At present, a lot of progress has been made in natural language processing technology. As a branch of natural language processing, computer processing of literary language is now in front of academia. With the support of the National Natural Science Foundation of China, this paper is trying to make preliminary explorations in this field. The focus of this paper is how to use machines to realize the style of poetry. As one of the essences of Chinese traditional culture, the classical poems have meaningful meaning, simple and deep sentiment, and their style is intoxicating. However, for a long time, the judgment of the style of poetry works is mostly based on the reader's judgment and cognition of the style based on experience and feeling. Moreover, traditionally, there are no clear quantitative rules and no formal rules. For machines, it can only rely on the text content of the poem to determine the style. From the form, the poem is also a paragraph of text, and the judgment of its style can also be regarded as the classification of the text style. Therefore, this problem is essentially transformed into a text classification problem in machine learning. That is, under a given style classification system, the machine automatically learns the rules according to the content of the text, and establishes a classification discriminator according to the rules, and the classification discriminator automatically determines the style of the text. Based on this, this paper proposes a model framework for computing the style of Chinese classical poetry based on machine learning. This research is of great significance for expanding the application field of machine learning, for the informatization and excavation of traditional poetry, and for the language understanding of poetry and the computer-aided research of various literary works.

As one of the treasures in the history of Chinese literature, poetry has been passed down through the ages because of its enduring charm. This literary form, favored by the general public and literati and poojas, has been growing, evolving, and disseminating and has reached the peak of its development in the Tang and Song dynasties. The research on Tang poetry has always been a research hotspot among scholars and literary lovers. Since ancient times, countless experts and scholars have carried on extensive and in-depth research on Tang poetry and poetry from a literary perspective. However, with the continuous development of information science and technology, people have begun to try to use information science and technology to deal with some of the language problems encountered in work and life. Natural linguistics has developed rapidly in recent years. Faced with the victories of natural language processing in modern Chinese, some natural language processing methods are applied to ancient poetry. At the same time, in view of the difference between ancient poetry and modern Chinese, from the perspective of computer, integrated data mining, genetic algorithm, and other technologies and resources such as HowNet, it focuses on the application of text classification technology in the classification of poetry style.

In the process of creating poems, the different talents, temperaments, literary accomplishments, life experience, ideological realm, and ideological feelings of the literati and the ink guest will affect the content and expression of the poems written by the literati and ink guest, and they will also have the ability to Poems with different characteristics, therefore, do not have the same style of poems. However, in the process of appreciating classical poems, if you blindly pay attention to the individual differences between poems and ignore the common characteristics of the poems, it is likely to cause the problem of nihilism.

This article combines the intelligent computer algorithm to apply the text classification algorithm to the poetry style analysis and builds an intelligent classification system, which lays the foundation for the intelligent classification of poetry.

2. Related Work

Using computer technology to assist in the study of the field of classical poetry literature, some scholars have begun preliminary attempts and explorations early on. The construction of the classical poetry database and cultural knowledge base is in the computer research laboratories of some universities and research organizations [1]. With the increasing progress of natural language processing technology in the study of Chinese language, it can even gradually support the analysis of rhythm, emotional element, and style characteristics of classical poetry [2]. "Computational Poetics" is proposed in this context [3]. There have been many research results on the related fields of poetry style. According to the literature [4] "The topic model-based corpus construction and computer-aided creation research," the topic model based on LDA uses the method of reference word recommendation to study and analyze the word characteristics in poetry, vocabulary semantic analysis, and style feature analysis. Literature [5] uses the vector space model (VSM) to represent the text of poems and proposes two types of classification models of classical poems, bold and graceful and graceful. The classification models are based on machine learning and natural language processing. Poetry styles are classified, and a good judgment effect has been achieved. According to literature [6] after segmenting the poems according to the poetry metric and statistical word segmentation methods, they established a poetry vocabulary database and used machine learning methods to analyze the characteristics of poetry styles, classification evaluation, and sentiment analysis. In addition, research in related fields has focused on the algorithm improvement of the poetry style machine classification model, in order to gradually improve the accuracy of the classification model for the poetry style evaluation. The early stage corpus construction and computer processing procedures have been very clear. Various research work is still in-depth [7]. It can be seen that there have been quite a lot of research studies on the classification and judgment of poetry style, which has accumulated rich experience for the classification and judgment of poetry style based on machine learning in this article.

The handling of poems can actually be regarded as a text handling problem with a special content in form [8]. Literature [9] developed a "Poetry Computer Aided Research System," which takes the vocabulary in the poem as the main research unit to realize word retrieval, word frequency statistics, and image indexing. Literature [10] proposed a natural language processing technology based on word connection and used it for the understanding of poetry language. It successfully carried out a test of poetry vocabulary material labeling, a preliminary analysis test of poetry language, and an evaluation test of poem language boldness and graceful style. Literature [11] combined naive Bayes with the genetic algorithm, and put forward a calculation model for judging the bold and graceful style of classical poetry based on each character of the poem as the smallest unit, and tested the corpus in the classic poetry. Good results have been achieved. Literature [12] introduced Bayesian classification technology into poetry research from the subject point of view and achieved good experimental results. Literature [13] proposed a classification method of poem topics based on point mutual information and LDA and achieved a good classification effect on the relationship between poem topics and the evolution of the times. Literature [14] uses the vector space model (VSM) to convert the poetry text into a vector and selects the word feature through the chi-square test. Finally, the text classifier is constructed based on the naive Bayes and support vector machine algorithm, and the average classification accuracy rate reaches 74.7%. With the rise of deep learning, the literature [15] applied the RNN neural network to the generation of ancient Chinese poetry, and used the entire historical corpus of poetry as training corpus, adding certain constraints between the words and lines of the generated poetry to achieve it has a better effect than the traditional poetry generation system. Literature [16] uses the RNN model to generate poetry quatrains, and successfully adds an attention mechanism, so that the poetry can learn semantics, structure, rhyme, and other information at the same time. Literature [17] based on the RNN model, by optimizing the word vector of poetry, introducing attention mechanism and hybrid training, a model that can produce topic-related poems based on keywords has been obtained, and good results have been achieved.

3. Knowledge Representation of Intelligent Poetry Text Generation System

Like many other intelligent systems, knowledge representation is a very important key decision during system construction. We treat Chinese characters and works of art as images in a parametric form. Mathematically, the "image" of Calligraphy C is represented as a band-shaped image area covered by a series of ellipses. It means that this series of C is composed of num_0 ellipses $P_1, P_2, \ldots, P_{\text{num0}}$. $F0 = \{1, 2, \ldots, \text{num}_0\}$, (x_i, y_i), and a_i, b_i are used as the center, semimajor axis, and segment semiaxis of ellipse P_i, respectively. We define the text of traditional Chinese poetry as

$$\text{Area} \triangleq \left\{(x, y) \in R^2 | \exists i \in F_0, \frac{(x - x_i)^2}{a_i^2} + \frac{(y - y_i)^2}{b_i^2} \leqslant 1\right\}. \quad (1)$$

The above knowledge representation method is inspired by the method of the paper. In this paper, a band-shaped area is defined as an ellipse moving along a predefined curve.

We now turn to the concept of equivalence and use a formalized definition of the hierarchical representation of the text of poetry. If R is an equivalence relation defined in the $A = \{a_1, a_2, \ldots, a_n\}$ field, that is to say, R is as follows [18]:

(1) Reflexive,

(2) symmetrical, and

(3) passed.

Domain A can be decomposed into a series of subsets $A_1, A_2, \ldots, A_m$ in relation R, which satisfy the following properties:

(a) If $i \neq j, 1 \leq i, j \leq m$, then $A_i \cap A_j = \phi$ and

(b) $\forall a_i \in A, \exists j, 1 \leq j \leq m\$$, s.t. $\$a_i \in A_j$.

Under the equivalence relation R, if $(a_i, a_j) \in R, 1 \leq i, j \leq n$, we say that a_i is equivalent to a_j, which can be expressed as $a_i \underset{R}{\leftrightarrow} a_j$.

In order to establish the hierarchical representation of poetry text, we introduced four equivalence relations R_1, R_2, R_3, R_4:

R_1: all the structural ellipses used to form the same original sign are equivalent to each other.

R_2: all the original strokes used to form the same combination sign are equivalent to each other.

R_3: all the combined strokes used to form the same radical are equivalent to each other.

R_4: all the radicals used to form the same Chinese character are equivalent to each other.

We assume that the constructed ellipse $C = \{Pt | t \in F0\}$ is decomposed into num_1 equivalence classes under the equivalence relation R_1, which can be expressed as $F_1 \triangleq \{1, 2, \ldots, \text{num}_1\}$. The num_1 original signs are decomposed into num_2 equivalence classes under the equivalence relation R_2, which can be expressed as $F_2 \triangleq \{1, 2, \ldots, \text{num}_2\}$. num_2 combined strokes are decomposed into num_3 equivalence classes under equivalence relation R_3, which can be expressed as $F_3 \underline{\Delta_1} \{1, 2, \ldots, \text{num}_3\}$. The num_3 radicals are decomposed into num_4 equivalence classes under the equivalence relation R_4, which can be expressed as $F_4 \triangleq \{1, 2, \ldots, \text{num}_4\}$ [19].

In other words, in a specific poetic text work C, there are a total of num_1 original strokes $P_{1,i}\$, \$i \in F_1$. Moreover, C contains num_2 combined strokes $P_{2,i}, i \in F_2$. We can say that C has num_3 radicals $P_{3,i}, i \in F_3$. We can also say that C consists of num_4 words $P_{4,i}, i \in F_4$. Obviously, when we use the granularity of a single word to apply comprehensive reasoning, $\text{num} \equiv 1$[20].

Now, the hierarchical representation of traditional poetry text works can be formally described as follows:

$$\left\{\begin{array}{c} \mathbf{P}_{k,1} = \left\{\mathbf{P}_{k-1,s} | \mathbf{P}_{k-1,s} \overset{R_k}{\leftrightarrow} \mathbf{P}_{k-1,1}, \quad s \in F_{k-1}\right\} \\ \mathbf{P}_{k,l} = \left\{\mathbf{P}_{k-1,s} | \mathbf{P}_{k-1,s} \overset{R_k}{\leftrightarrow} \mathbf{P}_{k-1,q} \text{ in which q} = \min\left(t | \mathbf{P}_{k-1,t} \notin \bigcup_{i=1}^{l-1} \mathbf{P}_{k,i} t \in \mathbf{F}_{k-1}\right) s \in \mathbf{F}_{k-1}\right\}, \quad l \in \frac{\mathbf{F}_k}{\{1\}} \quad k = 1, 2, 3, 4 \\ P_{0,l} = P_l, \quad l \in F_0 \end{array}\right\}, \quad (2)$$

where the number of elements in the set M is $|M|$. Therefore, the following hierarchical relationship expressed in poetry text works can be expressed as follows:

$$\left\{\begin{array}{ll} \sum_{s=1}^{|F_k|} \left|\mathbf{P}_{k,s}\right| = \left|\mathbf{F}_{k-1}\right| = \text{num}_{k-1}, & k = 1, 2, 3, 4, \\ \left|\mathbf{P}_{0,s}\right| = 1, & s = 1, \ldots, \left|\mathbf{F}_0\right|. \end{array}\right. \quad (3)$$

This hierarchical representation describes how the poetry text works at the lowest level are composed of structural ellipses. Each higher level describes how to generate a representation of its current level from the information of the lower level. In essence, it is a tree-shaped knowledge representation.

At the 0th level of the hierarchical representation, the poetry text works are regarded as a series of ellipses, denoted as P_0. These ellipses are called structural ellipses for poetry text works. For each construction ellipse, it is denoted as $P_{0,i}$, and (x_i, y_i) is taken as its center, and ai and bi are taken as its semimajor axis and semiminor axis, respectively. Then, the image of the poetic text work C will be presented as a series of image areas covered by an ellipse.

If a lower-level element cannot be merged with other elements at the same level, it will be promoted to an adjacent higher-level element. In the same way, it is also possible that a radical will be downgraded into a combined gesture, or even an original one. Through these upgrade and downgrade arrangements, we have obtained a unified 6-level hierarchical system, which will be used in the generation of poetry text.

We denote the first structural ellipse of the poem text work as $P_{k,s}$, and its corresponding topological structure is $T_{k,s}$. $k = 1, 2, 3, 4, s \in F_k$°$\mathrm{T}_{k,s}$ contains topology information, and through it, $P_{k-1,1+1}$, $P_{k-1,2+1}, \ldots, P_{k-1}, |Pk, s| + 1\,(l = \sum_{i=1}^{s-1} |P_{k,i}|)$ can be used to form $P_{k,s}$.

We denote the bounding box of the image area occupied by element $P_{k,s}$ as $C_k \cdot s = [\,CX_{k,s}\$s\$\ CY_{k,s}\ CH_{k,s}\ CW_{k,}$ $s]$, $k = 1, 2, 3, 4, s \in F_k$. Here, $CX_{k,s}, CY_{k,s}, CH_{k,s}, CW_{k,s}$ are the x, y coordinates of the lower left corner of the bounding box $C_{k,s}$ and its height and width, respectively. All coordinates are in the world coordinate system. Therefore, we have

$$T_{k,s} \triangleq \left(\mathrm{TCR}_{k,s}, \mathrm{TCS}_{k,s}\right) \triangleq \left(\begin{bmatrix} TR_{k,1+l} \\ TR_{k,2+l} \\ \vdots \\ TR_{k,|P_{k,s}|+l} \end{bmatrix}, \left(\begin{bmatrix} TS_{k,1+l} & TS_{k,2+l} & \cdots & TS_{k,|P_{k,s}|+l} \end{bmatrix} \right) \right). \tag{4}$$

Here, $l = \sum_{i=1}^{s-1} |P_{k,i}|$; $s \in F_k$; $k = 1, 2, 3, 4$. $\mathrm{TCR}_{k,s}$ and $\mathrm{TCS}_{k,s}$ is the scaling and transition matrix, respectively. The strict mathematical definition of matrix $TR_{k,z}, TS_{k,z}$ is as

$$\begin{cases} TR_{k,z} \triangleq \begin{bmatrix} RW_{k,z} & 0 \\ 0 & RH_{k,z} \end{bmatrix} \triangleq \begin{cases} \begin{bmatrix} \dfrac{CW_{k,s}}{CW_{k-1,z}} & 0 \\ 0 & \dfrac{CH_{k,s}}{CH_{k-1,z}} \end{bmatrix}, & (k = 2, 3, 4), \\ \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, & (k = 1), \\ z = 1 + l, & 2 + l, \ldots, |P_{k,s}| + l, \end{cases} \\ TS_{k,z} \triangleq \left[RX_{k,z} \quad RY_{k,z}\right]^T \triangleq \begin{cases} \left[\dfrac{CX_{k-1,z} - CX_{k,s}}{CW_{k,s}} \ \dfrac{CY_{k-1,z} - CY_{k,s}}{CH_{k,s}} \right]^T, & (k = 2, 3, 4), \\ \left[0 \ \ 0\right]^T, & (k = 1). \end{cases} \end{cases} \tag{5}$$

If $k \geq 1, P_{k,i}$ m must be a combination of one or more construction elements one level lower. We call the latter substructural elements. All the information needed to combine $P_{k,i}$ is stored in $T_{k,i}$, which is the topology constructor of $P_{k,i}$.

Through the topology constructor, we can build a one-to-one mapping of different levels of hierarchical representation. In other words, any hierarchical representation pixel $[\,x_{k,s}\ \ y_k, s\,]^T$ of the s-th structural element $P_{k,s}$ belonging to the k-th level can be uniquely mapped to the hierarchical representation pixel $[\,x_{l,t}\ \ y_{l,t}\,]^T$ of the c-th structural element $P_{1,t}$ of the first level. Among them, $l > k, 1, k = 0, 1, 2, 3, 4, \exists m_j \in F_{k+j}\,(j = 1, 2, \ldots,$ $1 - k - 1)\$$ s.t. $\$P_{k,s} \in P_{k+1,ml} \in \cdots \in P_{k+(1-k-1),ml-k-1} \in P_{1,t}$.

If we introduce the operator $\nabla^b_{m,n}$,

$$\nabla^b_{m,n} \begin{bmatrix} x \\ y \end{bmatrix}_{2\times 1} \triangleq TR_{m+1,n} \begin{bmatrix} x \\ y \end{bmatrix}_{2\times 1} + TS_{m+1,n}. \tag{6}$$

Then, there will be a relationship:

$$\left[\, x_{l,t} \quad y_{l,t} \,\right]^T = \nabla^b_{l-1,m_{l-k-1}}\left(\cdots\left(\nabla^b_{k+1,m_1}\left(\nabla^b_{k,s}\left[\, x_{k,s} \quad y_{k,s} \,\right]^T\right)\right)\right). \tag{7}$$

The s-th structural element of the k-th level of the hierarchical system is denoted as $P_{k\cdot r,s}$, and its parameter is denoted as $E_{k\cdot s}, k = 0, 1, \ldots, 4, s \in F_k$. We now introduce a new matrix operator ∇^c_n, which can be used to generate an $\mathrm{m} \times \sum_{l=1}^n d_l$ -dimensional matrix $M = (a_{i,j}) m \times \sum_{l=1}^n d_l$ and n $m \times d_1\, (l = 1, 2, \ldots, n)$-dimensional matrices $M_1 = (a_{l,i,j})_{m\times d1}\, (l = 1, 2, \ldots, n)$. If $\nabla^c_n (M_1, M_2, \ldots, M_n) = M$, then we have

$$a_{i,j} = \begin{cases} a_{z+1,i,j} - \sum_{t=1}^{z} d_t \text{ in which } \sum_{t=1}^{z} d_t < j \leqslant \sum_{t=1}^{z+1} d_t, & z = 1, 2, \ldots, n-1, \\ a_{1,i,j}, & j \leqslant d_1, \end{cases} \quad i = 1, 2, \ldots, m. \tag{8}$$

We further define a matrix operator ∇^d_n:

$$\nabla^d_n (A) \triangleq \nabla^c_n \underbrace{(A, A, \ldots, A)}_{n}. \tag{9}$$

Then, the hierarchy of poetry text works can be formally expressed as follows:

$$\left\{ E_{0,i} = \begin{bmatrix} x'_i, & y'_i, \\ E_{k,s}, & = \nabla_{\left|P^c_{k,s}\right|}\left(\nabla^e_{k-1,1+l} E_{k-1,1+l}, \nabla^e_{k-1,2+l} E_{k-1,2+l}, \ldots, \nabla_{k-1,\left|P_{k,a}\right|+l} E_{k-1,\left|P_{k,s}\right|+l}\right). \end{bmatrix} \right. \tag{10}$$

Among them,

$$l = \sum_{i=1}^{s-1} \left|\mathbf{P}_{k,i}\right|, \quad k = 1, 2, 3, 4, s \in F_k. \tag{11}$$

At this time, the operator is defined as follows:

$$\nabla^e_{n,m} E_{n,m} \triangleq \nabla^c_2\left(\left(\nabla^c_2\left(TR_{n,m}, 0_{2\times 2}\right)\right)^T, \left(\nabla^c_2\left(0_{2\times 2}, TR_{n,m}\right)\right)^T\right) E_{n,m} + \nabla^d_{\mathrm{col}\,(E_{n,m})}\left(\left(\left(\nabla^c_2\left(\left(T\mathbf{S}_{n,m}\right)^T, \left[\, 0 \quad 0 \,\right]\right)\right)^T\right). \tag{12}$$

Among them, $\mathrm{col}\,(E_{n,m})$ is the number of columns of matrix $E_{n,m}$, and $0_{2\times 2}$ is an 2×2-dimensional zero matrix.

In the above equation, each $E0, i$ represents an area covered by the constructed ellipse, and $((x - x'_i)^2/a'^2_i) + ((y - y'_i)^2/b'^2_i) \leq 1$. This ellipse is the normalized version of the original ellipse $((x - x_i)^2/a^2_i) + ((y - y_i)^2/b^2_i) \leq 1$ for its bounding box. That is, if $P_{0,i} \in P_1$ and $j, i \in F_0, j \in F_1$ is assumed, we have

$$\begin{bmatrix} x_i' \\ y_i' \\ a_i' \\ b_i' \end{bmatrix} = \begin{bmatrix} \dfrac{x_i - CX_{1,j}}{CW_{1,j}} \\ \\ \dfrac{y_i - CY_{1,j}}{CH_{1,j}} \\ \\ \dfrac{a_i}{CW_{1,j}} \\ \\ \dfrac{b_i}{CH_{1,j}} \end{bmatrix}. \tag{13}$$

For an element higher than the 0th level, such as $P_{k+1,1}$, for all $k > 0$, it is composed of $N_{k+1,1}$ adjacent lower-level elements: $P_{k,11}, P_{k,12}, \ldots, P_{k,1Nk+1,1}$. The corresponding shape matrix $E_{k+1,1}$ is deduced, which is obtained from the matrix $E_{k,11}, E_{k,12}, \ldots, E_{k,1Nk+1,1}$ by linking columns by column. Because the parameterized representation of constructing an ellipse is a 4×1-dimensional matrix, the above-mentioned recommended connection method will accurately generate a matrix with only 4 rows at a higher level. Each row of the generated matrix is called the parameterized representation domain of the element. The different domains of an element can be inferred independently.

The weight associated with the s-th field of the i-th source knowledge on the k-th level; that is, the weight of the i-th training example $(p_{k,l}^i)$ is denoted as $w_{l,s}^i$. $w_{l,s}^i$ $(s = 1, \ldots, 4)$ is the reasoning strength of $p_{k,l}^i$ in synthetic reasoning. Therefore, the set of similar reasoning strengths arranged in order constitutes the "view sequence" of the current comprehensive reasoning process. This is what we said that different sequences of showing training examples will lead to different results of poetry text.

For the comprehensive reasoning process generated by novel poetry text works, we assume that n comprehensive source knowledge $P_{k,11}, P_{k,12}, \ldots, P_{k,\mathrm{ln}}$ at the k-th level participates in this reasoning process. Moreover, each comprehensive source knowledge consists of m components, where $\forall i \neq j; i, j = 1, 2, \ldots, n \Rightarrow l_i, l_j \in F_k, l_i \neq l_j$. Therefore, we can use an $m \times 1$-dimensioned matrix to represent a single comprehensive reasoning source and use an $m \times \sum_{i=1}^{n} l_i$-dimensioned matrix to represent all active sources in the current comprehensive reasoning. If we apply synthetic reasoning at the single-character level, then $m \equiv 4$. The t-th attribute of source knowledge is denoted as P_{k,li,t°, which has an associated strength $W_{k,li,t}$ in the process of comprehensive reasoning, and they have the following relationship:

$$\sum_{i=1}^{n} \omega_{k,l_i,t} = 1\,(t = 1, 2, \ldots, m). \tag{14}$$

In the intelligent poetry text generation system, this reasoning intensity can be adjusted through a graphical user interface. The new knowledge generated in the synthetic reasoning process is denoted as $P_{k,r}$, and its matrix form parameterization is denoted as E_{k,r°. To apply the principle of comprehensive reasoning process, all source knowledge in reasoning must have equal dimensions. That is to say, if we apply synthetic reasoning on source knowledge P_k, s and $P_{k,t}$, their corresponding matrix form parameterized representations $(E_{k,s})_{m1 \times n1}$ and $(E_{k,t})_{m2 \times n2}$ must satisfy the relationship $n_1 = n_2$. This equal requirement is a soft constraint of the synthetic reasoning process. If it is violated, we can introduce a source knowledge equality operator ∇_t^e to relax this soft constraint. This is very similar to the mapping problem in similar reasoning. Next, we will introduce a few symbols and define ∇_t^e in a strict mathematical way.

We first denote en, $i \overset{\Delta}{=} [\, \sigma(i,1) \;\; \sigma(i,2) \;\; \cdots \;\; \sigma(i,n)\,]T$, where $\sigma_{(i,j)} = \begin{cases} 1, & i = j \\ 0, & i \neq j^\circ. \end{cases}$

We can also obtain a discrete curve composed of the centers of all the covering ellipses for each structural element in the intelligent poetry text generation system, which can be expressed as P_k. Its corresponding parameterization is expressed as E_k, ls°. Therefore, a dispersion curve acquisition method can be described as follows:

$$\begin{aligned} C_{k,l_s} &= \left(\nabla_2^c\left(\left(e_{4,1}^T \times E_{k,l_s}\right)^T, \left(\mathbf{e}_{4,2}^T \times E_{k,l_s}\right)^T\right)\right)^T \\ &= \begin{bmatrix} x_1 & x_2 & \cdots & x_{co} \\ y_1 & y_2 & \cdots & y_{co} \end{bmatrix}, \quad co = \mathrm{col}\left(E_{k,l_s}\right). \end{aligned} \tag{15}$$

Then, an overview of the key columns of a matrix can be introduced and defined. If a curve C_k has $v + 1$ key points and its coordinates are $C_k, 1se_{co,u0}, C_{k,1se_{co}}ul, \ldots, C_{k,ls}e_{co.uv}$, respectively, then the key column of $E_{k,ls}$ can be identified as $E_{k,1se_{co}.u0}, E_{k,1se_{co},u1}, \ldots, E_{k,1s}e_{co.uv^\circ}$. Aiming at the key point extraction of a given plane curve $C_{k,ls}$, we use the algorithm introduced in this paper. Moreover, more refined key point extraction algorithms are introduced in, but they may cause more serious computational overhead.

We assume that now we have identified $v + 1$ key columns, which are the $u_0, u_1, \ldots u_v$-th matrix column, through the parameterized representation $E_{k,ls}$ of a matrix form of a comprehensive reasoning source $P_{k,ls}$, where $1 = u_0 < u_1 < \cdots < u_v \$\$ = \mathrm{col}\,(E_{k,ls}), s = 1, 2, \ldots, n.$ Therefore, we can define the capacity equality operator of the comprehensive reasoning source ∇_t^e as follows:

$$\left(\nabla_t^e\left(E_{k,l_s}\right)\right)\mathbf{e}_{t,i} \triangleq E_{k,l_s} e_{\mathrm{col}\left(E_{k,l_s}\right),\theta}, \quad i = 1, 2, \ldots, t. \tag{16}$$

Among them,

$$\theta = \left[u_j + \frac{u_{j+1} - u_j}{[t \times (j+1)/v] - [t \times j/v]}\left(i - \left[\frac{t \times j}{v}\right]\right)\right];$$

$$\left[\frac{t \times j}{v}\right] < i \leqslant \left[\frac{t \times (j+1)}{v}\right]. \tag{17}$$

$j \in \{0, 1, \ldots, v - 1\}; s = 1, 2, \ldots, n.$ [] is an integer trimming operator. Specifically, if each column of matrix $E_{k\cdot ls}$ is considered to be a key column, we can use a simpler mapping to define the operator ∇_t^e:

$$\left(\nabla_t^e\left(E_{k,l_s}\right)\right)e_{t,i} \triangleq E_{k,l_s} e_{\mathrm{col}\left(E_{k,l_s}\right),\left[i\times\mathrm{col}\left(E_{k,l_s}\right)\right]/t}. \tag{18}$$

Among them, $i = 1, 2, \ldots, t$, and [] is an integer trim function. Based on the definition of ∇_t^e, we can further define a comprehensive inference source knowledge superposition operator ∇_t^f:

$$\nabla_n^f\left(M_1, M_2, \ldots, M_n\right) \triangleq \nabla_n^c\left(\nabla_h^e\left(M_1\right), \nabla_h^e\left(M_2\right), \ldots, \nabla_h^e\left(M_n\right)\right),\quad h = \max\{\mathrm{col}\left(M_i\right)|i = 1, 2, \ldots, n\}. \tag{19}$$

Through the operator ∇_t^f, we can obtain the matrix representation of the superimposed comprehensive reasoning source:

$$E_k \triangleq \nabla_n^f\left(E_{k,l_1}, E_{k,l_2}, \ldots, E_{k,l_n}\right). \tag{20}$$

With this operator, we can further calculate the feature matrix of all comprehensive inference source knowledge:

$$S_k \triangleq E_k - \nabla_n^c\left(\nabla_h^e E_{k,\mathrm{nor}}\right),\quad h = \max\left\{\mathrm{col}\left(E_{k,l_i}\right)|i = 1, 2, \ldots, n\right\}. \tag{21}$$

In the above equation, b, E_k, nor are the matrix representations of standard source knowledge at the k-th level.

According to the user input intensity $w_{k,li,t}$ for different comprehensive reasoning sources, we can calculate the comprehensive reasoning viewpoint matrix:

$$W_{k,t} \triangleq \left(\nabla_n^c\left(\omega_{k,l_1,t}\times I_{h\times h}, \omega_{k,l_2,t}\times I_{h\times h}, \ldots, \omega_{k,l_n,t}\times I_{h\times h}\right)\right)^T. \tag{22}$$

Among them, $h = \max\left\{\mathrm{col}\left(E_{k,li}\right)|i = 1, 2, \ldots, n\right\}$. I_{hxh} is a hxh dimensional unit matrix.

Now, we can generate a comprehensive reasoning feature result $S_{k,r}$ through the comprehensive reasoning process described by the following form:

$$S_{k,r} = \left(\nabla_m^c\left(\left(S_k\otimes W_{k,1}\right)^T e_{m,1}, \left(S_k\otimes W_{k,2}\right)^T e_{m,2}, \ldots, \left(S_k\otimes W_{k,m}\right)^T e_{m,m}\right)\right)^T. \tag{23}$$

In the above equation, $\otimes$ is a comprehensive reasoning simulation operator. If the synthetic reasoning process models human creative thinking as a linear process, then $E_k\otimes W_k = E_k\cdot W_k$, where $\cdot$ is an ordinary matrix multiplication operator. If the comprehensive reasoning process models human creative thinking as a z-order polygon, then $\otimes$ will be defined as follows:

$$A_{p\times q}\otimes B_{q\times r} = C_{p\times r}\Rightarrow c_{i,j} = \sqrt[z]{\sum_{k=1}^{q}\left(a_{i,k}b_{k,j}\right)^z},\quad i = 1, 2, \ldots, p;\ j = 1, 2, \ldots, r. \tag{24}$$

We can also model creative thinking as a geometric average process, as shown in the equation of (25):

$$c_{i,j} = \sqrt[q]{\prod_{k=1}^{q}\left(a_{i,k}b_{k,j}\right)},\quad i = 1, 2, \ldots, p;\ j = 1, 2, \ldots, r. \tag{25}$$

Generally speaking, we can use the comprehensive reasoning model to overload the comprehensive reasoning simulation operator $\otimes$ to achieve the purpose of simulating different types of creative thinking.

Finally, by adding the shape of $E_{k,\mathrm{nor}}$, which is the standard structural element related to the inference result $P_{k,\mathrm{nor}}$ in the process of comprehensive inference, we obtain the parameterized representation $E_{k,r}$: $E_{k,r} = S_{k,r}\otimes\nabla_h^e E_{k,\mathrm{nor}}$ of $P_{k,r}$, where $E_{k,\mathrm{nor}}$ is the matrix form of the parameterized representation of the shape of $P_{k,\mathrm{nor}}$.

The definition of operator $\oplus$ can be overloaded to realize different novel creative thinking activities in intelligent systems. Some simple synthetic reasoning simulation operators for topology constructors are as follows:

(1) The arithmetic mean is

$$T_{k,r} = \frac{1}{n}\sum_{i=1}^{n}\left(T_{k,l_i}\times\omega_{k,l_i}\right). \tag{26}$$

(2) The geometric mean is

$$T_{k,r} = \sqrt[n]{\prod_{i=1}^{n}\left(T_{k,l_i}\times\omega_{k,l_i}\right)}. \tag{27}$$

(3) The harmonic mean is

$$\frac{1}{T_{k,r}} = \frac{1}{n}\sum_{i=1}^{n}\left(\frac{1}{T_{k,l_i}\times\omega_{k,l_i}}\right). \tag{28}$$

The integrated reasoning process proposed in this paper is essentially either a value process or an extrapolation process. In other words, w^i is the interpolation weight or extrapolation weight of $P_{k,l}^i$, and the constraint $\sum_{i=1}^n w^i = 1$ needs to be satisfied here.

4. Analysis of Poetry Style Based on Text Classification Algorithm

In the research of this paper, the judgment of poetry style based on machine learning, that is, the flow chart of the pattern recognition of poetry text, is shown in Figure 1.

The development and design of the system are shown in Figure 2 according to the research and processing sequence.

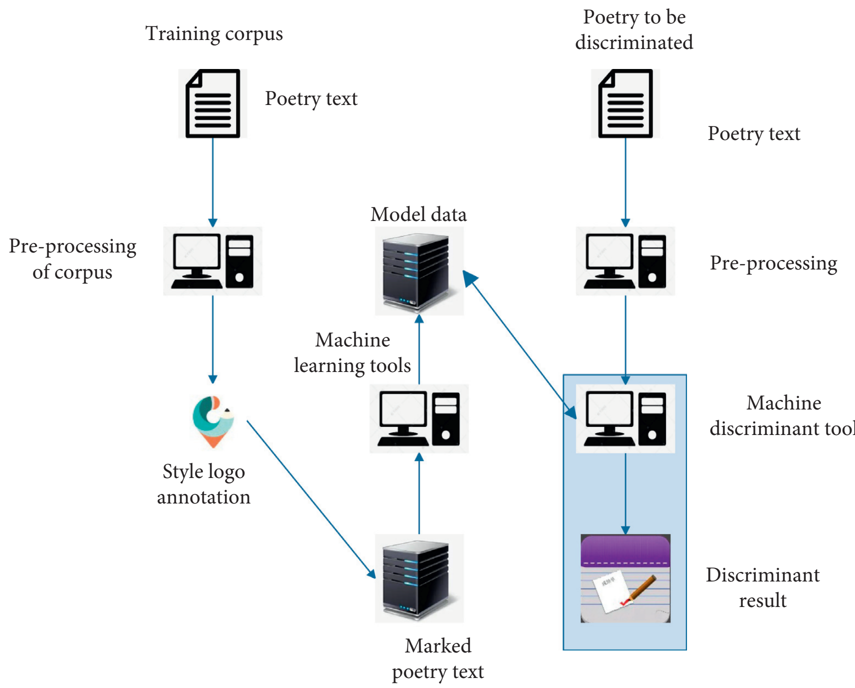

Figure 1: Flow chart of pattern recognition of poetry style.

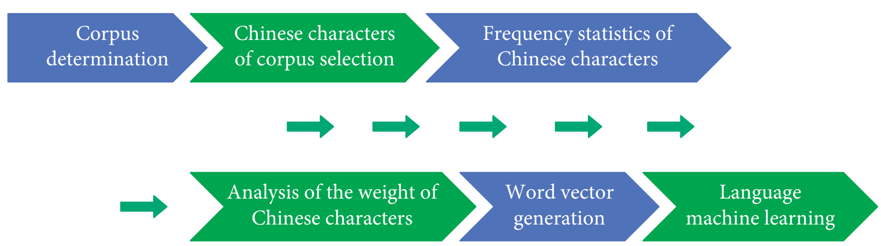

Figure 2: The processing flow chart of poem vocabulary material.

Judging the style of poetry is similar to the general process of text classification. First, the algorithm needs to preprocess the poetry documents in the corpus and then map them to the vector space that can be directly processed by the computer. The algorithm selects the poem documents that have been styled in advance as the training corpus and the test corpus. Subsequently, the algorithm uses machine learning methods to generate model data for style classification. Finally, the algorithm builds a machine judging tool for poetry style on the basis of the model data tested on the test corpus. This tool can judge the style of other poetry documents in the corpus. The flow chart of style evaluation is shown in Figure 3.

Poems are composed of text content and belong to unstructured data. It is difficult to analyze them using quantitative analysis methods. It is necessary to introduce data indicators that can be measured to perform data analysis and processing. The commonly used method is to segment the text content and then count the word frequency data. For high-frequency words such as "Wanli," "Jiangshan," "Dongfeng," and "Twilight" that often appear in poems, they can generally express the emotional bias and style characteristics of the poet's choice of poetry imagery. In order to classify and aggregate the genres of poets and poets, this paper mainly uses the method of high-frequency word statistics to classify and aggregate the style characteristics of the poets. The cluster analysis of word style is shown in Figure 4.

In order to obtain word vectors with more efficient algorithms, Word2Vec can efficiently train on millions of word lists and hundreds of millions of datasets. The obtained training result-word vector can well measure the semantic relevance and similarity between words. Word2Vec includes two network models: CBOW (Continuous Bag-of-Words) model and Skip-Gram model. The network structure is shown in Figure 5. Skip-Gram can be seen as the reverse process of CBOW. The essence of the CBOW model is a feed forward neural network language model (Feed Forward NNLM).

RNN is a neural network designed specifically for serialization problems, and its basic network structure is shown in Figure 6.

This article summarizes the sequence learning methods of the above two statistical language models. The framework

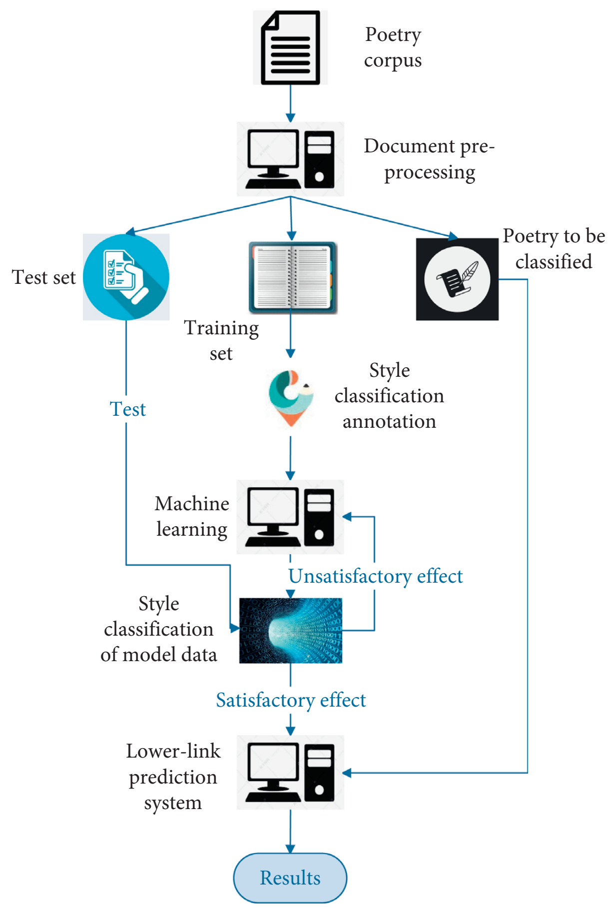

Figure 3: Poetry classification process.

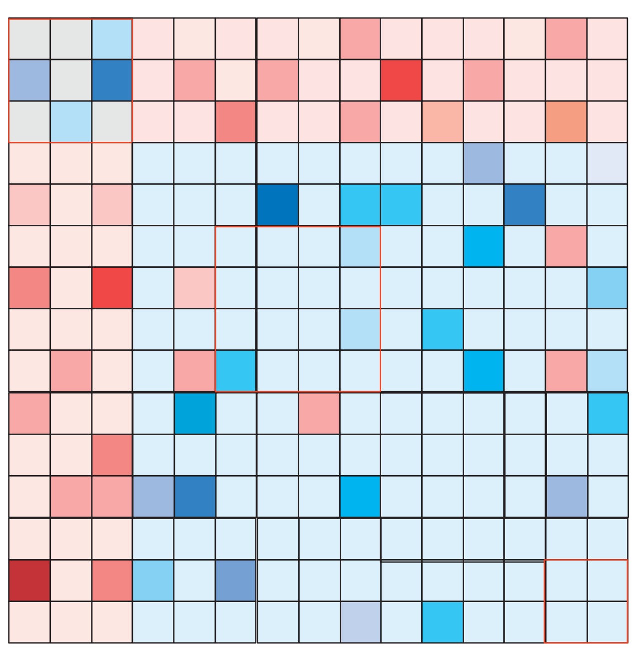

Figure 4: Cluster analysis of word style.

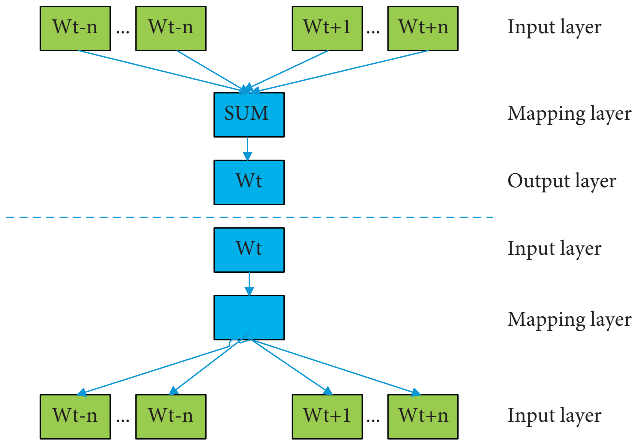

Figure 5: Structure diagram of CBOW and Skip-Gram model.

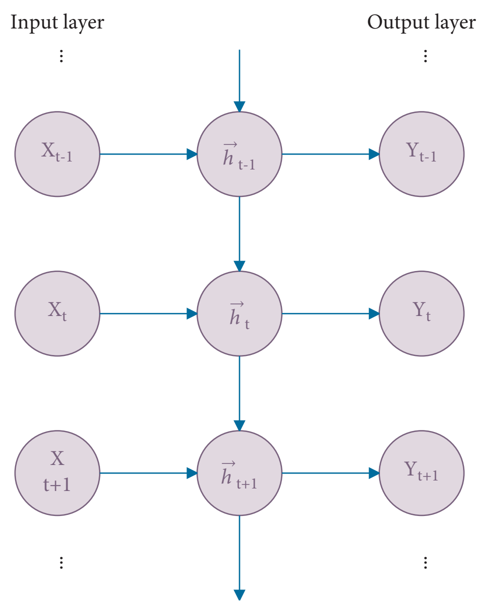

Figure 6: Basic network structure diagram.

of the joint language response model based on statistical learning is shown in Figure 7.

In the research of this paper, Brill's conversion learning method is used to cope with the generated context-sensitive rules in conjunction with the language. The flowchart of the learning algorithm is shown in Figure 8.

The text visualization technology is mainly composed of three modules: text analysis and processing, visual design presentation, and interactive design, as shown in Figure 9. First, the algorithm collects text information, preprocesses data and expresses knowledge, and transforms it into a corresponding structured data format. Then, the algorithm visually presents the information with graphics and color elements through visual coding. In the visual presentation, the algorithm should provide users with effective and reasonable visual presentation and interactive operations based on the user's cognitive characteristics. At the same time, the algorithm performs data operations on the visualized information elements through a reasonable interactive method to facilitate users to quickly and clearly understand the displayed information content, thereby realizing a complete visual design implementation process.

After constructing the above model, the effect of the model is verified, and the system function is verified based on actual needs. Moreover, this paper combines the simulation test to verify the effect of the poetry text classification and the poetry style verification of the system of this paper. The poetry text classification is shown in Table 1 and Figure 10.

From the above research, it can be seen that the poetry style analysis method based on the text classification algorithm proposed in this paper has a good classification effect. The experimental results of the poetry style analysis are shown in Table 2 and Figure 11.

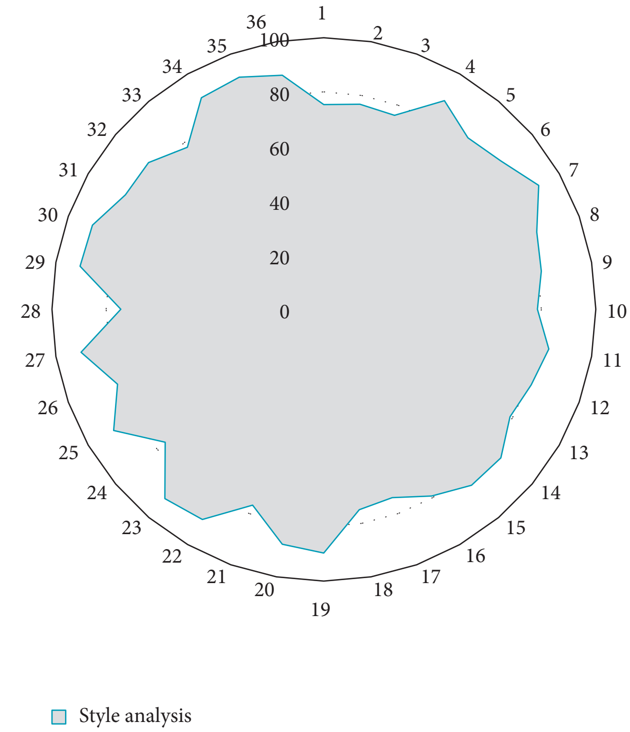

FIGURE 11: Statistical diagram of the effect of poetry style analysis.

From the above research, the effect of the poetry style analysis method based on the text classification algorithm proposed in this paper is very good, which meets the actual needs of poetry style analysis.

5. Conclusion

Before the classification of poetry text begins, the algorithm needs to represent the unstructured document data into a data form that the computer can understand. This requires the algorithm to perform corresponding preprocessing and feature representation of the document first and convert the unstructured or semistructured data form into a structured data form that can be processed by the computer. This includes a series of processes such as word segmentation, filtering of low-frequency words and forbidden words, feature representation, and feature extraction. The so-called word segmentation is to add a separator between each entry in a Chinese document to convert the continuous character stream form of the Chinese document into a discrete word stream form. At present, the main word segmentation methods used are forward and reverse maximum matching method, word-by-word traversal method, best matching method, and word frequency statistics method. In addition, there are two-scan method, adjacency constraint method, and so on. This paper applies the text classification algorithm to the analysis of the style of poetry and constructs an intelligent classification system. From the research results, it can be seen that the poetry style analysis method based on the text classification algorithm proposed in this paper is very effective and meets the actual needs of poetry style analysis.

Data Availability

The labeled dataset used to support the findings of this study are available from the corresponding author upon request.

Academic Editor: Tongguang Ni

Slow reading speed is a common problem among Chinese college students' English learning, limiting the amount of reading done and thus directly affecting English-level improvement. Teachers in English classes place a premium on improving students' reading skills but the results are not immediately apparent. Even if many students have strong vocabulary and grammar skills, they will never be able to read English fluently. Teachers should prioritize not only students' knowledge acquisition and intelligence development but also the development of students' interpersonal skills and emotional intelligence in order to maximize their potential. This paper uses multimedia technology to investigate the role of multimedia technology in improving college English-reading efficiency and analyzes how teachers and students can play a positive role in improving the efficiency of college multimedia teaching using data mining technology, which shows that students' predictive reading skills can help them improve their reading efficiency. Teachers can also supervise and ask questions about students' learning progress via computers, communicate effectively with students, and provide timely feedback on students' learning results using multimedia technology.

1. Introduction

The rapid development of the economy and society is inextricably linked to the advancement of teaching activities and the innovation of teaching methods. Multimedia has permeated primary and secondary school classrooms in most areas as IT has matured, from tape recorders, slides, and physical projectors in the 1990s to today's network equipment, liquid crystal screens embedded on blackboards, and so on [1]. Teachers' teaching concepts and students' learning concepts both change as teaching media technology evolves [2]. As a result, we must improve the quality of teaching in the interaction between teachers, students, and the media. The positive role of teachers and students in transforming the benefits of multimedia teaching into the benefits of teaching quality is critical. Traditional teaching content and methods are insufficient to meet the demands of modern higher education, necessitating fundamental changes [3]. The traditional basic theory should be retained within the specified class hours, while new content should be increased, and the contradiction between more content and fewer class hours is becoming increasingly apparent [4]. Multimedia has become widely used in College English Teaching (CET) as a result of the advancement of computer technology and the popularization of scientific and technological applications, as well as the deepening of English teaching reform [5]. Realizing the informatization of teaching content, the strategization of teaching processes, the modernization of teaching means, and the networking of teaching resources to improve educational quality and promote the all-round development of students' mind and body quality has become the torrent of the general trend of English education [6].

Cultivating strong reading ability is always the primary task of CET. Its purpose is to enable students to use English as a tool to obtain the required professional information [7]. Educational informatization is the core feature of educational modernization, which means making full use of multimedia network to develop education in the information environment

[8]. With its outstanding advantages, multimedia teaching mode has been unanimously recognized by the majority of teachers and students. Nowadays, universities and even high schools begin to use multimedia technology to carry out teaching work. Although multimedia technology has been applied in teaching for many years, it has not reached the expected goal in terms of teaching efficiency and effect [8]. The core task of educational informatization is to build information-based educational resources. Under the guidance of scientific teaching mode, use information-based teaching means to cultivate excellent information-based talents needed by the society and develop educational informatization industry [9]. The problem of slow reading speed is common among Chinese college students' English learning. It restricts the amount of reading and directly affects the improvement of English level [10]. Based on multimedia technology, this paper studies the role of multimedia technology in improving college English-reading efficiency, analyzes how to give full play to the positive role of teachers and students to improve college multimedia teaching efficiency, and explains the role of students' prediction skills in reading in improving their reading efficiency.

In ordinary English teaching, teachers also attach importance to the improvement of students' reading ability, but the effect is not obvious. The result is that although many students have considerable vocabulary and grammar skills, they cannot become a fluent English reader [11]. For reading, efficiency is therefore important but speed is also another standard to measure reading ability [12]. Teachers recognize that a single language analysis and skill training cannot meet students' English needs, and they begin to prioritize the development of students' comprehensive ability to use English [13]. They also begin to prioritize the research of new teaching strategies, the change of traditional methodology, and the cultivation of students' comprehensive ability to use English. To ensure the normal operation of social order, informatization talents make full use of educational informatization resources to develop and improve informatization laws, regulations, and policies [14]. The educational cause is constantly developing, and the level of educational informatization is gradually improving in a virtuous educational cycle. Multimedia technology aids in the memorization and storage of educational material. It can store a large amount of teaching data, including various types of teaching content, test questions, statistical data, and so on, and it can be accessed by teachers and students at any time [15]. Multimedia technology can be used in the classroom to create an on-site teaching environment, make students feel immersed, not only increase students' interest but also help them understand and master knowledge, and improve teaching effectiveness [16].

The following is how the rest of the paper is structured: Sections 2 and 3 review the study's related work, Sections 3 and 4 describe the paper's methodology, Section 5 presents the experimental results and analysis, and Section 6 summarizes the findings.

2. Related Work

Teachers in traditional classrooms frequently attempt to accomplish this goal by carefully preparing the introduction or reading the text aloud. Students can be quickly immersed in the situation related to the artistic conception of the text using multimedia to play a piece of music or an image related to the artistic conception of the text. Silence can be turned into sound, complexity into simplicity, micro into macro, and abstraction into image with multimedia teaching, resulting in the best teaching environment and arousing students' strong learning interest. According to Bai [17], there are two basic criteria for evaluating classroom teaching optimization. One is the effect standard, which states that each student has attained the highest level of teaching, education, and development that he was capable of achieving during this time period. In a college English-listening class, Yao and Scheepers [18] use fragmented learning based on multimedia technology. Ma [19] conducted a feasibility study on multimedia-based college reading learning. By combining students' purposeful fragmented learning with teachers' classroom teaching, Proctor et al. [20] provide an empirical study on the integration of IT and English curriculum. Richards-Tutor et al. [21] used data mining (DM) technology to analyze the online learning process, laying the groundwork for mobile personalized learning research using DM technology. You et al. [22] develop an open-source adaptive hypermedia system through adaptive navigation support and adaptive presentation technology, establishes a user model based on the user's cognitive level and user's access status data, and users can set the rules of their own user model to realize adaptive recommendation of learning content and navigation. Gottardo et al. [23] propose to mark learning content, learner model, and learning strategy with metadata marking method, so as to formulate adaptive learning rule engine. Reading teaching is that students learn one text after another on the basis of literacy, and its ultimate goal is to make students become independent readers and masters of learning [24]. The research on teaching strategies and teaching effects of multimedia-assisted resources is abundant, and the effect of multimedia-assisted teaching is fully affirmed. However, there are still a few teachers who cannot give full play to the auxiliary role of multimedia-assisted resources, and more efforts should be made in the training of teachers using multimedia-assisted teaching resources and the autonomous learning of students using auxiliary resources. Based on DM technology, this paper dynamically tracks the learning behavior and records the learning track in real time and then analyzes the positive significance of multimedia for improving college English reading efficiency.

3. Characteristics of Multimedia Teaching

Multimedia teaching that incorporates computer and network technology can not only complement traditional teaching but also provide benefits that traditional teaching cannot. The ability to optimize classroom teaching is becoming increasingly apparent thanks to modern multimedia technology. The development of people, particularly the development of personality, is at the heart of optimization theory. Text, pictures, sounds, images, and other different media information are all combined in multimedia teaching, making it more concrete and vivid than traditional blackboard or single media teaching [25]. The task of comprehensively solving the tasks of students' academic achievement, language practical application ability, and intelligent development is at the heart of CET optimization. Dealing with the relationship between time, energy consumption, and educational effect is the key to success. Multimedia technology's main purpose is to present various types of information to students, such as words, images, and sounds, using computer technology and automation technology, which is a new modern teaching method. Traditional teaching methods cannot be realized solely from this perspective. The reform of traditional teaching methods will greatly improve current education and teaching efficiency precisely because of the obvious advantages of multimedia teaching in these aspects.

You can prepare and make courseware in advance as a teacher during lesson preparation. As a student, I sometimes have trouble hearing the teacher's questions clearly, and my notes are incomplete or absent-minded. The use of multimedia technology can also help to improve the effectiveness of instruction. Multimedia instruction is a type of audio-visual instruction. It can attract students' attention and improve students' interest in learning through an effective combination of pictures and sounds, resulting in the best teaching effect [26]. As a result, multimedia technology is closely linked to improving classroom teaching. Multimedia teaching makes use of a computer network's connection point, allowing teachers and students to communicate with each other outside of the classroom at any time and from any location. In comparison to traditional single-mode teaching, multimedia teaching fundamentally alters traditional methodology by making the teaching process multidimensional, integrated, and interactive, which aids students in understanding and remembering the content and improves the teaching effect.

4. Application of Multimedia Technology in Reading Teaching

4.1. Enrich Reading Teaching Resources. Multimedia expands the breadth of reading teaching resources. The understanding of the article cannot be interpreted only from the text itself. Only through the introduction of the author's life and writing background, the comparison of related articles and the comments of others can we grasp the text from a higher angle. A courseware is like a movie, and it is often easier to design an excellent script because of the accumulation of teaching plans for many years. However, how to embody the intention and teaching ideas of scripts in courseware is not so easy, which is why the courseware written by a professional software designer according to the teacher's teaching plan often fails to achieve satisfactory results [27]. One-way communication of too many perceptual materials can strengthen stimulation, but it is also easy to cause sensory fatigue, which in turn leads to inhibition. Students are the main body of classroom teaching. In teaching activities, students' active thinking activities are the guarantee that the cognitive process can be effectively completed. Teachers should make effective use of the technical features of multimedia, such as expressiveness, controllability, and participation to guide students to participate actively.

In traditional teaching, English teachers only have limited resources for teaching reference and accumulated knowledge by themselves, and students can involve fewer resources. The process of resource sharing is often one-way. Multimedia teaching has completely broken this limitation. Teachers and students are faced with a great deal of relevant knowledge. Students have the ability to collect the resources related to texts in advance and do more extensive reading after class. The core elements and relationships of the model of co-creation and communication of multimedia educational resources are shown in Figure 1.

Multimedia teaching is the future development trend in education and teaching methods, and the quality of instruction will inevitably improve, with students being the primary beneficiaries. Students' primary role becomes more important as external objective learning conditions become more prevalent. Teachers must guide students to closely follow the text and read, as well as use multimedia to expand reading, to prevent students from becoming lost in the vast amount of information available on the Internet. The preview content assigned by the teacher should be closely related to the text as an aid to classroom teaching, such as clearly pointing out where the text's background, author's life, and other people's comments on this article can be found. Students' learning concepts should change in tandem with the advancement of modern educational technology, from text reading to hypertext reading, from hand-drawn to hypertext structure conception and writing. The multimedia teaching process essentially aligns with people's cognitive processes from perceptual to rational, allowing students' perceptual processes to be accelerated and cognition and understanding to be deepened. However, some students may struggle to adjust to the significant increase in classroom teaching information. Then, students should work on honing their ability to process a large amount of data. We discovered that in the past, film projection was used to deliver all of the teaching content at once. Although the amount of information was increased, different students' attention was easily dispersed on different information, resulting in an out-of-control small-scale teaching. Students can easily concentrate their attention by taking notes and thinking along with teachers' teaching ideas in traditional blackboard writing teaching, but the amount of information taught is relatively small. The research and practical application of multimedia teaching theory should be prioritized in schools. We should fully comprehend the multimedia teaching mode and make a greater breakthrough through continuous research against the backdrop of modern education and teaching theory.

Sustainability is the standard for judging the quality of teaching, transformation system, and subsystem. Based on the development speed of each subsystem:

$$D_i = a + \sum_{j=1}^{n} b_j p_j + r_i Y + u. \tag{1}$$

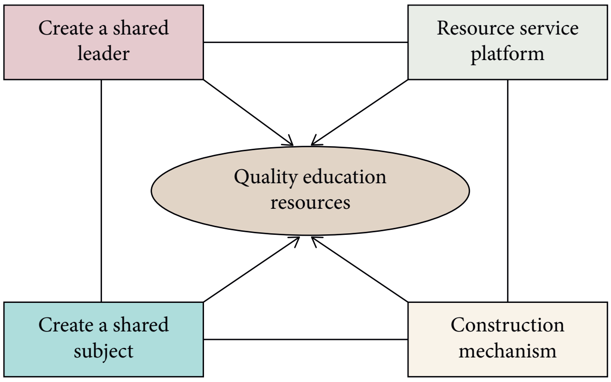

Figure 1: Educational resource sharing model.

Use clustering algorithm function method to find

$$D_i = a + \sum_{j=1}^{n} b_j \ln\left(p_j\right) + r_i \ln(Y) + u. \tag{2}$$

The calculated trend degree is

$$\ln\left(D_i\right) = a + \sum_{j=1}^{n} b_j \ln\left(p_j\right) + r_i \ln(Y) + u. \tag{3}$$

The traditional reading teaching resources are mainly words, supplemented by pictures, tapes, and other devices that can help students understand. In the process of multimedia teaching, these single media forms are compounded, and other forms such as animation, video, online courses, and online study groups are added on this basis, which innovates the means of reading teaching and makes the flat teaching method three-dimensional and comprehensive. Feedback can help teachers know the students' learning attitudes and emotions, the students' acceptance of multimedia teaching methods, the students' learning achievements, and other information in time. Feedback provides the basis for teachers to adjust and control various teaching designs including teaching degree, teaching progress, and teaching methods.

4.2. Improve Students' Reading Enthusiasm. Creating problem situations and implementing heuristic teaching is one of the most stimulating conditions for learning motivation. Students can assimilate new knowledge by applying their existing knowledge and experience in a real-world setting. Multimedia teaching is the future development trend in education and teaching methods, and teaching quality will inevitably improve, with students being the primary beneficiaries. The main role of students becomes more important as the external objective conditions of learning become more important. All human activities are dominated by needs, motives, and interests, according to psychology studies. Students' learning concepts should change in lockstep with the advancement of modern educational technology, from text reading to hypertext reading, from hand-drawn to hypertext structure conception and writing. The multimedia teaching process is designed to align with people's cognitive processes as they progress from perceptual to rational, allowing students to accelerate their perceptual processes and deepen their cognition and understanding. The implementation process of mixed English reading teaching based on multimedia technology is shown in Figure 2.

Students should approach the challenges posed by modern educational technology with optimism. On one hand, teachers should avoid situations in which students do not consider searching for answers directly on the Internet, such as writing extracurricular reading exercises by themselves based on the current situation of students in our school, or exercises after class that are primarily open-ended questions. On the other hand, to maintain communication and interaction, it is necessary to provide timely feedback to questions raised by students in the online learning platform. The main goal of multimedia teaching is to increase teaching efficiency and quality, so that students who are learning subjects can achieve high levels of learning efficiency only by giving it their all. According to modern teaching philosophy, class time should be reduced, and more time should be set aside for students to practice and think. An effective multimedia teaching process can effectively reduce classroom teaching hours, provide more time and space for students to learn independently, and increase the degree of freedom for students to design their own learning experiences. Students can independently search for a large number of reading materials and find out what they are interested in with multimedia, as long as the teacher chooses the theme. As the contents chosen by each student may differ significantly, students may experience double or even multiple reading effects as a result of their communication. Figure 3 shows a path analysis model for the construction dimension and learning effect of the English reading teaching environment.

Set up indicators for teaching quality evaluation. Describe them as the following quantitative comprehensive evaluation matter-element models:

$$\mathrm{CPV}(k) = \frac{\sum_{j=1}^{k} \lambda_j}{\sum_{j=1}^{m} \lambda_j}. \tag{4}$$

The matter-element model formed by the allowable value range of each index in the comprehensive evaluation of teaching reform is called the node-domain matter-element:

$$F_{ik} = \sum_{j=1}^{m} q_j x_{ij}. \tag{5}$$

Express the detected data or analysis results with matter elements:

$$f(t) = \sum_{j=1}^{N} \sum_{k \in Z} d_k^j \phi_{jk}(t) + \sum_{k \in Z} c_k^N \phi_{Nk}(t). \tag{6}$$

Use the weight coefficient of each feature to calculate the relevance of the teaching quality evaluation reform on the grade:

$$E_{mi} = \sum_{i=1}^{k} (i\Delta t) \cdot \left|S_{mi}\right|^2. \tag{7}$$

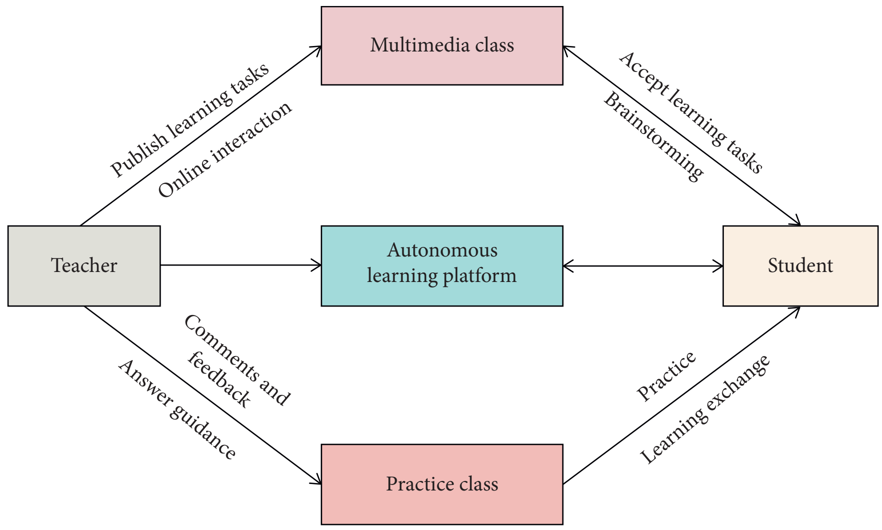

Figure 2: Blended English reading teaching.

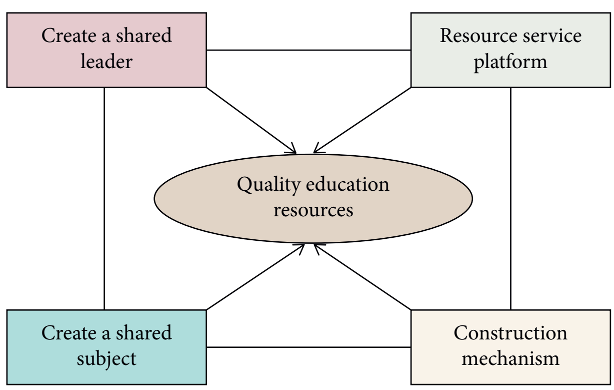

Figure 3: Path analysis model.

Students should actively cultivate their ability to acquire knowledge through various media in school so that they can continue to enrich and update their knowledge through various media once they leave school. Reading instruction can be made more orderly with the help of multimedia technology. Multimedia technology can assist teachers in providing reading instruction to students. Multimedia provides more possibilities for reading teaching as science and technology progress and teaching levels improve. Students can gain intuitive visual experience by transforming abstract images into concrete ones. Teachers can show students pictures of beautiful scenery during the course introduction to encourage students to love the motherland and nature when writing prose or poetry that depicts scenery. The primary goal of multimedia teaching is to increase teaching efficiency and quality, so that students who are learning subjects can achieve high levels of learning efficiency only by fully committing themselves.

5. Result Analysis and Discussion

Based on the teaching principle of constructivism, the teaching process is no longer a unilateral knowledge infusion, but the classroom is constructed by teachers and students. College English learning should create a real English-learning environment for learners with the support of multimedia network technology. In the real English-learning environment, learners re-organize and transform their own knowledge and experience and actively construct meaning to acquire new knowledge. The design of multimedia CET resources should conform to students' cognitive development level and psychological development law and design and select college English-teaching resources based on a full understanding of students' cognitive level and interests.

After the parameters are adjusted, the data flow quickly reaches a steady state. The initial rotation is too large, which may result in excessive data flow. Perform three sets of data testing and statistical results, as shown in Figure 4.

The main evaluation object and criterion for judging students' reading effect is the traditional teacher of reading teaching evaluation. It can be said that when the teacher is absent, the evaluation process becomes more difficult. However, when using multimedia reading instruction, the appropriate teaching software can be preprogrammed. After class, students can complete reading exercises based on the software's prompts, checking pronunciation, words, text comprehension, and other factors. The software can also make a corresponding evaluation on students' answers and enter different links, which not only saves teachers a lot of time revising exercises and explaining basic concepts but also allows students to receive evaluation feedback quickly after completing the questions. It is possible to generate and collect big data in the classroom, and it is critical for teachers to fully explore and practice these data. The simulation of multimedia education teaching design is analyzed from various angles during the teaching stage, using multimedia technology. The experimental results of three experiments are shown in Figure 5.

According to constructivist teaching theory, students' language skills must be acquired through a process of meaning construction, and learning a language in a real-world setting is the most effective method. Students benefit from the use of teachers' multimedia technology to create a

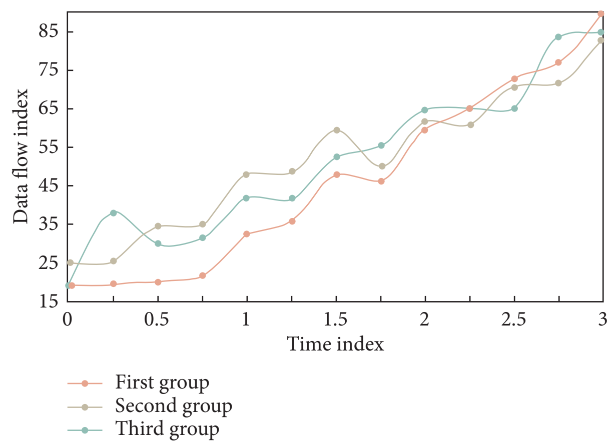

Figure 4: Data impact over time.

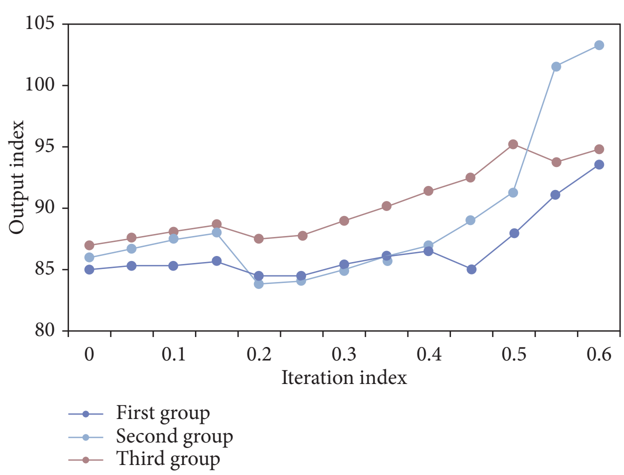

Figure 5: Iteration value and output relationship.

realistic learning environment. Students construct the meaning of knowledge and practice listening in this authentic language learning environment, which includes both visual and auditory stimuli. Multimedia teaching is an auxiliary teaching method in CET. Although multimedia technology can effectively improve the teaching effect in the classroom, teachers should still be in charge; multimedia technology can only serve as a technical auxiliary means for teachers to play the lead role. They can only assist teachers rather than replace them, and they cannot take over teaching responsibilities. A stage test should be conducted after the first stage of English reading instruction with multimedia is implemented. The test results serve as a foundation for not only evaluating students' learning effects at this stage but also for adjusting strategies at the next stage. The test results are shown in Figure 6.

According to the traditional way of reading evaluation, if teachers want to evaluate students' reading effect, they must do it in the classroom. However, using multimedia reading teaching and setting up an online learning platform, students can upload their collected reading materials and completed reading exercises to the platform, and teachers can give feedback immediately. For universal

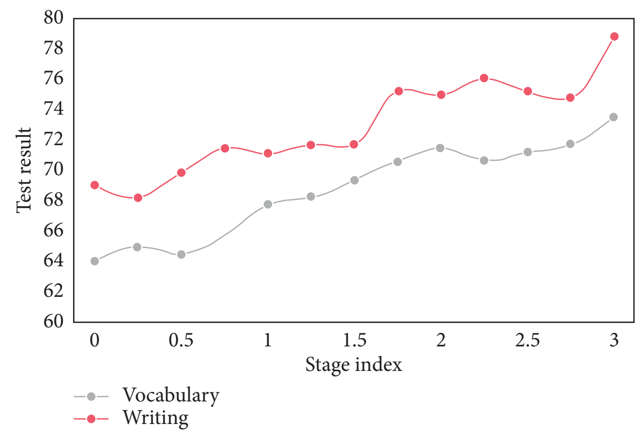

Figure 6: Comparison of achievements.

incomprehensible problems, teachers can also summarize them and re-emphasize them in class to deepen students' impression. Based on the developmental evaluation theory, multimedia-assisted CET resources must attach importance to the interest of the teaching process in the design process, so that students can experience the beauty of the teaching process, stimulate students' interest in learning and cultivate students' learning motivation. Teachers should inherit the essence of traditional methodology, seize the opportunity brought by modern IT revolution, give full play to the characteristics of traditional teaching methods and modern multimedia technology, complement each other, make full use of modern IT, such as multimedia and network, and promote the effective application of new teaching mode.

In CET, if the multimedia teaching system can be properly used to solve the audio-visual and other related teaching problems in English teaching, students can acquire basic English knowledge in a limited classroom, and at the same time, their basic language skills can be trained, thus achieving the real purpose of applying multimedia-assisted teaching system to CET. The results of the evaluation index parameters of reading teaching level can be regarded as the research object, and data clustering and information fusion are carried out. The evaluation results are shown in Figure 7.

The English proficiency test scores of the students in the experimental class and the control class were obtained, and the relevant data were statistically analyzed by statistical software. After the experiment, compare the class scores again. The results of the two classes before and after the experiment are compared as shown in Figure 8.

It shows that multimedia technology is of positive significance to improve college English prediction skills and reading efficiency. Using multimedia technology, teachers can also supervise and ask questions about students' learning progress through computers, communicate effectively with students and give timely feedback to students' learning results. Teachers can give students visual and auditory information through their own pronunciation, intonation, and expression, and then use the illustrated forms of multimedia to arouse their emotional resonance. With the support of multimedia technology, these advanced organizers are presented in the form of visual and dynamic images and videos, which changes the traditional

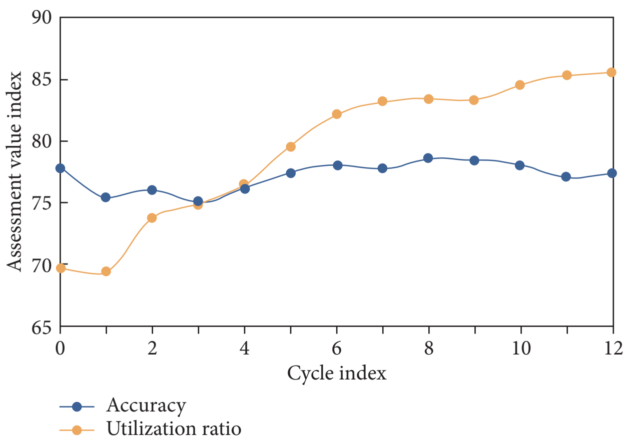

Figure 7: Evaluation test results.

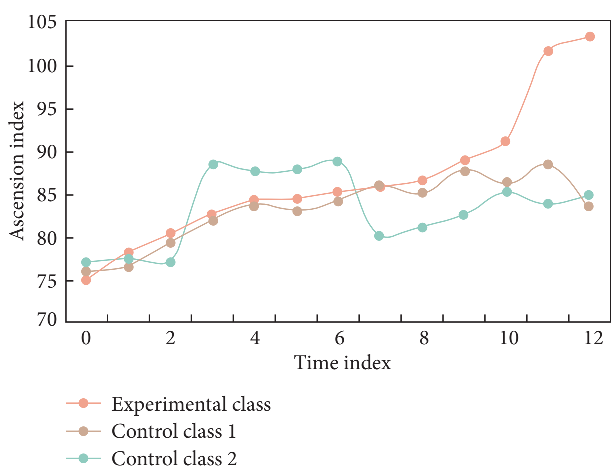

Figure 8: Comparison of results before and after the experiment.

presentation in the form of words and makes it easier for students to connect and integrate new and old knowledge, understand and master new knowledge in the process of learning new knowledge.

6. Conclusions

Education modernization is a widespread trend, but it must not become a form of zealous and blind pursuit. Instead, we should prioritize students' actual needs and implement multimedia instruction with the goal of improving students' reading efficiency. Improving the efficiency of reading instruction is not a simple task. The proper use of audio-visual media, on the contrary, has been demonstrated in practice to effectively stimulate students' learning subject consciousness, arouse their interest in learning, and achieve good teaching effect. Students construct the meaning of knowledge in this real-world learning environment using both visual and auditory stimuli, while teachers monitor students' learning progress and effect using multimedia-assisted teaching resources. The design of college English-assisted teaching resources should be based on the teaching principles of "student-centered, process-oriented, communication-oriented, and people-oriented," giving full play to the advantages of IT and multimedia resources in the educational information environment. We can only improve teaching efficiency and quality by organically combining multimedia technology, teachers' leading role, and students' main role. The breadth and depth of this study have some limitations, and some issues in the detailed explanation and discussion need to be investigated further in order to realize the optimization of college English classrooms in a multimedia technology environment.

In order to improve the effect of spoken English training, this paper combines multimedia information technology to reform the teaching of spoken English training, and integrates BP neural network English into spoken English training. Moreover, this paper combines the actual needs of spoken English training and the teaching framework of the multimedia system to construct the data set, clean up the data set, and implement the word vector representation of students and professionals. In addition, this paper constructs the entire system framework of the spoken English resource recommendation algorithm based on the graph convolutional neural network, and combines the BP deep neural network algorithm to construct the spoken English training system. Finally, this paper designs an experiment to evaluate the effect of this system. The experimental research results show that the multimedia based on the BP deep neural network proposed in this paper has a good effect in the application research of spoken English training, and can effectively promote the effect of spoken English training of students.

1. Introduction

Oral expression ability, as an important English language skill, promotes the formation of students' English pragmatic competence, and is also an important manifestation of the function of English communication tools. Therefore, it has attracted great attention from teachers and students [1]. In particular, in the current college English classroom, teachers increase the intensity of the students' oral expression training, and hope to seize the golden period of language ability formation at the university stage to lay the foundation for the development of students' oral expression ability [2]. However, many teachers find that students lack enthusiasm for oral training in English classrooms, and their participation is generally low, which leads to unsatisfactory oral training effects, and the students' oral level is not improved. In view of this situation, teachers need to take a variety of measures to explore the reasons for the students' problems in spoken English training, design oral training strategies suitable for students, and improve students' spoken English level [3].

With the continuous development of the times, in order to cultivate more useful talents for the society, we also deeply realize that the teaching activities of teachers must closely follow the pace of the development of the times, so as to provide more effective guidance for students. English teaching can be divided into four teaching sections: listening, speaking, reading and writing. With the continuous development of the times, we have to admit that the ability of students to "speak" is becoming more and more important. However, as far as the current college spoken English teaching is concerned, there are still some problems that affect the further improvement of students' oral ability. Therefore, this paper makes a simple analysis on it.

For university students, there is also a factor that affects the improvement of students' oral English in the learning of oral English, that is, the students' oral foundation is relatively weak. Spoken language learning, especially for college students, does not start from scratch. Therefore, students will be affected by their existing oral language skills in the process of oral learning. Students generally do not dare to speak, inaccurate pronunciation and other phenomena. Students can use English for flexible communication requires a long-term practice process, and the first step is for students to have the courage to "speak" and boldly communicate in English. Only when students have the courage to speak, can they truly go out of spoken English learning. first step. However, college students generally do not dare to "speak". Students are afraid of inaccurate pronunciation and fear of saying wrong. This kind of fear of students has seriously affected the improvement of students' oral English ability. Oral English learning is different from the learning of other English knowledge sections. Only in a certain environment can students truly achieve the purpose of oral practice, and only in a certain environment can students' oral ability be truly improved. As far as the current oral learning of university students is concerned, there is no specific environment for students to practice a lot of oral English. Students' oral practice is only limited to classroom conversations or some English activities organized by the school. In fact, this is far from enough for students' oral practice.

For improving the current situation of college students' spoken English, it is crucial to pay great attention to spoken English. Teachers should pay attention to spoken English teaching, and students should pay attention to spoken English learning. First of all, teachers need to pay attention to spoken English teaching. This requires teachers to change the traditional English teaching concept and take the new teaching concept as the guide. Moreover, teachers should not only pay attention to teaching students in other parts of English, but also pay attention to oral teaching to students, and be able to introduce effective spoken English teaching methods into classroom teaching to improve the effectiveness of spoken English classroom teaching. In addition, teachers should make students understand the importance of spoken English teaching, and spend part of their English learning time on spoken English learning.

This paper combines the BP deep neural network algorithm to construct an spoken English training system to improve the intelligent effect of spoken English training, and evaluates the performance of the system through experimental research.

2. Related work

Literature [4] believes that programmed language is "a part of automatic or semi-automatic memory reserve, even through the screening mechanism of dividing these words, they are still automatically stored". Literature [5] believes that spoken language is a series of words that people habitually use together. Literature [6] proposed that spoken language is a way for the sharing of words in natural texts to reach a statistically significant number: from the perspective of language programming, Wray's term "programming language" has a far-reaching impact. Formula language refers to: it is a combination of continuous or discontinuous words or other elements, is orderly and prefabricated: it is stored and retrieved as a whole in the process of language use, and is not affected by the generation and analysis of grammar Influence. Literature [7] proves that word chunks are cognitively processed as a single vocabulary unit. Moreover, word blocks are learning materials suitable for human cognition.

Literature [8] pointed out that there are a large number of lexical sequences ylJ (sequences) in English, and a large number of prefabricated sentences of this kind exist, which explains to us why the language of second language learners can be "as fluent as native speakers." And the answer to "choose like native speakers". Literature [9] pointed out that many of the native language users' knowledge are spoken languages that are not required and impossible to analyze outside of grammar. He explained that communicative competence is actually the ability to master a large number of assembled structures, formulaic formulas and a set of rules, and be able to make necessary adjustments according to the context. Literature [10] believes that language is not composed of traditional grammar and vocabulary, but composed of multi-word prefabricated spoken language. Literature [11] pointed out that the degree of language fluency is determined by the amount of programmed language stored in the brain's memory, rather than by the knowledge of grammar. Literature [12] pointed out: learning spoken language is more important than learning grammar, language knowledge is spoken knowledge to a considerable extent, and grammar is second. Literature [13] believes that spoken language is the basis of second language learning, and the teaching of common phrases (stock phraSe) in language teaching should be as important as vocabulary and grammar teaching.

Literature [14] studied the differences between college students and middle school students in the use of spoken English, and pointed out the wrong ways of using spoken English by students. Chinese English learners seldom use multiple words and idioms in oral English, and there are differences in the frequency of use of phrase structure and sentence structure. There is a significant difference between the oral language use of domestic speakers and English speakers. There is no significant difference between college students and middle school students, while the oral language use of college students is significantly higher than that of middle school students. Spoken language errors in oral communication include mother tongue transfer errors, acquisition errors, and redundancy Errors, mixed use errors, etc.

Literature [15] believes that: in the aspect of language learning, oral input can reasonably configure the cognitive resources of information processing; in the aspect of oral language, prefabricated oral language can help to communicate meaning first and coherently; in the aspect of reading, oral language is effective Prefabrication can process low-end information more quickly, thereby speeding up reading; in terms of writing, spoken language has a good effect on preserving short-term memory, and can vividly express one's thoughts in words. Literature [16] believes that the richer the storage of spoken language, the more proficient in calling the spoken language, which has a positive impact on all aspects of language learning, listening, speaking, reading and writing. Literature [17] pointed out: oral language also has its own limitations. In language learning, oral input cannot be one-sidedly emphasized, while grammar and other indispensable aspects of language learning are ignored. It is necessary to ensure that learners can stay in language learning for a long time. In order to make progress, only by correctly handling the direct relationship between oral input and grammar, and making up for each other's shortcomings, can the various abilities of the language develop in a co-ordinated manner. Literature [18] did research on whether the use of spoken language affects spoken English and writing. It is believed that the use of spoken language can affect students' English spoken and written scores, and the impact is greater. Compared with grammar knowledge, spoken language is in the structure of English knowledge. Obviously occupies a more important position. The oral English level of students largely depends on their ability to call the oral English in their minds. Students who can call as many oral English as possible more accurately tend to have higher oral English. The literature [19] found that the higher the student's writing score, the more proficient and richer the oral English.

3. Construction of spoken English resource recommendation model based on BP deep neural network

This article analogizes students as users, majors as projects, and students' class relationships as users' social networks, and establishes a professional recommendation model based on students' social interactions. The characteristics of students in social networks will be spread, which affects students' professional choices. Therefore, the influence propagation layer is introduced into the social recommendation network, and then a better loss function is selected to improve the accuracy of the recommendation result. The spoken language resource recommendation model proposed in this paper is divided into three parts. The first part is student modeling, which is divided into two models. The first model is to understand students' preference for majors through the interaction of the student-professional diagram. The second model extracts student characteristics from social networks, and integrates the characteristics of student friends into each student node in the social graph to model students. Combining the information of student-professional space and social space, the potential characteristics of students are intuitively acquired. The second part is professional modeling. In the interaction of the student-professional diagram, the evaluation of students of the same major is aggregated to reflect the potential characteristics of the major. The third part is the integration of the two models of students and spoken English. Through the full convolutional layer learning model parameters, the matching degree calculation between the student and the recommended spoken English is performed.

$U = \{u_1, u_2, \ldots, u_n\}$ and $V = \{v_1, v_2, \ldots, v_m\}$ are the sets of students and spoken English respectively, where n is the number of students and m is the number of spoken English. We assume that $R \in R^{n\times m}$ is the student-English speaking scoring matrix, which also known as the student-English speaking graph. If candidate u_i scores spoken English v_j, then r_{ij} is non-zero, otherwise we use 0 to indicate the score of spoken English v_j by candidate u_i, that is, $r_{ij} = 0.\Gamma = \{\langle u_i, v_j\rangle r_{ij} = 0\}$ is the set corresponding to the spoken English that student u_i has not evaluated. $T \in R^{n\times n}$ represents the social graph of students, where $T_{ij} = 1$ means that u_i and u_j are closely related.

The following is a detailed introduction to the spoken language resource recommendation algorithm based on the BP deep neural network.

The purpose of building a student model is to extract the potential characteristics of students. The student model is divided into two parts: the student-English speaking picture and the social network. The two parts are described separately below.

Because a student's score on a spoken English can tell the students' preference for the spoken English, the score of the spoken English and the characteristics of each spoken English can help students model. The student spoken English graph model in this paper is based on this to integrate spoken English features and spoken English evaluation to extract potential characteristics of students.

$$x_{ia} = g_v\left(\left[q_a \oplus e_r\right]\right). \tag{1}$$

Among them, x_{ia} is the multi-layer perceptron (MLP) of students and spoken English, x_{ia} is the interactive representation of each spoken English and score, q_a is the feature vector of spoken English, e_r is the feature quantity of five evaluation levels, and $\oplus$ represents the connection of two vectors. The calculation of formula (1) combines the scores corresponding to each spoken English and each spoken English to perform feature extraction. Since there are many spoken English that each student participates in the evaluation, it is necessary to aggregate all the spoken English that the students participate in the evaluation, and we introduce an aggregation function.

$$h_i^I = \sigma\left(W \cdot \text{aggretions}\left(\left\{x_{ia}, \forall a \in C(i)\right\}\right) + b\right). \tag{2}$$

Among them, $C(i)$ is the spoken English evaluated by student $u(i)$, W and b are the weights and biases of the neural network, and σ is the Relu activation function. The most common aggregation function is to directly aggregate the multiple spoken English evaluated by each student, that is, formula (3).

$$h_i^l = \sigma\left(W \cdot \left\{\sum_{a\in C(i)} \alpha_i x_{ia}\right\} + b\right), \tag{3}$$

$$\alpha_i = \frac{1}{|C(i)|}. \tag{4}$$

However, because the weight of each spoken English is different for students, the average aggregation cannot be directly calculated. In order to make up for the lack of average aggregation, the attention mechanism is introduced.

$$h_i^l = \sigma\left(W \cdot \left\{\sum_{acc(i)} \alpha_{ia} x_{ta}\right\} + b\right), \tag{5}$$

α_{ia} is the weight of the attention mechanism.

$$\alpha_{ia}^* = w_2^T \cdot \sigma\left(W_1 \cdot \left[x_{ia} \oplus p_i\right] + b_1\right) + b_2, \tag{6}$$

$$\alpha_{ia} = \frac{\exp\left(\alpha_{ia}^*\right)}{\sum_{a\in C(i)} \exp\left(\alpha_{ia}^*\right)}. \tag{7}$$

Among them, p^i is the feature vector of student u_i, and the interaction of spoken English and scoring is connected with the feature vector of the student. w_2^T, b_1, b_2 and W_1 are weights and biases, and the Softmax function is use to normalize the above attention weights to get the final attention weights. It can be understood as the contribution of interaction to the latent factors of the student-English speaking space. After the calculation of formula (1)-(7), we extracted the potential features of each student in the structure of the student-English speaking graph. The potential characteristics of students will also be reflected in the social relationships of students. Therefore, we introduce the student social network model to extract potential features.

This paper compares students as users, and oral English as projects, and compares students' class relationships to users' social networks, and establishes a model of oral English recommendation based on students' social interactions. In view of the fact that the social relationship of students will affect the students' choice of spoken English, the influence communication layer is introduced into the social recommendation network. The following is an improved social network model, as shown in Figure 1.

