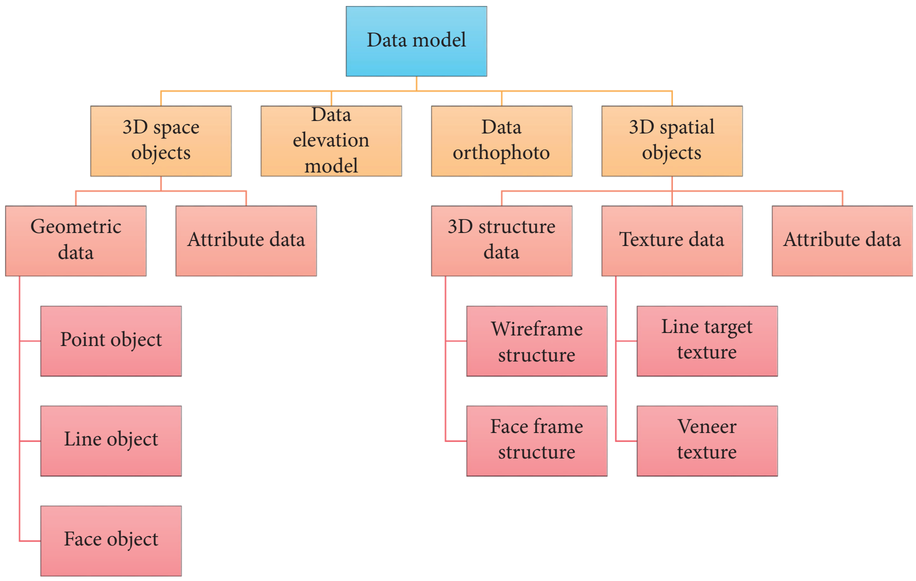

Figure 1: Data model of three-dimensional digital city.

according to the current environmental severity. The variable step size formula is as follows:

$$\text{step} = \frac{Y_m - Y_i}{Y_m - Y_w} \times \text{step}. \tag{1}$$

The current food concentration of artificial fish is Y_i, the maximum food concentration in the field of vision is Y_m, and Y_w is the lowest food concentration in the field of vision. This improved step size can get faster optimization speed in the initial stage of searching and reduce the probability of skipping the optimal value in the later stage, which can make more detailed optimization.

In order to automatically adapt to the phenomenon of fish aggregation, view gradually decreases with the increase of iteration times, and the adaptive formula of view is as follows:

$$\text{view} = V_{\max} \frac{(V_{\max} - V_{\min}) \times k}{it\ \max} \times \text{step}, \tag{2}$$

where $V_{\max}$ and $V_{\min}$ are the maximum and minimum value of view, k is the current iteration number, and it max is the maximum iteration number. At the initial stage of optimization, each artificial fish swims in a larger field of vision, expanding the search range of the algorithm and then gradually decreasing, so that the fish can search in a more detailed field of vision.

The shared function is used to correct the fitness value of individuals in the population to ensure the diversity of the population. The shared function is formed by the combination of coding difference and fitness difference. Assuming that there are two individuals x_i, x_j, the coding value distance between them is $d_1(x_i, x_j)$, and the fitness distance between them is $d_2(x_i, x_j)$, then the shared function $S(x_i, x_j)$ can be expressed as

$$S(x_i, x_j) = \begin{cases} 1 - \dfrac{d_1(x_i, x_j)}{a_1}, & d_1 < a_1, d_2 \geq a_2, \\ 1 - \dfrac{d_2(x_i, x_j)}{a_2}, & d_1 \geq a_1, d_2 < a_2, \\ 1 - \dfrac{d_1(x_i, x_j) d_2(x_i, x_j)}{a_1 a_2}, & d_1 \geq a_1, d_2 \geq a_2, \\ 0, & \text{other}, \end{cases} \tag{3}$$

where a_1 and a_2 are the niche radius. Incorporate the shared function into the fitness function of the individual to obtain the fitness function of the individual after correction:

$$\overline{f}(x_i) = \frac{f(x_i)}{\sum_{j=1}^{N} S(x_i, x_j)}, \tag{4}$$

where $\overline{f}(x_i)$ represents the revised individual fitness function, $f(x_i)$ represents the original individual fitness function, and N represents the total number of individuals.

When local search is carried out by subgroup, the worst fish X_w in subgroup learns from the best fish X_b in the group or subgroup. When learning, random replacement operators are used, and the two pixels are used as the upper left corner and the lower right corner to generate rectangular ranges, and the gene information of the learning target fish X_b in this range is intercepted and used to replace the genes corresponding to the worst fish X_w in the current subgroup to complete the update operation, as shown in Figure 2.

According to the fitness function, when the worst fish swarm X_w in the subgroup does not get better fitness after

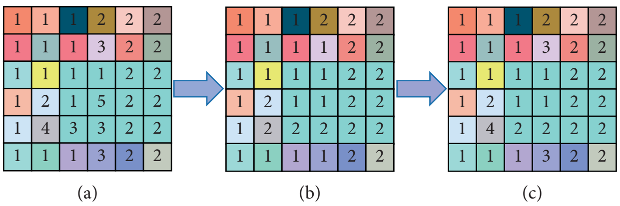

Figure 2: Update operation. (a) Worst fish. (b) Optimal fish school. (c) Worst fish after update.

updating operation, it is mutated, and the mutation operation flow is shown in Figure 3.

After the mutation, it is judged whether the area of landscape transfer exceeds the control of the probability matrix of landscape pattern transfer. If not, the mutation actually occurs; otherwise, the mutation does not actually occur.

When the point cloud dataset is added to the octree according to the set maximum depth, the octree is established. The node function of each node o of octree O is defined as

$$F_o(q) = F\left[\frac{q - oc}{ow}\right]\frac{1}{ow^3}. \quad (5)$$

The center of node o is oc, and the width of node o is ow.

Given a sampling point p, calculate the key sequence xyz of sampling point p and the sorted key sequence. The xyz key sequence of sampling point p is calculated from high to low. At $d\,(1 \leq d \leq D)$ depth:

$$x_d = \begin{cases} 0, & p, x < C_{\mathrm{dx}}, \\ 1, & \text{otherwise}. \end{cases} \quad (6)$$

D value sequence at depth xyz is defined as

$$x_1 y_1 z_1 x_2 y_2 z_2 L x_D y_D z_D. \quad (7)$$

It is easy to know that xyz sequence specifies the path from the following node to the current node, so when the depth is D, $3D$ bits are needed in total. At present, 32 bits can be used to represent k to allow that maximum depth of 10.

All sample points use xyz key sequence as sorting key. According to the coding principle, the xyz key sequence closer to the origin is smaller, and the xyz key sequence farther from the origin is larger.

4. Result Analysis and Discussion

The image was analyzed by RS and GIS technology, and the landscape elements were divided into seven landscape types, including cultivated land, garden, woodland, sandy wasteland, urban and construction land, water area, and unused land, based on the improved AFSA neural network research model of ecological landscape spatial pattern planning. Rasterize the image, with each raster measuring $300\,\mathrm{m} \times 300\,\mathrm{m}$. The remaining 20% of the sample is used as verification data, and the rest is used to train the improved AFSA model, yielding the corresponding landscape index prediction results. Several times, change the training times. The output results are stable, and the calculation results are shown in Figure 4.

The results show that the error values of the simulated output and expected output of the improved AFSA model samples are within ±4%, while the accuracy of the unmodified AFSA is generally ±6%. The training error of BP neural network can be controlled within ±7%. It shows that the output of the improved AFSA model is more accurate. The error is smaller. It provides a more accurate landscape pattern index. Provide scientific and powerful theoretical basis for the optimization of landscape pattern, and make the optimization of landscape pattern more reasonable.

Among all art forms, public art in the form of urban sculpture is the most likely to receive widespread public support. However, due to the nature of free public art appreciation and the characteristics of civilians, urban sculpture is no longer just a symbol of social status, but also reflects the public's deep meaning from the side. Nonetheless, urban sculpture is not a tool to solve social reality problems, nor is it a tool to blindly cater to and imitate the interests of the upstarts of the industrial and commercial circles. The degree of satisfaction is used to express people's recognition, and the method proposed in this paper is used to optimize the architectural landscape. Figure 5 depicts people's varying attention to square and pedestrian street evaluation factors, while Figure 6 depicts people's satisfaction with the optimized architectural landscape space. This paper assumes that the degree of satisfaction is divided into five different levels, and the corresponding score is 1~0.

The results of all evaluation factors are generally consistent after this algorithm has been optimized, as shown in Figure 6. People give more than "satisfactory" ratings to most architectural landscape evaluation factors, indicating that they are more satisfied with the Huaqiang North architectural landscape's optimized spatial layout. At the same time, it demonstrates that this algorithm is capable of achieving good architectural landscape spatial optimization. This demonstrates that the square satisfaction is the highest. The reason for this is that the square is the focal point for people's leisure activities, and its amenities and green space are well designed. However, on a pedestrian street, various shop decoration styles have their own merits, which are dazzling and easily cause aesthetic fatigue, and the vegetation greening rate along the street is low, resulting in low satisfaction.

Markov model is constructed by using Markov module of the software, and the transition probability matrix among various landscape types from 2020 to 2025 is generated, so as to predict the number transition of future landscape pattern in the county, which is used as the control condition in AFSA mutation operation to ensure that the optimized result of landscape pattern is consistent with the actual situation. The results are shown in Figure 7.

It can be seen from Figure 7 that forest land is the most active landscape type in the future evolution trend of county. The possible transfer area between building land and other landscapes is equally large, and the transfer amount is obviously larger than the transfer amount. The possible transfer area between sandy land and other landscape types is small,

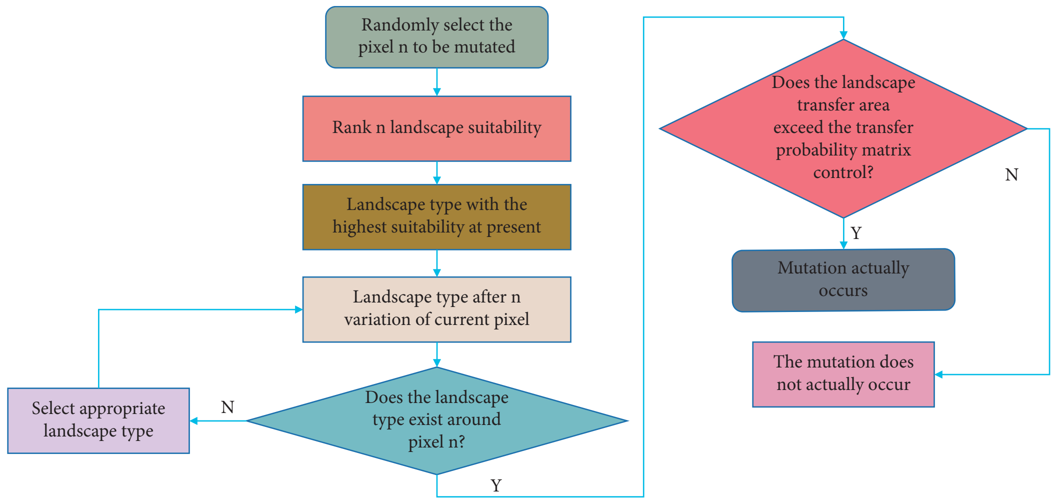

Figure 3: Operation variation.

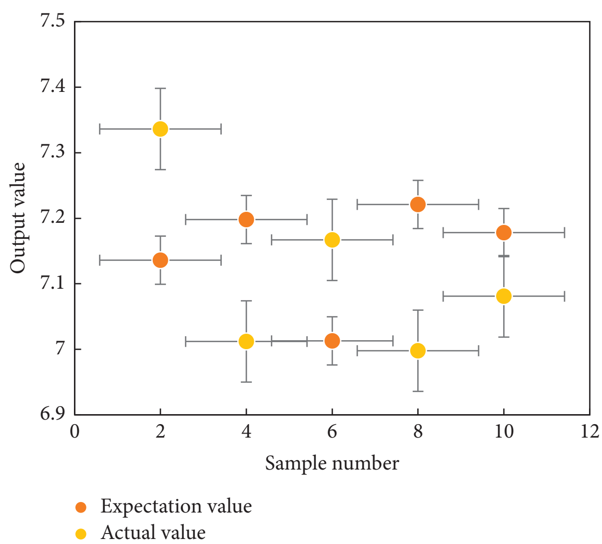

Figure 4: Comparison between simulation results and expected output.

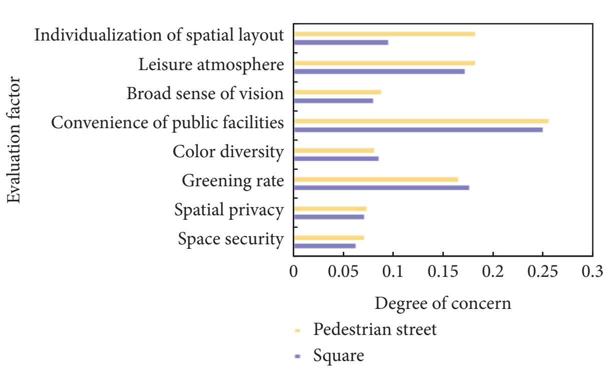

Figure 5: Different degrees of attention of evaluation factors of squares and pedestrian streets.

while that between sandy land and woodland is large. The landscape area of water body is small, the possible transfer area between water body and woodland and sandy land is large, and the transfer between water body and other landscapes is small. The possible transfer area of mountain landscape is the smallest among all landscape types.

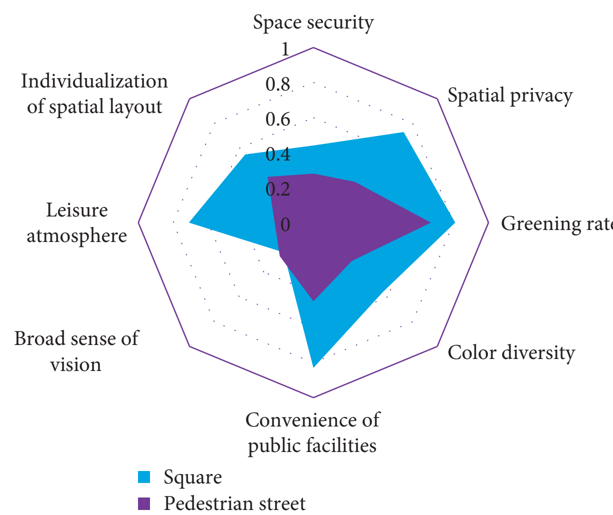

Figure 6: Satisfaction after optimization of architectural space.

Urban sculpture is a special material existence that exists at the level of form and acts on the level of image and meaning. They directly talk to our ideas and culture with external morphological features, which leads us to think about the spatial meaning, social life, and even human beings themselves. Therefore, the creation of urban sculpture should be based on people's visual psychological feelings.

Through the visual observation of the optimization results, it can be seen that the landscape aggregation degree of the two optimization models has been obviously improved, and the fragmentation of each landscape type has been well controlled. The distribution of landscape pattern in the study area in 2020 and the landscape aggregation index, the average landscape suitability index, and the transfer area beyond the control of the transfer probability matrix are calculated. The results are shown in Figure 8.

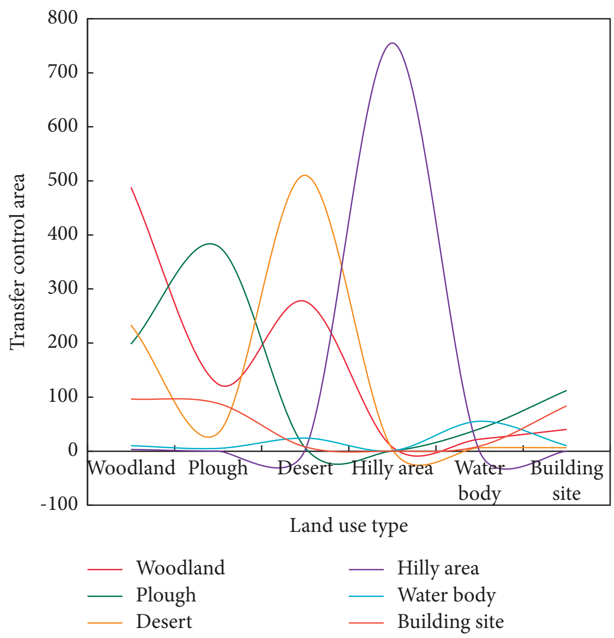

Figure 7: Landscape pattern transfer control area.

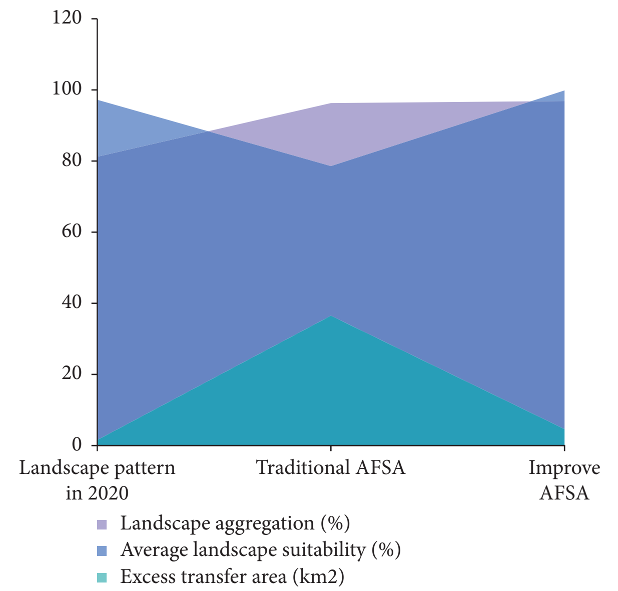

Figure 8: Comparison of indicators of landscape pattern optimization results.

Figure 8 shows how a higher landscape suitability index can ensure that county land is adapted to local conditions, prevent afforestation, reclamation of cultivated land, and other activities in areas with poor soil and water conditions, and play an important role in the rational use of county land. It differs from the transition probability matrix's control area in several ways. As a result of the excessive transfer area among some landscape types in the optimization results, there will be a disparity between the optimization results and the actual situation in the county, making the landscape pattern optimization scheme difficult to implement. As a result, the optimization algorithm must include control over the landscape pattern transfer probability matrix.

The experimental data used in this experimental system are the point cloud dataset provided by Poisson reconstruction algorithm official website, and the models used are bunny model and horse model. Analyze the horse dataset, and the specific situation of point average and area average generated by the horse dataset in the mixed parallel environment is shown in Figure 9:

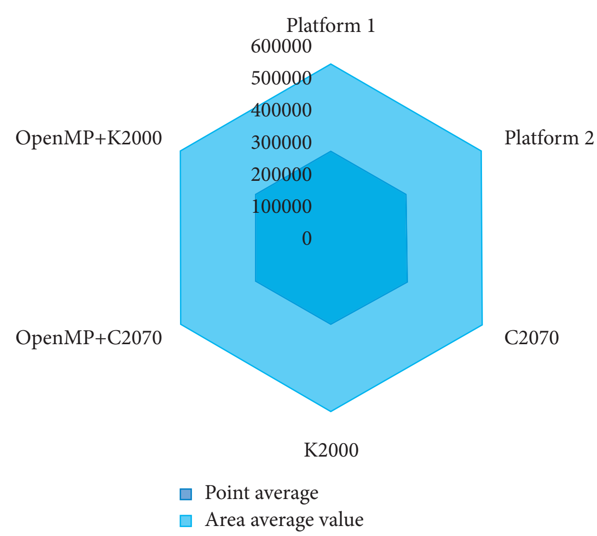

Figure 9: Experimental results of point average value.

However, modern cities no longer consider the division of urban space in a certain cultural or folk sense like ancient cities. Modern urban space is mainly divided by functional requirements, and then, it is designed and produced according to people's visual needs. For example, waiting rooms, mailboxes, guardrails, and other public facilities in modern urban streets are also important aspects to change the image of urban streets and shape the visual quality of cities, that is to say, in every street and public space of the city, starting from its functional requirements and human visual quality, from the aesthetic requirements of modeling and the unity of using functions.