The characteristics of each student are divided into potential characteristics and obvious characteristics. Obvious characteristics can be reflected by students' evaluation of spoken English, and latent characteristics are reflected by students' social relationships. Therefore, we set up latent features, perform free embedding on the latent features of students, and continuously update the latent features through social relationship fusion.

$$\text{embedding} = nn \cdot \text{Embedding}(n, d). \tag{8}$$

The input of the fusion layer is the apparent feature vector and latent feature vector of each student. The two feature vectors are fused, and the fully connected layer is used for feature extraction. At this time, the output h_i^0 is the entire feature of the student.

$$h_i^0 = g\left(W^0 \times \left[p_i, m_i\right]\right). \tag{9}$$

Among them, W^0 is the weight matrix, $g(.)$ is a fully connected layer, p_i is the potential feature of the student, and m_i is the obvious feature.

The influence propagation layer is shown in Figure 2. Among them, the green node represents the current node u_i, the gray node is the first-order neighbor node of the current node, and the red node is the current node is the neighbor node of the first-order neighbor node.

Due to the change of time, the influence in social networks is spreading. For the current node u_i, h_i^0 is the input of the fusion layer, and h_i^1 is the feature obtained by averaging the first-order neighbor nodes (all gray nodes) of the current node u_i. At this point, the current node has the characteristics of the four neighbor nodes on the blue background. h_i^2 is the first-order neighbor node of the first-order neighbor (the result of the fusion of the red node, and it can be seen that the node u_i at this time has the characteristics of all the nodes in the green background) is also the feature of average fusion. Therefore, if h is the student's feature vector after impact diffusion, $S(i)$ is the set of neighborhood nodes of student u_i, and h_b^{k-1} is the neighborhood node feature of student u_i after $k-1$ social networking. Through the feature fusion of the neighboring nodes after $k-1$ times of social network influence, the characteristics of student u_i are obtained as:

$$h_i^k = \text{pool}\left(h_b^{k-1} b \in S_i\right), \tag{10}$$

$$\text{pool}\left(h_b^{k-1}\right) = \sum_{b\in S(i)} \frac{1}{|S(i)|} h_b^{k-1}. \tag{11}$$

The social network and the student-English speaking graph provide the characteristics of the student from different angles. Therefore, in order to extract all the potential characteristics of the student, it is necessary to combine the student-English speaking graph model and the social network model.

$$c_1 = \left[h_i^l \oplus h_i^k\right], \tag{12}$$

$$c_2 = \sigma\left(W_2 \cdot c \frac{n!}{r!\,(n-r)!} \frac{n!}{r!\,(n-r)!_1} + b_2\right), \tag{13}$$

$$h_i = \sigma\left(W_l \cdot c_{l-1} + b_l\right). \tag{14}$$

Among them, the output h_i is a combination of the potential features of the student-English speaking graph model and the social network model, and the student features are extracted through the full convolutional layer.

Just like the student model, in order to learn the latent features of spoken English, the spoken English model aggregates the evaluations of students who select the same spoken English to reflect the latent characteristics of spoken English.

$$f_{jt} = g_u\left(\left[p_l \oplus e_r\right]\right). \tag{15}$$

Among them, f_{jt} is the potential feature of spoken English after connecting the feature vector of student t and the feature vector corresponding to the score, and extracted by the full convolution layer. Since there is more than one student participating in the evaluation of spoken English, it is necessary to aggregate all the students who evaluate the spoken English, and for this purpose, the student's aggregation function is designed.

$$z_j = \sigma\left(W \cdot \text{aggre}_{\text{users}}\left(\left\{f_{jt}, \forall t \in B(j)\right\}\right) + b\right). \tag{16}$$

Considering that each student has different meanings for extracting the potential features of spoken English, the fusion function needs to introduce an attention mechanism to give students who choose the same spoken English different weights.

$$\mu_{jt}^{*} = w_2^T \cdot \sigma\left(W_1 \cdot \left[f_{jt} \oplus q_j\right] + b_1\right) + b_2, \tag{17}$$

$$\mu_{jt} = \frac{\exp\left(\mu_{jt}^{*}\right)}{\sum_{t\in B(j)} \exp\left(\mu_{jt}^{*}\right)}, \tag{18}$$

$$z_j = \sigma\left(W \cdot \left\{ \sum_{EB(j)} \mu_{jt} f_{jt} \right\} + b\right). \tag{19}$$

Among them, z_j is the potential feature of spoken English extracted by the aggregation function after introducing the attention mechanism.

The recommendation algorithm of spoken English is simply to match the characteristics of the students with the characteristics of the spoken English. Proved that the fully connected layer can fit arbitrary functions. Therefore, we choose to use multiple full convolutional layers to learn the similarity function between students and spoken English features.

$$g_1 = \lfloor h_i \oplus z_j \rfloor. \tag{20}$$

Among them, h_i is the latent feature of the student, z_j is the latent feature of spoken English, and $\oplus$ means connecting the two vectors.

$$g_2 = \sigma\left(W_2 \cdot g_1 + b_2\right), \tag{21}$$

$$g_{l-1} = \sigma\left(W_l \cdot g_{l-1} + b_l\right), \tag{22}$$

$$r_{ij}' = w^T \cdot g_{l-1}. \tag{23}$$

Among them, l represents the number of hidden layers, and r_{ij}' represents the matching degree of student u_i to spoken English v_j.

The above process is to perform feature extraction of multiple fully connected layers (MLP) on the result of the splicing. Finally, the obtained feature matrix is mapped to a one-dimensional vector, that is, the predicted value of each spoken english.

The loss function of BP deep neural network based on social recommendation is:

$$\text{Loss} = \frac{1}{2|O|} \sum_{i,j\in O} \left(r_{ij}' - r_{ij}\right)^2. \tag{24}$$

Among them, O is a set of tuples (i, j), where tuples represent student u_i and graded spoken English v_j. Therefore, this loss function is to calculate the loss for all scoring spoken English. For the spoken English without scoring, the loss is not considered, and the L2 loss function. When the predicted value is significantly different from the original value, the loss penalty is too large. When the gradient descent method is used to solve the problem, the gradient is large, which may cause the gradient to explode.

Therefore, we smoothed the L2 loss function and chose the Smooth Loss loss function. The function is as follows:

$$\text{Smooth Loss} = \begin{cases} \lambda\left(x - x'\right)^2, & \left|x - x'\right| < 1, \\ \left|x - x'\right| - \lambda, & x - x' < -1,\ x - x' > 1. \end{cases} \tag{25}$$

It can be seen that when $x - x'$ is less than 1, there is only one parameter λ difference from the original second order. However, when the absolute value of $x - x'$ is large, compared with the original L2 loss function, the Smooth loss function reduces the loss penalty and becomes a first-order loss. Therefore, using the Smooth Loss function can reduce the proportion of outliers and alleviate the model's deviation to the outliers compared to using the L2 loss function.

In order to prove the basis for the selection of the loss function, we conducted experiments on common loss functions and compared the commonly used loss functions in the recommendation system. For the MSE loss function, Exp exponential loss function, and Smooth loss function with different parameters, according to experiments, it is found that when the parameter in the Smooth loss function is 0.6, the MAE calculation results, RMSE calculation results, and accuracy are the best.

$$\text{Smooth Loss} = \begin{cases} \lambda\left(x - x'\right)^2, & \left|x - x'\right| < 1, \\ \left|x - x'\right| - \lambda, & x - x' < -1,\ x - x' > 1, \end{cases} \tag{26}$$

$$\text{MSE}(y, \hat{y}) = \frac{1}{n} \sum_{i=1}^{n} \left(y_i - \hat{y}_i\right)^2, \tag{27}$$

$$\text{loss}\left(y, y'\right) = \exp\left(-yy'\right). \tag{28}$$

4. Research on application of multimedia in spoken English training based on BP deep neural network

The voice part of the audio can be detected and extracted to enter the text-to-speech alignment process. For the sake of continuity, this paper first analyzes and discusses the forced alignment algorithm based on Viterbi decoding. On this basis, this paper proposes an improved fault-tolerant alignment algorithm based on extended matching network. Moreover, this paper presents a detection method for insertion, deletion, and replacement errors at the word and phrase level, and a larger-scale dynamic alignment algorithm for sentence level. Figure 3 shows the basic flow of text-to-sentence matching of a single sentence.

This paper uses the matching network shown in Figure 4 to extend the search network of the traditional forced alignment algorithm, so as to achieve a fault-tolerant mechanism at the word and phrase level. SIL stands for silent model, OOV stands for garbage model.

This article further discusses how to provide a solution based on the idea of dynamic programming for the alignment of continuous corpus and incomplete matching corpus on a large scale (sentence level). The overall steps of the algorithm are shown in Figure 5.

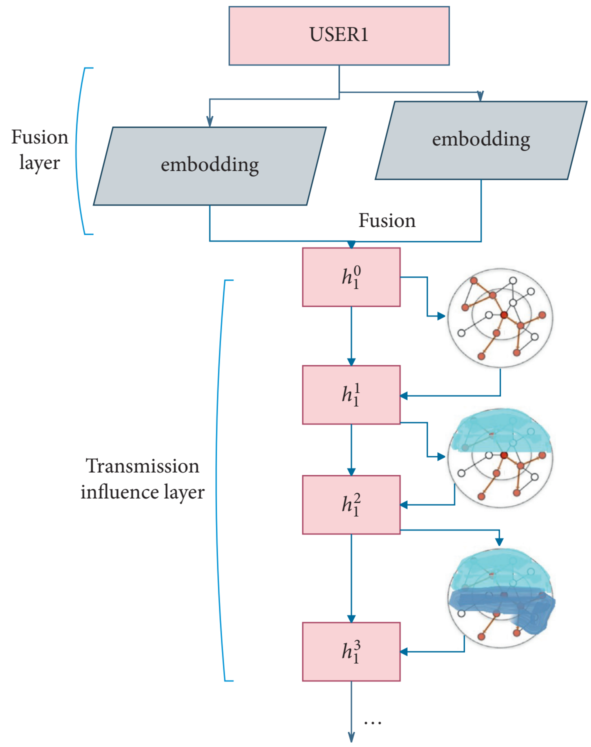

Figure 1: Improved social network model

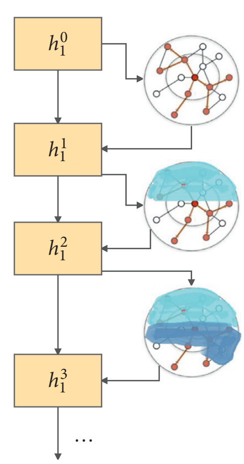

Figure 2: Influence propagation layer

Due to insertion, deletion, and replacement errors, not all models in the matching process can have corresponding nodes, especially the context-dependent HMM model (TRIPHONE) located at the word boundary. In the TRIPHONE model corresponding to syllable K as shown in Figure 6, since the word YOU is skipped during matching, the corresponding TRIPHONE model changes from <NG-K-Y> to <NG-K-V>. Therefore, in addition to comparing the corresponding nodes, it is also necessary to compare the word boundaries to prevent the expansion of the search subspace caused by some models in the second stage of matching because they cannot find the corresponding nodes.

The system front-end is based on the standard algorithm for feature extraction of the distributed speech recognition front-end of the European Telecommunications Standards Agency as shown in Figure 7. In order to ensure sufficient accuracy of the front-end features, a single-frame amplitude normalization technology is applied to make full use of the processing length of the processor to make the accuracy of fixed-point operations meet the requirements of the back-end recognition engine.

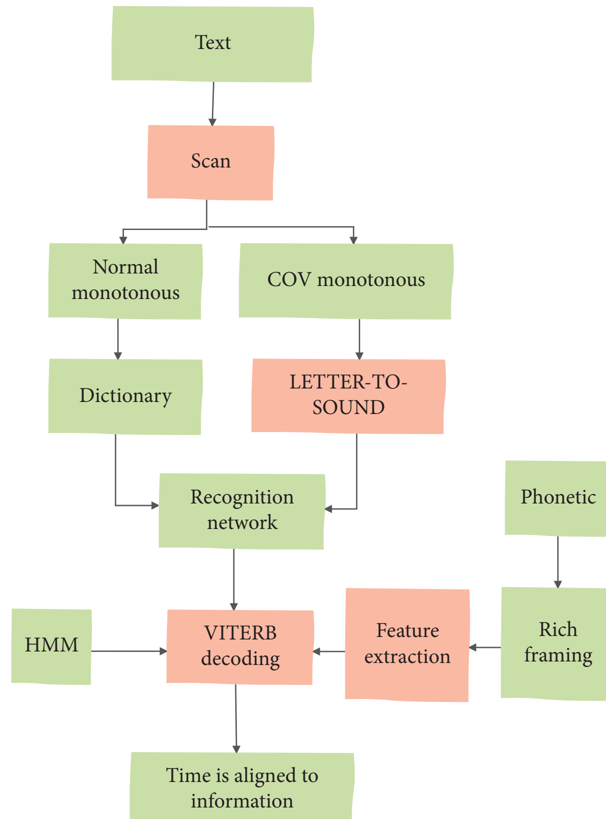

FIGURE 3: Flow chart of text-language matching.

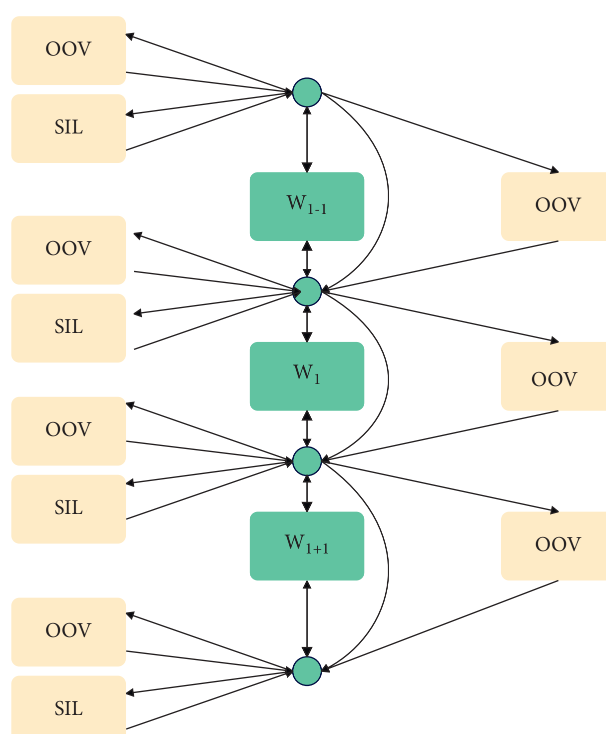

FIGURE 4: Extended network of fault-tolerant alignment algorithm.

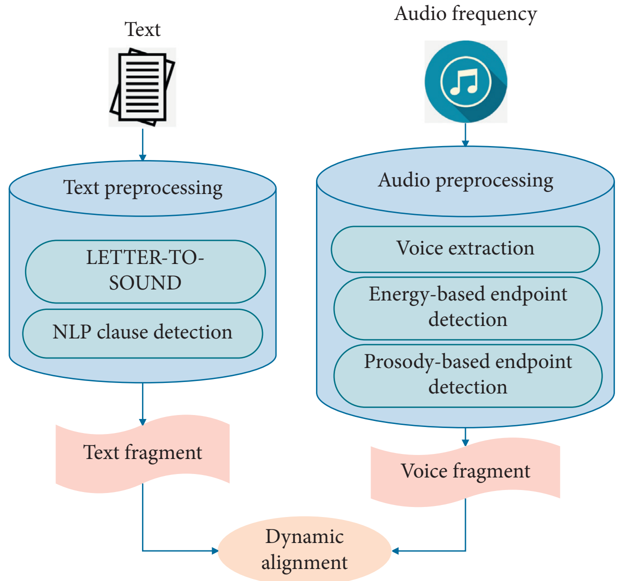

Figure 5: The flow of the alignment algorithm for a large number of continuous non-exact matching corpora.

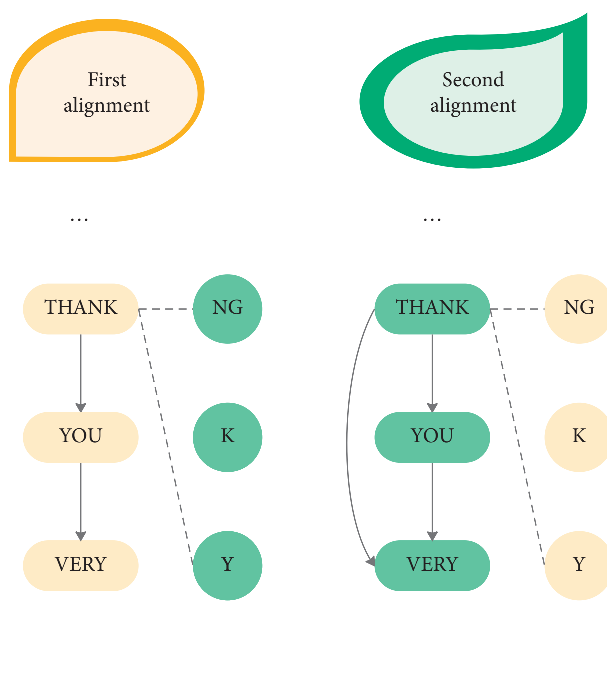

Figure 6: TRIPHONE changes in word boundaries caused by errors.

Figure 8 shows a schematic diagram of the voice processing flow of the system.

The modules of the speech recognition system include five parts: feature value extraction, phoneme recognition, phoneme association, pronunciation evaluation, and error detection. The speech recognition module is shown in Figure 9:

The external function realizes the visual window. The example sentence library view is played according to the specified example sentence or learning strategy. The information view displays sentences and phonetic symbols, displays monophony scores and corrections, displays sentence prosody scores and corrections, and plays corrections. The user management interface displays the user's transcripts, study files, and analyzes easy-to-mispronounce phonemes and common errors. The system can recognize English learners with a strong Chinese accent.

This paper conducts training research on the model of this paper, and the results are shown in Figure 10 below. It can be seen from Figure 10 that the student's speech

Table 1: Test data of spoken English training.

Number	Training effect	Number	Training effect	Number	Training effect
1	79.95	13	79.23	25	80.87
2	86.17	14	91.71	26	89.86
3	86.92	15	89.46	27	88.14
4	86.96	16	79.26	28	84.91
5	81.40	17	89.62	29	88.07
6	88.60	18	83.92	30	86.97
7	86.94	19	83.53	31	93.84
8	90.22	20	81.77	32	80.81
9	84.05	21	89.08	33	88.86
10	81.89	22	83.90	34	80.04
11	87.04	23	87.65	35	84.74
12	91.89	24	90.66	36	82.48

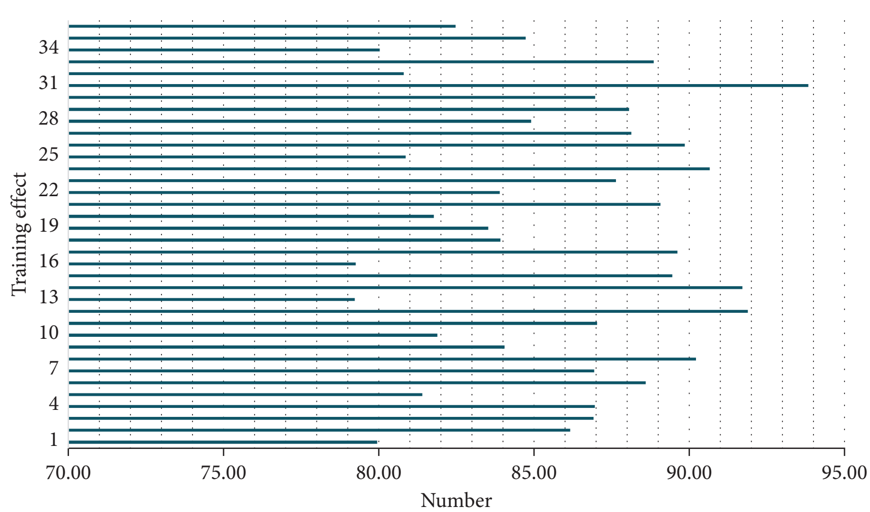

Figure 11: Evaluation of the training effect of spoken English.

waveform is similar to the standard speech waveform, which means that the student's spoken English h training is very effective and the student's spoken English is very standard.

On the basis of the above analysis, the effect of the spoken English training of this system is evaluated, and the results shown in Table 1 and Figure 11 below are obtained.

It can be seen from the above research that the multimedia based on BP deep neural network proposed in this paper has a good effect in the application research of spoken English training, and can effectively promote the effect of spoken English training of students.

5. Conclusion

In recent years, with the continuous advancement of new curriculum reforms, it is required to pay great attention to spoken English teaching. Although oral teaching has been improved to a certain extent compared with the previous teaching, it is still difficult to achieve the purpose of effectively training students' oral skills, which seriously affects the improvement of students' oral communication skills. The current intelligent spoken English learning system needs to provide functions such as recognition of the user's pronunciation, comparison with expert pronunciation, and error correction. The basis of all these functions is speech recognition. The accuracy of speech recognition and the robustness of the recognition algorithm will directly determine the overall performance of the learning system. This paper combines the BP deep neural network algorithm to construct the spoken English training system, improves the intelligent effect of spoken English training, and evaluates the performance of the system through experimental research. The experimental research results show that the multimedia based on the BP deep neural network proposed in this paper has a good effect in the application research of spoken English training, and can effectively promote the effect of spoken English training of students.

The psychological health education work of all universities is currently facing the same problem, despite the rapidly expanding scale of universities and the ever-increasing demand for students: there are few teachers engaged in this field, who cannot meet the urgent needs of the majority of students. Because of their mental illness, university students are unable to complete their studies in a timely manner, affecting their own development. One after the other, such occurrences occur. This paper uses the common mental disorder identification of university students as an example and builds a mental disorder identification model based on CNN. The model has the ability to learn on its own, allowing it to diagnose psychological disorders in university students and provide support for college psychological counselling and the psychological health team. However, because China currently pays little attention to the psychological health of this population, it is necessary to investigate and analyse the psychological health of university students at this time.

1. Introduction

Many people are experiencing varying degrees of psychological barriers as a result of increasing pressure from all directions in society, family, and life. Social stability, family harmony, and happiness have all suffered as a result of psychological obstacles [1]. The psychological health education work of all universities is currently facing the same problem, despite the rapidly expanding scale of universities and the ever-increasing demand for students: there are few teachers engaged in this field, which cannot meet the urgent needs of the majority of students [2]. The severe shortage of full-time psychological counsellors in universities has become a major impediment to psychological health education and intervention. According to the analysis of the factors affecting the psychological health of contemporary university students, we can summarize it into 10 influencing factors: personal future pressure, social pressure, economic pressure, environmental adaptation pressure, study pressure, emotional pressure, parental expectation pressure, family influence pressure, professional emotional pressure, and interpersonal pressure. We must take seriously the psychological health problems of university students, fully analyse and study the causes of university students' mental problems, and understand the factors affecting psychological health. Starting at the source, using effective approaches to detect early warning indications of psychological issues in order to reach the goal of prevention, to truly solve the problem of university students' psychological health, suffocate the emergence of psychological problems in the cradle. The development of artificial intelligence theory brings opportunities to computer-aided mental disorder identification [3]. The modeling and prediction of psychological disorders can help relevant experts and scholars understand the changing characteristics of psychological disorders and formulate relevant treatment plans for patients with psychological disorders. Therefore, the prediction of psychological disorders has very important social and practical application value.

People used experts to predict psychological disorders at first. In this method, the predicted outcomes of psychological disorders are insecure. Different experts can produce different forecast outcomes, and forecast outcomes are closely related to expert knowledge, making psychological disorder forecast outcomes highly subjective and unreliable [4]. They are exceptional young college students who represent the educated youth [5]. Many studies in the literature have shown that NN can effectively model and predict time series. This paper analyses the reasons affecting the psychological health of Chinese university students, expands the evaluation factors, collects the corresponding data, uses the convolution NN model to predict and analyse the psychological health of university students, and establishes a convolution NN forecasting model suitable for the identification of mental disorders, based on the current situation and characteristics of Chinese students.

Currently, universities only offer consultation and guidance in the field of psychological health education to university students through school psychological counselling teachers or hospital psychological experts. However, due to varying levels of experience and skill, it is unable to produce the desired effect. The NN expert system can perform complex pattern recognition and tasks with complex rules that cannot be predicted ahead of time. They are under significantly more psychological stress than their peers. As a result, research into the psychological well-being of today's university students is critical. In order to cope with psychological health demands in the future, researchers are looking into the internal law of numerous aspects affecting psychological health. This helps to generate new ideas for psychological health work. This paper developed a CNN-based [6] psychological disorder identification model. The error between the predicted outcomes and the measured value output by the ANN [7] is small after sample training, and the expected effect is well achieved. The model can detect university students' psychological status and provide diagnosis results in real time, as well as providing support for psychological consultation and psychological health teams in universities.

2. Related Work

Psychological health education in foreign universities is divided into three stages, according to literature [8]: initial stage, development stage, and mature stage. According to statistics in literature [9], university students who have dropped out of school due to various mental disorders caused by mental illness account for about half of all dropouts. Literature [10] combines knowledge discovery and NNs to produce forecast results that outperform traditional methods. A survey of 140 medical graduate students was conducted in literature [11]. It was discovered that the range values of various factors among major students differ significantly from the national average and that some factor scores are lower than those of ordinary people. The single factor analysis method is used to analyse related factors in literature [12] in the research of postgraduates' physical and mental symptoms. Social factors such as gender, whether they are an only child, and personality traits have been shown to influence graduate students' physical and mental symptoms in studies. Literature [13] surveyed postgraduates, showing that the psychological health of female postgraduates is significantly higher than that of male postgraduates in terms of both factor scores and the total score of the scale. In literature [14, 15], with the help of the idea of quadratic performance index in optimal control, it is proposed to use quadratic performance index to calculate the control law to obtain the desired optimization effect. Literature [16] mentioned that, with social changes and the influx of only children into universities, the number of university students suffering from psychological disorders had shown a clear upward trend. Literature [17] conducted a survey of 400 medical graduate students in Chengdu and found that the suicide probability of girls was 78.99%, while that of boys was only 58.60%. In literature [18], a survey of 289 medical master's students in a military school was grouped by gender, and the grouping results were compared with several domestic research results. The comparison shows that female students are higher than male students in some factors. Literature [19] proposed a hybrid learning algorithm that alternately uses a genetic algorithm and CNN algorithm. In literature [20], 828 postgraduates on campus are taken as the research objects regarding the personality differences of graduate students and the differences in their living conditions. Through discussion, it is found that some factors of the graduate student population are higher than the national norm range value. Due to the differences in the personality of this group, psychological health presents the phenomenon of "three highs" and "three lows." Literature [21] proposes to combine multiple population genetic algorithms with NNs, which can simultaneously consider global optimization solutions and local optimization solutions. Literature [22] uses NNs to establish mathematical models to solve practical problems. Literature [23] first applied the support vector machine model to time series forecasting in 1997. Literature [24] verifies the prediction effect of support vector machines on five financial time series data. The experimental results show that the evaluation indicators such as the prediction mean square error and the average absolute error on the five data samples of the support vector machine are better than the backpropagation NN. Literature [25] survey on university students across the country shows that 22.01% of the students have obvious psychological problems, and about 3/8 of the students have different degrees of psychological obstacles. Literature [26] proposed an NN forecasting model with lower complexity in 2009. In this paper, according to the current psychological health status of university students, a prediction system model of psychological health status of university students is established based on CNN. This model has high precision and high efficiency. Students' psychological problems can be predicted in advance, and corresponding measures can be taken in time. Finally, the stability and unity of the school and the growth of students will be realized.

3. Mental Disorder Prediction Based on CNN

3.1. NN Algorithm. In the field of computer science and artificial intelligence, artificial neural network (ANN) simulates the information dissemination mechanism of the biological nervous system so that the machine can imitate the human brain to learn and recognize information [27]. NNs perform calculations and spread information through a large number of interconnected neurons. They are commonly used to describe the complex relationship between input and output, as well as investigate data's internal structure and patterns. The topological structure of ANNs' connections, as well as the strength of synaptic connections or connection weights, determines their functional characteristics. A matrix W can be used to represent the weights of all NN connections. Its entirety reflects the NN's knowledge storage for the problem at hand. Through the learning and training of samples, the NN can continuously change the connection weight and topology of the network, bringing the network's output closer to the desired output. The dynamic adjustment of variable weights is the essence of this process, which is known as NN learning or training.

Artificial neuron is a simulation of the characteristics of weighted summation of the input information of biological neuron. It uses the activation function to map the obtained network input to realize the processing of amplifying or suppressing the output value of the neuron. Assuming that the n inputs of a neuron are represented by $x_1, x_2, \ldots, x_n$, the connection weight corresponding to each input is $w_1, w_2, \ldots, w_n$, the threshold is represented by θ, and the actual output value of the neuron is represented by y, then the input-output mapping relationship can be represented by the following formula:

$$y = f\left(\sum_{j=1}^{n} w_j x_j - \theta\right). \tag{1}$$

Here, f is called the activation function. Figure 1 shows the structure of a single artificial neuron computer system.

The learning method of CNN is the third major factor that determines the information processing performance of CNN, so the study of learning plays an important role in NN research [28]. Rules that change the weights are called learning rules or learning algorithms. When a single processing unit collectively adjusts the weights, the network shows "intelligent" characteristics. Meaningful information is distributed and stored in the adjusted weight matrix.

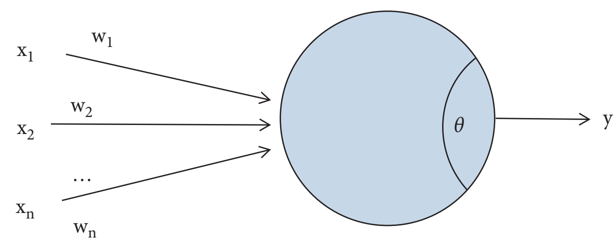

Figure 1: Artificial neuron.

3.2. The Evaluation Model of University Students' Psychological Health Status. The preparation of the data shows a very positive role in ANN. Good data can quickly balance the convergence of the network, and it is close to the output result. On the contrary, bad data, no matter how to modify the network parameters, cannot make the network achieve the required effect. Taking the identification of common psychological diseases of university students from five characteristics as an example, the development process of model service is illustrated. The five characteristics of input include behaviour, emotional state, diet and sleep, personality characteristics, and physical diseases. Four common mental diseases of university students are selected as training, and an NN for identifying mental diseases is constructed. In practice, the features of mental illness are much more complicated and huge, and there are many overlapping interactions among the features. Here, only five distinctive commonalities are selected to construct the training set of NN recognition.

The improved NN psychological barrier forecasting model works on the following principle. To begin, gather historical data on psychological barriers. The chaos algorithm is then used to preprocess historical data on psychological disorders in order to better understand how their characteristics change over time. Finally, NN is used to learn preprocessed historical data of psychological disorder, and the particle swarm optimization algorithm is used to improve NN's existing problems and establish the best psychological disorder forecasting model. Figure 2 depicts the working principle of the improved NN-based mental disorder forecasting model.

The period in which college students live is a critical transition period for a person to mature. During this period, they will face many problems such as emotion and going to the society. If not handled properly, various psychological problems will appear, such as depression and anxiety. Convolution layer uses local connection and weight sharing to reduce the number of network-free parameters and the complexity of network parameters. The convolution layer calculation formula is as follows:

$$X^{(l)} = f\left(W^{l} \otimes X^{(l-1)} + b^{(l)}\right). \tag{2}$$

Here, $X^{(l)}$ and $X^{(l-1)}$ represent the neuron activity of layer l and l-1, W^l represents the convolution kernel, and b represents the bias.

In order to make the training of NN more effective and improve the training speed of the established NN, the input and output data of NN should be preprocessed first. For NN calculation, it is necessary to convert literal concepts into numerical values. In order to facilitate the discrimination of data, six-dimensional vector values are used to represent each feature. The first three bits represent categories, and the last three bits represent features, so a total of 26 = 64 features can be accommodated. The outputs of the four subconvolution networks are fused in the full connection layer. The dimensions of the first full connection layer and the second full connection layer are 512 and 256, respectively. Finally, the Softmax function is selected as the output classifier. The Softmax function estimates the probability that input x belongs to a specific category $j \in \mathrm{k}$:

$$P(y = j \mid x) = \frac{\exp\left(x^T W_j\right)}{\sum_{k=1}^{K} \exp\left(x^T W_k\right)}. \tag{3}$$

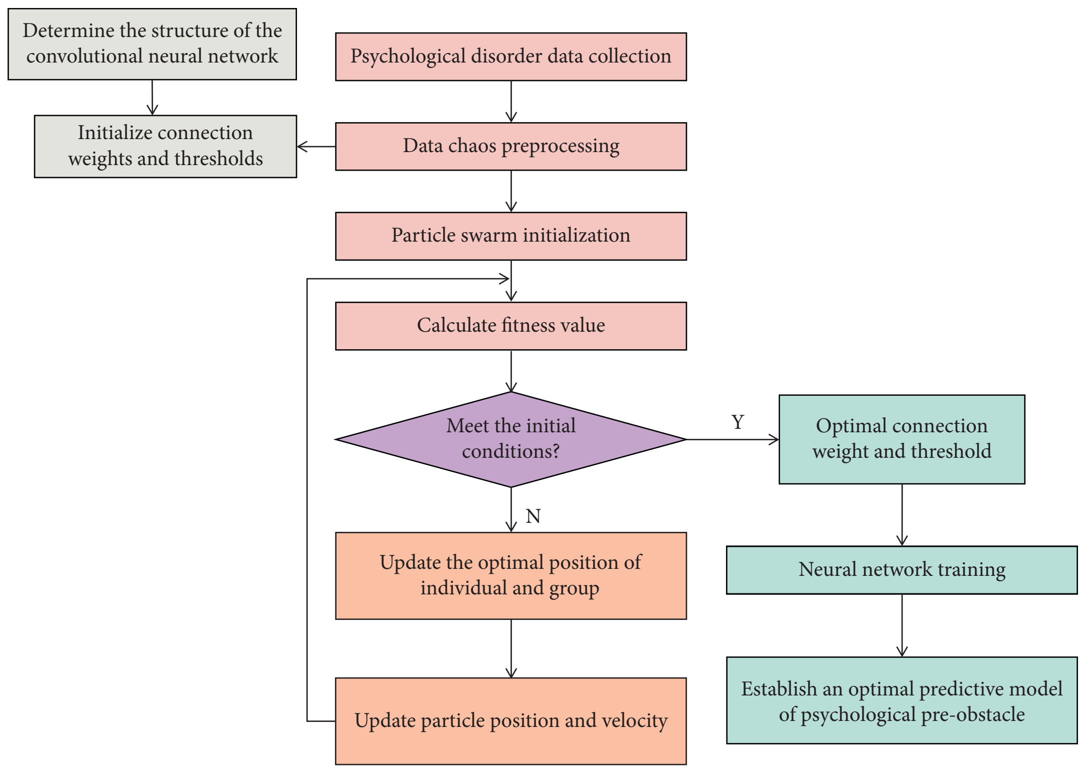

Figure 2: The working principle of the psychological disorder forecasting model of the improved NN.

Select the commonly used Rectified Linear Units (ReLU) as the excitation function. The ReLU excitation function can prevent gradient disappearance and overfitting. The ReLU excitation function is defined as

$$f_{\text{cov}}(x) = \max(0, x). \tag{4}$$

Dropout is an effective means to prevent overfitting and improve the effect in CNN. The feature representation of data is very important to the successful training of the model. Better data representation can reduce or even eliminate the influence of factors unrelated to the training task in the original data on the training results and save useful information that is beneficial to the training task.

The characteristics of each influencing factor are sorted according to the degree of psychological resistance, the index of the category affected by each influencing factor in the initial mental performance state is obtained, and the mental performance state of different influencing categories is obtained. For m-dimensional college students' psychological complexity, the total number of different mental performance state sequences is m, the probability of k different mental performance state sequences is assumed to be $P_1, P_2, \ldots, P_k$, and the probability of the mental state sequence is ranked. Define permutation entropy:

$$H_{PE}(m) = -j = 1\sum^{k} P_j In P_j. \tag{5}$$

Integrate the state sequence given by (5), and use (6) to express the emotional characteristics of behaviour corresponding to the mental state at this stage:

$$0 \leq H_{PE} = \frac{H_{PE}}{In(m)} \leq 1. \tag{6}$$

Suppose that $\{x(t), t = 1, 2, \ldots, N\}$ represents the time series set of behavioural emotional characteristics of college students' mental state. Due to the complexity of the behavioural tendency of college students dominated by psychology, it is necessary to construct a relationship with the psychological duration τ, select the duration sequence $x(t+\tau)$ to form a new duration point sequence $y(t)$, and determine it according to the correlation between the calculation of $x(t)$ and $y(t)$ and psychological duration τ.

This paper uses the prevalence of mental disorders as historical data of mental disorders. They compose a kind of time series data according to the chronological order, without considering related influencing factors, so that the historical data composes a one-dimensional time series data. In order to obtain a higher-precision mental disorder prediction structure, an improved NN mental disorder forecasting model is proposed. This model has the ability of autonomous learning and can realize the diagnosis of university students' psychological disorders.

4. Result Analysis and Discussion

Researchers simulated the computing power of real NN to create NN. Because it gradually demonstrates powerful functions such as learning, memory, and association during its development, NN is widely used in a variety of fields. Simple pattern recognition is realized through NN application research in the diagnosis of university students' psychological disorders, and the expected diagnosis effect is achieved. Currently, the system is just a simple simulation of a specific biological nervous system performance. The system can theoretically perform complex pattern recognition and complete tasks with complex rules that cannot be determined in advance if enough training and learning are done. The internal representations used by the neural network after learning the sample set are the weights and thresholds that can best meet the data requirements obtained by the neural network through adaptive learning. The feature data from the sample set to be identified is then fed into the trained network, which can then reason and identify the sample output results automatically. When viewed as a mapping from input data to output data, the neural network is highly nonlinear. Figures 3–6 show the results of the experiments.

It can be seen that no matter whether the input sample length is 20 or 30 when the convolution layer and downsampling layer are 1, the root mean square error and correlation coefficient of the forecast outcomes are better than when the convolution layer and downsampling layer are 2. The determination coefficient of the forecast outcomes is closer to 1. In this paper, it is considered that it is more reasonable to choose 1 for convolution layer and downsampling layer of convolution NN exchange rate forecasting model.

According to the degree of psychological resistance, the characteristics of each influencing factor are sorted, the indicators of the categories affected by each influencing factor under the initial mental performance state are obtained, and the mental performance states of different influencing categories are obtained. A single neuron can only perform very simple functions. If you want to realize the functional simulation of the human brain NN and complete complex tasks, you need to connect a large number of neurons in a certain way to form an ANN with different topological structures. We use the train() function to train the CNN model. The error curve after training is shown in Figure 7.

According to the graph description, it can be seen that, during the self-learning process of the network, the error is constantly decreasing, and the error basically reaches the target at Step 780. Through the continuous training of NN, the network can basically achieve the minimum error prediction. It can be seen that the forecasting model has a good prediction effect. Through the continuous training of NN, the network can basically achieve the minimum error prediction and thus can meet our needs. The comparison curve between the forecast outcomes and the true value for 2020 is shown in Figure 8.

Through the simulation test of several groups of data, it can be seen that the error between the predicted results and the true values of each group is very small, and the fitting degree of the input data basically meets the required requirements. It shows that the established model has certain accuracy and can fully predict the psychological health of university students.

The same parameters are used for the three subconvolution networks with dynamic input data. To extract the characteristics of each user's behaviour at different time points, the first convolution layer selects 64 convolution kernels with a size of 13. Following the convolution layer is the pooling layer, which is responsible for secondary feature

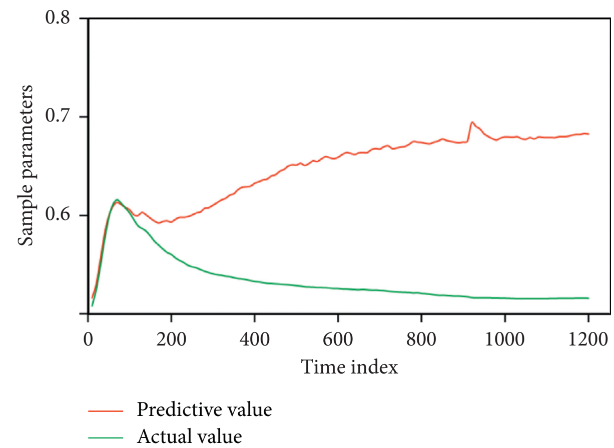

Figure 3: The forecast outcomes with the input sample length being 20 and the number of convolutional layers being 1.

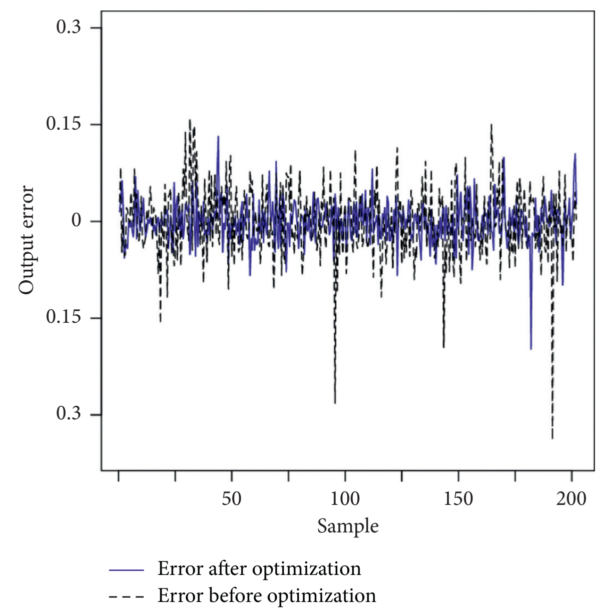

FIGURE 9: Error comparison before and after optimization.

extraction. Choose the most efficient pooling method. After the pooling layer, the second convolution layer is connected, and 128 convolution kernels with a size of 33 are chosen. The goal is to extract the characteristics of each user behaviour index at various time points, as well as the characteristics of multiple user behaviours at the same time. After the second convolution layer, a pooling layer is added. A convolution layer and a pooling layer are used to extract features from static input data. The convolution layer employs 64 13-size convolution kernels. Figure 9 shows the error comparison before and after the algorithm optimization.

It can be seen from Figure 9 that, by comparing the errors before and after optimization with a genetic algorithm, it can be found that the optimized NN forecasting model is better than that before optimization, and the optimized NN can achieve the data fitting effect faster.

Predicting the mental health of college students is a complex and systematic process. Because the process by which each specific factor performs its function is invisible and intangible and because the influence on the outcome may be nonlinear, a method that can reflect the corresponding relationship between the factors that affect the psychological state and the outcome is required to develop the prediction model. The ability of the optimized NN to fit data is clearly improved without changing the original network structure and network parameters. The reason for this is that the genetic algorithm uses the fitness function to determine the optimal weights and thresholds and then passes those weights and thresholds to NN training to replace the random weights and thresholds generated by Matlab in each training. This severely limits the ability to adjust the weight threshold on one's own. The number of iterative steps in the NN is significantly reduced after optimization, and the preset goal can be reached much faster. Experiments show that using a genetic algorithm improves the initial weights and thresholds of CNN, allowing it to fit the data better.

The ability of fuzzy clustering analysis and prediction of optimized mental health data is obviously improved because CNN finds out the optimal weights and thresholds through fitness function and then gives the weights and thresholds to neural network training to replace the initial weights and thresholds randomly generated by Matlab in each training, which greatly reduces the ability of self-adjustment of weights and thresholds. By changing the parameters of the NN, the calculation of the final result of the prediction system is simple and flexible, and the prediction efficiency and accuracy of the network model are greatly improved. This provides a good reference method for the study of university students' psychological health to a great extent.

5. Conclusions

The significance of psychological health among university students is self-evident. It has a huge impact on university students, schools, society, and the country as a whole. Nowadays, the pace of university students' studies and lives is quickening, and social influence is growing, as well as psychological pressure on students. In terms of psychology, university students experience a variety of negative reactions and maladjustment. Some of them are downright dangerous. Suspension from school, dropping out, and even wounding and suicide as a result of mental illness have all increased in recent years. Psychological factors are the primary cause of psychological illnesses. Psychological issues have a significant impact on university students' development. As a result, universities have made it one of their top priorities to prioritise psychological health education for university students. The psychological well-being of university students has recently become a hot topic. The ability of fuzzy clustering analysis and prediction of optimized mental health data is clearly improved because CNN finds the optimal weights and thresholds through fitness function and then gives the weights and thresholds to neural network training to replace the initial weights and thresholds randomly generated by Matlab in each training, greatly reducing the ability of weights and thresholds self-adjustment. As a result, this paper builds a forecasting model of university students' psychological disorders based on CNN. The results show that the improved NN overcomes the drawbacks of the current mental disorder forecasting model, allowing university students to know their psychological health status in real time. It is a high-precision, high-efficiency model for predicting psychological disorders with a wide range of applications. We can predict students who may have psychological problems in advance using this NN psychological forecasting model, so that appropriate attention or measures can be provided on time, avoiding the enlargement or aggravation of students' psychological problems and ensuring the positive and stable development of schools and students.

In order to improve the copyright protection effect of literary works and improve the healthy dissemination of digitized literary works, this paper combines data mining technology to conduct research on the copyright protection of literary works and constructs a literary copyright protection system. In digital literary works, watermarking algorithms can be used to watermark the characteristics of literary works to obtain digital literary works that have been watermarked. After that, this paper can combine data mining algorithms to perform text feature recognition and feature classification and improve the copyright protection effect of literary works. The experimental research results verify that the effect of the copyright protection system of literary works based on data mining algorithms is very good.

1. Introduction

The rapid development of computer storage technology and network technology has brought massive amounts of information to people. This information usually takes images, videos, audios, animations [1], and texts as the main manifestations, among which texts have the widest range of dissemination and the highest frequency of use. The massive dissemination of information brings convenience to people's work and life, but it also has shortcomings, such as many copyright disputes and illegal copying problems, which urgently needs author identification methods that can resolve copyright disputes. Through research, it is found that texts written by different authors or authors have greater style differences, and different texts written by the same author have the same writing techniques, usual sentence structure, vocabulary, etc. [2]. The author recognition method first extracts and counts the features of a large number of texts written by different authors and trains the classifier. Then, for the controversial text, it uses effective feature extraction methods to obtain statistical vectors and input them into the trained classifier. Finally, it outputs specific classification categories or specific authors. The method of text author recognition can assist in resolving copyright disputes of disputed works (especially disputed works of well-known authors), combating piracy, and maintaining integrity. The key part of the text author recognition method is training and building a classifier [3].

Classification is a typical machine learning method with teachers, and it is also an important research topic in the field of data mining. The classification function or classifier is obtained by continuously learning training data. When classification is needed, the test data can use the obtained function or classifier to output a given category. How to choose a suitable classification model in the application is an important issue. Text classification technology can be widely used in fields such as natural language processing and understanding, information management, data evaluation, and information filtering. The more common text classification methods include support vector machine, K-nearest neighbor method, Bayesian classification, neural network, and decision tree classification. Support vector machine is mainly used in pattern recognition and other fields. It is a pattern recognition method based on statistical learning theory. Its characteristic is that it can maximize the geometric edge area and minimize the empirical error at the same time. According to the situation of the known samples, the nearest neighbor algorithm can determine whether the new sample and the known sample are in the same category. The nearest neighbor algorithm has many developments and improvements, but the general idea is to store all or part of the training samples first and then calculate the distance between the test sample and the training sample through the similar function and finally determine the type of the test sample. The nearest neighbor algorithm can quickly achieve classification, especially in the field of statistical-based pattern recognition. The principle of the neural network is to simulate the structure of the human brain and treat the sample as a connected input/output unit. The training sample learns by adjusting the unit value.

Based on this, this paper combines data mining technology to conduct research on the copyright protection of literary works, constructs a literary copyright protection system, and improves the copyright protection effect of modern digital literary works.

2. Related Work

Literature [4] proposed Triangle Similarity Quadruple (TSQ) and Tetrahedral Volume Ratio (TVR). The TSQ algorithm constructs the Macro Embedding Primitive (MEP) and selects the ratio of the side length of the triangle or the ratio of the base to the height in the MEP as the watermark embedding primitive: the TvR algorithm selects the four sides after constructing the tetrahedral sequence. The volume ratio between the volumes is used as the watermark embedding primitive. Literature [5] calculates the distance from each vertex of the model to the center of the vertex field and the distance from the center of the model and embeds the watermark by modifying the ratio between the two. This algorithm is a non-blind watermarking algorithm, which can resist similar transformation, noise, simplification, and their joint attacks. However, the transparency of the watermark is insufficient.

Literature [6] proposed two digital watermarking algorithms based on local distance: Vertex Flood Algorithm (VFA) and Triangle Flood Algorithm (TFA). The VFA algorithm divides the vertex set according to the distance from the vertex of the model to the center of the selected triangle and embeds the watermark by modifying the distance from the vertex in each set to the center of the selected triangle; the TFA algorithm continuously selects the triangle and connects the adjacent triangles of the triangle, sorting into a triangle traversal sequence according to the distance from the non-shared vertex to the shared edge, and then modifying the height of each triangle in the traversal sequence to achieve the purpose of embedding the watermark. Literature [7] embeds the watermark by modifying the distance from the model vertex to the center of the model. As a global geometric feature, this distance can well reflect the shape of the 3D model and can maintain sufficient stability without changing the visual effect of the model. Therefore, the algorithm has better robustness against noise and simplification attacks; literature [8] improves the transparency of the watermark by controlling the intensity of local watermark embedding, and uses a weighting method to improve the simplification and reduction of the watermark during watermark extraction. Robustness of noise attacks: literature [9] embeds both robust and fragile watermarks in the 3D model by modifying this distance and uses the method of adding weights to improve the robustness of the algorithm when extracting the watermark. Literature [10] proposed a multiple digital watermarking algorithm. This algorithm uses the distance from the vertex to the center of the model to embed the watermark and at the same time introduces the affine invariant range and embeds the second watermark by modifying the vertex order of the triangle face. The complementary advantages of the two watermarks increase the types of algorithms against attacks. Literature [11] focuses on improving the transparency of watermarking. Literature [12] improves the method of controlling the embedding strength of local watermarks. Literature [13] uses the K-means clustering method to select a specific set of vertices according to the curvature of the vertices and uses genetic algorithms to embed the watermark.

Literature [14] proposed a digital watermarking algorithm based on Extended Gauss Image (EGI). The algorithm builds a set of triangle faces based on the normal vector of the triangle face and embeds the watermark by modifying the statistical feature of the mean value of the normal vector of each set. Literature [15] divides the vertices of the 3D model into 6 regions, and each region establishes an extended Gaussian image of the normal vector, which realizes the repeated embedding of watermark information in each region and optimizes the method of modifying the vertex coordinates. Literature [16] proposed a digital watermarking algorithm based on complex extended Gaussian image (Copmlex EGI), which establishes a complex weight for each partition and selects the partition with larger weight to embed the watermark, which effectively improves the robustness. Literature [17] uses the vertex neighborhood of each vertex to calculate an average vector and embeds the watermark by modifying the length of the average vector. The algorithm can handle polygonal mesh models with arbitrary topologies and has good robustness to affine transformations, but it cannot resist attacks such as mesh reconstruction and mesh simplification. Literature [18] uses the model center and principal component analysis method to transform the model into an affine invariant space and transforms the vertex coordinates into spherical coordinates and then constructs a histogram reflecting the value distribution of the radial component of the vertex according to the spherical coordinates. The histogram moderately changes the distribution of the radial component to embed the watermark. The algorithm can resist similar transformation and simplification attacks, but it cannot resist shearing attacks, and it has weak resistance to noise attacks. Literature [19] defines the distance from the vertex of the 3D model to the center of the model as the vertex norm and proposes a highly robust blind watermarking algorithm based on the statistical characteristics of the vertex norm. This algorithm establishes a histogram of all vertex norms, divides the histogram into several partitions according to the number of watermarks, and embeds the watermark by slightly changing the mean or variance of the vertex norm of each partition. This algorithm combines the stability of both the global geometric features and statistical features of the 3D model and has achieved good robustness against various common attacks. However, the algorithm depends on the center position of the model, so it cannot resist shearing attacks. And there are also shortcomings in transparency.

3. Literary Works Watermarking Algorithm Based on Text Data Mining

By analyzing the characteristics of common BIM model format DXF files, this paper combines the existing two-dimensional vector graphics digital watermarking algorithm to propose a digital watermarking algorithm for data copyright protection based on the BIM model. This paper selects the vertex coordinates of the multiface mesh of the entity of the BIM model data to embed the watermark. In order to solve the problem that the vertex coordinates in the BIM model have more identical values and less effective carriers used to embed the watermark in practical applications, random noise is added to the original coordinate data within the error tolerance to increase the embedding capacity of the watermark. In order to enhance the ability to resist pruning attacks, the watermark information needs to be embedded as evenly as possible in the X and Y coordinates of all multiface mesh vertices of the BIM model data. In order to maintain the synchronization relationship between data and watermark and realize blind watermark detection, the idea of coordinate mapping is adopted. At the same time, the security of the watermark is improved by Logistic scrambling of the watermark image. In this algorithm, firstly, it extracts the vertex coordinates of all the multiface meshes in the data to construct a vertex set and obtains the high-level part of the coordinate data. After that, it establishes a mapping relationship with the watermark through a one-way mapping function to use the low-order part of the coordinate value as the embedding carrier of the watermark and embeds the watermark into the vertex coordinate position using the quantization modulation method. Moreover, it selects the initial value of chaotic transformation as the key for watermark extraction. When the watermark is extracted, no original data is needed, and blind detection is realized. The embedding process of the watermark is shown in Figure 1.

Logistic mapping, also known as insect mouth model, is a typical chaotic sequence in chaos theory, and its equation form is formula (1). Chaos phenomenon is a random-like process that appears in a deterministic system. The process is bounded, non-convergent, and sensitive to initial values. The use of chaotic sequences to encrypt the watermark not only is simple and easy to use, but also has no periodicity and is difficult to crack, which can improve the security of the watermark. For an image of $M \times N$ size, a one-dimensional chaotic encryption sequence w is obtained after $M \times N$ iterations.

$$L_{i+1} = \mu L_i (1 - L_i), \ (i = 0, 1, 2, \ldots, m \times n). \tag{1}$$

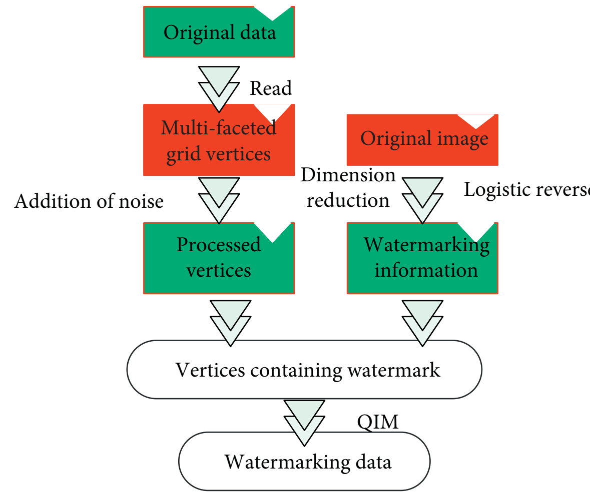

FIGURE 1: Flow chart of watermark embedding.

When the condition $0 < L_i < 1, 3.5699456 \ldots < \mu \le 4$ is satisfied, the Logistic mapping works in a chaotic state. In particular, when μ is close to 4, the iteratively generated value is a pseudo-random distribution state. This paper uses the Logistic chaotic map to encrypt an image of 32×64 size and then reduces the dimensionality of the generated binary watermark image to obtain a one-dimensional sequence w with a length of $S = w_m \times w_n$. The initial value $L_0 = 0.98$ of the chaotic transformation is selected for many trials. Figure 2(a) is the original image used in the experiment, Figure 2(b) is the chaotic image after scrambling, and Figure 2(c) is the decrypted image after inverse scrambling [20].

Due to the large number of coordinate repeated values in the BIM model, there are fewer effective carriers for embedding the watermark. To solve this problem, this paper adds random noise to the original coordinate data within the error tolerance to increase the embedding capacity of the watermark. The repeated coordinate values in the vertices set of the polyhedral mesh of the original data are subjected to the noise adding operation shown in formula (2) to obtain the processed vertex set V_e [21].

$$\begin{cases} x_e = x + \text{rand} \times Q \\ y_e = y + \text{rand} \times Q \end{cases}. \tag{2}$$

Here, (x_e, y_e) represents the vertex coordinates of the polyhedral mesh after adding noise, (x, y) is the vertex coordinates of the original data, rand is a random function that generates a random number within (0,1), and Q is the allowable range of error.

This algorithm embeds the watermark with the multifaceted mesh vertices of the BIM model data entity as the object. The vertices of the multifaceted mesh of the BIM model data are set V_K, denoted as $V_K = \{V_i\}, V_i = (x_i, y_i), i \in \{0, 1, 2, \ldots, K-1\}$. Among them, V_i represents the vertex of each polyhedral mesh, (x_i, y_i) is the X, Y coordinate value of the vertex, and K represents the number of vertices of the polyhedral mesh.

(a) (b) (c)

Figure 2: Original watermark.

The specific process of watermark embedding is as follows:

Step 1. The algorithm reads the BIM model data, extracts all the multiface mesh vertices in the model object entity, and constructs the multiface mesh vertex set V_K.

Step 2. The algorithm adds noise to the two coordinate values (x_i, y_i) of each vertex V_i in the set V_K and at the same time enlarges it by 10 times, which is denoted as V_i' , $V_i' = (x_i', y_i')$. Among them, V_i' represents each polyhedral mesh vertex after noise processing, and (x_i', y_i') is the two coordinate values after noise is added to the vertex.

Step 3. The algorithm selects the embedded bit x_w of the watermark according to the data accuracy requirements, and the selection method is as in formula (3). Then, the algorithm gradually modifies the vertex coordinates of the multiface mesh according to the mapping relationship between the high part of the data and the watermark bit $w(x_w)$;

$$x_w = \text{floor}\left(\text{mod}\left(\frac{x_i'}{p, S}\right) + 1.\right. \quad (3)$$

Here, floor represents rounding down, the mod function is the modulo operation and returns the remainder after dividing x_i'/p by S, p is the difference between the magnification and the most significant digit after the decimal point, and S represents the length of the watermark, and $p = 1000$ is selected in this paper.

Step 4. The algorithm uses quantization modulation technology to embed the watermark into the processed coordinate value x_i' and calculate the embedded watermark data x_i^w, where the quantization amplitude is R. There are two cases according to the value of the embedded watermark, as follows [22]:

$$\begin{aligned} x_i^w &= x_i' - \frac{R}{2}, \text{ if } w(x_w) = 0 \text{ and } \text{mod}(x_i', R) \geq \frac{R}{2}, \\ x_i^w &= x_i' + \frac{R}{2}, \text{ if } w(x_w) = 1 \text{ and } \text{mod}(x_i', R) < \frac{R}{2}. \end{aligned} \quad (4)$$

In the same way, according to the different embedded watermarks and the QIM method, the watermark is embedded in the y_i' coordinate of the vertex V_i' of the multifaceted mesh.

Step 5. The algorithm reduces the coordinate value (x_i^w, y_i^w) in V_i^w after the watermark is embedded by 10^t times, and merges the unmodified data with it to generate the watermarked BIM model data.

The extraction of watermark is the reverse process of watermark embedding (Figure 3). The specific steps to extract the watermark are as follows:

Step 1. The algorithm reads the BIM model data to be detected, extracts all the vertices of the multifaceted mesh that can be watermarked, and magnifies the vertex coordinates by 10^t times, where the selection of magnification index t is the same as the value of t when the watermark is embedded.

Step 2. According to the mapping relationship established by the one-way mapping function and the watermark, the algorithm finds the position x_w of the watermark.

Step 3. The algorithm performs QIM operation based on the quantized value R when the watermark is embedded, and extracts the value of the watermark bit $w'(x_w)$ by formula (6).

$$\begin{cases} w'(x_w) = w(x_w) - 1, \text{mod}(x_i^w, R) < \dfrac{R}{2} \\ w'(x_w) = w(x_w) + 1, \text{mod}(x_i^w, R) \geq \dfrac{R}{2} \end{cases}. \quad (5)$$

Step 4. In this algorithm, the same watermark is embedded multiple times, and the value of the watermark bit $w'(x_w)$ can be used to determine the value of the extracted watermark information w'':

$$\begin{cases} w'' = 1, w'(x_w) < 1 \\ w'' = 0, w'(x_w) \geq 1 \end{cases}. \quad (6)$$

This shows that when the value of the extracted watermark bit is less than 1, the value of the watermark information is 1; otherwise it is 0.

Step 5. The algorithm performs dimension increase processing on the obtained one-dimensional watermark information w' and inversely scrambles to obtain the watermark image W'.

Step 6. Finally, the watermark similarity is evaluated by calculating the normalized correlation coefficient

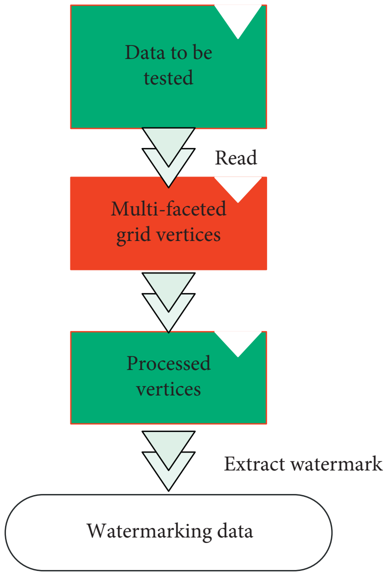

Figure 3: Flow chart of watermark detection.

between the original watermark and the extracted watermark. The calculation formula is as follows:

$$NC = \frac{\sum_{M}^{m=1}\sum_{N}^{n=1}[W'(m,n)\times W(m,n)]}{\sqrt{\sum_{M}^{m=1}\sum_{N}^{n=1}[W'(m,n)]^2}\times\sqrt{\sum_{M}^{m=1}\sum_{N}^{n=1}[W(m,n)]^2}}. \quad (7)$$

Here, NC is a measure of similarity. The greater the value, the greater the similarity. The size of the watermark image is $\times N$, $W(m,n)$ represents the original watermark information, and $W'(m,n)$ is the extracted watermark information.

The BIM model data is a digital expression of the physical function characteristics of the engineering project facility. Based on 3D digital technology, it integrates engineering data model data of various related information of construction projects. The diversity of BIM professional software has led to the diversification of data formats. The format of BIM model data is very important for the selection of hidden domains. The research and development of existing application systems are all based on geometric data models, and data exchange is mainly carried out through graphics information exchange standards such as IGES, DXF, and DWG.

DXF data model is often used for information exchange between AutoCAD and other software. It is mainly composed of graphic objects and non-graphic objects and also contains limited attribute information, which is convenient to operate. For BIM model data in DXF format, the vertices of the multifaceted mesh are an important feature position of the model data. However, the coordinates of the vertices of the multiface mesh in the BIM model data have many repeated values, and there are fewer effective carriers for embedding watermarks. In order to solve this problem, random noise is added to the frequency domain amplitude coefficient after transformation of the original coordinate data within the error tolerance range to increase the watermark embedding capacity. As shown in Figure 4, W1 is the watermark image extracted without any processing on the original data, and the image has serious noise, and W2 is the watermark extracted after the noise preprocessing, and the watermark image is clearly visible.

The algorithm proposed in this paper includes watermark embedding part and watermark extraction part. First, this paper selects the multiface mesh elements in the BIM model data as the unit and constructs a complex number sequence with all the multiface mesh vertices as characteristic points. Moreover, this paper uses the DFT transform to obtain the amplitude coefficient as the embedding carrier of the watermark, uses the QIM method to embed the watermark on the amplitude coefficient of the DFT frequency domain, and then performs IDFT transform to obtain the watermarked BIM model data. When it is attacked, the watermark is extracted, the watermark is extracted through the voting principle, and the correlation method is used to detect. At this time, the original data is not needed, and blind detection is realized. In order to enhance the ability to resist the attack of deleting entities, the watermark information is evenly embedded in the X and Y coordinate transformation coefficients of all multiface mesh vertices in the BIM model data as much as possible. In order to reduce the excessive influence on the original data, the amplitude value is enlarged. In order to maintain the synchronization relationship between data and watermark and realize blind watermark detection, the idea of coordinate mapping is adopted. According to the nature of DFT transformation, in order to avoid the large error caused by the translation attack on the data, the watermark is not embedded on the first transformation coefficient amplitude value of the set of vertices of the multiface mesh. To ensure the security of the watermark, Logistic chaotic mapping is used to scramble the original watermark image. The flowchart of the algorithm is shown in Figure 5.

First, the BIM model data in the space domain needs to be DFT-transformed to the frequency domain. The specific process of the transformation is as follows:

Step 1. $V_d = \{v_j\}, v_j = (x_j, y_j)$ represents the set of all polyhedral mesh vertices in the original BIM model data, where $j = 1, 2, \ldots, N$, v_j is the coordinates of the polyhedral mesh vertices, (x_j, y_j) is the X, Y coordinate value of the vertices, and N is the number of polyhedral mesh vertices. Using multiface mesh elements as the unit, the complex number sequence $\{a_j\}$ is generated as follows:

$$a_j = x_j + iy_j, j \in \{1, 2, 3, \ldots, N\}. \quad (8)$$

Step 2. For the N point sequence $\{a_j\}$, its DFT transformation is shown as follows:

$$A_l = \sum_{j=1}^{N} a_j\left(e^{-2\pi i/N}\right)^{jl} j, l \in \{1, 2, \ldots, N\}. \quad (9)$$

Here, A_l represents the data after DFT transformation. a_j in the formula can be a complex value. In practice, a_j is a real

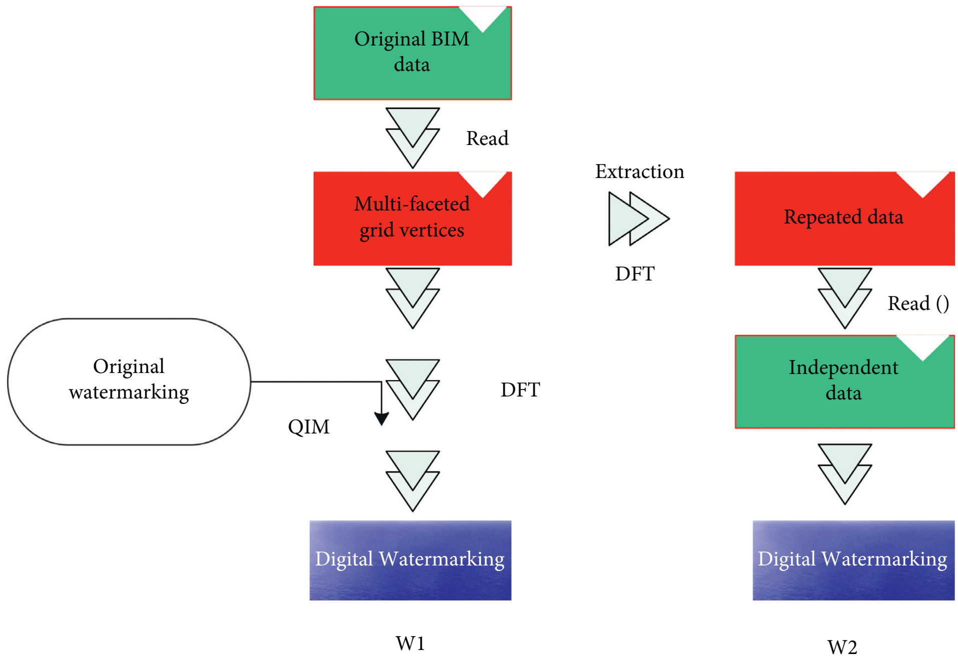

Figure 4: Preprocessing of raw data.

value, that is, the imaginary part is 0. At this time, the formula can be expanded to

$$A_l = \sum_{j=1}^{N} a_j\left(\cos\left(2\pi l \frac{j}{N}\right) - i\times \sin\left(\pi l \frac{j}{N}\right)\right), l \in \{1, 2, \ldots, N\}. \quad (10)$$

The sequence coefficient has two values, the amplitude coefficient $|A_l|$ and the phase coefficient $\angle A_l$, as shown in formula (11). The set of amplitude coefficients is denoted as $\{|A_l|\}$, and the set of phase coefficients is $\{\angle A_l\}$.

$$\begin{cases} |A_l| = \sum_{j=1}^{N} a_j \cos 2\pi l \frac{j}{N}, l \in \{1, 2, \ldots, N\} \\ \angle A_l = \sum_{j=1}^{N} -a_j \sin \pi l \frac{j}{N}, l \in \{1, 2, \ldots, N\} \end{cases}. \quad (11)$$

The specific steps of the watermark generation and embedding algorithm are as follows:

(1) The generation of watermark information. The algorithm reads an image with a size of $M \times M\,(M \geq 2)$ pixels as the original watermark image. In order to improve the security of the watermark, the original watermark is scrambled by Logistic mapping, and the dimensionality of the scrambled binary matrix is reduced to obtain a one-dimensional binary sequence W, where the sequence expression formula is $W = \{w_m = 0, 1 | m = 0, 1, \ldots, P-1\}$, and P represents the length of the watermark.

(2) The algorithm reads the BIM data, the amplitude coefficient $\{|A_i|\}$ obtained by DFT transformation of $\{a_j\}$ is expanded by 10^7, and the noise is added.

(3) The algorithm uses the QIM method to embed the watermark into the amplified amplitude coefficient and obtain the embedded watermark amplitude coefficient $|A_l|$ through the following equation:

$$\begin{cases} |A_l'| = |A_l| - \frac{R}{2}, w_m = 0 \text{ And} \bmod (A_l, R) \geq \frac{R}{2} \\ |A_l'| = |A_l|, w_m = 0 \text{ And} \bmod (A_l, R) < \frac{R}{2} \\ |A_l| = |A_l| + \frac{R}{2}, w_m = 1 \text{And} \bmod (A_l, R) < \frac{R}{2} \\ |A_l'| = |A_l|, w_m = 1 \text{ And} \bmod (A_l, R) \geq \frac{R}{2} \end{cases}. \quad (12)$$

(4) The algorithm scales the obtained $|A_l|$ to restore it to the original data size, and the reduction factor is equal to the enlargement factor.

(5) The algorithm combines the obtained embedded watermark amplitude value with the unmodified phase coefficient to generate a new coefficient $\{A_l\}$, and then IDFT transforms it to obtain the complex number sequence $\{a_l\}$ after embedding the watermark.

(6) The algorithm modifies the vertices of the multifaceted mesh according to $\{a_l'\}$ and obtains the set of multifaceted vertices V_d', $V_d' = \{v_j' = (x_j' + y_j')\}$, $j \in \{1, 2, \ldots, N\}$, after the watermark is embedded, so as to obtain the BIM data after the watermark is embedded.

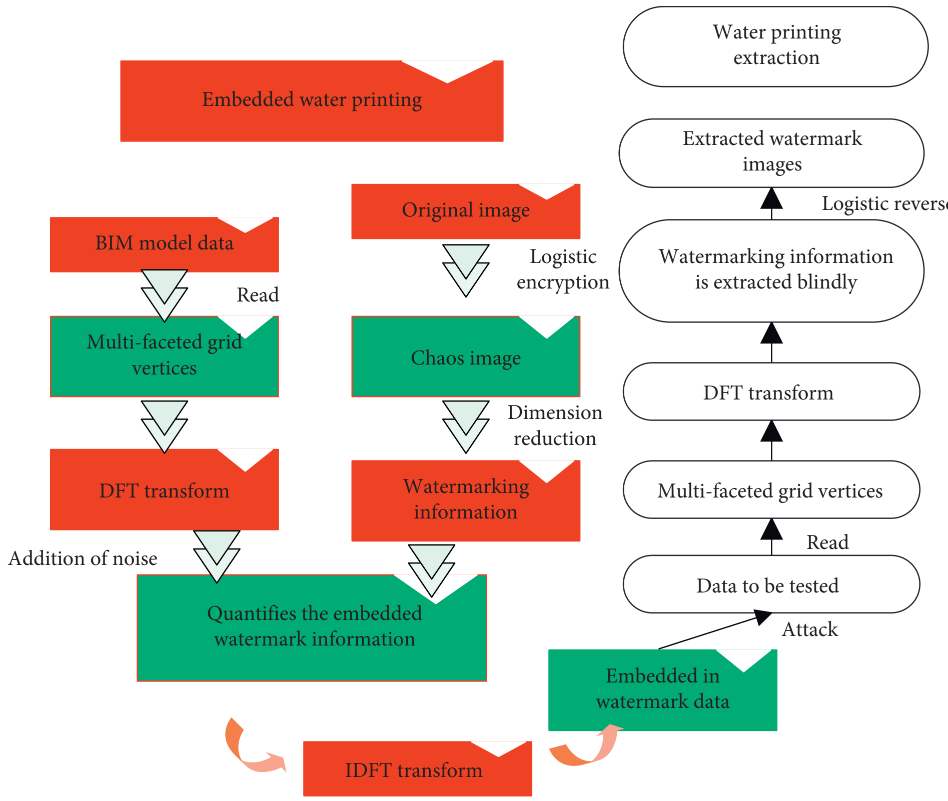

Figure 5: Watermark embedding and extraction framework.

The essence of watermark extraction is the reverse process of watermark embedding. When the data owner finds suspicious BIM model data, the algorithm extracts the watermark according to the following steps:

(1) The algorithm reads the vertices of the multifaceted mesh of the BIM data to be tested, forms a set V_d', and generates a complex number sequence $\{a_j'\}$ according to formula (8).

(2) The algorithm performs DFT transformation on $\{a_j'\}$ to obtain the amplitude coefficient of the coefficient $\{|A_j|\}$.

(3) The algorithm uses the parameters consistent with the embedding process and uses the QIM method to extract the value of suspicious $\{w_m'\}$. The extraction process is as follows:

$$\begin{cases} w_m' = w_m - 1, \mathrm{mod}\left(\left|A_l'\right|, R\right) < \dfrac{R}{2} \\ w_m' = w_m + 1, \mathrm{mod}\left(\left|A_l'\right|, R\right) \geq \dfrac{R}{2} \end{cases}. \tag{13}$$

(4) For the extracted one-dimensional watermark $W' = \{w_m' = 0, 1 | m = 0, 1, \ldots, P-1\}$, the algorithm performs dimensional increase processing and Logistic inverse scrambling to extract the watermark image.

(5) The algorithm uses equation (14) to calculate the normalized correlation coefficient between the extracted watermark image and the original watermark image to measure the robustness. The larger the value of NC, the more similar the two and the better the robustness.

$$NC = \frac{\sum_{m=1}^{M}\sum_{m=1}^{M} XNOR\left(W(m1, m2), W'(m1, m2)\right)}{M \times M}. \tag{14}$$

Here, $M \times M$ is the size of the watermark image, XNOR is the exclusive OR operation, $W(m1, m2)$ is the original watermark information, and $W'(m1, m2)$ is the extracted watermark information. Among them, the closer NC is to 1, the more robust the algorithm is.

4. Literary Works Protection Based on Data Mining Algorithm

In digitized literary works, we can use watermarking algorithm to watermark the characteristics of literary works to obtain digital literary works that have been watermarked. After that, we can combine data mining algorithms to perform text feature recognition and feature classification to improve the copyright protection effect of literary works.

Author recognition method mainly includes two modules: training module and classification module. The functions of the training module mainly include the process of preprocessing the original corpus, extracting key features of the text, and training to obtain the classifier. The function of the dispute text classification module is to preprocess the

dispute text, extract the statistical feature vector from the dispute text, and then input it into the trained classifier, and finally output the author category from the classifier. The methods used in the first two stages of these two modules are exactly the same. The main function of the training module is to build a training classifier. If it is a controversial work, then extract the key statistical features from it and input it into the trained classifier, and finally judge the author's category based on the similarity value. The flowcharts of the training module and the classification module are shown in Figures 6(a) and 6(b), respectively.

The corpus must first undergo text normalization processing, and after it is expressed in a form that can be processed by the computer, the normalized text segmentation is processed. The system structure is shown in Figure 7(a). The named entity refers to the actual content of the entity expressed in the Chinese text sentence, such as unit name, person, geographic name, organization name, etc. One of the basic tasks in natural language processing technology is named entity recognition, which plays an important role in word segmentation, syntactic analysis, and automatic translation with the help of machines and other technologies. At present, the lexical analysis technology researched by the Chinese Academy of Sciences and Harbin Institute of Technology has a module for Chinese text sentence named entity recognition. The principle of this module is shown in Figure 7(b).

After combining the watermarking algorithm to obtain the above model, this paper conducts experimental verification on the model. First, the effect of the text data mining algorithm in the feature recognition of the watermarking algorithm is verified, and the results shown in Table 1 are obtained.

The above verifies that the text data mining algorithm has a very good effect in the feature recognition of the watermark algorithm. On this basis, the copyright protection effect is evaluated. This part is carried out by the expert evaluation method, and the results are shown in Table 2.

The above research has verified that the copyright protection effect of literary works based on data mining algorithms is very good.

5. Conclusion

While the digitization of literary works brings a new production and lifestyle to people, its own characteristics have brought a copyright crisis to itself. When digital products exist in digital form, they can be easily edited, modified, and stored through computers or other digital equipment. At the same time, it can also carry out low-cost and lossless copying and transmission through various forms of storage media, computer networks, or other data transmission methods. The advantages of these original digital literary works make it very easy to illegally occupy, copy, edit, and disseminate unauthorized products that infringe on the owner's copyright. This paper combines data mining technology to study the copyright protection of literary works, constructs a literary copyright protection system, and improves the copyright protection effect of modern digital literary works. The experimental research results verify that the effect of the copyright protection system of literary works based on data mining algorithms is very good.

Improved SVM algorithm improves the efficiency of College English teaching effect evaluation and meets the requirements of College English teaching evaluation. Based on the relevant theories, this paper constructs the evaluation index system with teachers and students as the main body and takes the questionnaire survey results as the input samples of the LSSVM algorithm. Compared with the evaluation accuracy of an optimized BP neural network and the category weighted gray target decision-making method, the results show that the evaluation accuracy of optimized LSSVM algorithm is 96.26%. Taking SIT as an example, this paper uses the optimized LSSVM algorithm to evaluate its teaching effect and obtains that teachers' literature and teaching contents are important factors to improve the effect of English teaching. Therefore, this paper introduces the intelligent voice system to optimize the English teaching design of SIT. The teaching design is optimized from the dimensions of teaching objectives, learning situation, teaching content, teaching media and curriculum materials, and teaching procedures.

1. Introduction

Teaching effect evaluation has become a hot issue in the field of education at home and abroad. Teaching effect is the core of school survival and development. Teaching evaluation is a very important and indispensable part of the teaching process and an important means to test the teaching effect. Traditional teaching evaluation methods only focus on students' learning effect, which is not conducive to the reform of English teaching methods and contents.

English teaching effect evaluation refers to the evaluation of teachers' teaching effect from the aspects of teaching content, subject organization, teaching achievement, and learning interest. Through the evaluation, the direction of curriculum optimization can be put forward. Eleni et al. (2012) believe that teaching motivation and teaching satisfaction are the main factors of curriculum teaching effect and put forward effective evaluation methods for teaching motivation, such as the experimental method, questionnaire method, and text analysis method [1]. The traditional questionnaire survey and observation evaluation cannot objectively evaluate the classroom quality for a long time and cannot obtain clear evaluation results. In this case, Li et al. (2019) propose an intelligent school teacher quality evaluation platform. By considering the sensor information, flow information, and power information of mobile devices in the teaching process, the teacher quality evaluation score is given through the neural network training classification model [2]. Nalla (2019) proposes an evidence-based teaching strategy evaluation framework [3]. Leong et al. (2012) discuss the method of analyzing text mining of short message service (SMS) in teaching evaluation, and analyze and classify the information [4]. Ahmad (2018) analyzes how to the improve students' response rate to teaching curriculum evaluation through the survey results. The survey results show that the effective communication of teachers can effectively improve students' participation in the evaluation of teaching curriculum quality [5]. Cadez et al. (2017) analyze the relationship between learning style and academic achievement of accounting students through teacher evaluation [6]. Bi (2018) studies the teaching evaluation grade and uses the evaluation based on statistical process control theory and standard deviation diagram to evaluate the school teaching grade [7].

In the selection of evaluation methods, the emotion classification model is widely used. Mullen and Collier (2004) first analyze the syntax between texts and then further analyze the emotion of the text based on the SVM algorithm [8]. Moraes et al. (2013) integrate the machine learning algorithm and deep learning technology into teaching effect evaluation, compare the classification effect of the support vector machine algorithm with that of the artificial neural network algorithm, and prove that the classification effect of ANN is equivalent to that of SVM [9]. Besides, Fuzzy mathematics theory, analytic hierarchy process, and BP neural network are also commonly used in the evaluation of CETE. Kennedy and Eberhart (1997) proposed an evolutionary algorithm to solve discrete problems based on the study of bird foraging behavior. Compared with the genetic algorithm, it has faster convergence speed in solving multiuser detection problems [10].

Sun (2020) et al. have developed an online English teaching assistant system, which uses the decision tree algorithm and a neural network to generate an English teaching evaluation model based on decision tree technology and studies the potential relationship between the evaluation results and various factors [11]. However, optimizing the evaluation model of college teaching quality based on the BP neural network will ignore the factors of teaching quality, resulting in the low accuracy of CETE evaluation. Krohling and de Souza (2012) define the positive and negative target distance from each scheme to the positive and negative ideal scheme, and sort the schemes according to the comprehensive target distance of each scheme [12]. The teaching evaluation method based on category weighted gray target decision making has low evaluation efficiency due to the complex calculation process. In the application of the intelligent system to curriculum teaching, the student model of the intelligent teaching system based on the Bayesian network established by Lan (2020) can not only objectively evaluate students' cognitive ability but also infer students' next learning behavior [13]. Myers (2021) uses the intelligent teaching system to automatically detect students' emotional state and guide students into a positive learning state [14]. Ramadan and Vasilakos (2017) collected shallow brain activity signals, extracted specific brain waves according to specific frequencies, and evaluated students' attention, emotion, and cognitive load [15].

The existing CETE research mainly focuses on the selection of the evaluation model and the improvement of model accuracy, and there is less research on practical application and optimization means. This paper not only optimizes the evaluation model but also innovatively introduces information technology means such as the intelligent voice system to improve the level of College English teaching. Based on the past research, this paper finds that mathematical algorithms are widely used in the evaluation of CETE, but most of them only use one method, and the optimization of the algorithm needs to be further improved. In this paper, the SVM algorithm is used as the evaluation method of CETE, and the PSO algorithm is used to optimize the SVM algorithm.

This paper constructs the evaluation index system from the perspectives of teachers and students and fully considers students' interests and teachers' feelings. By comparative analysis, the algorithm with the highest accuracy is selected as the evaluation method of this paper, and the selected evaluation method is applied to practice to obtain the most important influencing factors. The intelligent voice system is introduced to optimize College English teaching curriculum design, the improvement of teaching evaluation quality is fully considered, and curriculum design optimization is carried out while improving students' English learning achievements and considering students' interests and learning needs. In the evaluation process of this paper, the effect of College English teaching is divided into four levels: excellent, good, pass, and fail, and the optimized algorithm is used for empirical research. Firstly, this paper selects the Shanghai Institute of Technology for a case study to evaluate its College English teaching effect. Secondly, according to the evaluation results of each index and the overall evaluation results, the most important index in the process of curriculum optimization design is obtained. Finally, the intelligent speech system is introduced to formulate the optimization scheme and suggestions of College English teaching curriculum design.

2. Evaluation Model of College English Teaching Effect

2.1. Evaluation Index System of College English Teaching Effect. There are many theories for the evaluation system of College English teaching effect. Teachers and students are the two main bodies of the classroom, and they participate in the whole process of teaching. Therefore, starting from these two subjects, CETE can be evaluated more comprehensively. According to the relevant theories, an evaluation index system with teachers and students as the theme is constructed, as shown in Figure 1. The evaluation index system constructed in this paper can evaluate the teaching effect more comprehensively from the main perspective of students and teachers and from the different perspectives of participants in teaching activities. From the perspective of students, the evaluation index mainly comes from their feelings in class. Therefore, the evaluation indicators from the perspective of students mainly include course content, class atmosphere, teaching order, teaching skills, sense of responsibility, and interest. From the perspective of teachers, the evaluation indicators mainly come from the actual teaching effect and the number of courses. Therefore, the evaluation indicators from the perspective of teachers mainly include students' performance, correcting homework, the number of classes dismissed in advance, the number of classes transferred, and the number of classes suspended. The interpretation and definition of indicators are shown in Table 1.

Teachers' sense of responsibility and English achievement are important indicators to evaluate the effect of College English teaching. The evaluation index data of College English teaching effect are used as the input sample of the least squares support vector machine to realize the evaluation of College English teaching effect.

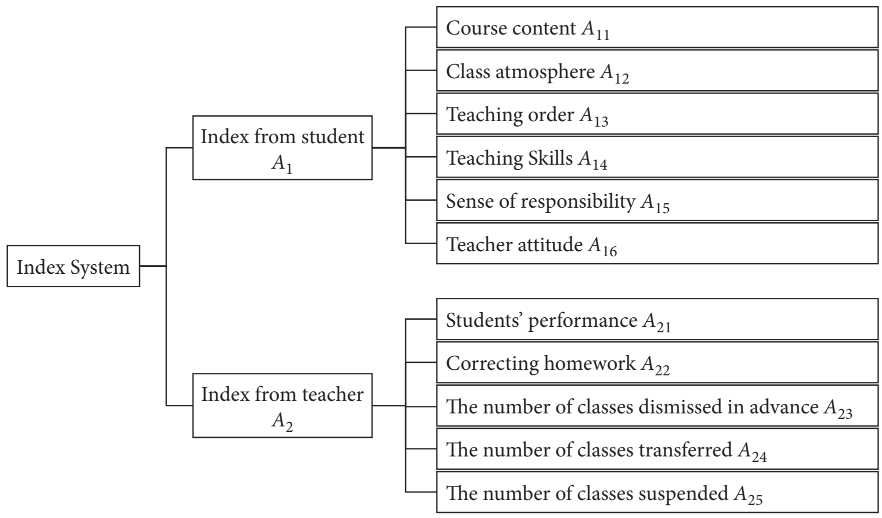

Figure 1: Evaluation index system of CETE.

Table 1: English teaching effect evaluation index.

	Index	Explanation
A_{11}	Course content	Reasonableness of English subject content
A_{12}	Class atmosphere	The quality of English topic atmosphere
A_{13}	Teaching order	The organization and hierarchy of lectures
A_{14}	Teaching skills	Teachers' teaching skills
A_{15}	Sense of responsibility	Teachers' sense of responsibility to students
A_{16}	Teacher attitude	The seriousness of teachers in correcting homework
A_{21}	Students' performance	Students' performance in class
A_{22}	Correcting homework	Accuracy of operation
A_{23}	The number of classes dismissed in advance	The teacher dismissed the class early for reasons other than the course
A_{24}	The number of classes transferred	Teachers change classes for reasons other than the course
A_{25}	The number of classes suspended	Teachers do not attend classes for reasons other than the course

2.2. Evaluation Principle of LSSVM. This paper uses the least squares support vector machine (LSSVM) method to evaluate English language teaching. LSSVM is one of the most widely used methods with good accuracy and precision in nonlinear signal processing. Compared with artificial neural networks, it can overcome the disadvantages of long training time, randomness of training results, and overlearning [16]. Compared with SVM, LSSVM transforms inequality constraints into equation constraints and quadratic programming problems into a linear system of equation problems, which greatly facilitates the solution of Lagrange multipliers λ. The computational efficiency of LSSVM is higher than that of SVM. Furthermore, LSSVM is equally suitable for classification and regression tasks in high-dimensional input spaces and can be extended to unsupervised learning and recurrent neural networks.

The main description of the CETE evaluation model used in this paper is as follows: a nonlinear mapping $\varphi(\mathbf{x_i})$ is chosen to map the sample vector with n-dimensional input data as x and one-dimensional output data as y $[(x_1, y_1), \ldots, (x_i, y_i), \quad \mathbf{x_i} \in \mathbf{R}^n, \; y_i \in \mathbf{R}, \quad i = 1, 2, \ldots, m]$, from the original space to the high-dimensional feature space. The regression equation of LSSVM is shown in the following equation:

$$y_i = f(\mathbf{x_i}) = \boldsymbol{\omega}^T \cdot \varphi(\mathbf{x_i}) + b. \tag{1}$$

In the above equation, ω is the weight vector and the constant b is the bias term. The optimization problem of LSSVM is shown in the following equation:

$$\min \frac{1}{2}\boldsymbol{\omega}^T \cdot \boldsymbol{\omega} + \gamma \cdot \frac{1}{2}\sum_{i=1}^{m} \xi_i^2. \tag{2}$$

In the above equation, γ is the regularization parameter and ξ is the error variable. Compared to SVM, the constraints of LSSVM are different, as shown in the following equation:

$$y_i = \boldsymbol{\omega}^T \cdot \varphi(\mathbf{x_i}) + b + \xi_i^2, \; i = 1, 2, \ldots, m. \tag{3}$$

The inequality constraint of the SVM is replaced by an equation constraint, and the Lagrange function is constructed for the solution, as shown in the following equation:

$$\begin{aligned} L(\boldsymbol{\omega}, b, \xi, \lambda) = {} & \frac{1}{2}\boldsymbol{\omega}^T \cdot \boldsymbol{\omega} + \gamma \cdot \frac{1}{2}\sum_{i=1}^{m} \xi_i^2 \\ & - \sum_{i=1}^{m} \lambda_i \left[\boldsymbol{\omega}^T \cdot \varphi(\mathbf{x_i}) + b + \xi_i - y_i\right]. \end{aligned} \tag{4}$$

In the above equation, λ_i is the Lagrange multiplier. The optimal value is calculated under the Karush–Kuhn–Tucker (KKT) optimization condition. The equation constraint is shown in the following equation:

$$\begin{cases} \dfrac{\partial L}{\partial \boldsymbol{\omega}} = 0 \longrightarrow \omega = \sum_{i=1}^{m} \lambda_i \varphi(\mathbf{x_i}) & , \\ \dfrac{\partial L}{\partial b} = 0 \longrightarrow \sum_{i=1}^{m} \lambda_i = 0 & , \\ \dfrac{\partial L}{\partial \xi} = 0 \longrightarrow \lambda_i = \gamma \xi_i , \\ \dfrac{\partial L}{\partial \lambda} = 0 \longrightarrow \boldsymbol{\omega}^T \cdot \varphi(\mathbf{x_i}) + b + \xi_i - y_i = 0. \end{cases} \tag{5}$$

By eliminating $\boldsymbol{\omega}$ and ξ in the above equation, the quadratic optimization problem is replaced by solving a linear system of equations, and the result is calculated as in the following equation:

$$\begin{bmatrix} 0 \\ \mathbf{Y} \end{bmatrix} = \begin{bmatrix} 0 & \mathbf{Q}^T \\ Q & \boldsymbol{\Omega} + \gamma^{-1}\mathbf{I} \end{bmatrix} \begin{bmatrix} b \\ \lambda \end{bmatrix}. \tag{6}$$

In the above equation, $\mathbf{I}$ is the identity matrix; α is a support vector; $\mathbf{Y} = [y_1, y_2, \ldots, y_m]^T$; $\mathbf{Q} = [1, 1, \ldots, 1]^T$; $\boldsymbol{\Omega}$ represents the inner product of the kernel matrix, $\boldsymbol{\Omega} \in \mathbf{R}^{m\times m}$, and $\boldsymbol{\Omega}_{ij} = \varphi(\mathbf{x_i})^T \varphi(\mathbf{x_j}) = K(\mathbf{x_i}, \mathbf{x_j})$, $i, j = 1, 2, \ldots, m$. Based on the kernel function in the original space, the regression of LSSVM is obtained function for the following equation:

$$y = \sum_{i=1}^{m} \lambda_i K(\mathbf{x_i}, \mathbf{x_j}) + b. \tag{7}$$

To circumvent the dimensional catastrophe, a radial basis kernel function commonly used in LSSVM is introduced instead of the inner product operation in the high-dimensional feature space. The radial basis kernel function is shown in the following equation:

$$K(\mathbf{x_i}, \mathbf{x_j}) = \exp\left(-\frac{(x - x_i)^2}{\sigma^2}\right). \tag{8}$$

In the above equation, σ represents the kernel function width. The generalization ability of LSSVM can be enhanced by optimizing two parameters, γ and σ . When LSSVM is used for University English teaching evaluation, the particle swarm algorithm can be used for the parameter finding problem, and the specific evaluation process is shown in Figure 2.

2.3. Parameter Optimization Based on PSO. Parameter selection is an important research direction in the field of LSSVM research. Many methods can be used to determine γ and σ, but there are deficiencies in memory and time. Particle swarm optimization (PSO) algorithms have the advantages of being less prone to local minima, easy to implement, and with fewer tuning parameters. Thus, PSO is often used to solve nonlinear, nonintegrable, and multimodal problems. In PSO, each potential solution to the optimization problem is called a "particle." Each particle has its own stance and velocity (which determines its direction of flight and distance) and an adaptation value determined by the function being optimized.

A population of m particles is set up in a d-dimensional search space, where the optimal position of particle i searched in the space is described by $\mathbf{p_i}$, $\mathbf{p_i} = [p_{i1}, p_{i2}, \ldots, p_{i\,d}]$; the velocity is described by $\mathbf{v_i}$, $\mathbf{v_i} = [v_{i1}, v_{i2}, \ldots, v_{i\,d}]$; the position of particle i is described by $\mathbf{x_i}$, $\mathbf{x_i} = [x_{i1}, x_{i2}, \ldots, x_{i\,d}]$; the optimal position searched for in the total population is described by $\mathbf{p_g}$, $\mathbf{p_g} = p_{g1}, p_{g2}, \ldots, p_{g\,d}$. The method to update the particle position and velocity is given in the following equations:

$$x_{i\,d}^{k+1} = x_{i\,d}^{k} + v_{i\,d}^{k+1}, \tag{9}$$

$$v_{i\,d}^{k+1} = \omega v_{i\,d}^{k} + c_1 r_1 \left(p_{i\,d} - x_{i\,d}^{k}\right) + c_2 r_2 \left(p_{g\,d} - x_{i\,d}^{k}\right). \tag{10}$$

Among them, ω is the inertia weight coefficient; c_1 and c_2 are the acceleration constants; k is the optimization algebra; $v_{i\,d}^{k}$ and $x_{i\,d}^{k}$ are the search velocity and position of the particle in the space at algebra k; r_1 and r_2 are the random numbers. The process of optimizing the parameters γ and σ by PSO is as follows:

(1) Normalize and preprocess the CETE evaluation data
(2) Set the parameter values
(3) Initialize processing
(4) Set the individual extreme value $P_{i\text{best}}$ and the global extreme value g_{best}, and calculate the adaptation value of each particle according to its current position, $f = \sum_{i=1}^{N} |y_i - y_1'|$, where N is the total number of samples
(5) In order to generate new populations, update the particle positions and velocities according to equations (9) and (10)
(6) Solve for the fitness value f for each particle within the new population
(7) Compared with the previous optimal speed and optimal position of the population, if it is excellent, the conversion will be implemented, otherwise, no adjustment will be made
(8) If the optimal ending condition is not met, we need to make the number of iterations $t = t + 1$ and return to Step 4 to find the optimal solution

2.4. Evaluation Process. Combined with the evaluation index system of College English teaching effect, a College English teaching effect evaluation model based on the particle swarm optimization algorithm and support vector machine is established. The flowchart of the model is shown in Figure 3.

The input sample of LSSVM is the value of CETE evaluation data, which is from the expert rating. And the evaluation results are obtained through the operation of the

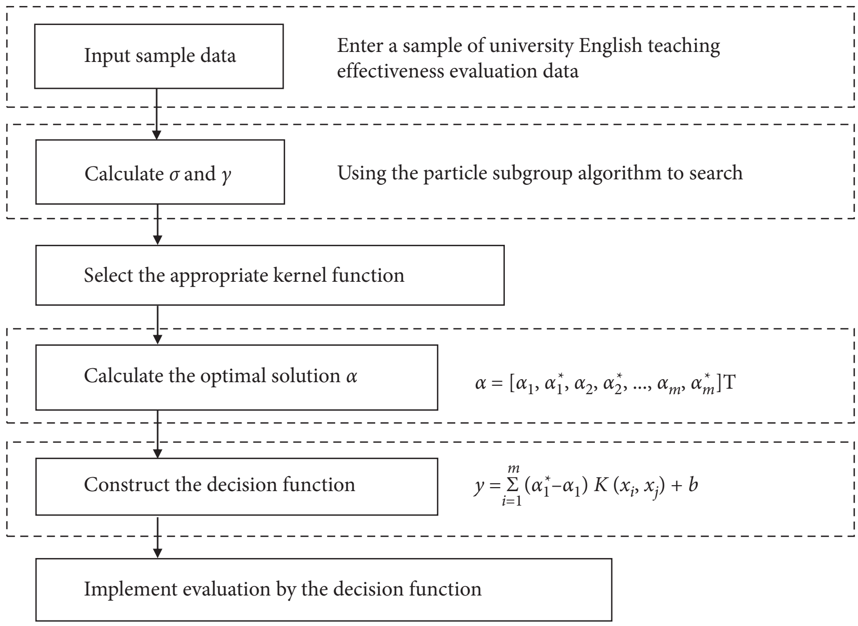

Figure 2: Evaluation model main process.

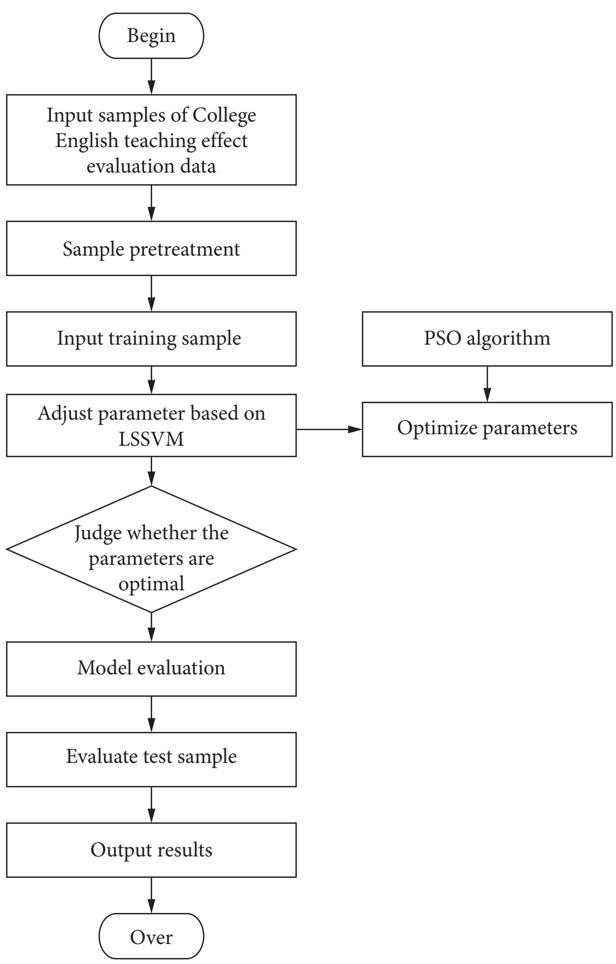

Figure 3: Flowchart of CETE based on the improved support vector machine algorithm.

SVM algorithm. This paper optimizes the evaluation algorithm by comparing the evaluation results before and after adding the PSO algorithm. The PSO algorithm mainly solves the optimal solutions of kernel function parameters and regularization parameters of LSSVM, and then optimizes the process of CETE evaluation. It judges whether the existing parameters are the optimal solution through the IF function. If the result is yes, the test samples are evaluated, and the results are output. If the result is no, the particle swarm optimization algorithm needs to be used to readjust the parameters to the optimal solution. The above process is a machine learning process, and the computer realizes the purpose of automatic tuning through its own learning.

3. Experimental Results and Analysis

This paper selects the English classroom teaching effect of Shangqiu Institute of Technology as the research object and collects sample data according to the evaluation index of CETE. Through the actual situation of College English teaching and the evaluation of College English teaching effect by experts, we can get the quality level of College English classroom teaching and 200 data samples for testing. In the model building process, this paper chooses the Gaussian radial basis function as the kernel function.

The training data of each degree of the six faults are input to the LSSVM regressor for learning, while the PSO algorithm is used for multiobjective optimization of the regularization parameters and kernel function parameters. The population size of PSO is set to 200, the learning factor to 1.49, the maximum number of iterations to 1000, and the inertia weight to 1 initially. The final choice of the best model parameters is $(\gamma, \sigma^2) = (2316.57, 224.46)$, $b = 9.93$. The regression performance of the model is evaluated by the ratio of the number of correct model predictions to the total number of samples, as shown in the following equation:

$$\text{accuracy} = \frac{\mathrm{TP} + \mathrm{TN}}{\mathrm{TP} + \mathrm{FP} + \mathrm{FN} + \mathrm{TN}}. \tag{11}$$

In order to verify the effectiveness of the PSO-LSSVM method for CETE assessment, we also use the BP neural network [17] and gray target decision method [18] for comparison testing. Three methods are used to test the experimental dataset to obtain their accuracy calculation results, as shown in Table 2 and Figure 4. As can be seen from Table 2, the average evaluation accuracy of the method in this paper is 96.26%, which is 5.36% and 14.29% higher than that of the BP neural network and gray target decision, respectively. Therefore, the PSO-LSSVM method has a very superior degree of accuracy and scientific performance.

Next, we performed 20 experiments on 10 datasets using the three methods, and the time used for the three methods (test time and training time) within the experiment was calculated while the average value was selected. The results of the comparison of the three methods are shown in Figures 5 and 6.

From the comparison results of Figures 3 and4, it can be seen that POS-LSSVM has obvious advantages over the other two methods in terms of time efficiency, the training time and testing time of this method are the lowest, the average training time is as low as 15 ms, and the average testing time is as low as 5 ms. Compared with the BP neural network, its training time saves 8 ms and its test time saves 5 ms; compared with gray target decision, its training time saves 3 ms and its test time saves 4 ms.

4. Teaching Optimization Design

The purpose of this paper is to come up with the most sensitive influencing factors through the constructed CETE evaluation model and then proposing some targeted ways to improve the effectiveness of English teaching. After further questionnaires and armor-piercing interviews, we conclude that A_{11}, A_{12}, A_{14} , and A_{21} play a more important role for English teaching. The four indicators were moved up and down by 5% and 10%, respectively, and the magnitude of the impact of each move on the evaluation results is shown in Figure 7. To facilitate the analysis of the degree of change in the evaluation results, the rate of change is expressed using the absolute value of the true value. Figure 7 illustrates that A_{11} and A_{14} have a higher degree of influence on the evaluation results compared to A_{12} and A_{21}, which suggests that the optimization of CETE in this paper focuses on both course content and teacher skills [19].

In language learning, interests will be a great help to students. Therefore, we must find suitable methods to improve teachers' literacy and enrich teaching contents so as to stimulate the interest of student and improve the teaching effect [20]. Starting from the reality of STL, this paper mainly improves College English teaching through the integration of information technology and curriculum design.

4.1. Observation Dimension of Curriculum Design. Before the beginning of curriculum optimization, this paper observes the English curriculum of SIT colleges and universities, obtains research materials by means of field observation, and mainly observes the curriculum design of English teaching in SIT colleges and universities, the application of technical tools, and the integration of technology and curriculum content. The specific observation dimensions include teaching objectives, learning situation, teaching content, teaching media and curriculum materials, and teaching procedures.

In terms of teaching objectives, SIT teachers focus on cultivating college students' basic knowledge and skills of English audio visual according to the syllabus and curriculum requirements and pay attention to the cultivation of students' emotions, attitudes, and values in the teaching curriculum planning. However, it does not focus on cultivating students' English thinking and lacks the cultural elements in English function. In terms of learning, SIT teachers regard students as the learning center. In the whole process of English teaching, teachers pay enough attention to students' learning status and performance. However, as a freshman of SIT, the basic knowledge of English is not solid, and the knowledge structure is not systematic and perfect. Teachers' teaching rhythm is not synchronized with students' learning status and ability. As a result, teaching is hindered. In terms of teaching content, SIT teachers have the phenomenon of following the book, lack of effective design of teaching content, and no fine processing and expansion of knowledge and skills. The teaching content adheres to the textbook itself, resulting in the lack of interest in the course. In the application of teaching media and curriculum materials, SIT classrooms are equipped with advanced teaching technology tools, but teachers are not well applied to practical teaching, only as the presentation and display of curriculum materials, and curriculum design lacks theoretical guidance.

In addition, in the actual teaching process, teachers only use textbooks, markers, and whiteboards for teaching. Therefore, teaching technology cannot give full play to its maximum function, and it is in a state of separation from the whole teaching process. In terms of teaching procedures, SIT teaching procedures tend to be old, mainly including review, main curriculum, practice, summary, and home work There are some practical problems in this teaching procedure, which should be optimized to add links between teachers' activities and students' learning activities.

Thus, the application framework of teaching links, activity forms, and technical tools of the specific observation dimension of SIT English course is obtained, as shown in Figure 8. In the review session, the teacher summarizes and reviews the basic English knowledge and skills learned in the previous course, including cognition, understanding, and skills. In the main curriculum link, the teacher will present the prepared course content in writing and oral form according to the teaching requirements, mainly including theme introduction, vocabulary obstacle removal, key explanation, text explanation, and extracurricular knowledge expansion. In the practice link, teachers test the students'

Table 2: Comparison of evaluation accuracy results.

Dataset	PSO-LSSVM (%)	BP neural network (%)	Gray target decision (%)
1	96.89	92.30	84.55
2	95.72	88.76	83.43
3	97.90	92.12	83.08
4	94.34	93.62	80.89
5	96.41	87.90	79.63
6	98.02	89.54	82.60
7	95.23	90.21	78.15
8	96.29	92.88	83.42
9	94.37	90.49	78.94
10	97.46	91.25	85.03

learning of course knowledge in groups by random roll call and random inspection, and restate and explain the knowledge points with high error rate. In the summary section, teachers apply the consolidation method to review the course and repeat the key and difficult points of the course to understand the students' understanding of knowledge. In the home work link, the teacher assigns homework after class. The types of homework include dictation and recitation of key words, and flexible collocation and application of phrases and sentence patterns.

4.2. Optimization and Perfection of Teaching Procedure. This paper chooses an optimized program guided by the integration of information technology and curriculum, mainly to address the current situation of outdated teaching

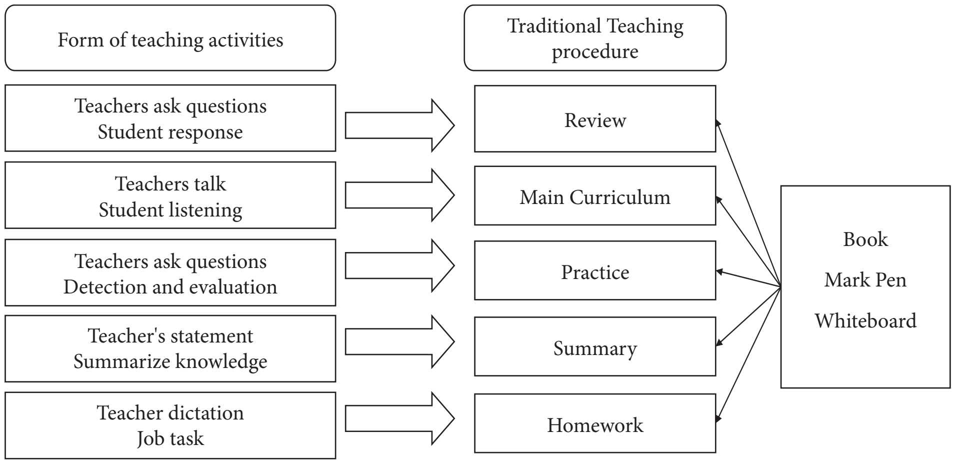

Figure 8: Teaching activity procedure of SIT universities before optimization.

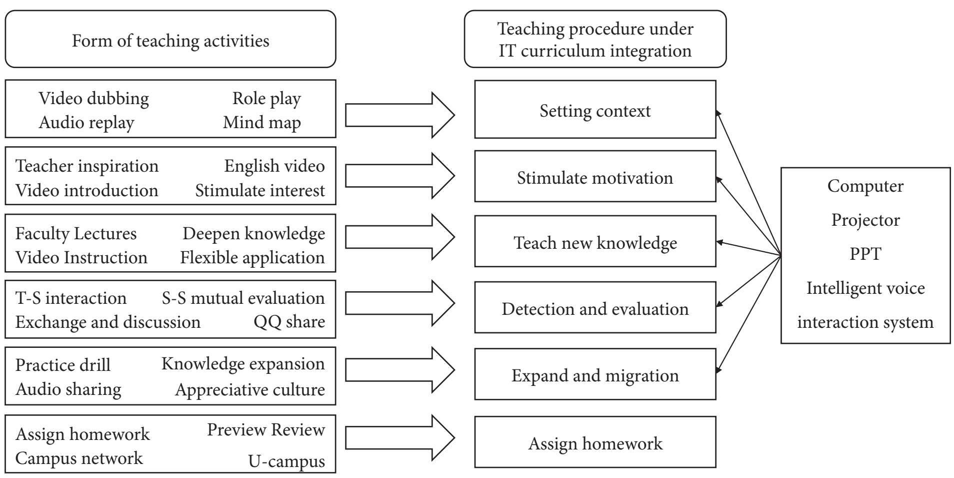

Figure 9: Teaching activity procedures under IT curriculum integration.

design, fragmentation, and disconnection between technological tools and actual teaching. The aim is to enhance the comprehensive ability of teachers, improve learning interest of students, and enhance the coherence of course content and teaching quality in future education and teaching. The main dimensions of teaching optimization design include the whole teaching process, using technology concepts and technology tools to integrate teaching dimensions. Every aspect of teaching is assisted and facilitated by the application of technology; the technology concept fully integrates the whole teaching process, the technology tools are no longer idle, and they are more efficiently integrated with teaching.

The intelligent voice system is integrated into all stages of the whole course teaching process to enrich the teaching content so that students can carry out role playing, audio and video appreciation, and other activities. This pedagogical optimization focuses on the teacher-led-student-subject role in the teacher-student teaching role position dimension. Students learn under the inspiration, guidance, and teaching of the teacher. Then, under the guidance of this theory of teaching-learning relationship, the optimization of teaching and learning under the guidance of IT and curriculum integration is achieved through the use of technological tools, pedagogical aids, and the integration of subject content concepts into the whole teaching process. In general, the study provides a careful design and detailed analysis of the procedures of teaching activities so that the optimized teaching design can be more effective. The specific contents of teaching optimization and the integrated application of information technology are shown in Figure 9.

5. Conclusion

The quantitative nonlinear functions between the CETE and each evaluation index are complicated. The complex mathematical relationships lead to subjectivity in the evaluation scores, which affects the objectivity and fairness of the evaluation. In order to accurately evaluate the effectiveness of College English teaching and improve the overall level of College English teaching, this paper studies the evaluation model of College English teaching effectiveness based on PSO-LSSVM. The average accuracy of the evaluation model in ten datasets is 96.26%, which has high advantages and is nearly 6% higher than that of the BP neural network. The average training time is 15 ms, and the average test time is

5 ms. The experimental results show that this method has the highest evaluation accuracy, short evaluation time, and the best evaluation results. Based on the method of this paper, it can improve the optimization plan for English teaching effect, which is of great practical significance for the improvement of College English teaching level.

During the implementation of this study, the concept of information technology and curriculum integration is applied to guide teaching and learning and to carry out teaching practices. This a priori concept optimizes and improves the whole teaching system, and each component of the teaching system incorporates the concept of technology integration. At the same time, it focuses on the integration of technology, pedagogy, and subject content. As a result, SIT is optimized, and students' English listening and speaking skills are improved.

Due to the limited time and energy, there are still some deficiencies to be further improved. Firstly, in order to improve the generalization of the research, we need to try to apply better methods to the in-depth study of College English teaching evaluation index system in future research so as to make it complete and more scientific. Secondly, more experimental datatests are carried out for the method in this paper, and the method is continuously optimized in the test. Finally, it is hoped that the in-depth study will apply better methods to College English teaching and make the evaluation accuracy and efficiency better.

Academic Editor: Tongguang Ni

That the aeroengine ignition device's ignition properties are set as a rule of thumb causes the waste of ignition device's resources, low efficiency of aeroengine's operation, and short service life of plugs. In this paper, a variable frequency and energy aeroengine ignition device is developed for improving aeroengine combustion chamber's ignition properties. The STC89C52 MCU was chosen as the device's core controller. Power supply circuit, MCU and external circuit, IGBT drive circuit, boost circuit, current-voltage monitor circuit, and discharge circuit are all part of the hardware circuit. Because the MCU is in charge of driving the IGBT and discharging the capacitor, the device can accurately generate a corresponding frequency output signal. It also creates frequency control and energy control modules, both of which can adjust ignition properties according to user needs. The ignition device proposed in this paper is stable and lighter and has a predetermined frequency and energy. It lays the groundwork for improving the aeroengine's ignition reliability.

1. Introduction

1.1. Research Status

1.1.1. Research Actuality. At present, many domestic ignition devices adopt reverse flyback converters to boost the voltage [1–3]. They use a gas discharge tube to discharge electricity. A few advanced ignition devices use MOSFET to boost the voltage [4–6]. That some western countries have begun to develop electronic ignition devices, which are small and light, and have precision frequency, laying a perfect foundation for the subsequent study of variable frequency and energy ignition devices.

The performance of domestic high-temperature semiconductors is very low, which cannot follow the desire of requesting large aeroengine high-temperature working environment [7, 8]. At present, domestic large aeroengine ignition device mainly uses a mechanical resonance inverter booster transformer to succeed inverter booster. It adopts gas discharge tubes as discharging control switches [9, 10]. Only some small engines, power plants, and starters which require low-temperature working environment use semiconductor power tube boost circuit [11].

1.1.2. Trend. Aeroengine fuel must be ignited by an ignition system and burned, which serves as a source of energy. Engines must have a low rate of controlling in-flight shutdown and good in-flight ignition capability. The ignition system [12, 13] is a critical component of the engine's starting and restarting process, and its operating characteristics and abilities have a direct impact on whether engines start and restart successfully, as well as the engine's overall safety. The following is a summary of the future development trend of domestic aeroengine ignition systems:

(1) From inductive energy storage to capacitor energy storage ignition device: the ignition device, which has a special energy storage device inside, is a key component of energy storage and release. The stored energy of an inductive energy storage ignition device is typically several dozens of millijoules, with high and uncontrollable discharge frequencies. The stored

energy of a capacitor energy storage ignition device can be several dozens of joules, with low and controllable discharge frequencies. The inductive energy storage system's stored energy is used for indirect ignition, which is heavy. The capacitor energy storage system's stored energy is used for direct ignition. Unless an old machine type is isolated, new machine types now use a capacitor ignition system rather than an inductive system. By controlling the energy-storing capacitance charge, the capacitance discharge ignition system accumulates enough voltages. It releases energy into the ignition spark plug by capacitance discharging instantaneously [14].

(2) From mechanical to electronic ignition device: The development of the ignition system is also the development of electronic components. Contact ignition device grows into contactless ignition device. And analog ignition device grows into digital ignition device.

The main difference between a contact and a contactless ignition device is whether or not there are any devices inside, such as a voltage converter, that have contact vibration. The DC-AC [15] contact ignition device with electromagnetic contact vibration has electromagnetic conversion abilities of vibration transformer coils, and low-voltage direct current becomes high-voltage pulse current. The diode then rectifies the signal and charges the energy-storing capacitance. When the capacitance voltage reaches the discharge tube's breakdown voltage, the discharge tube breaks down, releasing energy into the spark plug and cable. An electric spark is produced by the ignition spark plug. Then do it all over again. The operational life of a contact ignition device is shorter than that of a contactless ignition device due to the device's moving mechanical elements.

When the contactless ignition device is connected to a DC supply [16, 17], low-voltage DC power is converted to high-voltage AC power by filter circuit and DC converter circuit. It is rectified by time jitters of the diode and charges the energy-storing capacitance. When the voltage of the capacitance reaches the breakdown voltage of the discharge tube, the discharge tube breaks down. It discharges via the discharge tube and the spark plug generates an electric spark. The contactless ignition device is converted mainly by transistor devices.

1.2. Research Purpose. The ignition device, which is common in various aeroengines, is a control device that provides a rated voltage pulse for the combustion chamber in the aeroengine. In the aeroengine system, it is one of the most important control components. The ignition device ensures that the aeroengine system operates safely and reliably under a variety of external environmental conditions. A new type of revolutionary ignition device is a variable frequency and energy ignition device. Technology research on safe variable frequency and energy ignition device is underway in advance of the application needs for domestic aeroengines. The MCU and pulsed power key technologies are primarily used in its technology. It is a high-voltage pulsed power device that is required for concurrent hardware and software design jobs involving variable frequency and energy.

The purpose of this paper is to design a variable frequency and energy aeroengine ignition device [18]. Variable frequency and energy ignition technology is based on the traditional ignition system and is also advanced and intelligent. The big difference between the new system and the traditional system is the possession of abilities of variable frequency and energy. The core technology of the device is solid-state ignition technology. It uses semiconductor components instead of components such as contact transformer and gas discharge tube in traditional ignition technology. It has greatly improved. It has many advantages over traditional ignition device in electromagnetic compatibility, power adaptation, output stability, lifespan, reliability, and maintainability. In addition, variable frequency and energy ignition device adds control circuit based on solid-state ignition circuit to give control of frequency and energy. It can also provide a corresponding frequency electric spark for aeroengine in different climates.

A variable frequency and energy aeroengine ignition device can offer multiple combinations of frequency and energy [19]. The optimum ignition parameters can be progressively determined by matching with other engines under different operating conditions in the experiment. We can craft an ignition system limiting stored energy and a combustion chamber limiting ignition spark frequency by matching with each other from the minimum to the maximum. We determine the best composite value between stored energy and spark frequency under different operating conditions by carrying out experiments progressively. The ignition parameter under different engine operating conditions is given by further control logic. We can enhance start ignition reliability under different engine conditions effectively.

The function of variable frequency and energy is the leading technology in the ignition field, and the frequency and energy of traditional ignition are flat. When demand from customers changes, a new kind of device needs to be redesigned. It wastes time and cost. The variable frequency and energy ignition device designed in the paper has 75 kinds of combinations of frequency and energy. It is used more and more widely. That the aeroengine ignition device's ignition properties are set as a rule of thumb causes the waste of ignition device's resources, low efficiency of aeroengine's operation, and short service life of plugs. In this paper, a variable frequency and energy aeroengine ignition device is developed for improving the aeroengine combustion chamber's ignition function.

2. Hardware Design

The device uses MCU as the core controller. The MCU circuitry can simplify the control circuit and reduce the failure rate of the circuit. The principle block diagram of the ignition device designed in this paper is shown in Figure 1. The ignition device has a total of 15 kinds of frequency that

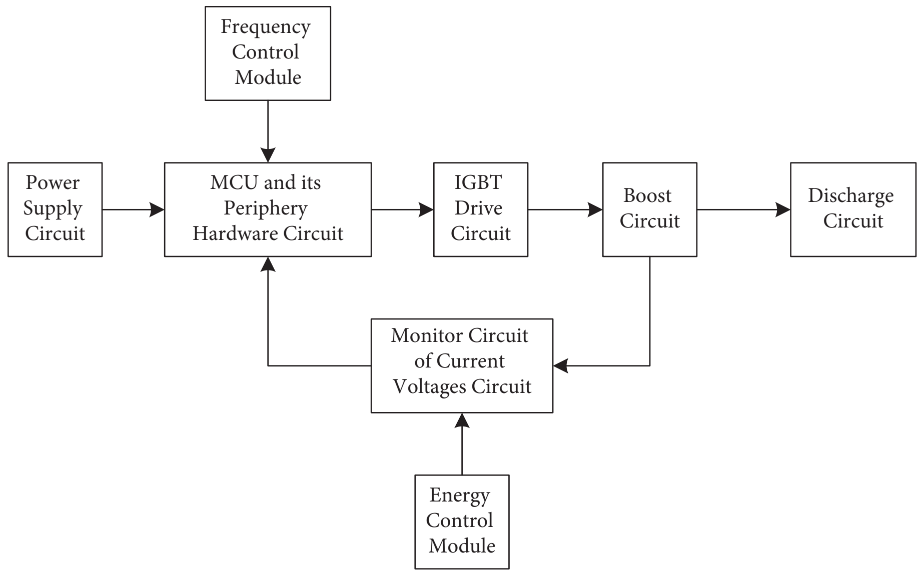

Figure 1: Block diagram of the variable frequency and energy ignition device.

ranges from 1 Hz to 15 Hz and 5 kinds of energy that ranges from 1 J to 5 J.

The variable frequency and energy ignition device works as follows: power source 28 VDC across the power circuit provides stable voltages of +24 V, +12 V, and +5 V, which provides a stable and reliable power for various follow-up modules. The frequency control module causes MCU to output corresponding frequency PWM signals [20]. The signal is then amplified by the IGBT driver module to generate enough high driving voltage. The voltage drives boost circuit made up of IGBTs. Then the diode conducts and the energy-storing capacitance is charged up exponentially. The MCU detects the voltage across the energy-storing capacitance by the monitor circuit of current-voltage circuit during charging. When the voltage is higher than the value set by the MCU, the MCU control ignition triggers port output high level, which triggers the discharge circuit. Then a steady stream of energy in the energy-storing capacitance is released by coil inductance, which breaks down the switch. At last, the ignition device realizes the ignition function. The frequency control module adjusts the frequency and the energy control module adjusts the energy.

2.1. Design of the Power Supply Circuit. The ignition device's input voltage is 28 VDC. The device adopts a 7800 series three-end integrate device that provides stable voltages of +24 V, +12 V, and +5 V for follow-up circuits. Its circuit schematic is shown in Figure 2. We put the filter capacitors C1~C6 before the input of the circuit to remove clutter from the input. We put the vibration-proof capacitor C7 after the output of the circuit to remove clutter from the input. At last, stable voltages of +24 V, +12 V, and +5 V are obtained, respectively.

2.2. MCU and Its Peripheral Hardware Circuit. The STC89C52 MCU of 8051 series is chosen, which is powerful, port richly functional, cheap, and mainstream. The circuit is core to MCU STC89C52 and the switching circuit and A/D converter circuit are designed for its peripheral circuit. The switching circuit selects the silicon chip CD4076, which is one of the sixteen analog switches, in order to choose frequency that ranges from 1 Hz to 15 Hz. The A/D converter circuit selects A/D converter TLC2543 [21]. It digitizes voltages obtained by the monitor circuit of the current-voltage module. Then the result will be input to the MCU. In order to perform well, we should speed up the running rate of the MCU. So 11.0592 MHz crystal is selected. Then the MCU can generate rectangle signals of corresponding frequency by its timer.

MCU hardware circuit is shown in Figure 3. Port P0.0 is the output interface of the PWM signal. Port P0.1 is voltage comparator circuit interface. Port P0.2 is ignition trigger interface. PWM-driven control adjusting theory is an operation that the power supply is opened and closed with some regular frequency. PWM is controlled by changing the length of switching power supply time. PWM frequency is changed by changing the timeframe in the ignition control system to generate PWM signal. So PWM is described as switch-driven device.

2.3. IGBT Drive Circuit. The maximum of the rectangle signal outputted by the MCU is +5 V, which is not sufficient to drive IGBT. So the IGBT drive circuit is needed. It can amplify the rectangle signal to some value which is enough to drive the IGBT. This module uses the silicon chip AST965 as the core controller. The amount of peripheral devices needed is minimal. And it is easy to operate. It can separate control circuits from functional circuits with minimal interference. The IGBT drive circuit is shown in Figure 4. The rectangle signal is input from port 1 and the amplified signal is output from port 8.

2.4. Boost Circuit. The single-ended flyback construction is used in the boost circuit, as Figure 5 shows. A flyback transformer actually is a multiple winding coupling inductance.

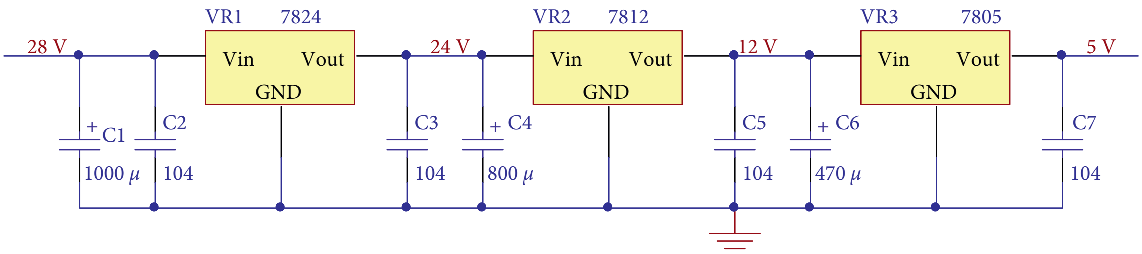

Figure 2: Power supply circuit.

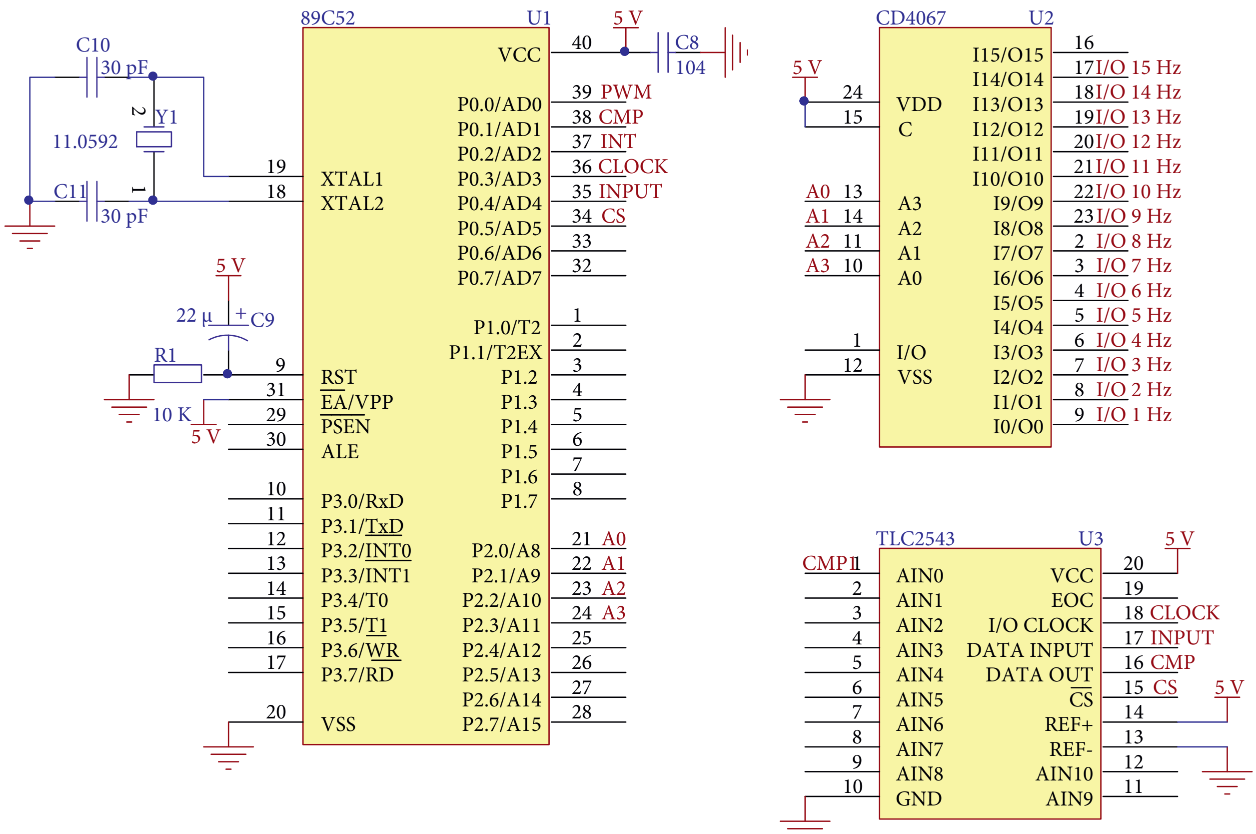

Figure 3: MCU and its peripheral hardware circuit.

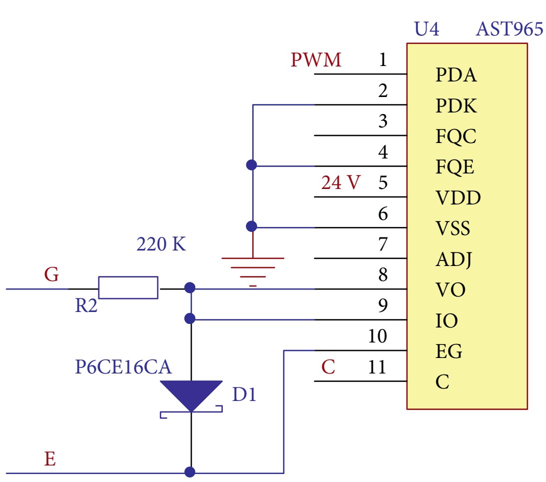

Figure 4: Drive circuit.

The flyback transformer stores energy and it transforms magnetic energy into electricity for transmission. When the IGBT is conducted, the diode is cut off and magnetic field energy is stored in the transformer T1 primary winding. When the IGBT is cut off, the voltage of the secondary winding breaks suddenly and induces a reverse voltage. Then the diode D3 conducts and magnetic field energy in the primary winding is released to the energy-storing capacitance.

During flyback conversion, the transformer has leakage inductance. Then both ends of the IGBT generate peak voltage that disturbs the circuit. So RDC absorbing circuit is designed in this module that inhibits peak voltage.

2.5. Monitor Circuit of Current-Voltage Circuit. The chief function is to monitor the voltage across the energy-storing capacitance. The voltage range of the MCU port is 0–5 V. So

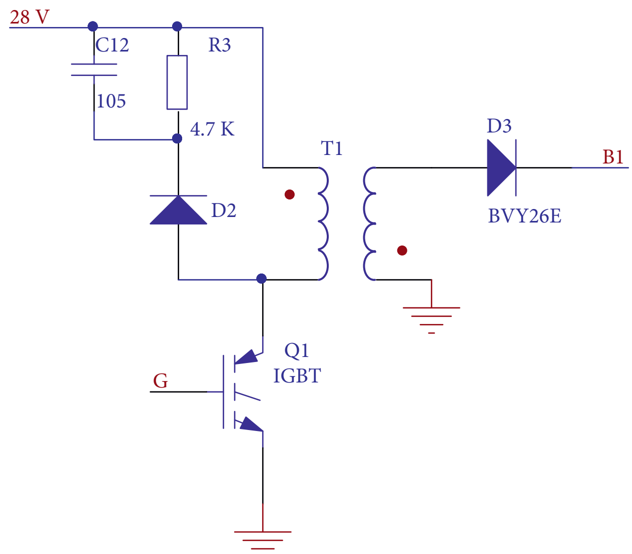

Figure 5: Boost circuit.

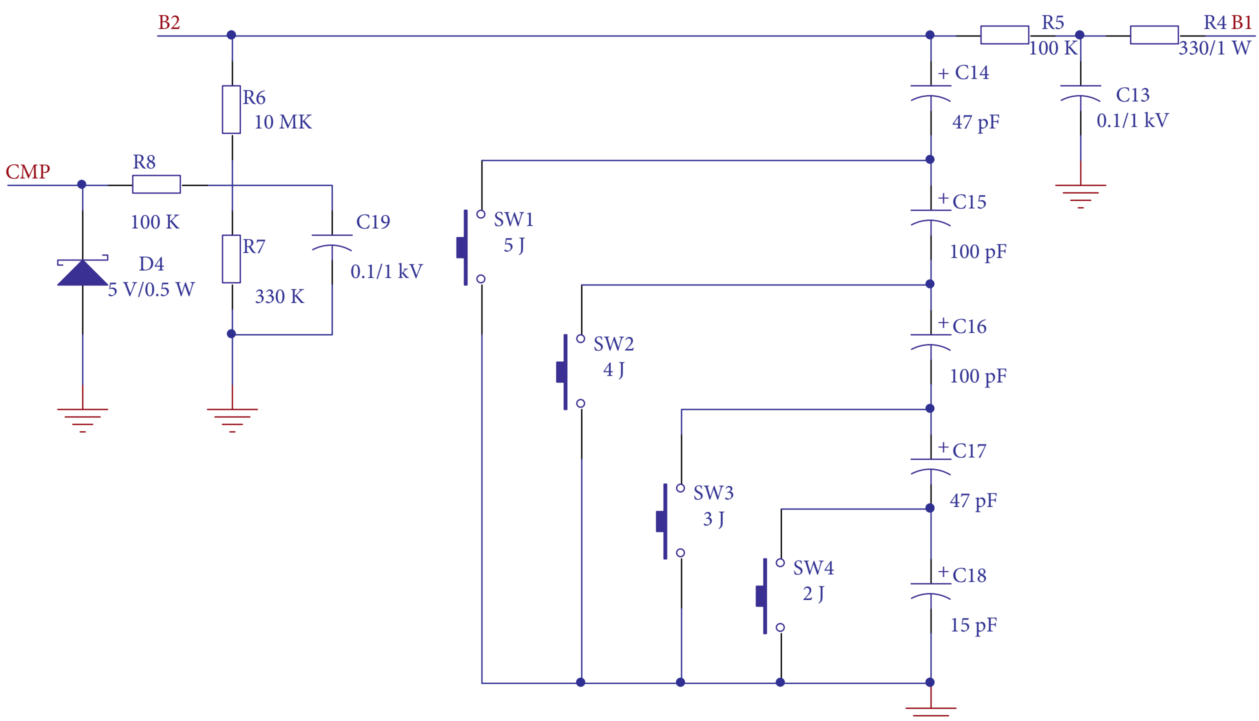

Figure 6: Monitor circuit of the current-voltage circuit.

collected voltage that is divided turns into a signal that can be recognized by the MCU. B1 is the input of the module, which is amplified by the boost module, as Figure 6 shows. It is filtered by the filter capacitor C13. Then it charges the energy-storing capacitance. The voltage across the energy-storing capacitance is divided by the resistors R6 and R7. The voltage across the resistor is just the signal needed to collect. If it is higher than the values set by the MCU, the ignition trigger port outputs high-level signal. If it is lower than the values set by the MCU, the ignition trigger port outputs low-level signal.

Four switches are designed in the monitor circuit of the current-voltage circuit to realize the function of changing energy. C14~C18 are energy-storing capacitors. When no switches are pressed, the energy output of the device is 1 J. When the switch SW1 is pressed, the energy output of the device is 2 J. When the switch SW2 is pressed, the energy output of the device is 3 J. When the switch SW3 is pressed, the energy output of the device is 4 J. When the switch SW4 is pressed, the energy output of the device is 5 J.

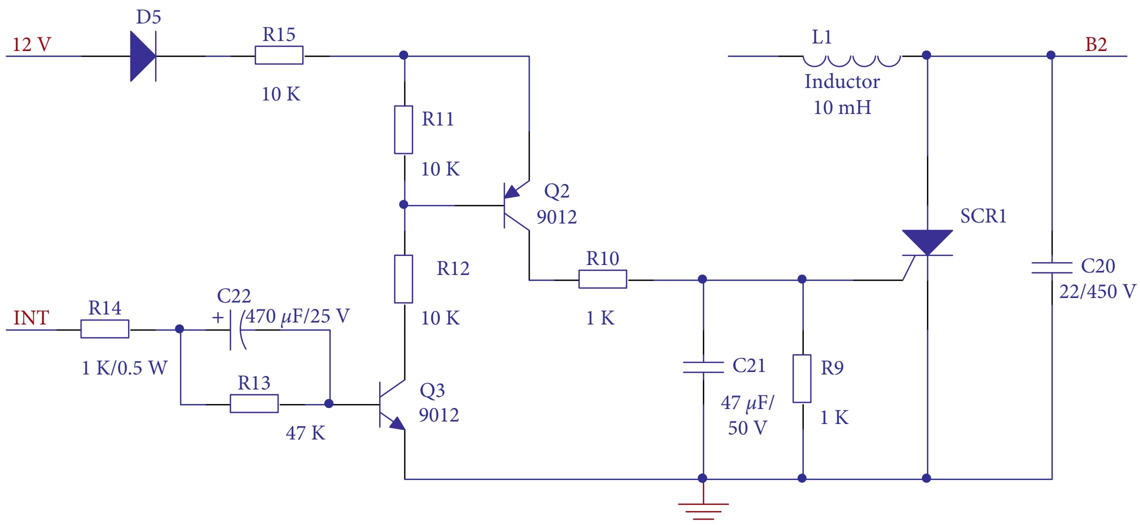

Figure 7: Discharge circuit.

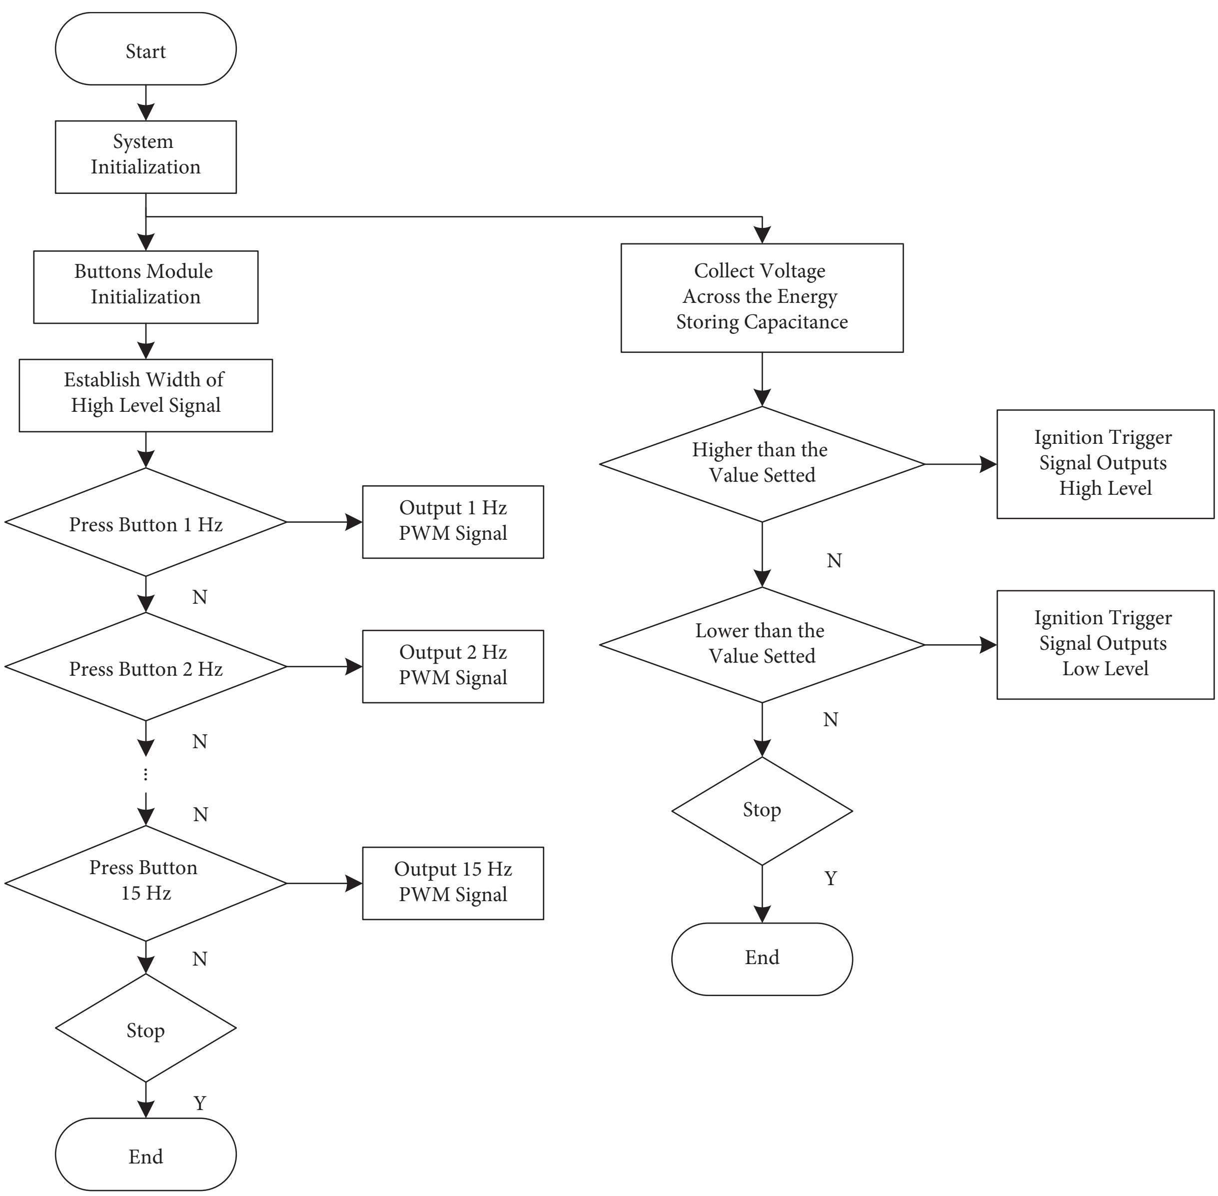

Figure 8: Software flow diagram.

2.6. Discharge Circuit. While the energy-storing capacitance is fully charged, the energy in the capacitor needs to be released to the spark plug as soon as possible in order to realize the ignition function. The SCR is used as a switching device, as Figure 7 shows. When the PWM signal is high, potential differences between the base and emitter region of the triode Q3 are present. Then the triode Q3 conducts. Meanwhile, potential differences between the base and emitter region of the triode Q2 are also present. Then the triode Q2 conducts. At last, the SCR is triggered. As the energy-storing capacitance discharges continuously, the current between the anode and cathode of the SCR reduces gradually. Then the SCR is cut off, and the discharge process of the energy-storing capacitance can be accomplished.

3. Software Design

This section introduces MCU code, which is divided between PWM signal generating and trigger discharging section. The code is downloaded in the MCU through the software Keil uVision [22]. The principal program flow is shown in Figure 8.

The following are the chief functions of the software design:

(1) The software makes port P0.0 of the MCU generate a PWM driving signal.

(2) The software makes the MCU generate a trigger signal. Port P0.1 of the MCU is the comparing port and port P0.1 is the ignition trigger port. When the voltage collected by the monitor circuit of the current-voltage circuit is higher than values set by the MCU, port P2.0 outputs high-level signal. When it is lower than values set by the MCU, port P2.0 outputs low-level signal.

(3) The software control frequency of the PWM signal is outputted by the MCU. The MCU controls frequency by code switches. The range of frequency is from 1 Hz to 15 Hz.

4. Conclusion

In this paper, a variable frequency and energy aeroengine ignition device is designed. It controls the frequency that ranges from 1 Hz to 15 Hz and energy that ranges from 1 J to 5 J. There are 75 kinds of permutations of frequency and energy. The device lays the foundations for the study of the combustion chamber's ignition property and the realization of maximizing the combustion chamber's lean ignition excess air coefficient and shortening ignition lag time. We can adjust the ignition abilities of ignition devices according to engine performance to make the engine reduce power consumption and lighten the flighting burden. I think that there will be a breakthrough in the number range of energy of ignition devices by software in the future. I should research on how to decrease the volume of the device. How to enhance the reliability and electromagnetic compatibility features of ignition devices deserves further investigation.

Academic Editor: Tongguang Ni

With the continuous development of social economy, urban real estate has gradually become an important commodity for trading, and to some extent, it also affects the trend of the national economy. In view of these limitations and demand, this paper introduces ant group algorithm, by combining the influence of urban real estate changes on the national economic trend; according to the relevant national policy impact, we analyze the national economy changes and fluctuations, try to build a "four-quadrant" model analysis of real estate market impact analysis, and clear national policy on real estate. In order to obtain better economic policies, we promote the healthy and stable development of urban real estate. Simulation experiment proved that ant colony algorithm is effective and supports the change of urban real estate value and national economy.

1. Introduction

With the continuous development of social economy, urbanization is becoming more and more mature, promoting the transaction of urban real estate. Therefore, as an important trading commodity, it will also affect the trend of the national economy to some extent [1, 2]. How to trace the urban real estate and macroeconomic changes is extremely important [3, 4]. Since the reform and opening up, China has gradually formed a socialist market economy system. However, due to its national conditions, it is more special and complex, rather than a single factor affecting the real estate market. Therefore, it cannot be fitted with single linear influence factors [5, 6]. Various economic crises in the world have a certain impact on China's economy. Although strong policies stimulate the economic development of domestic demand, it is still inevitably affected by the economic crisis; especially compared with the economic development of developed countries, there are still certain disadvantages and limitations [7, 8]. How to influence the influencing factors of China's economy, especially for the satisfaction of export and internal demand, and how to achieve China's economic growth? How to effectively develop urban real estate which can truly develop healthy socialist market economy? These are all problems that need to be solved by industry experts, entrepreneurs, etc.

In view of these problems and demand, this paper introduces ant algorithm, by combining the socialist market economy development of real estate and using four quadrant for real estate market changes; according to the relevant national policy influence, we analyze the national economy changes and fluctuation and aim to explore the macroreal estate development and change, for the long-term equilibrium analysis of urban real estate market.

2. Introduction of Ant Group Algorithm

Ant colony algorithm can divide the real estate market accordingly, into the property market and the asset market, and use the corresponding real estate rent and the newly developed construction real estate to establish corresponding connections. The so-called first quadrant is that the property demand determines the corresponding level of real estate rent, the second quadrant represents the asset market, this part is to use the corresponding real estate for capital realization, and the third quadrant is to increase the corresponding amount of new development, to achieve a certain scale of growth. The fourth quadrant is the long-term conversion of the newly developed construction volume to real estate.

2.1. Image Segmentation Feature Extraction. The image segmentation algorithm was designed based on the ant colony algorithm [9–11]. By extracting the image segmentation features as the starting point, the element features required in the image are determined to design the path of the image segmentation.

In an image, including the target background in addition to the desired target, the image segmentation method is to segment the target from the target background. In the process of segmentation, the edge value and noise need to be set, which mainly ensures that the segmentation route of the target is intact and the target required to protect the image from damage. When setting the image segmentation feature, the pixel gray scale is selected as the first feature of the image segmentation, and the pixel gray scale can be used to distinguish the image background from the image target. Entering the pixel gray scale into the colony yields the corresponding values. Identifying the segmentation route and entering the neighborhood gray scale and gradient into the colony give the edge values for image segmentation. The edge values largely control the route and noise point of the image segmentation, so they take the gray scale value and the neighborhood gray scale value and gradient as the auxiliary to determine the segmentation characteristics of the image and input the corresponding segmentation value into the ant group algorithm.

2.2. Build a Mathematical Model of the Ant Colony Search Process. After determining the image segmentation feature, the segmentation feature needs to be input into the ant colony algorithm, so the mathematical model of the ant colony search process is constructed [12–15]. The mathematical model simulates the trajectory of the ant colony searching for food to calculate, which can accurately determine the immediate obstacles in the search process and ensure the accuracy of the calculation results. Set the initial image as X. Each pixel in X forms a set. Set the set as X_j. The values of the elements in the set are not equal. Based on this, the travel path of ants is determined, and the image segmentation path is judged according to the process of ants looking for food.

The distance between x_{in} is arranged, and the distance between ant crawling is shown as

$$d_{ij} = \sqrt{\sum_{k=1}^{m} p_k \left(x_{ik} - x_{jk}\right)^2}, \tag{1}$$

where m represents the number of input image segmentation features. In this formula, the value of m is set to 3; p_k represents the weighted value of the Euclidean distance, and the magnitude of this value depends on the degree of clustering influence of pixels on the image. The distance between each pixel can be obtained by this formula.

Set the clustering radius of the image to r, ph_{ij} is the amount of information on the path of the ant colony, and determine the guiding function formula in the ant colony algorithm to obtain the guiding probability p_{ij}:

$$\begin{aligned} p_{ij} &= \frac{r}{d_{ij}} \\ &= \frac{r}{\sqrt{\sum_{k=1}^{m} p_k \left(x_{ik} - x_{jk}\right)^2}}, \end{aligned} \tag{2}$$

where the clustering radius r is in the numerator and the denominator d_{ij} is the distance, which is fixed. Therefore, the larger the clustering radius r, the larger the value of the guiding probability p_{ij} of the guiding function, that is, the greater the probability of the ant choosing the path and vice versa. According to the guidance probability, p_{ij} value of the guidance function is finally obtained; the ant's travel route is determined, so as to analyze the edge value of the image segmentation.

2.3. Set the Individual Ant Colony Rules. After completing the mathematical model of the colony search process, bootstrap rules were set against each colony for the calculated bootstrap probability values based on 3 features of the image segmentation [16–18].

2.3.1. Gray-scale Value Feature Rule. Gray-scale values are important features that distinguish the target in an image from the image background and can reduce a lot of computational workload when the gray-scale values in the image are determined. When using colony calculation, colonies can be arranged on the same starting point, the first gray-scale value. After then, the first gray-scale value is determined, the mathematical model calculation can be performed as described above, and the bootstrap probability return of the bootstrap function is determined based on the value of the pixel point.

2.3.2. Gradient Characteristic Rules. Gradient features are important features of analyzing critical and noise points, and different gradient images of the target and the background can be obtained according to the gradient, while also determining gradient pixels points in different ant colonies. Setting the number of pixels in different colonies to n, when n is greater than the pixel mean, indicates that the region of the colony is a cluster center. The gradient feature of 0 is set in the cluster center of the image so that the cluster center of the image segmentation can be resolved.

2.3.3. Neighborhood Gray-Scale Value Feature Rule. Unlike gray-scale values, neighborhood gray-scale values are mainly used for the calculation of image segmentation edges, controlling the details of image segmentation and playing an important role in protecting image pixel work. The neighborhood gray-scale value is set to the regional form of 3×3; combined with the gradient characteristics above, the region with gradient characteristics to zero is set to the cluster center, and the neighborhood gray-scale value feature is set to 6, so the corresponding field value can be obtained to determine the image segmentation direction.

2.4. Set Up the Initial Cluster Center. Setting the initial cluster center reduces a lot of computational work, where the colony moves within the specified range. When the initial cluster center is not set, the ant colonies will walk in the image irregularly, without guiding direction and guiding factors, resulting in excessive computational workload. Therefore, when setting the initial arrangement position of the colony, the initial cluster center should be determined, giving the colony a fixed region and reducing the search time.

When setting the initial cluster center, the cluster center may be located at the center or edge of the image and set according to the gradient characteristics of the image. At the edge of the target and background, the number of pixels is large and excessive pixels will result in the gradient value within the region being zero, so when setting the initial cluster center, the pixel number of the edge with the pixel value of the image target and the background as the starting point.

2.5. Implement the Polymorphic Ant Colony Algorithm for Image Segmentation. Through the setting of the initial cluster center, each ant colony is arranged in the cluster center. In the initial cluster center, the movement of the ant colony is irregular and blind. The distance between each pixel is measured, and the distance data d_{ij} are obtained, and a mathematical model is constructed according to the length of the distance. In this model, the movement of the ant colony mainly uses pheromone to calculate the path, calculates and analyzes the probability according to the movement of the ant colony, and obtains the path of the ant colony through the obtained probability, so as to realize the image segmentation of the polymorphic ant colony algorithm.

3. Principle of Macropolicy and Principle of Real Estate Industry

The continuous development of our economy, the price of real estate is very obvious, especially for economic growth, domestic market domestic demand, and urban real estate as a new stimulus consumption growth point, and demand is very obvious, as shown in Figure 1; in the domestic real estate market, with the growth of the demand curve in the first quadrant of ant algorithm, the real estate rent level and demand will increase at the same time. In particular, for the increase of the rent level in the real estate market, the government has issued various policies, such as tax cuts and preferential ways to encourage real estate transactions, leading to an increase in the price of real estate assets. Therefore, macroeconomic growth will make the residential market develop diffuse, as shown in Figure 2.

However, in the actual development process, the real estate industry has experienced overheated real estate investment in some areas. The prosperity of real estate has exceeded the development level of the local economy, showing the situation and characteristics of the mismatch with the economic development. Therefore, the state uses the corresponding policies, legal and administrative means to treat them differently, realizes the regulation of tax, interest rate, foreign investment, land, and other aspects, and realizes the adjustment of two angles of demand and supply.

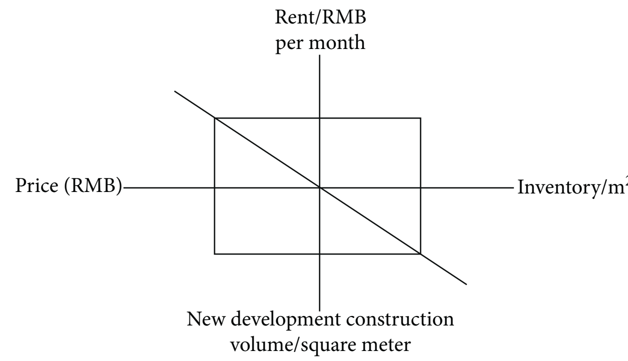

Figure 1: Four-quadrant pattern diagram.

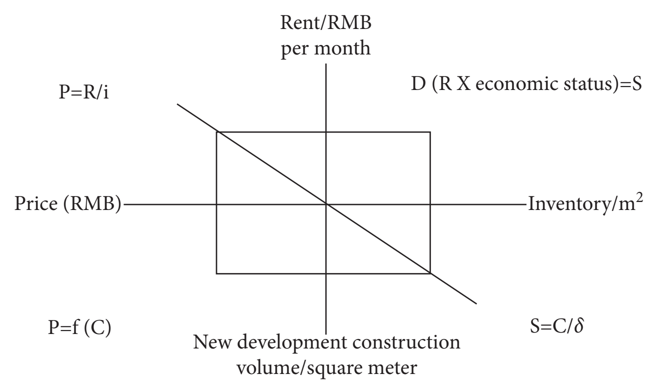

Figure 2: Four-quadrant pattern diagram.

3.1. From the Perspective of Control Requirements. First of all, the state and the government have issued a number of policies to conduct investment and trading rules and carried through a series of measures to conduct speculation in real estate and noninvestment demand. Through the corresponding ant colony algorithm and through the real estate improvement of loan and tax and the corresponding policy changes, the demand for real estate investment income has been improved. As shown in Figure 3, the improvement of different capitalization rates can bring about the corresponding equilibrium changes. When the expected development and construction amount is reduced, the property stock and rent of the related real property have increased. This is counterbalanced with the new amount of development and construction.

In the long run, the rent of real estate increases and the corresponding capitalization, so as to reduce the real estate price, reduces the development and construction volume of

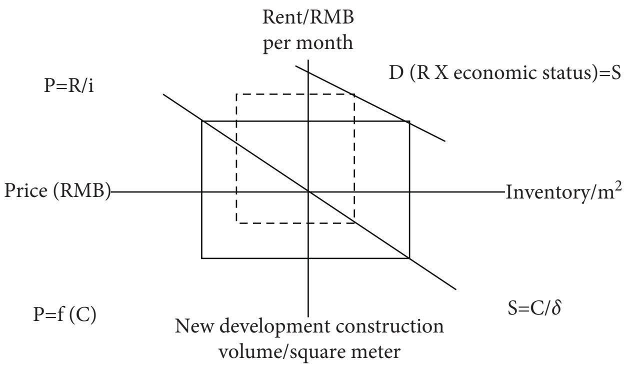

Figure 3: Four-quadrant pattern diagram.

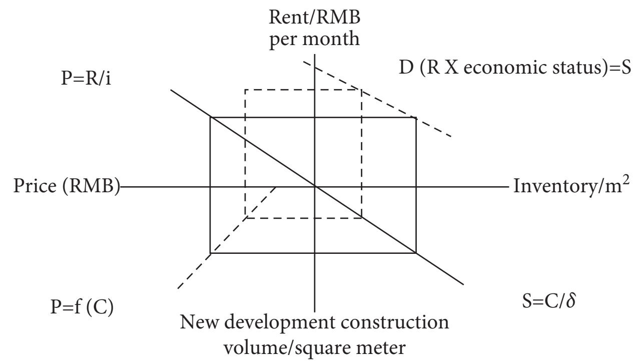

Figure 4: Four-quadrant pattern diagram.

the heart and stabilizes the real estate market. In the short term, the policy can reduce the demand for speculation to a certain extent, but due to the complexity of China's real estate market and the difference in regional development is too large, so the response of adjustment in real estate is too slow.

Equation (2) controls the supply.

From the perspective of supply control, it mainly covers credit, natural resources real estate, tax, etc. In terms of the ant colony algorithm, the land supply of the natural resource real estate, the control of the credit scale, and the real estate cost are reflected in the rays in Figure 4 to ensure that the balance state changes.

In the long run, these controlled supplies are in line with the long-term goal of the long-term control of the stable growth of China's real estate industry. In the short term, the real estate may have the supply ownership, but both the investment demands have been reduced. According to the corresponding theory of supply and demand relationship, the real estate price has been reduced and changed in a certain period of time, which means that the government can effectively control the housing price.

Through the ant group algorithm, in the case of the supply relationship changes to a certain extent, the real estate combining has been retained, and the use demand of real estate can meet different real estate ownership, and the rent will be relatively reduced. If the balance state changes and the demand curve is shifted, the speculative and nonspeculative demand for real estate will be reduced. When equilibrium is reached, the ant colony algorithm overall shrinks, contrary to economic expansion, as shown in Figure 5:

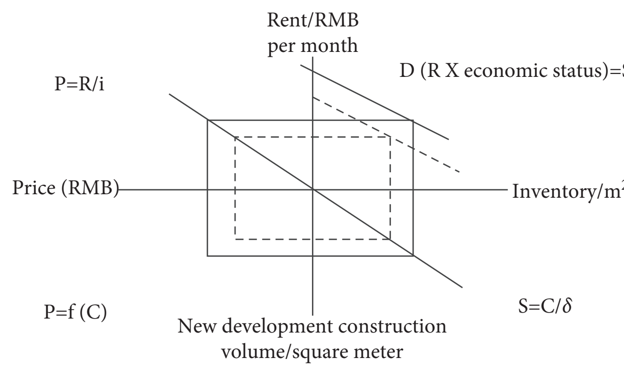

Figure 5: Four-quadrant pattern diagram.

National macrocontrol policies range from control to protection, with the focus on supporting residents in solving housing problems.

The contribution rate is the specific monitoring and measurement of the overall impact of a certain index on the economy:

$$\mathrm{Con}_{\mathrm{it}} = \frac{\Delta \mathrm{Val}_{\mathrm{it}}}{\Delta \mathrm{GDP}_t} \times 100\%. \tag{3}$$

From the calculation results, from 2018 to 2020, the contribution rate of the primary industry was on the rise, the contribution rate of the secondary industry was decreased, and the contribution rate of the tertiary industry showed a steady rise.

From the results in Figure 6, if the secondary industry declines, from the perspective of real estate alone, the economic contribution rate of real estate is basically about 7%, but there is still a big gap compared with the contribution of industrial economy to China's economic growth.

4. Simulation Experiment and Analysis

4.1. Analysis Based on State Space Models. State space models are a powerful tool for the dynamic analysis of interrelations between variables. The model uses a powerful iterative algorithm called the Kalman filter to incorporate unobservable variables into the observable model and obtains estimates with it:

$$\begin{aligned}
&\begin{cases} \log\left(\mathrm{GDP}_t\right) = \alpha_t + \beta_t \log\left(\mathrm{industry}_t\right) \times + \widehat{u} \\ \beta_t = a + b \times \beta_{t-1} + \widehat{\varepsilon}_t \end{cases}, \quad t = 1, 2, \ldots, T, \\
&\begin{cases} \log\left(GDP_t\right) = \alpha_t' + \beta_t' \log\left(\mathrm{realestate}_t\right) \times + \widehat{u}\,' \\ \beta_t' = a' + b' \times \beta_{t-1}' + \widehat{\varepsilon}_t' \end{cases}, \quad t = 1, 2, \ldots, T.
\end{aligned} \tag{4}$$

Using the data provided by the China Statistical Yearbook 2020, the changes in the parameters β_t and β_t' of the sample period can be obtained, as shown in Figure 7. The

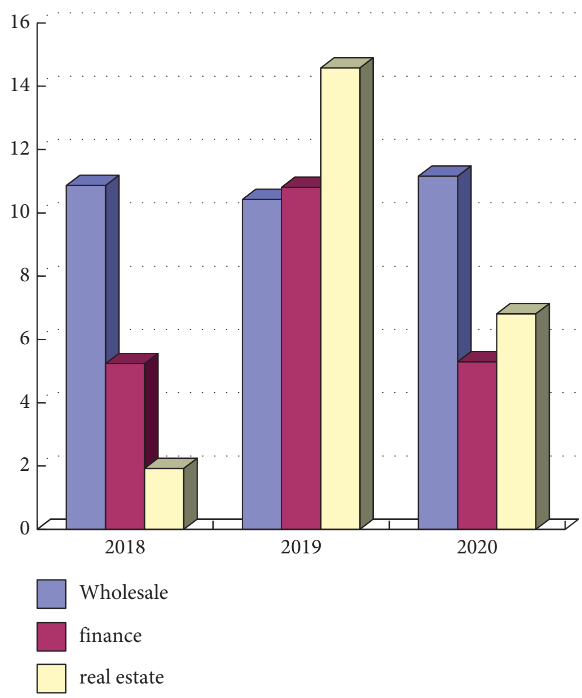

Figure 6: Industry contribution unit (%) from 2018 to 2020.

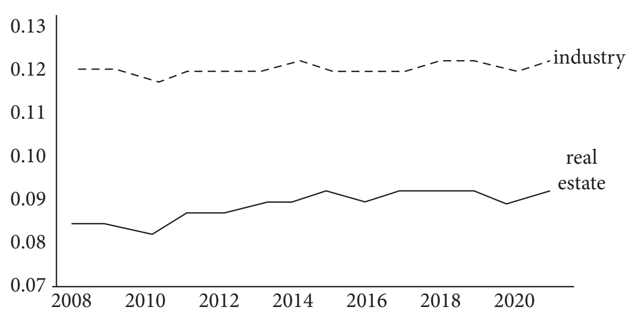

Figure 7: Parameter changes of the state space model from 2002 to 2015.

elasticity of GDP to industry is relatively stable, fluctuating around 0.12, while in the same period, although the elasticity of GDP to real estate shows the upward trend, the tertiary industry represented by real estate cannot yet replace the position of the secondary industry.

4.2. To Absorb Employment. From the perspective of urban employment personnel, among the 20 industries of China's national economy, the person directly engaged in real estate accounts for not much, only accounting for about 2%.The top three industries are manufacturing, construction, and education, accounting for 27.7%, 15.3%, and 9.5%, respectively, 12.1 times, 6.7 times, and 4.1 times the number of real estate practitioners, respectively (Figure 8).

As a capital company, the capital party, its purpose is to obtain operating profit. In the general concept, the real estate development is good, its operating profit is relatively high,

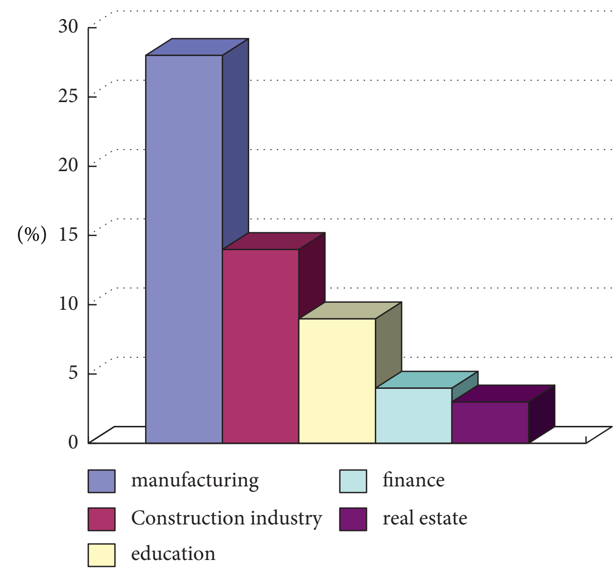

Figure 8: Employment of urban units in some industries accounted for units (%) in 2020.

the real estate development is not good, and its operating profit is relatively low. Although China's real estate market has basically maintained a bull market for more than ten years, the real estate industry profit should be a lot.

As a capitalist real estate company, the purpose of its operation is to obtain operating profits. In the general concept, if real estate develops well, its operating profit is relatively high. If real estate develops well, its operating profit is relatively low. China's real estate market has basically maintained a dozen or so despite occasional fluctuations. In the bull market of 2015, the real estate industry should have made a lot of profits.

According to China's current division of powers and financial powers, local governments undertake a large number of tasks, but financial powers are concentrated in higher-level governments, making local governments have to regard real estate as the "second fiscal" in order to complete economic and social development tasks. Real estate has a huge impact on local finances. To resolve the dependence of local governments on real estate development, it is necessary to solve the dependence of local finance on real estate development. Only by liberating local finance from land gains can the local government's benign guiding role in real estate development be fundamentally given play to. Reform the existing fiscal and taxation system and reasonably divide central and local affairs so that local governments have sufficient financial resources to effectively handle their affairs without relying on land and provide guarantees for local economic development, people's lives, and social stability.

The issue of human capital has always been a key area of economic research. In the history of economic research, Malthus' theory of population disasters has appeared, and the important role of human capital in economic growth has also been strongly promoted. Despite the school disputes, it is undeniable that human capital is an important factor in a country's economic growth. Empirical evidence shows that there is a close correlation between population growth and economic growth. The recession of the Japanese economy, the stagnation of the European economy, the arrival of an aging society, and the negative growth of the population appeared. As the world's most populous country, China's most basic resource is human capital. In 1978, China implemented reform and opening up. The low labor cost is one of the important reasons why the economy can develop in great strides. In addition to the large population, another important reason for the low labor cost in China is that China's family planning policy started in the last century has caused the dependency ratio to drop drastically and enjoy a huge demographic dividend. However, the current population aging in China is very fast. In 2015, the number of people over 60 years old in China exceeded 200 million, accounting for 16.1%, and the number of people over 65 years old has reached 140 million, accounting for 10.5%. According to the aging society standard that the population over 60 years old accounted for more than 10% and the population over 65 years old accounted for more than 7%, China has actually entered an aging society, and the aging degree will be further increased in recent decades. The heavier burden and the decline in the proportion of the right-age labor force have greatly increased the average cost of labor in our country and have brought tremendous pressure to the normal operation of enterprises and the normal operation of individual families. For China, maintaining the sustainable development of the economy and society is still the biggest task in the future period of history. It is recommended to further adjust the family planning policy to promote the moderate growth of the population and continue to maintain the competitiveness of China's enterprises and the sustainable development of the family.

The tax burden of economic units in China is relatively heavy. The measurement caliber of the macrotax burden has three categories: narrow caliber, medium caliber, and wide caliber. The narrow caliber refers to the proportion of tax revenue in GDP, the medium caliber refers to the proportion of fiscal revenue in GDP, and the wide caliber refers to the proportion of revenue that all governments can control or influence in GDP. China's narrow-caliber macrotax burden is less than 20%, the medium-caliber macrotax burden is slightly higher than 20%, and the wide-caliber macrotax burden is close to 40%. From the perspective of the relationship between households, enterprises, and the country and the development of households and enterprises, a wide-caliber macrotax burden is more reasonable. At present, China's wide-caliber macrotax burden has been much higher than the average level of developing countries and even higher than the level of some developed countries. The burden of taxes and fees makes the economic unit's operating results unable to be used for technological innovation and self-development, and the development of competitiveness is greatly affected. For China's sustainable development, tax cuts are an important way to mobilize the enthusiasm of households and enterprises and stimulate their creativity. In the future, necessary explorations should be made in tax cuts, especially structural tax cuts.

Science and technology are primary productive forces. Since the reform and opening up, China has gradually increased its investment in science and technology research and development, and the progress in science and technology has made rapid progress, which has promoted the rapid development of China's economy and has become the world's second largest economy. However, despite the rapid progress in science and technology in China, the gap with developed countries is still huge. The intuitive manifestation of the relatively weak technological innovation ability is the low added value of technology made in China. Technology is the main source of the added value of high-tech products, and the price of commodities is the most important competitiveness of non-high-tech products, but the price factor is greatly affected by the cost. In the context of reduced labor, higher tax costs, and rising raw material prices, the competitiveness of China's low value-added products has dropped significantly. In the future, we should optimize the technological innovation environment, increase investment in science and technology, improve China's technological innovation capabilities, especially the technological innovation capabilities of enterprises, and then increase the technological added value of Chinese products so that the advantages of Chinese products will be transformed from low prices to advanced technology.

5. Conclusions

With the continuous development of social economy, urban real estate has an influence on the macroeconomy, and how to trace its external influence factors is very important. In view of these limitations and needs, this paper is based on ant algorithm, by combining the operation of the real estate market to adjust the real estate market, using national policy impact analysis, explore the national policy on real estate, to effectively adjust the policy, using the "four-quadrant" model to analyze the impact of the real estate market, further promote the healthy development of real estate, and realize the effective development of national economy. Simulation experiments have proved that the ant colony algorithm is effective.

The new development concept is the theoretical guidance and important foundation for high-quality foreign trade development in the new era. This paper develops an evaluation index system to measure the high-quality development level of foreign trade based on the meaning of high-quality development of foreign trade under the new concept of development. The dynamic changing trend of high-quality development of China's provincial foreign trade from 2013 to 2019 and the ranking change of the development index are examined in this paper using a time series factor model. Finally, China's provinces are categorized based on the quality of their foreign trade development. The findings show that, from 2013 to 2019, China's high-quality foreign trade development has been on the rise; the level of high-quality foreign trade development has been raised to varying degrees in the eastern, central, and western regions of China, but each region plays a different role. Compared to 2013, the truly "high-quality" areas of China's provincial foreign trade development were always concentrated in the eastern region, which ranked high on the comprehensive evaluation index, while the "low-quality" areas were mainly concentrated in the central and western regions, which ranked low on the comprehensive evaluation index.

1. Introduction

China has made remarkable achievements in foreign trade over the course of more than 40 years of reform and opening-up and has risen to become the world's first trade power. China's foreign trade has successfully completed the "Quantity" leap while also greatly improving in "Quality," with the trade structure continuing to improve and trade competitiveness improving. However, China's foreign trade development is beset by difficulties. The new crown epidemic, in particular, continues to spread around the globe, and the external environment is becoming more uncertain and risky. The global economy remains sluggish in the face of profound changes unseen in centuries, making China's foreign trade situation more complex and severe, with numerous flaws. The promotion of high-quality foreign trade development has become a central issue in China's trade development. The 19th CPC National Congress pointed out that China's economy will develop from high speed to high quality. It requires that China's trade development change from high-growth to high-quality stage. In 2019, the CPC Central Committee and the State Council issued "the Guiding Opinions on Promoting High-quality Development of Trade," which further points out the direction for China's high-quality development of foreign trade in the new era and at the same time puts forward new requirements. Therefore, to scientifically build an evaluation system for the high-quality development of China's foreign trade, to measure the high-quality development of China's foreign trade in the new era, and to find out the sources of power and sources of resistance, it is of far-reaching practical significance to promote the high-quality development level of China's foreign trade.

So, has China's foreign trade's high-quality development level improved? What about China's provincial foreign trade's high-quality development level? What distinctions, trends, and gaps exist between regions? As a result, the paper develops a high-quality development index system for China's provincial foreign trade and employs the global factor model of time series to measure and analyze the high-quality development level of China's provincial foreign trade. This paper examines the advantages and disadvantages, as well as the potentials and barriers, to the development of foreign trade in each province in order to provide a reliable endogenous power source for the high-quality development of China's foreign trade.

At present, scholars' research on the high-quality development of foreign trade mainly focuses on the following aspects:

(1) The meaning of high quality in foreign trade. For example, Xiang and Song believe that "Imbalance" and "Inadequate" represent the new era of China's high-quality foreign trade development and from these two aspects give a specific definition [1]; Chen believes that the high-quality development of foreign trade represents the high-level economic and trade cooperation of "You have me, I have you" and can fully highlight the essential goal and development orientation of Integration [2]; Gao believes that an accurate understanding of the meaning of high-quality trade should not only reflect the inherent requirements of building a strong trading nation but also reflect the trend of the times that trade development conforms to the changes in China's social contradictions [3]; Ma believes that high-quality development of foreign trade should include five fundamentals: an optimized development structure, a more balanced development pattern, a sustained development momentum, a more open development model,, and a more inclusive development concept [4].

(2) The research on the measurement and evaluation of the high-quality development of foreign trade. Due to the high-quality development of foreign trade proposed in a relatively short time, the literature in this area are less.

For example, Qu et al. established the index system of high-quality development of foreign trade from the basis of trade, trade optimization, trade competitiveness status, trade comprehensive services, and international economic and trade rules status of five dimensions, which includes 34 indicators, but they did not use the index system to measure the high-quality development of foreign trade [5]; Tang and Xia set up a high-quality development evaluation index system from the perspective of trade in services, which includes five dimensions (openness and security, structural coordination, sustainable development, innovation drive, and international competitiveness) and 27 indicators, and they also used AHP method to carry out the related analysis [6]; Wu and Zhang selected 26 indicators from five aspects, namely, innovative trade, coordinated trade, green trade, open trade, and shared trade, to construct an indicator system which was based on the new concept of development, and then they used the entropy method to measure the high-quality development of China's foreign trade from 2001 to 2018 [7]; Cao and Lei also selected 17 indicators based on the new concept of development, from six dimensions of effective, innovative, coordinated, sustainable, open, and shared development, using entropy weight method to measure the high-quality development of China's foreign trade from 2006 to 2018 [8].