The time-consuming results of various improved parallel algorithms are shown in Figure 10.

To sum up, compared with simply using any kind of acceleration equipment, a higher acceleration ratio can be obtained through hybrid and degraded acceleration technology. This is because the research makes full use of the characteristics of various tasks in the algorithm and assigns tasks to appropriate processing equipment for processing. In this way, high performance can be obtained by using these two types of equipment together. Therefore, when accelerating and optimizing the algorithm, consider using a hybrid parallel acceleration model to optimize and improve the algorithm, and allocate the computing tasks reasonably to obtain better optimization results.

In urban space, sculpture, like buildings, trees, and decorations, is an element of a city. Urban sculpture is an

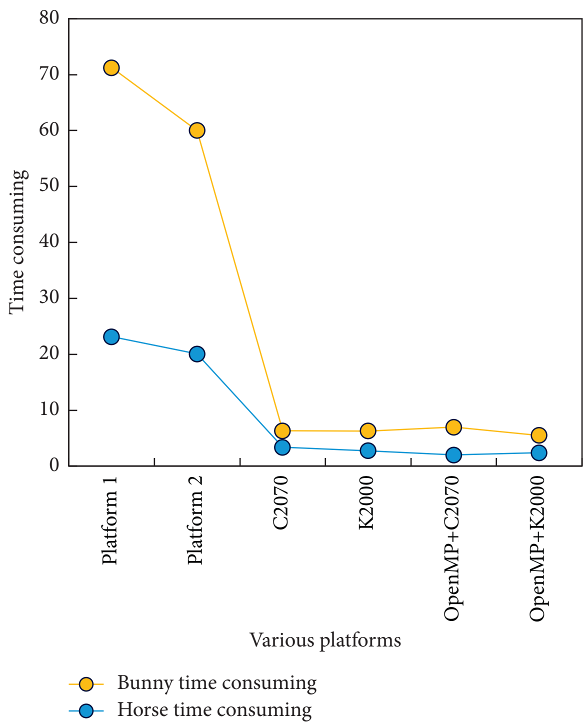

Figure 10: Time-consuming comparison of various platforms.

organic element that acts on the organizational structure of urban space. Unlike other elements, it has no specific function, so it will instead become the focus of a city in pure space. Only by paying attention to the necessity of this element can the city obtain a beautiful image and poetic praise.

Look for national characteristics and regional formal beauty in the overall beauty of the environment. Therefore, environmental sculpture should not only meet people's artistic quality requirements for their living environment, but also reflect people's constantly improving spiritual level in the cultural field. People's beauty of environmental art is no longer just the need for neatness and beauty, but the further pursuit of higher artistic realm and profound cultural connotation. Environmental sculpture is a kind of public art. It plays an important role in shaping the characteristics of the public environment and the humanistic environment of the city.

5. Conclusion

Public environmental art sculptures are not only an important part of people's daily lives, but they can also demonstrate the city's unique cultural charm. Because of their visual images, mature interactive public environment art sculptures can immerse the public in a deep cultural atmosphere in the urban environment. To improve the artistic value of sculpture, special attention should be paid during the design process to highlighting the city's uniqueness while also fully respecting local history and culture. The artistic sculpture of the public environment can be more closely combined with the city's root and thrive, fully demonstrating its unique city character, if sculpture planning is based on the analysis of spatial environment characteristics. Images are analyzed using RS and GIS technology. Improved AFSA can predict landscape indexes like category level and landscape level of landscape ecological pattern more accurately. It boosts the efficiency of landscape pattern optimization and provides a solid analytical foundation for achieving ecologically sound development.

The fact that self-organized physical education teaching systems in universities should have diversity and imbalance has been weakened, and we need to focus on the self-thinking, self-learning, and uncertain factors in the teaching process. The components of the entire teaching system are known as teaching elements. We cannot understand the integrity of teaching elements without understanding system theory. The teaching in physical education classes is the same way. This paper analyzes the elements and overall optimization of university self-organizing physical education teaching system using the methods of literature review and logical argumentation, starting from the perspective of holism and combining with the characteristics of physical education. The effectiveness and superiority of this model are tested by comparing sports performance data with ACOA (Ant Colony Optimization Algorithm) to optimize the sports video of SVM (Support Vector Machine). The findings show that the model can improve sports performance prediction accuracy, and the prediction results are more reliable, providing useful information for sports training.

1. Introduction

Many experts and scholars have conducted research on college physical education teaching models in recent years and have produced some impressive results, such as inductive analysis of typical college physical education teaching models, current state of college physical education teaching models, and experimental research on typical college physical education teaching models [1, 2]. Teaching in the classroom is a complex and comprehensive system with many components. The efficiency and quality of classroom teaching will be greatly improved if the individual vitality of these elements can be stimulated and their potential functions are fully realized [3]. Some philosophy of technology, which is emerging in the field of natural science, provides a new perspective for us to reexamine education, from the study of universal educational law to the search for situational educational significance.

There are five main elements within the university curriculum, disciplines, majors, curriculum contents, teachers, and students, which together constitute the university curriculum system [4]. However, the physical education in schools is responsible for the important physical exercise in the student period, but, through the investigation, research has found that there are many problems in college sports [5, 6]. In recent years, some scholars have applied the perspective of holism to the scientific research of physical education, which involves the exploration of the purpose of self-organized physical education, the prospect of the transformation of physical education paradigm, and so forth, and have made a useful discussion on applying the perspective of holism to teaching and training practice [7]. However, most of the results define self-organizing systems as individual students, and there are few results in analyzing the teaching process in which teachers and students participate together as a system from the perspective of holism. From the point of view of system theory, these factors that make up physical education teaching are a whole structural system, which not only belongs to the big system of school physical education but also contains its own subsystems such as goals, feedback, teaching contents, and teaching methods [8]. Teaching material (teaching content system) is the carrier of teaching theory and the object of teaching practice, which plays a key role in the overall framework of physical education teaching mode.

Teaching mode is defined as "a strategic system of relatively stable teaching procedures and methods that must be followed in the teaching process, which is formed based on teaching ideas and teaching rules, and includes the combination of various elements in the teaching process, teaching procedures, and corresponding strategies" [9, 10]. This paper builds on the nonlinear interaction between systems and the overall synergy effect to continuously develop in the direction of structure, organization, and multiple functions, from disorder to order and from order to higher order, in order to form positive influencing factors and evolutionary power and promote the optimization of physical education classroom teaching process.

2. Related Work

At first, the holistic perspective does not serve pedagogy subordinate to social sciences, and of course it also includes physical education, which is actually produced in natural sciences [11]. With the development of the times, more and more theories have explained and extended the holistic perspective, gradually improving the system into a group theory including many subtheories such as dissipative structure theory and synergetics, accelerating the evolution of holistic perspective in the field of natural science and laying a solid foundation for the field of auxiliary education in the future. Literature [12] holds that when interest factors occupy students' psychological tendency, students will show their physical strength and attention beyond usual and enjoy sports activities. Literature [13] holds that sports are an indispensable part in today's social activities and personal life. The sooner you realize this, the sooner you can shape a healthier body and mind. Literature [14] holds that the holistic perspective supported by many subtheories is in line with the current teaching needs. Literature [15] points out that today's traditional physical education relies too much on other organizations' interference, which limits the development of independent participation, self-thinking, and teaching methods in physical education. Literature [16] holds that it is necessary to improve the teaching methods of traditional teaching, which should be the center of our attention, highlight the subjectivity of students, and better impart knowledge. Literature [17] points out that although these traditional physical education teaching modes have played a certain role in the development of school physical education in China, they also show disadvantages in teaching; that is, they pay too much attention to sports technology learning and neglect the development of students' interests and the cultivation of independent thinking ability, which leads to some single physical education teaching methods. In literature [18, 19], by comparing the current teaching model with the needs of post-modern-curriculum reform, it is concluded that, nowadays, the traditional teaching mode has certain limitations, focusing on teaching, simplifying the teaching mode, and neglecting the cultivation of students' other qualities. However, modern physical education develops the teaching function of physical education from various angles, focusing on learning, implementing democratic teaching, and no longer sticking to a teaching mode but paying more attention to giving full play to students' learning initiative.

There are numerous sports video classifications available today. People used expert systems to classify sports videos at first. Expert systems, on the other hand, have high knowledge requirements and are unable to solve new sports video classification problems. At the moment, they are mostly computer-based automatic sports video classification methods [20]. According to literature [21], the current video similarity detection system has the problem of detection speed not being able to keep up with the actual production demand. The authors built a distributed platform for batch video similarity detection using cloud computing and the compound eye of insects, and the detection speed was greatly improved. Literature [22] created a distribution-based video content analysis platform. Offline and real-time video analyses are both possible with the platform. The platform is used in the testing stage to detect shot boundaries of multiple video segments at the same time, with a detection efficiency that is higher than that of a single machine. Literature [23] designed and implemented a distributed video processing platform that combines Storm and Hadoop, two distributed computing frameworks. In [24], a single frame image of video is parallel processed using Hadoop, and each frame block of the image is parallel processed using GPU. Literature [25] proposed a real-time video processing cloud platform based on embedded devices, on which Storm was deployed as a cloud computing environment and video streams were processed using the DL (Deep Learning) algorithm. Literature [26] proposed a video processing framework based on two cloud computing technologies, Storm streaming and Hadoop batch processing, and deep learning was employed to extract high-level semantic features from video data.

3. Research Method

3.1. Analysis of Various Elements of Physical Education. People usually equate the system with the whole. In fact, the system is a description of the whole. What people really care about is not the system but the whole. The purpose and essence of people focusing on the system lie in the whole. The essence of systematic holistic thinking is its wholeness, and system is actually an expression of wholeness; that is to say, from a systematic point of view, the wholeness of everything can be expressed by systematic terms and means. This is the system holism that we want to discuss.

From the static structure point of view, teaching is simply the activity where teachers teach students teaching content. Without any of these three, it cannot be called teaching. Without students, there is no teaching object; without teachers, teaching will lose its dominance; without teaching content, teachers and students will lose their teaching support. Trend shows that, to respect and develop students' personality, and attach importance to students' dominant position, insistence on diversification, flexibility, and individualization of teaching organization forms is a must. Therefore, letting students choose to participate in teaching classes with different project combinations in different periods can fully mobilize their learning enthusiasm, help to stimulate their interest and enthusiasm in learning physical education, and effectively promote the realization of the best teaching scheme.

In physical education teaching, good ideological quality is classified as the level of basic physical education quality. First, good ideological quality helps students to establish a correct world outlook, values, and outlook on life and plays a benchmark role for students to form a correct view of physical education quality. Second, with the rapid development of computer technology and information technology, various ideas and opinions are constantly emerging, students are in the whirlpool of information, and good ideological quality can improve students' cognitive ability. Of course, attention should also be paid to the teacher's self-development. In addition, the close cooperation between teachers can give students a better influence. Physical education teachers should investigate from many aspects such as skill level and sports theory. In teaching practice, they should not only teach students professional technical movements and sports theory knowledge but also cultivate students' good moral and will qualities.

A self-organizing physical education teaching system is an organic whole with specific functions which is made up of several interconnected and interacting elements. People are the main body of physical education and the main factor of the teaching system and the driving force behind the system's self-organization development. Individual differences as well as an overall identity exist among the various elements. Individual differences manifest as competition, whereas overall identity takes the form of synergy. They rely on one another, interact with and complement one another, and, through the teaching process, produce the overall effect (see Figure 1).

The model shown in Figure 1 shows that the integrity of the self-organizing system is the basic condition for this system to keep its own unique stipulation in motion. As a system, college physical education is a multilevel whole, which is not the simple addition of all the components but the organic combination of all the components. It reveals the distinctive characteristics where the interaction between teachers and students dominates the overall evolution of the teaching system. The main element of the physical education system is people, which has the characteristics of "initiative" and "liveliness." It is the key element of the system and plays a leading role in the operation and development of the system.

The course content of university is a process of getting rid of the rough and getting the fine in the selection of knowledge, and it does not form a direct correspondence with human activities. In addition, the course content is internalized into students' own knowledge structure through students' own choice and reconstruction in the process of transmission, and it is impossible to fully meet the university curriculum objectives. The integrated power thus formed is the leading force to promote the overall evolution and development of the teaching system. This is a new understanding of the integrity of the teaching system beyond the traditional holistic theory, and it is the essence of the integrity characteristics of the self-organized physical education teaching system.

The evolution and change of discipline is the most important factor in the evolution and change of the five elements of curriculum, and its fluctuation will inevitably lead to a change in specialty setting, followed by the selection and reorganization of learning materials, and a change in the numbers of teachers and students. The external environment of universities, particularly the development and changes of scientific knowledge, influences the development and changes of disciplines. Human cognition of the world produces scientific knowledge. It has a level and order of evolution, and it is evolving from a simple low level to a complex high level. As a result, it establishes the timeline for the evolution and change of the university curriculum system.

3.2. Overall Optimization of the University Self-Organizing Physical Education Teaching System. The system goes through ups and downs, producing random branches at the critical point, so as to achieve a new balance and order among the elements of the curriculum structure. This is the key to whether the university curriculum can realize its function. Relatively stable curriculum structure is an inevitable process of curriculum self-organization. The orderliness of university curriculum structure is manifested in "spatial orderliness" and "temporal orderliness." Therefore, the self-organization control of school physical education teaching must take into account the cultivation and combination of students' emotions, attitudes, and interests from the overall perspective of the system, so that students can apply what they have learned about physical education to practice.

With the advancement of multimedia technology, there are more and more types of image acquisition devices available, as well as an increase in the number of people participating in sports. Every day, mobile phones and cameras can collect a large number of sports videos, posing challenges for sports video management [1, 2]. The following is the principle of ACOA (Ant Colony Optimization Algorithm) optimized SVM (Support Vector Machine) sports video classification: To begin, sports videos are gathered, and a variety of sports video classification features are extracted. The features of sports video classification are then processed using the principal component analysis algorithm. A sports video classification model is established using SVM as the input and sports video category as the output, and the SVM is optimized by ACOA to produce the best sports video classifier.

SVM maps sports video classification samples by function $\phi(x)$ and then carries out the following processing in high-dimensional space:

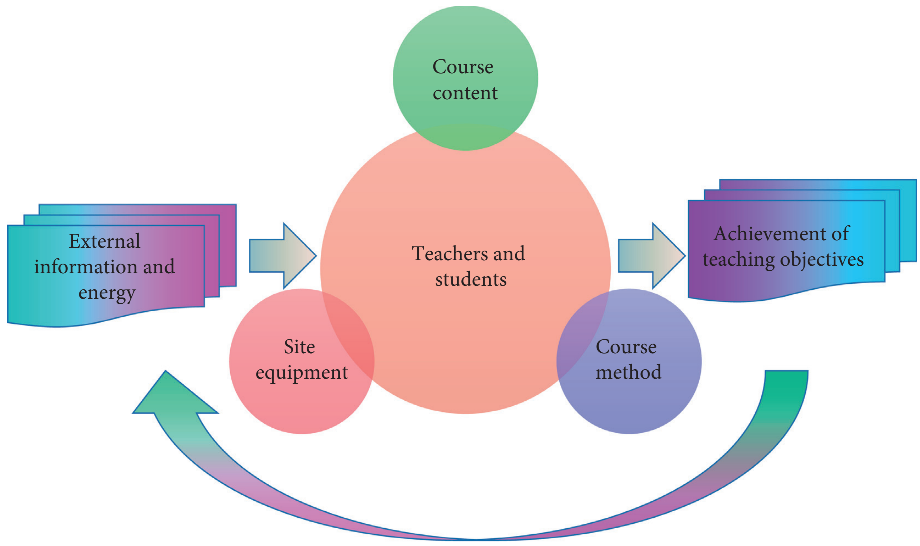

FIGURE 1: Sustainable operation of the university self-organizing physical education teaching system.

$$\min_{\omega,b,\xi} J(\omega,\xi_i)=\frac{1}{2}\omega^T\cdot\omega+C\sum_{i=1}^{l}\xi_i^2,$$
$$\text{s.t.}\quad\begin{cases} y_i=\omega^T\cdot\omega(x_i)+b+\xi_i, \\ \xi_i\geq 0, \\ i=1,2,\ldots,l, \end{cases}\tag{1}$$

where ξ_i^2 is the classification error and C is the penalty parameter.

According to the pheromone size left by ants, the next transfer probability of each ant is determined as follows:

$$p(i)=\frac{e^{T_0(\text{BestIndex})-T_0(i)}}{e^{T_0(\text{BestIndex})}},\tag{2}$$

where BestIndex represents the maximum pheromone concentration.

The pheromone depth is updated by the following formula:

$$T_0(i)=(1-\rho)*T_0(i)+\Delta(i).\tag{3}$$

Task scheduling is the process of allocating the best resources for the tasks that need to be completed, taking into account various factors such as time, cost, and resource utilization, in order to reduce task completion time and improve system resource utilization. HPSO (Hybrid Particle Swarm Optimization) is used to schedule the platform's tasks, with the goal of reducing task completion time as the algorithm's optimization goal. Figure 2 illustrates an HPSO-based task scheduling model.

For users, the main process of using the platform to process tasks is as follows:

(1) Initiate a task processing request to the user platform

(2) After receiving the user's task processing request, the task management module adds the task to the task queue

(3) The task scheduling module uses HPSO calculation to obtain the best task allocation scheme based on the status information of the computing cluster and the information of tasks to be processed

(4) The task distribution module distributes tasks to specific computing nodes for processing according to the scheduling scheme generated by the task scheduling module

(5) After the task processing is finished, the node feeds back the calculation result to the task management module, and the task management module informs the user that the task processing is finished

Assuming that there are N tasks and M virtual machines, the length of the particle position information is N, and the value of each element of the particle position is within the range of [1, M]. Formula (4) is an example of particle position coding.

$$X=\{x_1,x_2,\ldots,x_j,\ldots,x_N\},\quad 1\leq x_i\leq M,\tag{4}$$

where X represents the position information of a particle in the population, and for it contains any one-digit value x_j, j represents the task number, and x_i represents the virtual machine assigned to the task number i.

As all virtual machines process in parallel, the completion time of the task is the longest time needed to run among all virtual machines, and the calculation method is shown in the following formula:

$$\text{completeTime}=\max\{\text{totalTime}_i\},\quad i=1,2,\ldots,M.\tag{5}$$

Because the algorithm takes reducing the task completion time as the optimization goal, its corresponding fitness

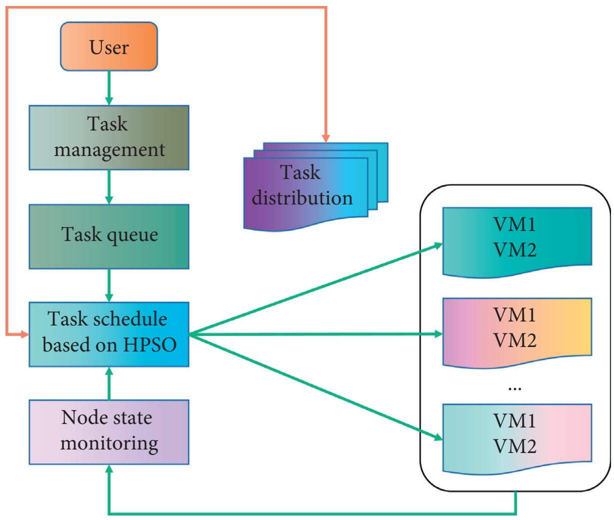

Figure 2: Task scheduling model based on HPSO.

function is shown in formula (6). The less the task completion time, the larger the fitness value.

$$\text{Fit} = \frac{1}{\text{completion time}}. \quad (6)$$

According to the number of iterations, the inertia weight is dynamically updated, and the velocity and position of each particle are simultaneously updated, and the best historical position of each particle and the global best position of the population are recorded.