(3) The ways and countermeasures of high-quality development of foreign trade. Some scholars, such as Yang, Chang, and Li, hold that innovative development is the foundation to promote the high-quality development of foreign trade and to strengthen the trade power [9–11]; scholars such as Rong and Xiang hold that the initiative to expand imports is a mechanism to promote high-quality development and its realization path [12, 13]; however, Scholars such as Zhao, Sheng, Pei, and Liu believe that the "fine brushwork" of creating a "Belt and Road" together can continuously open up the market and reduce the degree of dependence on the European and American markets, which is the only way to the high-quality development of foreign trade [14–16].

By examining the existing literature, we can see that, in recent years, an increasing number of scholars have begun to pay attention to China's high-quality foreign trade development, and the scope of the study has gradually expanded from the definition of high-quality foreign trade development to the establishment and measurement of the indicator system. However, because different scholars have different interpretations of what constitutes high-quality foreign trade development, different measurement indexes are chosen, and different measurement results are obtained. Meanwhile, there is little literature on China's high-quality provincial foreign trade. As a result, this paper's marginal contribution consists of the two following points: (1) In terms of the study's content, scholars are currently focusing on the connotation, current situation, and path countermeasures of high-quality foreign trade development, primarily focusing on qualitative analysis; however, measuring the high-quality development level of China's provincial foreign trade is uncommon. As a result, this paper chooses a scientific and rigorous method to measure the high-quality development level of China's provincial foreign trade under the new concept of development, and the research is more in depth. (2) On the research method, this paper uses the time series global factor analysis method to quantitatively analyze the high-quality development of China's provincial foreign trade and space-time dynamic differences, in order to avoid high correlation of variables and subjective randomness in selecting weights.

2. Establishment of an Indicator System for High-Quality Development of China's Provincial Foreign Trade

In order to investigate the changes in time and space of the high-quality development of China's foreign trade, this paper constructs the evaluation index system of high-quality development of China's provincial foreign trade, which is based on the connotation of the high-quality development of China's foreign trade under the new development theory.

2.1. The Construction of an Evaluation Index System. In the new era, the new development concept is the theoretical guidance for the high-quality development of China's foreign trade. Based on this, the paper describes the evaluation index system of high-quality development of China's provincial foreign trade from five aspects: the innovative development of trade, the coordinated development of trade, the green development of trade, the open development of trade, and the development of trade sharing. On the basis of the index system of high-quality development of China trade constructed by Wu and Zhang [7], this paper makes some additions, revisions, and deletions to the index system, as shown in Table 1.

2.2. Data Sources and Indicators Description. The variables of the indicator system in this paper are partly consulted by reference to the established practices and also partly by the following references: using the method of Xu and Lu, the technical complexity of China's provincial high tech exports is calculated in two steps [17]; drawing on research ideas such as those of John et al., from four aspects of transportation infrastructure, port clearance efficiency, system environment, and E-commerce, eight indicators are selected to measure the level of trade facilitation in China and its provinces [18]. Among them, adopting Shi's approach, transport infrastructure facilitation is measured in terms of road density (i.e., the number of miles per 100 square kilometres) and rail network density (i.e., the number of miles per 100 square kilometres) [19]. Using the methods of Yin and others, the customs clearance efficiency of the port is measured by selecting the efficiency of cargo clearance and the efficiency of personnel clearance [20]; using the methods of Chen and Li and Yao and Yan, China's institutional environment is measured by anticorruption efforts and the level of intellectual property protection [21, 22]. The basic data in this paper are from the Statistical Yearbook published by the provinces and regions, "National Economic and Social Development of a Statistical Bulletin," "China Statistical Yearbook on Science and Technology," "China Statistics Yearbook on Environment," "China's Ports-of-Entry Yearbook," the Provincial General Administration of Customs website, provincial statistics department website, and government website. Among them, Tibet is rejected because of too much missing data.

3. The Measurement of the High-Quality Development Level of China's Provincial Foreign Trade Based on the Time Series Global Factor Analysis

(1) Construction of global factor model of time series.

The time series global data sheet assumes that there are n regions as samples for high-quality development of foreign trade, and each sample has m index variables, thus forming a matrix of $n * m$ order with a time span of t years; a global data table A $(n * m * T)$ is constructed:

$$A = \{X_t, \quad t = 1, 2, \ldots T\}. \tag{1}$$

(2) Dimensionless treatment of evaluation index and calculation of correlation coefficient matrix.

(3) Computing covariance matrix.

Define the center of gravity of the global datasheet as follows:

$$\begin{aligned} Z &= \left(X_1, X_2, \ldots, X_m\right) \\ &= \sum_{t=1}^{T}\sum_{i=1}^{n} P_i^t Q_i^t. \end{aligned} \tag{2}$$

P_i^t represents the weight of individual Q_i of the sample in year t and satisfies

$$\sum_{t=1}^{T}\sum_{i=1}^{n} P_i^t = 1, \sum_{i=1}^{n} P_i^t = \frac{1}{T}. \tag{3}$$

Suppose that the overall variables for the measurement of the high-quality development of China's provincial foreign trade are X_j.

$X_j = (X_{1j}^1, X_{2j}^1, \ldots X_{nj}^1; X_{1j}^2, X_{2j}^2, \ldots, X_{nj}^2; X_{1j}^T, \quad X_{2j}^T, \ldots, X_{nj}^T)$.

Then the global variance function is $E_j^2 = \mathrm{var}(X_j) = \sum_{t=1}^{T}\sum_{i=1}^{n} P_i^t (X_{Xj}^t - \overline{X}_j)^2$.

The corresponding global covariance function is

$$\begin{aligned} E_{jk} &= \mathrm{cov}\left(X_j, X_k\right) \\ &= \sum_{t=1}^{T}\sum_{i=1}^{n} P_i^t\left(X_{Xj}^t - \overline{X}_j\right)\left(X_{jk}^t - \overline{X}_k\right). \end{aligned} \tag{4}$$

Thus, the global covariance matrix can be expressed as $V = \sum_{t=1}^{T}\sum_{i=1}^{n} P_i^t (Q_i^t - Z)(Q_i^t - Z)'$.

(4) Find the eigenvector of the covariance matrix

(5) Calculate common factors

When the global factor method is used to analyze the time series, the main steps to determine the weight of the index variables are as follows.

Step 1. Itis to find the expression of the global common factor as follows:

Table 1: Evaluation index system of high-quality development of China's provincial foreign trade.

Criterion	Indicator	Variable
Innovative development of trade	Innovation investment	Input intensity of R&D (+) Input intensity of education (+) Quantity of R&D personnel (+)
	Innovation output	TC index of trade in goods (+) TC index of trade in services (+) Processing trade's value-added rate (+) Export technical complexity of high-tech industry (+)
Coordinated development of trade	Structure of trade mode	Export share of general trade (+) Import share of general trade (+)
	Structure of trade entity	Proportion of foreign-capital enterprises in trade (+) Proportion of private enterprises in trade (+)
Green development of trade	Environmental effect	Emission intensity of export industrial waste gas (−) Emission intensity of export industrial waste water (−) Emission intensity of export industrial solid waste (−)
	Resource utilization	Resource consumption per unit export value (−) Proportion of imports of resource products (+)
Open development of trade	Dependence on foreign trade	Total volume of trade/GDP (+)

$$\begin{aligned} G_1 &= U_{11}X_1 + U_{21}X_2 + \cdots + U_{n1}X_n, \\ G_m &= U_{11}X_1 + U_{21}X_2 + \cdots + U_{nm}X_n. \end{aligned} \tag{5}$$

Among them, G_m is the global common factor m, X_n is the observation variable n, and U_{nm} is the score coefficient of the observation variable n in the global common factor m. After dimension reduction by factor analysis, it should be l $m < n$ in general.

Step 2. Itis to construct the expression of comprehensive evaluation score and calculate the index weight.

$$\begin{aligned} ZG &= \frac{(\theta_1 * G_1 + \theta_2 * G_2 + \cdots + \theta_m * G_m)}{(\theta_1 + \theta_2 + \cdots + \theta_m)} \\ &= \pi_{1*}X_1 + \pi_{2*}X_2 + \cdots + \pi_{n*}X_n. \end{aligned} \tag{6}$$

In the above equation, ZG is the comprehensive evaluation score of high-quality development of foreign trade and θ_m is the contribution rate of variance of the global factor m; $\pi_n = (\theta_1 * U_{n1} + \theta_2 * \quad U_{n2} + \cdots + \theta_m * U_{nm})/\ (\theta_1 + \theta_2 + \cdots + \theta_m)$.

Calculate the weight of indicator X_i: $V_i = |\pi_i|/(|\pi_1| + |\pi_2| + \cdots + |\pi_n|)$.

(1) Steps for measuring the high-quality development level of China's provincial foreign trade.

(i) The standardization treatment of single index
Because each index in the original data has a different order of magnitude, the index must first be standardized. Set 2013 as the base year and apply the following rules to the positive and negative indicators:
Positive indicators: Singl Index$J = W_j - W_{\min}/W_{\max} - W_{\min} \times 100$
Negative indicators: Singl Index$J = W_{\max} - W_j/W_{\max} - W_{\min} \times 100$
Among them, W_j is the original data of index j in the base period of a certain region; $W_{\max}$ and $W_{\min}$ are the largest and the smallest of the original values of index j in the base period of 30 provinces, respectively. For other years in each region, a single index is formed relative to the base period.

(ii) Checking the prerequisites
This paper used SPSS 23 software to perform the KMO and Bartlett sphericity tests. The value of KMO in Table 2 is 0.804, which is between 0.8 and 0.9, indicating that the index variable is easy to reduce dimension and is well suited to factor

Table 2: KMO and Bartlett's test.

KMO test	0.874
Bartlett's test of sphericity	df 378 Approx. chi-square 5754.949 Sig. 0.000

analysis. The Bartlett sphericity test has a significance of 0.000, which is less than 0.01 and is appropriate for factor analysis.

(3) The index weight is determined, and the comprehensive score of high-quality development of Chinese provincial foreign trade is calculated.

(i) To extract the global common factors of time series.
In this paper, the global common factor of time series is extracted by the rule that the feature root is greater than 1. As shown in Table 3, four common factors can be extracted, and the cumulative variance contribution is as high as 95%. The gravel map (Figure 1) also shows that selecting 4 common factors is a good fit.

(ii) Calculate the comprehensive index of high-quality development of foreign trade of Chinese provinces.
Firstly, determine the weight of each index; secondly, according to the variance contribution rate and formula of the four global common factors extracted, the comprehensive evaluation expression of high-quality development of China's provincial foreign trade can be obtained. Finally, the weight of 28 indicators can be obtained.

(4) According to the comprehensive index of high-quality development evaluation of Chinese provincial foreign trade, cluster analysis is carried out.

4. The Results of the Measurement of the High-Quality Development Level of China's Provincial Foreign Trade

Based on the global factor analysis model of time series, the measure steps are completed, and the weights of related indexes are obtained, China's provincial foreign trade quality development index from 2013 to 2019 (shown in Table 4).

4.1. The Result of High-Quality Development Evaluation Index of Chinese Provincial Foreign Trade. Table 4 shows the results of the comprehensive index of the high-quality development of China's provincial foreign trade from 2013 to 2019. Through observation and analysis, the results can be summarized as follows.

To begin with, the high-quality development of China's foreign trade as a whole shows a rising trend in fluctuation when compared to the national average. China's foreign trade quality development index climbed from 38.56 in 2013 to 39.99 in 2015 and then dipped in 2016 before rising to a new high of 40.81 in 2019. This clearly shows that China's high-quality foreign trade development has yielded phased results, effectively promoting the reform of foreign trade power and efficiency. In terms of rate of increase, China's composite index of high-quality development of foreign trade has risen by 2.25 in seven years, especially since 2017, reaching a new high, indicating that it has effectively promoted structural adjustment of China's foreign trade and a change in trade growth pattern in the context of high-quality development.

Secondly, from the perspective of the comprehensive evaluation index of high-quality development of China's provincial foreign trade, there is an obvious upward trend of fluctuations. Against the background of the overall high-quality development of China's foreign trade, the foreign trade development of the vast majority of provinces keeps pace with the high-quality development of China's foreign trade, even faster than that of the country, but, at the same time, the high-quality development index of foreign trade of some provinces appears to regress. This just shows that the high-quality development of China's foreign trade is not plain sailing, the growth rate of foreign trade in some provinces is facing the shift period, the period of painful adjustment of foreign trade structure, and the period of digesting the national foreign trade stimulation policy. The high-quality development of China's foreign trade not only has to face the uncertainty of the external environment but also has to bear the huge pressure of the "three-phase superimposition" in the internal regions. Therefore, in order to successfully pass the road of high-quality development of foreign trade and finally realize the trade power, it requires the coordinated development among the provinces to maintain the stability of high-quality foreign trade and finally to ensure the long-term power of the provincial government's high-quality foreign trade development and construction.

Finally, the high-quality development index of China's provincial foreign trade reveals the characteristics of regional imbalance based on the three regional averages. According to the average of China's three regional high-quality foreign trade development indexes, high-quality foreign trade development in each region has increased to varying degrees between 2013 and 2019, but there is a significant gap between regions. During the reporting period, the average value of the comprehensive index of high-quality development of foreign trade in the eastern region was always higher than the national average, indicating that it was the "leader" of China's high-quality development of foreign trade, while the average value of the central region was essentially the same as the national average, indicating that China's foreign trade is a high-quality development of the "Runner"; the western region has been lower during this period. Furthermore, it is easy to see the "high-quality" provinces in China's real foreign trade, which are primarily concentrated in the east, and the "low-quality" provinces in the Midwestern Sectional Figure Skating Championships.

4.2. The Analysis of the Ranking and Changes. According to the comprehensive evaluation index of high-quality

Table 3: Total variance explained.

Component	Initial eigenvalues			Extraction sums of squared loadings		
	Total	% of variance	Cumulative %	Total	% of variance	Cumulative %
1	20.761	74.145	74.145	20.761	74.145	74.145
2	3.294	11.763	85.908	3.294	11.763	85.908
3	1.552	5.543	91.451	1.552	5.543	91.451
4	1.001	3.576	95.028	1.001	3.576	95.028
5	0.386	1.379	96.407			

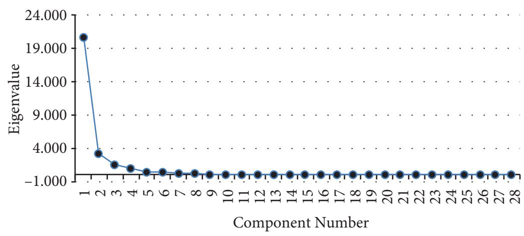

Figure 1: Scree plot.

development of China's provincial foreign trade from 2013 to 2019, the provincial ranking and changes are shown in Table 5.

Judging from the ranking of the comprehensive evaluation index of high-quality development of provincial foreign trade, in 2013, Beijing, Guangdong, Shanghai, Zhejiang, Jiangsu, Shandong, Anhui, Fujian, Tianjin, and Chongqing ranked in the top 10 on the comprehensive evaluation index for high-quality development of provincial foreign trade, with 8 of the top 10 in the eastern provinces, and the central and western provinces each had one; Hubei, Jiangxi, Guizhou, Shanxi, Liaoning, Jilin, Henan, Ningxia, Heilongjiang, and Gansu were ranked 11th to 20th, respectively, including one eastern province, six central provinces, and three western provinces; Hunan, Yunnan, Sichuan, Guangxi, Shaanxi, Hainan, Inner Mongolia, Qinghai, Hebei, and Xinjiang are ranked 21th–30th, and these ten provinces were three in the east, two in the centre, and five in the west. Based on this, it can be concluded that, in 2013, the provinces with the higher comprehensive evaluation index of high-quality development of foreign trade in China's provinces were mainly concentrated in the eastern region, while the middle-level provinces were concentrated in the central region, and half of the provinces in the west ranked relatively low. In 2019, Beijing, Guangdong, Shanghai, Zhejiang, Jiangsu, Fujian, Shandong, Chongqing, Anhui, and Guizhou were the top 10 ranked in China's foreign trade quality comprehensive evaluation index: seven eastern provinces, one central province, and two western provinces; Jiangxi, Tianjin, Hubei, Hunan, Jilin, Ningxia, Henan, Liaoning, Gansu, and Shaanxi were ranked 11th–20th, followed by Jiangxi, Tianjin, Hubei, Hunan, Jilin, Henan, Gansu, and Shaanxi: two eastern provinces, five central provinces, and three western provinces; Hebei , Heilongjiang, Yunnan, Shanxi, Inner Mongolia, Sichuan, Guangxi, Xinjiang, Hainan, and Qinghai were ranked 21st to 30th: three of the 10 provinces were in the east, three in the centre, and four in the west. Compared with 2013, in 2019, the provinces with higher comprehensive evaluation indexes for high-quality development of foreign trade in China's provinces were still concentrated in the eastern region, while the provinces with lower comprehensive evaluation indexes were still concentrated in the central and western regions; the phenomenon of "east high, middle high and west low" still existed.

From 2013 to 2019, the rankings of 12 provinces rose, accounting for 40% of the total: two provinces in eastern Hebei and Fujian, four provinces in central Inner Mongolia, Jilin, Jiangxi, and Hunan, and six provinces in the west: Chongqing, Guizhou, Shaanxi, Gansu, Ningxia, and Xinjiang. Hebei, Hunan, and Shaanxi all saw higher increases, with Hebei up 8, Hunan up 7, and Shaanxi up 5. Six provinces remained unchanged in the rankings during the same time period: Beijing, Guangdong, Shanghai, Zhejiang, Jiangsu, and Henan. The other 12 provinces fell during the same time period, with five in the eastern provinces of Tianjin, Liaoning, Shandong, Guangxi, and Hainan; four in the central provinces of Shanxi, Heilongjiang, Anhui, and Hubei; and three in the western provinces of Sichuan, Yunnan, and Qinghai, respectively.

4.3. The Cluster Analysis of the High-Quality Development of China's Provincial Foreign Trade. According to the comprehensive index of the high-quality development of China's provincial foreign trade shown in Table 4, based on the cluster analysis, 30 provinces are divided into 4 categories.

The first category includes Beijing, Guangdong, and Shanghai. These three cities are the regions where the foreign trade is developing with the highest quality, and their comprehensive index of high-quality development of foreign trade has maintained the top three places in the ranking from 2013 to 2019. The overall development of high-quality development of foreign trade is on a steady upward trend; it will play an important leading role in the high-quality development of foreign trade in other regions of China. Beijing, Shanghai, and Guangdong are China's economically powerful cities with convenient transportation and high level of infrastructure construction. No matter capital or talents, these three cities will be considered or selected optimally. All aspects are conducive to the development of their foreign trade. Guangdong, as a big and powerful trade city of China, has unique geographical conditions, is the window of China's opening up, and is the barometer of China's foreign trade. For Beijing and Shanghai, two international metropolises, all aspects of development follow the pace of the world, so they also have strength and advantages in high-quality development of foreign trade,

Table 4: 2013–2019 China's provincial foreign trade quality development index.

		2013	2014	2015	2016	2017	2018	2019
Eastern region	Beijing	55.48	56.29	58.31	58.39	57.43	60.26	60.41

	Hubei	38.20	38.47	39.54	40.09	39.88	39.40	40.37
	Hunan	34.47	36.10	35.10	38.70	36.62	39.06	40.23
	Shanxi	37.36	36.24	35.55	34.51	32.04	36.33	34.04
	Average	37.37	37.53	38.37	37.53	37.21	40.00	39.38
Western region	Guangxi	33.20	30.71	32.27	30.18	31.11	31.86	32.39
	Chongqing	38.77	37.51	41.89	41.62	42.59	43.05	43.50
	Sichuan	37.45	32.20	36.91	30.95	31.65	32.97	32.70
	Guizhou	37.65	37.28	41.06	39.25	36.88	36.99	42.32
	Yunnan	34.46	34.65	35.70	34.21	35.58	36.72	34.85
	Shanxi	32.81	32.43	33.38	34.13	35.10	35.70	36.66
	Gansu	35.20	35.86	39.28	33.99	39.19	38.75	36.9
	Qinghai	30.40	37.71	31.51	27.81	36.13	32.61	31.47
	Ningxia	35.26	38.72	34.84	37.40	41.72	42.50	40.11
	Xijiang	29.12	34.35	32.45	30.81	32.19	33.22	32.11
	Average	34.04	35.40	35.64	33.57	36.06	36.18	35.89
	Average of China	38.56	39.11	39.99	38.54	39.58	40.75	40.81

becomeing the leader of high-quality development of China's foreign trade.

The second category includes Jiangsu, Zhejiang, Anhui, Shandong, and Fujian. These provinces, except Anhui, are all eastern coastal provinces, all of which have good geographical conditions, strong base, and sufficient reserves of capital and talents, and have been playing an important role in the development of China's foreign trade. In the context of China's high-quality development, these provinces have followed in the footsteps of the country, promoted the position of foreign trade in the international value chain through transformation and upgrading, and strengthened their ties with other provinces within China; enhancing their own foreign trade development capacity at the same time also led to the development of foreign trade in other provinces. In terms of geographical location, these provinces are characterized by the encirclement of Jiangsu, Anhui, and Fujian, which encircles Zhejiang in the middle, and the border of Zhejiang, Jiangsu, and Anhui with Shanghai, an international metropolis, although Shandong is not in the first two areas, but with Jiangsu border. Therefore, it can be said that these five provinces are in a good environment, with their own strength, good geographical environment, resource environment, and foreign trade environment in the high-quality development of China's foreign trade, and must become the main force.

Tianjin, Jilin, Jiangxi, Henan, Hubei, Hunan, Chongqing, Guizhou, Gansu, and Qinghai are the ten provinces (or cities) in the third category. Five of the ten provinces are in the central region, four are in the western region, and only Tianjin is in the east. Foreign trade has grown rapidly in recent years in the five provinces of the central region. Jiangxi, Henan, Hubei, and Hunan provinces, in particular, have played a significant role in China's "Rise of the Central Region" and are an important base and integrated transportation hub for the country; they have also taken on the important task of transferring manufacturing industry; the growth rate of foreign trade in the four western provinces is faster and stronger than that in the central region after 2013. However, whether in the central or western regions, these provinces' foreign trade development is still based on the extensive development model. "Three high and one low" will become the biggest obstacle to the future development of the eastern region's trade in the process of developing foreign trade or undertaking industrial transfer.

The fourth category includes the 12 provinces of Hebei, Shanxi, Inner Mongolia, Liaoning, Heilongjiang, Guangxi, Hainan, Sichuan, Yunnan, Shaanxi, Ningxia, and Xinjiang.

Table 5: Ranking and changes of China provincial foreign trade quality development index.

	2013	2014	2015	2016	2017	2018	2019
Beijing	1	1 (0)	1 (0)	1 (0)	1 (0)	1 (0)	1 (0)
Tianjin	9	9 (0)	10 (−1)	11 (1)	12 (−1)	17 (−5)	12 (5)
Hebei	29	25 (4)	24 (1)	24 (0)	23 (1)	25 (−2)	21 (4)

Neimenggu	27	21 (6)	27 (−6)	29 (−2)	27 (2)	23 (4)	25 (−2)
Liaoning	15	16 (−1)	19 (−3)	23 (−4)	20 (3)	18 (2)	18 (0)
Jilin	16	10 (6)	15 (−5)	16 (−1)	15 (1)	13 (2)	15 (−2)
Heilongjiang	19	23 (−4)	20 (3)	22 (−2)	24 (−2)	20 (4)	22 (−2)
Shanghai	3	3 (0)	3 (0)	3 (0)	3 (0)	3 (0)	3 (0)
Jiangsu	5	4 (1)	5 (−1)	4 (1)	6 (−2)	4 (2)	5 (−1)
Zhejiang	4	5 (−1)	4 (1)	5 (−1)	5 (0)	6 (−1)	4 (2)
Anhui	7	7 (0)	8 (−1)	6 (2)	9 (−3)	8 (1)	9 (−1)
Fujian	8	8 (0)	6 (1)	8 (−6)	4 (4)	5 (−1)	6 (−1)
Jiangxi	12	15 (−3)	14 (0)	14 (0)	14 (0)	10 (4)	11 (−1)
Shandong	6	6 (0)	7 (−1)	7 (0)	7 (0)	7 (0)	7 (0)
Henan	17	20 (−3)	18 (2)	15 (3)	16 (−1)	12 (4)	17 (−5)
Hubei	11	11 (0)	12 (−1)	10 (2)	11 (−1)	14 (−3)	13 (1)
Hunan	21	18 (3)	23 (−5)	13 (10)	18 (−5)	15 (3)	14 (1)
Guangdong	2	2 (0)	2 (0)	2 (0)	2 (0)	2 (0)	2 (0)
Guangxi	24	29 (−5)	29 (0)	27 (2)	29 (−2)	29 (0)	27 (2)
Hainan	26	30 (−4)	25 (5)	28 (−3)	30 (−2)	30 (0)	29 (1)
Chongqing	10	12 (−2)	9 (0)	9 (0)	8 (1)	9 (−1)	8 (1)
Sichuan	23	27 (−4)	17 (10)	25 (−8)	28 (−3)	27 (1)	26 (1)
Guizhou	13	14 (−1)	11 (3)	12 (−2)	17 (−5)	19 (−2)	10 (9)
Yunnan	22	22 (0)	21 (1)	19 (2)	21 (−2)	21 (0)	23 (−2)
Shanxi	25	27 (−2)	26 (1)	20 (6)	22 (2)	24 (−2)	20 (4)
Gansu	20	19 (1)	13 (6)	21 (−8)	13 (8)	16 (−3)	19 (−3)
Qinghai	28	28 (0)	30 (−2)	30 (0)	19 (11)	28 (−9)	30 (−2)
Ningxia	18	13 (5)	16 (−3)	17 (−1)	10 (7)	11 (−1)	16 (−5)
Xinjiang	30	24 (6)	28 (−4)	26 (2)	25 (1)	26 (−1)	28 (−2)

From the point of view of the seven provinces in the western region, all of these provinces belong to the regions where the development level of foreign trade in China's provinces is relatively backward, and the foreign trade is developing at a slower pace and mainly exports resource-intensive and labor-intensive products; because of their geographical location, these provinces have a single foreign trade market structure. For example, Inner Mongolia, Yunnan, and Xinjiang provinces mainly trade with neighboring countries, while Sichuan, Shaanxi, and Ningxia mainly trade with the United States; as a result, the development of foreign trade is easily affected by the change of external environment; Liaoning in the eastern region and Heilongjiang in the central region are both old industrial bases in the northeast of China, and their geographical positions are similar, and the developments of foreign trade are similar. Taihang Mountains separate the eastern part of Hebei from the central part of Shanxi. Both provinces are rich in mineral resources. In the course of their development, they are affected by geographical location, resource endowment, and so forth, and the speed of foreign trade development is relatively slow.

5. Conclusions and Recommendations

Based on the connotation of high-quality development of foreign trade, this paper establishes an index system to measure the high-quality development level of foreign trade of Chinese provinces; using panel data of 30 provinces in China from 2013 to 2019, this paper measures the level of high-quality development of foreign trade in China's provinces and analyzes the ranking and changing trend of its comprehensive development index; 30 provinces were classified according to their high-quality development of foreign trade. The results show that, from 2013 to 2019, the high-quality development of China's foreign trade showed an upward trend; the level of high-quality foreign trade development in the eastern, central, and western regions of China has been raised to different degrees, but each region plays a different role in the development of high-quality foreign trade in China: the eastern region is the "leader," the central region is the "accompanying runner," and the western region is the "following runner." Compared with 2003, in 2019, the truly "high-quality" areas of the high-quality development of China's provincial foreign trade are still concentrated in the eastern region, ranking higher in the comprehensive evaluation index, and "low-quality" areas are concentrated in the Midwestern Sectional Figure Skating Championships, ranking lower in the comprehensive evaluation index.

Based on the previous research, this paper attempts to make policy recommendations from the three following points.

To begin with, trade innovation leads to high-quality foreign trade development. By continuously increasing investment in trade innovation, China's high-quality development of foreign trade can only improve the competitiveness of trade innovation output. We should adopt different policies, focus on innovation input, and aim to upgrade innovation output according to the situation of various provinces and different development priorities from the perspective of China's provincial trade innovation development.

Second, to promote high-quality foreign trade development by strengthening the coordinated development of regional foreign trade, the most important part of achieving a more balanced regional structure is optimizing China's provincial trade mode structure and main trade structure, and the optimization of China's provincial trade mode structure and main trade structure is the basic component to achieve this link. We can see from the cluster analysis that different types of provincial regions have different problems and shortcomings when it comes to trade coordination. As a result, each type of provincial region, in accordance with the overall direction of China's trade development and in combination with its own circumstances, can only develop China's trade in a harmonious manner by constantly adjusting and optimizing the trade structure.

Finally, high-level opening-up will help to accelerate the development of high-quality foreign trade. The concept of trade opening-up should be further developed in the new era. Various provinces should correctly understand the meaning of opening-up in the context of their own circumstances and use reasonable methods to promote the development of trade opening-up in order to improve the conditions for the development of China's foreign trade and to expand the external market space of foreign trade in a broader, deeper, and more reasonable direction.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

In view of the problems of poor correlation and poor calculation accuracy of the existing factors affecting economic fluctuations, this paper designs a new method for analyzing the factors affecting economic fluctuations based on the characteristics of the era of big data. First, after determining the factors influencing the economic fluctuations in the era of big data, the calculation method of key impact indicators is clarified. Then, the entropy law method is used to assign a weight value to the index, and the set is formed after the index is gathered. Then, the EM algorithm is used to assign the expected value to the data in the set. Finally, the set of influencing factors of the economic fluctuations is taken as input information, and the correlation evaluation model of influencing factors of economic fluctuations is constructed by the Monte Carlo method to complete the analysis of the influencing factors. The experimental results show that the correlation coefficient of influencing factors of economic fluctuations in the era of big data analyzed in this paper is high and the calculation accuracy of influencing factors is high, which proves the feasibility of this method.

1. Introduction

With the further deepening of the reform of the socialist economic system and the continuous improvement of the reform of the socialist market economic system, the means of national macrocontrol have played a more and more important role in the development of the social economy [1, 2]. The reform of China's market economic system has led China's economy into a new stage, and China's economy has begun to have economic cycle fluctuations with the characteristics of a market economy. Western economists have put forward many economic theories and economic models to explain the reasons for the economic cycle fluctuations in various countries under the market economy system [3]. Some economists have tried to monitor, analyze, and predict the fluctuation of the economic cycle since the beginning of the twentieth century. Cyclical fluctuations are only temporary deviations from equilibrium. The interior of the market economy system is very stable, and the power of the market can ensure the rapid recovery of the equilibrium state [4]. Economists at that time advised the administration not to intervene in the cyclical fluctuations of the economy. Because of this, the research on the economic cycle did not attract enough attention from economists at that time.

From a practical point of view, in countries dominated by the market economy, macroeconomic performance has become an important indicator to measure the administrative ability of the authorities. Therefore, the administrative authorities are trying to reduce the fluctuation range of the economic cycle and prolong the expansion stage of the economic cycle through macroeconomic policies, so as to make the economy in low unemployment stable operation under high growth rate and moderate inflation level [5–7]. The emphasis on macroeconomic performance and the enthusiasm to implement macroeconomic policies make the administrative authorities strive to seek the help of economists. At the same time, economists also hope that their research can affect the decision-making of the administrative authorities. This relationship also further stimulates economists' enthusiasm for the research of economic cycle issues. Globalization has provided a huge driving force for the world economy. Capital, labor, technology, natural resources, and markets have been reoptimized and allocated. The economies of various countries are increasingly interconnected and interdependent, and the international division of labor and international exchange has been expanded and deepened. However, due to the different economic systems and political and social environments of countries all over the world, there are constant collisions, competition, and infiltration in the process of economic globalization, which makes the economic situation complex and changeable. In addition, in recent decades, global environmental change, climate change, economic, social, and political emergencies, and other issues are superimposed with economic issues [8, 9].

The analysis of the influencing factors of economic fluctuations is an overall comprehensive and systematic analysis and judgment of the macroeconomy. It is the final judgment of macroeconomic development through the comprehensive sorting of many statistical data, and it is the progress and leap in the understanding of large complex statistical data. It is the supervision and measurement of a series of indicators representing the process and current situation of economic activities, and based on the understanding of the regularity of the process and the monitoring results, it puts forward an alarm for the possible turning points and major changes in economic activities in the future [10]. According to the analysis of the influencing factors of economic fluctuations, it is very important to adjust the effective strategies of economic development in real time. Therefore, relevant studies have analyzed the factors of economic fluctuation under the background of the big data era and achieved some results.

In the current study, relevant scholars analyzed the factors affecting the internal structure of the economy from the static perspective and found that the enterprises' profitability, debt-paying ability, development ability, operation ability, operation scale, industrial-chain added value, and other factors will have an impact on their capital structure [11]. Other scholars analyzed the changes of capital structure in recent years and found through model analysis that the adjustment speed of capital structure target was slow in the process of economic fluctuations. With the development of capital market, financing methods of listed companies will change, and excessive financing phenomenon exists to a certain extent in equity and debt financing [12]. However, in the existing studies, the impact of economic fluctuations without considering the background of the times is systematically analyzed, leading to poor accuracy of index correlation and impact degree calculation.

Therefore, based on the existing literature research, this paper studies the influencing factors of economic fluctuation in the era of big data. By constructing the index system of influencing factors of economic fluctuation, calculating the weight of each index, and predicting the risks in the index of economic fluctuation factors, this paper provides a certain theoretical basis for the analysis of future economic fluctuation. The technical route of this paper is as follows.

(1) After clarifying the index system of influencing factors of economic fluctuations in the era of big data, the calculation methods of key influencing factor indexes are established through different algorithms.

(2) The weight values of different indexes are determined by entropy law.

(3) The clustering algorithm is used to gather the indicators into a set, then the EM algorithm is used to give the expected value of the data in the set, and then the Monte Carlo method is used to construct the correlation evaluation model of the influencing factors of economic fluctuation. The set of influencing factors of economic fluctuation is used as the input of the model to complete the analysis of influencing factors of economic fluctuation in the era of big data.

2. Construction and Analysis of Index System of Influencing Factors of Economic Fluctuation

2.1. Index System of Influencing Factors of Economic Fluctuation. With the advent of the era of big data, the economic industrial chain is becoming more and more complex, and the characteristics of economic cycle fluctuation will be reflected in the data changes of some economic indicators [13–15]. In the economic fluctuation impact index system, according to the time sequence differences of indicators, they are usually divided into leading indicators, consistent indicators, and lagging indicators [16–19]. The leading indicator refers to the indicator that the occurrence time of its cycle turning point is stably ahead of the corresponding turning point of the overall market cycle and changes ahead of the overall market fluctuation in time. The reason it can predict the trend of economic prosperity is that it has a leading causal relationship with economic activities. Consistency index refers to the index whose cycle turning point appears almost simultaneously with the overall turning point of the market, and the fluctuation in time is consistent with the overall economy. Such indicators have two functions: to describe the boom state of the current economic operation. By analyzing the time difference between the consistent index and the leading index, the time of the overall cycle turning point can be estimated from the turning point of the leading index. The process of constructing the index system of influencing factors of economic fluctuations is shown in Figure 1.

According to the previously mentioned analysis, this paper constructs the key index system of influencing factors of economic fluctuations in the big data era according to the current actual situation. The overall indicators are shown in Table 1.

According to the indicators of different sectors determined, it lays a data foundation for the analysis of influencing factors of economic fluctuations under the background of big data era.

Among them, the calculation method of the determined index affects its analysis. Therefore, the calculation method of the index in the previously mentioned determined influencing factor index system will be clarified.

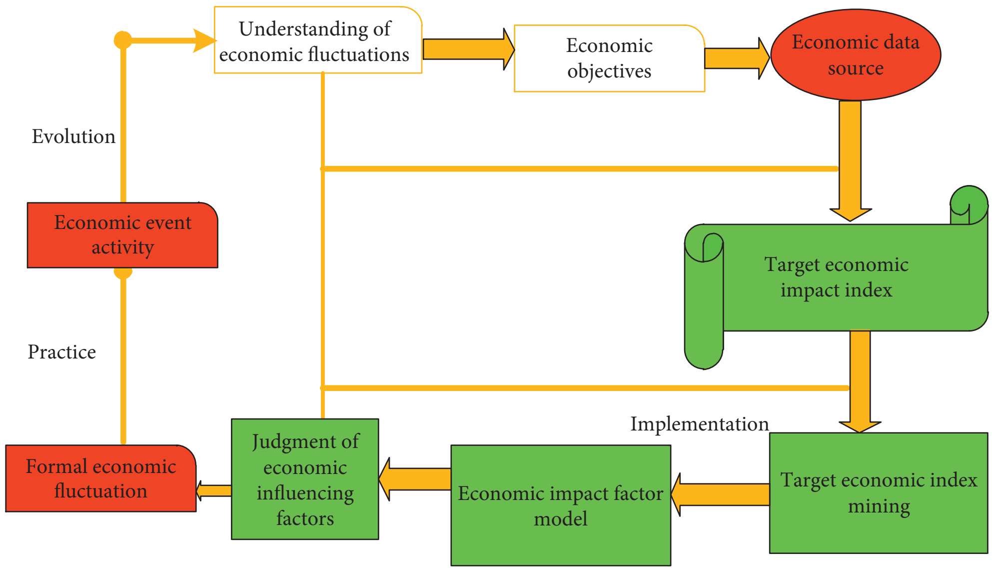

Figure 1: Construction of index system of influencing factors of economic fluctuation.

Table 1: Index system of influencing factors of economic fluctuations in the era of big data.

Level 1 index	Secondary indicators	Detailed
Market economy structure	Economic and industrial structure	Structural balance
	Rationalizing the economic and industrial structure	Market marketization of industrial structure
Economic market system	Economic volatility indicators	GDP and the national economic level
	Economic marketization	Individual economy, collective economy and private economy
Economic policy regulation	Macroeconomic policy	Subjective financial policy
	Microeconomic policy	We will fine-tune economic policies
	External demand	External output and input, etc.

2.2. Index Calculation of Influencing Factors of Economic Fluctuation

2.2.1. Changes in Industrial Structure. The change of industrial structure is the change of the proportion structure of various industries in the national economy, which reflects the adjustment of macroeconomy after the change of internal and external environment, and different industries in the national economy respond differently to the fluctuation of economic cycle. From the perspective of economic dynamic evolution, the change of industrial structure can be measured from the two dimensions of industrial structure rationalization and industrial structure modernization [20–23].

The fluctuation of industrial economic structure affects the fluctuation of the overall economy in the era of big data, which is a key factor that cannot be ignored in social and economic development. Because the structural rationality of different industries needs more factors to be calculated, this paper only focuses on the rationality and irrationality of industrial structure. Since the founding of the People's Republic of China, especially since the reform and opening up, great changes have taken place in China's industrial structure. The proportion of China's three industries in GDP is 15.1%, 45.9%, and 390% in 2019 and 11.3%, 486%, and 401% in 2020. Since then, there has been an upward trend of changes every year. As can be seen from the figure, China's secondary industry is still the leading industry, accounting for the largest proportion, but its proportion has been relatively stable, fluctuating between 41% and 49%. The proportion of the primary industry shows a downward trend year by year, from 28.2% in 2011 to 11.3% in 2020, a decrease of nearly 17 percentage points. The proportion of tertiary industry shows a gradual upward trend, from 23.9% in 2011 to 40.1% in 2020, an increase of 17 percentage points. The overall change trend is shown in Figure 2.

The rationalization of industrial structure also refers to the balance degree of industrial structure, which indicates the reasonable degree of the proportion between various industrial departments in the process of social production, or the balance degree of demand and supply structure of various industrial departments with input–output relationship [24]. This is a key factor in economic fluctuations in the context of big data. Structural deviation degree or structural imbalance degree is generally used to measure [25, 26], and its expression is as follows:

$$R = \sum_{i=1}^{n} \left| \frac{x_i/x_j}{x_i} - 1 \right|. \quad (1)$$

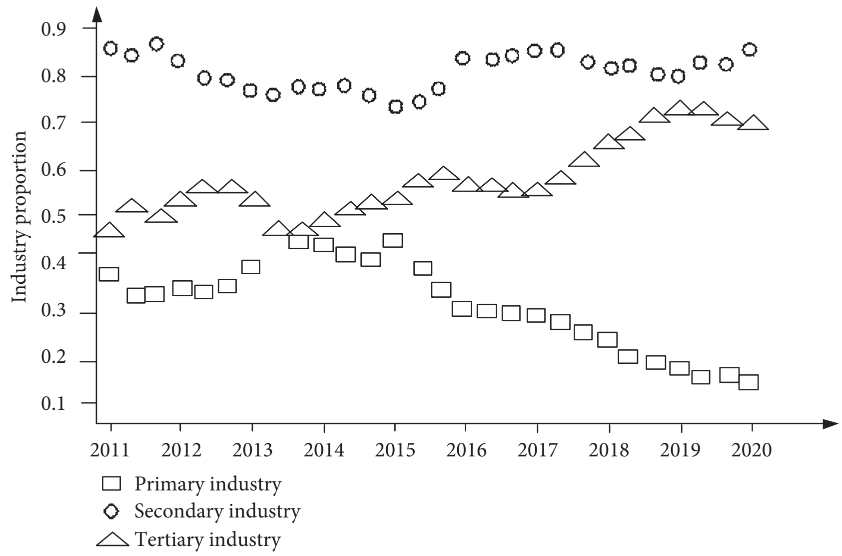

Figure 2: Change trend of proportion of three industries from 2011 to 2020.

Among them, i is the industry category, and $i \in n$, R indicates the imbalance of the industrial structure, x_i is the added value, x_j is the number of employees, and $x_i/x_j/x_i$ indicates the labor productivity.

When $R = 0$, the labor productivity of each industrial sector is just equal to that of the whole economy, and the whole society realizes the optimal allocation of resources. However, in the real economy, this is an ideal state, there is always a structural deviation, and the greater the R value, the more unreasonable the industrial structure [27]. However, this indicator ignores the relative importance of different industries in the national economy. Therefore, in order to reflect this, Theil index is used to measure the deviation degree of industrial structure [28], which is expressed as

$$TR = \sum_{i=1}^{n} \left(\frac{x_i}{x_j}\right) \ln\left(\frac{x_i}{x_j}/x_j\right), \tag{2}$$

where TR represents the imbalance degree of industrial structure.

Formula (2) shows that when the labor productivity of each industrial department is equal to the overall labor productivity, the economy is balanced and the TR is zero. The greater the value of the TR, the more unreasonable the industrial structure.

2.2.2. Calculation of GDP Growth Rate. When studying and analyzing the economic cycle fluctuation, the growth rate of GDP is generally taken as the index to measure the economic fluctuation. However, since the time series data are often nonstationary series data containing trend characteristics, it is necessary to deal with the original data and eliminate the trend components contained in the time series data, and the obtained periodic fluctuation part is taken as the series data of economic fluctuation. In practical application, HP filtering method has strong adaptability, so it is widely used in separating trend components and periodic fluctuations in time series. Therefore, this method is also used in this paper [29].

HP filtering method is based on the principle of symmetrical data moving average method. Its advantage is that it can eliminate the trend components and keep the periodicity of the original data unchanged; that is, the data does not have phase shift [30]. The specific method of HP filtering method is to decompose the time series data into growth trend components and periodic fluctuation components:

$$v_i = a_i + b_j. \tag{3}$$

In the formula, a_i is the trend component and the b_j component of periodic fluctuations. Since the trend component in the time series changes smoothly, it can be obtained by minimizing the following formula:

$$z = \sum_{i=1}^{t} \left(a_i - b_j\right)^2 + \gamma\left[a_{i+} + b\right]_j - \left(a_i - b_j\right)^2, \tag{4}$$

where γ is the smoothing parameter, in a practical application, and the general value is 100.

Due to the rapid rise of GDP, it can be seen from the previously mentioned analysis that when the proportion of the primary industry decreases and the proportion of the secondary industry increases more than the proportion of the primary industry to become the leading industry of the whole economy, the economy has strong volatility; when the proportion of the primary industry and the secondary industry decreases at the same time and the proportion of the tertiary industry continues to rise to a certain extent, the whole economy will show a more stable trend. The change trend is shown in Figure 3.

2.2.3. Economic Policy Indicators. Since the reform and opening up, China's market economic system has been continuously improved, but the government has little influence on the operation of the economy. Control and prediction still have an important impact. The government will use various economic policies to regulate the

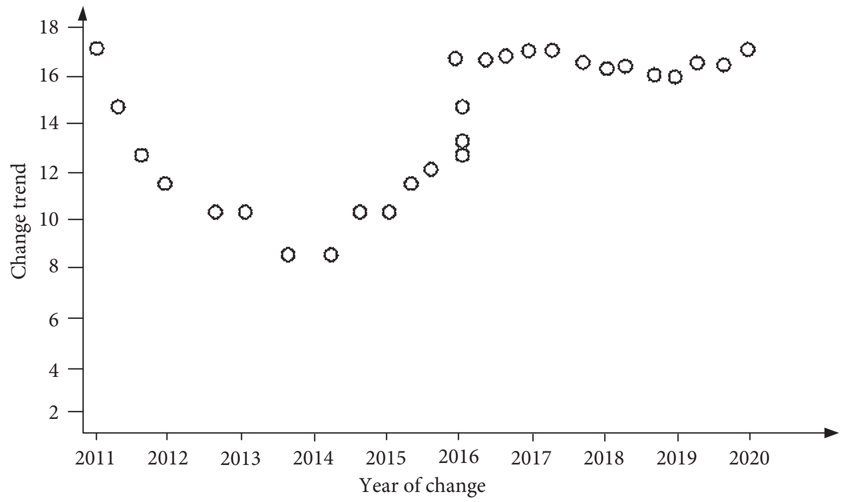

Figure 3: General trend of GDP change in 10 years.

economy, which plays a very important role in the fluctuation of the economic cycle. Among them, fiscal policy and monetary policy are the two most important policy tools for the government to regulate and control economic operation. Fiscal policy is included, and a macroeconomic policy status index, including monetary policy and fiscal policy, is established to measure the tightness of macroeconomic policy [31]. The monetary policy status index is expressed by the weighted average of percentage point changes of interest rate and exchange rate, and its formula is as follows:

$$C = e_i\left(E - E_0\right) + e_j\left(H - H_0\right). \quad (5)$$

Among them, H indicates the actual interest rate, H_0 is the initial interest rate, E indicates the effective exchange rate, E_0 is the initial exchange rate, and e_i and e_j indicate the corresponding weight of the actual interest rate and the effective exchange rate, respectively.

2.2.4. External Demand. Since the reform and opening up, with the expansion and deepening of opening to the outside world, China's trade openness has gradually improved. Foreign demand plays a very important role in China's economy, and the change of foreign demand directly affects the fluctuation of domestic economy. Here, the change of external demand is expressed by the export growth rate:

$$G_t = \frac{p_t}{p_{t-1} - 1} \times 100\%. \quad (6)$$

Among them, p_t represents the total export of the current year; p_{t-1} represents the total export of the previous year.

Opening to the outside world includes the opening of current account and capital account. China's capital account has not been fully opened.

Foreign direct investment (FDI) has been liberalized, but other financial projects are still under control. Here, it is expressed by the growth rate of FDI:

$$F_i = \frac{f_i}{f_{i-1} - 1} \times 100\%. \quad (7)$$

Among them, f_i represents the amount of FDI; f_{i-1} represents the amount of FDI in the previous year.

In recent years, the change trend of external demand indicators is shown in Figure 4.

According to the previously mentioned analysis, the relationship structure between the indicators of influencing factors and economic fluctuations can be determined, which is more complex, as shown in Figure 5.

To sum up, based on the analysis of the characteristics of the big data era, this study constructs the index system of influencing factors of economic fluctuations and defines the calculation method of key influencing factor indicators through different algorithms, so as to lay a foundation for subsequent research.

3. Weight Calculation and Correlation Evaluation of Influencing Factors

3.1. Weight Calculation of Influencing Factors of Economic Fluctuations in the Era of Big Data. There are many datasets in the influencing factors of economic fluctuations in the era of big data, so it is impossible to calculate one by one, which will increase the complexity of the research. Therefore, this paper calculates the weight of the key influencing index factors constructed as previously mentioned. The most commonly used diversification index is entropy index. The concepts and viewpoints related to nature defined in the entropy law, such as equilibrium state, maximum value, and uniform distribution, attract regional researchers to explore the measurement of economic diversity in this regard. Entropy is calculated as follows:

$$K = \sum_{i=1}^{n} q_{ij} \ln \frac{1}{q_{ij}}. \quad (8)$$

Among them, q_{ij} represents industry j employment in the share of total employment. The entropy index increases with

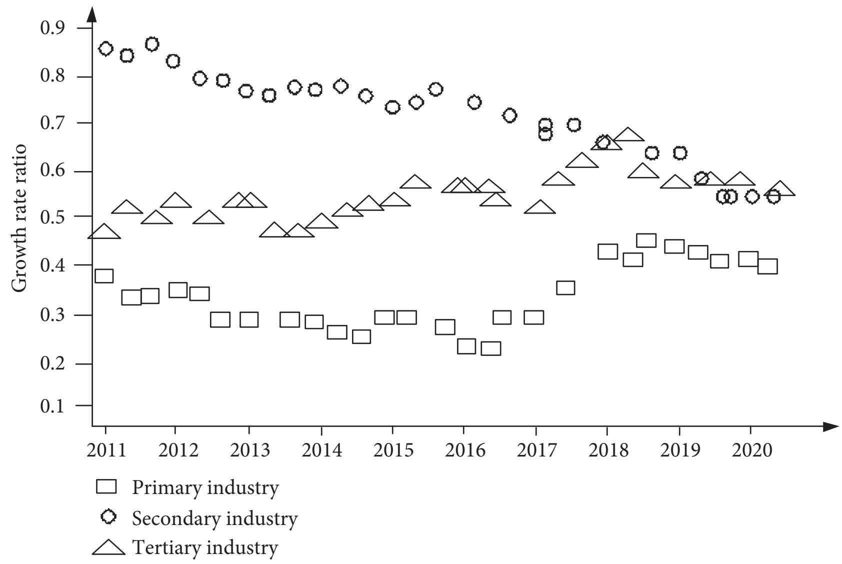

FIGURE 4: Variation trend of external demand indicators.

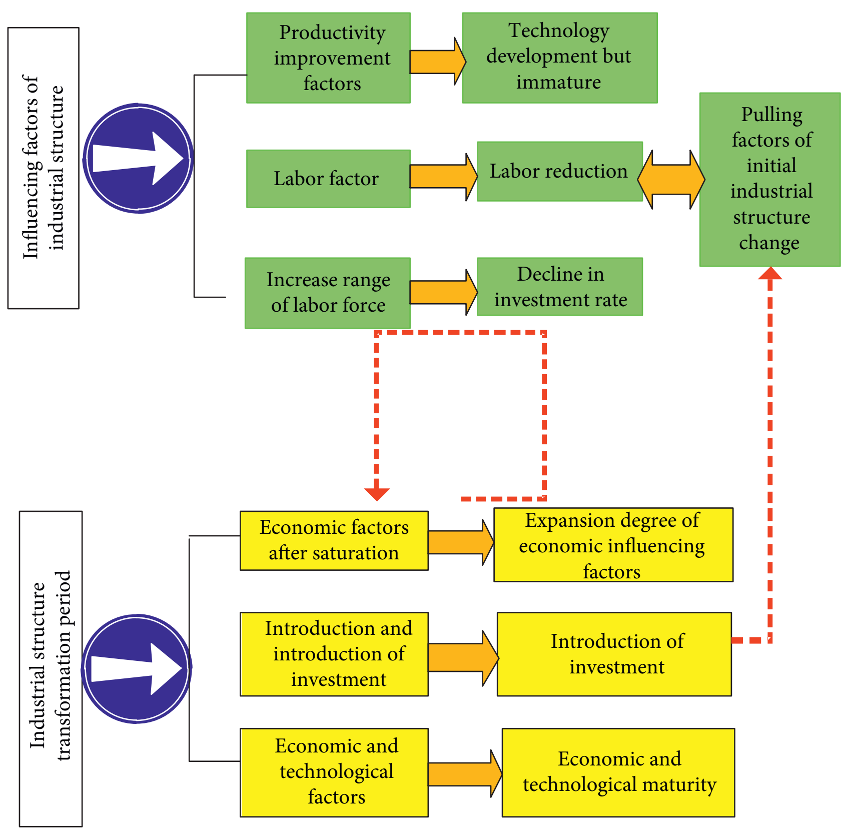

FIGURE 5: Structural diagram of the relationship between influencing factor indicators and economic fluctuations.

the growth of the number of departments in a region and the average of each sector. If the regional economy is completely evenly distributed among N industries, the entropy index reaches the maximum $\ln(1/q_{ij})$, representing complete diversification. Instead, if a region economy is concentrated in a certain industry, $q_{ij} = 1$ and the entropy index value is 0.

The construction of entropy also determines its superiority in use; that is, it can be easily calculated by using percentage distribution data.

General diversification measures can only integrate the number and size uniformity of sectors but cannot distinguish the degree of intersectoral differences and linkages. However, the differences and intersectoral linkages in various sectors must have different effects on economic growth and its fluctuations. Using the additivity of entropy, the previously mentioned entropy is decomposed into relevant diversification and irrelevant diversification:

$$K' = \sum_{i=1}^{n} q_{ij} \sum_{k=1}^{n} \sum_{k=n}^{m} \left[q_{ij} \left(\ln \frac{1}{p} \right) \right]. \quad (9)$$

Because the similarity of influencing factors of different economic indicators is low, the entropy index is defined as irrelevant diversity. The similarity of the same data is high, and the entropy calculated by taking the small department in the same large department as the unit is defined as correlation diversity.

Set the number of departments, namely, $k = 1, 2, 3, \ldots, K (K = 21)$; j is the number of small departments in the K large division. The first item in the formula-right is the related diversity (RV), which is the weighted sum of the lower entropy indicators composed of the share of the small sectors in the large sector, with the weight of

$$R_i = \sum_{k=1}^{n} p_j. \quad (10)$$

Among them, R_i is the weight of the index; p_i is the coefficient of the lower entropy.

3.2. Correlation Evaluation Model of Influencing Factors of Economic Fluctuation. According to the weight of the factors affecting economic fluctuations in the big data era determined as previously mentioned, to determine whether the economic indicators in this paper are effective indicators, it is necessary to determine whether the previously mentioned indicators are important factors affecting the economic fluctuations in the big data era according to the calculation of weight.

First, through the clustering algorithm, the influencing factors of economic fluctuations in the era of big data with large weight value are gathered into a set, and then, the data in the set are effectively collected as data input for the subsequent research of correlation evaluation model.

The steps of K-means algorithm are as follows: first, K samples of fluctuation influencing factors are randomly selected as the representative objects of K clusters. Calculate the distance between other samples and the center of K known clusters and add each sample to its nearest cluster. After assigning clusters to all samples, recalculate the average value of each cluster as the representative object of the cluster. Repeat the previously mentioned process until the samples in each cluster do not change. In practice, the sum of square errors is usually used as the objective function. As shown in the formula, when the value of the objective function does not change or changes below the set threshold, the final clustering result is obtained; that is,

$$\sigma = \sum_{i=1}^{k} \sum_{j=1}^{k} \left| w - c_i \right|^2, \quad (11)$$

where σ is the sum of squared error for all samples in the data set, and w represents a given single sample, and c_i is the mean of cluster C.

Then, the effective training is performed on the data in the set of economic fluctuations in the clustered big data era. The desired assignment was made to each fluctuation influencing factor index using the EM algorithm. The parameters of the mixed model were initially estimated and then repeated until convergence. Step E is called the expectation step, calculating the membership probability of each object according to the current parameter; the M step is called the maximization step, and the probability calculated by step E is used to update the parameter estimation. The probability of object O belonging to cluster C can be calculated by

$$T(t \in c_i) = \frac{T(c_i) t (t \in c_i)}{\sum T(c_i) t (t \in c_i)} \log T(c_i) \varepsilon (t \in c_i), \quad (12)$$

where $T(t \in c_i)$ represents obeying the mean, and $T(c_i) t (t \in c_i)$ represents the positive distribution of variance and the expected assignment coefficient.

Third, build the correlation evaluation model of influencing factors of economic fluctuations in the era of big data. In constructing the model, it is necessary to determine the occurrence probability of the correlation of the influencing factors of economic fluctuations. From the definition of probability, the probability of an event can be estimated by the frequency of the event in a large number of tests. When the sample size is large enough, it can be considered that the frequency of the event is its probability. Therefore, a large number of random sampling can be carried out for the random variables affecting its reliability, and then, these sampling values can be substituted into the functional function formula group by group to determine whether the structure fails, and finally, the failure probability of the structure can be obtained. The Monte Carlo method is based on this idea.

Assuming a statistically independent random variable $X_i = 1, 2, 3 \ldots k$, the corresponding probability density function is $f_x$and the functional number formula is $Z = g(x_1, x_2, \ldots, x_k)$. First, the value of group N random numbers $x_1, x_2, \ldots, x_k$ is generated according to the corresponding distribution of each random variable, and the correlation evaluation model of economic fluctuation influencing factors in the era of big data constructed is

$$\min \delta (X_i) = \frac{1}{n} |w|^2 + \frac{k}{l} \sum \left(s_i + s_j \right), \quad (13)$$

where δ represents the penalty coefficient, s_i represents the control fitting parameter, and s_j represents the dual coefficient.

Finally, input the set of economic fluctuation influencing factors in the trained big data era, and output the index correlation of the determined influencing factors; namely,

$$L(x) = \sum_{i=1}^{k} \left(s_i + s_j \right) \phi + b, \quad (14)$$

where ϕ represents the correlation regression coefficient and b represents the nonlinear relationship index.

To sum up, in the correlation evaluation model of economic fluctuation influencing factors constructed in this study, first, the clustering algorithm is used to gather the indicators into a set. After giving the index expectations, the Monte Carlo method is used to construct the correlation evaluation model of economic fluctuation influencing factors, so as to complete the analysis of economic fluctuation influencing factors in the era of big data.

4. Experimental Analysis

4.1. Experimental Scheme Design. In order to verify the effectiveness of this method in evaluating the influencing factors of economic fluctuation, an experimental analysis is carried out. In the experiment, a medium-sized and large enterprise in a certain place was taken as the research object. According to the changes of the enterprise's economic development in the past year in 2020, the key factors affecting the enterprise's economic change were set in the experiment, quantified, and evaluated according to the method setting. The parameters in the experiment are shown in Table 2.

4.2. Experimental Index Design. According to the previously mentioned experimental scheme, the comparative experiment is carried out using the comparative method. In the experiment, by comparing the methods of this paper and literatures [6] and [7], the correlation of the analysis index system and the accuracy of the calculation of the influencing factors are the experimental indexes. In order to ensure the accuracy of the experiment, the results obtained in the experiment have been iterated for many times.

4.3. Analysis of Experimental Results. In the experiment, first, the correlation of this method and the methods of literatures [6] and [7] on the sample economic data index system is analyzed. The correlation in the experiment takes the correlation coefficient as the research object. In the experiment, the value range of the coefficient is [0-1]. The larger the coefficient, the higher the impact of the determined economic impact index and fluctuation change. The experimental results are shown in Figure 6.

By analyzing the experimental results in Figure 6, it can be seen that the correlation of the sample economic data index system determined by the methods of this paper and literatures [6] and [7] is different. It can be seen from the experimental results that the correlation coefficient of the economic data impact indicators determined by this method is high, up to 0.92, and the lowest is about 0.80. The correlation coefficient of the economic data impact indicators determined by the methods of literatures [6] and [7] fluctuates more. Compared with this method, the fluctuation range of this method changes less, and the correlation is higher. This is because the calculation methods of key influencing factor indicators are defined through different algorithms. On this basis, the entropy law method is used to determine the weight value of indicators, and the clustering algorithm is used to gather the influencing factor indicators of economic fluctuation in the era of big data into a set to construct the influencing factor indicators of economic fluctuation, which improves the effectiveness of this method.

In the experiment, the accuracy of this method and the methods of literatures [6] and [7] on the calculation of sample economic impact indicators is analyzed. The results are shown in Figures 7–9.

Table 2: Experimental parameter design.

Parameter	Data
Number of evaluation indicators/piece	100
Value range of interference coefficient	[0, 1]
Test interval/S	0.5
Iterations/time	100

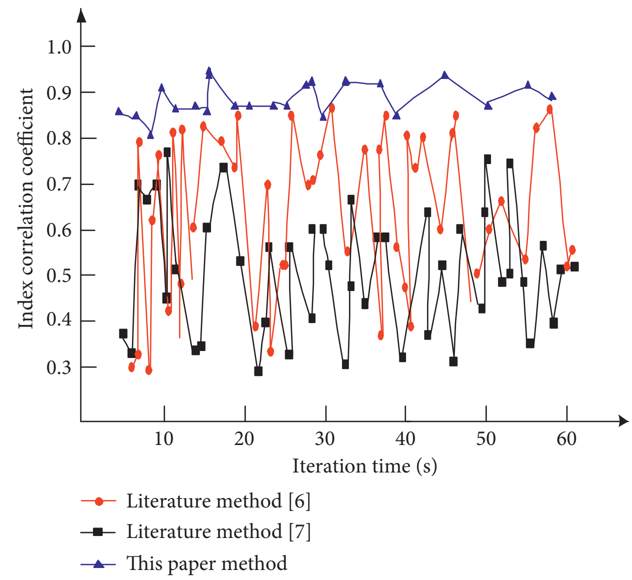

Figure 6: Correlation analysis of economic data index system determined by different methods.

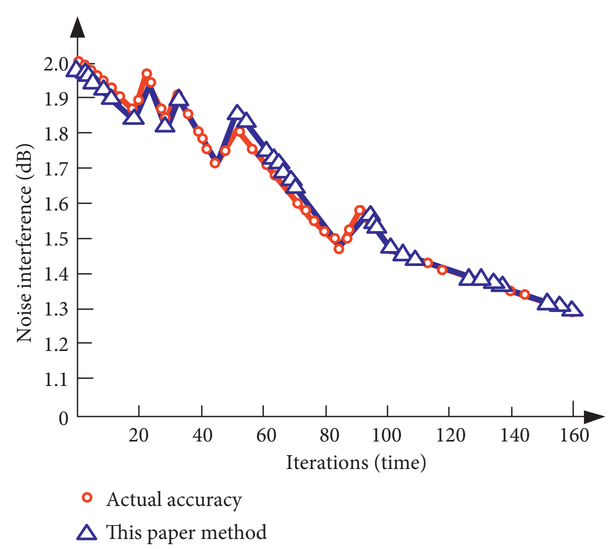

Figure 7: Precision results of sample economic impact index calculation by this method.

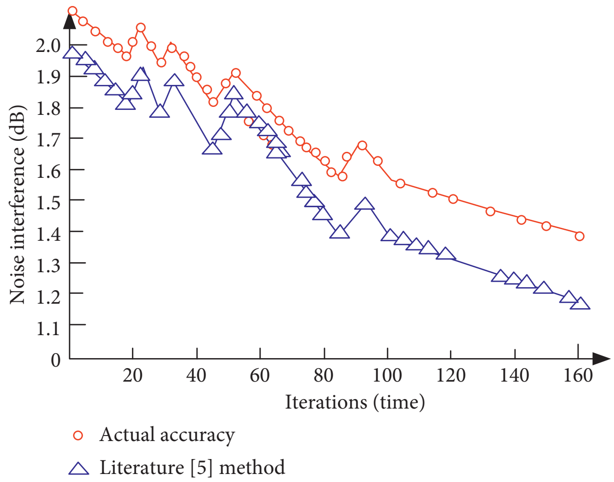

FIGURE 8: Precision results of sample economic impact index calculation by the method of literature [6].

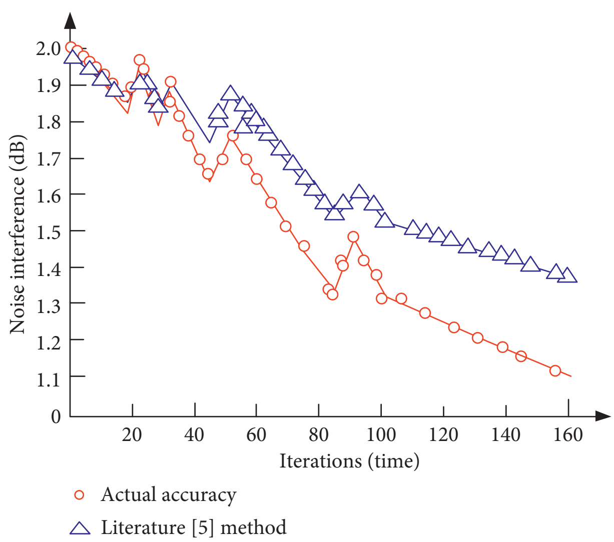

FIGURE 9: Precision results of sample economic impact index calculation by the method of literature [7].

By analyzing the experimental results in Figures 7–9, it can be seen that there are some differences in the accuracy of sample economic impact index calculation using the methods in this paper and literatures [6] an [7]. Among them, the accuracy of the sample economic impact index calculated by the method in this paper is relatively consistent with the actual calculation results. The accuracy of the sample economic impact index calculated by the methods in literatures [6] and [7] is different from the ideal value, and there are certain fluctuations. In contrast, the calculation accuracy of this method is better.

5. Conclusion

(1) With the continuous change of the economic environment, the index system of the existing economic fluctuation influencing factor analysis methods is less relevant. Therefore, this paper studies the economic fluctuation influencing factor analysis method in the new big data era. After clarifying the index system of influencing factors of economic fluctuations in the era of big data, the entropy law method is used to determine the weight values of different indicators. Then, the indexes are clustered into a set by clustering algorithm, and the EM algorithm is used to give the expected value of the data in the set. Finally, the Monte Carlo method is used to build the correlation evaluation model of the influencing factors of economic fluctuations to complete the analysis of the influencing factors of economic fluctuations in the era of big data.

(2) The experimental results show that the correlation coefficient of the influencing factors of economic fluctuations in the big data era analyzed by this method is high, the calculation accuracy of the influencing factors is high, and it is feasible.

(3) In the next research, we will further refine this analysis method, consider applying it to different fields, and expand the applicability of the analysis method.

The Internet of Things (IoT) has gotten a lot of attention as a next-generation Internet application, and its realization, which connects things, people, and things, is the focal point of a new round of high-tech competition around the world. Network technology has a significant impact on people's lives today, thanks to the rapid development of the Internet, and the Internet of Things (IoT) is a technological innovation of the times that promotes the development of information technology. The Internet of Things has given the logistics industry a new lease on life, allowing it to grow more intelligently. The modern logistics industry is a modern service industry that includes transportation, warehousing, freight forwarding, information, and other industries, and it is very important. This paper examines the technical system of the Internet of Things and the logistics economic management mode, as well as the impact of the Internet of Things on logistics economic management. A multidimensional collaborative management model of environment and economy is proposed, based on the background of IoT. It has laid the groundwork for the IoT's application and development in the logistics economy.

1. Introduction

The world is linked by electronic communication technology. It is possible to connect things thousands of miles apart, which has greatly aided the advancement of human communication [1]. The traditional logistics system has proven insufficient to meet today's development needs. The logistics industry's previous business model is changing. The state has previously paid attention to the logistics industry, which is represented by railway [2]. In recent years, IoT technology has aided the logistics industry's informatization, automation, and integration, as well as its overall development. In the process of information technology development and logistics service diversification, modern logistics collaborative management is a new logistics management problem [3, 4]. New problems in logistics management have emerged as a result of the Internet of Things. In this case, the logistics industry should seek out new approaches.

In recent years, China's Internet technology is constantly improving. Internet technology has gradually changed to IoT technology. IoT technology has broken the traditional Internet virtual environment. The IoT can combine the network and objects, so that the real and intelligent self-perception can be connected with objects, so as to achieve the purpose of global interconnection. As the main application of the next-generation Internet, it has received extensive attention [5]. At present, the development of Internet technology has gradually transformed logistics into the IoT. Through the development of IoT technology, the logistics industry and Internet technology are continuously integrated [6]. The logistics industry needs to adapt to the new features and seek the best method for the transformation of the logistics industry in the IoT [7]. In the logistics industry, the use of modern IoT technology can have a strong impact on the traditional logistics economic management, reestablish the recognition of logistics enterprises for science, technology, and information, improve the intelligent monitoring and management of logistics enterprises, promote the sharing of information resources among logistics enterprises, and finally achieve the purpose of win-win.

The logistics industry will usher in a comprehensive innovation against a modern backdrop. The use of IoT technology in the logistics industry can help to improve the logistics industry's operational efficiency, improve the quality of logistics work, and aid in the development of China's logistics industry [8]. IoT is a technology that perceives, analyzes, controls, and manages goods using integrated technologies such as intelligent sensing systems, computers, and the Internet. The IoT's emergence and development will inevitably bring certain opportunities and convenience to the development of modern logistics, particularly in the visualization of logistics transportation, intelligent transportation, and logistics information networking, where the benefits of the IoT are clear [9]. The current cloud computing expertise can largely stabilize IoT expertise, which can improve logistics economic management work efficiency and reduce the likelihood of problems at work [10]. This paper introduces the multiagent collaboration mode of modern logistics network layer under the cooperative game and the multidimensional collaboration classification of modern logistics, starting with IoT-related knowledge. It was decided to create a multidimensional environmental-economic collaborative management model. Information collaboration can significantly improve the efficiency of the logistics economic system and bring more economic effects, according to simulation and numerical experiments.

2. Related Work

Literature [11] expounds management synergy from the perspective of economic management. Zhou and Yuan [12] pointed out that the synergy between various social departments is not strong, resulting in the low efficiency of social management. Therefore, in order to improve the efficiency of social work, a mechanism of social synergy must be formed. The research on collaboration in [13] is specific to the management level. Literature [14] holds that collaboration is a simple combination of individual parts, which forms the overall state and business performance of the enterprise. Literature [15] regards the whole supply chain as an evaluation subject and believes that it is more practical and scientific to establish a group rather than a single evaluation index. Literature [16] uses economics to analyze and define synergy: the value of the enterprise as a whole is greater than the simple sum of individual components, and the effect of collaboration is far greater than that of individual operation, which is the reason for the emergence of economic scale. Literature [17] believes that collaboration can maximize the utilization of resources. Resources can be divided into two types: one is entity resources. Literature [18] pointed out that, in the face of the rapidly changing market environment, enterprises need to seize the fleeting market opportunities and effectively integrate intellectual resources. It is necessary to form a mechanism—management synergy. Literature [19] proposes that management collaboration is not a natural selection process. In order to ensure the smooth operation of the enterprise system, managers understand the development of the enterprise system and the changes of the environment from multiple angles. This behavior process aims to explain why enterprise systems need management collaboration. Literature [20, 21] believes that a good measurement standard should involve these key elements of the logistics process: time, distance, and capital. Literature [22] believes that there are many ways for enterprises to realize collaborative benefits, such as business behavior, information sharing, information flow, and so on. However, it does not mean that these means can completely solve the problem of synergy. The root cause is that sharing is limited. Only enterprises with innovation ability can truly realize synergy. Literature [23] believes that, with the wide application of Internet technology, collaborative logistics has become a new business model. This model focuses on the integration and unification of the overall value, attaches importance to the information sharing and collaborative operation between upstream and downstream partners of the supply chain, and forms a good business operation network environment by establishing efficient collaborative mechanisms and norms. Literature [24] pointed out that the information that can be shared is not only inventory and order information, but also sales information. Literature [25] analyzes the collaborative operation of regional logistics clusters. Literature [26] proposes a negotiation based method to solve the distributed project scheduling problem. It is pointed out that the information sharing can be improved by sharing the flexible information of enterprise dispatchers and improving the concentration and scheduling quality. Literature [27] proposed three modes of cooperative operation. According to the different degree and relationship of node members, it can be divided into point chain collaboration, line chain collaboration, and full chain collaboration. Literature [28] pointed out that qualitative analysis is the focus of current research, and there is a lack of discussion on quantitative research such as system collaboration level, system collaboration mode, and collaborative system construction. This paper studies the significance of multidimensional coordination of modern economy under the IoT system. Whether it is theoretical analysis or practice and application, a complete set of scientific theories and management methods are essential to guide the successful application of the IoT in the economic field. In this paper, based on the IoT environment, a multidimensional environmental-economic collaborative management model is established to solve the problem of economic management collaboration. Through simulation and numerical experiments, it is proved that information collaboration can significantly improve the efficiency of logistics economic system. The effectiveness of the algorithm is verified by numerical experiments. The results show that the algorithm can bring more economic effects.

3. Methodology

3.1. IoT. In recent years, China has developed IoT professional technology, which is an interconnection technology based on computer professional network technology. The Internet of Things (IoT) is a brand-new type of information and communication technology. It is an important component of the new generation of information technology as well as a critical stage in the "information" era's development. With the advancement of communication technology, the Internet of Things (IoT) has become an important guarantee for the growth of the logistics industry [18]. Because people can surf the Internet at high speeds on their mobile devices, the IoT technology development platform has a lot of room for growth. With China increasingly focusing on the development of the IoT industry, the IoT industry has emerged as China's primary technology. China's IoT industry grew and matured earlier, and it has now essentially formed a perfect IoT industry system. And the market's development of some fields has begun to take shape.

As the application of the next-generation Internet, the IoT has received extensive attention, and the realization of the IoT, which interconnects things, people, and things, is the commanding point of a new round of high-tech competition around the world. The technical system of IoT includes three levels: perception layer, network layer, and application layer. The sensing layer is mainly used to identify items through sensing devices, collect information data, and transmit data to gateway devices through transmission devices. The network layer will process the received information data to ensure the security and reliability of the data [29]. In the application layer, information is mainly shared across regions, information is analyzed, and intelligent management services under the IoT technology are realized.

The IoT is an information bearing system based on the development of Internet technology, computer technology, and network communication technology. The system can make the modules with independent functions communicate with each other. IoT technology mainly realizes the connection between objects through infrared positioning technology and Global Positioning System (GPS) technology and uses Internet protocol to combine the Internet with actual objects, so as to realize information sharing. In recent years, China's communication technology is also constantly improving, because today's mobile devices can use the high-speed network to access the Internet, so a lot of mobile device users have been increased, which directly shows that the opportunity of the IoT is coming.

3.2. Application of IoT Technology in Economic Management Industry. Perception technology, network communication technology, identification technology, system framework technology, security and confidentiality technology, and so on are all part of the IoT, which together form a massive technical system. The Internet of Things (IoT) is a new era information technology term that denotes the start of a brand-new information era. The Internet of Things (IoT) technology realizes the connection between things, and its core technology is the Internet, which it extends and expands in a sense, with the goal of expanding information exchange to include the exchange of things. In the logistics industry, the Internet of Things is primarily used in the technology of automatic bar code acquisition. The visual intelligent system can help different departments coordinate and unify, rationally allocate logistics processes, and improve the timeliness of logistics management, as well as improving the operational fluency and efficiency of transportation management, warehouse management, and customer information service management. Under the IoT, logistics economic management should create resource codes within logistics units so that logistics resources can be managed in a unified manner, and the authenticity and accuracy of resources must be ensured during the resource collection process. The Internet of Things can be used to create a visual logistics intelligent management system. To ensure that the circulation of articles is transparent and safe. Figure 1 depicts the visual intelligent management framework.

In the traditional logistics management, due to the influence of road, geographical location, and other reasons, the information collection ability of goods is limited, and it is difficult to realize all-round tracking of logistics information. However, the Electronic Prism Collimator (EPC) tag of the IoT has solved this problem. In the aspect of logistics economic management mode, with the rapid development of high technology, quota management mode has emerged, which has advanced management concepts and policies and is widely used in the logistics industry. The management system of quota management mode can promote the rapid development of logistics economy. Besides the quota for product delivery and storage, the comprehensive management of products also needs quota, so as to further clarify the consumption produced by products reaching customers and make the quota management mode of logistics enterprises exert the greatest benefits, thus bringing more economic effects.

Using supply chain management mode, logistics management can reduce transportation pressure and operation costs. The rest can be outsourced to other companies as long as businesses carefully build their own core industries. It can improve not only execution efficiency, but also customer satisfaction, achieve zero storage, and promote the maximization of logistics enterprise benefits in this way. The development of logistics enterprises will be more efficient and long-lasting if comprehensive logistics management capabilities are integrated.

The Internet of Things (IoT) has the potential to improve economic visualization. The most important point to remember during the practical application is to strengthen the integration between IoT technology and logistics economic management, so that the logistics economic management can be completed with greater quality. Electronic identification and analysis of goods can be accomplished using EPC electronic tag technology in logistics, which improves not only the efficiency of screening and distribution of goods, but also the accuracy and speed of distribution. At the same time, the Internet of Things plays an important role in logistics economic management statistics and calculations. It can quickly grasp data and calculate results based on the data, allowing for logistics economic management visualization.

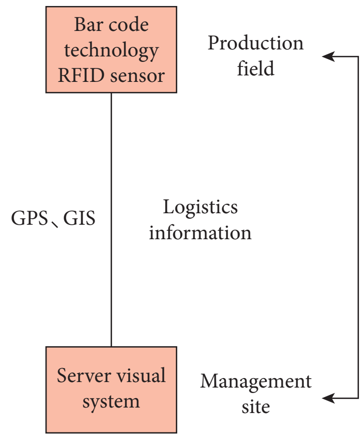

Figure 1: Visual intelligent management framework.

3.3. Economic Management of Multidimensional Collaborative Logistics under the Background of IoT. In the logistics industry, logistics economic management is one of the important works. The main responsibility is to plan, organize, command, coordinate, control, supervise, and encourage the whole process and systematic economic activities of logistics according to the basic economic laws and commodity circulation laws. With the support of IoT technology, the distribution speed of goods and goods information are more rapid and transparent. Goods do not need to stay in logistics companies for a long time, and the flow speed is accelerated. In the context of the IoT, combined with the basic characteristics of rapid logistics, bar code technology is set. When goods are converted or detained, as long as the bar code is scanned, the current transportation status of logistics can be displayed on the network platform through automatic identification. The multidimensional management of contemporary logistics economy has four characteristics. (1) Multidimensional. It includes technology collaboration, information collaboration, service collaboration, management collaboration, etc. (2) Coexistence. Each dimension promotes the others and does not hinder other dimensions. (3) Cooperation. It includes the competition and cooperation of different departments within the enterprise, different enterprises among industries, upstream and downstream supply chains of enterprises, etc. (4) Information sharing. The modern logistics industry is based on information network technology, which has realized a high degree of information sharing and real-time interaction and reduced departmental communication problems caused by information isolation. The multidimensional collaborative classification of logistics is shown in Figure 2.

Modern logistics is facing the necessity of multidimensional collaborative management. Based on the four-tier architecture of the IoT, aiming at the multidimensional collaborative management problems faced by logistics enterprises, this paper defines multidimensional collaborative classification from four dimensions, analyzes the phenomena of logistics enterprises in four-dimensional collaborative classification, and establishes the order parameter equation of logistics system. Suppose the system's cooperative efficiency is y, the nonhuman factor is x, and x is a function of time t. In the initial state of the system, the synergy efficiency is y_0, and in the lowest synergy efficiency state x_d, the synergy efficiency is y_d, and the balance synergy efficiency y_i; then:

$$y = \frac{\sin(x - x_i)}{x} + y_i, \quad x > 0. \tag{1}$$

Suppose the system's synergy efficiency is S, the nonhuman factor is γ, and S is a function of γ, so the formula (1) becomes

$$S(\gamma) = \frac{\sin(\gamma - \gamma_i)}{\gamma} + S_i, \quad \gamma > 0. \tag{2}$$

So S is the simultaneous function of ω, δ, ε, γ and η, ω, δ, ε, γ and η are also functions of time t, so

$$\frac{\partial S}{\partial t} = \begin{cases} \beta\omega(t) + S_{01}, & 0 < \omega < \omega_0, \\ 1n[\delta(t) + 1] + S_{02}, & 0 < \delta < \delta_0, \\ \arctan[\varepsilon(t) - \varepsilon_d] + S_d, & 0 < \varepsilon < \varepsilon_0, \\ \dfrac{\sin[\gamma(t) - \gamma_i]}{\gamma(t)} + S_i & \gamma > 0, \\ b\eta^2(t) + \sum S_n, & \eta > 0. \end{cases} \tag{3}$$

The macrochange of a complex logistics system is determined by the "synergy" between subsystems, not by the forced action of an external force. Whether it is technology collaboration, service collaboration, or management collaboration, it all starts with information collaboration and has an impact on information collaboration efficiency. The state formed by more than two collaborative requirements that are not of the same type is referred to as multidimensional. Modern logistics is confronted with a wide range of collaborative requirements. Storage space is not only an important index in the logistics industry, but also an important part of logistics economic management. Storage space is primarily used in the logistics link to store goods in the middle of logistics in order to ensure the integrity of goods and improve logistics efficiency during transportation or transshipment. IoT technology can help logistics companies improve their inventory management capabilities by allowing them to control warehouse storage information in real time, allowing them to check leaks and make up deficiencies in real time, and replenishing goods with insufficient storage in real time. The use of IoT technology condenses complex tasks while maintaining a high level of accuracy.

The mobile logistics service requesters and mobile logistics service responders are classified. According to the characteristics of logistics distribution, the nodes are divided into two categories. One is the mobile logistics service requester, represented by C_i; one is the mobile logistics service responder, represented by D_j. The trajectory information of the mobile node C in the practice period is expressed as

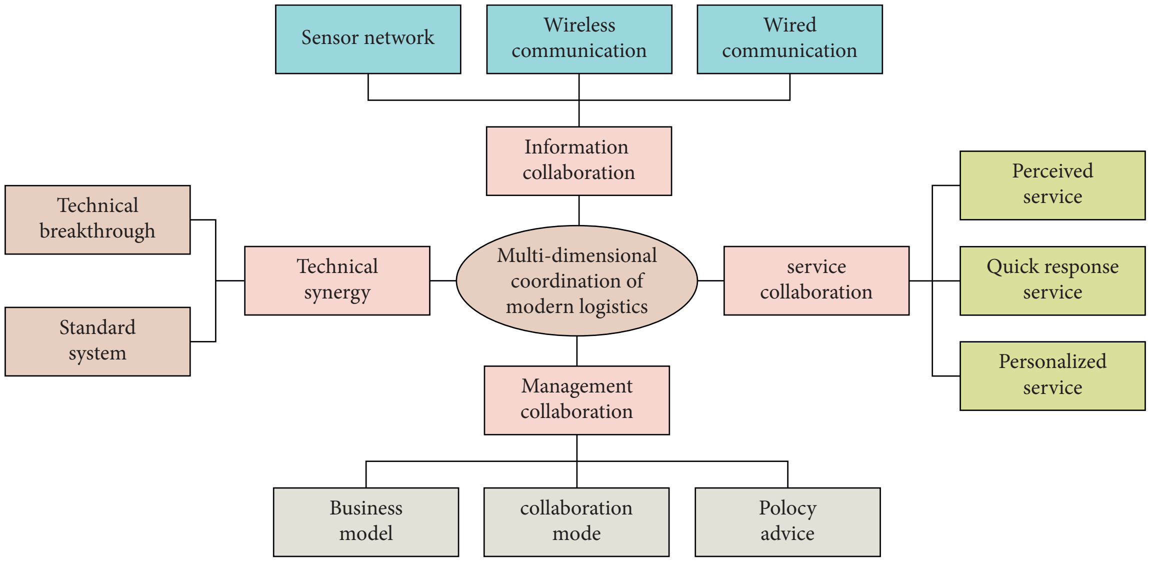

FIGURE 2: Logistics multidimensional collaborative classification.

$G = \{\cup_{i=1}^{k} L_i, S_i, E_i, \alpha\}$, where L is the location information of the sensing area, S and E are the time when the node arrives and leaves the area, and α is the time threshold, which is used to control the time interval for different nodes to reach the target area. The distance factor between nodes C and D is expressed as

$$L(C, D) = \frac{\sum_{i=1}^{k} \operatorname{sim}(G_i(C), G_i(D))}{T}, \tag{4}$$

where T is the time period; $\operatorname{sim}(G_i(C), G_i(D))$ is the position similarity function of mobile nodes C and D, which reflects the duration of different mobile nodes at position i, expressed as

$$\begin{aligned} &\operatorname{sim}(G_i(C), G_i(D)) = \max\{S_i(C), S_i(D)\} - \min\{E_i(C), E_i(D)\},\\ &\text{s.t} \begin{cases} L_i(C) = L_i(D) \\ |S_i(C) - S_i(D)| \le \alpha. \end{cases} \end{aligned} \tag{5}$$

There is a lot of information related to logistics, and there are extremely high requirements for accuracy and timeliness. In terms of logistics, information mainly includes inventory information, supply information, order information, purchasing information, etc. Controlling information is the most important thing in the logistics industry. Users can know the transportation time, destination, and so on of goods through the mobile phone terminal. This convenient technology can benefit both buyers and sellers. Automatic scanning technology can reduce the loss of goods, improve customer satisfaction, and make logistics and transportation transparent.

TSP_i is used to represent the distribution problem of the ith time slice, and N is the number of cities. $c_{i,j}(t)$ is the weight between city i and city j in time t, δt is the sampling period, $\Delta c_{i,j}$ is the change of weight between cities in the sampling period, T is the time period, and n is the sampling times in a period.

The distribution simulation problem based on collaborative information can be expressed as

$$\mathrm{TSP}(t) = \begin{cases} \mathrm{TSP}_1, & 0 \le t \le \Delta t, \\ \mathrm{TSP}_2, & \Delta t \le t \le 2\Delta t, \\ \dots & \\ \mathrm{TSP}_n(n-1), & \Delta t \le t \le n\Delta t, \end{cases} \tag{6}$$

$$o \cdot \min d(T) = \sum_{k=1}^{n} \sum_{i=1}^{N} \sum_{j=1}^{N} c_{i,j}(k \cdot \Delta t), \tag{7}$$

$$\begin{aligned} \text{s.t } \Delta t &= \frac{T}{n}, \\ \frac{\Delta c_{i,j}}{\Delta t} &= 0. \end{aligned} \tag{8}$$

Equation (6) indicates that the information-based collaborative delivery problem is a combination of different TSPs in different sampling periods. Among them, each TSP_i can be the same or different. When each TSP_i is the same, it becomes a traditional TSP; in the research of this article, they are different. Equation (7) indicates that the goal of completing the delivery is the sum of the target values of each TSP within the time period T; that is, it pursues overall goal optimization instead of local optimization. Equation (8) is the definition of the sampling period. Equation (8) indicates that the parameters in the sampling period remain unchanged.

People's production and lives will become more dynamic and refined in the IoT environment, and the way businesses operate will change dramatically. The Internet of Things (IoT) should be studied not only for its application of value-added, but also for the real difficulties and challenges faced by multidimensional collaborative logistics management in the IoT environment. Efforts should be made to incorporate IoT technology into all aspects of logistics management, as well as conduct targeted research to increase the value of its application in the field of logistics and provide greater benefits to logistics businesses.

4. Results Analysis and Discussion

The composition of IoT technology and logistics industry is relatively complex. By applying the IoT technology to logistics economic management, we can build an information-based network logistics public information platform. On this platform, customers can inquire about their own goods information at any time, so as to get the latest logistics information. Collaborative analysis is carried out from four levels: perception layer, network layer, application layer, and management layer, and the basic law of collaboration is summarized from the phenomenon of system self-organization and unbalanced phase change. Using quantitative analysis method, the multidimensional collaborative order parameter equation of modern logistics system is constructed.

The Internet of Things has the potential to greatly reduce the phenomenon of asymmetric economic information. It provides a profitable space for commercial banks because of the asymmetric information of small businesses in financing. The Internet of Things accurately and objectively reflects enterprise information, the market economy determines price, the transaction process is intuitive and transparent, and credit and risk assessment data are all open. The asymmetry of small businesses in the financial transaction process can be greatly reduced by analyzing network data. The most trusted technology in the application of IoT technology in logistics economic management is Internet information technology. Information transmission between various devices in the IoT system frequently requires the use of the Internet, which not only improves the rate of data transmission but also improves the efficiency of data processing. Perception technology is the foundation of the Internet of Things, allowing information management systems to "perceive" objects. Figure 3 depicts the market size and market segments of the IoT industry in China's modern logistics field from 2016 to 2020.

Because the application of perception technology has fueled its development, the demand for perception technology synergy has grown even stronger. The Internet of Things (IoT) is a technology that perceives, analyzes, controls, and manages objects using a variety of technologies such as intelligent perception systems, computers, and the Internet. The third information technology revolution is referred to as such. Under normal circumstances, logistics companies deal with a large volume of transactions and cargo transportation every day, so data calculation is a challenge for them. Traditional manual statistics and calculations are prone to errors when faced with such a large workload, and manual calculation is slow, making it difficult to grasp all data quickly. During this time, the IoT system can intelligently analyze goods, such as detailed classification of goods and specific sending areas, to ensure that goods in the same destination are managed and distributed uniformly, ensuring the efficiency of logistics work and the completion of logistics transportation and distribution in the shortest time possible. The real-time traffic information of this simulation system uses the congestion coefficient that obeys the time distribution as the input and divides the urban road traffic into two levels based on the frequency of road use, in order to simulate the real-time traffic information closer to the real situation.

Important path traffic: Urban arterial roads have a large traffic volume, and the road conditions are often in a saturated state. The traffic conditions of important paths are shown in Figure 4.

General route traffic: urban secondary roads and some branch roads. The travel time and frequency of people who use roads are regular, with obvious peaks and valleys in the morning and evening. The general route traffic conditions are shown in Figure 5.

The data in the IoT environment has a wide range of sources, a complex structure, and a large amount of data, and the data will be updated irregularly, so the data in the IoT environment has certain uncertainty. The IoT has certain advantages in mastering data and calculation results. To a certain extent, computers can replace people's work, which can quickly identify and merge logistics circulation characteristics, thus giving birth to barcode technology. "One thing, one standard" greatly facilitates the turnover and circulation of goods. Under the IoT environment, the application of IoT technology is conducive to the development of logistics economic management in the direction of intelligence. There are many independent logistics companies in China, but the information between them can be shared. Because the logistics information is updated very fast and the interaction is complicated, it is necessary to master the rapidly changing information with the IoT technology and increase the communication with other logistics companies.

Because the traditional simulation method takes the distance as the optimization goal and does not consider the road information, it cannot respond to the real-time road information in real time, and its path distance length has not changed significantly. However, when the main roads are congested, the simulation of information collaboration will choose other road sections with a little distance but good road conditions. Therefore, the whole distance will obviously increase during the peak period of traffic congestion. The analysis and comparison between the starting time and the whole distance is shown in Figure 6.

In the IoT environment, logistics development should provide timely feedback on information updates based on changes in various IoT data information, collect changes in information, adapt logistics development to market changes, know the market in real time, grasp the characteristics of big data changes in the IoT environment, and integrate information in real time, so that IoT data information can be integrated. To score the delivery service, receiving service, and online shopping satisfaction of logistics enterprises, choose 30 valid scoring data. The results are shown in Figures 7 and 8.

The continuous development of IoT economy will impact the traditional economic model, which will make adjustments in business composition, service object, service

attitude, and operation mode. Under the current background of the IoT, the logistics economic management has been innovated. Applying the IoT technology to the logistics economic management can effectively improve the quality and efficiency of the work, optimize the service functions of logistics enterprises in all directions, and enable customers to enjoy better logistics services.

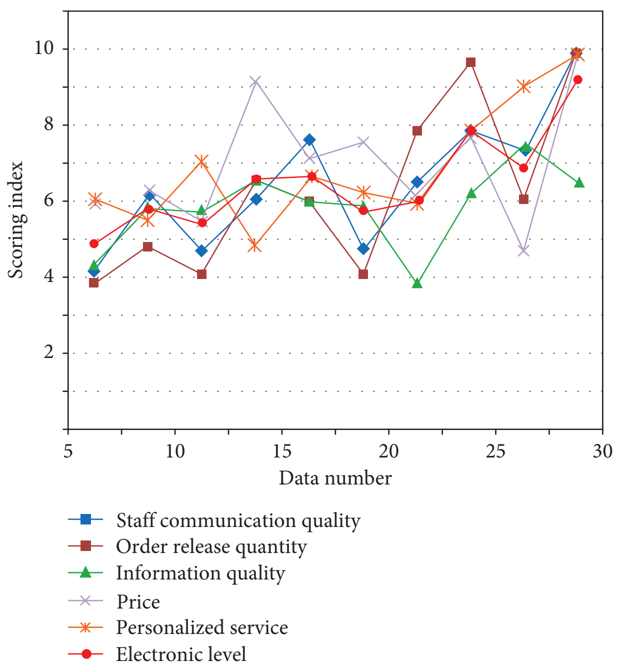

FIGURE 7: Online shopping satisfaction scoring results based on the Servqual scale.

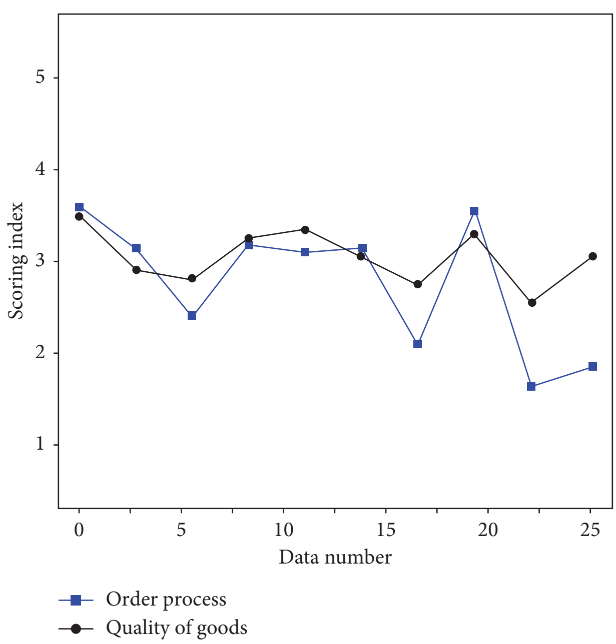

FIGURE 8: The scoring results of the quality of service delivery based on the Servqual scale.

By solving the equation with the algorithm, it is concluded that the information collaboration is the order parameter of the logistics system, which realizes the accurate use of the order parameter to control the fluctuation and balance of the logistics system and build a modern logistics collaborative service platform framework based on service-oriented architecture and solve the problem of service collaborative management through system platform and quality evaluation and improve the efficiency of logistics economic management.

5. Conclusions

The influence of the background of the IoT era on economic industry is revolutionary, and the IoT economy is the result of the full integration of computer network communication technology and economic industry. The application of the IoT has improved the running rhythm of modern logistics industry and has also made a revolutionary impact on the multidimensional collaborative management of modern logistics industry. From the current social logistics management process, it has almost subverted the operation mode of logistics. It has promoted the change of economic management concept, operation mode, and profit model and promoted the change of China's economic structure. It has formed innovative forms of financial circulation, such as payment, transaction, and financing, and provided convenience for financial business of all walks of life. Under the background of the Internet age, multidimensional collaborative management of environment and economy is necessary. The development of logistics industry plays a very important role in the transportation of logistics industry and promoting the growth of national economy. Although there are some problems in the IoT economic industry at present, with the supervision and guidance of the state in laws, regulations, and policies, the IoT economic industry will embark on a healthy, sustained, and stable road and become an important part of the driving force of China's economic development. In this paper, based on the IoT environment, the multidimensional collaborative order parameter equation of modern logistics system is constructed, and the simulation and numerical experiments verify that the model can significantly improve the efficiency of logistics system. This paper analyzes the influence of the IoT on the logistics economy, its application, and the problems to be solved at this stage, in order to help promote the development of the logistics industry.

Intervening in the revitalization and development of art villages is one of the ways to build regional brands in rural areas, fit in with contemporary aesthetics, and meet the needs of modern people for diversified life. At the same time, it is not limited by artistry itself, but a comprehensive artistic activity with modernity, industrial linkage, and sustainability. This paper uses the HPR (Hestenes–Powell–Rockafellar) multiplier method to solve and establishes a SSFCM-HPR (semisupervised fuzzy *C*-means clustering based on HPR) algorithm. The experimental results on datasets show that FCM-UserCF (fuzzy *C*-means-user collaborative filtering) algorithm effectively solves the problem of data sparsity and improves the accuracy of recommendation. Rural planning and design under the intervention of art is a kind of respect for local memory, an inheritance of folk crafts, a reshaping of history and culture, and an identification with the countryside itself. It also puts forward new development ideas and guiding methods for the sustainable development of rural areas.

1. Introduction

Rural areas, which are China's most difficult and pressing issue, are attempting to reshape rural order, protect ancient buildings in rural areas, and revive rural culture through art intervention. Rural revitalization has been a top priority of the Chinese government policy in recent years, and it is expected to continue to do so in the future. At the government level, China has issued a series of related policies in recent years, demonstrating the country's commitment and attitude toward rural revitalization. A new wave of development and construction has erupted in domestic villages, guided by the national rural revitalization strategy. Not only for rural material construction but also for multidisciplinary participation [1], creating beautiful countryside is a difficult and long-term task.

With the development of modernization and towns, rural society is facing the strong invasion of external modern culture, and there is also an endogenous cultural crisis. In the cultural environment of "coexistence of old and new," there are some problems in rural community culture, such as insufficient endogenous development power, insufficient innovation ability, declining vitality, and unsustainable development of traditional culture [2, 3]. Since the rural revitalization strategy was put forward, all parts of the country have responded one after another and continued to promote all-round inheritance and promotion of rural infrastructure construction, ecological environment management, and rural cultural custom protection [4]. Intervening in the revitalization and development of art villages is one of the ways to build regional brands in rural areas, fit in with contemporary aesthetics, and meet the needs of modern people for diversified life [5]. The uniqueness of contemporary Chinese villages is being dispelled, the traditional culture is being impacted, and the living environment has not been paid attention to and improved; instead, it has become an activity for artists to entertain themselves.

Involved in rural revitalization of art, it has unique advantages in creation design, ingenuity culture, cultural protection, and dissemination [6, 7]. Giving full play to the role of art is the inherent requirement of rural revitalization, and the involvement of art in rural construction has become the main practice of rural construction in China. Based on this, this paper explores the strategy of artistic mediation in rural design under the background of rural revitalization. This paper puts forward the value analysis and realization path of artistic intervention in rural revitalization based on FC (fuzzy clustering) algorithm, aiming at awakening villagers' cultural consciousness in cultural construction.

Based on the analysis and deduction of the four elements of the festival, this paper points out that, to meet the inherent demands of the four elements in the festival, the balance of each element can only be achieved through the corresponding linkage mechanism, which is also the necessary way to successfully hold the festival. The linkage mechanism is dynamic and flexible, which acts on the festival and also makes the festival produce different functions, meanings, and achievements under different backgrounds and conditions.

2. Related Work

How to involve the art festival in rural revitalization is not only a domestic topic but also a common concern of the whole world. If the scope discussed in this topic is further expanded—which is actually necessary—it should be extended to cities. In [8], from the perspective of social ecology, it is considered that the current rural areas present a "weak niche." Xu [9] used scientific experiments and stories to prove the practical "work" way of science and held that the so-called "culture" actually exists in a dynamic and constant "action." "Before the conflict with other people, no one lives in a certain ' culture,' enjoys a certain ' paradigm,' or belongs to a certain society. The emergence of these words is the result of expanding the network and crossing the alien crowd." Pan [10] made comprehensive statistics and research on the economic role, indirect benefits, comprehensive tourism income, and jobs provided by the art festival. Zhang et al. [11] presented a detailed description and evaluation of the public art and Art Festival on the coast. Shang [12] analyzed the development and ways of the creative industry through the case of ancient town drama festival.

The goal of clustering analysis is to divide a wide range of items into distinct categories (clusters). The things in each cluster have some similarities, and the things in different clusters have some differences. Clustering has been proven to be effective in a variety of scenarios and is an important research direction in big data mining. A new metric space based on the fuzzy induction topology was established in [13]. Unsupervised distance learning algorithm was proposed in [14, 15]. Researchers have been working on distance modification for the past two years. An unsupervised distance learning algorithm based on the DI-FCM (double-indices fuzzy C-means) algorithm framework—a double-index fuzzy C-means algorithm based on hybrid clustering learning HDDI-FCM (double-indices fuzzy C-means with hybrid distance)—was proposed in [16]. Karunambigai et al. [17] proposed a fuzzy scatter matrix-based clustering algorithm that aims to minimize the trace of the intraclass fuzzy scatter matrix while maximizing the trace of the interclass fuzzy scatter matrix, integrates hard and soft clustering, and assigns a hard core boundary to each class. A fuzzy kernel clustering algorithm with different attributes weighted in the feature space was proposed in [18], which can effectively deal with the clustering problems of linear inseparability and unbalanced attributes. A fuzzy kernel clustering algorithm based on comprehensive comparative analysis was proposed in [19]. These methods have partially solved the clustering problem for nonspherical distribution data, but the construction and selection of kernel functions, as well as the determination of kernel function parameters, have become new problems for these methods.

3. Research Method

3.1. Strategies and Methods of Art Intervention in Rural Planning and Design. As the birthplace of Chinese culture, the countryside bears Chinese excellent folk traditions, unique lifestyle, and behavior habits and is the resort of homesickness and the carrier of historical context. Under the influence of modernization and urbanization, in order to retain homesickness memory and historical context in the process of art intervention in rural planning and design, it is necessary to realize the mutual fit between the new and old environment in the process of art intervention and avoid tough intervention or conservative intervention.

Therefore, in the process of art intervention in rural planning and design, it is necessary to excavate rural local cultural resources to form the accumulation of original materials for art intervention [20]. For the excavation and acquisition of cultural resources, it can collect basic cultural resource materials, pictures and images of rural texture, style, beliefs, folk culture, and traditional skills through in-depth interviews, oral statements by the elderly, consulting documents and materials such as county records and rural history, on-the-spot investigation, and experience.

Historical cultural resources, celebrity cultural resources, religious cultural resources, folk cultural resources, and revolutionary cultural resources are the most common types of local cultural resources. To vividly express a variety of local cultural and artistic resources, to provide artistic design elements for art intervention in rural planning and design, and to extract the symbols of cultural elements needed for art to intervene in rural planning and design, it is usually necessary to analyze, classify, and screen the original materials, such as local cultural and artistic resources, combined with the needs of planning and design and the needs of villagers.

Typical local cultural element symbols have been formed after collecting, sorting, classifying, and refining the materials of local cultural resources. Then, using various artistic design techniques, these typical local cultural elements are transformed into "artistic design symbols" with special rural significance and finally applied to artistic intervention in rural planning and design to realize the fit between the new and old environment. The model of strategies and methods involved in artistic rural planning and design is shown in Figure 1.

Involved in artistic rural planning and design, the rural local cultural resources are first excavated through the oral method of the elderly and the method of consulting

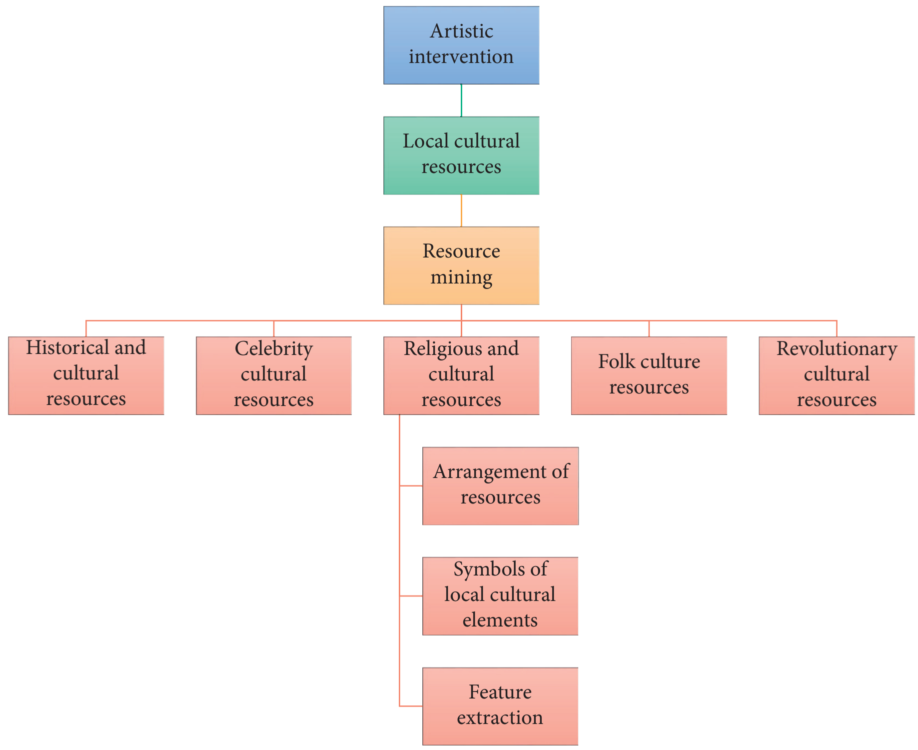

FIGURE 1: Strategy and method model of artistic rural planning and design.

documents and materials, and then the characteristic and typical local cultural element symbols are extracted by analyzing, classifying, and screening them in conjunction with the design needs and the needs of the villagers in order to complete the planning and design investigation and design analysis. The extracted symbols of local cultural elements are then refined in terms of color, shape, structure, texture, connotation, and other characteristics to form basic artistic design elements, and the local cultural resources are transformed into artistic forms using design techniques such as extension and reproduction, transformation and utilization, integration, and innovation. Finally, the art form is applied to the planning and design of rural art.

3.2. Analysis of the Semisupervised FCM Algorithm for Artistic Intervention. Because the rural culture is formed in the long-term local practice, it has the characteristics of life and locality and has a strong regional character. The cultural consensus formed by the community for a long time is the glue of the rural society, so the cultural break is likely to affect the stability of social order. Therefore, in the process of rural cultural revival, it is necessary to repair the cultural and social fractures caused by man-made in the social transformation, attach importance to the cultural value of local traditions, reshape the rural community through cultural revival, and rebuild the rural community identity.

The rational choice principle of choosing to use more advanced and efficient tools in human social changes cannot be changed, but although the old culture no longer has the tool value, its cultural value has become more important. Therefore, seeing that some valuable local cultures that have recorded human civilization for many years are gradually dying out, it needs to show our attitude and take practical actions to protect, inherit, and develop those most distinctive cultures and skills and record and preserve these living fossils of human civilization for future generations.

FCM (fuzzy C-means) is a typical FC algorithm, which applies fuzzy technology to the traditional C-means algorithm and has been proved to be one of the most effective clustering methods by practice [21]. However, FCM algorithm needs many iterations in the process of operation, and when the amount of data is particularly large or there are many attributes of data samples, the operation speed will be greatly reduced. The algorithm of SSFCM-HPR (semi-supervised fuzzy C-means clustering based on HPR (Hestenes–Powell–Rockafellar)) is proposed.

Assume that the number of clustering samples is $n_s + n$, among which n_s are labeled samples, n are unlabeled samples, and n_1 belong to the first class, $n_2 + n_1$ belong to the second class, and $n_s + n_{s-1}$ belong to the s class. Let the classification number be c and the membership matrix be $U = (U', U)$.

The expression of distance measurement between the sample and cluster prototype is defined as

$$\begin{aligned}(d_{ik})^2 &= \|X_k - P_i\| \\ &= (X_k - P_i)^T W (X_k - P_i),\end{aligned} \tag{1}$$

where W is the characteristic weighting matrix.

Because all the samples are independent of each other so that the columns of the partition matrix U' are independent of each other, one column of the partition matrix U' can be chosen as the research object. For the convenience of research, the kth supervised sample can be chosen as the research object. Because when k is determined, its corresponding labeled is also determined; that is, the category j is a known quantity.

$$\min J_k = \sum_{i=1}^{c} (u_{ik}^{*})^m d_{ik}^2,$$
$$\text{s.t.} \begin{cases} \sum_{i=1}^{c} u_{ik}^{*} = 1, \\ u_{ik}^{*} + \Delta u - u_{jk}^{*} + y_{ik}^{*} = 0, \quad i = 1, 2, \ldots, c, \; i \neq j. \end{cases} \tag{2}$$

For unsupervised samples, because the constraint conditions of membership degree have not changed, the formula of membership degree is the same as that of traditional FCM algorithm:

$$u_{ik}^{*} = \frac{1}{\sum_{l=1}^{c} \left(d_{ik}/d_{lk}\right)^{2/m-1}},$$
$$k = 1, 2, \ldots, n; \quad i = 1, 2, \ldots, c. \tag{3}$$

Because the solution of the clustering objective function is an iterative optimization process, if the weight of the k supervised sample is ω_{k,k_1} in the k_1 iteration, then

$$\omega_{k,k_1} = \frac{u_{jk,k_1-1}^{*}}{\max\limits_{i\in\{1,\ldots,c\}, i\neq j}\left(u_{ik,k_1-1}^{*}\right)}. \tag{4}$$

In the above formula, $j = \operatorname{argmax}_{i\in\{1,\ldots,c\}} (u_{ik,k_1-1}^{*})$.

3.3. Intervene in the Realization of Art and Rural Revitalization. Action that is based on participation art intervention, also known as social art intervention, is a type of art intervention that is commonly used in rural areas. Its art is based on field research and refined from the unique regional culture of rural areas, with a stronger emphasis on the intermediary nature of art action and the creation of rural regional culture. Intervening in artistic rural design is to revalue and repair the rural value and reconstruct the relationship between man, nature, and ancestors with the help of rural design, whose core elements are to repair rural production and life, ecosystem, rural social order, and ethical relationship and to promote the emergence and development of new industries and new platforms in rural areas. The restoration of the rural cultural system and ethics, paying attention to the explicit expression and invisible inheritance of rural culture, inspiring public participation and a sense of ownership, and creating a rural space rich in appreciation value are at the heart of artistic intervention in rural design. Art in rural areas not only preserves rural culture's unique value but also facilitates the exchange of rural information and improves the countryside's inclusiveness and openness.

At present, the countryside is facing a serious hollowing phenomenon, and rural public life is gradually declining. In order to revitalize rural public space, artists launched a series of artistic practice activities. By means of art and culture, the symbol resources can be transformed, and a new image of artistic villages and cultural villages with relaxed and rich cultural atmosphere can be created with lightweight rural field art creation. The artistic expression forms include overall planning of rural space, dot space art design, linear street space design, and area space art design. At the same time, reconstruct the villagers' public life, complete the reconstruction of rural capital through collective activities, enhance the display of rural cultural individuality, and promote the rural production and life sustainably.

The basic idea of FCM-UserCF (fuzzy C-means-user collaborative filtering) algorithm designed in this paper is as follows: firstly, FCM algorithm is used to cluster users with similar backgrounds into the same cluster to reduce the dimension of the matrix; then, the data matrix is preprocessed by Slope One algorithm, and the unrated data in the matrix are predicted and filled, so as to solve the disadvantage of the sparse user-item scoring matrix; finally, CF (collaborative filtering) is carried out based on the filled scoring matrix.

The FCM-UserCF algorithm can be disassembled into two steps: step 1: according to the background information of users, use FC to make the background of the same user group similar; step 2: fill in the missing data of the scoring matrix and make recommendations through the UserCF algorithm in CF.

FC algorithm needs to generate a membership matrix, and a fuzzy similarity matrix needs to be built for the data similarity in the matrix [22]. There are many methods to construct the similarity matrix, including the maximum-minimum calculation method, cosine angle method, and correlation coefficient method. In this article, the fuzzy similarity matrix $R(r_{ij})_{m\times n}$ is constructed by calculating the similarity statistic r_{ij} of data by using the maximum-minimum method, and the formula is

$$r_{ij} = \frac{\sum_{k=1}^{m} \min\left(x_{ik}', x_{jk}'\right)}{\sum_{k=1}^{m} \max\left(x_{ik}', x_{jk}'\right)}. \tag{5}$$

Among them, $i = 1, 2, \ldots, n$; $j = 1, 2, \ldots, m$, n represents the number of data pieces, m corresponds to the category that is the number of cluster centers, and x' represents the elements in the membership matrix.

Based on all scoring items $I_{ui} = I_u \cup I_i$ of users u and i, if there are missing scoring items in all items, the Slope One algorithm can be used for prediction. Calculate the target user U rating $P(u_j)$ for item j.

$$\text{dev}_{(j,i)} = \sum_{u\in I\cap J} \frac{u_j - u_i}{\text{num}(I\cap J)},$$
$$p\left(u_j\right) = \frac{I}{\text{num}(R(u)\cap D(j))} \sum_{i\in R(u)\cap D(j)} \left(u_i + \text{dev}_{(j,i)}\right). \tag{6}$$

In the formula u_i, u_j refers to the true score made by user U on item i, j, $\text{num}(I\cap J)$ refers to the number of all users who score the intersection of item i, j, $R(u)$ refers to all scoring items of user U, $D(j)$ refers to all average deviation value items calculated with item j, and $\text{num}(R(u)\cap D(j))$ refers to the intersection number of all items of $R(u)$ and $D(j)$.

The FCM-UserCF algorithm proposed in this article needs to cluster the dataset by FCM algorithm according to the user background information so that the user background information within the same class is similar after clustering; Figure 2 shows the specific flow of FCM-UserCF.

The planning of traditional rural folk cultural and artistic activities reflects the cultural significance of rural space, explains village characteristics, and influences villagers' daily lives and values. This emphasizes the critical role of traditional rural folk culture and art activities in art intervention in rural planning and design. The goal of planning and developing traditional rural folk culture and art activities is to improve the quality of life for villagers. As a result, the needs of villagers' lives should be the starting point for planning traditional rural folk culture and art activities. In conjunction with the trend of people flow, attention should be paid to the layout and creation of artistic space and cultural creative space, particularly in rural public space and places where people flow gather, as these are the places that can best influence and drive villagers' thought and value identity, as well as promote cultural communication.

Today's rural revitalization needs to pay attention to the long-term investment and long-term interests of rural industries. The goal of rural revitalization is to establish long-term regional brands and regional products that are compatible with them, cross-border, and diversified. The participation of art in regional brand building in rural areas is one of the most direct and effective ways to realize rural revitalization and promote rural sustainable development, and it is also one of the important contents of top-level design in rural revitalization.

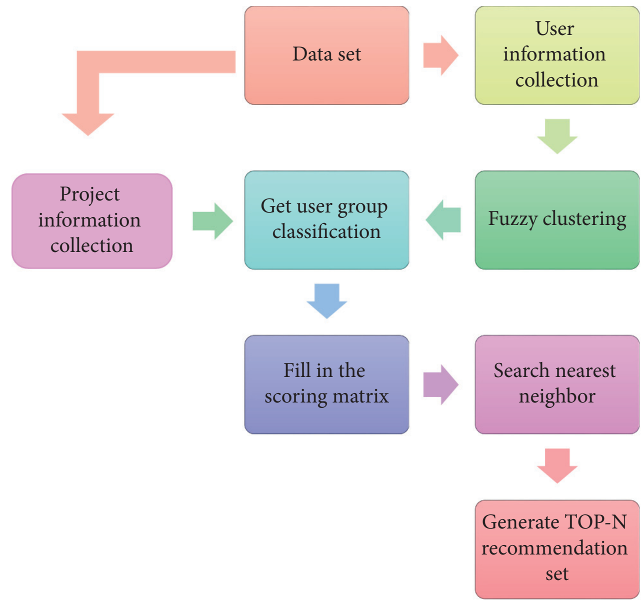

Figure 2: Flowchart of FCM-UserCF algorithm.

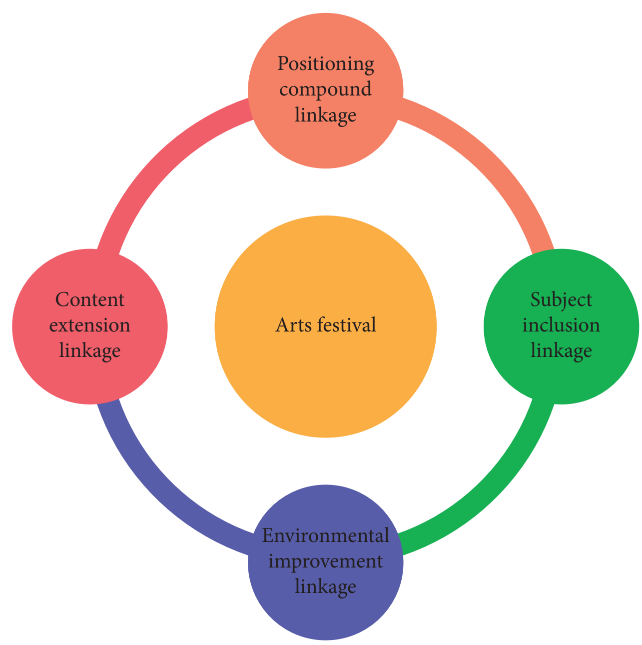

Figure 3: Illustration of the linkage mechanism of the art festival.

4. Results' Analysis and Discussion

4.1. Discussion on the Linkage Mechanism of Art Festivals Involved in Rural Revitalization and Development. Under the tide of China's economic development, the cultural ecology is constantly tearing, reorganizing, and constructing, especially in rural areas, where constant cultural acculturation makes the cultural ecology very fragile. However, it is impossible and undesirable to return to the traditional cultural ecology. The festival is a good choice in terms of the feasibility of the measures, the remarkable effect, and the cohesion of the organization.

The last step-by-step process of the festival is not a one-step process. After the completion and implementation of the whole art planning, diverse subjects will have different feedbacks. According to the feedbacks, the content of the festival will be constantly adjusted and enriched, and all of them need to operate the festival sustainably through four linkage mechanisms (Figure 3).

To begin with, the festival's origins are based on a variety of interconnected and contradictory demands from multiple subjects, as well as a need to coordinate problems across subjects through inclusive linkage. Second, the festival's surroundings are important amenities that contribute to the festival's uniqueness. As a result, strengthening the linkages to promote the win-win goal is necessary to protect the natural environment, make the best use of the situation, and tap potential. In the industrial chain, the life chain will work. Operating institutions, investment funds, and various modes of operation are all part of the industrial chain. The festival's theme is an ecological chain that will grow and connect to other ecological chains.

4.2. The SSFCM-HPR Algorithm Is Used to Analyze the Dataset. The clustering result of SSFCM-HPR algorithm is shown in Figure 4, and the clustering result is very ideal. It can be seen from Figure 4 that when the supervised samples contain outliers, SSFCM-HPR algorithm can handle the supervised outliers well so that it can correctly guide the clustering process.

China's rural revitalization is a road of all-round development, and it is an all-round revitalization of industry, ecology, local civilization, and quality of life. Through industrial implantation, ecological environment governance, and promotion, excavation, and activation of local culture, we can retain the local resident population, let urban people return to their hometowns to start businesses, change the rural population structure, reduce population loss, and improve the civilized quality of the whole rural population. Therefore, "people" are particularly important in the whole rural revitalization.

The IRIS dataset is classified by traditional FCM algorithm, FCM algorithm based on feature weighting, and SSFCM-HPR algorithm. The results are shown in Figure 5.

SSFCM-HPR algorithm has the lowest misclassification rate, and with the increase of the number of supervised samples, the recognition rate is significantly improved [23]. When the number of supervised samples is 7, IRIS datasets can be completely separated correctly.

In order to further illustrate the practicability of this algorithm, two face databases, ORL face database and YALE face database, are used for experiments [24]. PCA [14], LDA [15], LPP [16], and MFA [17] algorithms are used for comparison, and the experiments are repeated for 20 times. Figure 6 shows the average recognition rate of various algorithms.

SSFCM-HPR algorithm can better guide the clustering process. Of course, compared with SSFCM-HPR algorithm, FCM_DNE algorithm also has its own characteristics: FCM_DNE algorithm can effectively alleviate the dimension disaster problem in high-dimensional data classification, and at the same time, it maps data to low-dimensional space, which reduces the computational cost of FCM algorithm.

In order to further illustrate the robustness of this algorithm, now, discuss the situation when the label information of the supervision sample is wrong. For the data provided by Kong et al. [18], when labeling the supervision samples, this paper specially gives the supervision samples with wrong classification information. The 2nd, 10th, 41st, and 55th special samples are taken as supervised samples, and two misclassified samples are produced by using Bensaid–Bezdek algorithm. Using SSFCM-HPR algorithm, the result is shown in Figure 7, and there is no misclassification sample. The experiment shows that this algorithm is insensitive to the "typicality" of supervised samples.

Figure 8 shows the membership degree of each sample belonging to the first class when the α-value takes some representative values. Obviously, when α is 5, the ideal classification result is not obtained, and when α is 6 or above, the classification result is ideal.

Although the supervised sample's membership value approaches the labeled membership value as the scale factor is increased, the clustering results of the SSFCM-HPR algorithm are very sensitive to the value of the scale factor, and when the value is small, the role of the supervised sample cannot be displayed, and the clustering results tend to fall into a local optimum, resulting in clustering failure. The

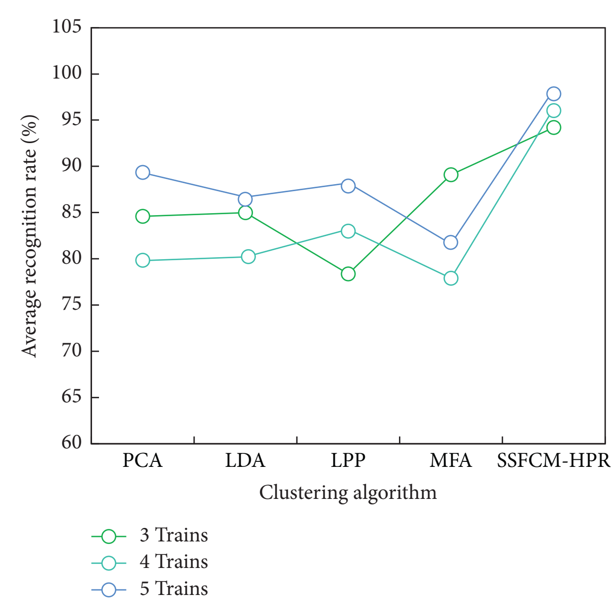

FIGURE 6: Average recognition rate of various algorithms on the ORL database.

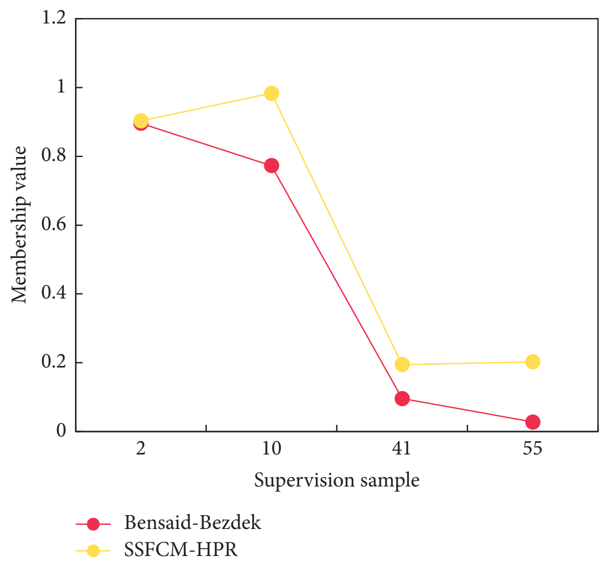

Figure 7: Comparison of weights and membership values of supervised samples by each algorithm.

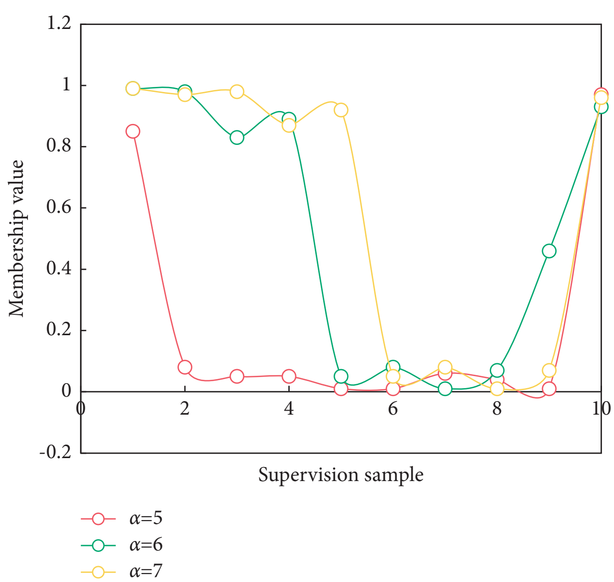

Figure 8: Dividing value of the membership degree of each sample.

weight of unsupervised samples increases as the value increase, weakening the guiding role of supervised samples in the clustering process.

4.3. The Analysis of FCM-UserCF Algorithm. This paper devised a performance test experiment to determine the efficacy of the FCM-UserCF algorithm. The experimental dataset for this study is MovieLens. The data come from a nonprofit research-oriented web recommendation system website. The dataset has two main components: a large number of users and a large number of movies, and the users' movie rating data are sufficient. The experimental dataset includes a training dataset and a test dataset, similar to other types of machine learning datasets. The training set-to-test set

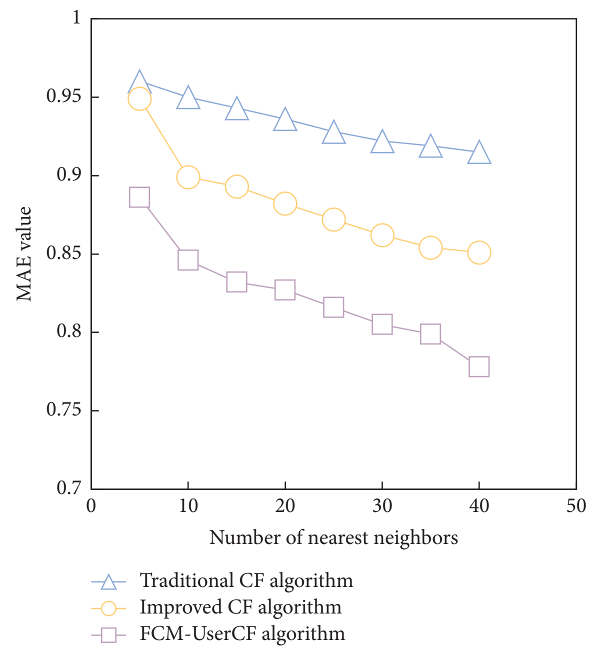

Figure 9: Comparison of algorithm effects.

ratio is 8 : 2. The MAE (mean absolute error) experiment is used to assess the algorithm's effectiveness. The MAE value is inversely proportional to the recommendation quality because it is the average of the absolute values of errors between all individual user ratings and real ratings.

Comparing the parallel FCM-UserCF algorithm, the improved CF algorithm proposed in [20], and the traditional CF algorithm, when calculating the average absolute error value, the number of nearest neighbors takes 5 as the starting value and increases to 30 at intervals of 5. Figure 9 compares the effects of the algorithms.

In this paper, considering that users with similar backgrounds are more likely to have similar tastes in life, FC is carried out according to user background information, and similarity calculation is carried out among users with similar backgrounds. Moreover, the Slope One algorithm is used to fill the missing data before CF, which is conducive to better selecting the nearest neighbor, thus improving the accuracy of recommendation.

In this paper, experiments are carried out with different scales of data, and the time consumption of parallelizing FCM-UserCF algorithm and serializing FCM-UserCF algorithm under different scales of data is compared. The calculation time of the data scale from 50,000 to 300,000 is shown in Figure 10.

Serialized FCM-UserCF algorithm is more time-consuming than parallelized FCM-UserCF algorithm, which is due to the large memory consumption in FC and similarity matrix calculation, and such intensive calculation is also the shortcoming of the CPU.

In contrast, the parallelized FCM-UserCF algorithm adopts a distributed form when dealing with large amounts of data, and each node calculates at the same time, splitting and merging big data, which also fully embodies the advantages of parallel calculation of master-slave nodes.

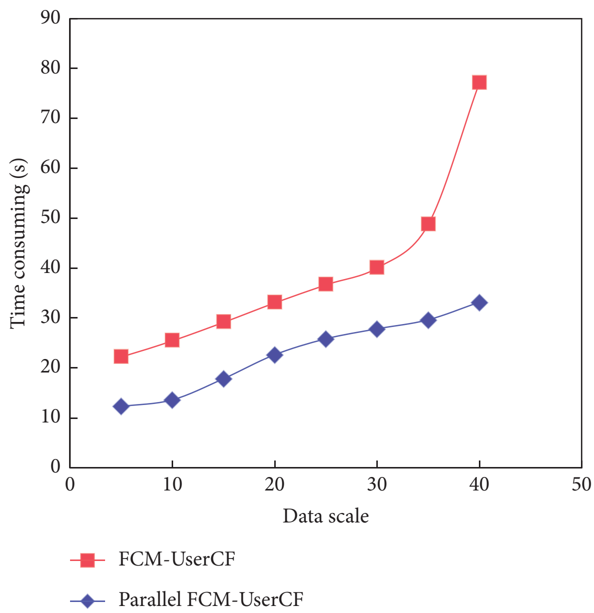

FIGURE 10: Time consumption comparison.

5. Conclusion

The preservation and transmission of concrete material culture, as well as the preservation and transmission of its cultural subject and lifestyle, are all part of the reconstruction of local culture. Art's role in rural revitalization offers distinct benefits in terms of creation design, ingenuity culture, cultural preservation and dissemination, and so on. This paper introduces a novel SSFCM-HPR algorithm. This algorithm not only preserves the fuzziness of supervised sample division but also better reflects the clustering process's guiding role of various supervised samples. It should be treated with FCM-UserCF. The analysis of system requirements, the design of the system architecture and functions, and the design of the database are all completed. The system interface's realization effect is shown, and the function test is completed. The test results demonstrate that the work presented in this paper is practical. Recognize the value and importance of rural culture in the development of urbanization and modernization, and use proper protection and inheritance methods to ensure that rural revitalization continues to progress and live forever.

The implementation mechanism, personnel organization structure, and funding sources required by art intervention in rural planning and design were not discussed in depth in this study. As a result, the study's main findings must be continuously practiced and verified in the future.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

Academic Editor: Tongguang Ni

The horizontal competition-cooperation game of technological innovation in a two-stage automobile cluster supply chain composed of a duopoly of automobile manufacturers and a single automobile dealer is studied. The four game models are constructed based on the relationship of horizontal competition cooperation between automobile manufacturers and research and development (R&D) mode, and each game model gives the optimal price decision and optimal technical content decision of new products when the automobile manufacturer and automobile dealer maximise their profits. By comparing the equilibrium results of each game model and conducting numerical simulation analysis, we reveal the effects of the competition-cooperation relationship and R&D mode on supply chain decision-making. The results show the following: (1) A fully cooperative innovation strategy can maximise the total profit of automobile manufacturers, but it will reduce the profit of the automobile dealer. (2) When the horizontal competition is not fierce and the consumption preference for technical content is weak, innovation strategy of competition cooperation (competition but cooperative R&D) can enable the automobile dealer to obtain the maximum profit. (3) Market preference for the technological content of automotive products accrues greater potential benefits to the whole supply chain channel.

1. Introduction

In the contemporary knowledge economy and information revolution, technological innovation has become a key factor in enterprise development. That enterprises improve the technical content of new products through R&D activities is an inevitable choice for improving supply chain game capabilities. Under the background of increased homogenisation of automobile products, technological innovation is also driver of development in such enterprises; therefore, automotive enterprises must continuously engage in technological innovation to improve the competitiveness of the industry. The cluster mode of a supply chain can induce more convenient conditions for technological innovation in the automobile industry. In the operational environment of the cluster supply chain, an atmosphere of competition and cooperation prevails: supply chain members adopt cooperative innovation to cope with environmental pressure, but they will also compete in the final product market for the maximisation of their own interests; for example, GAC and SAIC jointly develop core technologies but compete in the final product market. Automobile enterprises conduct horizontal cooperation in R&D of key technologies to stimulate market demand, creating large economic and synergistic benefits. Obviously, the problem of choosing technological innovation strategies in automobile cluster supply chain is essentially a game problem that constantly meets and stimulates consumer demand to seek the equilibrium of interests, and the competition-cooperation game of supply chain members and the choice of R&D mode have an important influence on the solution of the above problem. This paper mainly provides a reasonable solution path for the coordination of the interests of all parties in the game, and also provides theoretical basis and technical support for automobile enterprise managers to boost profit and innovate management decisions, so as to improve the competitiveness of our country's automobile industry clusters.

The remainder of this paper is organized as follows: Section 2 introduces related work. Section 3 raises research question and makes model assumptions. Section 4 constructs four game models of technological innovation and proposes the equilibrium strategy in different game situations. The analysis of calculation examples and numerical simulation is discussed in Section 5. Finally, Section 6 summarises the paper.

2. Related Work

At present, the research into supply chain technological innovation is relatively abundant, but it mainly focuses on vertical cooperation and seldom studies from the perspective of competition cooperation, and it involves less research on competition and cooperation game in the automotive supply chain. The research on the cooperative innovation of supply chain mainly focuses on the importance of cooperation, cooperation model, mode selection, benefit distribution, and so on. In terms of the importance, Du et al. [1] analysed the importance of cooperative investment contract between suppliers and manufacturers to sustainable innovation through a Stackelberg Game model. Lu et al. [2] studied the technological innovation decision-making problem of the supply chain by using the method of competition and cooperation. The fundamental motivation for enterprises to participate in technological innovation cooperation is to obtain more benefits from the cooperation. Therefore, the distribution of benefits in cooperative innovation has attracted the attention of scholars. Yoon and Jeong [3]explored the problem of maximising personal profits and total profits in the reverse supply chain from the perspective of profit distribution. Zhang [4] used the Shapley value method to propose a reasonable income distribution system for collaborative innovation in the supply chain. In terms of mode selection, Wang [5] studied the selection of vertical technological innovation mode of new products in the supply chain. Mu et al. [6] studied technological innovation in a two-stage supply chain on an e-commerce sales channel under different cooperation modes. Wei and Wang [7] used differential game methods to analyse the technological innovation of manufacturers and suppliers in terms of carbon emission reduction. The above studies have studied the longitudinal technological innovation of the supply chain from different aspects, but the research on the technological innovation from the perspective of the automotive industry is still insufficient. Most scholars' research on technological innovation of automotive supply chain focuses on its influencing factors and internal mechanisms and mainly adopts methodologies such as system dynamics and game theory. For example, Li et al. [8] used system dynamics to analyse the influencing factors of the technological innovation capability of the automobile industry. Li et al. [9] used a three-stage dynamic game model to explore the relationship between technology diffusion, innovation performance, and technology research and development in the automotive industry. Deng [10] used game theory to explore the internal mechanism of technological innovation in the automobile industry cluster. Li et al. [11] established an evolutionary game model of cooperative innovation between automobile manufacturer and battery company. It can be seen that the research on the technological innovation of the automotive supply chain seldom explores the horizontal game of technological innovation cooperation between manufacturers, and the research on the competition-cooperation relationship between enterprises is relatively lacking.

Research on horizontal competition-cooperation games involving technological innovation in supply chains mainly focuses on price and production competition, but it rarely considers the technical content of new products. Liu and Feng [12] studied "Price–Greenness" competition in a horizontal competitive game. Seyedhosseini et al. [13] proposed a new competitive demand that is price dependent for a two-stage competitive supply chain composed of a monopoly manufacturer and two duopoly retailers. Hong and Naihan [14] discussed the production and price decisions of two logistics suppliers by using the Cournot competitive model and the Bertrand competition model. Li et al. [15] built two price game models of horizontal recyclers. Mai et al. [16] constructed a dynamic Cournot model based on price competition for duopoly manufacturers. A few scholars have considered the influence of technical content of products. For example, Hu et al. [17] analysed the game problem regarding optimal technical content of duopoly enterprises with heterogeneous products. Chu [18] assessed the impact of technical content of product on channel decision by using game theory, but he focused on the improvement mechanism of technical content of product and seldom considered the combined effect of price and technical output of the product. The above research mainly discusses the horizontal competition and cooperation game problem from the aspects of price competition, green degree competition, output competition, etc. However, the research involving "price-technology content of new product" competition is still insufficient.

In summary, scholars' research on technological innovation of supply chain mostly considers vertical cooperation, production competition, and price competition; however, it does not involve competition in terms of the technical content of new products. In addition, a few studies take the automobile industry as an example to study the horizontal competition-cooperation game of technological innovation. In view of the deficiencies in the existing literature, we discuss the game equilibrium strategy of profit maximisation between two automobile manufacturers and automobile dealer in the process of horizontal competition cooperation in technological innovation under different cases from the perspective of balance of interests. It provides some theoretical support for the stakeholders along the automotive supply chain to meet the market demand and seek the balance of interests in the horizontal competition-cooperation game of technological innovation.

3. Problem Description and Assumption

3.1. Description. We studied the horizontal competition-cooperation game of technological innovation in the two-stage supply chain of automobile industry cluster composed of a duopoly of automobile manufacturers $M_i\,(i = 1, 2)$ and a single automobile dealer R. Two automobile manufacturers produce homogeneous but alternative products, which are different in terms of technical content due to their different levels of technological innovation. Since the horizontal cooperation mode is a form of joint participation in technological innovation and cooperation for enterprises in the same industry [19], therefore, whole automobile manufacturers can develop new products through technological innovation to promote the realisation of the market for new products. Automobile manufacturers sell products to an automobile dealer at price ω_i, and then the automobile dealer sells products to the consumer at price p_i; lastly, consumers determine the demand for product i according to its price ω_i, p_i, and technical content t_i. The process is displayed in Figure 1.

In this supply chain model, there is horizontal competition cooperation between two automobile manufacturers. In horizontal competition, two automobile manufacturers pursue maximisation of their own interests. Two automobile manufacturers pursue maximisation of overall income in horizontal cooperation. Meanwhile, there are two modes of R&D: cooperative and independent.

Consumers have demand preference when buying technologically innovative products, and they have higher rigid demand for products with high technical content. Both products have different technical contents because of the difference in technological innovation ability of enterprises, and consumers exactly perceive the difference of products through the difference in technical content of products; therefore, enterprises can affect consumer demand preference for products according to p_i and t_i. In addition, the high similarity of new products developed jointly leads to the reduction of consumer perception of the difference between the two products and the increase of substitutability. Therefore, the competition between products is more intense. The four game equilibrium strategies are developed based on the horizontal competition-cooperation relationship and R&D mode between two automobile manufacturers (Figure 2).

In Figure 2, OL is an Innovation Strategy of Pure Competition and CJ is an Innovation Strategy of Full Cooperation. CL and OJ are Innovation Strategies of Competition Cooperation, they indicate that there is a cooperative relationship between the two automobile manufacturers but independent R&D, or there is a competitive relationship between the two automobile manufacturers but cooperative R&D.

3.2. Symbol Description. The meaning of each variable of the game model is shown in Table 1.

3.3. Supplementary Premise

Assumption 1. In the automotive cluster supply chain, there are two dominant automobile manufacturers upstream in a duopoly market that has similar technological strength and equal status; there is a big $M_i\,(i = 1, 2)$ automobile dealer R downstream. The two manufacturers cooperate in technological innovation to develop and produce new products which will be sold to the automobile dealer at price ω_i.

Assumption 2. The parameter $\lambda\,(0 < \lambda < 1)$ is the degree of product substitution, namely, competition intensity. It reflects the substitution effect of another product when the price of one product changes, $\lambda \longrightarrow 0$ indicates that the products are irreplaceable, and $\lambda \longrightarrow 1$ indicates that the products are completely replaceable. At the same time, the larger λ, the more intense the competition between two automobile manufacturers.

Assumption 3. The production cost of M_i can be reduced after technological innovation, and the amount of cost reduction x_i can also represent the level of technological innovation; $\beta_i = 1$ refers to coefficient of technology spillover between two enterprises, which is affected by some factors such as knowledge transmission ability and communication ability between supply chain enterprises. Under normal circumstances, $\beta \in [0, 1]$, and $\beta = 1$ when the two parties cooperate in R&D, because the enterprise will unreservedly contribute its own technological know-how to cooperative innovation. The marginal cost of production of M_i can be expressed as $c_i = c_{M_i} - x_i - \beta x_j$, $c_{M_i} > x_i + \beta x_j$, $i,\ j = 1, 2$.

Assumption 4. The technical content of the two products is $t_i\,(t_i > 0)$. There is a diminishing effect of marginal return on R&D investment of new products, so it can be written as $I_i = (1/2)t_i^2$. In the case of independent R&D, all R&D costs shall be borne by M_1 and M_2 alone; in the case of cooperative R&D, the two enterprises jointly discuss the total investment of innovation which is $I_i = (1/2)t_0^2$, the share borne by M_1 is θ, and the share borne by M_2 is $(1 - \theta)$.

3.4. Demand Function Construction. Technological innovation comes from the pull of market demand, and enterprises seek technological innovation under the guidance of market demand [20]. In terms of model expression, demand function is the extremely important part of enterprise profit structure. The inverse demand function is defined as $p_i = a - q_i - \lambda q_j\,(i, j \in \{1, 2\}, i \neq j)$, where a is the basic market potential. Without loss of generality, when there is competition in price and technical content of new products, the demand function [7] is as follows: $q_j = a - (1/1 - \lambda)p_i + (\lambda/1 - \lambda)\ \ p_j + \mu((1/1 - \lambda)t_i - (\lambda/1 - \lambda)t_j)$, $a > c_1 + c_2$. The two manufacturers can choose to develop either jointly or independently in terms of new key technologies for development of new products. Cooperative R&D can bring about a reduction in differentiation and higher competitive intensity between products. It is assumed that ξ represents the increased competitive extent caused by cooperative R&D, and $0 \leq \xi\lambda < 1$. The demand function is $q_j = a - (1/1 - \xi\lambda)p_i + (\xi\lambda/1 - \xi\lambda)\ \ p_j + \mu((1/1 - \xi\lambda)t_i - (\xi\lambda/1 - \xi\lambda)t_j)$, where $\xi \geq 1$ means that competition is more intense because the difference between products perceived by consumers is reduced.

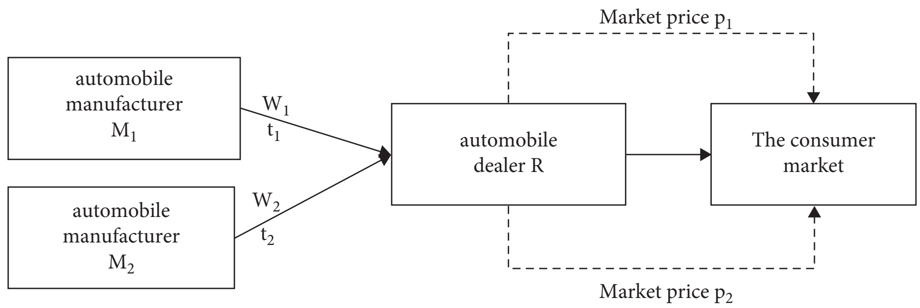

Figure 1: Two-stage supply chain with technological content and price competition of new products.

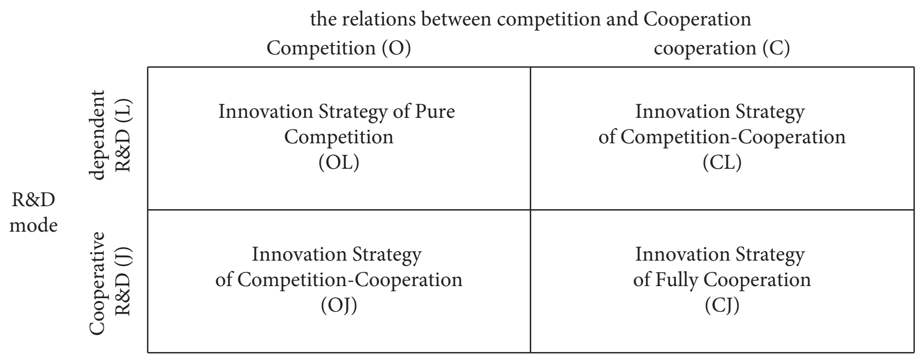

Figure 2: The four game equilibrium strategies.

Table 1: List of symbols.

Symbol	Description
$\mathbf{i}$	Automobile manufacturer product, $i = 1, 2$
λ	Alternative levels of products, namely, competition intensity $(0 < \lambda < 1)$
$\mathbf{c}_{\mathbf{M}_i}$	Production cost of automobile manufacturers
$\mathbf{c}_\mathbf{i}$	The marginal production cost of automobile manufacturers
$\mathbf{I}_\mathbf{i}$	The R&D investment cost of new products
$\mathbf{x}_\mathbf{i}$	The cost reduction caused by technological innovation
$\beta_\mathbf{i}$	Coefficient of technology spillover, $0 < \beta_i < 1$
$\mathbf{t}_\mathbf{i}$	Technical content of product i, $t_i > 0$
$\mathbf{t}_0$	Technical content of new products in cooperation development
θ	Share of R&D investment undertaken by automobile manufacturer M_1
ξ	The increased competitive extent caused by cooperative research and development
μ	The sensitive coefficient of new products' technical content, namely, consumption preference for technical content, $\mu > 0$
$\mathbf{a}$	Basic demand for entire automobile manufacturers, $a > 0$
$\mathbf{q}_\mathbf{i}$	Demand for automobile manufacturers
$\mathbf{p}_\mathbf{i}$	Market price
$\omega_\mathbf{i}$	Wholesale price
$\pi_{\mathbf{M}_i}$	The profit of automobile manufacturer
$\pi_\mathbf{M}^\mathbf{T}$	The total profit of automobile manufacturers
$\pi_\mathbf{R}$	The profit of automobile dealer

4. Construction and Analysis of the Game Model of Technological Innovation

According to the horizontal competition-cooperation relationship and R&D mode between two automobile manufacturers, we constructed four game models of technological innovation.

The four game models of technological innovation, namely, four game equilibrium strategies of technological innovation, are constructed according to the different competition-cooperation relationship and R&D modes of two automobile manufacturers. The game model can be described as the profit expression of each member of the supply chain, which is the marginal profit multiplied by the demand function from which R&D investment in new products is then subtracted. When calculating the profit, the marginal profit is equal to the wholesale price minus the production cost or the market sales price minus the wholesale price; R&D investment in new products is expressed as a quadratic function of technical content of new products; the marginal production cost of automobile manufacturers is calculated by subtracting the reduction of production cost caused by technological innovation from the production cost. The model is solved by backward induction to obtain the equilibrium strategy of each game case, corresponding to the optimal wholesale price, the optimal market price, and the optimal technical content of new products, giving the equilibrium profit of each channel member. To facilitate differentiation, "*" is used herein to represent the best decision.

4.1. Game Equilibrium Strategy of Pure Competitive Innovation (OL). In the OL strategy, two automobile manufacturers have a competitive relationship and independently develop new products. The game rules are such that automobile manufacturers first decide the wholesale price of two products and the technical content of new products based on maximisation of their own profit; then the automobile dealer decides the market price of the two products. The game model is described as follows:

$$\text{S.t.}\begin{cases} \max \pi_{M_1}^{OL} = \left(\omega_1 - \left(c_{M_1} - x_1 - \beta x_2\right)\right)\left(a - \dfrac{p_1^* - \mu t_1}{1-\lambda} + \dfrac{\lambda\left(p_2^* - \mu t_2\right)}{1-\lambda}\right) - \dfrac{1}{2}t_1^2, \\ \max \pi_{M_1}^{OL} = \left(\omega_2 - c_2\right)\left(a - \dfrac{p_2^* - \mu t_2}{1-\lambda} + \dfrac{\lambda\left(p_1^* - \mu t_1\right)}{1-\lambda}\right) - \dfrac{1}{2}t_2^2, \\ \left(p_1^*, p_2^*\right) \text{must meet the following condition}: \\ \max \pi_R^{OL} = \left(p_1 - \omega_1\right)\left(a - \dfrac{p_1 - \mu t_1}{1-\lambda} + \dfrac{\lambda\left(p_2 - \mu t_2\right)}{1-\lambda}\right) \\ +\left(p_2 - \omega_2\right)\left(a - \dfrac{p_2 - \mu t_2}{1-\lambda} + \dfrac{\lambda\left(p_1 - \mu t_1\right)}{1-\lambda}\right). \end{cases} \tag{1}$$

Proposition 1. *In the OL strategy, the optimal wholesale price and the optimal technical content of new products of manufacturers and the optimal market price and the optimal technical content of new products of dealer can be written as*

$$\begin{aligned} \omega_i^{OL^*} &= \frac{a + c_{M_i} - x_i - \beta x_j}{2} + \frac{\mu^2\left(a - c_{M_i} + x_i + \beta x_j\right)}{8 - 2\mu^2}, \\ t_i^{OL^*} &= \frac{\mu\left(a - c_{M_i} + x_i + \beta x_j\right)}{4 - \mu^2}, \\ p_i^{OL^*} &= \frac{3a + c_{M_i} - x_i - \beta x_j}{4} + \frac{3\mu^2\left(a - c_{M_i} + x_i + \beta x_j\right)}{16 - 4\mu^2}. \end{aligned} \tag{2}$$

Proof. By backward induction, we find the market price of automobile dealer when given the wholesale price decision and the technical content of decision $(\omega_1, t_1, \omega_2, t_2)$ of the automobile manufacturers. Firstly, taking the first-order partial derivatives of π_R^{CJ} with respect to p_1 and p_2, respectively, and taking the second-order derivatives, the Hessian matrix is obtained:

$$H = \begin{bmatrix} \dfrac{\partial^2 \pi_R^{OL}}{\partial p_1^2} & \dfrac{\partial^2 \pi_R^{OL}}{\partial p_1 p_2} \\ \dfrac{\partial^2 \pi_R^{OL}}{\partial p_2 p_1} & \dfrac{\partial^2 \pi_R^{OL}}{\partial p_2^2} \end{bmatrix} = \begin{bmatrix} \dfrac{2}{\lambda - 1} & -\dfrac{2\lambda}{\lambda - 1} \\ -\dfrac{2\lambda}{\lambda - 1} & \dfrac{2}{\lambda - 1} \end{bmatrix}. \tag{3}$$

Note that $\partial^2 \pi_R^{OL}/\partial p_1^2 = 2/\lambda - 1 < 0$ when $\begin{vmatrix} 2/\lambda - 1 & -2\lambda/\lambda - 1 \\ -2\lambda/\lambda - 1 & 2/\lambda - 1 \end{vmatrix} = 4(1+\lambda)/1 - \lambda > 0$; π_R^{CJ} is a strictly concave function of p_i, so there is a unique maximal solution. Taking the first-order partial derivative of p_i and setting it to zero gives

$$\begin{cases} a + \dfrac{p_1 - \omega_1}{\lambda - 1} + \dfrac{p_1 - \mu t_1}{\lambda - 1} - \dfrac{\lambda(p_2 - \mu t_2)}{\lambda - 1} - \dfrac{\lambda(p_2 - \omega_2)}{\lambda - 1} = 0, \\ a + \dfrac{p_2 - \omega_2}{\lambda - 1} + \dfrac{p_2 - \mu t_2}{\lambda - 1} - \dfrac{\lambda(p_1 - \mu t_1)}{\lambda - 1} - \dfrac{\lambda(p_1 - \omega_1)}{\lambda - 1} = 0. \end{cases} \tag{4}$$

According to equation (4),

$$\begin{cases} p_1 = \dfrac{\omega_1 + a + \mu t_1}{2}, \\ p_2 = \dfrac{\omega_2 + a + \mu t_2}{2}. \end{cases} \tag{5}$$

Substituting equation (5) into the profit function $\pi_{M_1}^{CJ}$ of automobile manufacturer M_1 gives

$$\pi_{M_1}^{OL}(w_1, t_1) = \left(\omega_1 - \left(c_{M_1} - x_1 - \beta x_2\right)\right)\left(a - \frac{(\omega_1 + a + \mu t_1/2) - \mu t_1}{1 - \lambda} + \frac{(\lambda(\omega_2 + a + \mu t_2)/2) - \mu t_2}{1 - \lambda} - \frac{1}{2}t_1^2.\right. \tag{6}$$

Taking the first-order partial derivatives of $\pi_{M_1}^{OL}(w_1, t_1)$ with respect to ω_1, t_1, respectively, and taking the second-order derivatives, we obtain the Hessian matrix:

$$H = \begin{bmatrix} \dfrac{\partial^2 \pi_{M_1}^{OL}(\omega_1, t_1)}{\partial \omega_1^2} & \dfrac{\partial^2 \pi_{M_1}^{OL}(\omega_1, t_1)}{\partial \omega_1 t_1} \\ \dfrac{\partial^2 \pi_{M_1}^{OL}(\omega_1, t_1)}{\partial t_1 \omega_1} & \dfrac{\partial^2 \pi_{M_1}^{OL}(\omega_1, t_1)}{\partial t_1^2} \end{bmatrix} = \begin{bmatrix} -1 & \dfrac{\mu}{2} \\ \dfrac{\mu}{2} & -1 \end{bmatrix}. \tag{7}$$

Since $(\partial^2 \pi_{M_1}^{OL}(\omega_1, t_1)/\partial \omega_1^2) < 0$ and $\begin{vmatrix} -1 & \mu/2 \\ \mu/2 & -\theta \end{vmatrix} = 1-$ $(\mu^2/4) > 0$, $\pi_{M_1}^{OL}(w_1, t_1)$ is a strictly concave function of ω_1 and t_1. Taking the first derivative of $\partial^2 \pi_{M_1}^{OL}(w_1, t_1)$ with regard to ω_1 and set it to zero, ω_1 can be written as follows:

$$\omega_1(t_1) = \frac{a + c_{M_1} - x_1 - \beta x_2 + \mu t_1}{2}. \tag{8}$$

Substituting equation (8) into equation (6), the profit of manufacturer M_1 is as follows:

$$\pi_{M_1}^{OL}(t_1) = \left(\frac{a + c_{M_1} - x_1 - \beta x_2 + \mu t_1}{2} - \left(c_{M_1} - x_1 - \beta x_2\right)\right)$$
$$\left(a - \frac{\left(\left(\left(a + c_{M_1} - x_1 - \beta x_2 + \mu t_1\right)/2\right) + a + \mu t_1/2\right) - \mu t_1}{1 - \lambda} + \frac{\left(\lambda\left(\left(a + c_{M_1} - x_1 - \beta x_2 + \mu t_2/2\right) + a + \mu t_2\right)/2\right) - \mu t_2}{1 - \lambda} - \frac{1}{2}t_1^2.\right. \tag{9}$$

Setting the first derivative of equation (9) with respect to t_1 to zero, the optimal technical content of the new products is described as

$$t_1^* = \frac{a\mu - \left(c_{M_1} - x_1 - \beta x_2\right)\mu}{-\mu^2 + 4}. \tag{10}$$

Substituting equation (10) into equation (8), the optimal wholesale price can be obtained:

$$\omega_1^* = \frac{a + c_{M_1} - x_1 - \beta x_2}{2} + \frac{\mu^2\left(a - c_{M_1} + x_1 + \beta x_2\right)}{8 - 2\mu^2}. \tag{11}$$

By the same calculation, the optimal wholesale price and technical content of new products of automobile manufacturer M_i are written as follows:

$$\begin{aligned} t_i^{OL^*} &= \frac{\mu\left(a - c_{M_i} + x_i + \beta x_j\right)}{4 - \mu^2}, \\ \omega_i^{OL^*} &= \frac{a + c_{M_i} - x_i - \beta x_j}{2} + \frac{\mu^2\left(a - c_{M_i} + x_i + \beta x_j\right)}{8 - 2\mu^2}, \\ p_i^{OL^*} &= \frac{3a + c_{M_i} - x_i - \beta x_j}{4} + \frac{3\mu^2\left(a - c_{M_i} + x_i + \beta x_j\right)}{16 - 4\mu^2}. \end{aligned} \tag{12}$$

Proposition 1 is proved. □

Inference 1. In the OL strategy, the sensitive coefficient of the technical content of new products is positively correlated with technical content of new products, wholesale price, and market price.

Proof

$$\frac{\partial t_i^{OL^*}}{\partial \mu} = \frac{\left(a - c_{M_i} + x_i + \beta x_j\right)\left(\mu^2 + 4\right)}{\left(\mu^2 - 4\right)^2} > 0,$$
$$\frac{\partial \omega_i^{OL^*}}{\partial \mu} = \frac{\left(a - c_{M_i} + x_i + \beta x_j\right)\left(\mu^3 + 16\mu\right)}{\left(2\mu^2 - 8\right)^2} > 0, \quad (13)$$
$$\frac{\partial p_i^{OL^*}}{\partial \mu} = \frac{96\mu}{\left(4\mu^2 - 16\right)^2} > 0.$$

Inference 1 indicates that the more consumers are sensitive to technical content in new products, the more likely they are to buy high-tech automobile products, which can stimulate automobile manufacturers to improve the technological content of products and also bring about higher wholesale price and market sales price.

The equilibrium profit $\pi_{M_1}^{OL^*}$, $\pi_{M_2}^{OL^*}$ of two automobile manufacturers and the equilibrium profit $\pi_R^{OL^*}$ of automobile dealer can be obtained by Proposition 1 and equation (1). □

4.2. Game Equilibrium Strategy of Competition-Cooperation Innovation (CL). In the CL strategy, the automobile manufacturers enjoy a competitive relationship but cooperate to develop new products. The game rule is such that two automobile manufacturers cooperate in R&D and, respectively, bear the costs thereof. They first set the common technological content t_0 of the two products based on the maximum total revenue, M_1 bears the R&D cost in proportion θ, which is $(1/2)\theta t_0^2$, and M_2 bears the R&D cost in proportion $(1-\theta)$, that is, $(1/2)(1-\theta)t_0^2$. The two automobile manufacturers decide their wholesale price based on their maximum profit; then the automobile dealer decides their market price based on acquiring maximum profit. The game model is described as follows:

$$\text{S.t.}\begin{cases} \max_{t_0}\pi_M^{CL} = \left(\omega_1^* - c_{M_1} + x_1 + \beta x_2\right)\left(\alpha - \dfrac{p_1 - \mu t_0}{1 - \xi\lambda} + \dfrac{\xi\lambda\left(p_2 - \mu t_0\right)}{1 - \xi\lambda}\right) \\ +\left(\omega_1^* - c_{M_1} + x_1 + \beta x_2\right)\left(\alpha - \dfrac{p_2 - \mu t_0}{1 - \xi\lambda} + \dfrac{\xi\lambda\left(p_1 - \mu t_0\right)}{1 - \xi\lambda}\right) - \dfrac{1}{2}t_0^2, \\ \left(\omega_1^*, \omega_2^*\right) \text{ must meet the following condition}: \\ \max_{\omega_1}\pi_{M_1}^{CL} = \left(\omega_1 - c_{M_1} + x_1 + \beta x_2\right)\left(\alpha - \dfrac{p_1^* - \mu t_0}{1 - \xi\lambda} + \dfrac{\xi\lambda\left(p_2^* - \mu t_0\right)}{1 - \xi\lambda}\right) - \dfrac{1}{2}\theta t_0^2, \\ \max_{\omega_2}\pi_{M_2}^{CL} = \left(\omega_2 - c_{M_2} + x_2 + \beta x_1\right)\left(\alpha - \dfrac{p_2^* - \mu t_0}{1 - \xi\lambda} + \dfrac{\xi\lambda\left(p_1^* - \mu t_0\right)}{1 - \xi\lambda}\right) - \dfrac{1}{2}(1-\theta)t_0^2, \\ \left(p_1^*, p_2^*\right) \text{ must meet the following condition}: \\ \max_{p_1,p_2}\pi_R^{CL} = \left(p_1 - \omega_1\right)\left(\alpha - \dfrac{p_1 - \mu t_0}{1 - \xi\lambda} + \dfrac{\xi\lambda\left(p_2 - \mu t_0\right)}{1 - \xi\lambda}\right) + \left(p_2 - \omega_2\right)\left(\alpha - \dfrac{p_2 - \mu t_0}{1 - \xi\lambda} + \dfrac{\xi\lambda\left(p_1 - \mu t_0\right)}{1 - \xi\lambda}\right). \end{cases} \quad (14)$$

Proposition 2. *In the CL strategy, the optimal wholesale price and the optimal technical content of new products of manufacturers and the optimal market price and the optimal technical content of new products of dealer are as follows:*

$$t_0^{CL^*} = \frac{\mu\left(a - c_{M_i} + x_i + \beta x_j\right)(1 - \xi\lambda)}{2\theta(2 - \xi\lambda)^2 - 2\mu^2(1 - \xi\lambda)^2} - \frac{\mu\left(c_{M_1} - x_1 - \beta x_2 + c_{M_2} - x_2 - \beta x_1\right)}{4},$$
$$\omega_i^{CL^*} = \frac{\left(a - c_{M_i} + x_i + \beta x_j\right)(1 - \xi\lambda)}{\theta(2 - \xi\lambda)^2 - \mu^2(1 - \xi\lambda)^2}, \quad (15)$$
$$p_i^{OL^*} = \frac{2a - \mu\left(c_1 + c_2\right)}{4} + \frac{\left(a - c_i\right)(1 - \xi\lambda)(1 + \mu)}{2\theta(2 - \xi\lambda)^2 - 2\mu^2(1 - \xi\lambda)^2}.$$

Proposition 2 can be proved by backward induction in a manner similar to Proposition 1.

The equilibrium profits $\pi_{M_1}^{CL^*}$ and $\pi_{M_2}^{CL^*}$ of two automobile manufacturers and the equilibrium profit $\pi_R^{CL^*}$ of automobile dealer can be obtained by the combination of Proposition 2 and equation (13).

Inference 2. In the CL strategy, the improvement of technical content of new products is conducive to the increase of total profit earned by the automobile manufacturers.

Proof. Based on the above conclusions, the partial derivative of the total profit of automobile manufacturer on the technical content of new products can be obtained:

$$\frac{\partial \pi_{M_1}^{CL^*}}{\partial t_0} > 0, \quad \frac{\partial \pi_{M_2}^{CL^*}}{\partial t_0} > 0. \tag{16}$$

Inference 2 indicates that the technical content of new products must be improved to maximise the total profit of automobile manufacturers. This is mainly because increasing the technical content of new products can bring about higher wholesale price and stimulate market demand, which will lead to more profits. On the one hand, the improvement of technical content requires more R&D investment costs, manufacturers' assembly costs are also higher, so the wholesale price is higher; on the other hand, consumers have a demand preference for high-tech products. The higher the technical content of the product is, the more it will be favoured by consumers, and the market demand for a product is greater under the influence of the relationship of supply and demand. □

4.3. Game Equilibrium Strategy of Competition-Cooperation Innovation (OJ). The two automobile manufacturers in an OL strategy enjoy a cooperative relationship but independently develop new products. The game rule is such that the two automobile manufacturers decide their respective wholesale price and technical content of new products based on the maximum total revenue accruing to both parties, and then the automobile dealer sets the market sales price of the two products based on its maximum revenue. The game model can be described as follows:

$$\text{S.t.} = \begin{cases} \max_{t_1,\omega_1,t_2,\omega_2} \pi_M^{0j} = \left(\omega_1 - c_{M_1} + x_1 + \beta x_2\right)\left(\alpha - \dfrac{p_1^* - \mu t_1}{1-\lambda} + \dfrac{\lambda(p_2^* - \mu t_2)}{1-\lambda}\right)\dfrac{t_1^2}{2} \\ + \left(\omega_2 - c_{M_2} + x_2 + \beta x_1\right)\left(\alpha - \dfrac{p_2^* - \mu t_2}{1-\lambda} + \dfrac{\lambda(p_1^* - \mu t_1)}{1-\lambda}\right) - \dfrac{t_2^2}{2}, \\ (p_1^*, p_2^*) \text{ must meet the following condition :} \\ \max_{p_1,p_2} \pi_M^{0j} = (p_1, p_1)\left(\alpha - \dfrac{p_1 - \mu t_1}{1-\lambda} + \dfrac{\lambda(p_2 - \mu t_2)}{1-\lambda}\right) \\ + (p_2, p_2)\left(\alpha - \dfrac{p_2 - \mu t_2}{1-\lambda} + \dfrac{\lambda(p_1 - \mu t_1)}{1-\lambda}\right), \end{cases} \tag{17}$$

Proposition 3. *In the OJ strategy, the optimal wholesale price and the optimal technical content of new products of manufacturers and the optimal market price and the optimal technical content of new products of dealer are as follows:*

$$\begin{aligned} t_i^{OJ^*} &= -\frac{\mu\left(a - c_{M_i} + x_i + \beta x_j\right)(1+\lambda)}{\mu^2 + \lambda\mu^2 - 4}, \\ \omega_i^{OJ^*} &= \frac{a + c_{M_i} - x_i - \beta x_j}{2} - \frac{\mu^2\left(a - c_{M_i} + x_i + \beta x_j\right)(1+\lambda)}{2\left(\mu^2 + \mu^2\lambda - 4\right)}, \\ p^{OJ^*} &= \frac{3a + c_{M_i} - x_i - \beta x_j}{4} - \frac{3\mu^2\left(a - c_{M_i} + x_i + \beta x_j\right)(1+\lambda)}{4}. \end{aligned} \tag{18}$$

Proposition 3 can be proved by backward induction in a manner similar to Proposition 1.

Inference 3. In OJ strategy, the inhibitory effect of competitive intensity on wholesale price is greater than that on market price.

Proof. Since $\partial\omega^{OJ^*}/\partial\lambda = ((-\mu^2\, a - c_{M_i} + x_i + \beta x_j t(\lambda + 1)n - q\ \ \mu^2 h(a - c_{M_i} + x_i + \beta x_j)(\lambda\mu^2 + \mu^2 - 4)/2) < 0$, $\partial p^{OJ^*}/\partial\lambda = ((-3\mu^2(a - c_{M_i} + x_i + \beta x_j))/4) < 0$, so competitive intensity has a restraining effect on wholesale price and market price. At the same time, $(\partial\omega^{OJ^*}/\partial\lambda) - (\partial p^{OJ^*}/\partial\lambda) = (u^2(a - c_i)[3 - 2(\lambda\mu^2 + \mu^2 - 4) - 2\mu^2(\lambda + 1)]/4) > 0$ when $0 < \lambda < 1$, we can obtain $(\partial\omega^{OJ^*}/\partial\lambda) - (\partial p^{OJ^*}/\partial\lambda) > 0$; thus, inference 3 is proved.

Inference 3 shows that the wholesale price and market price will decrease with the increase of competitive intensity in the OJ strategy. Therefore, the two automobile manufacturers should take measures to reduce the competitive intensity between them to alleviate the overall loss of profit caused by intensified competition.

Combining Proposition 3 and equation (16), the equilibrium profit $\pi_{M_1}^{OJ^*}$ and $\pi_{M_2}^{OJ^*}$ of two automobile manufacturers and the equilibrium profit $\pi_R^{OJ^*}$ of automobile dealer can be obtained. □

4.4. Game Equilibrium Strategy of Fully Cooperative Innovation (CJ). In the CJ strategy, two automobile manufacturers enjoy a cooperative relationship and cooperate to develop new products. The game rule is such that the two automobile manufacturers share the R&D costs of new products. First, the common technical content t_0 and their respective wholesales are determined based on the maximum total revenue of both parties, and then the automobile dealer determines the market selling price of new products based on their own profits. The game model is described as follows:

$$\text{S.t.}\begin{cases} \max_{t_0}\pi_M^{CL} = \left(\omega_1^* - \left(c_{M_1} + x_1 + \beta x_2\right)\right)\left(\alpha - \dfrac{p_1 - \mu t_0}{1-\xi\lambda} + \dfrac{\xi\lambda\left(p_2 - \mu t_0\right)}{1-\xi\lambda}\right) \\ +\left(\omega_2^* - \left(c_{M_2} + x_2 + \beta x_1\right)\right)\left(\alpha - \dfrac{p_2 - \mu t_0}{1-\xi\lambda} + \dfrac{\xi\lambda\left(p_1 - \mu t_0\right)}{1-\xi\lambda}\right) - \dfrac{t_0^2}{2}, \\ \left(\omega_1^*, \omega_2^*\right) \text{ must meet the following condition}: \\ \max_{\omega_1,\omega_2}\pi_{M_1}^{CL} = \left(\omega_1 - \left(c_{M_1} + x_1 + \beta x_2\right)\right)\left(\alpha - \dfrac{p_1^* - \mu t_0}{1-\xi\lambda} + \dfrac{\xi\lambda\left(p_2^* - \mu t_0\right)}{1-\xi\lambda}\right) \\ +\left(\omega_2^* - \left(c_{M_2} + x_2 + \beta x_1\right)\right)\left(\alpha - \dfrac{p_2^* - \mu t_0}{1-\xi\lambda} + \dfrac{\xi\lambda\left(p_1^* - \mu t_0\right)}{1-\xi\lambda}\right) - \dfrac{t_0^2}{2}, \\ \left(p_1^*, p_2^*\right) \text{ must meet the following condition}: \\ \max_{p_1,p_2}\pi_R^{CL} = \left(p_1 - \omega_1\right)\left(\alpha - \dfrac{p_1 - \mu t_0}{1-\xi\lambda} + \dfrac{\xi\lambda\left(p_2 - \mu t_0\right)}{1-\xi\lambda}\right) + \left(p_2 - \omega_2\right)\left(\alpha - \dfrac{p_2 - \mu t_0}{1-\xi\lambda} + \dfrac{\xi\lambda\left(p_1 - \mu t_0\right)}{1-\xi\lambda}\right). \end{cases} \tag{19}$$

Proposition 4. *In the CJ strategy, the optimal wholesale price and the optimal technical content of new products of manufacturers and the optimal market price and the optimal technical content of new products of dealer are as follows:*

$$\begin{aligned} t_0^{CJ^*} &= \frac{\mu\left(c_{M_1} - x_1 - \beta x_2 + c_{M_2} - x_2 - \beta x_1\right)}{2}, \\ \omega_i^{CJ^*} &= \frac{a + c_{M_i} - x_i - \beta x_j}{2} - \frac{\mu^2\left(c_{M_1} - x_1 - \beta x_2 + c_{M_2} - x_2 - \beta x_1\right)}{4}, \\ p_i^{CJ^*} &= \frac{3a + c_{M_i} - x_i - \beta x_j}{4} - \frac{3\mu^2\left(c_{M_1} - x_1 - \beta x_2 + c_{M_2} - x_2 - \beta x_1\right)}{8}. \end{aligned} \tag{20}$$

By backward induction, the proof of Proposition 4 is akin to that of Proposition 1.

Inference 4. The demand of automobile manufacturers will increase with the technical content of new products.

Proof

$$q^{CJ} = a - \frac{1}{1-\lambda}p_i^{CJ} + \frac{\lambda}{1-\lambda}p_j^{CJ} + \mu\left(\frac{1}{1-\lambda}t_i^{CJ} + \frac{\lambda}{1-\lambda}t_j^{CJ}\right),$$

$$\frac{\partial q_i^{CJ}}{\partial t_i} = \frac{\mu}{(1-\lambda)} > 0,$$

$$\frac{\partial q_i^{CJ}}{\partial t_j} = \frac{\lambda}{1-\lambda} > 0. \tag{21}$$

Inference 4 implies that the technical content of new products is positively correlated with consumer demand preference. Consumers perceive the difference of products by the technical content of products and tend to buy automobile products with high technical content at an acceptable price, so automobile manufacturers can increase consumer demand by improving the technical content of their new products.

Combining Proposition 4 and equation (18), the equilibrium profit $\pi_M^{CJ^*}$, $\pi_{M_2}^{CJ^*}$ of two automobile manufacturers and the equilibrium profit $\pi_R^{CJ^*}$ of automobile dealer can be obtained by solving the equation. □

4.5. Comparative Analysis of the Equilibrium Results of the Game of Technological Innovation

Proposition 5. *Comparing the technical content of new products under the equilibrium state of different games, we can see as follows:* $(1) t_i^{OJ} > t_i^{OL} > t_0^{CJ}$\ *and* $(2) t_0^{CL} > t_0^{CJ}$.

Proof. $t_i^{OL} - t_0^{CJ} = ((\mu\ (a-c_i))/(4-\mu^2)) + ((\mu(c_1 + c_2))/2) > 0$, namely, $t_i^{OL} > t_i^{CJ} t_i^{OL} - t_i^{OJ} = ((\mu(a-c_i))/(4-\mu^2)) - ((\mu(a-c_i)\ (1+\lambda))/(4-\mu^2-\lambda\mu^2)) > 0$, namely, $t_i^{OL} > t_i^{OJ}$; $t_i^{CL} - t_i^{CJ} = ((\mu(a-c_i)(1-\xi\lambda)))/\ (2\theta(2-\xi\lambda)^2 - 2\mu^2(1-\xi\lambda)^2) + (\mu(c_1+c_2))/4 > 0$, namely, $t_i^{CL} > t_i^{CJ}$.

In the same way, other inequalities can be proved. From Proposition 5, we can see that for the technical content of new products, OJ is greater than OL and CJ, and CL is bigger than CJ. This is because the competition and cooperation environment is more conducive to stimulating enthusiasm towards R&D between horizontal enterprises, thus continuously improving the efficiency of R&D and the technical level of new products. In addition, due to consumer preference for technological content, enterprises will also be forced to improve their core competitiveness by improving the technical content of new products in independent R&D to win greater market share. □

Proposition 6. *Comparing the wholesale price decision in the equilibrium state of different games, it can be known that* $(1) \omega_i^{OJ} > \omega_i^{OL}$ *and* $(2) \omega_i^{CJ} > \omega_i^{OL} > \omega_i^{CL}$.