Collect the sports performance data and process it with the following formula:

$$\hat{x}_i = \frac{(x_i - x_{\min})}{(x_{\max} - x_{\min})}, \quad (7)$$

where $\hat{x}_i$ is the sports result after processing; x_i is the original sports achievement; and $x_{\max}$ and $x_{\min}$ represent the maximum and minimum values, respectively.

After the prediction, the prediction results of sports performance are processed by the following formula:

$$x_i = \hat{x}_i \times (x_{\max} - x_{\min}) + x_{\min}. \quad (8)$$

According to the fitness function, the positions of fireflies are evaluated. Fireflies with weak attraction move to those with strong attraction, and the positions of all fireflies are updated.

4. Results Analysis and Discussion

The acquisition of high-level knowledge in the learning process is dependent not only on teachers' instruction but also on students' ability to learn on their own. Others organize the former, while learners organize themselves for the latter. Self-organization does not rely solely on students but rather requires the guidance and intervention of teachers. In the field of social sciences, self-organization demonstrates its scientificity, emphasizing the importance of guiding students to establish an orderly knowledge system, improving students' interest in learning, and promoting students' development as the fundamental idea of teaching design. The pretest and posttest experiments of EG (experimental group) are compared after the teaching experiment. The comparison results of the EG pretest and posttest experiments are shown in Figure 3.

According to the self-comparison results in Figure 3, it is shown that the open and cooperative teaching method from the perspective of holism can effectively improve students' learning interest, autonomous participation in class, and autonomous learning after class. After years of studying and living on campus, students have long been full of rejection of the teaching environment organized by him, so students regard physical education class as an opportunity to liberate themselves. When students find that sports still need a lot of repeated learning, students will naturally have resistance.

In order to maintain this achievement, it is necessary to enrich the teaching constantly, so that physical education can have more choices in content selection and purpose setting. From passive learning to active learning, we get the freedom and autonomy we deserve. On the basis of developing sports technology and maintaining physical and mental health, the openness of physical education is to develop students' subjectivity by using a more open teaching environment and a coordinated teaching atmosphere, so that the disorderly knowledge system can build an orderly knowledge structure in the open environment.

After the statistics, CG (control group) compares its own pretest and posttest experiments. Figure 4 shows the comparison results of CG pretest and posttest experiments.

After seeing the experiment, the scores of CG in four dimensions have slightly improved, indicating that, regardless of the teaching method used in physical education, students' interest in physical education learning can be significantly improved, but self-organized teaching can greatly improve the teaching effect in a short period of time. Five types of sports video data were chosen as the experimental objects in order to test the ACOA optimized SVM's sports video classification effect. Learn the training samples, establish corresponding sports video classifiers, and then classify the verification samples and count their sports video classification accuracy using the ACOA optimized SVM, the sports video classification method without parameter optimized SVM, and the sports video classification method of BPNN (BP neural network). The results are shown in Figure 5.

It can be seen from Figure 5 that this method can effectively reduce the error rate of sports video classification and obtain better sports video classification results.

The development of students' sports knowledge and skills and the construction of physical and mental health are all influenced by positive psychological tendencies. The formation and cultivation of autonomy are not only the purpose of teaching but also an indispensable feature for every member of society to move towards the continuous development of society. The inherent law of cultivation and students' self-organizing ability in the process of physical education study and exercise allow physical education to better cooperate with quality education and effectively develop students' physical and mental qualities.

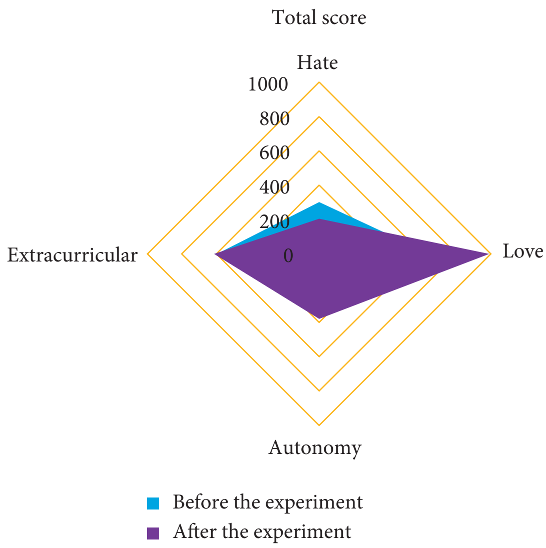

Figure 3: Comparison results of EG pretest and posttest experiments.

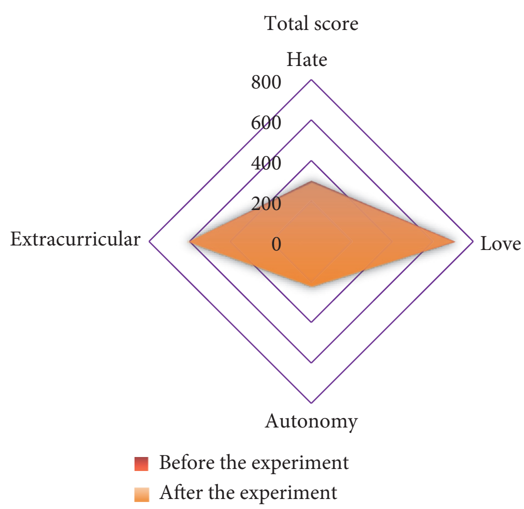

Figure 4: Self-comparison chart of CG pretest and posttest experiments.

Statistics of sports video classification time of the three methods are shown in Figure 6.

As can be seen from Figure 6, this method reduces the time of sports video classification and accelerates the speed of sports video classification.

Open physical education teaching demonstrates a wide range of learning objectives, all of which are complex and challenging. Students are part of a fast-paced information delivery system that is rich in differences and innovations. Knowledge is constantly being refreshed, new action structures are constantly being generated, and there is always something new to discover. In this way, knowledge gradually develops from disorder to order in a teaching situation with independent thinking as the primary component, and a reasonable external intervention force will aid in the formation of orderly knowledge. In the collective, there will be collaboration and competition. This migration force will be infinitely magnified and deeply portrayed in the minds of other students once an individual's technology model is recognized by the majority of people in the collective. Students who differ from the recognized technology model will consciously imitate and learn or even want to outperform their competitive behavior, develop autonomous and spontaneous learning, and then form an orderly and effective knowledge structure from a disorderly structure.

In order to verify the superiority of HPSO algorithm in convergence speed, it is compared with the algorithms in literature [22], literature [22], and literature [24]. A comparative experiment was conducted with 20 virtual computing resources and 500 tasks. The experimental results are shown in Figure 7.

When the number of iterations is 20, the task completion time of HPSO is obviously less than that of [22]. The specific reason is that the random method is used to initialize particle swarm in the algorithm of [22]. However, HPSO uses the method based on chaos opposition to initialize the population, which improves the diversity of the population, and makes the algorithm have a greater chance of searching for the relative optimal solution in the early stage than in the literature [22].

In the experiment, the number of tasks remained unchanged at 600, and the number of virtual machines was 10, 20, 30, 40, and 50, respectively. The task completion times required by literature [22], literature [24], and HPSO were compared. All the experiments were repeated five times, and the average completion time of five times was taken as the experimental result, as shown in Figure 8.

Literature [24] introduced the mutation operation of genetic algorithm into PSO, which ensured the diversity of population in the iterative process. HPSO also introduces the centroid of particle swarm to keep the diversity of the population. In addition, it uses chaos-based and opposition-based learning to initialize the population, which makes the initial diversity of the population higher, thus making the algorithm more likely to obtain the optimal solution.

Students are allowed to play freely for the sake of a broad teaching range. Teachers will guide and improve students' thinking as they take effective actions or responses to the teaching contents, in order to increase their participation, strengthen their self-learning, increase their interest in physical education, and guide them to improve their existing knowledge structure through mutual cooperation and reasonable competition in physical education. Physical development of students can be accelerated, and classroom quality can be improved. How students' states change over time is observed, breakthrough points are identified, students are encouraged to keep approaching these breakthrough points, and, finally, the conditions for technological progress are created. The teacher is allowed to lead the students through a sudden shift in their interests.

In order to improve the prediction accuracy of sports performance, a sports performance prediction model based on firefly optimized neural network is proposed to solve the problem of determining the connection weights and thresholds of BPNN. Grey model, BPNN, and RBF neural network were selected for comparative test, and 1000 m running result was selected as the experimental object. Their results are shown in Figure 9.

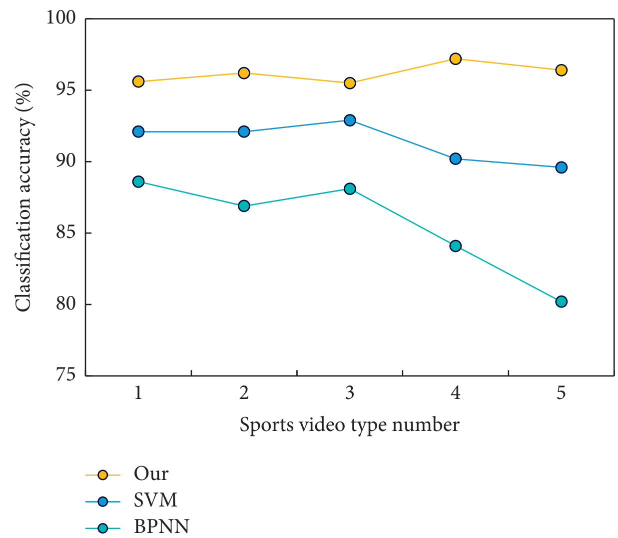

FIGURE 5: Comparison of accuracy rate of sports video classification.

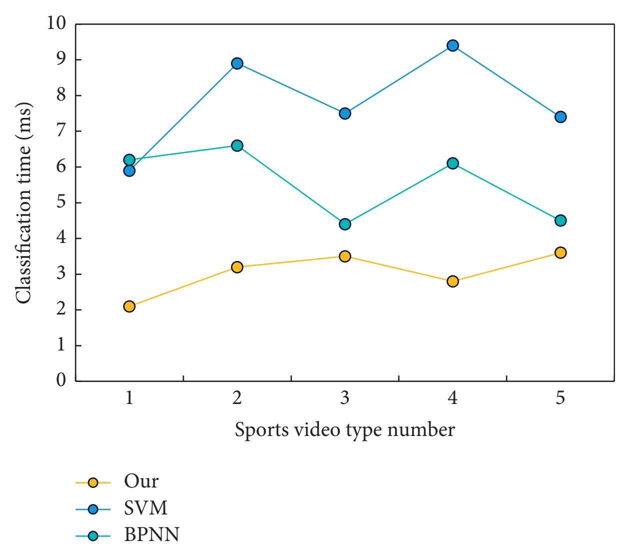

FIGURE 6: Comparison of sports video classification time.

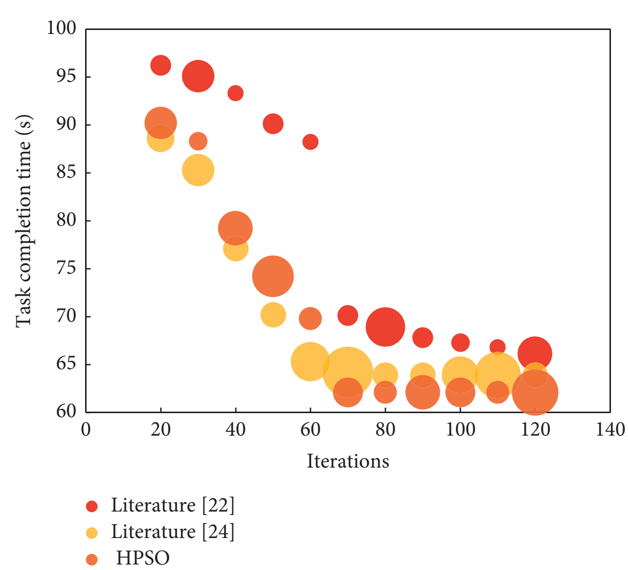

FIGURE 7: Comparison of convergence speed of different algorithms.

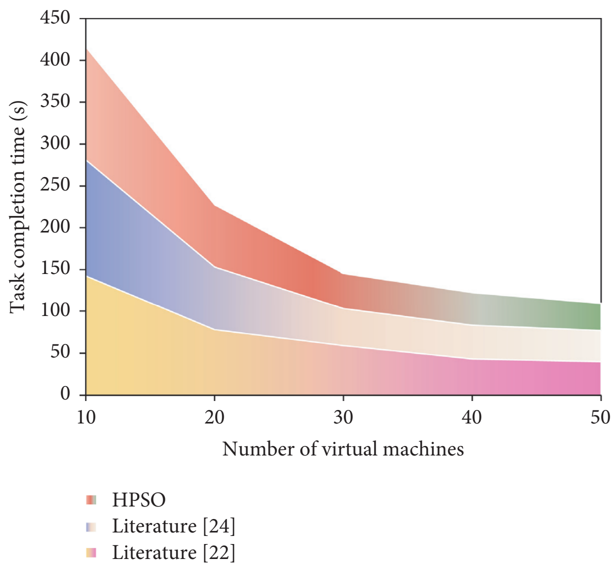

FIGURE 8: Comparison of task completion time under different virtual machines.

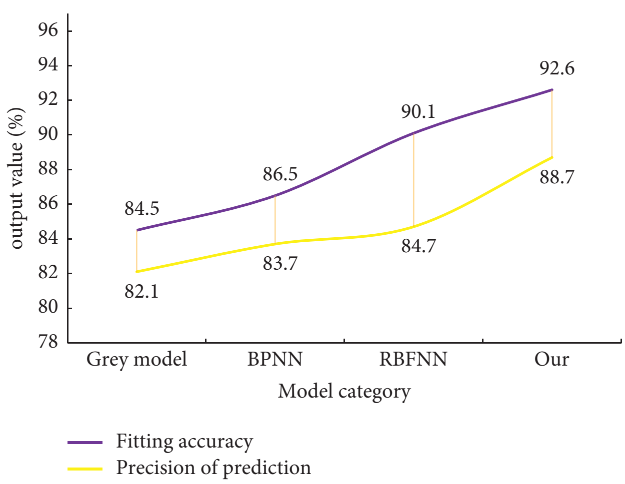

FIGURE 9: Universal test results.

As can be seen from Figure 9, the performance of athletes' performance fitting and prediction of this model is better than that of the comparison model.

In a physical education class, because students have to constantly adapt to the needs of teaching content, it is essential to adjust students' heart rate. Only under the appropriate heart rate condition can students' practice achieve the expected effect. In addition, because physical exercise is a gradual process in physical education, the sports load system not only reasonably grasps its rhythm in one class but also needs to consider the size of sports load according to the arrangement of sports activities (morning exercises, recess exercises, physical education class, extracurricular sports activities, amateur training, and competition activities) and teaching activities in a week to promote the healthy development of students.

Each school's situation is unique, and the physical education teaching mode is similarly unique. A comprehensive university, for example, with a large scale, multiple campuses, and a wide range of disciplines, may not be able to meet the needs of all students by using just one teaching model. Different disciplines and training goals, on the other hand, necessitate that teaching models reflect their own uniqueness on the basis of commonality. Several small groups of friends or classmates with varying levels, hobbies, and needs to practice are allowed, so that the interpersonal relationship between students and teachers is cordial and harmonious, boring and monotonous exercises become lively and interesting, and students' creative and enterprising motivation is stimulated, thus improving the teaching quality of physical education class.

5. Conclusion

For a long time, self-organization control theory has been widely used in the fields of nonlinear science and natural science, but there has been very little research into its application in college physical education. We should start with the teaching objectives, refine the objective structure, and create a multilevel objective system when teaching physical education classes. A new concept of physical education is formed based on the holistic theory, which attempts to establish a physical education teaching paradigm that focuses on students' subjective development and diversified transformation. The results of the HPSO algorithm show that it has some advantages over other algorithms in terms of task completion time and convergence speed. Sports video classification has a higher accuracy rate than other current sports video classification methods, and the error rate is controlled within the scope of sports video application, which overcomes the limitations of other sports performance prediction models, and the prediction results are more reliable, which can improve the scientific decision-making basis for sports training.

Sculpture art, as an important carrier of spiritual civilization, also portrays a prosperous scene as an industry with urban and cultural development. Three-dimensional technology offers a new platform for sculpture creation, allowing for the digitization of sculpture works via electronic information technology, and the display of sculpture works in front of people via displays, facilitating the exchange and dissemination of information and promoting the growth and progress of the entire sculpture creation industry. We plan to use digital enhancement technology to conduct small-scale creation experiments on traditional sculpture works, discuss the method of GA (Genetic Algorithm) in image restoration processing, investigate the method of image segmentation processing based on the genetic algorithm, and propose the method of image segmentation processing based on the fuzzy membership surface genetic algorithm, in order to verify and solve the creation difficulties of traditional sculpture works.

1. Introduction

As time passes, new technological means emerge one after the other. The use of new technology has resulted in significant changes in the way artists create art. The use of digital technology in the design and production of sculptures is becoming increasingly common [1]. Sculptors are increasingly turning to computers to create virtual sculptures. Sculptors can not only design sculptures with computer software but they can also simulate the space environment in which the sculptures will be displayed for a better display effect [2, 3]. The creative process of sculpture art and even the sculpture itself have separated from the limitations of material materials thanks to three-dimensional modeling design, which expands the creative means of sculpture to the computer's three-dimensional virtual space.

Digital sculpture is a small branch of digital art. A digital sculpture is a combination of three-dimensional modeling technology and traditional easel carving art, and artistic creation by computer [4]. Digital sculpture, as a new discipline integrating art and science, has broad development space and application fields. Three-dimensional technology comes from life, develops in life, and feeds back into life. Three-dimensional digital technology refers to a computer-related science and technology, which identifies and processes images, sounds, characters, images, etc., through advanced cushion equipment, converts them into binary numbers "0" and "1" that can be identified and processed by computers, and carries out operations, processing, storage, transmission, and restoration through a series of algorithms [5, 6]. Sculpture, as a traditional art category, plays an important role in human history. As an important cultural carrier, sculpture art has always had extraordinary significance in human social and cultural life. It is for this reason that the combination of contemporary sculpture art and the most advanced digital technology can be regarded as the inevitable trend of the times and the inevitable result of the development law of sculpture art [7]. With the support of digital technology, the creation accuracy of sculpture works will be significantly improved, and the creation cycle and cost will also be reduced, saving artists a lot of time and energy to invest in more artistic creation.

It has been more than ten years since virtual technology was used in sculptures. It has progressed from a supporting technical tool to a singular artistic expression in the hands of artists [8]. After a long period of development and improvement, 3D technology [9] now has a powerful data simulation capability, allowing it to simulate and display various detailed aspects in a virtual environment, such as light and shadow, object material and color, motion track and way, and geographic location, through practical operations. In this paper, digital technology is combined with traditional sculpture art's creative methods, and the research of a sculpture art creation method based on digital technology is presented in order to meet the demand for increased accuracy and efficiency in sculpture art creation.

2. Related Work

Although digital technology has been introduced into the process of sculpture art creation by some artists, most of the known research studies and attempts at present are the two combinations between 3D scanning technology and 3D printing technology, or digital carving technology and 3D printing technology, but it is rare to study the comprehensive application of the three technologies [10]. 3D printing technology, as the key technology of digital technology to finally create entities, has a great influence on the realization of the idea of digitalization of sculpture art. Literature [11, 12] is eager to use digital technology in their own artistic creations, and they regularly hold personal digital work exhibitions to demonstrate the benefits of science and technology to art and to encourage young artists to pursue careers in this field. Literature [13] investigates the characteristics and connotations of art under the influence of numbers, with the help of calculations. The majority of studies in literature [14] are focused on digital media, virtual art, and digital aesthetics, with only a few theoretical studies on the use of digital technology in sculpture. On the one hand, only sculptures on yellow mud, Chinese painting on rice papers, and prints on copper plates, according to literature [15], can be considered true works of art. Computer graphics, on the other hand, are highly technical, untouchable, and emotionless, and thus cannot be called art. Literature [16] predicts that computers will evolve from rational technology to artistic beauty and that digital technology will have limitless applications.