Proof. $\omega_i^{OL} - \omega_i^{OJ} = (\mu^2(a-c_i))/(8-2\mu^2) - ((\mu^2\ (a-c_i)(1+\lambda)))/(8-2\mu^2-2\lambda\mu^2) < 0$, namely, $\omega_i^{OJ} > \omega_i^{OL}$; $\omega_i^{CJ} - \omega_i^{CL} = ((6a + 2c_i + 3\mu^2(c_1+c_2))/8) + ((a-c_1)(1-\xi\lambda)/\theta(2-\xi\lambda)^2 - \mu^2(1-\xi\lambda)^2) > 0$, namely, $\omega_i^{CJ} > \omega_i^{CL}$.

Similarly, other inequalities can be proved. According to Proposition 6, the game equilibrium strategy of fully cooperative innovation can allow the two automobile manufacturers obtain higher wholesale price. The wholesale price of OJ is higher than that of OL, indicating that the cooperative relationship can result in a higher wholesale price than the competitive relationship when two automobile manufacturers undertake independent R&D, because in a competitive environment, companies tend to adopt low-price strategies to win a greater market share. □

Proposition 7. *Comparing the market price decision under the equilibrium state of different games, we find that* $(1) p_i^{CJ} > p_i^{CL}, p_i^{OJ}, p_i^{OL}$ *and* $(2) p_i^{OL} > p_i^{OJ}$.

Proof. $p_i^{CJ} - p_i^{OJ} = (3\mu^2(a-c_i)(1+\lambda)/4) - (3\mu^2\ (c_1+c_2)/8) > (3a+c_i/4) - (3a+c_i/4) = 0$, namely, $p_i^{CJ} > p_i^{OJ}$; $p_i^{OL} - p_i^{OJ} = (3\mu^2(a-c_i)/\ 16-4\mu^2) + (3\mu^2(a-c_i)(1+\lambda)/4) > 0$, namely, $p_i^{OL} > p_i^{OJ}$. Other inequalities can be proved in the same way. According to Proposition 7, the game equilibrium strategy of fully cooperative innovation results in the highest market price, because a cooperative relationship weakens price competition, and joint R&D can yield higher technical content in new products; thus, the automobile dealer can obtain a higher market sales price than when in a competitive relationship.

Considering the complexity of game model, it is difficult to compare the total profit of an automobile manufacturer and the profit of the automobile dealer in different game scenarios through mathematical derivation alone. This study will be conducted using sample calculations and numerical simulation analysis in the following section. □

5. Examples and Numerical Simulation Analysis

The previous content describes an analysis of the equilibrium solution of each member in the four game situations: the further to analyse the influence of the main factors influencing the model on the supply chain decision value, we used MATLAB™ software to conduct sample calculations and numerical simulation analysis, thus providing insight into technological innovation cooperation and recommendations for decision-making. The parameters used in this section are established [12] and salient automobile market data:

$$\begin{aligned} \mu &= 0.9, \\ a &= 2, \\ \lambda &= 0.3, \\ \xi &= 2, \\ \theta &= 0.6, \\ \beta &= 0.4, \\ x_i &= 0.4, \\ c_{M_1} &= 0.5, \\ c_{M_2} &= 0.5. \end{aligned} \tag{22}$$

5.1. Profit Comparison under Different Game Equilibrium Strategies of Technology Innovation. Four types of game equilibrium profits can be obtained by substituting the above parameters into the model, as shown in Table 2.

It can be seen from Table 2 that the game equilibrium strategy of fully cooperative innovation enables two automobile manufacturers to maximise their prices to maximise profits but will damage the interests of automobile dealers. For automobile dealers, CL is better than CJ, and OL is better than OJ, because horizontal competition will stimulate automobile manufacturers to innovate to gain a competitive advantage, thus maximising the profit of the automobile dealer.

5.2. Influence of the Sensitivity Coefficient of New Product Technical Content on the Equilibrium Solution. In this section, we describe analysis of the influence of the sensitivity coefficient of the technical content of new products on wholesale price, market price, total profit accruing to the automobile manufacturers, and those of the automobile dealer (Figures 3–7).

Figure 3 shows that as the sensitivity coefficient of new product technical content increases, the technical content of new product of all strategies increases. When $0 < \mu < 0.8$, CL > OJ > OL > CJ; when $0.8 < \mu < 1.3$, OJ > CJ; therefore, when consumers are not sensitive to the technical content of new products and there is competition between horizontal enterprises, cooperative R&D is better than independent R&D. Independent R&D is better than cooperative R&D when the sensitivity coefficient of the new product's technical content increases and there is a cooperative relationship between horizontal enterprises.

Figure 4 indicates that with the increase in the sensitivity coefficient of new product technical content, the wholesale price will increase under each strategy. When $0 < \mu < 1.15$, CL > OJ > OL > CJ, the game equilibrium strategy of fully cooperative innovation is optimal; when $\mu > 1.15$, OJ > CJ > OL > CL, the game equilibrium strategy of competition-cooperation innovation (collaboration-independent R&D) is optimal.

Figure 5 demonstrates that as the sensitivity coefficient of new product technical content increases, the market price of each strategy also increases. In the case of $0 < \mu < 0.13$, CL > OJ > OL > CJ, cooperation is better than competition; when $\mu > 0.13$, OJ > OL > CJ, competition is better than cooperation.

Figure 6 shows that as the sensitivity coefficient of new product technical content increases, the total profit of the automobile manufacturer in the four game scenarios also increases. When $0 < \mu < 1.2$, OJ > OL > CJ, the game equilibrium strategy of competition-cooperation innovation (competition-cooperative R&D) is optimal; when $\mu > 1.2$, a game equilibrium strategy of pure competitive innovation is optimal.

Figure 7 illustrates that in the four game scenarios, the profit accruing to the automobile dealer increases with the increase of the sensitivity coefficient of new product technical content, and OJ > CL > OL > CJ. When the sensitivity coefficient of new product technical content is low ($0 < \mu < 0.5$), the influences of competition and cooperation relationship and R&D mode on an automobile dealer are not obvious; when the sensitivity coefficient of new product technical content is high ($\mu \geq 0.5$), the influences of

Table 2: Comparison of game equilibrium profit.

Game equilibrium strategy of technology innovation	π_M^{total}	π_R^{total}
OL	20	49.3
CL	33.5	68.5
OJ	43.5	32.2
CJ	55	50

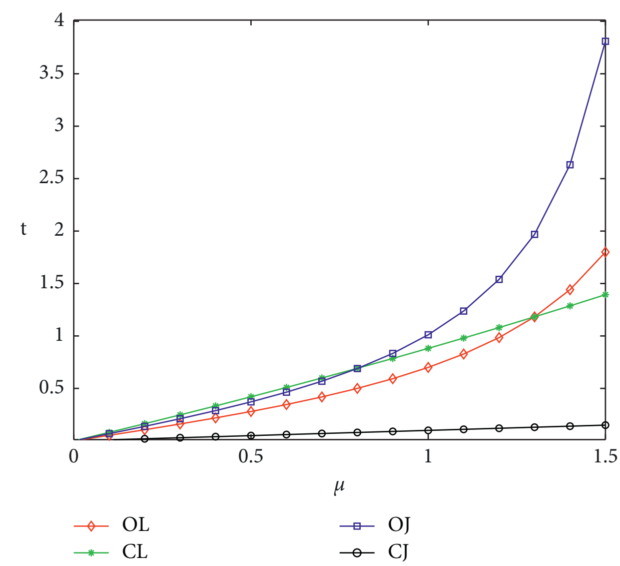

Figure 3: The influence of the sensitivity coefficient of the new product technical content on the new product technical content.

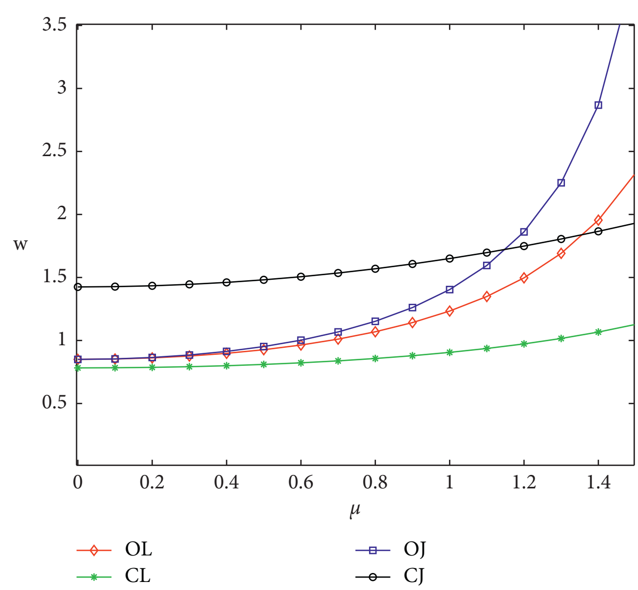

Figure 4: The influence of the sensitivity coefficient of the new product technical content on wholesale price.

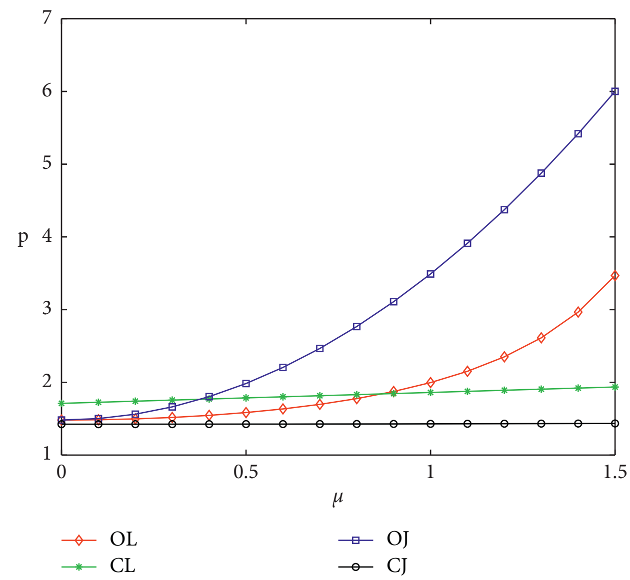

Figure 5: The influence of the sensitivity coefficient of the new product technical content on market sale.

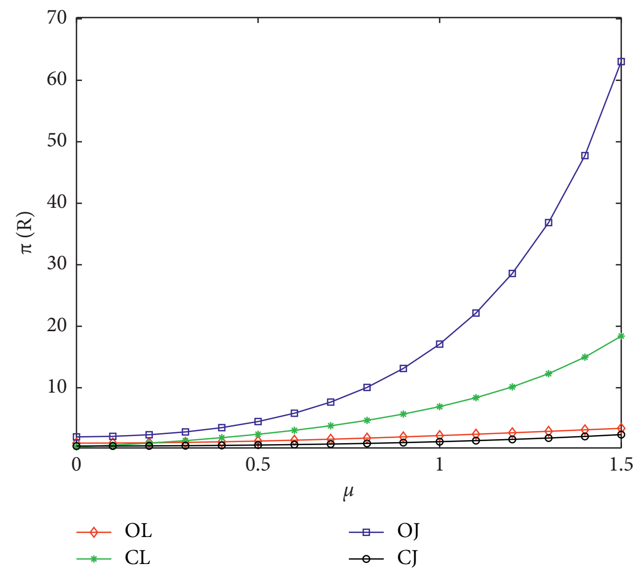

Figure 7: The influence of the sensitivity coefficient of the new product technical content on the profit accruing to the automobile dealer.

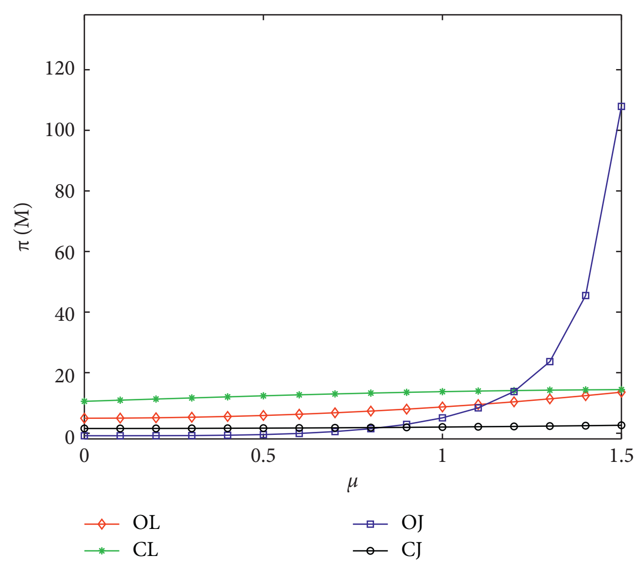

Figure 6: The influence of the sensitivity coefficient of the new product technical content on the total profit of automobile manufacturers.

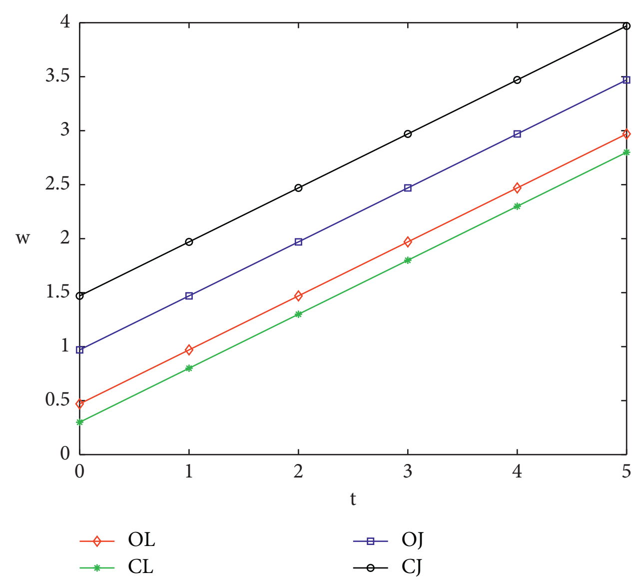

Figure 8: The influence of new product technical content on wholesale price.

competition and cooperation relationship and R&D mode on automobile dealers are evident, and the degree of influence thereof increases with increasing sensitivity coefficient.

5.3. Influence of New Product Technical Content on Equilibrium Solution. Here we describe an analysis of the influence of new product technical content on wholesale prices, market prices, demand, total profit accruing to the automobile manufacturers, and that of the automobile dealer. The results are shown in Figures 8–12.

Figure 8 shows that with the improvement of new product technical content, the wholesale price wholesale price in every game equilibrium strategy also gradually improve, and CJ > OJ > OL > CL. It can be seen that when two companies have a cooperative relationship, cooperative R&D results in a higher wholesale price than independent R&D regardless of changes to the technical content of new products; when there is a competitive relationship between the two companies, independent R&D results in a higher wholesale price than cooperative R&D.

Figure 9 illustrates that the market prices under the four game equilibrium strategies all increase with the increase in the technical content of new products, and the market prices under CJ conditions are significantly higher than when adopting other game strategies. In addition, when $0 < t < 4$,

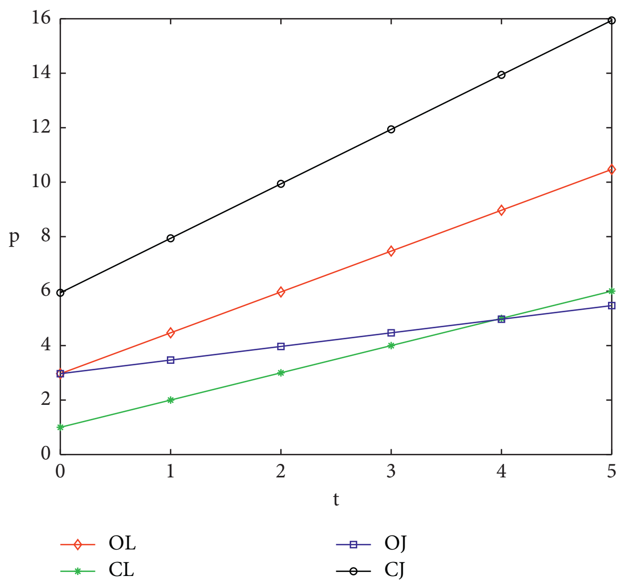

FIGURE 9: The influence of new product technical content on market price.

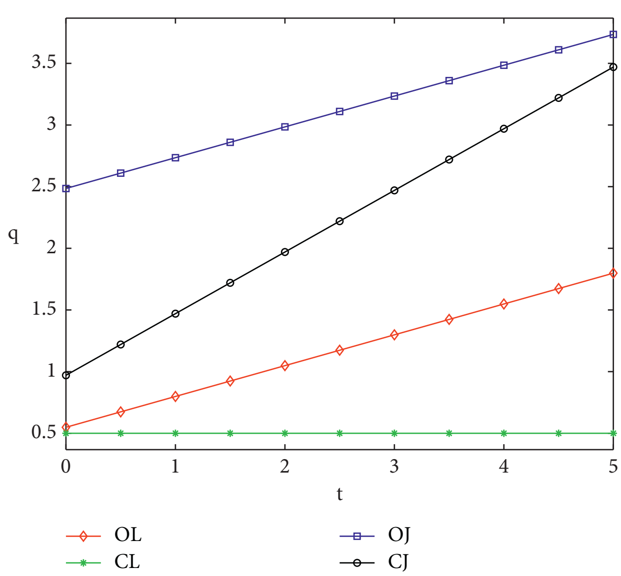

FIGURE 10: The influence of new product technical content on optimal demand.

OJ > CL, cooperation is always better than competition; when $t > 4$, OJ > CL, and competition is better than cooperation.

Figure 10 shows that the technical content of new products is positively correlated with the demand of automobile manufacturers, with OJ > OL and CJ > CL. This shows that a cooperative relationship is always better than a competitive relationship regardless of R&D mode.

Figure 11 depicts that the technical content of new products is also positively correlated with the total profit of the automobile manufacturer, and CJ is the optimal strategy. This indicates that, if automobile manufacturers want to earn a greater total profit, they must improve the technical content of their products.

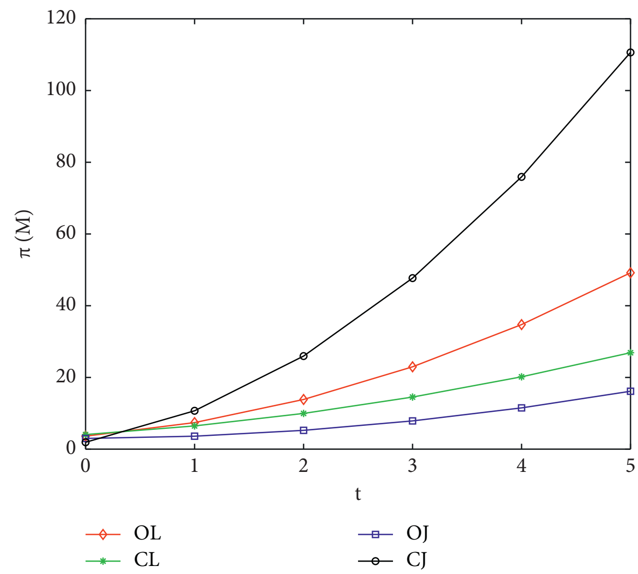

FIGURE 11: The influence of new product technical content on total profit of automobile manufacturers.

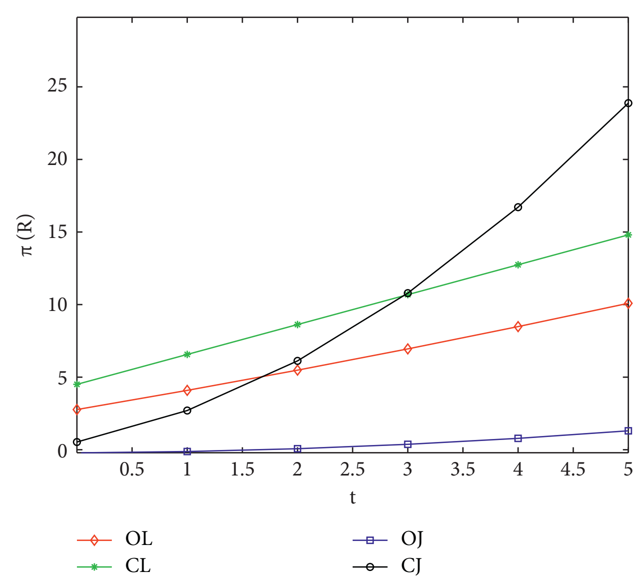

FIGURE 12: Influence of new product technical content on the profit accruing to an automobile dealer.

Figure 12 suggests that the improvement of technical content of the new product can enable automobile dealers to earn greater profits. In addition, when the technical content of the new product is relatively high ($t > 2.96$), the game equilibrium strategy of fully cooperative innovation is much better than the other three game situations.

5.4. Influence of Competitive Intensity on Equilibrium Solution. Herein, the influence of competitive intensity between two automobile manufacturers on the equilibrium solution of the supply chain is evaluated. The results are illustrated in Figures 13–17.

Figure 13 shows that, with the increase of competitive intensity, CJ > OJ > OL, and CL first increases and then

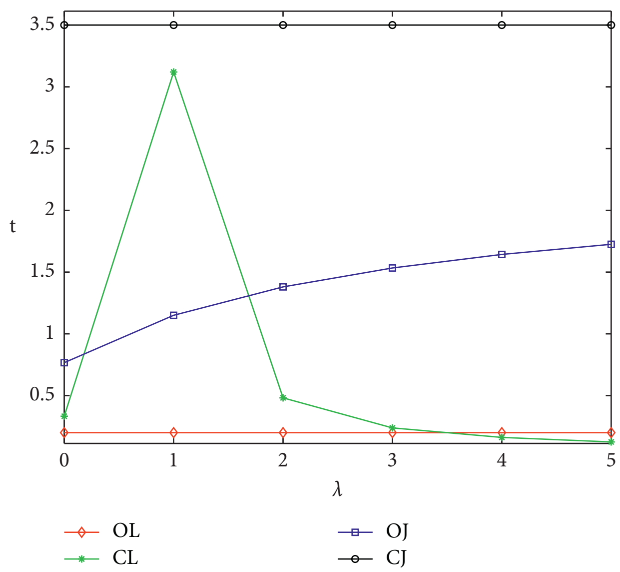

Figure 13: The influence of competitive intensity on new product technology content.

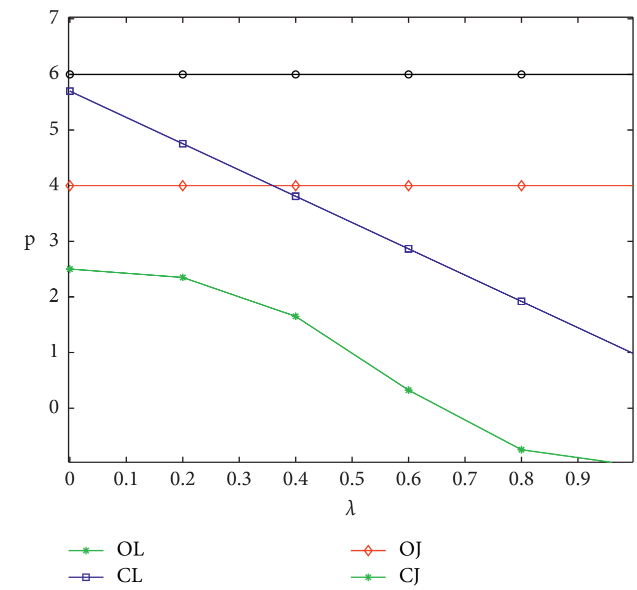

Figure 15: The influence of competitive intensity on market price.

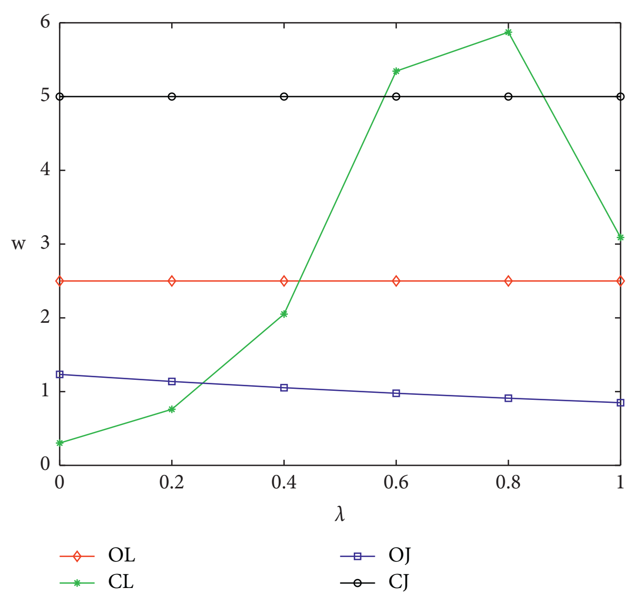

Figure 14: The influence of competitive intensity on wholesale price.

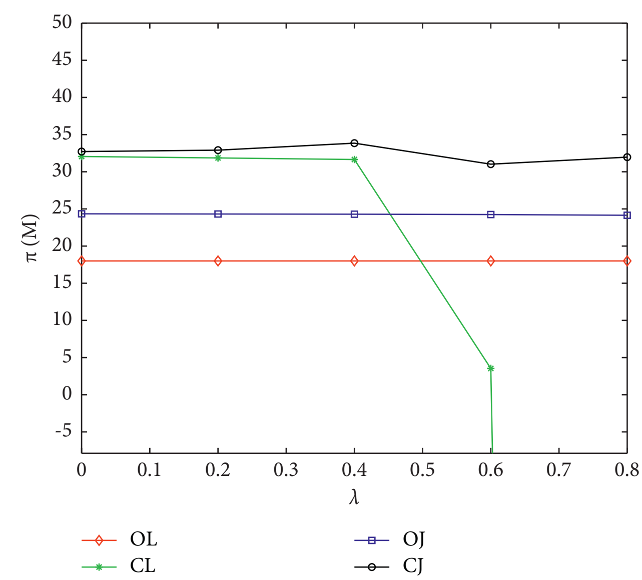

Figure 16: The influence of competitive intensity on total profit of automobile manufacturers.

decreases. To improve the technical content of new products, the competitive intensity must be controlled within a reasonable range. Meanwhile, the technical content of new product in OL and CJ will not change with the increase in the intensity of competition but will increase in OJ.

Figure 14 illustrates that the competitive intensity does not affect the wholesale price of OL and CJ, and CJ > OL > OJ, indicating that cooperative R&D is better than independent R&D. In addition, when $0 < \lambda < 0.8$, the technical content of new products of CL increases with the competitive intensity.

Figure 15 shows that the competitive intensity does not affect the market price of CJ and OJ, while the market price of CL and OL decreases with increasing competitive intensity. When the competition is not fierce, $0 < \lambda < 0.36$, cooperative R&D is superior to independent R&D; when $\lambda > 0.36$ and the competition is increasingly fierce, independent R&D is superior to cooperative R&D.

Figure 16 demonstrates that the competitive intensity does not affect the total profit of manufacturers under OJ and OL strategies. Whether the competition is fierce or not, the automobile dealer can obtain the highest profit under the CJ strategy. When $\lambda \geq 0.6$, the total profit of automobile manufacturers under a CL strategy decreases to zero, indicating that, when the competition is fierce, the CL strategy will reduce the profit earned by the automobile dealer.

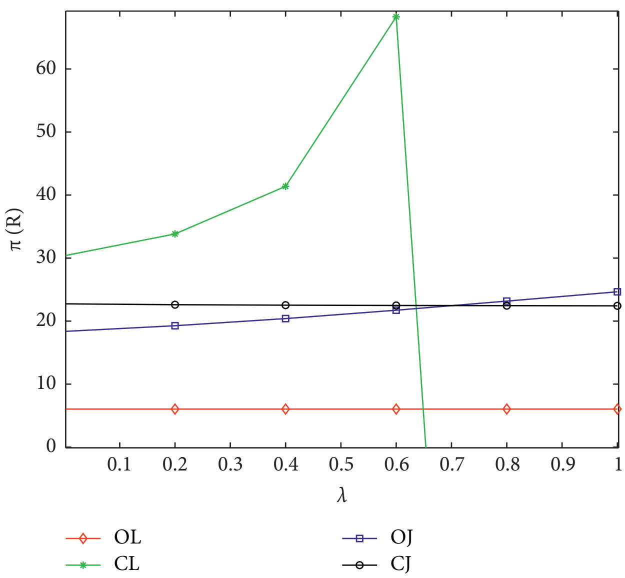

Figure 17: The influence of competitive intensity on the profit accruing to an automobile dealer.

Figure 17 depicts that as the competitive intensity increases, the profit of automobile dealer remains unchanged under the OL strategy, and increases under the OJ and CJ strategies, and first increases and then decreases under the CL strategy. In the case of $\lambda < 0.6$, the automobile dealer can obtain the maximum profit under the CL strategy, and CL > CJ > OJ > OL, indicating that cooperative R&D is better than independent R&D. When the competition is very fierce ($\lambda > 0.6$), OJ > CJ > OL, OJ is superior to OL.

6. Conclusion

The horizontal competition-cooperation game strategy of technological innovation in two-stage automobile cluster supply chain composed of duopoly of automobile manufacturers and a single automobile dealer is explored. According to the competition-cooperation relationship and R&D mode of horizontal automobile manufacturers, four game models of technological innovation are constructed and used to analyse the equilibrium solution under different game situations. The main conclusions and recommendations are as follows:

(1) The game equilibrium strategy of fully cooperative innovation can maximise the technical content of new product, wholesale price, and total profit of automobile manufacturers but cannot maximise the profit to the automobile dealer. This is mainly because fully cooperative innovation can reduce repetitive R&D costs resulting in the highest wholesale price, thus bringing more profits to automobile manufacturers; however, for the automobile dealer, OJ is the optimal strategy. Therefore, to maximise the total profit of automobile manufacturers and dealer, cooperative R&D mode should be selected to improve the degree of information sharing and share the R&D costs.

(2) When the horizontal competition is not fierce and the consumption preference for technical content is weak, the OJ strategy will bring the maximum profit to the automobile dealer, but will reduce the profit of automobile manufacturers, and the profit of the manufacturer is the lowest among the four game strategies under OJ strategy; with the intensification of horizontal competition, automobile manufacturers will inevitably lower the wholesale price to seize the market, increasing the profit of the automobile dealer under the game equilibrium strategy of OL to a level above that accruing under the OJ strategy. In addition, it also suggests that automobile manufacturers should adopt a differentiation strategy to maintain certain differences of products when developing new products in horizontal cooperation, thus reducing the competitive intensity between the two products and obtain more profits.

(3) No matter how the competition and cooperation relationship and the R&D model change, the market demand, wholesale price, market sales price, and technical content of new products will increase with the increase of consumer preference for the new products' technical content, but the growth rate under each game equilibrium strategy is different, and is greatest under the OJ strategy. Therefore, channel members along the automotive supply chain will enhance the technical content of new products by increasing investment in new product R&D and accelerating technical innovation. In addition, market preference for technical content of automotive products can bring more potential benefits to supply chain channels. Supply chain decision-makers should grasp the market opportunities brought by technical content preference to promote the benign development of the automotive supply chain.

In order to improve the visual display effect of the artistic conception of ancient poems, this paper combines AI technology to construct a multimedia-assisted artistic conception creation system of ancient poetry and combines probabilistic latent semantic analysis to analyze the semantic artistic conception of ancient poetry. Moreover, with the support of multimedia simulation technology, this paper improves the multimedia teaching mode to improve the effect of multimedia-assisted ancient poetry teaching. In addition, this paper constructs a multimedia-assisted artistic conception creation system of ancient poetry based on AI technology and designs experiments to conduct system performance research. The experimental research results show that the multimedia-assisted artistic conception creation system of ancient poetry proposed in this paper has a good teaching effect and has an important role in promoting the study of the artistic conception of ancient poetry.

1. Introduction

It is difficult to understand the author's thoughts and feelings and experience the beauty of the artistic conception of poetry. When teaching ancient poems to students, the teacher needs to combine the cognitive characteristics of different ages to make students fully understand the writing mentality and historical background of the poet during the creation period, so as to induce students' interest in learning ancient poems. Therefore, before each study of an ancient poem, we will arrange a certain amount of spare time for students to go online and use network technology to find, view, and collect relevant information to understand the author's profile, historical background, and corresponding introduction of the poem, so that students have a rough understanding of the poems they have learned and lay a certain teaching foundation.

In the current Chinese teaching in my country, whether it is before or after the release of the new curriculum standard reform, ancient poetry plays a very important role in Chinese teaching at the university level. The reason is that, compared with modern poems and essays, ancient poems have extraordinary significance. Ancient poetry contains a wealth of traditional culture, and through the study of ancient poetry, college students can effectively improve their language expression ability and understand the many situations of ancient society. The improvement that this brings to the students is an improvement in comprehensive literacy, not a unilateral improvement. Especially in recent years, college Chinese textbooks have continued to change, and the proportion of ancient poems in them is increasing, which also proves the importance of ancient poems in the current college Chinese teaching. Multimedia technology is an innovative teaching model that emerged after informatization has penetrated into teaching, which is very popular among students. In addition, it can effectively improve the quality of teaching and can also fully stimulate students' interest in learning. In the current college Chinese ancient poetry teaching, the use of multimedia technology will inevitably improve the teaching effect.

Although the ancient poems at the university stage are relatively simple ancient poems, and some can even be understood in the vernacular way, in the process of teaching, because the college students are younger, they are understanding a lot. In the process of the content, due to insufficient cognitive level and insufficient life experience, there will be more serious problems in understanding. For many ancient poems, college students cannot understand the meaning of ancient poems, not to mention the rich thoughts and feelings contained in them. Therefore, in the process of teaching ancient poetry, teachers need to use their own teaching strategies to help students enter a specific teaching situation and guide students to understand the meaning of poetry. To understand the text in ancient poems, multimedia will help us a lot in this process. Using multimedia to create teaching situations can not only effectively improve efficiency but also better integrate students into the teaching situation.

Most of the life experiences of ancient poets have many ups and downs, and the works created by these poets in different periods completely express different thoughts and feelings. Therefore, teachers can use this in the process of teaching. The feature allows students to understand the author's life experience first, and then to understand the author's work, so that students will experience the author's mood at the time and have a better understanding of the thoughts and feelings to be expressed in the article. Poets are great. Most, in the process of writing poems, describe their own circumstances or ideals at the time. Therefore, it is more important to understand the circumstances of the author at that time. So the most effective way to help students understand the author is nothing more than multimedia. Teachers can use the Internet to search for the author's life events in detail, highlighting the key points and the events experienced by the author in the process of writing this poem, so that students can understand the poet at that time more clearly.

This paper combines AI technology to improve the multimedia teaching mode and improve the effect of multimedia-assisted ancient poetry teaching, which lays the foundation for the subsequent improvement of the quality of ancient poetry teaching.

2. Related Work

A physics-based simulation method simulates the painting process by building models of painting tools such as pens and paper, using image analogy, texture synthesis, and other methods to achieve the artistic effect of virtual reality. Literature [1] proposed a method of simulating hand-painting with style strokes, and literature [2] proposed a virtual brush model (HairyBrush), which can simulate simple ink painting effects. Reference [3] proposes a virtual art pen model based on the elasticity theory, which satisfies the elastic deformation law and models the art pen as an inverted cone to achieve real-time display effects; reference [4] proposes a virtual art pen model. brush model, which can generate more realistic writing effects. Literature [5] proposed a physics-based Mao Fei physical simulation method mainly to simulate the rendering effect. The model proposed in [6] can simulate the effect of ink diffusion on paper. The system developed in [7] can be used to draw trees, and the effect generated by the system is similar to the effect of oil painting. The method proposed in [8] simulates the effect of artistic painting and develops a corresponding system.

In terms of simulation based on painting effects, literature [9] uses the method of image analogy to achieve artistic style drawing. Literature [10] proposes a method of texture synthesis, proposes common textures from artistic paintings, establishes a texture library, and then selects appropriate textures from the texture library to synthesize new ink paintings. Literature [11] designed a paint model that can express a variety of painting forms including traditional Chinese paintings and watercolors. Many scholars are dedicated to studying how to use computers to generate artistic painting effects. Literature [12] proposes a method of synthesizing artistic paintings based on images and has conducted research on computer rendering of artistic paintings. Literature [13] proposed an art painting system simulation rendering algorithm based on texture synthesis. Literature [14] has done research on the rendering effect of art, which is an attempt to realize the style application of animation ink and wash effect. Literature [15] proposes a design method of dynamic artistic conception in order to protect cultural heritage. The 3D mountain rock model constructed in [16] successfully realized the 3D rendering of the art painting simulation effect of the pen and ink method. This method is based on summarizing the shape and distribution of the pen and ink method in the art painting and proposes a fractal modeling method based on the sketch line. Literature [17] designed a form that can automatically generate ancient cultural connotations from pictures in real time. Literature [18] proposes a tool based on the movement trajectory of the artistic pen and the painting material, which can vividly show the process of artistic painting. In recent years, the innovation of computer technology has led to the rapid development of programmable graphics hardware. Programmable graphics software has become an important tool for scholars to conduct research on 3D graphics rendering. Literature [19] proposed the use of programmable graphics hardware to achieve the effect of hand-drawn Chinese painting. In terms of interactive experience, [20] pointed out that, in order to protect art treasures but still allow people to appreciate them, an interactive desktop that can watch artworks at close range is developed. Viewers can achieve partial magnification of the screen through touch points on the desktop. Literature [21] proposed a new method of displaying and restoring ancient famous paintings from a three-dimensional perspective using TIP technology. Now this system can only display animation effects and cannot achieve interaction.

3. Multimedia Virtual Semantic Extraction of Ancient Poetry

Probabilistic latent semantic analysis (PLSA) is a statistically significant model proposed by Hofmann, which is mainly used in text classification and natural language research. When researching natural language, it is often necessary to research synonyms. Probabilistic latent semantics is a better way to solve this kind of research problems. By mapping the high-dimensional sparse vector space of the actual observable "document-word" to the low-dimensional latent space, a connection beyond the vocabulary level is established.

In the PLSA model, we set the document set $D = \{d_1, d_2, \ldots, d_N\}$ and the word set $W = \{w_1, w_2, \ldots, w_M\}$, and the $N \times M$ cooccurrence matrix N composed of the document set D and the word set W, as shown in

$$N = \begin{bmatrix} n(d_1, w_1) & n(d_1, w_2) & \cdots & n(d_1, w_M) \\ n(d_2, w_1) & n(d_2, w_2) & \cdots & n(d_2, w_M) \\ \vdots & \vdots & \ddots & \vdots \\ n(d_N, w_1) & n(d_N, w_2) & \cdots & n(d_N, w_M) \end{bmatrix}. \quad (1)$$

Here, d_i represents the i-th document, w_j represents the j-th word, and $n(d_i, w_j)$ represents the number of times the j-th word appears in the i-th document. In matrix N, each row represents the number of times each word appears in a certain document, and each column represents the number of times a certain word appears in each document. We assume that there is an implicit variable z, that is, the subject variable. If $P(d_i)$ is used to indicate the probability of selecting the i-th document, $P(z_k \mid d_i)$ is the probability of the topic z_k appearing in the i-th document. $P(w_j \mid z_k)$ represents the probability that the word w_j appears in the k-th topic, and the relationship between the three is shown in Figure 1.

If it is assumed that document d and word w are conditionally independent under topic z, formula (2) can be used to express the cooccurrence probability of document d and word w.

$$P(d_i, w_j) = P(d_i)P(w_j \mid d_i) = P(d_i) \sum_{k=1}^{K} P(w_j \mid z_k) P(z_k \mid d_i). \quad (2)$$

It can be seen from formula (2) that PLSA is actually a mixed model, and there are two model parameters $P(z \mid d)$ and $P(w \mid z)$. Here, $P(z \mid d)$ is the probability distribution of topic z under a given document d, and $P(w \mid z)$ is the probability distribution of word w under a given topic z. In the PLSA model, the parameters $P(z \mid d)$ and $P(w \mid z)$ are estimated by using the maximum likelihood estimation method to maximize the probability of the generated sample data. The maximum likelihood function is shown in

$$\begin{aligned} L &= \sum_{i=1}^{N} \sum_{j=1}^{M} \log P(d_i, w_j)^{n(d_i, w_j)} \\ &= \sum_{i=1}^{N} \sum_{j=1}^{M} n(d_i, w_j) \log P(d_i, w_j) \\ &= \sum_{i=1}^{N} n(d_i) \left[\log P(d_i) + \sum_{j=1}^{M} \frac{n(d_i, w_j)}{n(d_i)} \log \sum_{k=1}^{K} P(w_j \mid z_k) P(z_k \mid d_i) \right]. \end{aligned} \quad (3)$$

Here, $n(d_i) = \sum_{j=1}^{M} n(d_i, w_j)$, and $n(d_i)$ is not model parameters, so the formula can be reduced to

$$L \propto \sum_{i=1}^{N} \sum_{j=1}^{M} n(d_i, w_j) \log \sum_{k=1}^{K} P(w_j \mid z_k) P(z_k \mid d_i). \quad (4)$$

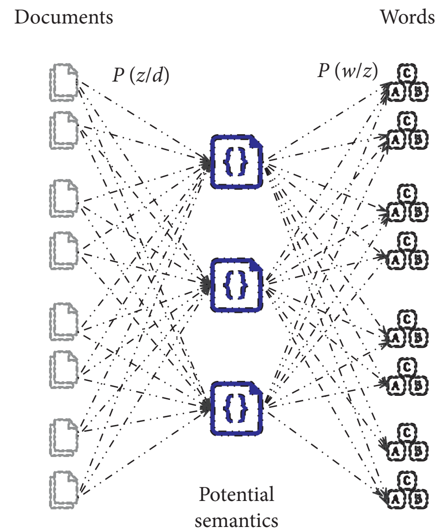

Figure 1: The relationship diagram of "document-latent semantics-word."

It can be seen from formula (4) that $P(z \mid d)$ and $P(w \mid z)$ are the parameters required by the maximum likelihood estimation function. However, since the likelihood function is difficult to maximize, the EM algorithm must be introduced.

The algorithm is an iterative algorithm, divided into two steps. The first step is a step, and what you ask for is expectations. The second step is step, which is the maximum value. The details are shown in formulas (5), (6), and (7).

(1) Step E: the algorithm generates a posterior probability $P(z_k \mid d_i, w_j)$ for each (d_i, w_j):

$$P(z_k \mid d_i, w_j) = \frac{P(w_j \mid z_k) P(z_k \mid d_i)}{\sum_{k=1}^{K} P(w_j \mid z_k) P(z_k \mid d_i)}. \quad (5)$$

(2) Step M: the algorithm reestimates the model parameters $P(z \mid d)$ and $P(w \mid z)$:

$$P(w_j \mid z_k) = \frac{\sum_{i=1}^{N} n(d_i, w_j) P(z_k \mid d_i, w_j)}{\sum_{j=1}^{M} \sum_{i=1}^{N} n(d_i, w_j) P(z_k \mid d_i, w_j)}, \quad (6)$$

$$P(z_k \mid d_i) = \frac{\sum_{j=1}^{M} n(d_i, w_j) P(z_k \mid d_i, w_j)}{\sum_{i=1}^{N} \sum_{j=1}^{M} n(d_i, w_j)}. \quad (7)$$

(3) Iteration termination condition is as follows:

After initializing $P(z \mid d)$ and $P(w \mid z)$, the EM algorithm alternately performs E and M steps for iterative calculation and generates new $P(z \mid d)$ and $P(w \mid z)$ until $E(L)$ reaches convergence:

$$E(L) = \sum_{i=1}^{N} \sum_{j=1}^{M} n(d_i, w_j) \sum_{k=1}^{K} P(z_k \mid d_i, w_j) \log \left[P(w_j \mid z_k) P(z_k \mid d_i) \right]. \quad (8)$$

PLSA is mainly divided into two processes of training and testing in image quality evaluation. Among them, in the training process, the visual words and the visual word distribution under each latent semantics are obtained by extracting features and clustering from the training image set. In the testing process, the latent semantic distribution of the test image set is compared with the latent semantic distribution of the reference image, and then the quality score of the image is obtained. The specific process is shown in Figure 2.

It can be seen from Figure 2 that the image quality score is obtained by calculating the semantic similarity of the latent semantic distribution $P(z \mid d_{train})$ of the training image set and the latent semantic distribution $P(z \mid d_{test})$ of the test image set. The specific process is to separately propose the latent semantic distribution of the undistorted image and calculate the average value of the latent semantic distribution according to formula (9) as a reference value for comparison. The specific process is to separately propose the latent semantic distribution of the undistorted image and calculate the average value of the latent semantic distribution according to formula (9) as a reference value for comparison. Here, N_p is the number of reference images.

$$P_G = \frac{1}{N_P} \sum_{i=1}^{N_P} P(z \mid d_i). \tag{9}$$

There should be a certain nonlinear relationship between the subjective data and the objective data of image quality evaluation. Generally, the nonlinear function selected should be monotonous, and it is best to avoid data overfitting. Therefore, this paper uses the commonly used logarithmic regression function for fitting, and the function expression is

$$SS_p = f(OS) = \frac{b_1}{1 + \exp(b_2 * (OS - b_3))} + b_4 * OS + b_5. \tag{10}$$

Here, f represents the nonlinear relationship, SS_p is the fitted value, that is, the predicted subjective quality value, which is a deformation of OS, and OS is the objective evaluation value. b_1, b_2, b_3, b_4, b_5 can be obtained by fitting. Figure 3 shows the prediction accuracy of the subjective MOS value, where the curve is the fitting curve of the nonlinear regression function, and the scattered points near the curve represent the data pair (OS, SS_P).

In Figure 3, the smaller the error between SS_P and MOS, the higher the accuracy of the algorithm. Currently, the commonly used method is taken from the performance evaluation algorithm proposed by the Video Quality Evaluation Group (VQEG). That is, the five indicators of Pearson correlation coefficient (CC), root mean square error (RMSE), average absolute error (RMSE), Spearman rank correlation coefficient (ROCC), and rate of dispersion (OR) are used as methods to evaluate the accuracy of the algorithm:

The Pearson correlation coefficient (CC) is

$$CC = \frac{\sum_{i=1}^{n} (X_i - \overline{X})(Y_i - \overline{Y})}{\sqrt{\sum_{i=1}^{n} (X_i - \overline{X})^2 \sum_{i=1}^{n} (Y_i - \overline{Y})^2}}. \tag{11}$$

Here, X_i and Y_i are subjective and objective evaluation scores, respectively, and $\overline{X}$ and $\overline{Y}$ are, respectively, the mean value of subjective and objective evaluation.

(2) The root mean square error (RMSE) is

$$RMSE = \sqrt{\frac{1}{n} \sum_{i=1}^{n} (X_i - Y_i)^2}. \tag{12}$$

Here, X_i is the subjective evaluation score, and Y_i is the SS_P value.

(3) The average absolute error (MAE) is

$$MAE = \frac{1}{n} \sum_{i=1}^{n} |X_i - Y_i|. \tag{13}$$

Here, X_i is the subjective evaluation score, and Y_i is the SS_p value.

(4) The Spearman rank correlation coefficient (ROCC) is

$$ROCC = 1 - \frac{6 \sum_{i=1}^{n} (RX_i - RY_i)^2}{n(n^2 - 1)}. \tag{14}$$

Here, RX_i and RY_i, respectively, represent the data after the subjective and objective scores are sorted in the same order.

(5) The dispersion rate is

$$OR = \frac{n_{owt}}{n}. \tag{15}$$

Here, n_{out} is the number of points where the deviation between the fitted value and the subjective value is greater than 1.5.

In formula (11), the Pearson correlation coefficient can measure whether two data sets are on a straight line. The greater the absolute value of the correlation coefficient, the stronger the correlation. The root mean square error in formula (12) can measure the deviation between the predicted value and the subjective value. The smaller the deviation, the better the algorithm performance. The Spearman rank correlation coefficient in formula (14) can measure the monotonicity of two data sets. The larger the absolute value of ROCC, the stronger the monotonicity. The smaller the OR in formula (15), the higher the degree of aggregation of the algorithm. Therefore, the larger the value of CC and ROCC, the better the performance of the image quality evaluation algorithm. The smaller the MAE, RMSE, and OR, the worse the image quality evaluation algorithm.

Image semantics is the basic description carrier of image information content. It can convert the complete image content into an intuitively understandable text-like language expression. It is the high-level content in the field of image research and plays a vital role in the objective quality evaluation of images.

In the PLSA-based image quality evaluation, the specific application of image semantics reflects two aspects. One

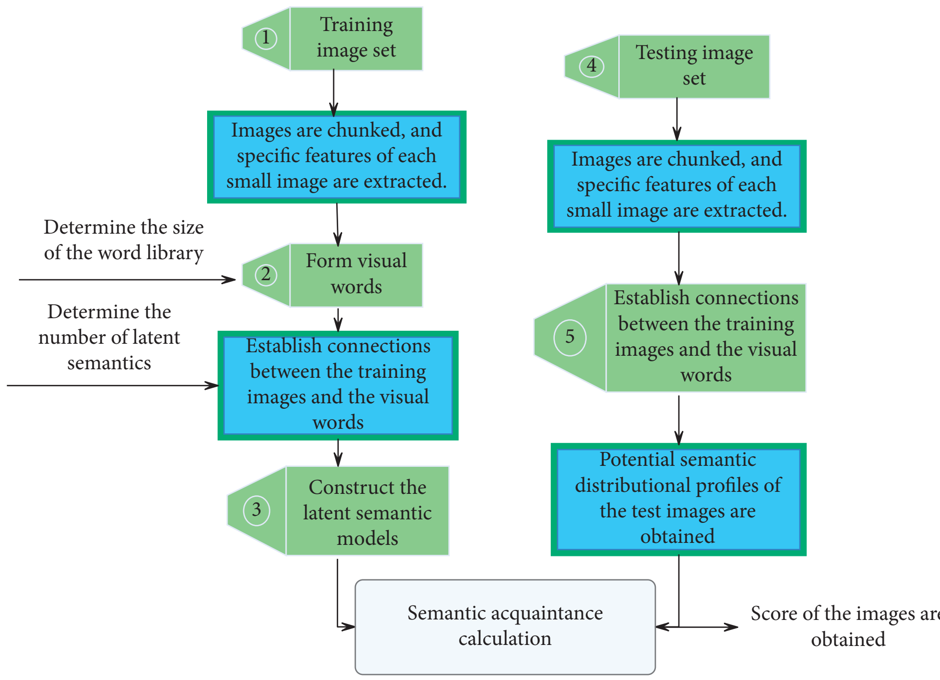

Figure 2: Flowchart of image quality evaluation.

aspect is the construction of the model. That is, after the low-level feature extraction is performed on the undistorted images and training images, the semantics are implicitly incorporated into them. This maps the high-dimensional "image-visual word" cooccurrence matrix to the low-dimensional space, thereby establishing a probability model between "image-latent semantics-visual word." On the other hand, it is reflected in the analysis of semantics, that is, the measurement of semantic similarity. Based on the rule that the latent semantic distribution of distorted images of the same type and level has similar laws, the latent semantic distribution of distorted images of different types or different levels often has certain differences. The semantic similarity measure takes the latent semantic distribution $P_{pristine}(z \mid d)$ of the undistorted image as the criterion for evaluation and comparison and then compares it with the latent semantic distribution $P_{\text{test}}(z \mid d)$ of the test image to obtain the objective score of the image. Therefore, choosing a reasonable semantic similarity measurement method is the final key step to obtain a better image quality evaluation algorithm.

For a given distorted image, this paper first calculates the normalized brightness through local mean subtraction and standardized splitting.

Ruderman believes that a local nonlinear operator can be added to the logarithmic ratio brightness to remove the local mean deviation and the standardized local variance, and there is no correlation between the two. This operator can be obtained from a given image:

$$\widehat{I}(i,j) = \frac{I(i,j) - \mu(i,j)}{\sigma(i,j) + C}. \tag{16}$$

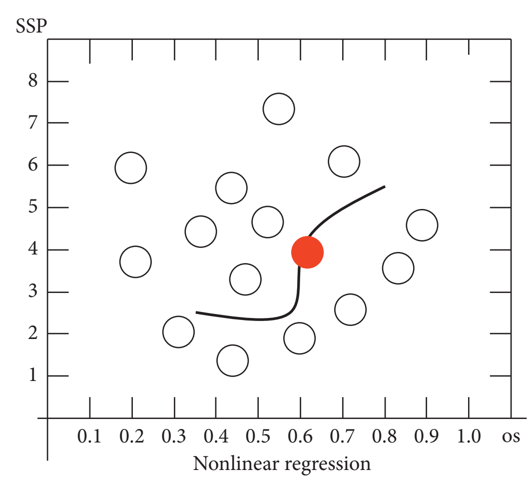

Figure 3: Accuracy map of subjective MOS prediction.

Here, $i \in 1, 2 \ldots M$, $j \in 1, 2 \ldots N$.M, N is the height and width of the image. $C = 1$ is a constant, because when the denominator approaches 0, $C = 1$ can prevent system instability.

$$\begin{aligned} \mu(i,j) &= \sum_{k=-K}^{K} \sum_{l=-L}^{L} \omega_{k,l} I_{k,l}(i,j), \\ \sigma(i,j) &= \sqrt{\sum_{k=-K}^{K} \sum_{l=-L}^{L} \omega_{k,l} \left(I_{k,l}(i,j) - \mu(i,j)\right)^2}. \end{aligned} \tag{17}$$

Here, $\omega = \{\omega_{k,l} \mid k = -K, \ldots, K, l = -L, \ldots, L\}$, and ω is a set of two-dimensional circularly symmetric Gaussian weight functions.

Ruderman also observed that the normalized brightness value of natural images tends to unit Gaussian features, and this feature can be used in the contrast gain mask processing model in early human vision. In the image quality evaluation system, the brightness value $\widehat{I}(i, j)$ can be converted into MSCN (mean subtracted contrast normalized) coefficients. In the picture shown on the left picture of Figure 4, it can be seen that there is a relatively high correlation between adjacent pixels, and a diagonal structure is observed in the left picture. As shown on the right side of Figure 4, the normalization method reduces the correlation between adjacent pixels of the image.

Of course, this problem can be solved by modulating the matrix of the topic distribution probability under each image, but this also causes the score of the test image to exceed the score of the reference image. Therefore, it is unreasonable. This also shows that, to some extent, KL distance is actually not suitable as a semantic similarity algorithm for image quality evaluation. However, Hellinger distance does not have this problem. Hellinger distance is to calculate the square of the difference between P_G and $P(z \mid I)$, so we only need to subtract the two matrices and then square each element, and we do not need to consider other factors. Therefore, Hellinger distance is more suitable for image quality evaluation than KL distance, and it can be used as a semantic similarity algorithm together with cosine similarity in image quality evaluation.

The MSCN coefficient has the characteristic of changing with the distortion, and this feature can ensure that the distortion type that affects the image quality is predicted through the image distortion change. The distribution of MSCN coefficients of blur features (blur) is closer to the Laplacian feature, while the distribution of MSCN coefficients of white noise (wn) reduces the weight of the tail of the histogram. The generalized Gaussian distribution (GGD) can effectively capture the statistical characteristics of the distorted image, and its zero-mean expression is as follows:

$$\begin{aligned} f\left(x; \alpha, \sigma^2\right) &= \frac{\alpha}{2\beta\Gamma(1/\alpha)} \exp\left(-\left(\frac{|x|}{\beta}\right)^{\alpha}\right), \\ \beta &= \sigma\sqrt{\frac{\Gamma(1/\alpha)}{\Gamma(3/\alpha)}}, \\ \Gamma(a) &= \int_0^{\infty} t^{a-1} e^{-t} dt \quad a > 0. \end{aligned} \tag{18}$$

Here, $\Gamma(.)$ is the gamma function. Since the coefficient distribution is symmetric, it can be described by the zero-mean GGD distribution. Among them, the parameter (α, σ^2) of the GGD distribution can be fitted by the time-moment matching method.

In fact, in the GGD distribution model of the reference image and the distorted image, the parameter settings are almost the same. For each image, the MSCN coefficient can be fitted by estimating the two parameters (α, σ^2) in the GGD distribution model. These two parameters form the first two dimensions of the multidimensional feature and are used to capture the distortion type of the image. As for the other several-dimensional features of multidimensional features, the asymmetric generalized Gaussian distribution model can be used, and its formula is as follows:

$$f\left(x; \nu; \sigma_l^2; \sigma_r^2\right) = \begin{cases} \dfrac{\nu}{(\beta_l + \beta_r)\Gamma(1/\nu)} \exp\left(-\left(\dfrac{-x}{\beta_l}\right)^{\nu}\right), \\ \\ \dfrac{\nu}{(\beta_l + \beta_r)\Gamma(1/\nu)} \exp\left(-\left(\dfrac{-x}{\beta_r}\right)^{\nu}\right), \\ \\ x \geq 0. \end{cases} \tag{19}$$

Here,

$$\begin{aligned} \beta_l &= \sigma_l\sqrt{\frac{\Gamma(1/\nu)}{\Gamma(3/\nu)}}, \\ \beta_r &= \sigma_r\sqrt{\frac{\Gamma(1/\nu)}{\Gamma(3/\nu)}}. \end{aligned} \tag{20}$$

ν is the shape parameter of the image, which determines the distortion type of the image, and ${\sigma_l}^2$ and ${\sigma_r}^2$ are the scale parameters that control the distribution of each side of the model. In fact, the AGGD model is a generalization of the GGD model. The reason is that the AGGD model is mainly for the asymmetric MSCN coefficient distribution, and the slope of the distribution is an equation about the left and right scale parameters. When $\sigma_l^2 = \sigma_r^2$, the AGGD model is transformed into the GGD model. When $\eta = (\beta_r - \beta_l)(\Gamma(2/\nu))/(\Gamma(1/\nu))$, the parameters $(\eta, \nu, \sigma_l^2, \sigma_r^2)$ of the best AGGD model can be fitted.

Due to the existence of image distortion, adjacent MSCN coefficients will show a certain "structure." Therefore, this "structure" can be obtained by calculating the statistical relationship between adjacent pixels in the four directions of the horizontal direction (H), vertical direction (V), main diagonal (D1), and subdiagonal (D2), as shown in Figure 4 and formula (21).

$$\begin{aligned} H(i, j) &= \widehat{I}(i, j)\widehat{I}(i, j + 1), \\ V(i, j) &= \widehat{I}(i, j)\widehat{I}(i + 1, j), \\ D1(i, j) &= \widehat{I}(i, j)\widehat{I}(i + 1, j + 1), \\ D2(i, j) &= \widehat{I}(i, j)\widehat{I}(i + 1, j - 1). \end{aligned} \tag{21}$$

In this way, the abovementioned four directions are considered at the same time, and each direction is described by four parameters; that is, a total of 16 parameters constitute the 16-dimensional feature of the image.

Since human vision is multiscale, when people are observing images, the acquisition of image feature information will be interfered by scales. According to recent research on image quality evaluation, the quality evaluation algorithm combined with multiscale information can better express the correlation with human perception. Therefore, two scales of the original image and the reduced one-time image can be used to extract a total of 36-dimensional features of the image.

4. The Multimedia-Assisted Ancient Poetry Teaching System Based on AI Technology

The learning system creates virtual characters in the first person by default, and learners roam and learn in the virtual scene according to the prompts. The overall technical block diagram of the system is shown in Figure 5.

Through the intelligent teaching system, it is helpful to mobilize students' enthusiasm and initiative in the classroom, to improve their learning efficiency, and to cultivate students' practical ability and innovation ability. The overall design framework of the system is shown in Figure 6.

This paper uses Proteus and Keil software to build an embedded system virtual simulation platform. The simulation process of 5l one-chip computer embedded system is shown as in Figure 7. First, this paper uses Proteus to draw a schematic diagram, selects Keil software to design the source code, then compiles the code, generates the target file, and then loads the HEX file in the Proteus software.

This research designs its system architecture for VR/AR teaching needs. It mainly describes the abstract components that directly constitute the VR/AR teaching system, including VR/AR teaching research architecture, VR/AR teaching design and teaching strategy framework, and VR/AR education resource engineering framework. The specific research content is shown in Figure 8.

The AR/AR space layer contains various learning spaces of the system, including VR direct interaction space, AR superimposed space, morphological space, and virtual-real interlaced space. These spaces can be divided into four types according to their structure and properties: isomorphism and homogeneity, heterogeneity and homogeneity, isomorphism and heterogeneity, and heterogeneity and heterogeneity. In addition, the VR space also reflects the bearing relationship between people/story and space. There are four relationships between them: 1 : 1, 1 : N, N : 1, and N : N. It is one person and one space, one person and multiple spaces, multiple people and one space, multiple people and multiple spaces, one story and one space, one story and multiple spaces, multiple stories and one space, and multiple stories and multiple spaces. In the space, learners complete their own learning process through fixed navigation, adaptive navigation, and creative navigation, as shown in Figure 9.

This paper takes "Wanglu Mountain Waterfall" as an example to conduct multimedia-assisted research on ancient poetry teaching, and its image processing is shown in Figure 10.

Through the analysis of Figure 10, it can be seen that the multimedia-assisted artistic conception creation system of ancient poetry based on AI technology can basically meet the

teaching needs. On this basis, this paper conducts research on the performance of the system and counts the immersion and teaching effect brought by the system to students. The results are shown in Tables 1 and 2.

From the above research, we can see that the multimedia-assisted artistic conception creation system of ancient poetry proposed in this paper has a good teaching effect and has an important role in promoting the study of the artistic conception of ancient poetry.

5. Conclusion

The linguistic features of ancient poems are very obvious; generally each sentence does not exceed seven characters. In a brief narrative, it either portrays a magnificent scene or a melancholy picture, which depends entirely on the author's thoughts and feelings at the time and the theme of the work itself. Therefore, ancient poems are an important form of writing in ancient China, and they are also of great significance in contemporary times. Many of the profound ideas still have reference significance today. This paper combines AI technology to improve the multimedia teaching mode, improve the effect of multimedia-assisted ancient poetry teaching, and lay the foundation for the subsequent improvement of the quality of ancient poetry teaching. The research shows that the multimedia-assisted artistic conception creation system of ancient poetry proposed in this paper has a good teaching effect and plays an important role in promoting the study of the artistic conception of ancient poetry.

China is experiencing a serious aging crisis, with the number of elderly people rising at an unprecedented rate. First and foremost, the pension industry's service object is the pension. To build an old-age industry complex, make use of the unique natural resources in the countryside, provide the original ecological old-age care services, and transform, optimize, and make efficient use of the existing policies and technologies. The drawbacks of the traditional pension model are becoming increasingly apparent. We must investigate a new pension model in order to ensure the long-term development of China's pension system and reduce the increased pension burden on governments at all levels. The rural areas' unique natural resources should be utilized to provide unique ecological elderly care services, and transformation and optimization must be implemented (that is, making efficient use of existing policies and technology to construct an elderly care industry complex). As a new pension mode for the elderly to become more connected to the natural world and improve their physical and mental health, ecological pensions have emerged as a new economic growth point that can fill the gap in the pension industry's supply while also meeting the elderly's growing spiritual and cultural needs. A constrained clustering algorithm is proposed in this article. Unsupervised learning is used in the constrained clustering algorithm. The clustering algorithm must determine the data objects to be clustered because they are not labeled. Because the data objects have no prior knowledge, the clustering algorithm analyzes them using the same principles. The effectiveness of the clustering results is determined by the dataset's adherence to the previously stated principles. The constrained clustering algorithm has greatly improved the transformation and optimization of the rural ecological elderly care industrial chain.

1. Introduction

With the deepening of China's aging population, the pension industry has gradually become a new sunrise industry, with an immeasurable development prospect [1]. China has been involved in a serious wave of aging, and the number of elderly people is increasing at an unprecedented rate. The existing old-age care institutions are far below the actual expectations of the people in terms of number and service quality [2]. The number of people over 60 years old will increase from 178 million to 221 million, with an average annual increase of 8.6 million. The proportion of the elderly population will increase from 13.3% to 16%, with an average annual increase of 0.54 percentage points. According to the forecast of the National Bureau of Population Statistics, by 2050, China's elderly population will reach 437 million, accounting for 30% of the total population, and the number will exceed the sum of the elderly population of developed countries in the world [3]. China is about to become a highly aging society, and the problem of providing for the aged has seriously restricted the development of China's economy. From the whole development process and coverage of the old-age care industry, it can be shown that the main characteristics of the old-age care industry are wide coverage, long industrial chain, sustainability, and environmental friendliness. First of all, the service object of the pension industry is pension. We made use of the unique natural resources in the countryside, provided the original ecological old-age care services, and transformed, optimized, and made efficient use of the existing policies and technologies to build an old-age industry complex [4]. The disadvantages of the traditional old-age care model are becoming more and more obvious. In order to make the long-term development of China's old-age care reduce the burdens of the old-age care on the governments at all levels, which are getting heavier and heavier, we must explore a new old-age care model [5]. Old-age care mainly includes family care, community care, and institutional care. Institutional care in real life includes pension yuan, nursing homes, and apartments for the elderly. These institutions are either public institutions or private institutions that provide old-age care services. As a new old-age care model, ecological old-age care, which enables the elderly to get close to the ecological environment and gain physical and mental health, has become a new economic growth point. Comparatively speaking, the investment risk of social capital is relatively high, and a complete mature model of investment in old-age care institutions has not yet been formed and most of the capital is still on the sidelines, which make it difficult for the government to really implement measures to encourage social forces to enter the old-age care industry [6, 7].

The clustering method is an unsupervised learning method. The data objects to be clustered are unmarked and need to be determined by the clustering algorithm itself. Because there is no background knowledge about data objects, the clustering algorithm uses the same principles to analyze these data, and whether the clustering results are effective depends on the degree to which the dataset conforms to the preestablished principles [8]. Clustering is the process of dividing objects into similar object classes according to some attributes of objects [8]. The goal of clustering is to make the objects in the class as similar as possible and the objects between classes as different as possible. Unlike classification [9–11], clustering usually has no prior knowledge or background knowledge as guidance. It is an automatic recognition [12] and unsupervised learning process based on object similarity [13].

The selection of cluster centers is based on the direction relationship instead of random selection, which makes the selection of cluster centers have good distribution and avoids the decrease of convergence speed caused by the concentration of cluster center distribution. Clustering with constraints refers to the method of expressing specific domain knowledge in the form of "constraints" and embedding it into the clustering process [14, 15]. Because of the use of domain knowledge, the clustering algorithm can obtain more heuristic information, thus reducing the "blindness" in its search process and improving the efficiency and clustering quality. Clustering with constraints refers to the method of expressing specific domain knowledge in the form of constraints and embedding it into the clustering process [16]. Because of the use of domain knowledge, the clustering algorithm can obtain more heuristic information, thus reducing the "blindness" in its search process and improving the efficiency and clustering quality. Supervised learning methods [17–19] require each data record to have a class label, while unsupervised learning methods do not consider any guiding information [20, 21]. Because users often have clear application requirements, in many practical applications, effective solutions tend to add user preferences or constraints to the clustering process, which has an important impact on the results of knowledge discovery and helps us find the knowledge patterns that users are interested in or more in line with users' needs. After the constrained clustering algorithm, through the analysis of the decision graph, a series of data points that may be the center of the cluster are selected in various ways, which is called the initial center point. The number of initial center points may be more than the real number of clusters, but the initial center points must be local high-density points in the data. By selecting the initial center point, the potential hierarchical structure information of the system can be extracted, which can serve as a heuristic for subsequent clustering [22].

2. Related Work

Literature [23] pointed out that the combination of specialization and integration, the combination of public welfare and marketization, the combination of real estate sales and diversified business, and the combination of independent management and cooperative management should be emphasized in the marketization strategy. In literature [24], through the method of big data analysis, the current old-age policy is not working well at present, the change of family structure has a double influence on old-age care, and the existing old-age care in rural areas is still dominated by families, so the old-age care in rural areas during the social transformation period needs policy support. In literature [25], building and optimizing the pension industry chain is an effective way to promote the healthy and long-term development of China's pension industry, and the key lies in the optimization and integration of the pension industry chain. At present, the definition of industrial chain risk has not reached an agreement in domestic and foreign academic circles. However, for the specific industrial chain, scholars have given a definition of industrial chain risk with strong pertinence but narrow applicability. Literature [26] pointed out that the strategy of healthy China and rural revitalization clearly highlighted the concept of coordinated development of healthy old-age care and rural revitalization in the elaboration of the implementation framework of the two strategies. In literature [27], through the big data analysis method, China has been involved in a serious wave of aging, the number of the elderly population is increasing at an unprecedented rate, and the existing elderly care institutions are far from the actual elderly care service expectations of the people in terms of number and service quality. How to collect the actual needs of the elderly population has become one of the difficulties in implementing such a platform. Literature [28] pointed out that the disadvantages of the traditional pension model are becoming more and more obvious. In order to make the long-term development of China's pension reduce the heavier pension burden of governments at all levels, we must explore a new pension model. Literature [28] stated that the construction of leisure agriculture and rural tourism provides better methods for elderly care services. In literature [29], through the big data analysis method, the current willingness of the elderly to choose elderly care institutions for the elderly shows an increasing trend. It is considered that the reasons restricting the economic growth of China's pension institution industrial chain include income level and capital source. The effective way of economic growth of pension institution industrial chain in the future should take the road of industrialization development. Literature [30] showed the agricultural development of the central region, analyzed the main problems and obstacles it faces, advocated the establishment of a reasonable responsibility-sharing mechanism to support the development of agricultural product processing industry, improved rural infrastructure construction, and realized the sustainable and stable development of agriculture. Literature [31] pointed out that for the elderly lifestyle, old customers mostly choose apartments or elderly care centers, followed by hotels and restaurants, which is related to the frugal consumption mentality of the elderly.

3. Constrained Clustering Algorithm

3.1. Definition of Constrained Clustering. Constrained clustering refers to a method in which specific domain knowledge is expressed in the form of "constraints" and embedded in the clustering process. $\mathrm{CCD}_{\mathrm{default}}$ refers to the updated value, that is, the updated value of enterprise industrial chain tightness calculated regularly through supply chain relevance, enterprise chain relevance, value chain relevance, and spatial chain relevance $(Cl_1, Cl_2, \ldots, Cl_k)$, so that the objective function $\mathrm{DISP} = \sum_{i=1}^{k} \mathrm{disp}\,(Cl_i, \mathrm{rep}_i)$ is the smallest, and each class satisfies constraint c. Among them, $\mathrm{disp}(Cl_i, \mathrm{rep}_i)$ is defined as $\sum_{p \in Cli} df\,(p, \mathrm{rep}_i)$.

According to the rural ecology, the algorithm formula of correlation degree of pension industry chain is deduced as follows:

$$\begin{aligned}\mathrm{OCD} = \mathrm{CCD}_{\mathrm{default}} + \mathrm{CCD}_{\mathrm{default}} = \mathrm{CCD}_{\mathrm{default}} \\ + f\,(\mathrm{SCD}, \mathrm{ECD}, \mathrm{VCD}, \mathrm{RCD}).\end{aligned} \tag{1}$$

$\mathrm{CCD}_{\mathrm{default}}$ refers to the default value, that is, the initial value of the algorithm calculated according to the basic information of the enterprise. $\mathrm{CCD}_{\mathrm{default}}$ refers to the updated value, that is, the updated value of enterprise industrial chain tightness calculated regularly through supply chain relevance, enterprise chain relevance, value chain relevance, and spatial chain relevance. According to the above $\mathrm{CCD}_{\mathrm{default}}$ calculation principle, the $\mathrm{CCD}_{\mathrm{default}}$ decomposition formula is derived as follows:

$$\mathrm{CCD}_{\mathrm{default}} = \sum_{i=1}^{n} B_i \times W_i, \tag{2}$$

where n represents the amount of enterprise basic resource information involved in the calculation; it means the evaluation parameter calculated by the Ith basic resource information of B_i according to the set judgment conditions, which should meet $0 \leq B_i, \leq 1$. It indicates the importance percentage of the Ith basic resource information in the basic information of the enterprise. All the importance percentages must meet the following conditions: $0 \leq W_i \leq 1$, $W_1 + W_2 + \cdots + W_n = 1$.

According to the above description of the four dimensions of the industrial chain, $\mathrm{CCD}_{\mathrm{default}}$ is composed of four basic parameter combinations: SCD, ECD, VCD, and RCD. Set the importance percentage of these four basic parameters in $\mathrm{CCD}_{\mathrm{default}}$ as $\alpha, \beta, \gamma, \vartheta$, respectively, and then use the following formula

$\mathrm{CCD}_{\mathrm{update}}$ can be derived as follows:

$$\begin{aligned}CCD_{\mathrm{update}} &= f\,(SC\,D, EC\,D, VC\,D, RC\,D) \\ &= \alpha \times SC\,D + \beta \times EC\,D + \gamma \times VC\,D + \vartheta \times RC\,D.\end{aligned} \tag{3}$$

$\alpha, \beta, \gamma, \vartheta$ shall meet the following conditions: $0 \leq \alpha, \beta, \gamma, \vartheta \leq 1$, $\alpha + \beta + \gamma + \vartheta = 1$.

Constrained clustering algorithm has made progress in solving scalability, but these features are not available in clustering algorithms in the field of statistics or machine learning. It is a hybrid clustering method based on grid and density, which better meets the above requirements. In a high-dimensional space, it can effectively cluster and find clusters nested in the subspace of high-dimensional data space. The basic idea of the algorithm is to combine the constraint condition with the antimonotone property of the constrained clustering algorithm and jointly use it to prune the candidate clusters, reduce the blindness in the searching process of the constrained clustering algorithm, and improve its efficiency and clustering quality. The general framework of the algorithm is shown in Figure 1.

Constraints, for instance, pairs, can be determined by parameters (Con = : Must-Link constraint set, con ≠: cannot-link constraint set). For example, in pair constraints, the basic idea of constraint clustering algorithm is as follows:

(i) Firstly, scan the dataset D and cluster it on K 1-dimensional spaces
(ii) Select dimension $D_{\min}$ with the smallest number of classes in K 1-spaces
(iii) The condition dense elements on $D_{\min}$ are obtained by imposing constraints on $D_{\min}$
(iv) Candidate dense cells are generated by using conditional dense cells on attribute $D_{\min}$ and other dense cells in $(k-1)$ 1-dimensional spaces
(v) The following steps are the same as those of the constrained clustering algorithm

3.2. Constraint Types and Algorithms. Domain knowledge is a very big concept, and there is almost no unified expression form. It can be expressed in various forms. In addition to the guidance form of "class label," there is information about the structure of the problem, heuristic guidance rules, the relationship between data objects, or the combination of the

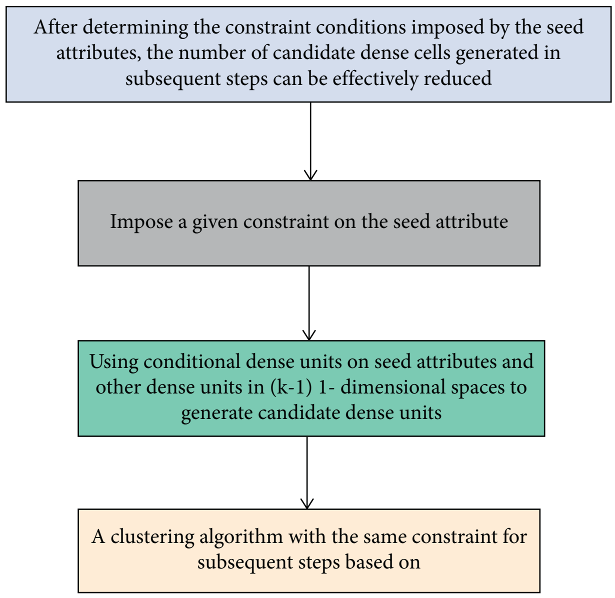

Figure 1: Overall framework of the constrained clustering algorithm.

above forms. The selection of central objects in the constrained clustering algorithm is random. If the randomly selected central objects are concentrated, the number of iterations to form the final partition may be increased, which affects the clustering speed. Therefore, selecting an appropriate central object can speed up the convergence of the algorithm. Since all spatial objects have spatial relationships, the appropriate central object can be selected according to the directional relationship of the residential object. According to the constraint clustering algorithm and matching algorithm, the association compactness of the pension industry chain is sorted from high to bottom. The ranking results of the association compactness of the pension industry chain are shown in Figure 2.

Then, combined with the enterprise reputation model, the optimized constrained clustering algorithm is used to calculate the association tightness of the elderly care industry chain. The numerical comparative analysis results before and after are shown in Figure 3.

Our algorithm is based on a mathematical morphology clustering algorithm. The obstacle constraint and the idea of dealing with the obstacle constraint are introduced. It not only has the advantages of a mathematical morphology clustering algorithm but also has low complexity. It can find clusters of arbitrary shapes. Moreover, the data on both sides of the obstacle can be effectively divided into different classes. The algorithm involves linear obstacles in two-dimensional space, and planar obstacles are considered as polygons surrounded by multiple linear obstacles. According to the scope of objects imposed by constraints, it can be divided into the following four categories:

(i) Global-level constraints work on the data objects participating in clustering.

(ii) Cluster-level constraints are constraints for each class, such as the number of data points owned in each class.

(iii) Feature-level constraint is a constraint applied to the features describing data. When the features meet certain conditions, some rules are enabled.

(iv) Instance-level constraints are for data objects or constraints between data objects.

4. Necessity of Transformation and Optimization of Pension Industry Chain

4.1. Definition of Constrained Clustering. With the increasing aging of the population, however, the contradiction between the growing demand for the aged and the traditional family pension has become increasingly prominent due to the change of family structure and the acceleration of population mobility. In the traditional old-age care service industry, public old-age care institutions are supported by the government's financial support, forming a situation of long-term dependence on the government, which is often only targeted at specific subsidy groups. The institutional old-age care model can no longer meet the needs of the elderly, and the ecological old-age care model will become the development trend. The old-age care industry provides professional social services for the elderly at home to meet the diversified needs of the old-age care services. However, with the increase of the immunization rate, the reduction rate of the spread range has dropped all the way, especially when the proportion of the node enterprises implementing immunization exceeds 0.08, the reduction rate of the spread range has obviously slowed down. As shown in the figure, the risk spread range caused by $h = 08.0$, $h = 1.0$, and $h = 12.0$ has little difference. It can be seen that there is a threshold value for the proportion of immune enterprises when implementing the target immunization strategy for key node enterprises. In the aging population, accelerating family structure, and population mobility, the contradiction between the ever-increasing needs of providing for the aged and family support has become increasingly prominent. Social institutions for the aging population have been unable to meet the needs of providing for the elderly, and the way of providing for the aged population at home will become the future development trend. A municipal committee on aging released an analysis report chart of the aging situation of a certain population from 2015 to 2020. The latest data show that as of the end of 2019, the aging population in a certain city has increased the most. as shown in Figure 4.

According to the statistics in the table, the city has already entered an aging society, and the degree of aging is gradually deepening. The problem of population aging has profoundly impacted the social life, economic development, and cultural development of Wuhan. At the same time, it also puts forward tests and requirements for the social welfare and security system. Positive measures must be taken in the fields of pension medical care and pension insurance, and pension culture. In the process of sustainable social and economic development, transforming and optimizing industries can drive other industries in society. The pension industry intersects with many industries. For the special consumer groups of the elderly, the development of the pension industry can not only meet the pension needs of the elderly but also effectively stimulate domestic demand. The

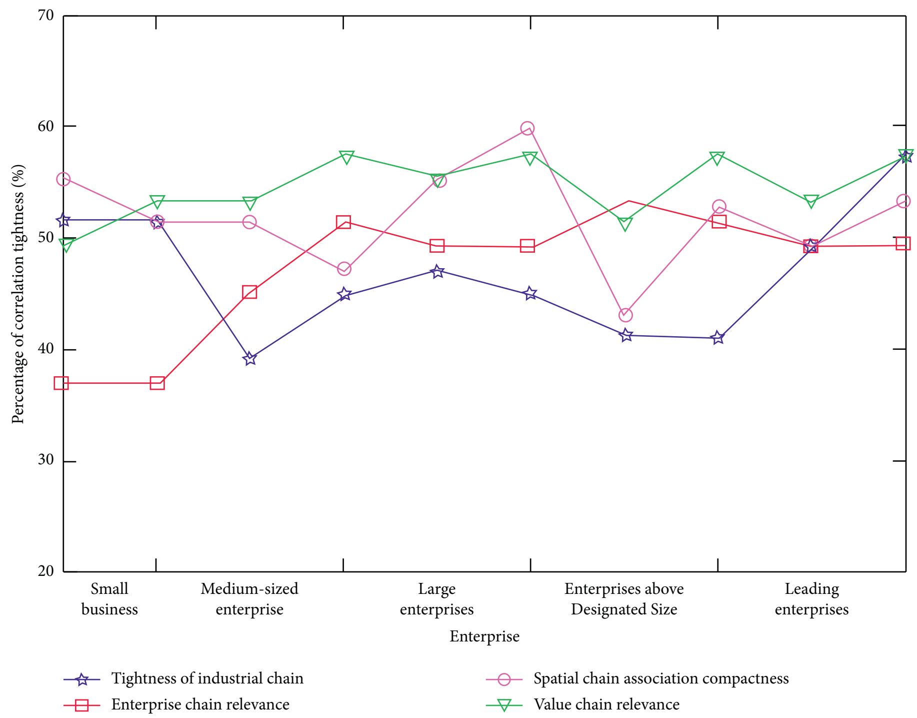

Figure 2: Ranking diagram of correlation degree of pension industry chain obtained by the constrained clustering algorithm.

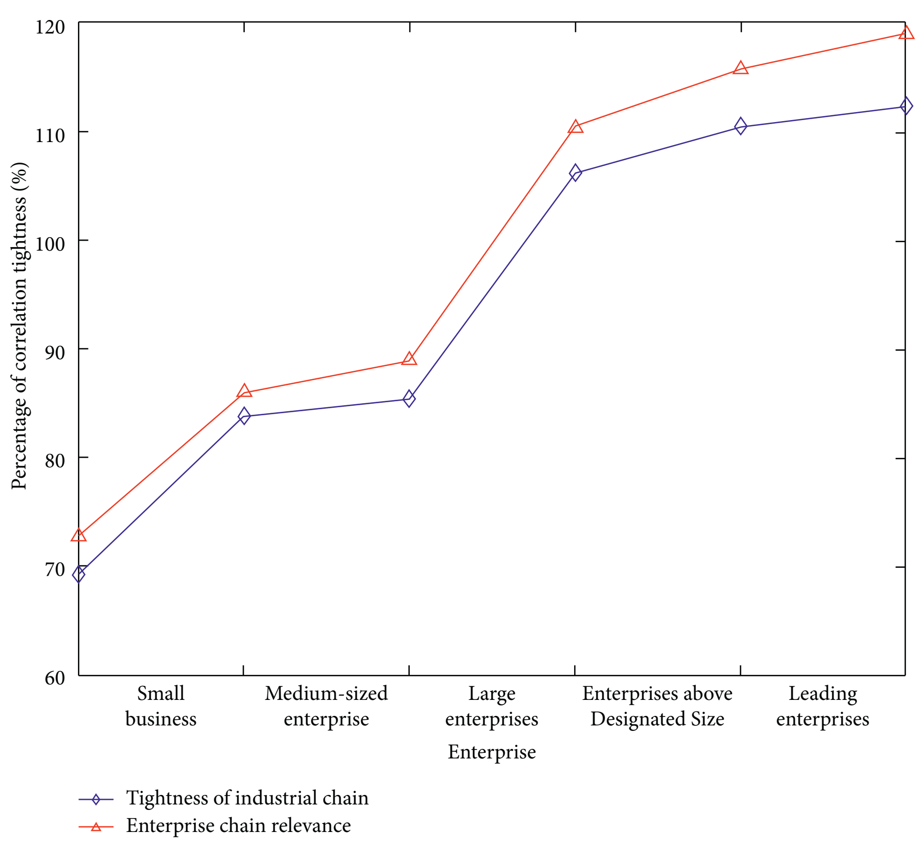

Figure 3: Comparison chart of correlation degree of pension industry chain before and after optimization.

change of risk propagation range of complex network of rural ecological elderly care industry chain based on target immunity and random immunity is shown in Figure 5.

It can be seen that the scope of risk spread has obviously shrunk after targeted immunization of industrial chain networks, with an average drop of more than 26%. However,

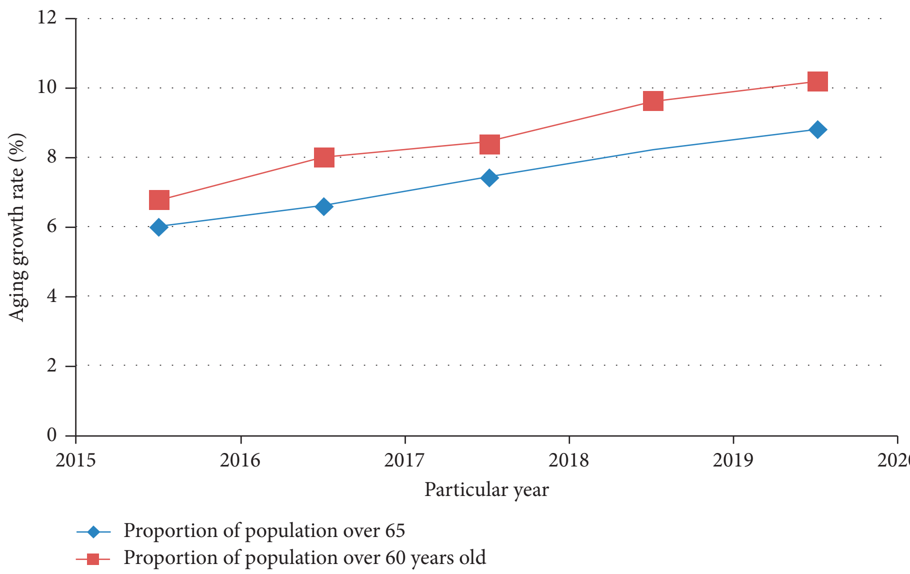

FIGURE 4: Population aging growth rate of a city.

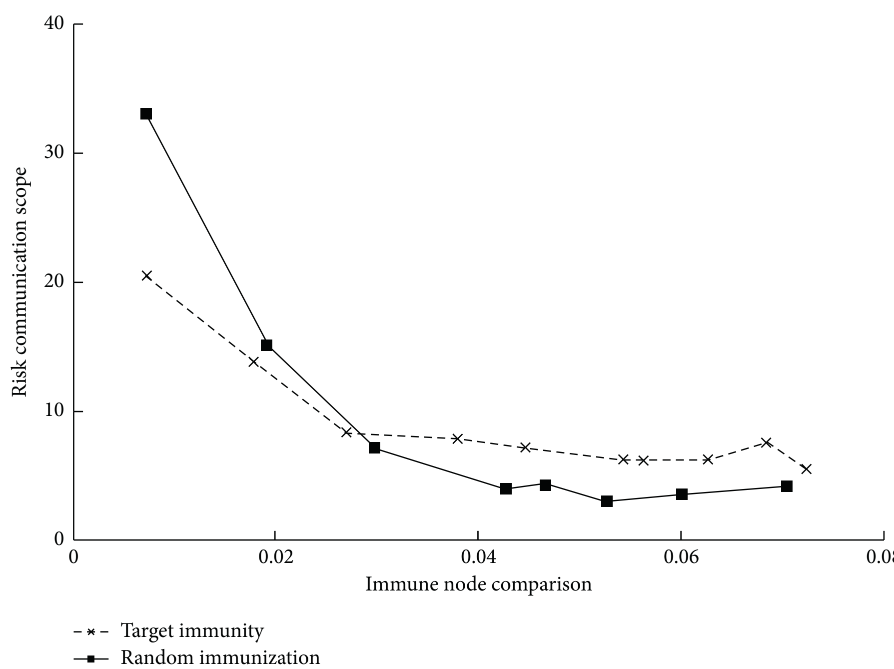

FIGURE 5: Change of risk transmission effect of pension industry chain under target immunization.

with the increase of the immunization rate, the reduction rate of the spread range has dropped all the way; especially when the proportion of the node enterprises implementing immunization exceeds 0.08, the reduction rate of the spread range has obviously slowed down. As shown in the figure, the risk spread range caused by $h = 08.0$, $h = 1.0$, and $h = 12.0$ has little difference. It can be seen that there is a threshold value for the proportion of immune enterprises when implementing the target immunization strategy for key node enterprises. When the proportion of immune enterprises is less than the threshold value, the control effect of industrial chain risk transmission is very obvious with the increase of the proportion. When the proportion of immune enterprises is greater than the threshold value, increasing the immune enterprises does not cause a significant reduction in the scope of risk transmission.