Augmented reality technology is a technology that "seamlessly" superimposes information from the virtual world to the real world. By superimposing information generated by computers into the real world, users can achieve sensory experiences beyond reality. In Literature [17], using an unsharp mask to enhance images, the contribution of sharpening path is mainly controlled by adaptive filters; contrast enhancement is needed in detail areas; little or no sharpening is needed in smooth areas. Literature [18] proposed a subimage histogram equalization enhancement method based on exposure, and the exposure threshold was used to divide the original image into subimages with different gray levels. Literature [19] proposed a hybrid image enhancement algorithm, which is based on the contourlet transform of sharp frequency localization and adaptive histogram equalization. Literature [20] reset the coefficients of the Laplacian pyramid directly after decomposing the image with the Laplacian pyramid, which is easier to operate on the coefficients, but it will cause a halo. The initial weights of BPNN (BP neural network) are optimized using an improved GA in literature [21]. The simulation results show that this method effectively improves the convergence speed of the BP neural network by reducing the likelihood of it falling into a local minimum. Literature [22] proposed the concept of self adaptation, which adaptively adjusts the crossover rate and mutation rate in response to individual sensitivity and population diversity change, thereby improving GA convergence speed. A better GA (Genetic Algorithm) based on population dissimilarity was proposed in literature [23]. The algorithm uses a heuristic crossover strategy and can adjust the crossover scale, mutation scale, and mutation rate of each gene in the mutant according to the population's diversity, avoiding premature population convergence and speeding up evolution.

3. Research Method

3.1. Demand Analysis of Digital Enhancement Technology in Sculpture Creation. Digital art is an artistic means by which artists use computer technology as a support to simulate three-dimensional scenes through digital information. This way, artists' creative consciousness is brought into space from the plane, and an impossible thing is realized, which greatly improves the scope of art. The Internet's high-speed media has enhanced the distance between the audience and technology, and the aesthetic interaction between the audience and art [24].

In the information age, computer technology endows art with infinite possibilities, which makes its creation and expression tend to be diversified. In the art of sculpture, with the intervention of 3D digital software technology, a sculpture is presented to everyone with a brand-new look. The demand for digital technology in sculpture creation is manifested in two aspects:

(1) In the ordinary sculpture creation practice, using computer to engrave 3D model, the structure of the model is analyzed clearly at any time by marking, and undo and advance continuously, which is a function that traditional sculpture cannot achieve. Practicing the component model in the software is helpful for everyone to understand and master the structure.

(2) In some large-scale sculpture creation, it is necessary to enlarge the model according to the manuscript. In the real world, there are some errors in the data of the scanning model, which cannot meet the precise requirements of large-scale projects. However, the data of the model carved in the software are very accurate, which can ensure the accuracy of the scaled size.

Sculpture molding is a time-consuming and difficult process in traditional sculpture creation. First and foremost, the sculpture image must be designed. A draft or a sample can be used in the design process. Sculpture mud, clay, oil mud, pulp, gypsum, and other easy-to-form materials are commonly used to create samples. The clay sculpture is then made in equal or reduced proportion to the draft or sample. Of course, there are times when the draft or sample is not used, and the equal proportion creation is performed on the spot. It is necessary to construct the sculpture skeleton as well as screen, and suppress the clay for a sculpture before beginning to create the clay sculpture. Figure 1 is a schematic diagram of the sculpture-making process under traditional technical conditions.

In the aspect of 3D digital molding technology, it is necessary to have a deep understanding of 3D printing, engraving technology, and other digital molding technologies. To understand different molding processes, different molding materials, and basic properties of materials in 3D printing technology, understanding basic knowledge of these can predict the effect of shaping the work. Because for 3D printing technology, different molding processes are suitable for different molding structures; for example, a stereolithography apparatus process is suitable for a complex mechanism and precision requirements. Today's mainstream design software generally updates its version once a year, and each update will increase its function. In order to better create art, attention is always paid to software version upgrades, and new features of the software are constantly studied.

When using 3D digital modeling technology to create sculptures, it is essential to master the basic knowledge of sculptures and basic techniques of creation, and it is also necessary to master 3D digital software and fully understand related molding technologies. Cultural literacy refers to the sculptor's understanding, accumulation, mastery, and perception of human cultural knowledge.

To begin with, only when sculptors have a thorough understanding of human culture, particularly art culture, the sculptures they create can have full vitality because they bear the connotation of human culture, and they can perform the aesthetic education function that art is supposed to perform. Traditional sculpture art is rooted in a rich historical and cultural heritage, as well as a rich national culture. It is more easily accepted and recognized by the audience because it has a strong affinity with the audience's psychology and feelings. As a result, cultural genetic defects of new means can only be compensated for when digital sculpture creators use their own cultural literacy and integrate cultural factors into sculpture creation.

Secondly, sculptors must have the ability to discover beauty. Artists should be discerning and discover the beauty that ordinary people cannot find so as to remind people that there are always beautiful things in the world. Furthermore, an artistic expression ability is an essential artistic accomplishment for artists. Art expression refers to the process of using professional skills to express artistic thoughts, that is, artistic creation.

In addition, as a sculptor uses modern technology to create a sculpture, it is very important to have the quality of science, especially computer science. Combining cultural literacy, artistic literacy, and scientific literacy and creating excellent digital sculpture works is one of the necessary qualities for sculptors who use 3D digital molding technology to create.

3.2. Digital Enhancement Application of Traditional Sculpture Art. GA (Genetic Algorithm) is a kind of randomized adaptive search algorithm that draws lessons from natural selection and natural genetic mechanism in biology. Because GA is a global optimization search algorithm, it can quickly and effectively calculate complex nonlinear multidimensional data space. Using a membership surface instead of a threshold surface can also realize adaptive dynamic image segmentation based on pixel clustering.

Several key steps in the implementation of GA based on the fuzzy membership surface are as follows [25]:

(1) Chromosome coding. Because the membership surface is used to realize dynamic image segmentation, chromosomes are encoded into a two-dimensional matrix with membership function values of each pixel as elements. The membership function value is a real number within [0, 1]. For the convenience of operation, the membership function value of each pixel is quantized by 8 bits so that the solution space is $256^{M\times N}$.

(2) Initializing the population. Let the population size be K. Firstly, the gray range of the image is sampled at equal intervals, and K. thresholds are collected for global thresholding. Then, K membership functional value surfaces $u_2(x, y; T)$ about the background fuzzy set are calculated as follows:

$$u_2(x, y; T) = \begin{cases} \dfrac{1}{2}\left|\dfrac{f(x, y) - m_1(T)}{C}\right|^{\alpha}, & 0 \le f(x, y) \le T, \\ 1 - \dfrac{1}{2}\left|\dfrac{f(x, y) - m_2(T)}{C}\right|^{\alpha}, & T \le f(x, y) \le L, \end{cases} \tag{1}$$

where constant C is the normalization factor, T is any one of the K thresholds, and m_1, m_2 is the average gray value of two types of pixels, which can be estimated from both sides of T in histogram $h(g)$:

$$\begin{aligned} m_1(T) &= \frac{\sum_{g=0}^{T} gh(g)}{\sum_{g=0}^{T} h(g)}, \\ m_2(T) &= \frac{\sum_{g=T+1}^{T} gh(g)}{\sum_{g=T+1}^{T} h(g)}. \end{aligned} \tag{2}$$

α is the compactness parameter of the mean value of the element pair within the class, which can describe fuzzy semantics such as approximate, close, and similar, $\alpha \ge 0$.

(3) Designing fitness function. The mask selects the following two energy functions:

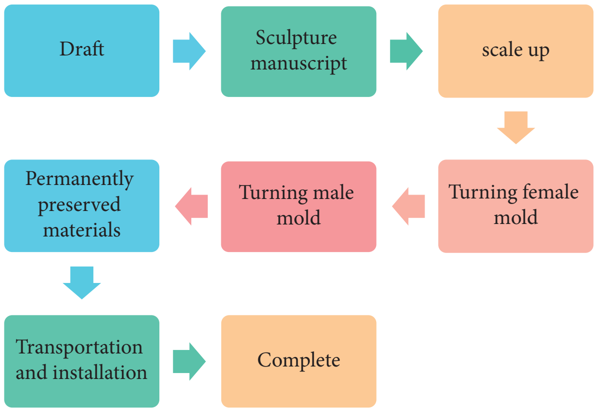

FIGURE 1: Sculpture-making process under traditional technical conditions.

$$E_1 = \sum_{x=1}^{M}\sum_{y=1}^{N}\sum_{l=-d}^{d}\sum_{k=-d}^{d}\left[u_2(x,y) - u_2(x+l,y+k)\right]^2,$$
$$E_2 = \sum_{x=1}^{M}\sum_{y=1}^{N}\sum_{l=-d}^{d}\sum_{k=-d}^{d}\left[u_2(x,y) + u_2(x+l,y+k) - 1\right]^2, \tag{3}$$

where E_1 is a consistency measure, and the smaller E_1 is, the closer the membership values of adjacent pixels with respect to the same class. E_2 is a measure of mutual exclusion. The larger E_2 is, the greater the difference between the membership values of adjacent pixels with respect to different classes.

Horizontal filtering, vertical filtering, downsampling, upsampling, and difference calculation are all part of the Laplacian algorithm. Vertical filtering includes adding horizontal boundary padding and vertical filtering, whereas horizontal filtering includes adding vertical boundary padding and horizontal filtering. Each row's two padding elements are calculated from four elements of their neighboring peers, and the process is independent and irrelevant with good parallelism. After padding is applied, the 1 $*$ 5 calculation window is shifted backward one bit at a time, and the values of five elements in one row are used to calculate the target value corresponding to the window's central element in the target matrix. Each window size's element calculation is relatively independent, resulting in good parallelism.

As shown in Figure 2, the upsampling is divided into two parts: boundary calculation and body calculation. The boundary value is calculated from the values of its adjacent rows or columns. It moves backward one bit in turn with a window of 1 $*$ 2 size, gets two elements of one row at a time, and calculates the two-element values of the boundary row of the target matrix. Actually, the first element value is directly filled, and the second value is calculated from the two values obtained. If the number of rows is odd, it is necessary to calculate the boundary value of the first row, and the rest of the row can be filled with the main body.

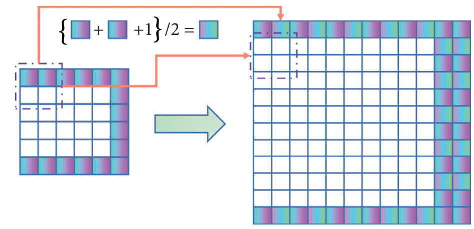

FIGURE 2: Upsampling process.

If the number of columns is odd, only the value of the last column needs to be calculated, and the rest is filled by the main part. Subject: moving back one bit by row and column in a window of 2 $*$ 2 sizes, obtaining four elements of the source matrix each time, and calculating the values of four elements of the target matrix.

The model coordinate system and image projection in the virtual space are transformed into the geometric transformation of the camera coordinate system. Camera pose estimation is to calculate the pose of the mobile phone camera in real time, and the initial matching point set is obtained after obtaining the feature matching of the above-mentioned image and the identification image.

With homography matrix transformation, the reversible transformation from real projective plane to projective plane, this mapping can be expressed by matrix multiplication:

$$P = A \times W \times M, \tag{4}$$

where P represents the coordinates of the two-dimensional image; A represents the camera parameter matrix; W stores the camera's internal parameters; M is the coordinate of the three-dimensional world.

W consists of two parts: the physical transformation of the object plane for positioning observation and the projection R, T of the parameter matrix in the current camera. $[R \mid T]$ is a 3×3 matrix, and the world coordinate system is transformed into the camera coordinate system. The corresponding projection transformation relation is as follows:

$$W = [R \mid T]. \tag{5}$$

The world coordinate system and camera coordinate system used by the Unity3D rendering engine are both left-handed coordinate systems. On the android platform, JAVA and C# methods are called each other through Android JDK, and the camera pose parameters of the parameter matrix R and T are transferred from Android to Unity3D so as to realize the tracking registration of the virtual model from 2D to 3D.

In this way, the algorithm as a whole will have a conditional judgment for one row, which contains a conditional compilation for the last column parity judgment; the last line contains a conditional compilation judgment, which contains a conditional compilation for the last column of parity judgment; partial calculation includes a conditional compilation of parity judgment for the last column.

SIMD (single instruction multiple data) is an instruction to operate multiple data. It is an extension of the basic instruction set of the CPU. It is mainly used to provide fine-grain parallelism, that is, the parallel operation of small pieces of data.

In view of the simplicity of the Laplacian algorithm here, this part is combined with vertical filtering, which reduces the calculation of some data. While optimizing SIMD of vertical filtering, the data needed for downsampling are directly reserved. There are a lot of shift operations in the improved algorithm, all of which use a shuffle instruction to align data. The upsampling algorithm is not suitable for SIMD optimization because of its many judgment conditions.

4. Result Analysis and Discussion

Traditional sculpture is taken as an example for developing a traditional sculpture image recognition system. the mobile device's camera is initialized, keyframe photos of the real scene are obtained, feature points are matched to identify feature images, the mobile terminal's pose is estimated, the spatial distance is calculated between the virtual model and the real scene, and superimposed on the current window to generate the virtual model's fused output. Figure 3 shows a comparison of the effects of various feature detection algorithms.

Other methods are likely to have a large number of features, slow calculation speeds, and a limited number of feature extraction speeds. The algorithm described in this paper has a faster calculation speed and a higher recognition efficiency of feature points, making it suitable for displaying complex textures of traditional sculptures on mobile devices. The algorithm detects local features with a high recognition rate and a high tolerance for light, noise, and small visual angle changes. Furthermore, this algorithm's feature distribution has more correct areas, and the matching accuracy is relatively high. The improved feature matching algorithm of this algorithm performs better in real time and high-efficiency systems.

In the image segmentation method based on basic GA, nine traditional sculpture images of 191×257 are segmented by setting different segmentation parameters. Figure 4 shows the corresponding relationship between parameters and images.

As can be seen from Figure 4, the size of the cluster has a great influence on the segmentation effect and the computer time consumed by image segmentation. The larger the population, the better the segmentation effect, and of course, the more computer time it takes. Search algebra also has a great influence on the segmentation effect. The more search algebra, the better the segmentation effect. However, the search algebra has little influence on the computer time consumed by segmentation; so in order to improve the segmentation effect without consuming too much computational time, the search algebra can be increased. The number of variations has little effect on the segmentation effect, and it also has little effect on the computer time of image segmentation.

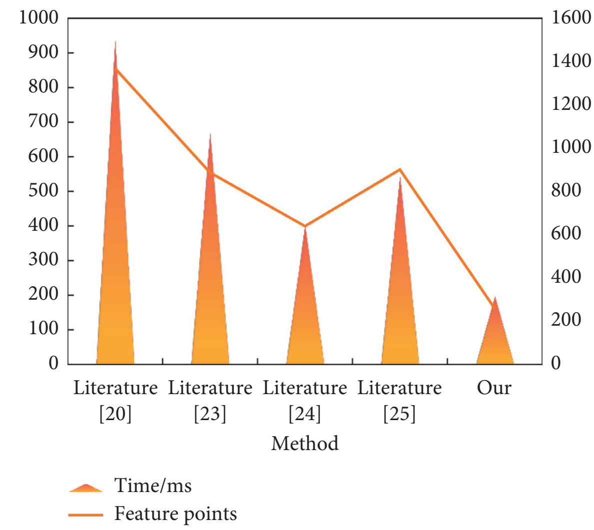

Figure 3: Effect comparison of different feature detection algorithms.

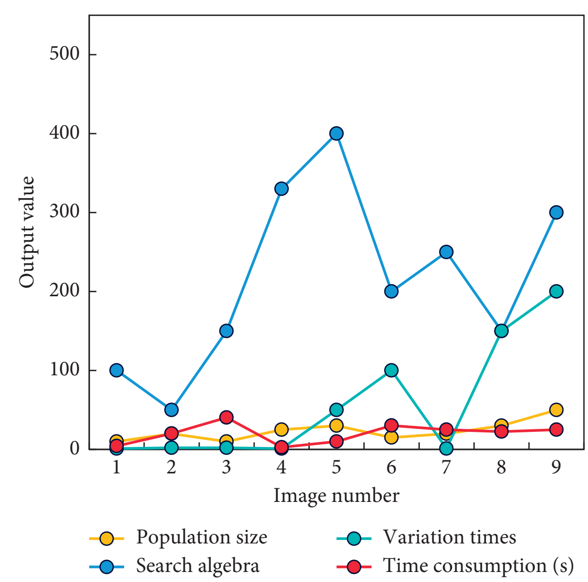

Figure 4: Segmentation result.

The adjustable parameters of the GA segmentation method based on the fuzzy membership surface include population size, mutation times, search algebra, and fitness function parameters. Next, by setting different parameters, the image is segmented, and the segmentation results are compared. The corresponding relationship between parameters and images is shown in Figure 5.

It can be seen from Figure 5 that the size of the population has a great influence on the segmentation effect and the computer time spent on image segmentation. The larger the population, the better the segmentation effect, and of course, the more computer time it takes. Search algebra also has a great influence on the segmentation effect. The more search algebra, the better the segmentation effect. However, the search algebra has little influence on the computer time consumed by segmentation; so in order to improve the

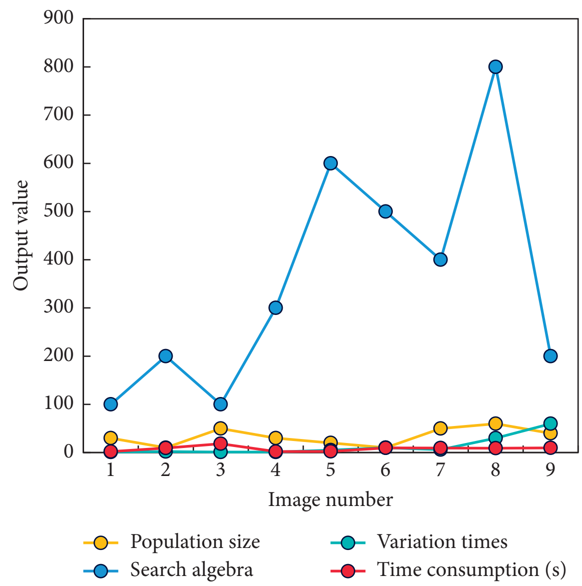

Figure 5: Segmentation result.

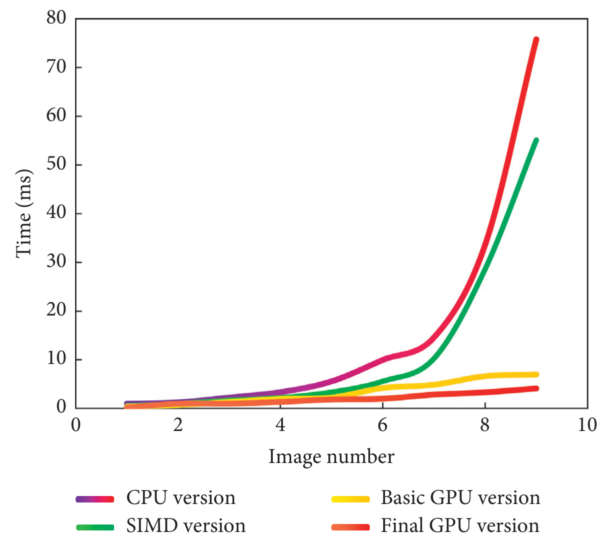

Figure 6: Performance comparison of optimized GPU versions.

segmentation effect without consuming too much computational time, the search algebra is added. The number of variations has little effect on the segmentation effect, and it also has little effect on the computer time of image segmentation.