Private old-age care institutions built by social forces are difficult to maintain and operate, with few sources of funds, low profits, and no good industrialization form. The transformation and optimization of the old-age care industry should be accelerated, and high-quality life products and services for the elderly should be better provided. Comparatively speaking, the investment risk of social capital is relatively high, and a complete mature model of investment in old-age care institutions has not yet been formed, and most of the capital is still on the sidelines, which makes it difficult for the government to really implement measures to encourage social forces to enter the old-age care industry.

4.2. The Need to Promote Sustainable Socioeconomic Development. The transformation and optimization of the old-age care industry are critical engines for future economic growth, with a significant economic driving effect. The old-age care industry is a sunrise industry with many industries, and the old-age care industry's market supply system, which is generated by the satisfaction of six "old-age" needs, has a lot of room for growth. The old-age care industry has its own unique characteristics, and its core components are old-age care services and old-age care products, and the old-age care industry chain is comprised of many aspects of economy and society, a long industrial chain, reliance and interaction with the environment, and requirements for sustainable development. In a market economy, vigorously developing the pension industry is an unavoidable requirement for the development of population aging. The retirement industry will usher in a new era of rapid growth. As an emerging industry, The pension industry is critical to adjusting the industrial structure, improving employment rates, promoting coordinated economic and social development, and improving the socialist market economy. The chain of ecological pensions is usually in a state of rapid development. Although the market has recognized new products to some extent, more capital investment and technological advancement are still required to expand market share. Figure 6 depicts the parameters.

Let $U = [\mu_{ik}]_{c\times n}$ be a hard partition matrix, where C is the number of clusters, which is the number of samples. The cluster center point set of a partition $P=\{P_1, P_2, \ldots, P_C\}$. According to the sample division method, then

$$\mu_{ik} = \begin{cases} 1, & d_{pik} = \min\left\{d_{p1k}, d_{p2k}, \ldots, d_{pck}\right\}, \\ 0, & \text{Other}, \end{cases} \quad k = 1, 2, \ldots, n; \quad i = 1, 2, \ldots, c, \tag{4}$$

where d_{Pik} is the reachable distance between the sample X_k in class I and the center point pi of class I. If the sum of within-class squared errors (WGSE) is used as the clustering objective function, then the clustering objective function is as follows:

$$f(U, P) = \sum_{k=1}^{n}\sum_{i=1}^{c}\mu_{ik}\left(d_{pik}\right)^2. \tag{5}$$

If the natural coding scheme is adopted, the volume coding is

$$b = \left\{\text{Num}_{p1}, \text{Num}_{p2}, \ldots, \text{Num}p_{pi}, \ldots, \text{Num}_{pc}\right\}, \tag{6}$$

where $\text{Num}_{pi}\,(1 \le \text{Num}_{pi} \le n)$ means that the cluster center $p_i\,(i = 1, 2, \ldots, c)$ is taken from the Num_{pi} sample in the sample set. According to our knowledge of analytic geometry, the edges (x_i, x_j) and edges $(y_{km}, y_k(m+1))$ meet the following conditions:

$$\begin{cases} \left(a_l \times y_{kml} + b_{lkm2} + c_1\right) \times \left(\alpha_1 \times y_{k(m+1)l} + b_{lyk(m+1)2} + C_1\right) < 0, \\ \left(a_2 \times x_{i1} + b_2 x_{i2} + c_2\right) \times \left(\alpha_2 \times x_{j1} + b_2 x_{j2} + c2\right) < 0. \end{cases} \tag{7}$$

Based on the matching model of the same evaluation index, the following mathematical model is established:

$$\max \sum_{i=1}^{I}\sum_{j=1}^{J}\alpha_{ij} * x_{ij} + \sum_{i=1}^{I}\sum_{j=1}^{J}\beta_{ij} * x_{ij}, \tag{8}$$

$$0 < \sum_{j=1}^{I} x_{ij} \le p_i, \forall_i, j, \tag{9}$$

$$0 < \sum_{i=1}^{I} xi_j \le q_j, \forall i, j. \tag{10}$$

In the above model, (8) is the objective function, which means to maximize the total matching degree of matching parties as much as possible. Formula (9) means that the caregiver I matches pi loved ones at most. Formula (10) means that the cared-for j matches q_j caregivers at most. Moreover, (4) is a 0-1 decision variable.

Compared with the traditional elderly care industry, the ecological elderly care industry is a new industry that gives full play to the ecological advantages of resources and environment so as to meet the needs of elderly care and leisure services. This kind of industry has the characteristics of low-carbon and environmental protection. Through appropriate government guidance and policy support, the development of the pension industry is bound to inject new vitality into China's current economic development, promote new growth of the national economy, and further promote the sustainable development of the current economy and society.

4.3. The Need to Improve the Level and Efficiency of the Aged Care Service Industry. The development of China's pension industry lags behind, the supply of pension products and services is insufficient, and the pension industry chain is immature. Therefore, the transformation and optimization of the pension industry are imperative. It can be seen that the scope of risk spread has obviously shrunk after targeted immunization of industrial chain networks, with an average drop of more than 26%. In addition, the elderly care service is inseparable from the care and greetings of the elderly. When the proportion of immune enterprises is less than the

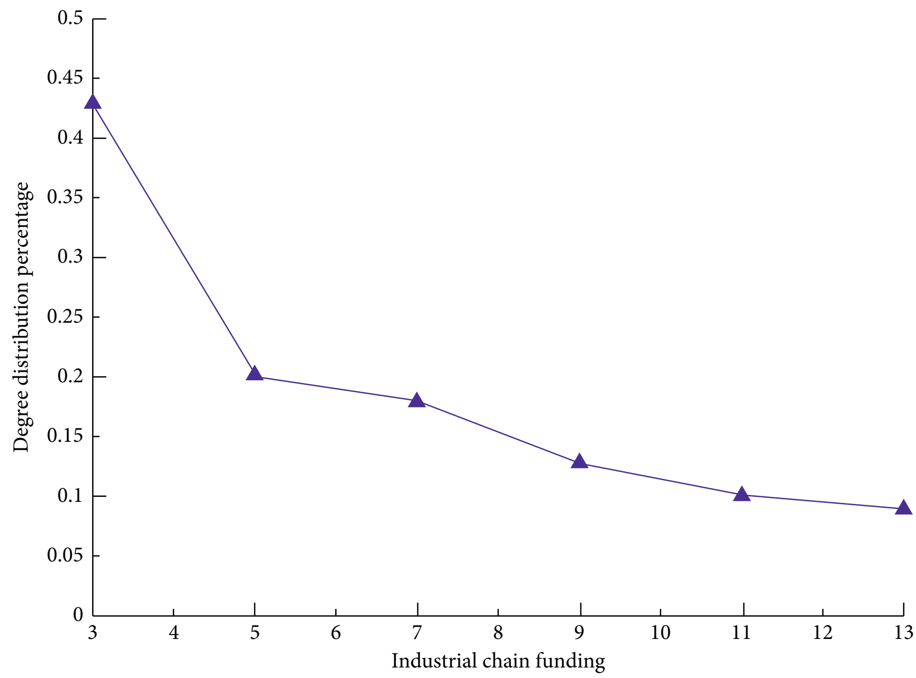

Figure 6: Distribution chart of capital change degree of the ecological pension industry chain.

threshold value, the control effect of industrial chain risk transmission is very obvious with the increase of the proportion. In the care greeting network, both the caring person and the cared person contain multiple matching indicators. Under the centralized construction mode of care greeting network, matching is carried out according to the indicators of the caring person and the cared person, so as to achieve the overall optimal goal of the network. In the network of caring and greeting, the main consideration is the matching between the caring person and the cared person. There are both the same matching indicators and different matching indicators between them, as shown in Figure 7.

Matching indicators of loved ones are educational background, work experience, geographical location, and service demand. Caregiver matching indicators are educational background, work experience, geographical location, knowledge, and skills. In the process of matching, each matching index is matched in one-to-one correspondence, in which the service needs of the loved ones are matched with the knowledge and skills of the loved ones.

According to the educational background, match the schools of the caregivers and the loved ones, take the names of different schools as the matching basis, and calculate the number of schools where the two sides have the same attendance so as to determine the matching degree. In the care and greeting network, caregivers and loved ones continue to join through the network platform, and we are concerned about how to reasonably match them. In the matching process, taking the optimal overall matching degree as the goal, under multiple matching indexes, the matching degree between matching objects is calculated according to the individual preference of matching objects, and then the connection between them is established intensively. In the care and greeting network, it is assumed that there are six caregivers and six loved ones. The maximum matching number of caregivers is 3 and the maximum matching number of loved ones is 6. The matching degree between caregivers and loved ones is shown in Figure 8.

From the perspective of the industrial chain, such distribution characteristics reflect the following. (1) There is no significant difference in the number of partners between node enterprises, which means that although a small number of core enterprises with comparative advantages have been formed in the industrial chain, this advantage is not obvious. (2) There are a large number of enterprises with a medium competitive advantage, and some of them may stand out and become industry leaders. (3) The number of enterprises in the third echelon is small, and there are mainly two types. First, enterprises or institutions with special properties, such as product certification bodies, mainly provide certification services for a small number of enterprises, so there are fewer partners in a single industrial chain. Second, the backward enterprises in the industrial chain, whose development scale is small and the speed is slow, cannot win a large number of partners and are likely to be eliminated in the competition, as shown in Figure 9.

By sorting out the factors that affect the industry consolidation for the aged population, this article sets six potential variables that can not be directly observed, namely, the environment of the aged care service, the demand structure of the aged group, the management of the aged care service, the intelligent aged care service system, the development status of the intelligent aged care industry, and the service feedback effect. Each potential variable is represented by a group of significant observable variables, with a total of 16 significant variables. The theoretical framework of

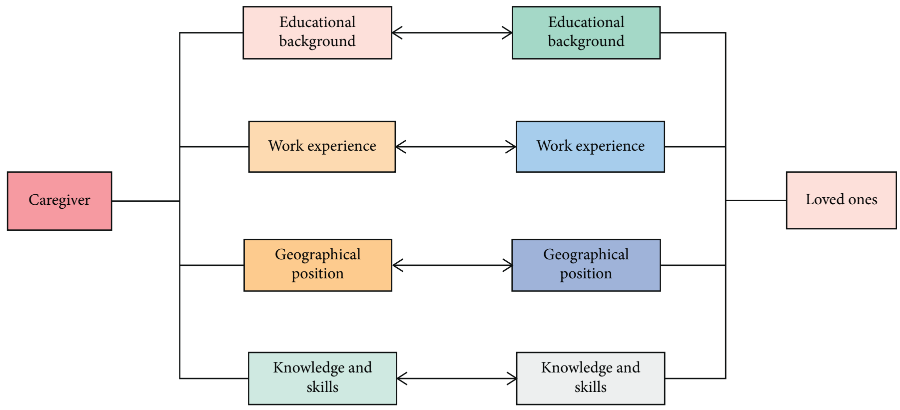

FIGURE 7: Matching relationship of network indicators.

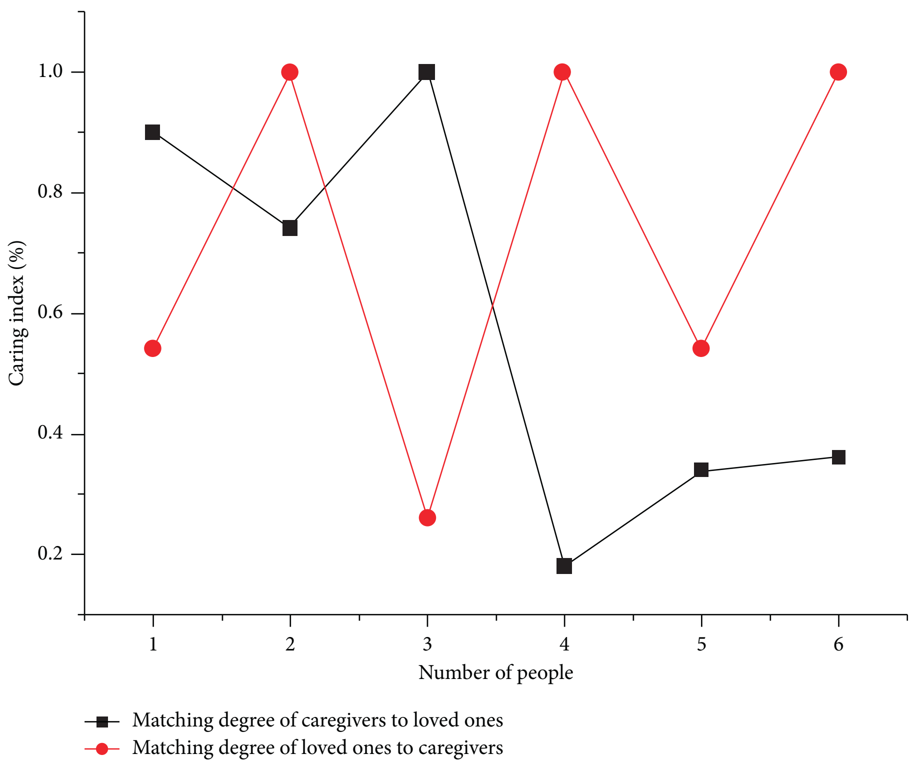

FIGURE 8: The matching degree between the caregiver and the loved one.

"triple functional relationship" mainly refers to the analysis framework of the influencing factors of the industry consolidation of smart pension, as shown in Figure 10.

With the increasingly prominent problem of population aging, it is necessary to promote the modernization, scale, industrialization, specialization, and institutionalization transformation of traditional aged care services, from the government to the combination of government-led and market-oriented mechanisms and from the traditional low-level aged care services to the high-level aged care services. Farmers should be encouraged to implement land circulation and form agricultural cooperatives through various forms such as joint ventures and shareholding so as to make full use of local ecological advantages and make use of idle land. The transformation and optimization of the old-age care industry should be accelerated, and high-quality life products and services for the elderly should be better provided. It is important to carry out investment attraction, establish a special management committee, reasonably allocate and coordinate relevant resources, and carry out

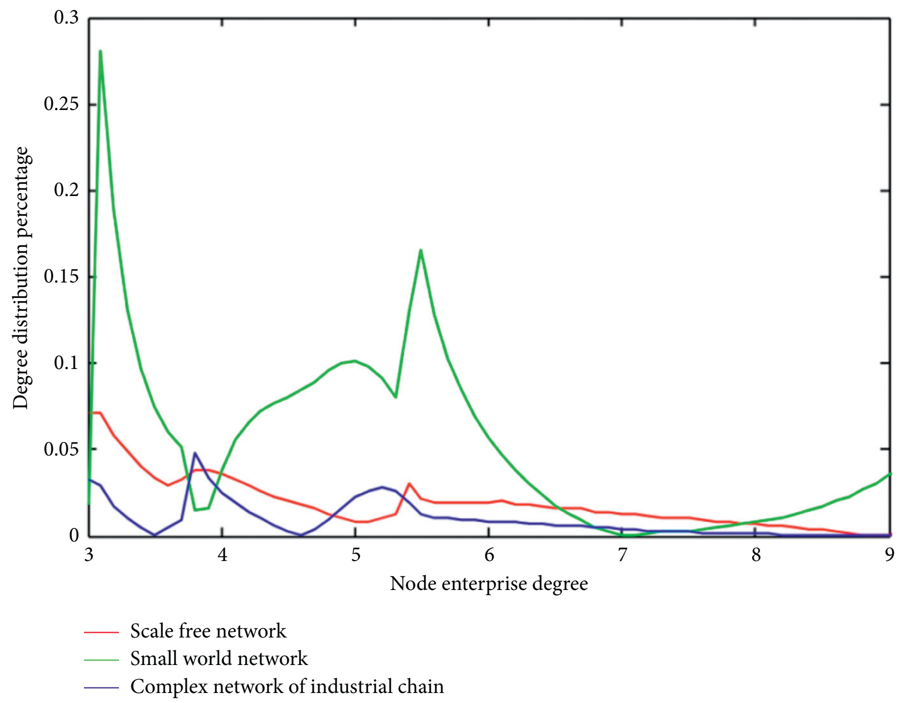

Figure 9: Degree distribution of three network structures.

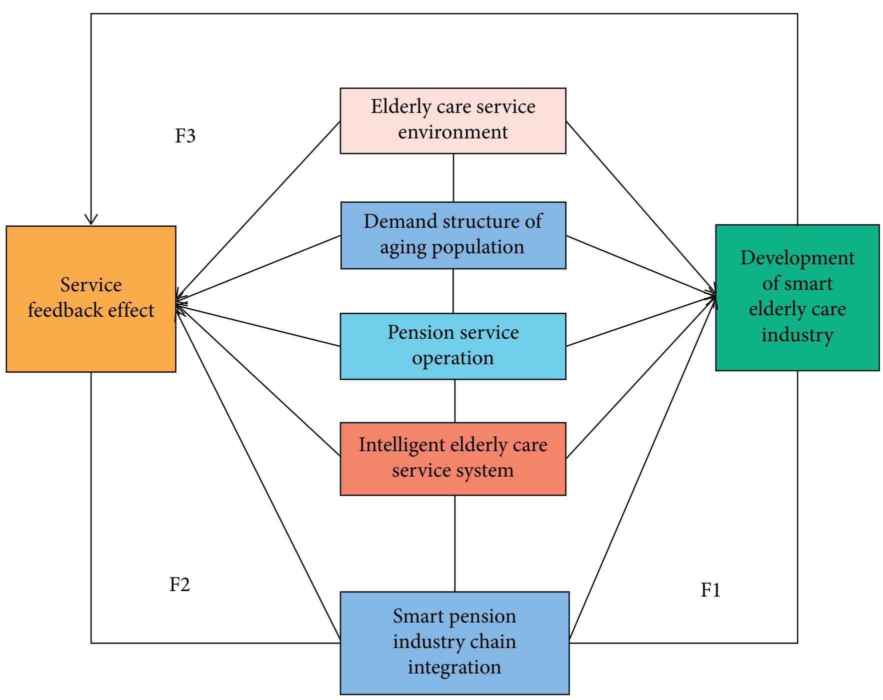

Figure 10: Theoretical framework of "triple function relationship" of influencing factors of pension industry chain integration.

classified management. Farmers can operate some small farmhouses, and enterprises can invest in large sightseeing parks.

5. Conclusions

In a word, in the process of increasing the social aging population, strengthening the transformation and development of elderly products is of great significance to the safe and stable development of the whole society and effectively promotes the development of the social economy. This article studies the effectiveness and importance of constrained clustering algorithms in the transformation and optimization of rural ecological elderly care industrial chains. The choice of ecological pension industry model is one of the frontier issues in the economic theory research of the pension industry, and the research on the implementation path of rural revitalization is the main focus of the development theory research of "agriculture, rural areas, and farmers." Private old-age care institutions built by social forces are difficult to maintain and operate, with few sources of funds, low profits and no good industrialization form. At present, the academic circles have made some progress in researching the mode selection of the ecological pension industry. Although scholars have different opinions on the specific mode selection, they have reached a consensus in some aspects. As the ecological pension industry is a new industrial form in China, and the rural revitalization strategy has only been put forward in recent years and the research on it by domestic scholars is extremely limited and is still in the primary exploration stage. The effective use of background knowledge can make the constrained clustering algorithm obtain more heuristic information to reduce the blindness in the search process and improve the efficiency and clustering quality of the algorithm. This article describes in detail the role and advantages of the constrained clustering algorithm in transforming the rural ecological elderly care industrial chain. At the same time, we should also strengthen the supervision of various forms of community pension models such as private and public assistance, public construction, and private and public construction. In the process of supervising these forms of old-age care, we also need to pay attention to matters such as staffing, investment and use of government funds, and service quality.

Hybrid online and offline teaching is becoming the mainstream teaching method in the postepidemic era. However, research on assessing its teaching quality is still limited. This article thus develops a teaching quality evaluation model based on the BP neural network. A three-dimensional indicator system involving 19 indicators is set in the model. The established model was demonstrated and validated by a case study. The results show that the developed model can accurately assess the teaching quality of hybrid online and offline teaching. Findings from this study can provide valuable references for improving the quality of hybrid online and offline teaching.

1. Introduction

In the digital era, digital technologies represented by the new generation of Internet technology have significantly reduced the cost of information dissemination. Students can, therefore, easily access a vast amount of high-quality teaching resources through the Internet. In this context, both "teaching" and "learning" are given a new connotation of the times [1]. A lot of online teaching platforms like Coursera, Udacity, and edX have emerged. More and more schools, including some top universities like Harvard and MIT, have opened their public courses. Online teaching is beginning to be accepted by the public and is increasing [2]. Especially in the wake of the 2020 New Crown Pneumonia outbreak in countries around the world, online teaching has become a choice many universities have to make in the context of epidemic prevention and control [3]. Even though the epidemic has been initially controlled in some countries and regions, the situation of epidemic prevention and control is still very serious [4]. At present, more and more universities select hybrid online and offline teaching for daily teaching tasks, such as Hong Kong Polytechnic University, Sydney university, and so on. The Ministry of Education has issued policy documents such as "Action Plan of Education Informatization 2.0" and "Opinions on Strengthening the Application and Management of Online Open Courses in Higher Education Institutions." And at the same time, the Ministry of Education has held a series of meetings such as the "National Conference on Higher Undergraduate Education in the New Era" to promote the construction of online resources of various courses [5]. It encourages universities to actively build online resources of multiple classes and promote the deep integration of modern information technology and education [6]. In November 2020, the first batch of 5118 national first-class undergraduate courses, including 868 online and offline hybrid first-class courses, was launched. Facing the new challenges in the postepidemic era, the large-scale hybrid online and offline teaching tends to become the mainstream mode of teaching in the future [7].

Even though the mode of hybrid online and offline teaching has obtained certain development and achievements, there are still many teachers, students, and experts who doubt that the online and offline hybrid teaching mode cannot achieve the expected teaching effect and thus negatively affect the personnel training of the universities. Prospective research on the evaluation of teaching quality of hybrid online and offline teaching is apparent [8]. However, at present, systematic and comprehensive assessment indicators and approaches are unavailable.

To address the research gap, this study proposes a process model and develops an indicator system for assessing the teaching quality of hybrid online and offline teaching from the perspective of the whole process of curriculum construction, teaching implementation, and teaching effects. An evaluation model based on BP neural network is also developed. A lecture called Introduction to Machine Learning in a university in Shanxi, China, is selected for a case study to demonstrate and validate the established model. On the one hand, findings from this study can make up for the deficiency of emphasizing teaching process evaluation rather than course evaluation in current research on hybrid teaching quality evaluation. On the other hand, it provides suggestions and improvement direction for similar colleges to perfect the construction of related curriculums and improve the quality of hybrid online and offline teaching.

2. Related Works

From the late 1990s to the present, scholars have experienced three stages of technology-centered, teacher-centered, and student-centered cognition of hybrid teaching, which is a teaching mode combining online and offline teaching. Most scholars believe that the online part of blended teaching includes MOOC teaching, SPOC teaching, APP teaching, and other forms [9, 10], and the offline part is mainly face-to-face teaching in classrooms, but the application of modern digital technology should be emphasized. Baragash and Al-Samarraie conducted a large-scale survey on perceptions of hybrid teaching and learning in US colleges and universities [11]. They found that faculty perceptions of hybrid teaching and learning have moved beyond technology integration to a higher level of content and effectiveness improvement. Laura et al. suggest that teachers and students derive greater psychological satisfaction from hybrid online and offline teaching than from traditional instructional programs based on cognitive theory [12]. Furnes et al. found that a 2-year follow-up study of a hybrid online and offline teaching program for undergraduate students at the University of Miami [13]. They also found that the hybrid online and offline teaching program significantly improved students' communication and innovation skills and was a highly effective teaching model.

Teaching quality is a direct reflection of the effect of educational activities [13, 14], and global scholars have conducted a lot of research on teaching quality evaluation, covering various aspects, such as influencing factors, dimension classification, evaluation indexes, and methods [15–19]. In terms of factors influencing online teaching quality, Xu et al. identified interaction (including the interaction between students, the interaction between students and teachers, and the interaction between students and contents), online self-efficacy, and self-regulated learning habit as essential factors influencing the quality of hybrid online and offline teaching for university students [20]. In terms of hybrid teaching quality dimension division, Huang et al. pointed out that during the new crown pneumonia epidemic, the construction of an online teaching quality assurance system in national universities showed comprehensive, diversified features from three dimensions of supervisors, teachers, and students [21]. Scholars have also proposed using big data methods and machine learning methods to convert macroscopic, qualitative evaluation to microscopic, quantitative evaluation [19, 22, 23].

In summary, in the face of the rapid advancement of digital technologies and the impact of the new coronary pneumonia epidemic, worldwide scholars continue to be enthusiastic about hybrid online and offline teaching and learning and have achieved specific achievements in the research of hybrid online and offline teaching quality assessment. However, there are still the following deficiencies:

(1) The hybrid online and offline teaching mode is becoming more affluent, especially with the development of mobile Internet, which further promotes the diversification of hybrid online and offline teaching. But the current research on the evaluation of hybrid online and offline teaching quality has not yet paid attention to this new change.
(2) The existing research on the quality of hybrid online and offline teaching mainly starts from the perspective of the general process of teaching activities, ignoring the impact of hybrid online and offline teaching courses as the basic unit and new mode teaching mode on educational effects.
(3) The hybrid online and offline teaching quality evaluation indicator system established by the existing research is relatively brief, ignoring the key index points that affect the quality of hybrid teaching, such as course objectives, course philosophy, and teaching team, which affects the completeness of the hybrid teaching quality evaluation system.
(4) The current research on the implementation strategy of hybrid teaching has not yet formed a good echo with the research on teaching quality evaluation, and the suggestions on the implementation strategy of hybrid teaching quality evaluation based on the expansion of practice level will help the application and promotion of the hybrid teaching.

3. Development of Evaluation Indicator System

3.1. Principles. Hybrid online and offline teaching is based on constructivist learning theory and emphasizes student-centeredness. Currently, the development of 5G technology and the popularity of mobile Internet have expanded hybrid teaching to new forms, such as mobile Internet APP, and the basic elements involved in hybrid teaching, such as teaching resources, are also expanding. This paper proposes the principles that should be followed in constructing a hybrid teaching quality evaluation indicator system from the following aspects.

3.1.1. Integration of Course Evaluation and Implementation Evaluation. The quality evaluation system of hybrid online and offline teaching must start from the curriculum as the high level of curriculum is the prerequisite and fundamental to ensure the quality of blended teaching. The prerequisite and foundation for the quality of hybrid online and offline teaching is a high-level curriculum. The evaluation of the implementation and feedback of hybrid teaching is carried out to grasp the fundamental elements of the curriculum in hybrid teaching. The quality evaluation system of hybrid online and offline teaching should be based on the whole teaching process, and the coverage of teaching quality evaluation index points should be improved.

3.1.2. Combination of Process Evaluation and Outcome Evaluation. The student-centered teaching concept requires that the evaluation of hybrid online and offline teaching quality should focus on process evaluation on the one hand and outcome evaluation on the other. The process evaluation needs to focus on the dimensions of teacher-student interaction, student-student interaction, and teaching contents, and its forms include learning behavior evaluation on the desktop and mobile end of the teaching platform, offline learning behavior evaluation, stage assignments, and so on; the form of outcome evaluation includes test papers, essays, defenses, and so on.

3.1.3. Diversification of Evaluation Subjects and Evaluation Indicators. Hybrid online and offline teaching includes both flexible online desktop teaching and mobile APP teaching and traditional offline, face-to-face teaching. Both teachers and students are deeply involved in the whole process of teaching activities, especially in the construction of hybrid teaching courses; the teachers' overall design of the course has an important impact on the teaching quality. Therefore, in the selection of evaluation subjects, teachers, students, and experts inside and outside the university and the teaching platform should be included in the evaluation subjects, and the application of learning behavior data from the desktop and mobile ends of the teaching platform should be emphasized. As for the evaluation indicators, the diversified design of combining qualitative and quantitative indexes, objective data, and subjective judgment should be insisted on.

3.1.4. Comprehensive Evaluation Content and Evaluation Method. As the course construction and organization implementation process in hybrid teaching are relatively complex, the quality evaluation needs to be more comprehensive and detailed, focusing not only on the all-round examination of the course construction but also on the evaluation of questions, tests, and assignments in the traditional offline teaching process, as well as the evaluation of video viewing, chapter tests, topic discussions, and other contents in the online teaching process. In terms of evaluation methods, evaluation can be carried out with the data from the online desktop and mobile APP teaching platforms, and phase evaluation and rolling dynamic evaluation can also be carried out according to the course teaching progress.

3.2. Indicator System. The key to constructing a hybrid teaching quality evaluation system is the selection and determination of evaluation indicators. This paper develops a hybrid teaching quality evaluation system containing three first-level indicators: course construction evaluation, teaching implementation process evaluation, and teaching effect evaluation.

Firstly, in the evaluation of hybrid teaching course construction, combined with the specific elements contained in the course, we focus on whether the system meets the basic construction standards and, at the same time, has the essential characteristics of hybrid teaching. Specifically, seven secondary indicators such as course objectives, teaching content, and teaching design are evaluated comprehensively and should be considered by different evaluation subjects because of the difference in the connotation of secondary indicators of different dimensions. The indicator system is shown in Table 1.

Secondly, in evaluating the teaching implementation process of hybrid teaching, we aim to improve the interactivity and build a teaching process evaluation system based on the interaction between "teaching" and "learning." Specifically, it includes four secondary indicators, namely, students' online session, teachers' online session, students' offline session, and teachers' offline session, as shown in Table 2.

At last, in the evaluation of hybrid teaching effect, the teaching effectiveness of both online teaching and offline classroom is combined to make a comprehensive judgment. Specifically, from two dimensions of process assessment and outcome assessment, eight secondary indicators are designed, including assessment objectives, assessment forms, assessment contents, and assessment quality, as shown in Table 3.

4. Assessment Methods

4.1. Model Development. Traditional assessment methods such as the single-factor evaluation method, the comprehensive evaluation method, fuzzy mathematics, operation research, multivariate statistical analysis, multidimensional scalar analysis, and so on have been used to evaluate the quality of hybrid teaching. Even though these methods could achieve certain results to different degrees, they were imperfect, mainly in the following aspects: (1) It is difficult to determine the weights of each secondary index, and the evaluation is usually subjective and arbitrary by virtue of experts' experience. There is thus a specific error with the actual value. (2) It is difficult to make an accurate evaluation of the results of specific indicators by traditional methods. (3) The calculation is complicated, and the solution is tedious. (4) The algorithm lacks self-learning ability. Therefore, this study tries to obtain a fast, effective, and accurate method of hybrid teaching quality evaluation.

Table 1: Evaluation indicators of hybrid teaching course construction.

Indicators	Subindicators	Meanings	Subjects
Course construction evaluation X1	Course objectives X11	(1) In line with the school's orientation (2) In line with the professional training objectives (3) Covering the three dimensions of knowledge, quality, and ability (4) Reflecting innovation, high order, and challenges	Internal and external experts
	Teaching content X12	(1) Clearly expressed; measurable, quantifiable, and assessable in terms of achievement (2) Implementing the requirements of the construction of curriculum thinking and politics (3) Reflecting the frontier and modernity (4) Reflecting the integration of multiple disciplines (5) Meeting the teaching objectives	Internal and external experts
	Teaching design X13	(1) Reasonable arrangement of online and offline teaching hours (2) The online and offline teaching contents are cross-complementary (3) Close connection between online and offline teaching activities	Internal and external experts
	Teaching team X14	(1) Upholding the concept of student-centered, output-oriented, and continuous improvement (2) Strong awareness of teaching reform and outstanding teaching ability (3) Clear division of labor and mutual collaboration	Internal and external experts
	Teaching resource X15	(1) In line with the teaching objectives (2) Teaching resources are abundant in various forms (3) Teaching resources are updated in a timely manner and have a short periodicity	Internal and external experts
	Teaching platform X16	(1) Easy and fast operation of the platform and stable operation (2) Instant monitoring, feedback, and statistics (3) Convenient interaction between teachers and students, students and students in various forms (4) Supporting for a variety of functions, such as testing, assessment, and live streaming (5) Facilitating teachers' personalized teaching design and students' personalized learning	Teachers and students
	Teaching environment X17	(1) Software and hardware configurations to meet teaching needs (2) Stable network environment (3) Supporting new technologies and tools	Teachers and students

Artificial Neural Network, in the field of machine learning and cognitive science, is a mathematical or computational model that mimics the structure and function of biological neural networks (the central nervous system of animals, especially the brain) for estimation or approximation of functions [24]. A neural network consists of a large number of artificial neurons linked for computation. In most cases, artificial neural networks are able to change their internal structure based on external information and are adaptive systems, which are commonly known as having a learning function. Modern neural networks are a nonlinear statistical data modeling tool, and they are usually optimized by a learning method based on a mathematical, statistical type, so they are also a practical application of mathematical, statistical methods, which allow us to obtain a large number of local structural spaces that can be expressed as functions [25, 26]. On the other hand, in the field of artificial perception in artificial intelligence, we can do decision problems in artificial perception through the application of mathematical statistics (i.e., through statistical methods, artificial neural networks can have the ability to make simple decisions and superficial judgments like human beings), and this method has advantages over formal logical reasoning [27]. Like other machine learning methods, neural networks have been used to solve a wide variety of problems, such as machine vision and speech recognition. These are problems that are difficult to be solved by traditional rule-based programming.

BP neural network, also called "error backpropagation neural network," provides a novel technique for teaching quality evaluation, which can effectively overcome the shortcomings of traditional evaluation methods. In essence, this is a category of dynamic information processing systems composed of a large number of information processing units through a wide range of linkages, and this system is unique in processing various kinds of paradoxical, ambiguous, random, large volumes dynamic, and low-precision information. It has the functions of learning, remembering,

Table 2: Evaluation indicators of hybrid teaching implementation process evaluation.

Indicators	Subindicators	Meanings	Subjects
Teaching implementation process evaluation X2	Students' online session X21	(1) Length of students' study (2) The number of times of students' study (3) Percentage of students completing task points (4) Students' online chapter test scores (5) The number of times of students extending their learning (6) The number of times of students participate in activities (7) The number of times of students post and reply to posts (8) The degree of completion of student group tasks (9) Quality of student group task completion	Platform and teachers
	Teachers' online session X22	(1) The number of teacher postings (2) The number of times of teachers answering questions (3) Coverage rate of teachers' Q&A (4) The time limit for teachers to answer questions (5) The number of times of teachers guided, supervised and instructed students in their studies (6) The number of teaching activities organized by teachers	Platform and students
	Students' offline session X23	(1) The number of times of students asking or answering questions (2) The quality of questions asked or answered by students (3) The number of times of students participated in classroom activities (4) The student's performance in completing classroom tests (5) The clear division of work among group members (6) The degree of completion of group tasks (7) Quality of group tasks completed	Platform and teachers
	Teachers' offline session X24	(1) The number of questions asked by teachers (2) The organization of classroom activities by teachers (3) Development of team learning by teachers (4) Experiential learning by teachers (5) The conduct of classroom tests by teachers (6) Training students to solve complex problems (7) Teaching with digital teaching tools (8) Teachers' guidance to students (8) Teachers guide students in learning, summarizing, and reflecting on the situation	Platform and students

	Quality of outcome evaluation X38	Evaluation quality	Teachers

associating, summarizing, generalizing, extracting, guest error, and self-adaptive capabilities and is a system that can handle nonlinear problems.

A typical BP neural network is a three-layer feed-forward hierarchical network consisting of an input layer, an implicit layer, and an output layer. The learning process of a BP neural network consists of forwarding propagation of information and backward propagation of errors. When given a set of input patterns to the network, the BP network will sequentially learn this set of input patterns in turn in the following manner: first, the input pattern is transmitted from the input layer to the implicit layer unit, and after being processed by the implicit layer unit layer by layer, an input pattern is generated and transmitted to the output layer, which is called forward propagation [28]. The output result is then compared with the expected value [29]. If it does not meet the anticipated expectation, it is transformed into a backpropagation of the error, which returns the error along the original path and makes the error signal smaller by modifying the connection weights of the neurons in each layer. These forward and backward propagation alternate with each other and are seen as a "memory training" process. The system repeats these two processes until the error between the output value, and the expected value is reduced to within a specified range [30]. At this moment, the new samples are fed into the already trained network, and the corresponding output values are obtained.

The BP neural network model for hybrid teaching quality evaluation is established in the following steps.

4.1.1. Determination of the Number of Neurons in the Transmitter Layer. According to the evaluation indicator system of hybrid online and offline teaching quality, there are 19 subindicators in the system. These 19 subindicators can be used as the input neurons of the model. Therefore, the number of neurons in the input layer n is determined as $n = 19$.

4.1.2. Determination of the Number of Neurons in the Output Layer. This study uses the evaluation results as the output of the developed network and the number of output layers $m = 1$. The desired outcomes are grade A for excellent; grade B for good; grade C for pass; and grade D for fail.

4.1.3. Determination of the Number of Implied Layers of the Network. The indicated layer can be one or more layers. According to the theory of Kolmogorov, the following has been proved: for any given continuous function, a three-layer neural network can then accurately implement the predefined model functions. Therefore, in the hybrid online and offline teaching quality evaluation model, we choose the hidden layer as one layer.

4.1.4. Determination of the Number of Neurons in the Hidden Layer. In general, the number of neurons in the hidden layer is determined based on the convergence performance of the network. Too few neurons in the hidden layer may not train the network, or the obtained network may not be "strong" enough to recognize previously unseen samples, and the error tolerance is poor. However, too many neurons in the hidden layer may make the learning time too long, and the error may not be optimal either. Therefore, there is a problem with how to determine the appropriate number of neurons in the hidden layer of the network. Generally, the "trial-and-error method" can be used to compare the network output error with the desired error and select the simulation effect. The number of hidden layer nodes used for the best simulation results is chosen by comparing the fit between the output and desired errors, but this approach is tedious and time-consuming. The number of neurons in the hidden layer can also be determined by referring to some empirical formulas to determine. The following equations are two widely used empirical formulas.

$$s = \left(0.43mn + 0.12m^2 + 2.54n + 0.77m + 0.35\right)^{1/2} + 0.51, \tag{1}$$

$$s = (n + m)^{1/2} + a, \tag{2}$$

where a is a constant between 1 and 10, n is the number of neurons in the input layer, and m is the number of neurons in the output layer. In this paper, we initialize the number of neurons in the hidden layer based on the relevant empirical formula as $s = 12$.

4.1.5. Determination of Neuronal Transition Function. BP neural network neuron conversion function is generally chosen as sigmoid function:

$$f(x) = \frac{1}{\left(1 + e^{-\lambda x}\right)}, \tag{3}$$

in which the coefficient λ determines the degree of compression of the sigmoid function.

4.1.6. Determination of the Model Structure. From the above results, it can be determined that the structure of the hybrid online and offline teaching quality evaluation model based on the BP neural network is shown in Figure 1.

4.2. Model Training. A lecture called Introduction to Machine Learning in a university in Shanxi, China, is selected for a case study to demonstrate and validate the established model. We conducted a questionnaire survey among 60 students of this lecture. Surveyed subjects are asked to mark the 19 indicators from 0 to 9. The three-layer BP neural network shown in Figure 1 was used for identifying the above hybrid online and offline teaching quality assessment system. The numbers of neurons in the input layer, implicit layer, and output layer are 38, 12, and 1, respectively, and the learning rate $\eta = 0.85$. 40 randomly selected samples of data were considered as the training set of the neural network. The target error is 0.001. The specific training process is shown in Figure 2.

4.3. Model Test. After the training of the network was completed, it was tested using the remaining 20 sets of data. Then, the error between the evaluation target value and the actual evaluation target value output by the neural network is checked and compared, and the comparison results are shown in Table 4. It can be learnt that the output values of the hybrid online and offline teaching quality evaluation model built based on the BP neural network are very close to the real values. In other words, the model can accurately determine the teaching effectiveness based on each evaluation indicator.

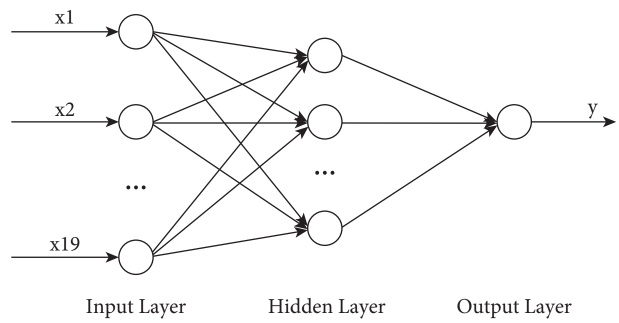

Figure 1: Structure of the BP neural network.

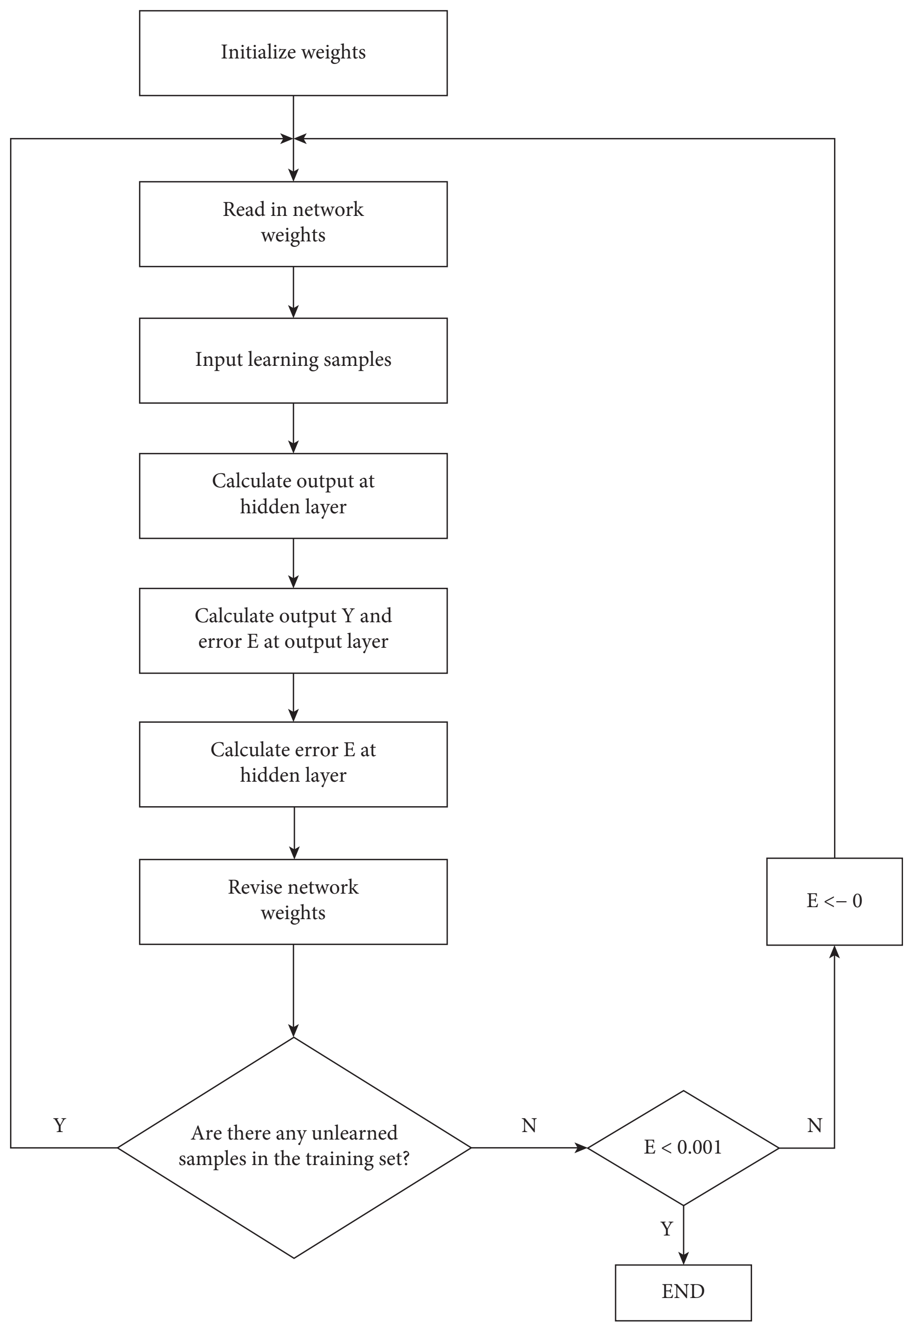

Figure 2: Process of model training.

Table 4: Results of model tests.

No	True value	Output from the model	Error (%)
1	6.89	7.01	1.74
2	6.46	7.01	8.51
3	5.75	5.79	0.70
4	6.24	6.66	6.73
5	8.48	9.03	6.49
6	9.12	8.94	1.97
7	8.25	8.22	0.36
8	7.77	7.2	7.34
9	6.48	6.99	7.87
10	6.99	6.99	0.00
11	8.48	8.55	0.83
12	7.98	7.99	0.13
13	8.02	7.95	0.87
14	8.23	8.01	2.67
15	6.73	6.52	3.12
16	5.77	5.61	2.77
17	6.97	6.83	2.01
18	9.03	9.11	0.89
19	9.24	9.99	8.12
20	7.35	7.74	5.31

5. Conclusions

The hybrid online and offline teaching quality evaluation system is a complex nonlinear system with many uncertainties between the input and output. The BP neural network model can effectively overcome the defects of traditional evaluation methods and weaken the human influence factors of index weight determination in traditional evaluation methods because of its highly nonlinear function mapping function and self-adaptive and self-learning ability. It is not only feasible but also has high accuracy. After the empirical study, we found that the error between the output value of the BP neural network model and the real value is relatively small. The performance can fully meet the requirements of practical applications. In addition, the output accuracy of the network depends on the number of input training samples, and the more the number of training samples, the closer the output teaching effect evaluation value is to the actual evaluation value. In conclusion, the developed hybrid online and offline teaching quality evaluation model established based on the BP neural network is expected to provide helpful reference for universities and teaching management departments to seek scientific solutions for teaching quality evaluation and improvements. This research still has two main limitations: (1) the evaluation model is still superficial; (2) only a case is applied to validate the model. In the future, the evaluation model can be further improved by introducing big data and deep learning. In addition, more cases should be used to further validate the developed indicator system and evaluation model.

Scientific sports training plans are only possible if you can accurately predict a player's performance. Accurate prediction of sporting performance not only is useful for athletes, but also helps to guide the development of sports. Research methods used in traditional forecasting include the time series method, analogy method, regression analysis, and other methods of analysis. Most of the data used to make these projections are derived from a relatively small set of static problems. A sports performance prediction model based on deep learning is proposed to address the current model's low prediction accuracy. Deep learning models are more accurate at predicting sports performance than traditional methods, and the difference between the two is greater in this study. Also, it performs well when it comes to both convergence and robustness.

1. Introduction

Sports performance prediction can help schools, sports teams, and sports training institutions develop scientific training methods that reflect the changing trends in sports performance [1]. Thus, athletes and coaches will be able to use these opinions as a basis for reforming physical education and training. The level of sports training is reflected in a person's ability to perform well in sports. In order to improve sports training and teaching, accurate prediction of sports achievement can be used to uncover the regular factors and characteristics of human training [2]. Because of this, the prediction of sports performance has always been a hot topic in the study of sports. There are many factors that influence a player's performance, and these factors interact and interact with each other in complex ways, making it difficult to predict a player's performance accurately using traditional methods [3]. At the same time, it is of great significance to study the prediction model of sports performance in promoting scientific training and improving sports performance [4].

Sports is the most attractive activity in modern society. As a special cultural phenomenon, its development has a profound and extensive influence on the development of sports culture, which in turn affects the development of other related cultures in society [5]. In light of the growing interest in sports development, this paper proposes a method for accurately predicting sports performance based on deep neural networks (DNN) [6–8]. Training and preparation goals are directly affected by accurate sports performance prediction, as well as the discovery of performance development rules. There is, however, a great deal of uncertainty in the data because of the small amount of data on which the current forecast is based, as well as the large randomness and hidden influence factors in the data generation process. Predicting sports performance is complicated because of the numerous variables involved (changes in human characteristics, age, various environmental factors, etc.). Sports performance prediction models are built using multivariate and multi-parameter statistical analysis. Statistics, information processing, and modern mathematics are among the topics covered in the course. Forecasting success hinges on selecting an appropriate and highly precise method. A sports performance prediction model based on DNN is proposed in order to improve the scientific guidance of sports training and predict sports performance.

The traditional method of predicting sports performance has some problems, such as high computational cost and poor adaptive anti-interference of parameters in the process of prediction, which leads to low prediction accuracy. Neural network (NN) is generally used in uncertain input-output function mapping, which can determine the linear correspondence. It has stable effectiveness and adaptability, forward propagation signal, and backward propagation error, and is often used in various fields [9]. It can accurately assess the athletes' physical quality level and make the key points and objectives of athletes' training content clear so as to have targeted and scientific training. Based on this, this paper puts forward a sports achievement prediction model based on deep learning. The quantitative evaluation system of special movement techniques has been established. This system can scientifically monitor and evaluate the development level of each athlete's athletic ability so that athletes can get scientific training. The performance test of the model proposed in this paper shows that the model improves the accuracy of sports performance prediction, and the prediction error can meet the requirements of practical application.

2. Related Work

Using a deep learning network, literature [10] predicts South Korea's daily comprehensive stock price index better than BPNN and case-based reasoning. Fernandez Molanes et al. [11] combines deep learning network and empirical mode decomposition to predict the error sequence of the initial prediction set and use this prediction value as a correction to correct the original prediction. In order to create a scientific, practical, and effective evaluation system for journals, literature [12] used DNN to build a dynamic evaluation model of journals. Neural network (NN) technology is employed in the literature [13] to model the project's value. It improves the back-propagation algorithm, which supervises and trains samples to obtain the weight factor, in order to determine the value of a project and help the decision-maker in project evaluation and decision-making. Biochemistry is a field where NN is used in the literature [14]. The biomolecular feature data matrix is obtained by extracting molecular features from biological structure analogs and selecting gene bonds and functional groups as discriminant factors. Multiple layers of NN structure have been proposed in the literature [15] as the basis for DNN architectures. Layer-by-layer training is typically used to abstract the data's unique characteristics before optimizing the network model as a whole. An artificial neural network (ANN) can be used to evaluate the total economic benefits of an enterprise, according to reference [16]. The economic indicators of enterprises are taken as the input of artificial NN, and the classification function of the network is used to classify enterprises. Literature [17] proposed a pattern integration operator based on the NN model. Compared with the mean operator, it is found that for multi-level time series, the prediction accuracy of the NN model can be greatly improved by using the pattern inheritance operator. Liu [18] proposed that the NN model has a three-layer NN structure. An input layer, hidden layer, and output layer. Each layer is connected with each other, and the connection weights are repeatedly learned and trained through error back-propagation until the corresponding weights can meet the requirements of the training mode. Literature [19] proposed that the DNN structure containing multiple hidden layers can be obtained through certain feature extraction and training methods. Literature [20] established a DNN prediction model based on the annual best performance data of the world women's heptathlon. Literature [21, 22] describes how to apply the NN method to the prediction in the field of market evaluation, enterprise evaluation, and economic management. The system block diagram of how to implement it in the language environment is given. The steepest gradient descent method is used to modify the weight and threshold. Literature [23, 24] pointed out that nonlinear sports models mainly include NN, grey model, Markov chain, and support vector machine. Literature [25] proposed that the combination of multi-population genetic algorithm and NN can consider the global optimization solution and local optimization solution at the same time. Literature [26] verified the prediction effect of a deep learning network on five financial time series data. The experimental results show that the prediction of mean square error and mean absolute error of deep learning network samples are better than back propagation neural network (BPNN). This paper establishes a sports performance prediction model by using the method of DNN and analyzes the reliability and error of the model. The test shows that the performance prediction model established by DNN can predict sports performance and evaluate the development level of physical quality more accurately than traditional prediction methods. This model can bring great convenience to the prediction of sports performance, and further improve the efficiency of modeling and the accuracy of prediction performance.

3. Methodology

3.1. Principles of Sports Performance Prediction. Changes in various natural conditions have an important impact on sports performance. The change of temperature, humidity, and atmospheric pressure will affect the change of ball speed. Natural conditions, such as the intensity of sunshine and the change of wind direction, will affect the individual achievements of players. This directly affects the players' technical level. Sports performance is related to many factors, and various factors interact with each other, which leads to very complicated changes in sports performance. The linear model assumes a periodical or rising trend of sports performance, which is inconsistent with the actual change characteristics of sports performance, and its application scope is limited [27]. Considering the influence of environment and weather on the accuracy of sports performance prediction, in the process of building the mathematical model of sports performance, according to fractional Fourier transform, a class of fractional generalized integrodifferential equations with distributed time delay is obtained, which represents the solution space model of sports performance prediction.

NN has the nature of biological NN type, and it can improve its own performance and understand the environment through learning. After the artificial NN is stimulated by the external environment, it can adjust the parameters of the NN to make the NN respond to the external environment in a new way [28]. DNN is mainly aimed at improving the shortcomings of traditional artificial NN. The artificial NN is prone to fall into local minimum and gradient disappearance when using gradient descent. The DNN divides training into two parts, namely, feature extraction and parameter optimization. Feature extraction is an unsupervised learning method, which can be completely based on unlabeled data, which is especially important for scenes with severe training data, and features and feature weights learned by automatic methods. Finally, the tagged data is used to fine-tune the parameters, which has achieved good results in the actual scene [29]. It truly reflects their inherent characteristics, thus overcoming the shortcomings of the multiple regression model and grey model. In this paper, the self-similar regression model of sports achievement is constructed, empirical mode decomposition and factor analysis are carried out on the time series of sports achievement, and the feature information clustering and information fusion processing of sports achievement are carried out by using the DNN classification model, so as to optimize the prediction model.

The number of nodes in the hidden layer is not only related to the number of nodes in the input and output layers but also related to the complexity of the problems to be solved, the types of transfer functions, and the characteristics of sample data. Suppose the collected sports scores form a sequence $\{y_1, y_2, \ldots, y_n\}$. Since the current sports score y_1 is related to its impact factor, there is a certain nonlinear relationship between them, namely,

$$y_i = f\left(x_{1,} x_{2,} \ldots, x_d\right), \quad (1)$$

where d is the embedding dimension of the input vector, which is selected by principal component analysis. F () is a nonlinear mapping function. The analysis of formula (1) shows that the fitting of the nonlinear mapping function f () is the key in the process of sports achievement modeling. Based on deep learning, this paper establishes a sports achievement prediction model. The workflow of deep learning for sports performance is shown in Figure 1.

The DNN model is extensible and can be optimized. The data in the sample library can be enriched by accumulating historical samples. The DNN's performance and prediction accuracy can be steadily improved over time by adding to and perfecting the expert sample data. Athletes' perceptions of the value of their sports training can be shaped by the public. By looking at the quality parameters of athletes who have achieved the expected value, a sports plan can be created. Improve the training plan's clarity and efficiency by adjusting the target parameters during the stage training effect test. Sports performance is modeled using the DNN model. In terms of chronology, previous sporting accomplishments are typical. The training set is used to train the combination kernel function correlation vector machine, and the adult prediction model of correlation vector scores based on the combination kernel function is established, and the test set is predicted to output the prediction results of sports scores based on the combination kernel function.

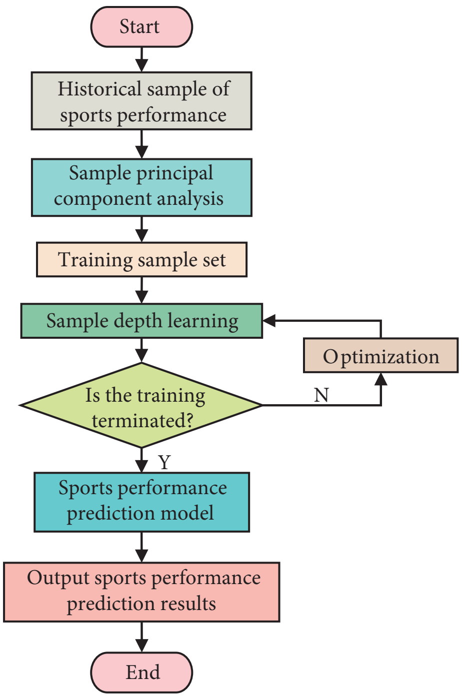

Figure 1: Deep learning workflow for sports performance.

3.2. Sports Performance Prediction Model Based on Deep Learning. The existing prediction models of athletes' special performance generally establish the functional relationship between special performance and quality training level through multiple regression methods and grey model and then predict athletes' special performance. The linear fitting feature space of sports performance is established, and the prediction model is constructed by the multiparameter constraint reconstruction method, which has a good prediction effect. To a certain extent, these prediction models reflect the relationship between special performance and training indicators and provide appropriate guidance for athletes' training [30]. However, these methods have some problems, such as high computational cost, poor adaptive anti-interference of parameters in the process of prediction, etc. And the determination of these models is based on certain assumptions. They need to set the mathematical expression of the special performance prediction model in advance. In fact, the functional relationship between special achievements and related factors is quite complicated, and the mathematical expression assumed in advance can't fit the relationship well. As a result, the prediction model of sports performance caused great errors and the prediction accuracy was low.

The establishment of the algorithm model of DNN requires seven steps: (1) Collection and grouping of sample data, (2) preprocess the data, (3) determining the number of hidden layers, (4) determining the number of hidden layer nodes, (5) training of DNN, (6) determining the initial weights of the network, and (7) testing the performance and generalization ability of the network algorithm model. Because of the huge amount of calculation, this algorithm requires high computer configuration, especially memory. Therefore, in the earlier period, many people advocated other algorithms to replace the problem of less network weights. However, with the rapid development of computer science and technology, there is no need for this concern, and the advantages of this algorithm are fully demonstrated. The training process consists of 10 modules, as shown in Figure 2.

Using the method of DNN, the nonlinear evaluation model of motor skill level, body shape, basic quality, and special quality is established, fitted, and predicted. Sports achievement data can be regarded as a set of nonlinear time series. The nonlinear time series method is used to analyze the trend of sports achievements, and the sports achievements are statistically analyzed. The fitting state model of using a multivariate statistical characteristic equation to describe sports performance is as follows:

$$\begin{pmatrix} X \\ P(X) \end{pmatrix} = \begin{Bmatrix} a_1, a_2, \ldots, a_m \\ p(a_1), p(a_2), \ldots p(a_m) \end{Bmatrix}. \tag{2}$$

In the formula $0 \le p(a_i) \le 1\,(i = 0, 1, 2, \ldots, m)$ and $\sum_{i=1}^{m} p(a_i) = 1$, representing the autoregressive statistical characteristic parameters.

Through the covariance matrix decomposition of the solution vector of the statistical equation, the principal component of the statistical characteristic information a_{ii} is obtained.

Research into the relationship between sports performance and body shape, function, basic quality, and special quality is extremely difficult in sports. This model is based on a functional relationship between sports performance and a variety of indexes of body shape, function, basic quality, and special quality. Regression based on logic can be thought of in the same way that neural networks are thought of in the same way that NNs are thought of. Because of its better parameter tuning and parallelization capabilities and higher feature magnitude than NN, logical regression is preferred over NN for large-scale feature estimation and analysis. Logic regression is a linear model, while DNN is a non-linear model, so it is necessary to double process features in order to get the best results.

(1) A non-zero random number is set whose V_{kl} is small, and the setting range is the weight coefficient of each layer.

(2) $A = (a_1, a_2, \ldots, a_m)$ is the input sample, and $E = (e_1, e_2, \ldots, e_m)$ is the corresponding expected output.

(3) The output of the k$^{\text{th}}$ neuron is located in the h layer, as shown in formula (3).

$$\begin{aligned} G_k^h &= \sum V_{kl} A_k^{h-1}, \\ A_k^h &= s\left(G_k^h\right). \end{aligned} \tag{3}$$

Usually, formula (3) will be expressed as a sigmoid function:

$$s(a) = \frac{1}{(1 - \exp(-a))}. \tag{4}$$

(4) Evaluate the learning error d of each layer, and $h = n$ in the output layer:

$$f_k^n = A_k^n \left(1 - A_k^n\right)\left(A_k^n - E_k^n\right). \tag{5}$$

The remaining layers, there are

$$f_k^h = A_k^h \left(1 - A_l^h\right) \sum V_k f_k^{h+1}. \tag{6}$$

(5) Modify the weight coefficient V_{kl}:

$$V_{kl}(p + 1) = V_{kl} - q \cdot f_k^h \cdot A_l^{h-1}. \tag{7}$$

(6) Judge whether the calculated weight coefficient of each layer can meet the requirements. If it can meet the requirements, the calculation can be finished; otherwise, the process has to be repeated from step (3).

On the basis of the statistical analysis model of sports achievement, a prediction model of sports achievement is established by using DNN. Empirical mode decomposition and factor analysis are carried out on the time series of sports achievements in DNN. The logical regression is better for discrete features. Therefore, it is necessary to discretize the normalized features. There are many ways to discretize features. Usually, continuous features are mapped to fixed values. Generally, the feature value domain is equally divided into fixed intervals, and the intensity of each interval can be customized.

Sports performance prediction can help schools, sports teams, and sports training institutions develop scientific training methods that reflect the changing trends in sports performance. We can monitor the progress of athletes' physical fitness and sports performance during training, comparing the results to theoretical expectations and making adjustments to the training plan as needed, thus keeping the entire training process in check. One of the most important features of the NN is its ability to learn on its own, as well as its ability to generalize. This paper's deep learning model outperforms both the multiple regression model and the grey model in terms of performance. The mathematical expression of an athlete's unique performance prediction model does not need to be determined in advance. Fitting and prediction accuracy can be improved by more objectively mapping the correlation between athletes' quality training levels and their performance.

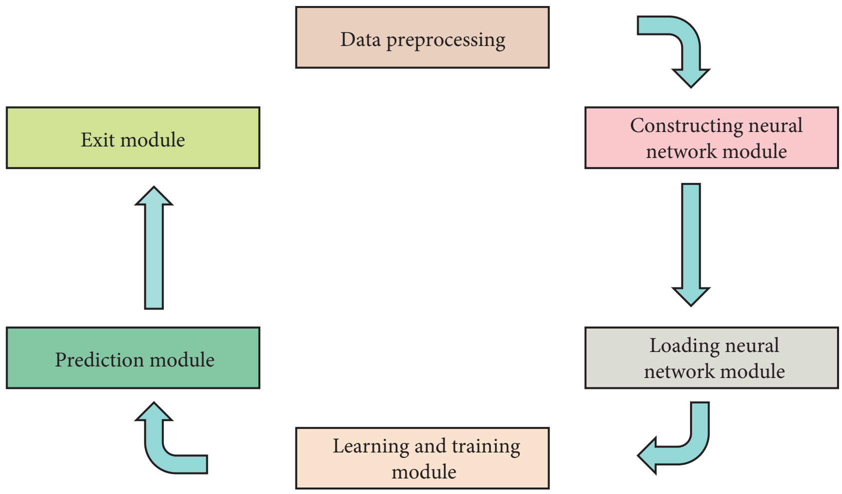

Figure 2: Training prediction process.

4. Result Analysis and Discussion

The problem of performance prediction is characterized by the strong randomness of data, many influencing factors, complex interaction and relationships among factors, etc. Therefore, the research results of sports performance prediction obtained by traditional prediction research methods are not ideal. Through sports, survival of the fittest and ranking, we can test the technical level of sports, select talents, motivate backward players, and attract more people to participate in sports.

A large amount of measured data needs to be filtered and filtered in order to conform to a sample set of effective patterns. Sample libraries can be built up over time as more historical data is accrued, allowing the model's inputs and outputs to be filtered based on the reality of a given situation, as well as the results from statistical calculations. The principal component analysis (PCA) is performed on these variables because there are some recurring relationships between athletic performance and things like height, weight, vital capacity, 50-meter running, sitting and bending forward, 800-meter running, and one-minute sit-ups. Figure 3 depicts the time domain waveform description of the sample data as described by the simulation settings and used to design the sports performance prediction model.

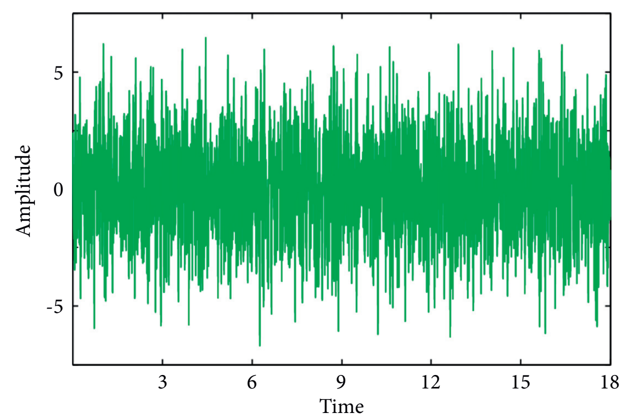

Figure 3: Time-domain waveform of sports performance statistics.

After many training and prediction tests, it is found that the addition of some test data will affect the convergence speed and prediction accuracy of the model. For example, athletes with insufficient training years or athletes whose test results in deviation of some indexes due to some special conditions. Therefore, this kind of data is excluded. Taking the collected statistical samples of sports performance as the test set, the simulation analysis of the sports performance prediction model is carried out, and the comparison results of prediction errors of different methods are shown in Figure 4.

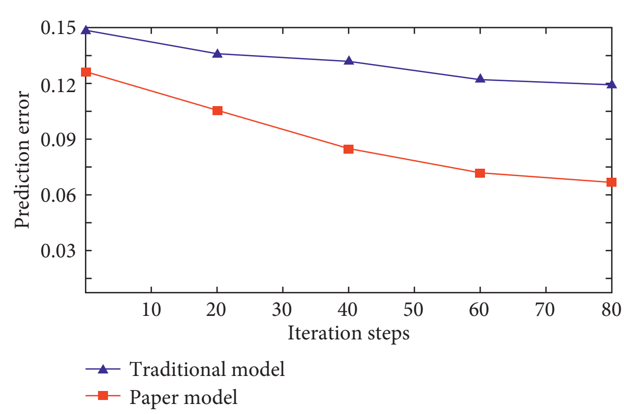

Figure 4: Forecast error analysis.

Each node in a DNN's input layer is defined as a feature, and nodes in the same layer are mutually independent. Features must be normalized before they can be compared in logistic regression or deep neural networks (DNN). The model jitter will not deviate when the normalized features are trained in the model, and the weights of the features will be more stable. In order to make predictions about an athlete's special performance, models that use multiple regression and a grey model establish a functional relationship between special performance and quality training level. The statistical distribution of unified samples and the unification of basic measurement units can be achieved by normalization. The trend of deep learning neural training in this paper is shown in Figure 5.

More samples in the input layer mean more computation, more hardware requirements, and longer time consumption when using a DNN to train samples repeatedly. That's why cutting down on the number of training indicators is essential. For calculating the correlation coefficient and figuring out the degree of correlation between each index and the level of movement technology, we use the correlation analysis method. Multiple indicators with significant and conclusive impact on the level of motor skill have been eliminated using cluster analysis. Pictured in Figure 6 is a curve that shows the relationship between expected and actual deep learning outcomes. It can be seen in Figure 6 that the predicted long jump value and the actual long jump value are very close. A great deal of research has led to excellent standing long jump results. There was a significant improvement in prediction accuracy with the prediction model.

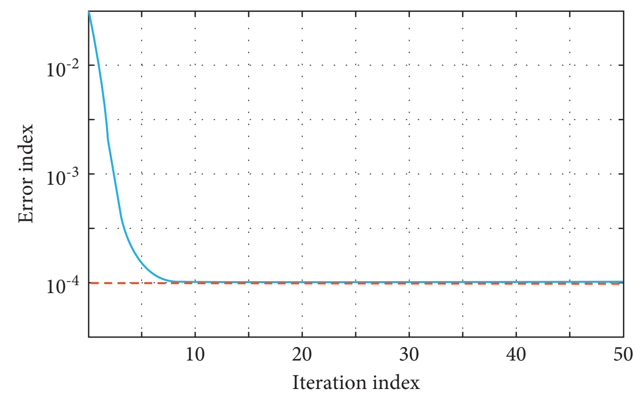

Figure 5: Trends in DNN training.

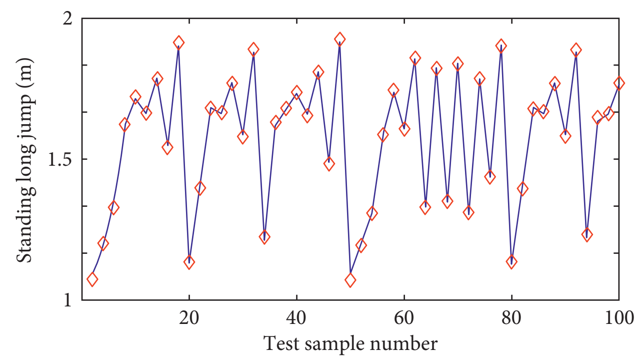

Figure 6: Fitting curve of predicted value and actual value of deep learning.

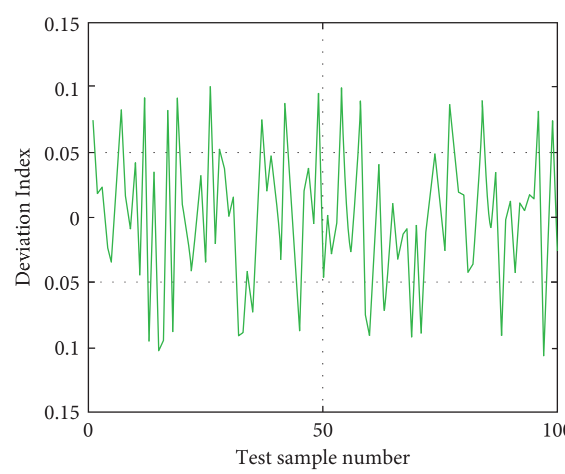

Figure 7: The prediction deviation curve of deep learning.

Filter and screen a large number of measurement data to make them conform to the sample set for establishing effective patterns. Because there are some rules and relationships between the input and output of the model, which data should be retained and filtered are mainly determined by the actual situation, experience, and statistical calculation results. This sample library can be gradually supplemented and improved with the increase of historical data. The model has a small error range and high prediction accuracy for athletes' performance, which shows that the model is accurate and effective. In some practical problems, no standard function model or function analytic model is highly nonlinear, so we can use DNN to predict the approximate value. The change curve of prediction deviation of deep learning is shown in Figure 7. It can be seen in Figure 7 that the deviation between the predicted value and the actual value of sports performance is relatively small. And the variation amplitude of the prediction deviation is also small. The results show that it is feasible and effective to introduce the deep learning model into the standing long jump performance prediction.

Sports achievement is an important manifestation of sports training levels. Through the accurate prediction of sports performance, we can dig out the regular factors and characteristics of human training, thus promoting the improvement of sports training and sports teaching. Sports have a special activity flow, clear purpose, distinctive competitive features, and a complete set of competition rules and methods. At the same time, it is of great significance to study the prediction model of sports performance to promote scientific training and improve sports performance. As a new algorithm in current machine learning, the DNN is excellent in model representation and data processing ability. The DNN can produce better results in data representation through complex network structure and deep network layers. Using the hierarchical structure of the DNN can realize the nonlinear intersection of features. Compared with the simple combination intersection of discrete features, the DNN can learn features more fully and accurately. This model shows the mapping relationship between athletes' performance and various factors. And the convenience and accuracy of sports performance prediction are realized. Furthermore, it improves the efficiency of modeling and the accuracy of performance prediction.

5. Conclusions

People today place a high value on participating in sports. A lot of time and money was also invested in the collection of sports performance data. For the future direction of sports teaching, it is important to analyze historical sports achievement data and predict future sports achievement. There is a synergistic relationship between scientific research and the project's development. For coaches on the front lines, a lack of theoretical research will inevitably stifle the development of movement technology. Sports performance and related factors must be studied quantitatively, using interdisciplinary approaches, as soon as possible. The multivariate and multiparameter statistical analysis is used to build a model for sports achievement prediction. Statistics, information processing, and modern mathematics are among the topics covered in the course. In this paper, a sports performance prediction model based on deep learning is developed using the nonlinear modeling advantage of NN, and the model's performance is thoroughly tested and analyzed through several prediction examples. Using this model, the sports performance prediction accuracy has increased and the prediction error has decreased, compared to traditional methods. The model can be used in a real-world setting.

The development of a financial analysis system is essential for modern businesses to improve their management systems. In light of the global financial crisis, it is even more critical for businesses to develop a rigorous financial analysis system to avoid risks. DM does not necessitate the development of a complex mathematical theory; as long as data are filtered, hidden features between data can be found. The decision tree algorithm is one of several DM methods. With the rapid advancement of DM technology, theories and applications related to it are maturing at a rapid pace. This study will develop a decision tree-based enterprise financial risk analysis and early warning model, analyze enterprise financial influencing factors, apply the decision tree method to enterprise financial risk analysis and early warning, and provide a reference for enterprise financial risk early warning and risk control decision-making.

1. Introduction

Many scholars studying enterprise management focus on how to make businesses succeed, but pay less attention to how to keep businesses from failing [1]. However, a large number of enterprise management case studies show that due to the uncertainty of the objective environment and people's limited ability to understand it, as well as poor internal management of the enterprise, it may lead to an enterprise crisis, but the enterprise has no forewarning of the crisis, and no preventive measures, resulting in enterprise management failure [2]. A financial analysis system is a real-time monitoring system for potential risks in business management activities based on enterprise informatization [3]. The construction of a financial analysis system is of great practical significance to improve the management system of modern enterprises. Especially under the background of global financial crisis, the establishment of a scientific financial analysis system is more important for enterprises to prevent risks [4]. Enterprise financial management involves many and complicated work contents, which requires financial managers to plan and deploy enterprise financial management contents reasonably based on the development of market economy, so as to ensure the smooth progress of enterprise financial management activities. Therefore, how to find and correctly predict financial crisis as soon as possible is of great practical significance for reducing enterprise operation risk, protecting the interests of investors and creditors, supervising listed companies by government departments, and preventing financial crisis [5]. If an enterprise can establish an effective financial analysis system, it can find and take effective measures to avoid greater losses when the enterprise's financial situation is just in crisis, so that the enterprise can remain invincible in the fierce market competition [6].

Data mining (DM) does not require complex mathematical theoretical derivation. As long as data filtering is used, the hidden characteristics between data can be found [7]. A decision tree is a case-based induction system that can generate decision tree representation classification rules from a set of unorganized and irregular examples [8, 9]. Traditional statistical models include multivariate discriminant analysis model and logarithmic regression model [10]. Statistical models have obvious interpretability, but they often require data to obey assumptions such as multivariate normal distribution, and their stability is not high [11]. Financial risk exposure is often the last stage of overall risk exposure; that is, all potential problems begin to appear and are exposed in the form of financial risk [11, 12]. This study will establish the enterprise financial risk analysis and financial crisis early warning model based on the decision tree algorithm, analyze the enterprise financial influencing factors, apply the DM method to the enterprise financial risk analysis and crisis early warning, and provide reference for the enterprise financial risk crisis warning and risk control decision-making.

With the development of IT, some classification and prediction algorithms of AI and machine learning have also been introduced into the field of financial credit risk assessment, mainly including the methods of an artificial neural network [13, 14] and decision tree [15]. The fault tolerance, flexibility, and generalization functions of an artificial neural network are all excellent. However, neural network modeling is a difficult approach to master; training a model takes a long time and thousands of iterations, and it also needs human troubleshooting [16]. The traditional financial management strategy is no longer applicable to the current enterprise financial management. It can be said that seeking an innovative and forward-looking financial management strategy has become an urgent problem to be solved in the current enterprise financial management [17]. Decision tree is a top-down classification method. It constructs a decision-making knowledge representation by learning a group of training samples [18]. According to the essential requirements of the theoretical connotation of enterprise financial early warning mechanism, taking the theoretical scientificity and practical operability as the basic requirements, this study starts from two aspects of short-term early warning and long-term early warning, and uses the early warning analysis methods of qualitative, quantitative, and qualitative and quantitative to establish an early warning system that can effectively predict enterprise financial crisis. Compared with a neural network, decision tree is easier to understand. Decision tree has the advantages of low requirements for data preparation, allowing the existence of outliers, high speed, high precision, and simple generation mode.

2. Related Work

Literature [19] proposes that the establishment of a decision tree can be completed as long as the database is scanned several times, which also means that less computing resources are required, and the situation containing many predictive variables can be easily handled. Literature [20] employs a linear probability model to examine the banking industry's early warning system for financial crises. A linear probability model is a subset of a multivariate analytic model that may be used to evaluate the likelihood of a company failing. According to literature studies [21, 22], the financial crisis early warning model must be adjusted in accordance with the production and operation status as well as the financial status of enterprises, in order to ensure that the discrimination rules of the early warning model are suitable for the current market environment, given the continuous development of computer technology and AI and the increasing necessity of enterprises to deal with the changeable market competition environment. Literature [23] questioned the traditional way of using all available financial ratios to predict enterprise crisis based on the correlation between some financial ratios and the lack of distinction between the importance of each ratio. Literature [24] first used discriminant analysis to extract 5 financial indicators with prediction ability from 22 financial indicators and conduct modeling analysis. The decision tree algorithm has a greater accuracy for financial crisis early warning than the Z-score scoring model, according to literature [25]. Literature [26] uses nine independent variables and finds at least four types of variables that significantly affect the company's bankruptcy probability: company size, asset structure, company performance, and current asset liquidity, which are put into the model.

Most of the financial early warning indicators put forward in the above research are common financial evaluation indicators. Financial evaluation indicators cannot sensitively and timely reflect the risk degree of enterprise financial situation, and they do not correspond the financial risk analysis with early warning indicators one by one, so as to accurately diagnose the hidden dangers of enterprise financial crisis. Based on the theory of enterprise early warning management and macro-economic early warning methods, this study analyzes the financial warning sources that lead to enterprise failure and the financial influencing factors that identify enterprise crisis, and builds a financial early warning model based on the decision tree algorithm.

3. Methodology

Cash is the blood of the enterprise, the primary factor restricting the business activities of the enterprise, and the focus of attention of operators, investors, and creditors [27]. The bankruptcy of many enterprises is caused by insufficient cash flow and inability to repay debts when due. The analysis basis of cash flow early warning is the cash flow statement of various industries and enterprises. If the cash flow exceeds the needs and there is surplus cash, it has strong adaptability. Income quality mainly analyzes the proportional relationship between accounting income and net cash flow [28]. The operating ability index is an index to measure the efficiency of an enterprise in using its resources, which reflects the enterprise's ability to manage assets [29]. If the operating ability is poor, it may indicate the possibility of financial crisis in the future.

The definition of the information entropy can be described as follows:

$$\text{Entropy}(s) = \sum_{i=1}^{n} -p_i \log_2 p_i. \tag{1}$$

Here, p_i is the proportion of S belonging to category I, S represents the sample set, and n represents the number of target attributes.

We can define the information gain as follows:

$$\text{gain}(S, A) = \text{entropy}(S) - \sum_{v \in \text{Value}(A)} \frac{|S_v|}{|S|} \text{entropy}(S_v). \tag{2}$$

Among them, Value (A) is the value set of attribute A, v is a value in Value (A), $|S_v|$ is the number of samples whose attribute A takes the value of mouth, and $|S|$ is the total number of samples.

We can define the information entropy as follows:

$$\begin{gathered} \text{gain ratio}(S, A) = \frac{\text{gain}(S, A)}{\text{SI}}, \\ \text{SI} = -\sum_{i=1}^{n} \frac{|S_i|}{|S|} \log_2 \frac{|S_i|}{|S|}. \end{gathered} \tag{3}$$

Among them, S_1 to S_n are a set of n samples formed by dividing S with n-valued attributes.

We can define the normal gain as follows:

$$NG = \frac{\text{gain}(S, A)}{\log_2 n}. \tag{4}$$

It is shown that the information gain standard tends to prefer finer division, whereas the information gain rate prefers uneven division, and the normal gain is more effective than the former two.

In order to ensure the innovation effect of enterprise financial management, enterprise managers should give priority to building a good corporate financial culture atmosphere and provide a good guarantee for the smooth progress of various financial management activities of enterprises. In the process of practice, it is suggested that the internal publicity and management of enterprises should focus on the importance of financial innovation, so that all employees can form a good sense of enterprise financial management [30]. It is best to integrate humanistic ideas into the process of creating financial innovation culture to ensure the formation of a harmonious atmosphere of corporate culture. To change the traditional concept of enterprise financial management, first of all, it is necessary to make the enterprise management pay attention to and accept the brand-new financial management system, and have its own system to change the concept of enterprise financial management. The adoption of brand-new management concepts by management in enterprise management can effectively promote the pace of reform and innovation of financial management concepts, and fully implement the reform and innovation of enterprise financial management concepts.

Usually, the cash flow of business activities should be positive, the cash flow of investment activities should be negative, and the cash flow of financing activities should be positive and negative. However, as a whole, cash can flow between operation, investment, and fund-raising activities, and it is not possible to judge whether an enterprise is safe and its security degree only by the flow level of a certain activity, the positive and negative ratio among various activities. Figure 1 shows the structure of an intrusion detection system for the enterprise financial system.

The first year or previous year's data of an enterprise should not be taken as a critical point of the enterprise's security or crisis, so financial ratios such as the growth rate of the enterprise's net operating cash flow calculated from this can only reflect the fluctuation of the enterprise's cash flow, not the security or crisis degree of the enterprise. Cash flow is what an organization can really use to pay off its debts, and a comparison of cash flow and debts can better reflect its solvency. The cash flow ratio and total cash liabilities ratio are two financial early warning indicators that reflect liquidity. The cash flow ratio is the most detailed financial ratio for evaluating an organization's short-term solvency. It corrects the flaw in traditional ratio analysis that is the current ratio index, and it can dynamically and historically monitor a company's short-term solvency. According to the premise of the decision tree algorithm, financial early warning necessitates index selection, training, and testing. The specific design concept is depicted in Figure 2.

Solvency refers to the ability of an enterprise to repay debts due, and the income obtained by the enterprise in the current period should first repay various debts. The indicators of solvency include the repayment ratio of principal and interest of due debts, the ratio of operating net cash flow, the guarantee multiple of cash interest, and so on. The analysis indexes of enterprise's ability to pay mainly include the net cash flow of common stock per share operating activities, the net operating cash flow of paying cash dividends, the financing ratio of investment activities, and the cash reinvestment ratio. However, these indicators are not in line with the definition of enterprise's ability to pay. The income earned by enterprises should be used to repay debts first and then used to meet various expenses. The enterprise financial crisis early warning theory is a broad concept that spans several fields. It is a knowledge that covers many disciplines, such as enterprise risk management, project investment management, dynamic information technology, and mathematical modeling. The research of enterprise financial crisis early warning is to mine rules with high trust according to the fluctuation of financial indicators. When the fluctuation of indicators exceeds a certain range, the system should give an early warning.

If $x_i \in R^n$ is the factor influencing the financial risk forecast, y_i is the financial risk forecast value. The financial risk prediction model based on the decision tree algorithm is to find out the relationship between x_i and y_i, which is given as follows:

$$\begin{gathered} f\colon R^n \longrightarrow R, \\ y_i = f(x_i), \end{gathered} \tag{5}$$

where R^n is the factor that affects the financial risk forecast. According to the decision tree algorithm, establish the financial risk prediction model as follows:

$$f(x) = \sum_{i=1}^{k} (a_i - a_i^*) K(x, x_i) + b, \tag{6}$$

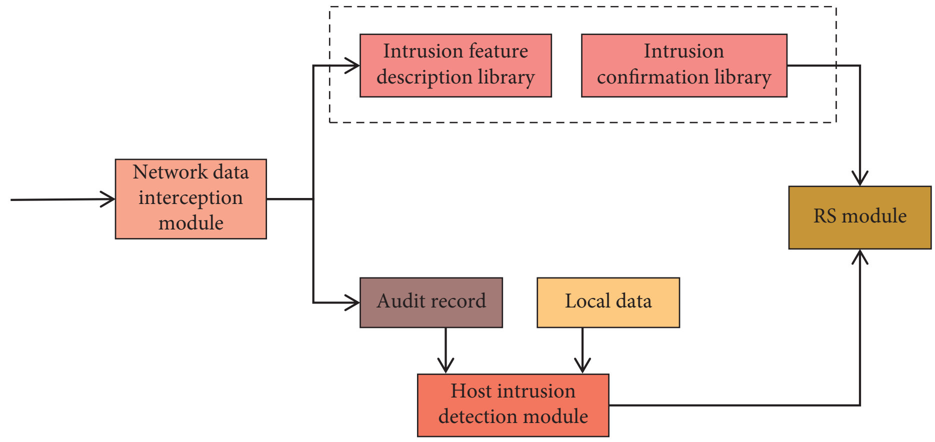

FIGURE 1: The construction of an intrusion detection system for an enterprise finance system.

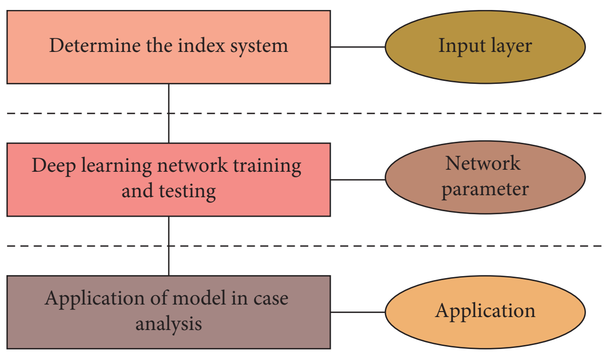

FIGURE 2: Design idea of a financial early warning model.

where x is the factor that affects financial risk and x_i is the i sample in the k sample. $K(x, x_i)$ is the kernel function, which is given as follows:

$$K(x, y) = \exp\left|-\frac{\|x - y\|^2}{2\sigma^2}\right|. \tag{7}$$

In the case of insufficient assets, entrepreneurs must borrow or finance a large amount, so they must mortgage most of the income obtained when the project is successful. When an enterprise lacks solvency, it will result in insufficient funds, delayed payment of interest, and principal to creditors, which will easily lead to financial crisis and bankruptcy. In financial early warning, the ratio of long-term debt to working capital and asset-liability ratio are mainly used. The asset-liability ratio is the core index of long-term financial early warning, which reflects how much of the total assets are raised by borrowing and reflects the long-term solvency of enterprises. When the rate of return on investment is greater than the loan interest rate, the more loans, the more profits, and the greater the financial risk.