The Figure 6 shows the performance comparison among the CPU (central processing unit) version, SIMD optimized version, basic GPU (graphics processing unit) version, and optimized GPU version of the Laplacian algorithm.

It can be seen from Figure 6 that as the image size continues to grow, the acceleration ratio also increases. Therefore, it can be seen that using the SIMD optimization technique to optimize the CPU serial code is significant for improving algorithm performance, and it is a very effective optimization method.

The performance comparison between the optimized version of GPU and the basic version of GPU will be compared in detail in the performance improvement chart brought by the following optimization methods. Here, in order to show the acceleration of GPU relative to the CPU version, the performance improvement of the optimized version of GPU for the basic version of GPU is not obvious.

The main feature of geometric sculpture is that its modeling is mainly geometric figures. In 3D software, it is the modeling obtained by adding or subtracting figures through the Boolean operation. Although geometric sculpture is not as rich in surface changes as other shapes, it gives people a simple and straightforward feeling with its unique and minimalist shape.

Structural sculpture mainly emphasizes the structure of works, which is its external manifestation and also the embodiment of its essence and spirit. Usually, the structure is not only the support but also the main component of the enriching sculpture form, and its change will directly affect the change of the sculpture shape. In many art exhibitions, you can see many structural sculptures with rich changes and aesthetic feelings.

The boundary padding part is integrated with the horizontal filter kernel, and the horizontal filter kernel is optimized by combining boundary optimization, conditional compilation, and vectorization. The performance results are shown in Figure 7.

As can be seen from Figure 7, with the increase of the image size, the acceleration ratio greatly increases, and the acceleration ratio is between 14 and 173.

An improvisation is a form of entertainment for artists, as it allows them to express their innermost feelings as quickly as possible. It is a dialogue between mind and matter, as well as a state of selflessness, that is embodied in sculpture creation. The characteristics of the object are conformed and caught, the “truth” of the object lurking in the depths are dig out, and finally, the work is completed according to the original characteristics of creative materials. This method of creation necessitates the author’s artistic ability, as well as keen insight and judgment, and the process of creation is the process of conforming to “God’s will” and gradually releasing it from mixed purity. Because the scheme is uncertain, each step is the work’s birth process, and each step gives the creator a new feeling.

Figure 8 shows the performance improvement of the upsampling algorithm after kernel fusion, conditional compilation, and boundary processing optimization. It can be clearly seen that with the increase of the image size, the speedup ratio increases greatly.

The choice of technical means will undoubtedly affect the presentation form of sculpture works, as sculpture is an artistic form expressed by modeling features. We can only deal with the sculpture language and then express artistic ideas using certain technologies. Many sculpture creators nowadays use the pursuit of pure art as an excuse to avoid personally participating in the technical work of sculpture, believing that as long as the artistic conception is presented by themselves, it is regarded as their own creation, regardless of who provides the technical work or what kind of technology is used to complete it. As a result, once technological

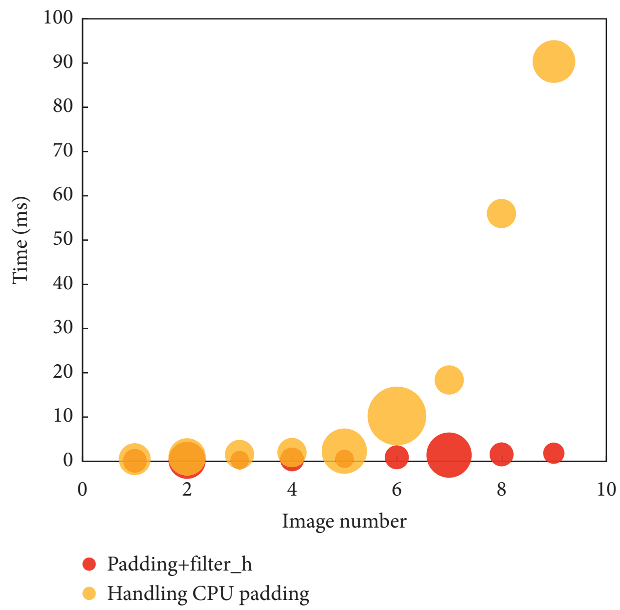

Figure 7: Performance comparison of boundary padding and horizontal filter kernel before and after optimization.

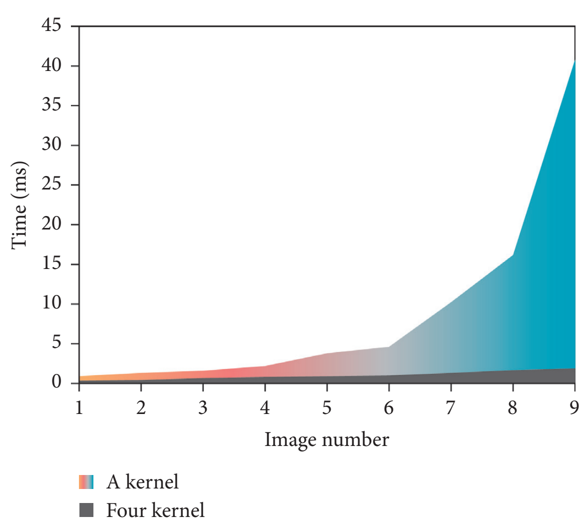

Figure 8: Upsampling optimization performance comparison.

research has progressed to a certain point, digital sculpture creation requires the guidance of artistic theory and artistic achievement, as well as the coordinated development of technical means and artistic achievement so that it can not only demonstrate technology but also create artistic works that shock the soul.

Figure 9 shows the performance of several optimization methods with obvious performance improvement for the basic GPU version. This section gives the performance comparison data of vertical filtering and downsampling after partial optimization.

From Figure 9, it can be seen that vertical filtering and downsampling are used to optimize by processing four columns at the same time, which can improve the distinguishable performance. It can be seen that the simplified

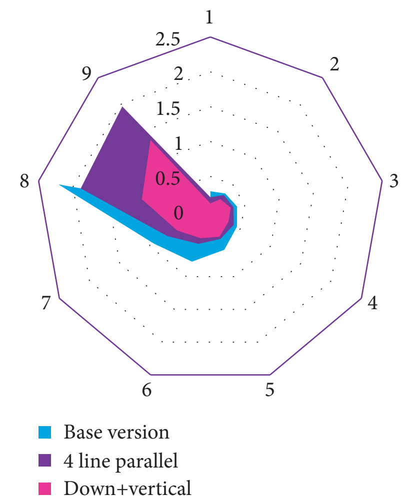

Figure 9: Performance improvement brought by the optimization method on GPU.

algorithm is indeed helpful to performance optimization, but it is not the bottleneck problem of the algorithm performance and has limitations on the optimization effect of the algorithm. Adding the optimization method of padding does not improve the performance, but it does enable the GPU kernel to handle input images with more diversified sizes, and the performance will not be reduced by adding conditional judgment, which theoretically optimizes the algorithm in the process of improving the algorithm.

Digital modeling technology participates in sculpture design and production. Although it has brought a more efficient way of creation to sculpture art and some negative effects to traditional sculpture art, as long as the new technology is treated calmly and used, the development of sculpture art will be promoted.

Some people who have not received professional sculpture training can also use software to make sculpture-like shapes, but such shapes lack the language features that sculpture should possess and reflect through professional knowledge. After all, a pile of mud made by people without professional knowledge in sculpture art cannot be called "mud." The sculpture is called art because it has thresholds and requirements.

5. Conclusion

Three-dimensional technology provides a new carrier for sculpture creation, and sculpture works are displayed in electronic display instruments through electronic information technology, which just promotes the development and spread of sculpture culture and the development and progress of the whole sculpture creation industry. Software belongs to software thinking. Therefore, in artistic creation activities, the creator's thinking is the main guide, supplemented by software thinking. Dealing with the interaction between the two will make artistic creation more efficient, provide artists with modeling forms beyond their own thinking limits, bring new thinking enlightenment, and stimulate artists' creative ability. This paper discusses the method of GA in image restoration processing, and the experimental results show that the image restoration processing method based on GA can improve the image resolution and quality. Future works will continue to solve the problem of matching recognition between traditional sculpture art and the human face. By recognizing facial expressions, we can display different mask expressions with rich cultural connotations and further improve the mobile terminal to add new functions in displaying other interactive experiences of traditional sculpture art.

Urban publicity translation, as a cross-cultural communication activity, should aim for communication, employ various translation strategies, adapt to the target language's expression habits, overcome cultural differences, and make the translation easy to accept for target readers. In order to achieve the goal of external promotion, publicity texts should respect and conform to the target culture's language expression as well as the psychology of the audience during the initial stage of urban publicity translation. This paper analyzes the causes of cultural vacancies in the translation of urban publicity materials, starting with the classification and sorting of cultural vacancies in the translation of publicity materials. This paper focuses on using a computer corpus to reconstruct cross-cultural text for urban publicity translation. An automatic corpus expansion method combined with the EM (expectation-maximization) algorithm is proposed to solve this problem. The model is iteratively trained after the generated single corpus is combined with the original data set to create a parallel corpus. Finally, as another important feature of words, the word cooccurrence degree is incorporated into the interword relationship extraction model to create a new word translation evaluation index. Finally, the experiment demonstrates that the EIWR (extraction of interword relations) has higher accuracy than the VSM (vector space model).

1. Introduction

The external image of a city is a comprehensive material and cultural impression that the city shows to the public, and it is an important part of the city's competitiveness. With the continuous improvement of China's international influence and economic strength, China has closer ties with other countries. As an important means of foreign communication, the translation of city publicity is an important means to show the traditional culture, regional features, and development characteristics of the region to the international community, and plays a vital role in improving the image of the city, enhancing the international reputation and strengthening the opening to the outside world [1]. In recent years, scholars at home and abroad have increasingly studied the translation of urban publicity, and the translation of urban publicity has made great progress.

Corpus linguistics is a new interdisciplinary field that combines linguistics, computer science, applied linguistics, and cognitive linguistics. It is still in its early stages of development. Corpus linguistics uses actual language facts as the research object and performs macroscopic and microscopic, qualitative and quantitative statistics and analysis on a large number of corpora using computer tools, revealing the objective laws of language use and the complexity of natural language [2, 3]. The parallel corpus has strong text alignment and high translation accuracy because it is made up of source language texts and translated texts that correspond to the source language texts. However, the parallel corpus's construction costs are high, and parallel corpus resources are scarce and difficult to come by, making it difficult to cover all fields of research. At the same time, the artificial translation quality has a significant impact on translation accuracy [4]. China is a vast country with many ethnic groups, and each region has its own distinct local characteristics and national culture. Chinese cities want a place on the international stage, and language texts are particularly important when they show their own culture and characteristics to foreign audiences [5, 6].

Many different types of corpora have been built and used in the past, depending on the purpose and nature of the corpus. A Chinese-English parallel corpus, as well as an analogy corpus [7], were used in this study. This paper proposes a model training method combined with the EM(expectation-maximization) algorithm to solve the problem of cross-cultural text reconstruction in urban publicity translation. The joint EM optimization method is used to learn translation models from source language to target language and from target language to source language and to complete the bilingual dictionary extraction based on the word relation matrix. Finally, experiments are used to verify the feasibility of this extraction method, which is compared to VSM (vector space model), and the impact of variables such as context window size, corpus size, dictionary size, and word frequency on the final experimental results of the two models is examined.

2. Related Work

The translation is a medium form of cross-cultural communication, and publicity is a cross-language and cross-cultural information exchange and communication with nations, regions, and countries as the main body. The essence and basic task of urban publicity translation are cross-language and cross-cultural information dissemination, which is an important way of external communication [8, 9]. If a city wants to go global, it must first create an international environment conducive to city publicity, which will be recognized and supported by the international community. Literature [10] clearly puts forward the stage theory of urban publicity translation, that is, in the first stage, due to the dominant target language culture, the purpose of publicity is to win the recognition and understanding of the international community, mainly adopting the translation strategy based on the target language; Literature [11] points out that the differences between Chinese and western cultures directly lead to the great differences in vocabulary system and meaning expression between Chinese and English. Because the audience of urban publicity translation is foreign readers, and there are many differences between Chinese and English languages and cultures, it is difficult to achieve the expected publicity effect if mechanical literal translation is adopted. Literature [12, 13] proposed a method of dependency constraint on the target language part of translation knowledge, which effectively improved the translation accuracy. Literature [14] deals with translation knowledge in a semistructured way and proposes an example-based machine translation method. In their experiments, the effect of this method is significantly better than that of a statistical machine translation system. Translation knowledge automatically acquired from corpus usually contains a lot of noise, which affects the translation process. Literature [15] proposes a method to filter monotone combination phrase pairs and a method to filter combination phrase pairs by using a logarithmic linear model.

The subject of translation is the translator, and the translation theory of urban publicity places higher demands on translators. Not only linguistic equivalence but also cultural equivalence and communication equivalence should be considered when translating publicity texts. With the help of the concept of intermediate language, literature [16] proposes a many-to-one translation mechanism. These methods solve the problem of data sparsity, but they also complicate the model and increase the training costs. By introducing tags into the input, literature [17] proposes a method of training translation models. Despite improvements in training efficiency and translation performance, data scarcity remains a problem. Literature [18] proposes a multilingual translation model with an incremental self-learning strategy, which solves the problem of data scarcity by generating pseudobilingual data automatically, but the pseudobilingual data may have noise issues, lowering translation quality. The cooccurrence rule of words in the target language in both parallel and comparable corpora is essentially the same as in the source language, according to the literature [19]. The calculation assumes a one-to-one correspondence between the words in the source language and the target language text. According to the literature [20], a third-party intermediate language could be used to complete the construction of a bilingual dictionary. Its basic concept is to use a common intermediate language, such as English, and a multilingual vocabulary to first translate source-language words into intermediate language words, and then to translate the translated intermediate language words into target language words using the vocabulary to complete the construction of a bilingual dictionary. According to the literature [21] there is a random translation matrix from the source language to the target language, which can translate the source language to the target language, assuming a one-to-many relationship in translation. The local ambiguity problem is solved by this method, but the global ambiguity problem is not. Literature [22] proposes a dependency tree-based method for completing the construction of a context vector and extracting bilingual dictionaries. Literature [23] proposed a method for extracting parallel resources from comparable corpora based on document-level alignment. The basic idea is to use alignment information instead of word context information.

3. Research Method

3.1. Selection and Design of Translation Model for Urban Publicity. The translation of urban publicity is aimed at foreign readers, so that foreign readers can understand and accept the information conveyed by China. In the process of urban publicity translation, the common problems are that translators lack awareness of cross-cultural communication, do not know enough about the thinking patterns of foreign audiences, and cannot translate according to the thinking habits of target audiences. To solve this problem, literature [24] puts forward the principle of "three closeness" in the translation of urban publicity, that is, "the translation of urban publicity should be close to the reality of China's development, the needs of foreign audiences for Chinese information and the thinking habits of foreign audiences".

To maximize the cross-cultural communication effect of urban publicity translation, it should follow the principle of "communication priority" and begin with the foreign audience to truly understand and accept cross-cultural information. In this paper, powerful models are not required for initialization training, but there are two popular models: statistical machine translation and neural machine translation. Because the neural machine translation model is prone to overfitting when the data is sparse, it performs worse in low-resource situations than the statistical machine translation model. The transformer model [25], whose structural design is shown in Figure 1 was chosen among many neural machine translation models for this study.

In this paper, two transformer models in opposite directions are initialized and pretrained, that is, one-way tasks from the source language to the target language and one-way tasks from the target language to the source language.

The pretraining process is completed by the traditional method based on the maximum likelihood principle. The general approach of this method is to maximize the logarithmic conditional probability of correct translation, give the model parameter θ of the source language sentence, and its goal is to get θ^* which satisfies the following formula:

$$\theta^* = \arg\max_{\theta} \sum_{i=1}^{N} \sum_{j=1}^{|t_i|} \log\ p\left(t_{i,j} \mid t_{i,0\longrightarrow j-1}, s_i\right), \tag{1}$$

where N is the scale of training corpus, $|t_i|$ is the length of the target language sentence t_i.

After pretraining, the iterative training process of the model is carried out. Given the original parallel corpus (real corpus) $D = \{S_i, T_i\}_{i=1}^{N}$ and the target language monolingual corpus $T' = \{t_i\}_{i=1}^{P}$, the training goal of the model is to maximize the possibility of bilingual data and monolingual data, namely

$$L^*\left(\theta_{S\longrightarrow T}\right) = \sum_{i=1}^{N} \log p\left(t_i|s_i\right) + \sum_{i=1}^{P} \log p\left(t_i\right), \tag{2}$$

where the first part represents the conditional probability of generating the target language T for the source language S; the second part represents the language model of T, whose main function is to maximize the possibility of sentences.

The degree of vocabulary variation is defined as the number of different words in a given length corpus that reflect the diversity of vocabulary. The number of different words is referred to as the shape symbol number, whereas the number of different word shapes is referred to as the class symbol number. The amount of information and difficulty of a text can be reflected in lexical density. The higher the vocabulary density, the more meaningful words there are, and the more information and difficulty the text contains. The lower the vocabulary density, the less information the text contains and the easier it is to understand. The purpose of calculating instance similarity is to determine the degree of similarity between the source language phrase of the translation instance pair and the input sentence phrase fragment. The expression form of the translation instance is closely related to the similarity judgment. Language surface matching is a type of character-based matching. Two parts to be matched are treated as strings in this method. In general, it only takes into account the length of common substrings in two strings, and the common substrings must be ordered.

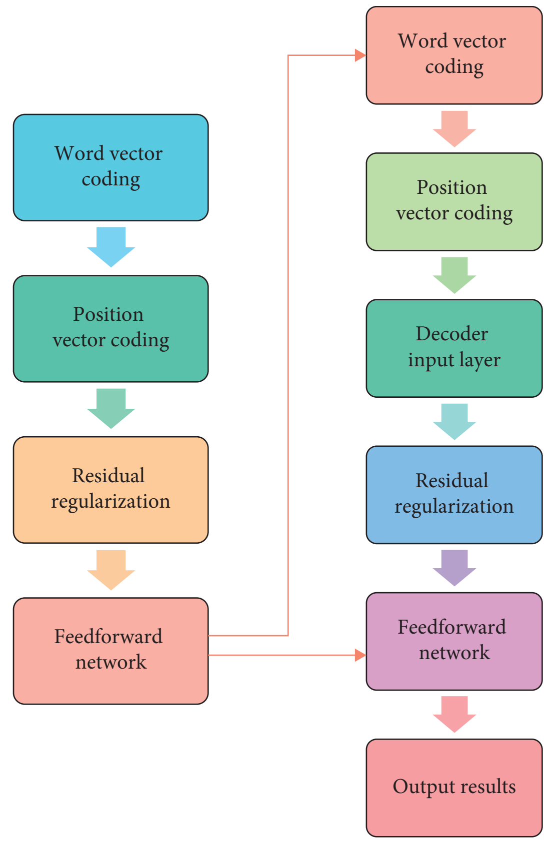

Figure 1: Transformer model architecture diagram.

Among the algorithms based on character matching, the method of editing distance is the most widely used one. This method can be used to calculate the minimum cost $D(m, n)$ of transforming from one string $S = s_1, s_2, \ldots, s_m$ to another string $T = t_1, t_2, \ldots, t_m$.

The algorithm is based on a dynamic programming algorithm, and its complexity is $O(m * n)$. The following are the core parts of the algorithm:

$$D(i, j) = \begin{cases} 0, & \text{if } i = j = 0, \\ D(0, j-1) + w\left(t_j\right), & \text{if } i = 0, j! = 0, \\ D(i-1, 0) + w\left(s_i\right), & \text{if } i! = 0, j = 0, \\ \text{Min}\begin{bmatrix} D(i-1, j) + w\left(s_i\right) \\ D(i, j-1) + w\left(t_j\right) \\ M(i, j) \end{bmatrix}, & \text{other}, \end{cases}$$
$$M(i, j) = \begin{cases} \text{Max}\left(w\left(s_i\right), w\left(t_j\right)\right), & s_i \longrightarrow t_j, \\ 0, & s_i = t_j. \end{cases} \tag{3}$$

Among them, the three transformation operations are replacement, insertion, and deletion. $w(t_j)$ is the cost of inserting t_j , $w(s_i)$ represents the cost of deleting s_i in S, and $\mathrm{Max}(w(s_i), w(t_j))$ represents the cost of replacing s_i with t_j.

In word-based matching, matching is investigated in terms of words. Because the semantics of words should be considered, semantic dictionaries play a very important role. Commonly used semantic dictionaries include WordNet and synonym word forest. In English, apart from semantic dictionaries, word-building analysis is usually required.

At the same time, in order to reduce the workload of the algorithm, a stoplist is often used to filter out these words. Then, judge the similarity between sentences according to the remaining meaningful words. There are many kinds of VSM, among which the most well-known one is $tf - idf$ value.

3.2. Cross-Cultural Text Reconstruction of Urban Publicity Translation. The ideal state of translation is to be able to translate word for word along with the original text. However, in the translation of urban publicity, this situation is very rare. Because English is hypotaxis structure and Chinese is parataxis structure, the two languages are completely different in writing structure and writing habits and are difficult to be compatible at the syntactic level. Therefore, in Chinese-English translation, in order to accurately express the meaning of Chinese and achieve good translation effect, the method of "reorganizing the original text" can be adopted, reasonably change sentence patterns or adjust word order in some parts of the original text, and if necessary, can "reinvent the stove" and reintegrate to reduce the influence of Chinese grammar and sentence patterns, so as to make the translation richer in English charm.

Translators must explore the cultural differences between English and Chinese and cultivate a cross-cultural perspective when working on translation projects. Translators must be culturally aware, observe idiomatic expressions and thinking differences in English, use English expression habits and thinking styles, and cannot create words out of thin air or break the horizontal combination relationship between words and words. They should take responsibility for themselves, their culture, and the target language users in translation, as well as contribute their own efforts to help foreign friends and export China's excellent culture. In general, a single word cannot express a complete theme, it must be combined with other words to do so. Different words are combined to express various theme contents. This word combination reflects the semantic information of words as well as the correlation between them. Because only nouns, verbs, adjectives, and adverbs in comparable corpora are studied in this paper, the corpus must be preprocessed.

In this paper, based on the selection rules of seed word pairs, the seed dictionary is extracted from the general dictionary, but the uniqueness of words in the seed dictionary needs to be ensured in the process of mapping relations between words, so this paper adopts certain selection rules to extract seed word pairs from the general dictionary, among which the selection rules of the seed dictionary are shown in Figure 2.

In this paper, the words with low similarity in the source language are selected first to ensure the differentiation of the correlation between words in the seed dictionary, among which is the formula for calculating the similarity of words in the source language.

$$S\left(W_{s_i}, W_{s_j}\right) = \sum_{1<k<m} V_{s_{ik}} \times V_{s_{jk}}, W_{s_i}, W_{s_j} \in \text{Set}. \quad (4)$$

In the formula, V_s represents the word vector of the word, k is the component of the k-th dimension in the word vector, and m is the dimension value of the VSM trained word by the source language corpus.

If the frequency of the word W_{t_i} in the target language corpus is too low, the relevance with the target words will be lower, which can not reflect the relevance between the words in the target language. If the frequency of W_{t_i} is too high, it may be related to the words in the whole target language corpus, which can not achieve the purpose of taking the relationship between words as an important distinguishing feature of words.

Therefore, if the word frequencies are the same, the word pairs with the smallest index value are selected according to the index values in the dictionary, and if the number of selected word pairs can not meet the calculation requirements, then the word pairs are selected from low frequency to high frequency.

In this paper, the correlation between a word and other words is regarded as an important distinguishing feature of the word, and the correlation is quantified by the similarity of word vectors. The construction of the interword relationship matrix is completed by the seed dictionary, and at the same time, the correlation between the interword relationship VSM of the source language and the interword relationship VSM of the target language is also completed. The specific steps are shown in Figure 3.

Firstly, the rules are extracted from the general dictionary through the seed dictionary, and the seed dictionary is extracted. The number of seed word pairs is N, and the seed set formed is expressed as $\left\{W_{s_i}, W_{t_i}\right\}, i \in \{1, 2, \ldots, N\}$, W_s is the source language word, W_t is the translation word corresponding to W_s in the target language, and i is the index value of W_s in the seed dictionary.

Then, the correlation degree between each word in the source language and the words in the source language in the seed dictionary is constructed by the word vector. For the quantification of the correlation between the unknown word W_{s_x} and each word in the seed word set, this paper adopts the calculation method of vector inner product

$$M\left(V_{s_x}, V_{s_i}\right) = \sum_{1<j<m} V_{s_{xj}} \times V_{s_{ij}}, i \in \{1, 2, \ldots, k\}. \quad (5)$$

In the formula $V_{s_i} \in \left\{V_{s_1}, V_{s_2}, \ldots, V_{s_k}\right\}$, $V_{s_{xj}}, V_{s_{ij}}$, j represents the component of the j-th dimension of the word vector V_{s_x}, V_{s_i}.

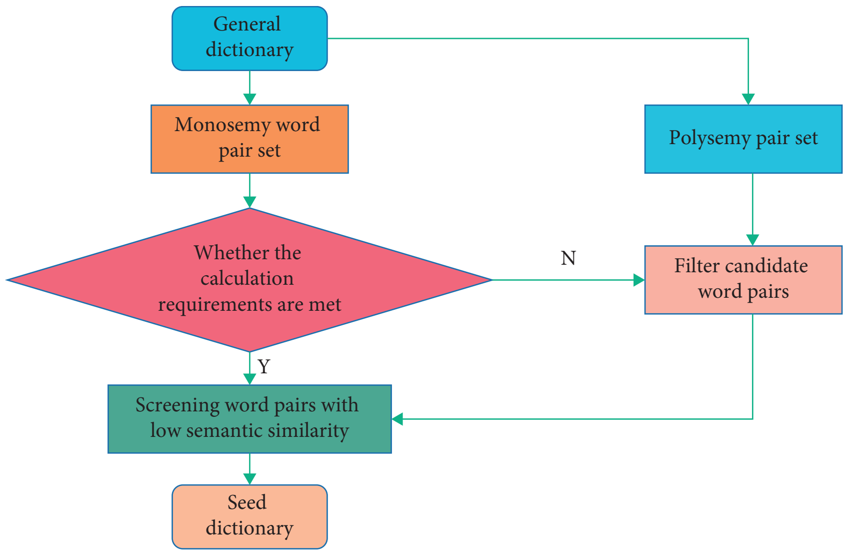

Figure 2: Seed dictionary extraction rules.

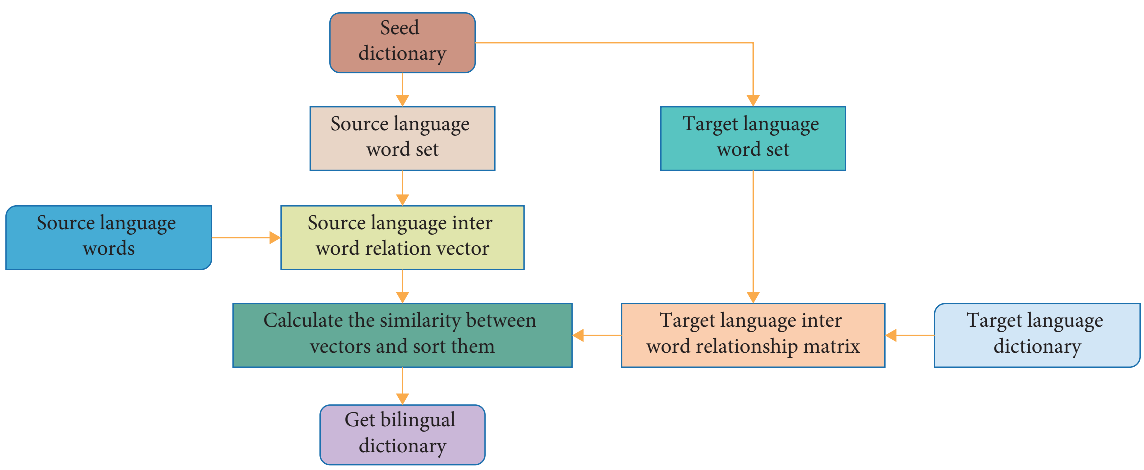

Figure 3: Extracting bilingual dictionaries based on the relationship between words.

Finally, the cosine similarity is used to calculate the relation vector between two words, which can be expressed as

$$S\left(V_{m_s}, V_{m_t}\right) = \frac{\sum_{1<i<k} V_{m_{si}} \times V_{m_{ti}}}{\sqrt{\sum_{1<i<k} V_{m_{si}}^2 \times V_{m_{ti}}^2}}. \quad (6)$$

The translation appears to be a process of changing one linguistic sign to another, but in reality, it is a cross-language and cross-cultural communication activity. As a result, translation is more than just a language conversion; it is also a social and cultural transformation process. Different scholars advocate for various translation standards and methods in the translation process, and various translation methods and standards have reached a theoretical level. The original text has more nouns and adjectives than the translated text, but the latter has slightly fewer verbs and adverbs. The difference in vocabulary density between the two subdatabases can be attributed to a large number of nouns and adjectives in the original text.

4. Results Analysis and Discussion

4.1. Comparison of Parameters and Results. In this paper, the transformer model is used as the baseline model of translation training. After several rounds of parameter combination optimization, the relevant important parameters of the transformer model are set in the experiment to achieve the best performance of the model.

In order to explore the corpus generation of the new method in this paper in more detail, according to the convergence of the iterative model of EM algorithm, Figure 4 shows the curve of the performance of the model changing with each iteration process from different translation tasks.

As can be seen from Figure 4, when the EM algorithm is iterated for 10 times, it tends to converge, and the performance of the model is hard to be improved, which also proves that the method in this paper makes the model tend to be stable after a certain iteration process.

Different versions are born as a result of the subjectivity of the translators. The translator's cultural mentality is full of contradictions, both submissive and treacherous, in the translated text. As target readers, it may be difficult to imagine the translator's confusion and cultural references in the translated text. The cultural oddity in the translation demonstrates that the target readers generally lack the background knowledge necessary to appreciate the source culture, and the translator must perform some cultural filtering in order for the translation to be accepted. Figure 5 depicts the relationship between the confusion of generating corpus and the EM algorithm iteration times in order to see the benefits and drawbacks of the transformer model's corpus as the EM algorithm iterates.

As can be seen from Figure 5, after 10 iterations, the confusion of the generated corpus will not decrease significantly, which is consistent with the convergence of the model and avoids the possibility of the model falling into local optimum.

The phenomenon and activity of translation is a cross-ethnic cultural phenomenon and activity. Cultures of different countries are at different stages of development, with different characteristics and cultural positions, due to the imbalance and asymmetry of cultural development. When universal things are localized, they frequently face local opposition, and when local things are globalized, they are often misunderstood or suppressed. More importantly, when different cultures collide and clash, it is difficult to come to an agreement on values, behavior patterns, problem-solving methods, and procedures, and cultural friction or conflict can quickly spiral out of hand, escalating into difficult-to-adjust disputes.

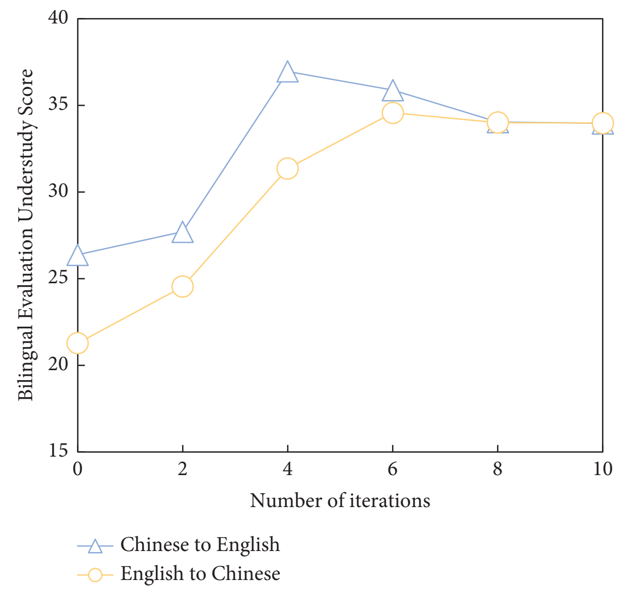

FIGURE 4: Variation curve of model performance.

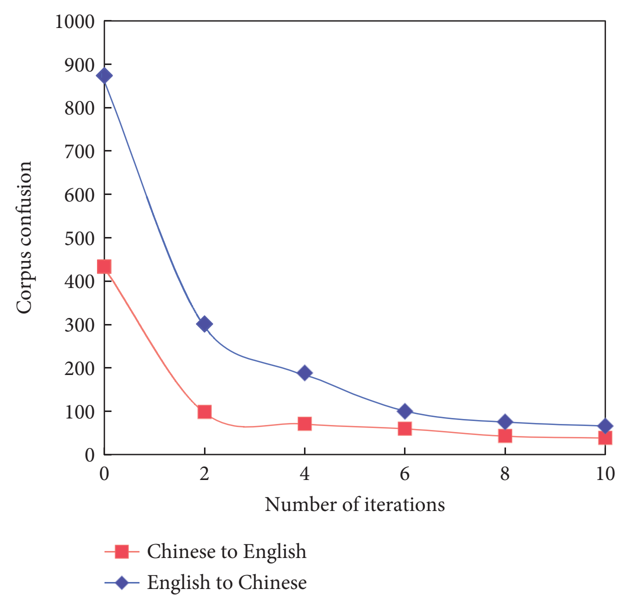

FIGURE 5: Curve of the confusion degree of corpus generated by the model with the number of iterations.

4.2. Corpus-Based Dictionary Extraction Analysis. The translation of urban publicity is like a fish swimming between the ponds of two languages, and this state just provides the prerequisite for cultural hybridity, internalization, transformation, and reconstruction. The essence of translation is to translate meaning. However, the symbols of cultural meaning contained in the source text are the most difficult to control, copy, and reconstruct in the process of translation. Many texts, reluctantly translated, cannot make the target readers feel similar to the source readers. Cultural or aesthetic failure shows that such translation of city publicity is a failure.

The corpus of this experiment is English and Chinese. English-Chinese bilingual dictionaries are extracted with English as the source language and Chinese as the target language. Dictionaries are another important resource of this experiment, including English dictionary, Chinese dictionary, English-Chinese bilingual dictionary, English stoplist, and Chinese stoplist. In the experiment, 10% of words in the English dictionary were randomly selected as the test set, and the corresponding translations of English words were obtained from the English-Chinese bilingual dictionary as the verification set to calculate the accuracy of bilingual dictionary extraction.

Accuracy is the most direct index to evaluate a model. Firstly, this paper compares the overall accuracy of VSM and EIWR (extraction of interword relations), in which the context window size is set to 10, and the experimental results are shown in Figure 6.

From Figure 6, it can be seen that it is feasible to quantify the relationship between words by using word vectors in a comparable corpus and to apply the relationship between words as the extraction feature of words in information extraction.

Whether for VSM or EIWR, the window will affect the expression of word context to a certain extent. For VSM, if the window is too small, the context semantics of the current word cannot be accurately expressed. Therefore, this paper takes the window as a parameter and takes the value of n in P@N as 20 to study the influence of the window on the final

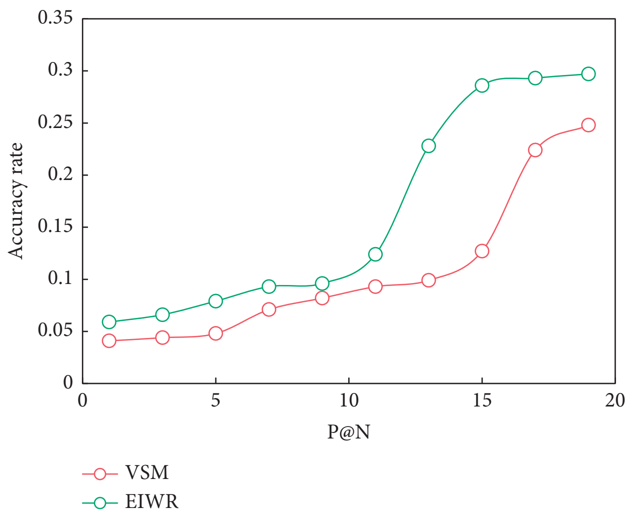

Figure 6: Model accuracy.

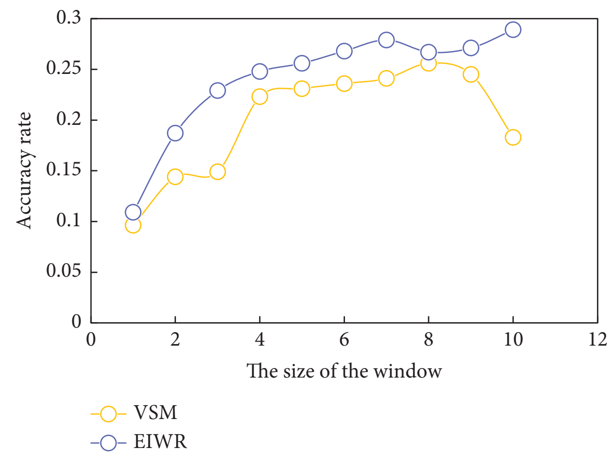

Figure 7: Influence of window on the accuracy of two models.

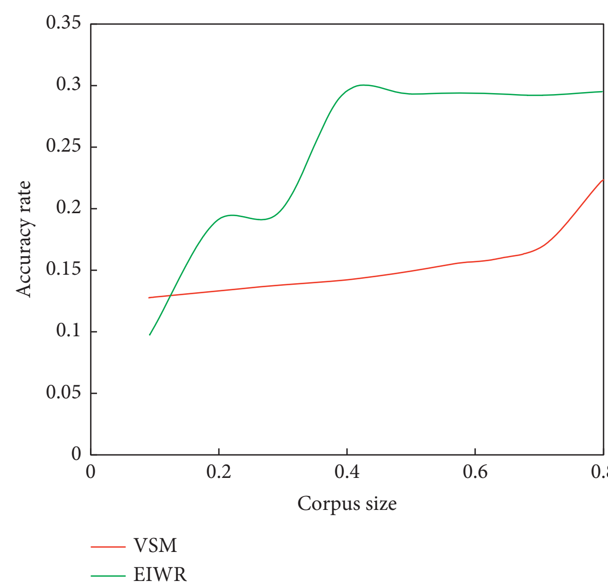

Figure 8: The influence of corpus size on the accuracy of the two models.

extraction effect of the two models. The experimental results are shown in Figure 7.

From Figure 7, it can be seen that the window size has a certain influence on the experimental results of the two models. Especially for VSM, the window size has a particularly obvious influence on the final extraction results. At the beginning of the experiment, the accuracy of VSM is positively correlated with the window size, and when the window size exceeds 10, the accuracy is negatively correlated with the window size, which also verifies the hypothesis that VSM introduces more useless information with the increase of window size.

Experiments show that choosing different sizes of windows in VSM or VSM will affect the final extraction effect, and choosing the correct window value will help to improve the accuracy of bilingual dictionary extraction.

In VSM, the size of the corpus will directly affect the calculation of word frequency and document frequency. In Fan model, the size of the corpus will also directly affect the generation of word vectors, so the size of the corpus will directly or indirectly affect the final dictionary extraction results. Therefore, this paper selects different corpus sizes for experiments. The experimental results are shown in Figure 8.

The experimental results in the graph above show that the corpus size has an impact on the final experimental results of the two models. The accuracy of VSM is higher than that of EIWR in a small-scale corpus, but as the corpus grows larger, the experimental results of EIWR clearly outperform those of VSM. Whether using the VSM or Pa model, the seed dictionary is an important component of bilingual dictionary extraction because it serves as a link between the source and target languages. The effect of seed dictionary size on experimental results is investigated in this paper.

It can be seen from Figure 9 that the size of the seed dictionary has a certain influence on the extraction results of both models, but it is more significant for VSM, and its accuracy is positively correlated with the size of the seed dictionary. On the other hand, it also shows that using a small-scale bilingual seed dictionary in the interword relationship model can achieve higher accuracy and greatly reduce computational complexity.

Figure 10 shows that the VSM is better than EIWR for low-frequency words. However, the accuracy rate of using EIWR for our daily use of high-frequency words has increased from 31.4% to 48.8%, and the improvement effect is obvious, which also shows that the relationship features of our daily use of high-frequency words are more distinguishable than the contextual features.

Accurate comprehension is the foundation of urban publicity translation. It is impossible to talk about style or aesthetic transmission of translation if the meaning is not understood correctly. Information transmission is not automatic or superficial; it necessitates decoding and interpretation. The meaning of reading is directly related to the context in the translation transformation process, and the context plays an important role in the generation of

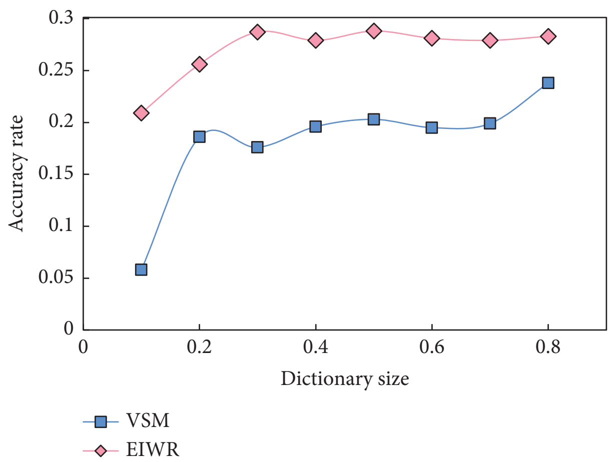

Figure 9: Influence of dictionary size on accuracy of two models.

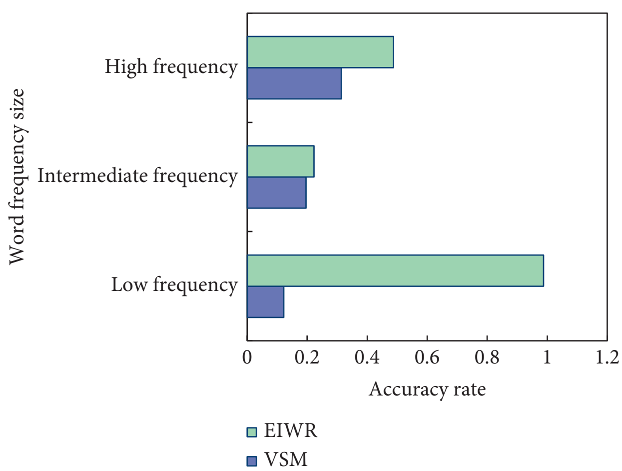

Figure 10: Accuracy of two models with different word frequencies.

meaning. Aside from accurate interpretation, the translated object's publicity effect cannot be overlooked. After analyzing the composition and characteristics of various components in the target language, one of the challenges of urban publicity translation is maximizing their inclusion and synthesis in the target language. The ecological environment, religious beliefs, national customs, aesthetic taste, way of thinking and values, and so on differ between nationalities. The same thing will inevitably produce different associative meanings based on the concept of vocabulary itself under the influence of their own unique cultural traditions. This associative meaning is not always related to the word's actual meaning, but it can evoke a familiar feeling in a particular culture.

5. Conclusion

The translation of city publicity is an important tool for a city to project its image to the rest of the world, as well as a cross-cultural communication medium. Starting with the translation of publicity materials, this paper focuses on using a computer corpus to reconstruct cross-cultural text for urban publicity translation. The two translation models are optimized using a joint EM training algorithm to improve their translation performance. On Chinese-English machine translation tasks, the experimental results show that the machine translation model based on this method outperforms the current popular strong baseline system. Experiments show that the interword relation model, when compared to the basic model, can significantly improve the extraction effect of bilingual dictionaries in comparable corpora, particularly for the translation words of high-frequency words, with an accuracy rate of 48.8%.

The assumption that the correlation between words is symmetrical is used by EIWR, but this assumption does not apply to all situations in real life. If future work can use linguistics' grammar and semantic knowledge to analyze the correlation between words, the relationship between words can be evaluated and quantified more thoroughly, and the final extraction effect can be improved.

MT (multimedia technology) music teaching has changed the rigid, unitary, and boring teaching form of traditional music teaching, which has made a comprehensive breakthrough and impact on traditional university music education and has shown a brand-new teaching form to contemporary college students, greatly increasing their strong interest in learning music. In this paper, an objective evaluation method of vocal music quality based on the comparison of sound parameter characteristics is proposed by using the technology of sound signal parameter analysis and extraction. Through confidence measure, reliable data are selected for online adaptive updating of Gaussian mixture model, and the recognition results are smoothed to further remove the instantaneous mutation error. The main melody of singing is discriminated by fundamental frequency discrimination model. Experiments show that the overall accuracy rate of the main melody of vocal music extracted by this algorithm is 86.24%.

1. Introduction

MT (multimedia technology) is the product of the progress of the times and the demand of educational development [1]. With the development of the times and the progress of science and technology, MT and its related teaching methods have gradually played an increasingly important role in China's higher education system because of their synchronization, integration, and interactivity [2]. Vocal music teachers usually have professional knowledge of music theory but lack systematic computer knowledge. The evaluation of students' singing level is mainly based on their personal experience and feelings, with strong subjectivity. Therefore, it is of great practical and promotional value to study and develop an intuitive and easy-to-operate interactive multimedia vocal music teaching system.

The progression of music art from early concrete music to modern synthetic electronic music to post-modern computer music reflects not only the evolution of the music art form, but also the evolution of music technology [3, 4]. Music education at the university level is an important part of modern education. It not only enriches young students' after-school activities, but also provides them with another professional skill, allowing them to enter society with a skill [5]. The advantages of MT include an intuitive image and strong interaction. Exploring and applying the benefits of MT can help students form scientific sound concepts, improve their intonation and rhythm, cultivate their expressive force in vocal music singing, and create favorable conditions for the formation of their personalized performance style [6, 7]. College vocal music teachers should gain a scientific understanding of the value of MT, find the best combination of technology and vocal music teaching, promote innovation and reform in the vocal music teaching mode, and improve the efficiency and quality of vocal music instruction.

With the continuous development of network technology and information technology, many universities have adopted MT in the course content of auxiliary harmony, solfeggio, impromptu accompaniment, etc., which can show the vocal music teaching process more intuitively, make the teaching content illustrated with pictures, and thus stimulate students' enthusiasm for learning vocal music [8]. In this paper, an objective evaluation method of vocal music quality based on the comparison of sound parameter characteristics is proposed by using the technology of sound signal parameter analysis and extraction. Select reliable data through confidence measure to realize online adaptive updating of GMM (Gaussian mixture model), and get GMM that better matches the audio signal to be segmented, thus improving the recognition accuracy. In the song melody positioning part, based on the difference of timbre between song and accompaniment, the fundamental frequency discrimination model using neural network is added, and the probability that the dominant fundamental frequency track belongs to song melody based on subsection statistics can effectively reduce the false alarm rate of melody positioning and improve the overall accuracy.

2. Related Work

Literature [9] discusses three aspects: the historical evolution of music communication media, the appearance of new audio-visual media competition, and the dominant trend of network music communication. Literature [10] gives appropriate suggestions on the function and selection of modern teaching media. In [11] by comparing with the old standards, this paper analyzes the importance of the requirements of teachers' information and communication technology and cooperation ability in the professional competence standards for primary and secondary school teachers issued by the French Ministry of Education. In [12] by allowing students to actively participate in various music teaching practice activities and respecting their different learning methods and different music experiences formed as an independent individual, students' aesthetic ability can be comprehensively improved, so that students' creative thinking can be fully developed, thus forming their good humanistic quality. Literature [13] regards everyone as an independent individual, encourages students to dare to express their opinions, and encourages students to think creatively. On the basis of the existing theoretical analysis, this paper comprehensively analyzes the principles, learning modes, and implementation methods in the integration of information technology and music curriculum. In [14] according to the current situation that MT is applied to music teaching, through the breadth and depth of multimedia application and teaching results, this paper makes some thoughts and studies on the role and prospect of multimedia in the actual process of music education. Literature [15] points out that the correct use of multimedia teaching means in music teaching is of great significance to the improvement of music teaching theory and norms. Literature [16] studies people's activities in music education from the psychological point of view, including the psychological activities of students in feeling music, expressing music, creating music, learning music knowledge and skills and music culture, and psychological activities in music appreciation, etc., which are found out to guide educational activities. This paper is of great help to the research of music classroom in primary and secondary schools.

Speech plays an important role in modern life as a means of communication. People's demand for speech signal processing technology is growing every day as society and science and technology progress, and it has been vigorously developed, including speech coding, speech decoding, speech synthesis, speech recognition, speech enhancement, and so on. The AR (autoregressive) model is used in [17] to build a model of source signal separation that realizes the separation of single channel source signals. Pitch estimation is used to generate sound music templates in [18]. In [19] the amplitude spectrum of mixed signals is separated into a sparse matrix and a low-rank matrix using the sparsity of speech signals and the low-rank nature of music accompaniment, and then the separation of vocal music is realized using binary templates. The separation of different music signals is extended using nonnegative matrix decomposition. One of the major drawbacks of this method is that it requires a lot of computation and the separated signals are too simple. For nonnegative matrix decomposition, there are also some improved methods and supervision methods. A main melody extraction method based on speech separation has been proposed in [20, 21]. Experiments show that main melody extraction algorithms that include speech separation perform better than those that do not. Literature [22] calculates the saliency function using the source-filter model and harmonic weighting, extracts several candidate melody lines based on melody continuity, and finally locates the song melody and extracts the main melody based on a set of candidate melody line characteristics.

3. Research Method

3.1. Feasibility of Modern MT in Vocal Music Teaching. The ultimate goal of MT in music class is to increase the vitality of college music teaching activities. The multimedia class should be elegant, simple, and convenient to operate, the selection of teaching materials should be scientific and reasonable, other contents that are not helpful to the teaching focus should be stopped, and music content that is helpful but difficult for college students to understand should also be carefully selected.

MT can provide more abundant music information resources for autonomous learning for college students with high music literacy than in the classroom, and MT can provide key technical support for college students to carry out music extracurricular activities and online retrieval, and this type of autonomous learning in spare time is simply an effective extension of college music classroom learning. Students can choose the learning content that best suits them if they are made aware of autonomous learning. Furthermore, multimedia can assist students in learning independently by utilizing its inherent benefits and by providing more comprehensive learning resources. Using MT for music education is a good combination of music instruction by teachers in the classroom and independent learning by students outside of the classroom, and it gradually evolves into a new teaching mode that not only broadens students' horizons but also improves their learning efficiency.

Using MT for music teaching has become an inevitable choice for the change of teaching form, but multimedia is only a tool, which cannot replace teachers' position in the classroom. Therefore, it is necessary to strengthen the training of music teachers' ability to use MT and deepen teachers' understanding of MT and its significance to today's music teaching, not only to let teachers learn how to use MT, but also to make teachers learn how to use MT reasonably, so as to make it a tool to promote music classroom teaching rather than a tool to hinder music classroom teaching process.

Music aesthetic psychology refers to the psychological state and ability of the appreciator in aesthetic activities, including music perception, music thinking, and music emotion. The aesthetic performance is the difference of the appreciator's aesthetic attitude, aesthetic preference, and aesthetic ability. In music classroom teaching, apart from the differences in individual physiological and psychological performance, there are differences in their musical aesthetic psychology. Through the sound level, intensity, and rhythm, intuitively feel the brightness of the object, the ups and downs of modality, and the excitement of feeling. In hearing, the higher the pitch, the higher the sense of space, and the brighter the vision. In a good mood, the individual's active thinking and concentration make students more sensitive to the feeling and discrimination of the basic elements of music.

Multimedia teaching can transform a dull classroom into three-dimensional content, which can pique students' interest in learning by incorporating the vivid design of hearing, vision, and feeling appreciation that textbooks demand. Teachers cannot show concrete objects in areas where teaching conditions are limited, students do not recognize the sound effects of musical instruments in textbooks and pictures, and they are unfamiliar with the customs of a few areas. These difficult multimedia can be presented one at a time to pique students' interest and pique their curiosity, allowing them to appreciate and comprehend more stereoscopically.

From the age of seven to eleven years, they are called the early school age. They are in the specific operation stage, and their unintentional memory is dominant, their intentional memory is gradually strengthened, their memory of intuitive images is stronger than that of abstract logic, and the time of continuous concentration of attention increases with the development of age. The research on memory ratio, as shown in Figure 1, also learns a content. After comparison, it is found that through the combination of audio and video, people can master knowledge more firmly and more efficiently through various senses.

In the stage of formal operation, intentional memory is dominant in middle school students. In attention, they can take the initiative to pay attention according to their own preferences and purposes. With the increase of age, their ability to understand music and control their bodies is enhanced, and their learning efficiency is naturally enhanced. When the knowledge learned is logically arranged across the length of time and presented to the students, the students can absorb it at a glance. The collection and editing of audio-visual materials can enable the teachers to extract the important and difficult points independently and save the time and efficiency of repeated appreciation from the beginning to carry out other teaching activities and improve the teaching efficiency.

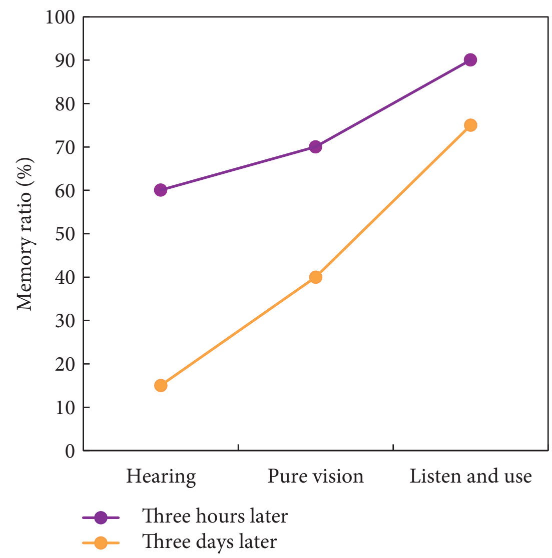

Figure 1: Memory ratio.

Multimedia teaching can provide a good atmosphere for students. Sensory stimulation can make students' music imagination and music thinking active. This environment enables students to follow the teacher's steps. They can also have an epiphany during this period, which is also the sublimation stage of music aesthetics, enabling them to complete the teaching content efficiently.

If teachers make rational use of differences in college students' knowledge structures, carefully set teaching objectives, and create scientific teaching design, it will not only help to promote college students' music learning, but also help college students learn as much about music knowledge as possible in a short class by taking advantage of the cross between disciplines and deepen their understanding of music and related art culture, in order to realize the educative goal.

3.2. MT-Based Holistic Teaching Method of Vocal Music Course for College Music Performance Major

3.2.1. Vocal Music Evaluation Method. The key to the research and development of multimedia vocal music teaching system is to establish the corresponding vocal music measurement method and scoring mechanism. Vocal music scoring is different from voice scoring. The multimedia vocal music teaching system established in this paper adopts the scoring mechanism of standard sound materials [23, 24], and the vocal music singing quality evaluation system using standard sound materials mainly consists of three parts: sound feature extraction, feature parameter matching, and scoring mechanism, as shown in Figure 2.

The corresponding feature parameters are extracted and matched after preprocessing the evaluated singing

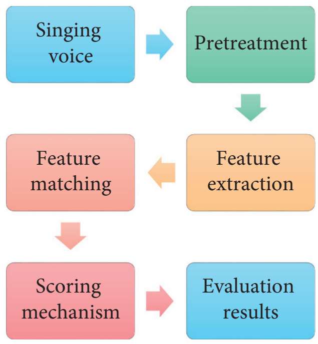

Figure 2: Vocal music evaluation system based on feature comparison.

voice and a standard voice, respectively. The higher the similarity, the higher the score given by the scoring mechanism to the evaluated voice. The volume intensity curve, fundamental frequency trajectory, and breath smoothness are the most important feature extraction parameters. The dynamic time warping method is used to compare similarity in feature matching.

Singing refers to performing activities with human body as sound generator. When singing, human body and spirit should enter and maintain the required state of singing. Correct breathing is the driving force of singing. Therefore, breath plays an important role in singing. The measurement of breath is a process of self-comparison, and the degree of breath stability can be measured by calculating the standard deviation of test sound waveform.

Standard deviation is a measure of the degree of dispersion of a set of values from the mean value. A larger standard deviation means that most of the values differ greatly from their average values, while a smaller standard deviation means that most of the values are closer to the average values. For vector X, its standard variance function $\mathrm{std}(X)$ is

$$\mathrm{std}(X) = \left(\frac{1}{n-1} \sum_{i=1}^{n} (x_i - \overline{x})^2 \right)^{1/2}, \tag{1}$$

where n represents the number of sampling points; $\overline{x}$ represents the average amplitude.

In sight singing, syllables and notes have a one-to-one correspondence. Seven singing names have no zero initial consonant, so the vowels are alternated. The score can be used to determine the roll call of notes, and phonetics knowledge can be used to predict the acoustic characteristics of each phoneme. As a result, note segmentation can be transformed into the following problems if the singer does not omit or add notes:

Given the score sequence M and the singing sequence S, solving an optimal match T between them can minimize the cost function, that is:

$$\arg\min \mathrm{Cost}(T|S, M). \tag{2}$$

Research shows that people's perception of pitch depends on the pitch of the most stable part inside the note. Therefore, the histogram of all sampling points on the pitch curve is taken according to the preset granularity, and the component with the most sampling points in the histogram is taken as the actual pitch of the note. On this basis, the pitch deviation between singing S and reference score M is defined as the average value of the difference between the actual pitch of all notes and the pitch of reference score (after transposition) weighted by the length of notes, namely:

$$\mathrm{pitch\_diff} = \frac{\sum_{i=1}^{N} \mathrm{Dur}_i \times \left|\mathrm{pitch}M_i - \mathrm{pitch}S_i\right|}{\sum_{i=1}^{N} \mathrm{Dur}_i}. \tag{3}$$

$\mathrm{pitch}M_i$ represents the pitch of the i th note in M, $\mathrm{pitch}S_i$ represents the actual pitch of the i th note in S, $Du\ r_i$ is the duration of the i th note, and N is the total number of notes in the song.

Duration accuracy reflects the consistency of note duration in singing. Similar to rhythm, the score does not specify the absolute length of notes, so it is necessary to normalize the length of notes in actual singing by using the beat number of notes in the score. In the concrete implementation, this paper uses the standard deviation coefficient of normalized note duration to measure the duration deviation between score M and singing S, namely:

$$\mathrm{dur\_dev} = \frac{\mathrm{std}(\mathrm{dur}S_i/\mathrm{dur}M_i)}{\mathrm{mean}(\mathrm{dur}M_i)}, \quad i \in [1, N], \tag{4}$$

where $\mathrm{dur}M_i, \mathrm{dur}S_i$ represent the duration of note i in M and S, respectively; $\mathrm{mean}(A)$, $\mathrm{std}(B)$ represent the mean and standard deviation of A, B.

The purpose of vocal music score is to give an objective evaluation of the singer's grasp of the melody of the music, mainly including sound intensity, pitch, and breath. The higher the score, the more accurate the singer's interpretation of the music; the lower the score, the less accurate the singer's grasp of the melody of the music. The scoring formula is as follows:

$$\mathrm{score} = k_1 - \frac{100}{1 + a_1 (\min \mathrm{disv})^{b_1}} + k_2 \frac{100}{1 + a_2 (\min \mathrm{disp})^{b_2}} + k_3 \frac{100}{1 + a_3 (\mathrm{st})^{b_3}}. \tag{5}$$

Among them, $k_1 \sim k_3$ is the weight of each scoring parameter in the scoring mechanism; min disv, min disp are the distance of sound intensity and pitch parameter, respectively; st represents the breath stability parameter. The choice of weights can be adjusted according to different requirements or different scoring priorities.

3.2.2. Extraction of Main Melody of Vocal Music. Melody is the most important musical element, which is composed of single tones with different pitches and durations. The main melody can be divided into vocal melody and general melody. If polyphonic music contains songs, the pitch sequence of songs is considered as the main melody of vocal music. If there is no singing voice, the pitch sequence of the instrumental playing sound dominated by energy is the main melody of the instrumental music.

From the perspective of physics, pitch is determined by fundamental frequency. Based on the characteristics of singing voice, this paper proposes an automatic labeling model (as shown in Figure 3).

Short-term stationarity is a property of music, which means that the signal characteristics are essentially stable over a short period of time. Stationarity can last anywhere from a few hundred milliseconds to several seconds depending on the characteristics of the music signal. The continuous nonstationary signal stream is segmented into a series of short-term stationarity segments, which is known as segment presegmentation.

Segment presegmentation divides the music signal into many segments s_i, $i = 1, 2, \ldots, N$, and assumes that each s_i belongs to either vocal segment or nonvocal segment.

Let $|x_{i,1}, x_{i,2}, \ldots, x_{i,M}|$ be the M-frame feature vector of s_i segment and let $\lambda_v, \lambda_{\mathrm{nv}}$ be the GMM (Gaussian mixture model) of vocal music and nonvocal music, respectively, and the logarithmic likelihood ratio of s_i to $\lambda_v, \lambda_{\mathrm{nv}}$ is as follows:

$$\begin{aligned} \log P(s_i|\lambda_v) &= \sum_{j=1}^{M} \log P(x_i \mid \lambda_v), \\ \log P(s_i|\lambda_{\mathrm{nv}}) &= \sum_{j=1}^{M} \log P\big(x_{i,j} \mid \lambda_{\mathrm{nv}}\big). \end{aligned} \tag{6}$$

If $\log P(s_i \mid \lambda_v) > \log P(s_i \mid \lambda_{\mathrm{nv}})$, then s_i is identified as a vocal category; otherwise it is a nonvocal category.

One of the key technologies for music segmentation is the training of vocal and nonvocal music models. The accuracy of recognition is influenced by the quality of the models. The instruments, playing methods, singers' voices, and vocals are all very different because of the various types and genres of music and songs. As a result, the key technologies for improving segmentation accuracy are reducing model complexity and bringing them closer to each piece of music to be processed.

Amplitude compressed pitch estimation filter is a robust multifundamental frequency extraction method [9, 10]. In this paper, the pitch saliency function is calculated by convolution of logarithmic domain comb filter and logarithmic domain spectrum. A voiced signal has fundamental frequency f_0, whose frequency domain expression is

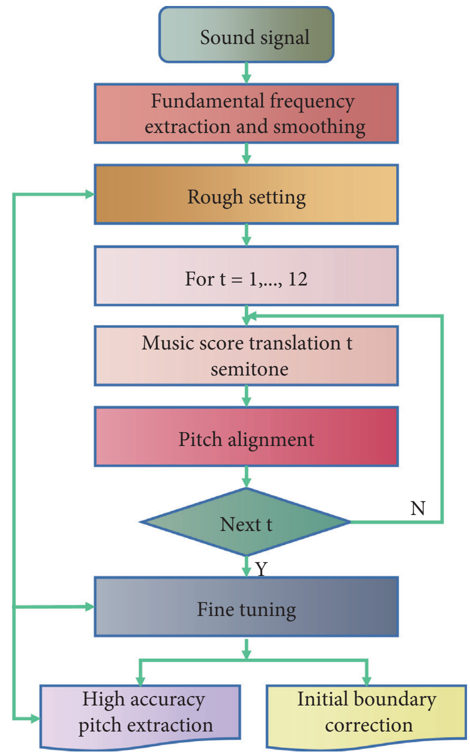

FIGURE 3: Automatic vocal music annotation model.

$$Y(f) = \sum_{k=1}^{K} a_k \delta(f - kf_0), \tag{7}$$

where a_k is the coefficient of the k harmonic.

Both singing and instrumental music have harmonic structure, so the mixed music spectrum has approximate sparsity. The comb filter can be used to extract the harmonic spectrum of the corresponding sound source according to the dominant fundamental frequency, and the MFCC (Mel frequency cepstral coefficients) of the extracted signal is sent to the neural network to judge whether the corresponding fundamental frequency is singing. Main melody discrimination steps:

A comb filter with a frequency range of 0–4 kHz is constructed from the dominant fundamental frequency F_0, as shown in

$$h(f) = \sum_{k=1}^{K} \delta(f - kF_0) * b(f), \tag{8}$$

where K is the number of harmonics in the range of 0–4 kHz; $b(f)$ is the basic waveform of comb filter (rectangle is used in this paper).

The MFCC is sent to the neural network to identify whether the dominant fundamental frequency F_0 is the fundamental frequency of singing.

Count the frame number of the fundamental frequency of the voice in each voiced segment, and if it is more than half of the total frame number of the voiced segment, determine that the dominant fundamental frequency track of the voiced segment is the main melody of the voice.

4. Results Analysis and Discussion

4.1. Evaluation and Analysis of Vocal Music. In this paper, the vocal music quality measurement method and scoring system are simulated on Matlab. The scoring test is mainly aimed at skill training etudes, which are the most commonly used etudes in vocal singing training. Focus on specific vowels, phonetic syllables, and skilled vocalization for targeted training. In the experimental simulation, five basic vowel vocal training materials *A*, *E*, *I*, *O*, and *U* and male closed humming training songs are selected for testing and analysis.

In the comparison of sound intensity, the average amplitude of each frame signal is calculated by the standard of practice music and the audition music, respectively, as the sound intensity parameter of this frame, thus drawing the volume intensity curve, as shown in Figure 4.

Although MT can bring many benefits to music teaching, teachers should grasp the utilization of MT and cannot let it replace teachers in teaching music knowledge. Teachers use MT in music classroom to improve classroom efficiency and teaching vitality. Therefore, in courseware making, they should not add too much content that is not related to classroom teaching, but should ensure that the whole courseware is simple and generous, which is convenient for teachers to operate and students to watch.

In pitch comparison, the fundamental frequency tracks of two pieces of music are obtained separately by cepstrum method, as shown in Figure 5. It can be found that the average standard fundamental frequency is 157.36 Hz and the average audition fundamental frequency is 159.01 Hz.

When calculating similarity, DTW (Dynamic Time Warping) method is used to get the average distance of the closest two features. Figure 6 is the DTW comparison between the standard song and the test song.

Here, it is important to point out that no matter how powerful and convenient MT is, it is only a teaching aid, which can only help teachers to impart knowledge and skills. Therefore, in the practice of vocal music teaching, attention should be paid to teacher-student interaction and the cultivation of the comprehensive quality of teachers and students. MT brings an opportunity for vocal music teaching innovation, which requires teachers to seize the opportunity, actively reform the teaching mode, enliven the classroom teaching atmosphere, break the limitations of traditional vocal music teaching, and let students have more room for development and innovation.

Teachers can use MT to simulate the stage background and stage performance situation for students, so that students can actively participate in stage performance activities, show their talents and skills, and increase their artistic expression. For example, in the practice teaching of vocal music performance for students, in order to bring students into the corresponding performance situation and motivate students to perform and show actively, teachers can use MT to simulate the stage background and stage performance situation for students, so that students can actively participate in stage performance activities, show their talents and skills, and increase their artistic expression. When students arrive, they will have a better understanding of vocal music knowledge and skills. They will also have close communication and interaction with other students, learn some useful methods and skills, and save money for their future growth and progress.

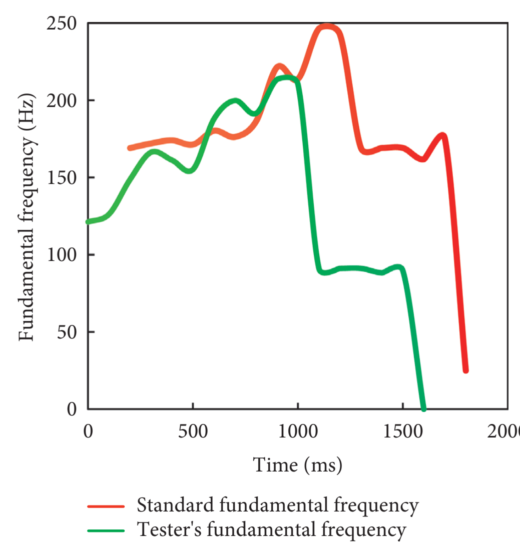

Figure 5: The track of the fundamental frequency of the male closed-mouth humming practice song.

4.2. Extraction and Analysis of Main Melody. Figure 7 shows the segmentation error rates of three models (initial model, model updated with all data, and model updated with reliable data) without smoothing the recognition results. For each model, the final segmentation error rates are compared when the presegmentation segment length changes from 0.1 to 1.0 s.

As can be seen from Figure 7, the data selection model updating algorithm based on confidence measure proposed in this study significantly reduces the error rate of music segmentation, and the segmentation result is further improved by smoothing the recognition result.

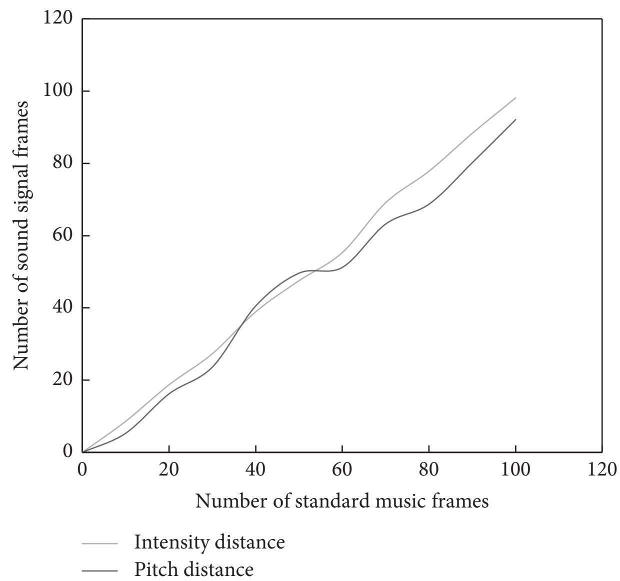

Figure 6: DTW comparison between standard song and test song.

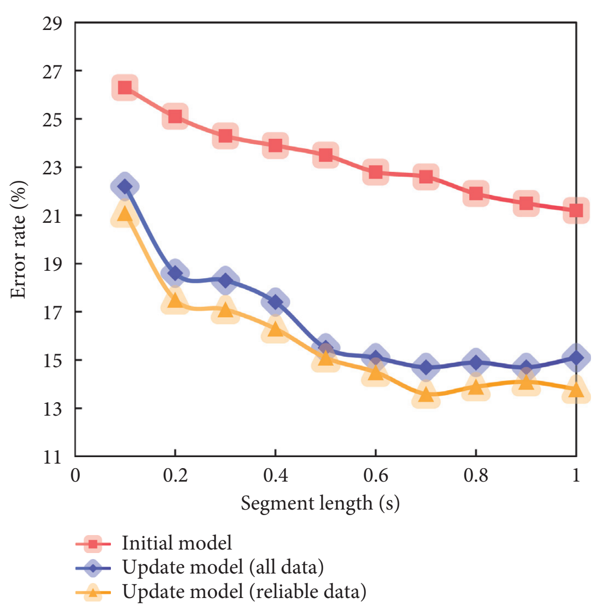

Figure 7: Unsmooched processing.

Figure 8 shows the corresponding segmentation error rate after smoothing the recognition result, where the error rate is defined as the percentage of the length of the incorrectly classified music signal to the total signal length.

Figure 8 shows that the smoothing process is effective when the length of presegmented segments is short. With the increase of segment length, the smoothing process causes each continuous segment to be too long but introduces additional segmentation errors.

Therefore, in music teaching, the subject should always be grasped, use MT appropriately and moderately, and do not become the teaching slave of MT. The use of modern educational technology means such as multimedia is just one of the ways of expressing teachers' creativity, a kind of teaching means and teaching methods, and a tool for serving teachers. To use it reasonably, it should not be used lightly; of course, it should not be used greatly, but it should be used by me. Teachers cannot rely entirely on MT to reflect their teaching level.

Figure 9 shows the minimum error rate value on each curve in Figures 7 and 8, that is, the best result obtained when the presegmentation length of each algorithm changes.

It can be seen from Figure 9 that the segmentation error rate is reduced from 18.6% to 13.9%. Compared with the

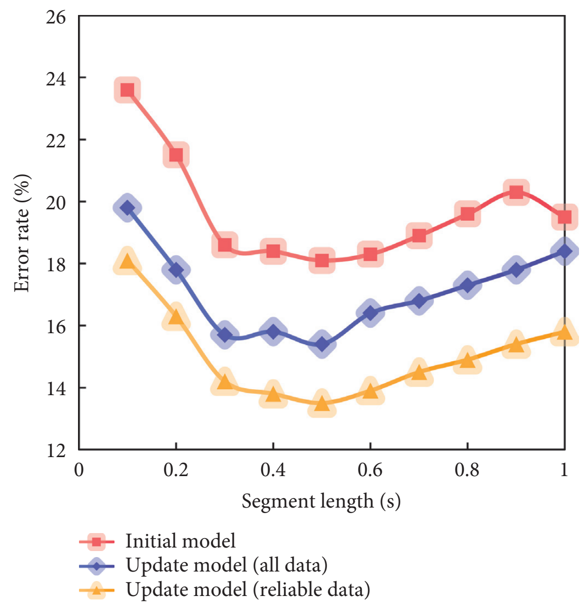

Figure 8: After smoothing.

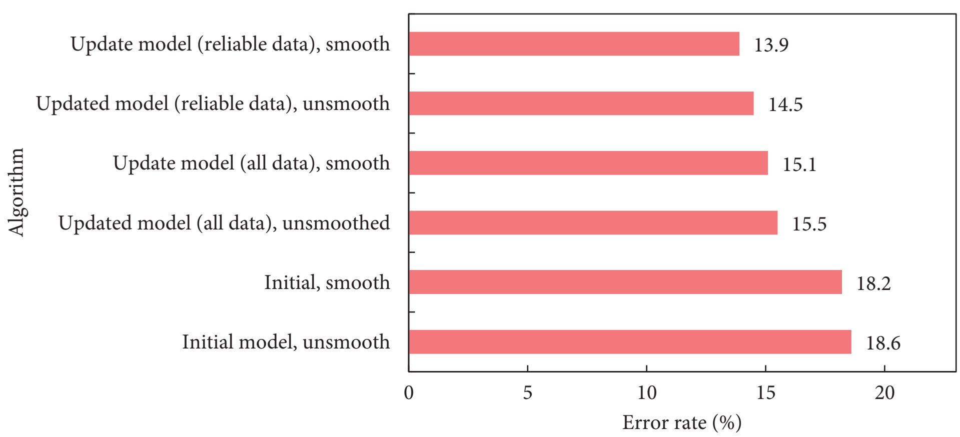

Figure 9: Comparison of music segmentation error rate.

original model and without smoothing, the segmentation algorithm proposed in this study has improved the error rate.

In order to verify the accuracy of the automatic extraction algorithm of vocal music melody, this section uses 500 pieces of music in the test set as test data and carries out the experiment under the condition that the signal-to-interference ratio is 5 dB, respectively. The experimental results are shown in Figure 10. Among them, the following five performance indexes are used to evaluate the algorithm performance [19]: VRR (Voicing Recall Rate), VFAR (Voicing False Alarm Rate), RPA (Raw Pitch Accuracy), RCA (Raw Chroma Accuracy), and OA (Overall Accuracy).

It can be seen that the overall accuracy of the main melody extracted by this algorithm reaches 86.24%. In this paper, the fundamental frequency discrimination model is introduced, and the statistical method is used to judge whether the dominant fundamental frequency track of each voiced segment belongs to the main melody of the song. Therefore, in rare cases, the song melody segment will be misjudged as the accompaniment melody segment, which will reduce the recall rate of melody location. However, in most cases, the accompaniment melody segment will not be judged as the song melody segment, which will reduce the false alarm rate of melody location and help to improve the overall accuracy rate of the algorithm.

To improve the comprehensiveness of students' knowledge in college vocal music teaching, in addition to thoroughly learning the teaching materials, it is necessary to increase classroom teaching capacity and expand teaching information with MT, so that students can fully grasp the connotation of works in future vocal music learning and

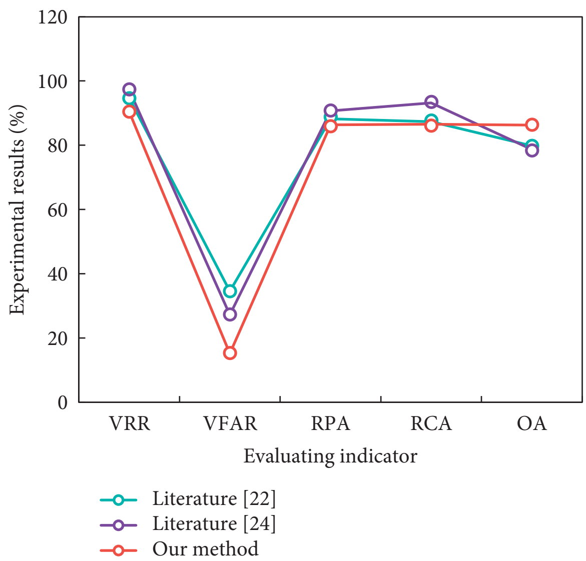

FIGURE 10: Experimental results when the signal-to-interference ratio is 5 dB.

practice. In the past, students could not form a systematic and deep impression from a single classroom explanation, nor could they access as much knowledge and information as possible. As a result, teachers can introduce MT, make full use of computers' powerful storage capabilities, actively consult a variety of materials and information, and provide rich information resources for vocal music instruction.

5. Conclusion

Combining college music teaching with MT meets the needs of the times. It can not only increase students' learning desire and improve students' learning ability, but also have considerable influence on teachers' teaching quality. It is the art of music, the art of practice, and the art of emotion. Simply emphasizing the description of language is boring for students. Teachers should understand students' aesthetic psychology of music when designing classes. By analyzing and displaying the waveform of the singer's voice, this paper makes vocal music teaching intuitive and visible. On this basis, according to the short-term stationary characteristics of the music signal, the instantaneous mutation error of the segment in the recognition result is further removed by smoothing the recognition result. Experiments show that the main melody extraction algorithm in this paper can effectively reduce octave error with a signal-to-interference ratio of 5 dB, the false alarm rate of melody location is obviously lower than other algorithms, and the overall accuracy is higher than other algorithms, which can effectively extract the main melody of vocal music.

However, there are still many shortcomings in MT teaching. Teachers need to improve the problems step by step according to their own actual teaching situation and improve the teaching quality to a new field by updating MT, so as to contribute to the cultivation of high-quality music talents in China.

Data Availability

The data used to support the findings of this study are included within the article.

In order to realize the effect of intelligent poetry style analysis, this paper applies the text classification algorithm to the poetry style analysis, combines the knowledge representation algorithm to perform text classification and recognition, improves the algorithm, and applies it to the poetry style analysis model. Moreover, this paper combines intelligent algorithms to construct a poetry style analysis system, constructs the system's functional modules, preprocesses the poetry documents in the corpus, and maps them to the vector space that can be directly processed by the computer. In addition, after constructing the system model, this paper verifies the poetry style analysis system based on the text classification algorithm through simulation experiments. From the research results, the effect of the poetry style analysis method based on the text classification algorithm proposed in this paper is very good, which meets the actual needs of poetry style analysis.

1. Introduction