4. Result Analysis and Discussion

Enterprises cannot grow without the support of funds, which are required for their operations. Enterprise fund management is a critical component of enterprise financial management, as it introduces risks to enterprise internal management, such as capital, management, and business risks. Enterprise financial management objectives evolve and change in response to changes in the market economy environment of their industries, and financial management objectives evolve and change in response to changes in the market economy and social consciousness. As a fundamental assurance to enable the seamless implementation of business financial innovation management, financial innovation culture may have a direct influence on enterprise financial management level to some extent.

The risk assessment of this study will start from qualitative and quantitative aspects, and qualitative assessment, such as expert consultation and scenario analysis, will be used for moral hazard judgment. Regarding the cash flow of enterprises, the financing amount will be determined quantitatively, such as the decision tree algorithm. Most of the current risk management is limited to compliance and internal control. Most of the operating funds of enterprises come from financing channels, and most enterprises belong to family nature, which is influenced by the family factors of initial enterprise financing. Family management is also the obstacle of enterprise fund management, and most financial management problems appear here. Because there is no professional management of funds, the management effect of enterprises is not good. Because most of the funds raised by enterprises are bank credit, the low reputation of enterprises will lead to difficulties in bank loans, which will have an impact on enterprise financing. If enterprises lack funds for development, it will lead to difficulties in capital turnover and hinder the progress of enterprises. Figure 3 depicts the link between enterprise size and cost.

As a matter of fact, the enterprises themselves lack awareness of innovative ideas, which leads to the lack of awareness of innovative ideas of financial management among enterprise financial managers. In the long run, the financial management of enterprises is difficult to reach the expected level and even lags behind. The basic function of enterprise financing is to enable enterprises to obtain certain capital for further development and expansion with the lowest risk, and this kind of financing method belongs to the basic financial financing method. However, as the economic

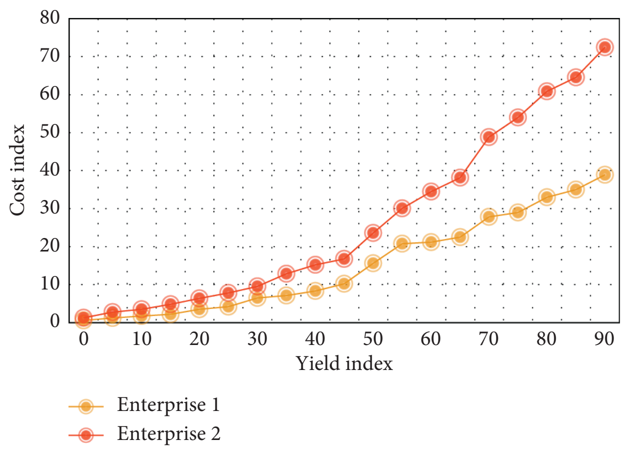

Figure 3: The cost-benefit analysis of the link between business size and cost.

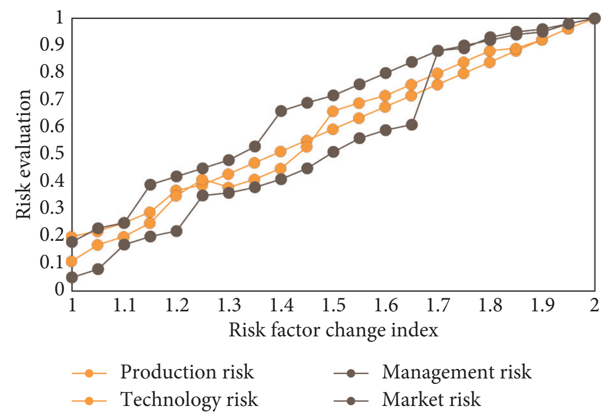

Figure 4: Evaluation and change of risk factors.

system develops and changes, the concept of knowledge economy gradually gains a dominant position in the composition of enterprise assets, and enterprises will include knowledge capital in financing, laying a solid foundation for knowledge capital to become the core capital of enterprises and, as a result, knowledge capital will gradually become an important core capital for enterprises to survive. Internal control is a key component of enterprise financial management, as it ensures the legality of financial actions, the real effectiveness of financial information, and the integrity of firm assets.

Enterprise financial management evaluation is an important link in enterprise financial management, and it is also the best way to test enterprise financial management ability and innovation ability, which can effectively help enterprise financial management to find out shortcomings, thus contributing to the reform and innovation of enterprise financial management. Moreover, the construction of enterprise financial management evaluation mechanism mainly depends on the economic added value of enterprises, the amount of circulating capital, and the market demand in the industry. The evaluation is only aimed at the capital value targets of enterprises, and isomorphic and effective evaluation methods are used to find out the development process of innovation mechanism of each unit in enterprise management.

The major purpose of business financial early warning is risk control, which includes not only anticipating financial hazards but also identifying the reasons that contribute to financial difficulties in a timely manner. Figure 4 depicts the evaluation and modification of risk variables.

The analysis shows that the business is sensitive to business risks and less sensitive to financial risks. The financial management system lacks the support of an innovative theory, and it is generally difficult to provide internal driving force for the deepening development of enterprise financial management. In addition, appropriate combination or introduction of modern financial management technology can provide guarantee for the sound development of the enterprise financial management system. However, some enterprises lack this awareness, so they lack soundness in the construction of the financial management system. The improvement of enterprise management ability comes from all directions, and with the popularization and development of new enterprise management concepts and methods in the current era, the overall management level of enterprises in all aspects is constantly improving, and as the core of enterprise management, the enterprise financial department should constantly study and improve the enterprise financial management ability. For example, the importance of implementing innovative financial management should be made clear, and the inefficiency of financial management in the past should be avoided. When necessary, relevant innovation management training activities can be held regularly, so that financial personnel can know the shortcomings of their own management consciousness in time. In practice, it is suggested that financial personnel should actively improve specific problems, avoid previous management risks, and ensure that the overall financial management effect of enterprises can achieve the expected results.

Compare the indexes at the same level and provide a proportionate scale score based on the indexes' relative relevance. Figures 5 and 6 depict the data link between weight and assessment value.

In view of the lack of innovative awareness of financial management in enterprises at present, it is suggested that enterprise leaders should deepen their awareness of financial management in enterprises from multiple working levels, so that all employees in service can clearly understand the importance of innovative financial management. Focus on the integration and strengthening of enterprise financial management activities, and try to infiltrate financial innovation management into all management links. With the continuous development of China's market economy, the competition among enterprises is becoming more and more fierce, and the financial management department has gradually played a greater role in the management of enterprises. However, with the development trend of modern enterprises, enterprises have put forward higher requirements for the ability and professionalism of the staff of the financial management department, and enterprises need to regularly carry out knowledge learning and skills training for

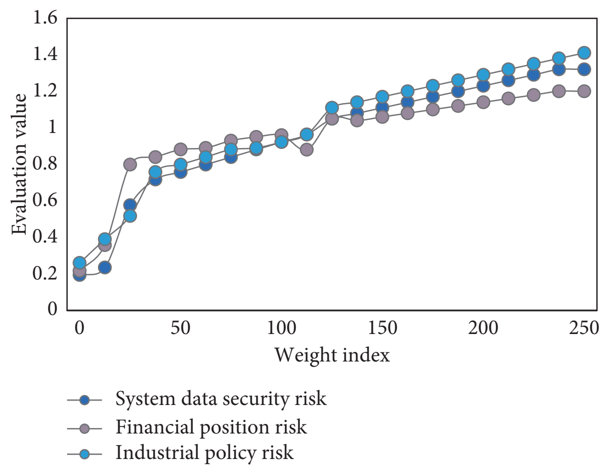

Figure 5: The weight of financial risk and the value of evaluation.

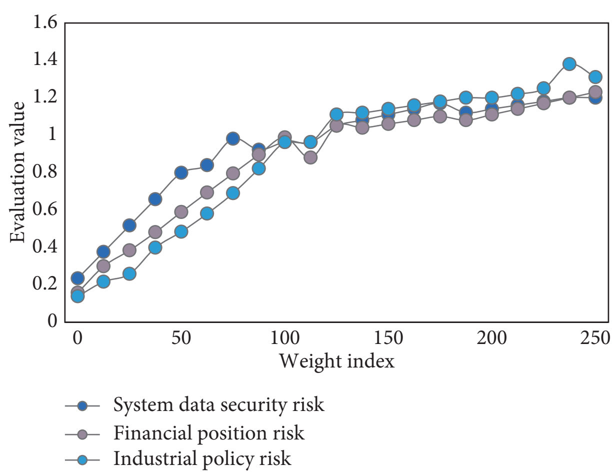

Figure 6: Financial risk weight and evaluation value.

the staff of the financial management department, so as to improve the standards of financial management.

Modern enterprise management believes that the implementation of enterprise financial innovation culture is the prerequisite to effectively promote the scientific implementation of various business management activities of enterprises, and it must be implemented and implemented with emphasis. The indispensable part of the financial management system innovation is the support of the financial management system. In reality, there is a big difference between enterprise financial management innovation and financial management system, which makes them unable to form a mutually promoting relationship. However, the lag of the financial management system leads to that the financial management system cannot provide institutional support for financial management innovation. As promoters of various financial management activities, it is necessary for financial personnel to shoulder their own heavy responsibilities, make clear the importance of implementing innovative financial management, and avoid the inefficiency of financial management in the past. In this study, Figure 7 shows a performance comparison of the decision tree approach with the conventional technique.

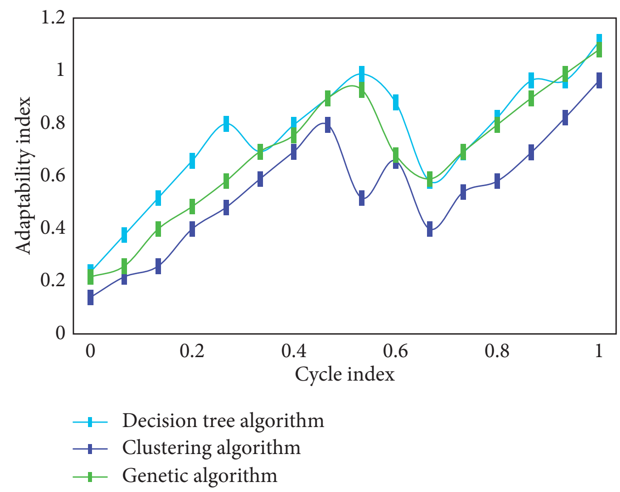

Figure 7: Algorithm performance comparison.

The financial department of an enterprise not only meets the development needs of the enterprise, but also improves the market competitiveness of the staff of the financial department through continuous training and study of professional ability, and provides new impetus for the reform and innovation of the financial management ability of the enterprise, thus realizing the dynamic innovation of the financial management of the enterprise. In practice, it is suggested that enterprise managers should give priority to improving the content of the financial management system to solve the problem of insufficient internal driving force of financial management in the past. At the same time, combining with IT, the related management platform system is built to reduce the delayed effect of financial information management.

As illustrated in Figure 8, the decision tree algorithm model is used to the risk prediction of sample data, and the prediction results are mostly consistent with expert recommendations.

In practice, each assessment index is divided into three zones: safety, early warning, and crisis, with critical values for each zone specified. The actual value is compared with the critical value to determine the region where the early warning index is located, so as to judge the degree of risk faced by the enterprise. Single variable model analysis is relatively simple, but it cannot comprehensively explain the overall financial situation of the company. With the knowledge capital gradually becoming the dominant factor in the capital structure of enterprises, it is necessary to add the ratio of knowledge capital to the distribution of enterprise wealth, and by confirming the status of knowledge capital, people with certain knowledge capital can enter the distribution of enterprise wealth through their own knowledge capital and get due remuneration. In addition, the wealth distribution system, which is used to distribute employees' salaries according to the assessment mechanism such as working hours and work quantity, has been effectively reformed and innovated, thus transforming into the way of salary distribution based on the value created by individuals for enterprises.

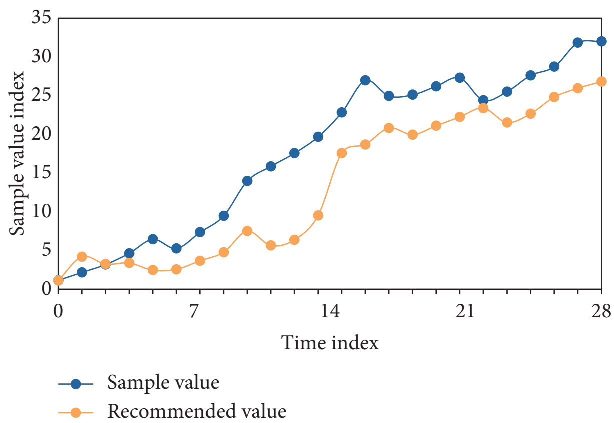

Figure 8: Comparison of recommended values and evaluation values.

5. Conclusions

With China's enterprise bankruptcy and stock market exit mechanisms improving all the time, most businesses have realized the importance of putting in place a financial presubstitution system, and their risk awareness is increasing. Traditional statistical techniques require a lot of assumptions, so they cannot handle a lot of data and are often limited to financial data. This research will use the decision tree algorithm to develop an enterprise financial risk analysis and financial crisis early warning model, assess enterprise financial influencing factors, and apply the DM technique to enterprise financial risk analysis and crisis early warning. If a warning is found in this month's operation, you should check the detailed indicators to determine the causes and departments of the problems, and take appropriate measures to solve and effectively control the problems.

Compared with neural networks, decision trees are easier to understand. Decision tree has low requirements for data preparation, allows the existence of outliers, and has the advantages of fast speed, high precision, and simple generation mode. This article is just the first attempt to apply DM technology to financial early warning research. I believe that with the development of IT, there will be more newer and more accurate data analysis methods applied to the research of financial distress early warning systems.

As a form of artistic expression, dance accompanied by music enriches the cultural life of human beings and stimulates the creative enthusiasm of the public. Choreography is usually done by professional choreographers. It is highly professional and time-consuming. The development of technology is changing the way of artistic creation. The development of motion capture technology and artificial intelligence makes computer-based automatic choreography possible. This paper proposes a method of music choreography based on deep learning. First, we use Kinect to extract and filter actions and get actions with high authenticity and continuity. Then, based on the constant Q transformation, the overall note density and beats per minute (BPM) of the target music are extracted, and preliminary matching is performed with features such as action speed and spatiality, and then, the local features of the music and action segments based on rhythm and intensity are matched. The experimental results show that the method proposed in this paper can effectively synthesize dance movements. The speed and other characteristics of each movement segment in the synthesis result are very uniform, and the overall choreography is more aesthetic.

1. Introduction

Movement is the soul of dance. The first problem that needs to be solved in computer choreography is how to digitize dance movements. Kinect is a somatosensory device released by Microsoft in 2010. Its working principle is to automatically recognize the joint motion data of the human skeleton through infrared rays and capture the skeleton of human motion. Kinect is known as the epoch-making work of the third generation of human-computer interaction technology. In recent years, the use of Kinect for action extraction and then realization of computer dance art has become a research hotspot. In the display of dance, the traditional method is that the choreographer verbally explains or tells the performer by drawing a picture, and then, the dancer shows the specific movement, and subsequent modifications need to be carried out on the actual effect. This requires many repetitive performances by the actors, and the workload is heavy. The use of computer for choreography can show the choreography dance through 3D virtual reality technology so that the choreographer can create, arrange, modify, and preview the effect in the computer in advance. Based on the above technology, it is possible to make simple choreography using a computer.

Many existing motion generation technologies based on machine learning have been applied to dance research, including dimension reduction technology [1], Gaussian process [2], and hidden Markov model [3], so as to capture the potential correlation between music and dance motion characteristics. Dimension reduction technology can map the high-dimensional features of motion to low-dimensional space, so as to capture the potential correlation behind joint rotation in motion capture data [4]. However, the algorithm needs preprocessing steps, such as sequence alignment and fixed data length, and cannot directly model the timeliness of motion data, which limits its application in real dance motion data. Gaussian process late variable models can effectively summarize the changes of human cloud force, but they are not suitable for real-time generation because they require a lot of computing and memory resources [5]. HMM model overcomes the limitations of the two types of models mentioned above, but its ability to capture data changes is limited [6]. In order to solve the defects of computer choreography based on machine learning, this paper will introduce deep learning method to improve the novelty and coherence of generated actions.

2. Methods

2.1. Overview. First of all, the problem that needs to be solved is motion capture based on Kinect. When Kinect captures human body motion data, it captures 20 joint nodes of the human body through infrared rays. As long as you face Kinect and do dance movements, you can record the corresponding raw data. This avoids the need to place sensors on the capturer during traditional motion capture, which hinders the fluency of dance movements. Convert the captured raw data into the BVH file format to save the dance moves. The motion data file in BVH format is one of the standard file formats in the motion capture industry and is widely supported by mainstream animation production software. When using Kinect to collect dance movements, it is conducive to the optimal display and file storage of virtual dances based on the "Principle of Optimal Movements" and "Principle of Minimal Data Simplification" [7].

Secondly, it is necessary to edit and integrate dance movements. Using the 3D software MAYA as the platform, the basic dance moves stored in the BVH format are imported into MAYA for editing. The choreographer can make modifications and combinations based on the existing basic dance moves, such as modifying the angle of the limbs, the speed of a certain movement, and the number of repetitions [8]; at the same time, they can also arrange and integrate the sequence of specific dance moves to express different dance themes. In addition, the choreography of dance emphasizes innovation. Using Kinect equipment, you can capture newly designed dance moves at any time. After converting it into BVH format, it becomes the new basic action element.

Finally, it is necessary to match the skeleton and the character and realize the three-dimensional display. After the preliminary editing of a certain dance movement is completed, the 3D characters can be driven to dance. MAYA provides the function of binding the skeleton to the model so that the 3D model follows the movement of the skeleton. Modify the bound model by adjusting the weight of the model, the size of the skeleton, and other factors so that it can express the dance effect as realistically as possible. For the choreography of large-scale dances, after the choreography of a certain model is completed in advance, the skinned models can be copied and arranged directly to create the ideal formation and stage effect.

2.2. Motion Capture

2.2.1. Two-Dimensional Key Point Recognition Network. The key points of the two-dimensional human body are identified using the Stacked Hourglass Network architecture. This network is constructed by loop nesting of the Hourglass subnetwork. The Hourglass subnetwork is composed of a basic structure called residual module. The residual module structure is shown in Figure 1(a). The input value will pass through the upper and lower paths. This design is inspired by the residual network. The above path is a convolution path, which contains three convolution layers with different sizes of convolution kernels, which are represented by white rectangles in the figure. The three lines of text in the rectangle represent the number of input channels (N_{In}), the size of the convolution kernel (K), and the number of output channels (N_{Out}) from top to bottom. Among the three convolutional layers, there are also batch regularization layers and nonlinear activation layers (RELUs), all of which are represented by gray rectangles. The lower path is a jumper path. This path contains only a convolutional layer with a convolution kernel size of 1×1, which will change the number of channels of the input value, and its output value will be directly added to the output value of the upper path.

The structure of the Hourglass subnetwork is shown in Figure 1(b). Each white rectangle in the figure represents one of the above residual modules. In the upper half, feature extraction is performed continuously, and in the lower half, downsampling is performed through the maximum pooling operation first, and after several residual modules, the nearest neighbor interpolation method is used for upsampling. The two gray rectangles in the figure represent the downsampling and upsampling processes, respectively. It can be seen that there is a dashed line frame in the Hourglass subnet structure diagram. The dashed line frame is replaced by an Hourglass subnet, which is called a second-order Hourglass network. In this study, the Hourglass subnetwork is looped and nested four times for two-dimensional key point detection, namely, the fourth-order Hourglass network.

2.2.2. Three-Dimensional Keypoint Regression Neural Network. After the two-dimensional human body key points are recognized, a set of two-dimensional coordinate values of the human body key points will be output. Then, use this set of two-dimensional coordinates $x \in R^{2n}$ and use the neural network to return to the corresponding set of three-dimensional coordinate values $y \in R^{3n}$. The mapping relationship of the three-dimensional coordinates regressed from the two-dimensional coordinates is $f\colon R^{2n} \longrightarrow R^{3n}$. Optimize the neural network by minimizing the following prediction errors, namely,

$$f^{*} = \min \frac{1}{N} \sum_{i=1}^{N} L\left(f\left(x_i\right) - y_i\right). \tag{1}$$

Among them, L represents the Euclidean distance between vectors as the loss function, N represents the total number of key points to be identified, and f^{*} represents a regression neural network. The structure of the regression neural network model is shown in Figure 2. First, the dimension is converted to 1024 dimensions through a fully connected layer. After that, it passes through the batch regularization layer, the RELUs layer, and the Dropout layer in turn and contains a jump-through path. The structure in the

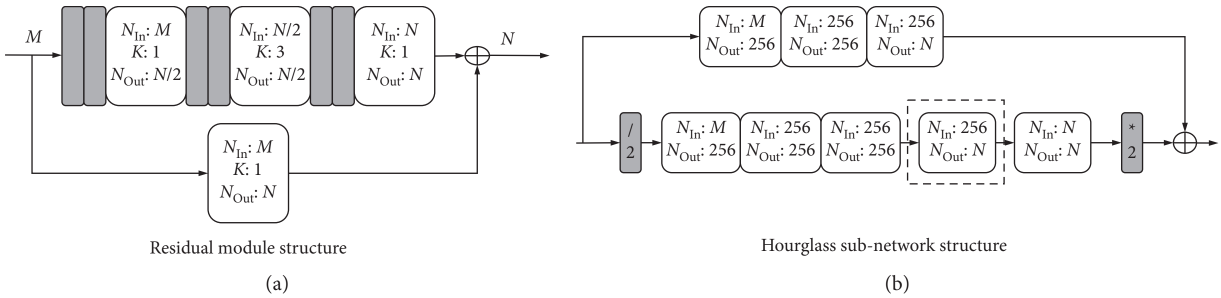

FIGURE 1: Two-dimensional key point recognition network. (a) Residual module structure. (b)Hourglass subnetwork structure.

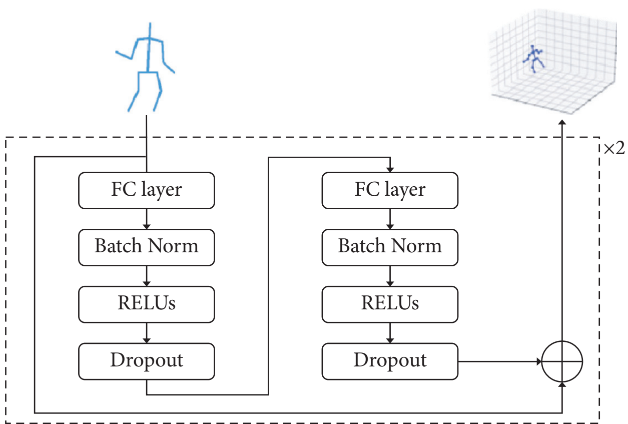

FIGURE 2: Three-dimensional key point regression neural network.

dashed frame in Figure 2 will be repeated once, and finally, a $3n$-dimensional output vector will be formed through a fully connected layer. So far, the three-dimensional coordinates of the key points of the presenter are obtained.

2.3. Action Recurrence. After obtaining the coordinates of the key points of the presenter, they need to be mapped to the robot. The control of the robot takes the angle of each joint as the control command, and the process of using the coordinate value of each key point to calculate the joint angle is called inverse kinematics calculation of the robot. The names of each joint and the actual range of degrees of freedom are shown in Table 1.

In this paper, for each joint of the robot, its angle value is represented by θ_m, and $m\,(m = 1, 2, \ldots, 16)$ is the number of the joint. The $n\,(n = 1, 2, \ldots, 15)$ th key point captured by the motion capture is represented by point p_n, and the vector formed by points p_{n_1} and p_{n_2} is $p_{n_1}p_{n_2}$. The key point numbers detected are shown in Figure 3.

In the angle calculation, there are mainly three situations: the angle between the vector and the vector, the angle between the vector and the plane, and the angle between the plane and the plane [9]. The following examples illustrate the calculation formulas for the three cases.

2.3.1. Calculation of the Angle between the Vector and the Vector. Here we take θ_3 as an example to introduce how to

TABLE 1: List of joints.

12	LHipRoll	0~180
13	LHipPitch	0~150
14	LKnee	30~180
15	LAnklePitch	0~180
16	LAnkleRoll	0~110

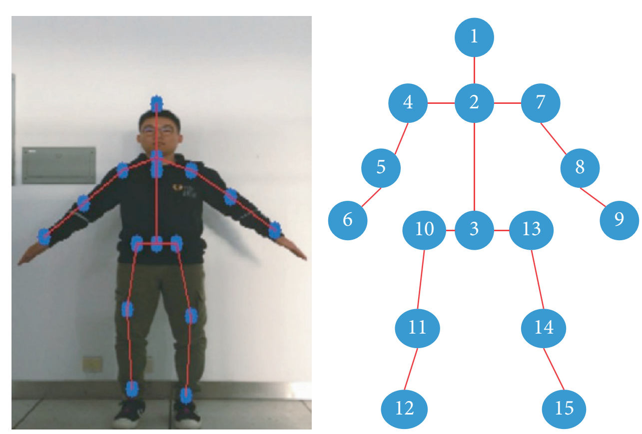

FIGURE 3: Correspondence of feature points.

calculate Relbow. The value of θ_3 is the angle between the vector p_4p_5 and the vector p_5p_6. The calculation formula is

$$\theta_3 = (p_4p_5, p_5p_6) = \arccos\left(\frac{p_4p_5 \cdot p_5p_6}{|p_4p_5||p_5p_6|}\right). \tag{2}$$

2.3.2. Calculation of the Angle between the Vector and the Plane. For example, the angle θ_8 of the joint RHipPitch is the angle between vector $p_{10}p_{11}$ and the plane formed by vectors p_3p_{10} and p_3p_2. To solve θ_8, first use the cross product of p_3p_{10} and p_3p_2 to obtain the normal vector $n_{2,3,10}$ of the plane, then calculate the angle of the normal vector $p_{10}p_{11}$, and then calculate the remaining angles to obtain θ_8:

$$\theta_8 = \frac{\pi}{2} - \left(n_{2,3,10}, p_{10}p_{11}\right) = \frac{\pi}{2} - \arccos\left(\frac{n_{2,3,10} \cdot p_{10}p_{11}}{\left|n_{2,3,10}\right|\left|p_{10}p_{11}\right|}\right). \tag{3}$$

2.3.3. Calculation of the Angle between the Plane and the Plane. For example, if the RShoulderPitch angle θ_1 of the joint is solved, the angle between the plane and the plane is solved. Specifically, first cross-multiply vectors p_5p_6 and p_5p_4 to obtain a plane normal vector $n_{4,5,6}$, then cross-multiply vectors p_2p_4 and p_2p_3 to obtain a normal vector $n_{2,3,4}$ of another plane, and then calculate the angle between the two normal vectors to obtain θ_1:

$$\theta_1 = \left(n_{4,5,6}, n_{2,3,4}\right) = \arccos\left(\frac{n_{4,5,6} \cdot n_{2,3,4}}{\left|n_{4,5,6}\right|\left|n_{2,3,4}\right|}\right). \tag{4}$$

In the calculation process of each angle, due to the selection of the vector direction, it is necessary to find the complementary angle or the complementary angle according to the situation; considering the angle range of each joint, it is necessary to limit the calculated angle value to ensure that it is not exceeding the maximum allowable angle value.

The above calculation process can get all the angle values except the two degrees of freedom of the ankle [10]. For the calculation of the angle of the ankle joint, the relative position of the robot and the ground needs to be taken into consideration because the sole of the foot must be parallel to the ground. As shown in Figure 4, θ_{10} is the angle between the vector $p_{12}p_{11}$ and the plane $\mathrm{Zp}_{10}Y$, and θ_{11} is the angle between the plane where the legs are located and the plane $\mathrm{Zp}_{10}Y$, where the plane and the legs are located is the plane formed by the vectors $p_{12}p_{11}$ and $p_{11}p_{10}$. θ_{15} and θ_{16} can be obtained in the same way.

2.4. Action Selection Algorithm Based on Continuity. Just as a classification model cannot guarantee that the classification accuracy rate reaches 100%, the actions generated by the action generation model also guarantee that every frame generated is a real, coherent, and high-quality action. Therefore, in order to make the generated action suitable for music-based dance choreography, it is necessary to perform a coherence-based action screening first to remove mutation data, so as to ensure that the action data of each frame in an action segment is coherent and improve the quality of the generated action [11].

If an action sequence is coherent, then the actions of adjacent frames in the sequence should have sufficient similarity, which is reflected in the small distance between the corresponding joint points. The motion data used in this article are sampled at a frequency of 30 frames per second. The distance between the corresponding joint point positions in two adjacent frames can be approximated as the speed of the joint at that moment. Because the overall speed

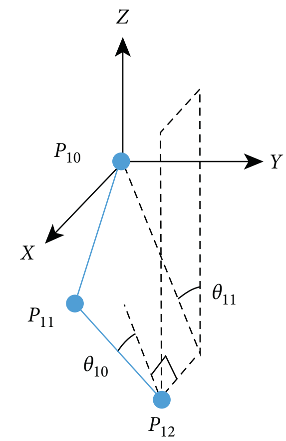

Figure 4: Schematic diagram of ankle joint angle calculation.

of different action sequences is different, it is not easy to judge whether there is a sudden change or a pure rapid movement based solely on the absolute position change [12]. This study believes that, for a coherent action sequence, regardless of the overall speed, the rate of change of the speed between adjacent frames should be small, that is to say, for a sequence with a faster action speed, the instantaneous speed of each frame is higher. For a sequence with a slower action speed, the instantaneous speed of each frame is smaller, but for a continuous action sequence, the speed difference between adjacent frames should be relatively stable.

Therefore, this paper conducts continuous screening of the action sequence based on the rate of speed change. First, calculate the sum of the absolute value of the first-order difference of the joint speeds of adjacent frames:

$$\begin{aligned} V(f) &= \sum_{k=1}^{c} \left|v(f+1,k) - v(f,k)\right|, \\ v(f,k) &= \left\| x_{f+1}^{(k)} - x_f^{(k)} \right\|. \end{aligned} \tag{5}$$

Among them, f is the sequence number of the frame in the action segment N_i, x is the action vector, $x_f^{(k)}$ is the k th dimensional action data of the f th frame, and c is the vector dimension of the action per frame. $v(f,k)$ represents the speed of the kth dimensional data of the fth frame.

Set the maximum threshold $\varepsilon_{\max}$ if the fth frame action satisfies $V(f) \le \varepsilon_{\max}$; the action at that moment meets the continuity requirement. According to the condition, the action sequence is divided, and the continuous action frame that meets the condition is divided into a new action sequence. In order to remove new sequences whose length is too short after segmentation, a minimum length threshold value needs to be set, and only new sequences whose length exceeds this threshold value can be saved in the generated action database.

2.5. Choreography and Composition. Through the feature extraction and matching algorithm of music and action in the previous section, multiple action segments that match the target music have been obtained, and the connectivity constraints between adjacent segments have been met. In this section, on this basis, the adjacent action segments will be transitionally connected to solve the problem of sudden action changes. The action segments will be spliced into a complete sequence of actions to complete the final choreography. The sudden change of action referred to in this section refers to the fact that there is a certain distance between the action at the connection between the action segment and the adjacent action segment N_{i+1}, which causes the directly connected actions to be incoherent, which affects the visual effect of the dance.

This section uses the intermediate frame interpolation algorithm to interpolate between the end k frames of the action segment M and the intermediate action of the action segment N according to the interpolation weight to obtain the final interpolation action. The interpolation action obtained by using this algorithm can realize the natural connection of two action segments and, at the same time, retain the characteristics of the ending action of the previous action segment to a certain extent [13]. The interpolation action ensures the continuity of the action, but there may be unreal actions such as footsteps. In order to avoid the long duration of the interpolation action and affect the perception, the value of k should not be too large. In this study, $k = 14$ is used in the experiment.

Suppose the length of the action segment M is m, the last k frame action is recorded as $M_{m-k+1} = \{f^M_{m-k+1}, f^M_{m-k+2}, \ldots, f^M_m\}$, and the first k frame intermediate action of the action segment N is recorded as $N_{1,\ldots,k} = \{f^N_1, f^N_2, \ldots, f^N_k\}$. First, the starting position of the intermediate action $N_{1,\ldots,k}$ is translated to the same as M_{m-k+1}, and then, the interpolation action $P_{1,\ldots,k}$ is synthesized. Among them, $P_{1,\ldots,k} = \left\{f^P_1, f^P_2, \ldots, f^P_k\right\}$ performs linear interpolation on the node displacement:

$$
\begin{aligned}
p_i^{P,s} &= \alpha(i) f^{M,s}_{m-k+i} + (1 - \alpha(i)) f^{N,s}_i, \quad 1 \le i \le k, \\
\alpha(i) &= 2 \cdot \left(\frac{i}{k}\right)^3 - 3 \cdot \left(\frac{i}{k}\right)^2 + 1, \quad 0 \le i \le k - 1.
\end{aligned}
\tag{6}
$$

Among them, $p_i^{P,s}$ represents the coordinates of the sth joint point of the ith frame of the P action segment, and $\alpha(i)$ is the interpolation weight.

3. Experiments and Results

3.1. Dataset. In recent years, the research on dance movement synthesis is mainly based on motion capture data. At present, the main public motion capture motion datasets are as follows. (1) SBU dataset includes 8 types of actions, a total of 230 sequences of 6614 frames, but the actions in the dataset are all nondance movements such as handshake and punching. (2) HDM05 data set contains about 100 action types, with a total of 2337 sequences of 1840046 frames, but basically all kinds of nondance actions such as walking and kicking. (3) UCY dataset (University of Cyprus), containing a total of 161 sequences 147509 frames, providing dance moves in Greek, Cypriot dance, and other styles, but only 8 of them are relatively complete movements accompanied by music, a total of 28892 frames, and the rest of the sequences are single movement fragments with a short time, which is not conducive to complete dance [14]. (4) The CMU dataset contains a total of 2235 sequences of 98,7341 frames. This is the largest motion capture dataset published so far, covering a wide range of motion types, of which only 64,300 frames are for pure dance movements, with no accompanying music. To sum up, although there are some public exercise datasets, most of them are not dance moves, and there are very few dance moves' data accompanied by music [15]. For the study of the relationship between music and dance movements based on deep learning, movement and music data play a key role in the training of the model.

Therefore, this paper additionally constructs a music-action dataset composed of a complete music choreography sequence. Compared with using professional dancers, it is more economical and convenient to obtain enough dance data through motion capture equipment and download the motion data in VMD format corresponding to different music on the Internet. This paper uses the VMD action files obtained from the Internet and the accompanying WAV music files to construct a music-dance action dataset, with a total of 192 segments, 1057344 frames, and about 587 minutes. Each segment is an independent dance.

The music and dance styles contained in the dataset constructed in this study are not exactly the same, and the speed is also fast and slow. Therefore, it is necessary to classify the actions before performing network training. Based on manual experience, combined with the overall characteristics of the 192 songs and dances in the dataset, the overall style of music and dance can be divided into three categories: modern dance, street dance, and house dance. The overall speed is divided into two categories, fast and slow, for a total of six categories. Since the overall speed of the movement in the same song and dance is not static, for example, the movement is more relaxed at the beginning and end of the song and the movement is more intense at the climax of the song, so the overall dance speed of the entire song is not enough. To classify actions, based on the overall speed of the dance, this study continues to divide movements into fast and slow based on the frame granularity. Based on the above principles, this study manually annotates the constructed dataset. Table 2 shows the number of frames and duration of various actions after classification.

3.2. Model Training and Prediction. In order to obtain good results in deep neural network training, it is necessary to provide sufficient data so that the neural network can fully tap the inner relationship between the data. For the three types of dances, house dance, street dance, and modern dance are included in the dataset constructed in this paper; according to the data volume of different speed movements, this paper trains different movement generation models. During training, 12 Gaussian distributions are used to form a mixed model ($m = 12$), the number of batches (batch size) is set to 100, the sequence length of one-time input is set to 120, the learning rate is 500, and the total training is 500 cycles (epoch), optimized using the RMS Prop optimizer and

Table 2: Detailed information of various types of data in the dataset.

Dance style	Overall speed	Number of fragments	Frame rate	Number of frames	Duration (min)
House dance	Fast	54	Fast	285393	158.6
			Slow	26428	14.7
	Slow	35	Fast	157175	87.3
			Slow	54034	30.0
Street dance	Fast	67	Fast	357287	197.4
			Slow	18048	10.0
	Slow	6	Fast	25504	13.7
			Slow	9063	4.9
Modern dance	Fast	5	Fast	21679	12.6
			Slow	249	0.1
	Slow	25	Fast	41516	22.6
			Slow	56410	31.9

the learning rate is set to 0.01. Table 3 shows the training results at different times.

Figure 5 shows the model loss of the training set and validation set during model training. It is worth noting that the error function E^q needs to be minimized during the model training process. Unlike the commonly used loss functions in other networks (such as cross entropy), E^q does not meet the condition of constant greater than zero. Therefore, when the model loss is less than zero, the training process will be terminated in advance, as shown in Figure 5(a). The loss of the validation set and the loss of the training set are inconsistent, and there is even no obvious downward trend. This is because dance movement generation tasks are different from other tasks such as target classification. The choreography and expression of dance moves are not unique. This is where the diversity of dance moves lies. The training process of the movement generation model seeks regularity in it. The diversity and regularity of data are a pair of contradictory standards. Although the actions in the dataset have been preliminarily classified, in the limited dataset, it is difficult to ensure that the verification set selected at random each time has the same law as the training set. Therefore, in the verification set during the first 350 cycles of training, the loss has not changed much. As the model continues to be trained, overfitting occurs, resulting in a sharp increase in the loss of the validation set. You can refer to the loss of the validation set to judge the training situation of the model.

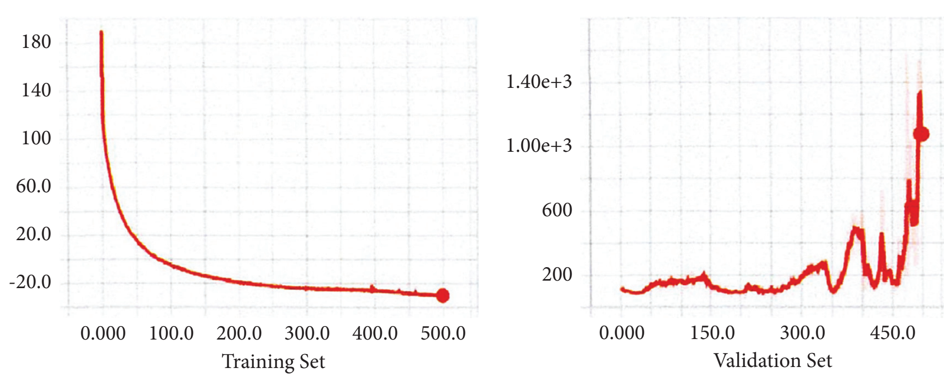
3.3. Qualitative Results. According to the visual effect of the synthesized dance, the choreography result is evaluated, and the effect of the algorithm in this paper is evaluated. First, extract the overall characteristics of "Tokyo Teddy Bear;" after calculation, the BPM value is 126.05, the duration of the change note is 1.93, and the rapid house dance motion generation model is selected to generate the candidate motion database, which is consistent with the user's intuitive hearing. Observing the final dance effect, you can feel that the rhythm and intensity of the dance and the target music match to a certain extent, and the movements are smooth and coherent. Figure 6 shows a posture snapshot of the synthesized dance. Only from the intuitive visual effects, the choreography algorithm in this paper can be considered to be effective.

3.4. Quantitative Results. Experimental purpose: use user ratings to analyze the synthesizing effects of three styles of dance. First, analyze the style of the music according to the overall characteristics of the target music (BPM and the duration of changing notes) and generate the corresponding choreography. This experiment analyzes a number of target music, selects three target music suitable for generating hip-hop, house dance, and modern dance, and choreographs them. The detailed information and overall characteristic values of the target music are shown in Table 4. The test users, respectively, judged the dance styles of the three segments and evaluated the matching degree of music and dance and the continuity and authenticity of dance movements, and the results are shown in Table 5.

From the results, it can be found that the average value of the coherence, authenticity, and matching with music of the three styles of dance are all above 4 points, indicating that users are satisfied with the results of the synthesized dance styles. Therefore, the music choreography algorithm proposed in this paper is Effective. The three indicators of street dance have the highest scores, followed by modern dance, and finally house dance. This study interviewed these users after they completed the test. The users said that the rhythm of hip-hop style movements is obvious and the range of movements is larger, while the range of house dance movements is generally small. Sometimes, it is difficult for users to distinguish between small movements and jitter data. After analysis, the reason why the synthesis result of house dance is worse than that of street dance is that, in the action dataset constructed in this study, the diversity of house dance actions is more abundant, and the concentration of actions is worse than that of street dance, so it is not conducive to the training and learning of the action generation model. Among the 33 users who participated in the score, only 1 user made a wrong judgment on the style of hip-hop and home dance, and the judgments of other users were accurate. After follow-up interviews, the user stated that it was because she did not know the specific concepts of home dance and hip-hop and unable to judge.

Table 3: Action generation results at different times (street dance actions).

Epoch	Time	Generate sample action poses	Describe
1	2.5 min		Unable to generate qualified actions, most joint positions are random, and the outline of the human body can be vaguely seen
50	~2 h		Understand the joint positions and be able to generate basic movements
200	~9 h		The relative relationship of joints is more stable, which can generate richer and more stable movements
500	~22 h		The generated action has unstable continuity and may be overfitting



(a) (b)

Figure 5: Model loss. (a) Training set. (b) Validation set.

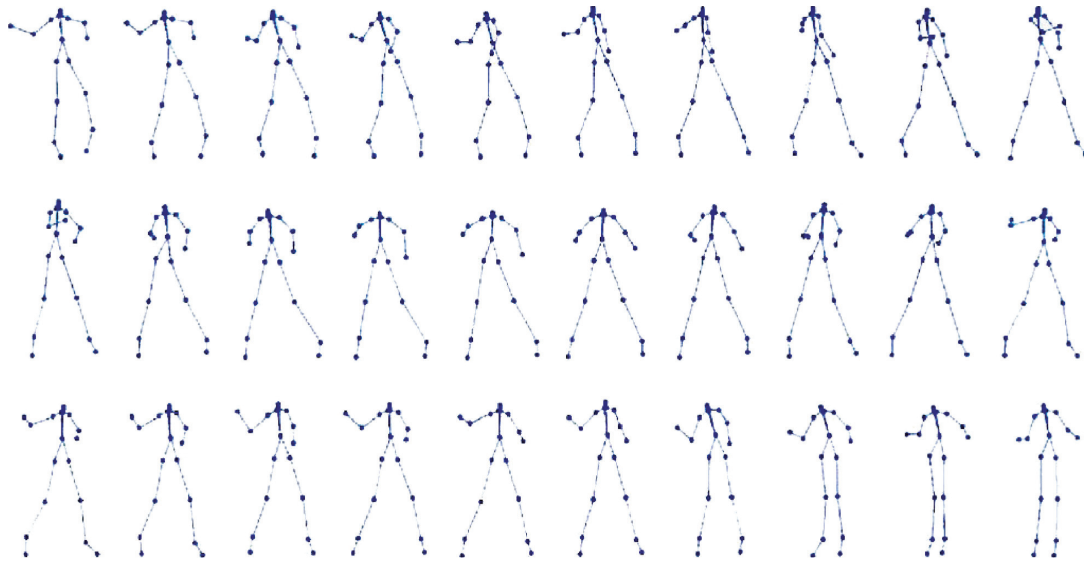


Figure 6: "Tokyo teddy bear" synthetic dance pose snapshot.

Table 4: Details of the three target music.

Music name	Duration	Music BPM	Varying note duration	Dance style
Bad apple	00:05:10	138.6	1.57	Street dance
Chocolate	00:03:46	129.2	1.66	House dance
From Y to Y	00:05:30	96.4	2.54	Modern dance

Table 5: Manual scoring of three styles of dance.

Dance style	Music and dance match	Continuity	Authenticity	Style judgment accuracy (%)
Street dance	4.28 ± 0.10	4.07 ± 0.07	4.04 ± 0.10	96.9
House dance	4.13 ± 0.09	4.05 ± 0.08	4.02 ± 0.08	96.9
Modern dance	4.22 ± 0.11	4.08 ± 0.08	4.08 ± 0.11	100

4. Conclusion

This paper proposes a dance choreography algorithm based on the deep learning model, starting from improving the harmony of music and choreography. First, extract the overall characteristics of the music, including the average duration of BPM and notes, and perform preliminary matching of the action speed characteristics based on this. Then, complete segmentation of music and action sequences and feature extraction of rhythm intensity and combine the results of feature matching and connectability analysis to obtain action sequences that match the target music. Finally, the adjacent action fragments are interpolated to complete the computer music choreography. In this paper, qualitative and quantitative experiments are designed to evaluate the effectiveness of the algorithm. The experimental results show that the local bone movement speed feature extraction algorithm and the dance spatial feature extraction algorithm proposed in this paper can effectively reflect the corresponding characteristics of dance; the overall characteristics of music can accurately reflect the style of music, and the corresponding styles can be synthesized accordingly. Choreographed action: the hierarchical feature matching algorithm is better than the feature matching algorithm based on local rhythm and intensity. The addition of the overall feature matching can synthesize a dance that is more matched to the target music. In the future, it is necessary to further improve the accuracy of the model through the optimization of the model structure to make the generated actions more realistic.

In order to improve the effect of college English teaching reform, this paper puts cellular automata English into English teaching simulation and uses the cellular automata model to study the behavior of complex teaching systems. Moreover, this article uses the method of man-machine combination to establish the corresponding dynamic evolution model and design the local evolution rules of the complex system to simulate the English teaching process, including the movement of students and teachers, the interaction of the teaching process, the development of teaching activities, and the processing of teaching resources. In addition, this paper constructs the functional structure of the system and conducts system verification through experimental research. The experimental research results show that the English classroom teaching evaluation system based on the cellular automaton proposed in this article is very effective, and it has a certain role in promoting English teaching.

1. Introduction

In the process of higher education reform and development, teaching has always been regarded as the core link of higher education, and the quality of teaching can directly reflect the level of teaching in the school. The overall teaching level of national colleges and universities can prove from the side whether the national education guidelines, policies, and systems are correct, thereby further promoting the reform and development of education. For the evaluation of teaching quality, while satisfying the satisfaction of the government and society, all colleges and universities pay more attention to the level of satisfying students. Since the 1980s and 1990s, constructivist learning theories and constructivist teaching theories have become increasingly popular in the West. They all advocate student-centeredness and emphasize that students are processors of information and active constructors of the meaning of knowledge, and the role of teachers is to guide and help. This has brought a great impact on the traditional teacher-centered "filling and filling" teaching view and the learning view of students passively accepting knowledge.

In recent years, with the breakthrough development of software and hardware such as virtual engines, texture rendering, computers, and VR equipment, virtual reality has once again become a hot spot for research and development. Virtual reality technology is an important direction of simulation technology; that is, through computer science technology, the physical and digital data in the physical environment are converted into visual or even touchable 3D virtual scenes, and the combination of computers and peripheral devices allows users to enter the 3D space created by the computer model for perception and interaction [1]. In virtual reality, through diversified interactions such as vision, sound, touch, and operation, users can apply perception experience and cognitive processing capabilities to interact with objects in virtual reality just like in the real world and observe natural changes in the world. Virtual reality uses three elements to construct a virtual reality context [2]: (1) immersion, allowing users to have an "immersive" feeling and blending into the simulated virtual world; (2) interactivity, users passing sensory stimulation and reaction interact with and give feedback to the virtual situation; the system responds to the user in the shortest time and allows the user to feel the response in a simulated situation; (3) conceptual, virtual reality is a fictitious simulated situation. In addition to feeling the sound and light stimulation, you can also conceive of situational design and object attributes and express intangible abstract concepts in concrete forms. Virtual reality has strong flexibility, repetition, and adaptability. People can create the real world from scratch in the computer at a low cost, can repeatedly use virtual reality for training in the same situation, and can quickly learn to use and interact with virtual reality, can realize some areas that cannot be visualized in reality (brain, whole body structure, etc.) and virtual operations, and can obtain reliable information equivalent to the real environment from virtual reality. Another important advantage of virtual reality is safety. Users can make virtual errors and make virtual collisions without harming anyone or themselves. Therefore, virtual reality is widely used in the fields of spatial cognitive assessment, rehabilitation, and psychological research, training, and education. Especially in the field of training and education, because low-cost and high-efficiency virtual reality brings learners an immersive learning environment, enhances the learning experience, bridges the gap between learners and educators in terms of teaching, and makes virtual reality technology, this can help students learn better [3].

Based on the above analysis, this article applies cellular automata to the improvement of English teaching and uses the cellular automata model to study the behavior of complex teaching systems. Moreover, this article uses the method of man-machine combination to establish the corresponding dynamic evolution model and design the local evolution rules of the complex system to improve the teaching effect of colleges and universities.

2. Related Work

Cellular automata simulation is an important method for studying complex systems, and it has been widely used in natural sciences and social sciences. Literature [4] established a cellular automata model for classroom teaching based on the principles of sociology and psychology, and literature [5] simplified the cellular automata model. However, all of its model establishments only looked at the teaching process as the process of knowledge imparting and believed that the amount of knowledge of students should not exceed that of teachers. This is inconsistent with reality, and it is also contrary to the idea of analyzing and researching teaching activities with the viewpoints and methods of complexity science. Literature [5] uses the cellular automata evolution rule of lattice point trend to produce more complicated evolution patterns with fewer evolution rules. Literature [6] believes that a system with a variable evolution rule can better reflect the adaptation of the actual system to environmental changes and studies the chaotic edge effect of a cellular automaton with a variable evolution rule. Inspired by the new cellular automata model, based on the study of the complexity of the university teaching process, based on the driving effect of herd mentality and emotional satisfaction, quality training goals, and education and teaching strategies, the elementary cellular automata and random cellular combining automata establish a cellular automata model of the university teaching process [7].

Literature [8] uses a series of cellular automata models to simulate certain situations and analyze the characteristics of each situation. According to the characteristics of cellular automata, it can be applied to the fields of fluid mechanics and solid mechanics. Literature [9] proposed a method of combining finite element and cellular automata and analyzed the related problems of the fluid-solid interface in composite materials. The movable cellular automata make it possible to simulate complex mechanical systems. Some cellular automata research work has been extended to mechanics, but it should be pointed out that it is compatible with traditional calculation methods (such as finite element method and boundary element method). In comparison, there are few written text introductions related to cellular automata in solid mechanics [10]. As a new exploratory application of cellular automata, literature [11] proposed a simple cellular automata method, which can be combined with finite elements. It should be pointed out that the cellular automata model established above is based on randomly generated free nodes instead of traditional regular grids, and the local rules of cellular automata are based on physical concepts rather than differential equations [12].

There are some results in the research on the evolution law of complex systems based on cellular automata. Literature [13] uses the cellular automata model to develop an intelligent simulation program, which has the ability to simulate the evolution of a complex system. The essence is to simulate the evolution process of simple two-dimensional cellular automata. It allows people to fully realize that simple rules can make cellular automata produce complex evolutionary behaviors. Literature [14] carried out in-depth research on elementary cellular automata through a large number of computer experiments and qualitatively divided the evolutionary behavior of all rules of the cellular automata into four categories from the perspective of dynamic behavior. The method of formal language proves that some rule-evolving languages are formal languages, which explains the complexity of the cellular automata-evolving languages of these rules. Literature [15] proposed the parameter λ to describe the evolution of cellular automata. Through a lot of research, the internal evolution mechanism of cellular automata was revealed, and the concept of "the edge of chaos" was proposed. This concept refers to the bizarre phase transition from "order" to "chaos" in the evolution of cellular automata. Literature [16] divides cellular automata into 6 types, reclassifies stationary cellular automata into zero configuration and fixed type, and divides partial periodic cellular automata into local chaotic types. Literature [17] proposed a power spectrum method to quantitatively describe the evolutionary behavior of cellular automata and found that the evolutionary graph of cellular automata has spatial drift characteristics. Literature [18] studies the evolution properties of certain finite element cellular automata.

3. Establishment of English Teaching Model of Cellular Automata

This model is based on the cellular automata model. The cell space is used to represent the classroom where classroom teaching occurs, the cells are used to represent students, and the various states of cells are used to represent the different effects of students' meaning construction. Each cell has its own meaning construction value through calculation, and there is a mutual influence among cells.

(1) *Cell Space*. A 12×8 matrix is used to represent a classroom. Because in colleges and universities, the interior design of ordinary classrooms is not square but rectangular, so the ordinary model of $m \times m$ is not adopted, but the model of $n \times m$ is adopted, $n \neq m$. Normal classrooms in colleges and universities can generally accommodate about 100 students, so the classroom seats designed in the model are $12 \times 8 = 96$.

(2) *Cells*. A cell represents an individual learner, and an ordered pair (i, j) is used to represent the position of a learner in the cell space, $1 \leq i \leq 8, 1 \leq j \leq 12$. The model assumes that the classroom is full of students, so there are 96 cells in total [19].

(3) *Neighbors*. The neighbor mode of the model refers to the Moore model, that is, the neighbor cell set of the central cell composed of 8 surrounding cells. However, in the model, since the cell space describes a classroom, the form of neighbors will be determined according to the position of the center cell. As shown in Figure 1, the brown cell represents the central cell, and the light gray cell represents the neighbor cell. When the central cell is located at a nonboundary position (such as cell a_{55}), the mode of its neighbor cells is consistent with Moore's neighbor mode. However, when the center cell is located at the boundary of the classroom, the number of neighbor cells will be less than 8. There are two types of boundary positions for the central cell. One is where the cells a_{11}, a_{19}, a_{91}, and a_{99} are located; that is, at the four corners, these cells have only 3 neighbor cells. The other is where the a_{11}, a_{51}, a_{59}, and a_{95} cells are located; that is, at the center point of the boundary, these cells have 5 neighbor cells.

(4) When the cell state set K is selected, $K = \{-1,0,1\}$ represents the cell state set of the model, and the meaning of each state is shown in Table 1. [20].

In the simulation process, the five links of situational teaching are divided into two major links. One is the self-learning link, which includes three links: creating affection, determining problems, and self-learning. Because in these three links, the process of collaborative learning with surrounding students is not involved, the other is the collaborative learning link, which includes two links: collaborative learning and effect evaluation. Because these two links involve the process of discussion and communication, they are the focus of experimental research.

Figure 1: Neighbor mode.

Human behavior is determined by internal eds and external environment. The learner's meaning construction behavior is no exception. It is also affected by internal factors and the external environment. The functional expression of meaning construction is

$$F(t) = F_I(t) + F_O(t). \tag{1}$$

In formula (1), $F_I(t)$ represents the internal factor function thaffects the learner's meaning construction, and $F_O(t)$ represents the environmental factor function that affects the learner's meaning construction, also known as external factors.

The self-learning link focuses on the teacher's guidance and the process of students' self-study. Therefore, the meaning construction effect produced by the students through this link is affected by internal factors, namely, their own knowledge level, and external factors, namely, the teacher's context setting. The following formula can be used to express the meaning construction effect of students in the autonomous learning process.

$$F(t) = F_L(t) + F_S(t). \tag{2}$$

Formula (2) indicates that ignoring other complex factors, the learner's meaning construction function $F(t)$ at time t is the result of the interaction between the student's own knowledge background function $F_L(t)$ and the teacher's context setting function $F_S(t)$.

$F_L(t)$ represents the learner's own knowledge background, also known as the basic level, and represents the knowledge base, knowledge structure, and amount of knowledge that the learner has related to the current content to be learned. Each student has different types of knowledge related to this course, so the value of the learner's own knowledge background function $F_L(t)$ is represented by l, and l is evenly distributed in [0,1]. Each learner has a constant l value during the experiment. The larger the l value, the thicker the learner's knowledge background, which is more conducive to the construction of their own meaning, and vice versa.

Students' meaning-making effects at any moment are the result of a combination of internal and external factors. In free mode collaborative learning without teacher participation, the meaning construction effect of student (i, j) at moment t is related to the student's own meaning construction effect at moment $t-1$ (internal factors) and the

Table 1: The meaning of each state of the cell.

Condition	Implication
$K_{i,j} = -1$	Meaning construction does not meet the standard, and the learning quality of learners in this state does not meet the minimum requirements of the teacher
$K_{i,j} = 0$	Meaning construction meets the standard, and the learning quality of learners is average, between substandard and excellent
$K_{i,j} = 1$	Meaning construction is excellent, the learner's learning quality is very good, and it can meet the teacher's teaching expectations

meaning construction effect of surrounding students at moment $t-1$ (external factors).

$$F_{i,j}(t) = \alpha \times F_{i,j}(t-1) + \beta \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^*. \tag{3}$$

As shown in formula (3), $F_{i,j}(t)$ represents the meaning construction effect of students (i,j) at time $t-1$, and $F_{i,j}(t-1)$ represents the meaning construction situation of students (i,j) at time $t-1$. The formula $\sum_{n=1}^{n=n^*} F_n(t-1) \div n^*$ indicates that the students (i,j) are affected by the meaning construction effect of surrounding students at time $t-1$, which is represented by the average influence of neighbor cells on the central cell in the model. Among them, n represents the n-th neighbor cell of the central cell (i,j), and n^* represents the number of neighbor cells. Depending on the position of the central cell, the number of neighbor cells may be 3, 5, or 8, so there are three possible values for n^*. $F_n(t-1)$ represents the meaning construction of the n-th neighbor cell.

α and β are, respectively, the weights of internal factors and external factors on the meaning construction of learners, and they are all the weights of first-level indicators. The first-level indicator system of this evaluation is $\{W_e | e = 1, 2\}$, and its corresponding weight system is $\{V_e | e = 1, 2\}$, $0 < V_e \leq 1$, and it satisfies $V_I + V_2 = 1$. Among them, W_1 represents the effect of internal factors, V_I represents its weight, and $\alpha = V_I$; W_2 represents the influence of external factors, V_2 represents its weight, and $\beta = V_2$. Through the subjective experience method, it can be known that when students have poor meaning construction effects, they are more susceptible to environmental factors; when students have good meaning construction effects, they are not easy to be affected by environmental factors. Therefore, the value of the weight system is changed according to the state of the cell.

When $K_{ij} = -1$, it means that the learner's meaning construction is not up to the standard, and he is more susceptible to external factors, so $\alpha = 0.3, \beta = 0.7$. [21].

When $K_{i,j} = 1$, it means that the learner has a good sense-building effect, and he is more susceptible to internal factors and not easy to be affected by the external environment, so $\alpha = 0.7, \beta = 0.3$.

When $K_{i,j} = 0$, it means that the learner's meaning construction effect is average, and it is affected by internal and external factors with equal strength, so $\alpha = 0.5, \beta = 0.5$.

The formula after finishing is as follows:

$$\begin{cases} F_{i,j}(t) = 0.3 \times F_{i,j}(t-1) + 0.7 \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^*, & K_{i,j}^{t-1} = -1, \\ F_{i,j}(t) = 0.5 \times F_{i,j}(t-1) + 0.5 \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^*, & K_{i,j}^{t-1} = 0, \\ F_{i,j}(t) = 0.7 \times F_{i,j}(t-1) + 0.3 \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^*, & K_{i,j}^{t-1} = 1. \end{cases} \tag{4}$$

In the process of collaborative learning, it is impossible for every student to have the opportunity to communicate with the teacher. Therefore, most students are still in a situation where they have not communicated with the teacher. When students cannot get the guidance of teachers in the process of collaborative learning, the expression of the meaning construction effect is consistent with formula (4). When students get the opportunity to communicate with teachers in the process of collaborative learning, the student's meaning construction effect function is shown in

$$F_{i,j}(t) = \alpha \times F_{i,j}(t-1) + \beta \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^* + \lambda. \tag{5}$$

The state of the central cell still determines the value of the first-level weights α and β, and the value method is consistent with the value method without teacher participation. After sorting, the expression of the student meaning construction function with teacher participation is shown in

$$\begin{cases} F_{i,j}(t) = 0.3 \times F_{i,j}(t-1) + 0.7 \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^* + \lambda, & K_{i,j}^{t-1} = -1, \\ F_{i,j}(t) = 0.5 \times F_{i,j}(t-1) + 0.5 \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^* + \lambda, & K_{i,j}^{t-1} = 0, \\ F_{i,j}(t) = 0.7 \times F_{i,j}(t-1) + 0.3 \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^* + \lambda, & K_{i,j}^{t-1} = 1. \end{cases} \tag{6}$$

Unlike the free model of collaborative learning, the group model of collaborative learning has a very clear collaborative learning group, that is, group members. In the collaborative learning group, the leader of the group—the group leader—is arranged, and the group leader plays a leadership role, and he plays a key role in the collaborative learning of the whole group. Under the leadership of the group leader, the group members will have an orderly discussion. In fact, dividing the group is to divide the whole class, a large collective, into smaller groups that are almost identical to its model, in which the group leader acts as the teacher in the larger group.

In the actual teaching process, when teachers use the subgroup mode for collaborative learning, each group generally has 4 to 6 members. This experiment will choose the 6-person group mode. Because there are 96 students in the class, the class is divided into 16 groups.

As shown in Figure 2(a), the 6 students in the dark gray area are a group, and the 6 students in the light gray area are another group, a total of 16 groups. The diagonal line in each group represents the group leader. Each team has two types of members, and one is the leader and the other is the member.

For the group leader (i, j), the internal factor affecting his meaning construction at moment t is the group leader's meaning construction at moment $t-1$, and the external factor is the average meaning construction effect of the five group members at moment $t-1$, as shown in Figure 2(b). Therefore, the meaning construction function at moment t is shown in

$$F_{i,j}^{g}(t) = \alpha \times F_{i,j}(t-1) + \beta \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^*. \tag{7}$$

In formula (7), $F_{i,j}^{g}(t)$ means that the student (i, j) is the group leader, and the value of n^* can be determined here. Because each group leader has 5 group members, $n^* = 5$, the weight value of the group leader's internal and external factors is still affected by his own state, and the value is consistent with the value method in the no-group mode. After finishing, formula (8) is obtained.

$$\begin{cases} F_{i,j}^{g}(t) = 0.3 \times F_{i,j}(t-1) + 0.7 \times \sum_{n=1}^{n=5} F_n(t-1) \div 5, & K_{i,j}^{t-1} = -1, \\ F_{i,j}^{g}(t) = 0.5 \times F_{i,j}(t-1) + 0.5 \times \sum_{n=1}^{n=5} F_n(t-1) \div 5, & K_{i,j}^{t-1} = 0, \\ F_{i,j}^{g}(t) = 0.7 \times F_{i,j}(t-1) + 0.3 \times \sum_{n=1}^{n=5} F_n(t-1) \div 5, & K_{i,j}^{t-1} = 1. \end{cases} \tag{8}$$

For a group member (i, j), the internal factor that affects the meaning construction of the group member at time t is the group member's meaning construction situation at time $t-1$. There are two external factors here. One is the meaning construction effect of the team leader at time $t-1$, and the other is the average meaning construction effect of the remaining 4 team members at time $t-1$. As shown in Figure 2(c), the gray squares represent group members (i, j). Since the team leader is at the core of the team, the team leader's influence on the team members is greater than the other four team members' influence on the team members in terms of external factors. Here, a secondary weight will be introduced to describe the influence of the two external factors on the meaning construction of group members, as shown in

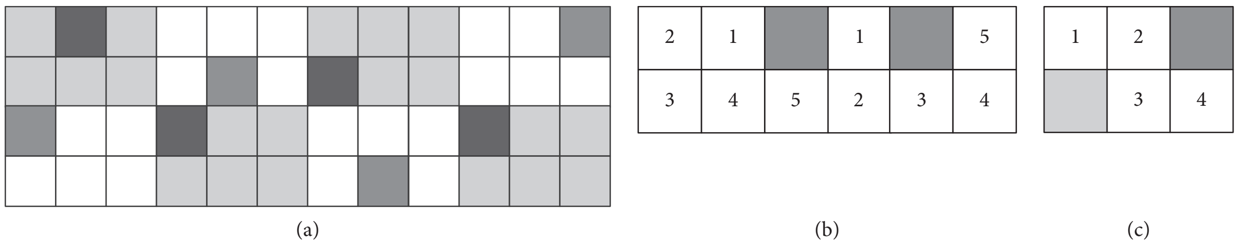

Figure 2: Schematic diagram of the cell. (a) Grouping diagram. (b) Schematic diagram of the external factors of the team leader. (c) Schematic diagram of the external factors of the team members.

$$F_{i,j}(t) = \alpha \times F_{i,j}(t-1) + \beta \times \left(\gamma \times F_{i,j}^{g^*}(t-1) + \delta \times \sum_{n=1}^{n=n^*} F_n(t-1) \div n^* \right). \tag{9}$$

In formula (9), the function $F_{i,j}^{g}(t-1)$ represents the meaning construction effect of the group leader in the group to which the group members (i, j) belong at the time t–1. The formula $\sum_{n=1}^{n=n^*} F_n(t-1) \div n^*$ represents the influence of the average meaning construction of other group members in the group to which the group member (i, j) belongs. It is certain that $n^* = 4$ here.

In formula (9), γ and δ, respectively, represent the weight value of the influence of the group leader's meaning construction situation and the group member's meaning construction situation on the group member's (i, j) meaning construction in the external factors. In equation (9), α and β belong to the first-level weight, γ and δ belong to the second-level weight, and they satisfy

$$\alpha \times \beta \times (\gamma + \delta) = 1. \tag{10}$$

In formula (10), α and β still represent the weight values of internal factors and external factors, and their values are still affected by the cell state, and their values are consistent with the previous text. In order to highlight the core role of the team leader, by referring to the values of α and β in the previous article, we set $\gamma = 0.7$ and $\delta = 0.3$. Formula (11) is obtained by sorting.

$$\begin{cases} F_{i,j}(t) = 0.3 \times F_{i,j}(t-1) + 0.7 \times \left(0.7 \times F_{i,j}^{g*}(t-1) + 0.3 \times \sum_{n=1}^{n=4} F_n(t-1) \div 4 \right), & K_{i,j}^{t-1} = -1, \\ F_{i,j}(t) = 0.5 \times F_{i,j}(t-1) + 0.5 \times \left(0.7 \times F_{i,j}^{g*}(t-1) + 0.3 \times \sum_{n=1}^{n=4} F_n(t-1) \div 4 \right), & K_{i,j}^{t-1} = 0, \\ F_{i,j}(t) = 0.7 \times F_{i,j}(t-1) + 0.3 \times \left(0.7 \times F_{i,j}^{g*}(t-1) + 0.3 \times \sum_{n=1}^{n=4} F_n(t-1) \div 4 \right), & K_{i,j}^{t-1} = 1. \end{cases} \tag{11}$$

The evolution starts with the initialization of all metacells so that each metacell has its own state. For an average class in reality, there are always basic good, average, and poor students in the class, and the number of good, average, and poor students in an average class has a distribution pattern of small at the end and large in the middle. A study of the student structure of a class in this college showed that the ratio of the number of good, average, and poor students was $2:5:2$. Before the lecture started, that is, at $t = -0$, learners possessed their respective knowledge background levels, and students with good, medium, and poor knowledge background levels were defaulted to students with good, medium, and poor levels of meaning construction in the experiment during initialization. At $t = 0$, the system randomly assigned l values, $l \in [0, 1]$, to each tuple to distinguish students' basic levels. In order to express the proportion of the three types of students in the general class more accurately, the three types of students can be identified according to the range of values l, and the ratio of the number of the three types of students is $2:5:2$, as shown in Table 2.

In the process of evolution, the state of the cell is determined by judging the meaning of each cell to construct the function value $F_{i,j}(t)$. The specific situation is shown in Table 3. The results in Table 3 are derived from the reasoning and calculations in Tables 4 and 5.

The conversion conditions were determined based on the students' own knowledge background function $F_L(t)$ and the values of the teacher's context setting function $F_S(t)$. Because both functions take values in the range [0, 1], in the initialization, students with $l < 0.22$ are classified as students with poor knowledge background, students with $l > 0.78$ are classified as students with good knowledge background, and

Table 2: Judgment criteria for three types of students in initialization.

	Poor students $K_{i,j} = -1$	Ordinary student $K_{i,j} = 0$	Excellent student $K_{i,j} = 1$
The value of l	$l < 0.22$	$0.78 \geq 1 \geq 0.22$	$l > 0.78$

students with $0.78 \geq l \geq 0.22$ are classified as students with average knowledge background. Referring to the practice of classifying students into three categories by the value of l, students were also classified into three levels in the experiment with respect to the value of s at which they obtained the effect of contextualization. Similarly, students with $S < 0.22$ were classified as students with poor contextualization, students with $s > 0.78$ were classified as students with good contextualization, and students with $0.78 \geq S \geq 0.22$ were classified as students with average contextualization. In order to investigate the effects of these two functions on students' meaning construction effects in detail, it is necessary to further subdivide the students with average knowledge background and those who obtained average context setting effects, as shown in Table 4.

Before the collaborative learning, the student's meaning construction function is determined by the student's own knowledge background function $F_L(t)$ and the teacher's context setting function $F_S(t)$, and the value of the meaning construction function determines the student's state. Therefore, the status of the student is determined by the

student's own knowledge background and the effect of the teacher's situation setting. The relationship between the student's status and the student's own knowledge background and the effect of the teacher's context setting is shown in

$$K_{i,j} = f\left(l_{i,j}, s_{i,j}\right). \tag{12}$$

Formula (12) indicates that the state of the student can be determined according to the student's own knowledge background and the effect of the teacher's context setting.

Because l can represent students with 4 kinds of knowledge backgrounds, and s can represent students with 4 kinds of context setting effects, so the combination of l and s has $4 \times 4 = 16$ situations. The regulations are as follows:

(i) f (poor, poor) $= -1$;

(ii) f (poor, worse) $= -1$;

(iii) f (poor, better) = uncertain;

(iv) f (poor, good) $= 0$;

(v) f (worse, poor) $= -1$.

(vi) f (worse, worse) = uncertain.

(vii) f (worse, better) $= 0$.

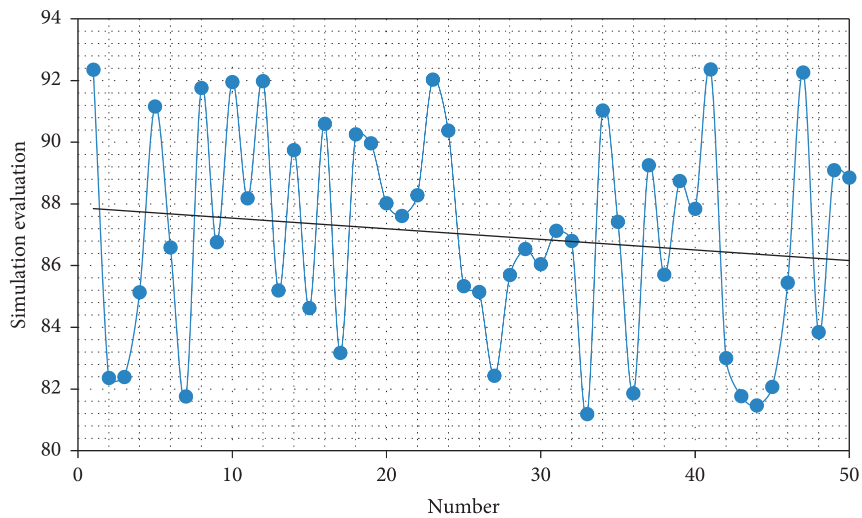

FIGURE 9: Statistical diagram of the teaching effect of the English classroom teaching evaluation system.

(viii) f (worse, better) = uncertain.

(ix) f (better, worse) = uncertain.

(x) f (better, worse) = 0.

(xi) f (better, better) = uncertain.

(xii) f (better, good) = 1.

(xiii) f (good, poor) = 0.

(xiv) f (good, worse) = uncertain.

(xv) f (good, better) −1.

(xvi) f (good, good) = 1.

For the 10 cases in which the state can be determined among the 16 cases, the range of values of the meaning construct function can be calculated by equation (1), as shown in Table 5.

Through the display in Table 5, the state transition rules in Table 3 can be summarized.

4. Construction of an Improved English Teaching Model Based on Cellular Automata

After the grid information is recorded, it is necessary to set the grids occupied by different areas, and the typical areas are classrooms, corridors, and stairs. Different areas and grids can be used to initialize the distribution of people, and at the same time, the distribution of people can be counted to analyze and evaluate the evacuation process. The teaching building is used as a place for students to attend classes, and the personnel can be initialized and distributed based on the classroom curriculum. Each classroom contains information about desks and chairs (as shown in Figure 3). The number of desks and chairs is the maximum capacity of the classroom, and people can be distributed behind the desks and chairs to simulate a real situation.

In Figure 4, the circle represents the pedestrian, the square represents the obstacle, and the arrow represents the direction of the pedestrian's moving speed. We use the red pedestrian as an example. Since he is at the opposite speed from the pedestrians on both sides, he will be subject to the friction of the two pedestrians against him, which will hinder his movement. Moreover, the pedestrians behind him move in the same direction as him, and he will be pushed by the pedestrians behind him.

To sum up, after abstracting pedestrians into particles, each pedestrian particle has a moving direction in the mobile mode. According to the direction, a 3×3 matrix M can be constructed for each particle. The elements in the matrix represent the size of the expected velocity value in the direction (i, j) of the particle, as shown in Figure 5.

As shown in Figure 6, the English teaching system model based on cellular automata consists of six parts: client, resource node, user authentication management service system, teaching resource management system, resource catalog service system, and resource management service system.

The construction of the cellular automata-based English teaching model educational resource grid configuration information platform can not only manage various resources uniformly but also provide users with safe and transparent grid services more conveniently, as shown in Figure 7.

After constructing the above model system structure, the performance of the system is verified. The system in this paper can be used to simulate the English teaching process, including the movement of students and teachers, the interaction of the teaching process, the development of teaching activities, and the processing of teaching resources. Therefore, this article combines the actual situation to deal with it systematically and, from the actual situation, design experiments to study the simulation effect of this system on English classroom teaching and obtain the results shown in Table 6 and Figure 8.

From the above test evaluation, it can be seen that the teaching effect of the English classroom teaching evaluation system based on the cellular automaton proposed in this paper is good. On this basis, the teaching effect of this system is evaluated, and the results shown in Table 7 and Figure 9 are obtained.

From the above research, we can see that the English classroom teaching evaluation system proposed in this article has a very good teaching effect and has a certain role in promoting English teaching.

5. Conclusion

The teacher evaluation system designed by colleges and universities for students, the establishment of rich elective courses, and the opening of "green channels" for students to reflect the various teaching problems of the school all reflect the main status of students, and colleges and universities gradually treat students as an object for service. Similar to the pursuit of customer satisfaction by businesses, the school also considers student satisfaction as a core indicator to reflect on its own performance. Moreover, English teaching needs to be improved through the use of intelligent methods to assist teaching and to change the traditional teaching mode. This article applies cellular automata to the improvement of English teaching and uses the cellular automata model to study the behavior of complex teaching systems. In addition, this paper uses the method of man-machine combination to establish the corresponding dynamic evolution model. Finally, this paper constructs an intelligent simulation system and then designs experiments to conduct system evaluation. The experimental research results show that the teaching effect of the English classroom teaching evaluation system based on the cellular automaton proposed in this article is very good, and it has a certain role in promoting English teaching.

Academic Editor: Tongguang Ni

The needs of visualization of multidimensional information of the earth, 3D virtual construction, and engineering design are driving research into some technologies of 3D landscape interactive design. The function and availability of the 3D landscape interactive system are largely determined by an efficient interactive algorithm, which is an essential part of the interactive design system of commercial architecture landscape. This paper investigates and evaluates the current state of 3D landscape intersection in landscape design, compares and evaluates existing 3D landscape modeling methods, and proposes some recommendations for the feasibility of a 3D commercial building performance scheme that will serve as a model for future large-scale urban commercial building landscape modeling. When the landscape is represented by objective substances like visual images, people are more likely to actively engage with nature and make automatic decisions based on physiological responses. The introduction of 3D technology has given people's lives a new lease on life, and it is critical to optimize urban planning and management.

1. Introduction

Today's society is rapidly entering a digital world, thanks to advances in global informatization and the development of digital technology, computer software and hardware, database technology, network information industry, database technology, computing graphics and images, virtual reality technology, and so on [1]. The city provides the necessary space for human production and life, that is, urban space, as a relatively concentrated area of human life on the earth [2]. Everything has its own three-dimensional spatial information in reality, which is a true three-dimensional geometric space. It is necessary to create a three-dimensional landscape model of the city in order to express and process the three-dimensional data of urban space [3]. Commercial complexes can provide more convenient centralized living areas based on the needs of users to adapt to the fast-paced urban development [4]. Diversified retail businesses that are closely related to life disrupt the traditional residential business environment model and create a brand new integrated business model of urban agglomeration based on life, pleasure, and a variety of choices [5]. Urban complex is the product of urbanization. It is composed of social living spaces with different properties and uses in the city. Through the introduction of urban public space, it comprehensively combines various scattered spaces, gives full play to the coordination of architectural space and the complementary role of architectural functions, and shows great vitality and abundant development potential [6].

As the social economy has grown, a new commercial format has been introduced from abroad, as evidenced by its name. The urban commercial complex is a significant commercial center in a city, and its significance has outstripped the general concept of structures [7, 8]. There will be a variety of feature models as well as complex and changeable geomorphic models throughout the city. To improve modeling efficiency and quality, we must choose appropriate modeling methods for various features and geomorphology. In this paper, the performance of 3D architecture in landscape design is taken as the main starting point, and the information obtained from field investigation is taken as the main source of thesis materials, and analysis and suggestions are made in the form of investigation report. This paper studies and analyzes the performance status of 3D landscape intersection in landscape design, and puts forward some suggestions on the feasibility of 3D commercial building performance scheme. The existing three-dimensional landscape modeling methods are compared and analyzed, and their respective characteristics are summarized, so as to provide reference for future large-scale urban commercial building landscape modeling.

Commercial complex itself has many characteristics such as intensification and unity. At present, it is favored by many consumer groups. It is under this background that urban commercial complex architecture has developed rapidly in China in recent years [9]. With the development of commercial architecture performance technology, it not only produces new things, but also makes outstanding contributions to social reform [10]. The performance art of commercial architecture is particularly important [11]. The three-dimensional landscape interactive design method gives the three-dimensional virtual scene of urban landscape, so that designers can deal with the virtual environment flexibly and creatively, establish effective information exchange and interaction between information map and human vision, and carry out knowledge mining [12].

2. Related Work

In literature [11], based on the principle and classification of landscape model expression in urban 3D geographic information system, a batch 3D model construction method of symbol matching and triangulation was proposed for abstract point, line, and area objects, and a set of rapid 3D model construction tools was developed based on this method. Literature [13] points out that the performance of landscape images needs a deeper definition to show them, which is the process that can finally realize the whole view. Literature [14] points out that urban commercial animation is not only a work of art with originality, aesthetics, image, and emotion, but also a commodity and a special cultural product. In literature [15], based on 2DGIS, a 3D city map was developed, and the building model within the city was built with simple geometry. Literature [16] puts forward the idea of establishing the 3D model base of urban landscape to realize the rapid reconstruction of urban 3D landscape. Literature [17] mentioned in the research that, in the process of urban construction, we should maintain the existing urban history and culture, do a good job in the publicity and popularization of urban history and culture, and create a strong urban cultural atmosphere and noble urban humanistic spirit.

Literature [18] discusses the scientific and technological expression methods of landscape design. In order to meet the requirements of the new world and people's fast-paced lifestyle, the three-dimensional landscape design has become increasingly prominent, allowing people to place themselves in the digital three-dimensional and experience the unique visual and auditory feelings that virtually brings to people. Literature [19] shows the realistic animation of urban outlook landscape, which can intuitively reflect the development process of the city, make the performance of urban context and image more prominent, and show people's life forms in the city. Literature [20] shows that the three elements of space, path, and visual threshold give full play to the interaction and show multimeaning space. Its organizational mode causes overall environmental participants to increase their autonomous activities, improve their sense of self-satisfaction, provide positive feedback to the environment, affect the interactive experience between the environment and participants once more, and effectively realize interactive media interaction and communication. The combination of various formats, complementary interests among formats, close relationship with cities, and other characteristics of urban complexes are mentioned in literature [21]. Many factors contribute to the operation's success. Although external open space landscape design is one of them, its function is indispensable. The rules of urban design may be reversed, interrupted, or even abandoned for different people under different circumstances. It examines the city's construction from a different perspective, and it also aids my search for a new learning angle in this topic's research. The construction of a virtual city landscape, the use of three-dimensional landscape intersection, and the method of three-dimensional landscape modeling are all examined in this paper.

3. Methodology

3.1. Virtual City Landscape Construction. For a large-scale complex scene, the establishment and optimization of the model are extremely important. Interactivity and realization intention need to be considered. Compared with animation model, there are usually fewer details to improve the real-time effect. On the existing basis, people can only sacrifice the perfect and accurate visual art, achieve a higher level of realism through the balance with real time, and construct a virtual environment that can realistically simulate the real world [22]. With the rapid development of software technology, the computing speed of microcomputer exceeds one billion times. The new technology of computer graphics display card greatly accelerates the computing and processing of landscape data and makes the visual development system of landscape reach a new level of rapid interaction. Three-dimensional landscape visualization equipment has also been greatly developed, and a large amount of production is also slowly carried out. The development of software has mushroomed, and a series of 3D landscape visualization software has been developed [23].

Natural topography and human landscape are included in three-dimensional landscape, which includes complex three-dimensional topography, simple matchbox-shaped houses with regular shapes, trees, waters, and even moving cars and pedestrians, among other things. The foundation of the entire virtual scene and one of the most important research fields in the virtual geographical environment is urban landscape modeling. For a long time, computer scientists have been attempting to replicate a real three-dimensional scene in the real world in the computer [24]. Computers can now draw various complex and realistic 3D scenes in real time, thanks to advances in 3D visualization technology, virtual reality, and real-time realistic graphics, and this ideal is becoming a reality. Drawing based on graphics or geometry, which is actually the simulation of the light interaction process of objects in real scenes, is the traditional method of 3D representation of real objects. The brightness of each visible point on the screen is calculated by the drawing algorithm. Figure 1 depicts the procedure.

People have an insatiable desire for city life in order to survive and develop in the city and to live better in the city. Currently, the urban commercial complex has established itself as a significant commercial center of the city, gradually replacing the previous single architectural model by appearing in the form of a building complex, combining the contents of urban living spaces such as office, business, and residence in the city, and establishing a dynamic relationship of mutual benefit and interdependence on this basis. We can establish an object behavior model independent of user input, in addition to mathematical modeling of the direct response of object motion and physical characteristics to user behavior, as the embodiment of virtual reality's autonomy. The research of a new generation of modeling methods represented by behavior modeling is on the rise, and its application prospects are very promising [25]. With the continued development of virtual reality technology and the expansion of the application field of virtual reality technology, the research of a new generation of modeling methods represented by behavior modeling is on the rise, and its application prospects are very impressive. Determine the spatial position and geometric shape of each building object using the urban basic geographic information database, then get its basic three-dimensional shape using height information, and then map according to the texture of each facade to get the building's basic model.

The building viewpoint data model mainly applies the storage method of point data in vector data; that is, the coordinate points of the building are stored. The attribute data model in the system can be designed into several attribute information tables by applying the design principle of general relational database. The object hierarchy in the vector data model is shown in Figure 2.

The modeling environment provides interactive, multidisplay, and user-defined 3D graphic viewer and a two-dimensional hierarchical structure diagram. All the displays are interactive and fully related, and this flexible combination accelerates the organization of database, model generation, modification and editing, and the definition of structural relationship. In general, there are two types of virtual scene model object representation, specifically representing the outline and shape of primitives in the objects, which can save calculation time during generation but requires a lot of time and space to store and access, and specifically representing the outline and shape of primitives in the objects, which can save calculation time during generation but requires a lot of time and space to store and access. It is beneficial to storage in principle, but it must be recalculated each time it is used. When drawing graphics, it switches among these detail models based on the distance of viewpoint or other standards and automatically selects the corresponding display level, allowing the scene's complexity to be changed in real time without affecting the visual effect. However, the primary goal of using examples is to save memory; as a result, the display speed will be accelerated; however, because the geometric position of objects must be obtained through geometric transformation, the amount of calculation required by the system will obviously increase as the number of example objects increases.

3.2. Application of 3D Landscape Intersection in Commercial Building Complex. Landscape visualization emerges when information technology has progressed to a certain point. The three-dimensional landscape has become the main stage as a result of the advancement of electronic technology. Despite the fact that China is late in developing landscape visualization, many advances have been made in recent years, including research and development of 3D technology for urban landscape visualization, interactive operation of 3D scene models, 3D dynamic interactive visualization models, and visualization technology and its application in geological exploration. Communication expresses the superiority of three-dimensional architectural design, and traditional renderings based on artificial modification contain some misleading elements. However, by presenting the real estate to the developer in the form of a 3D animation, the developer can make an accurate assessment of the scheme's characteristics and quality based on personal experience, allowing the developer to select the best strategy, maximize land utilization and construction project development rates, and significantly increase the cost. By displaying large-scale projects with vivid 3D technology, a vivid 3D model can be built, which can meet the requirements of the masses from multiple angles, levels, and directions, and make reasonable distribution for each key point and channel of the building itself, which resonates with people's design ideas [26]. According to the requirements of the planning scheme, various 3D building models are arranged on it, the simulated digital terrain is generated according to the contour lines of the actual terrain, and with the help of 3D animation software, an animated tour path is created, and finally a section of building roaming with the help of 3D software is completed. Later, text description, music background, graphic materials, and so on can be added to it by software, and some simple query functions can also be realized.

We can show the exterior and interior of the building in detail, as well as the surrounding environment, using 3D representation technology, as if we were on the spot. As a result, first, the workload of the building created using 3D representation technology is reduced, and second, people can more easily feel the information they require. Finally, thanks to advances in 3D technology, people can now modify their dissatisfaction at any time and from any location, greatly reducing time and improving quality. Virtual modeling using geometric models is based on computer graphics, which abstracts the real scene and creates a 3D geometric model of a virtual landscape using polygons. After that, texture mapping and control parameter setting takes place. Finally, using software control, real-time rendering and drawing of the visual picture on

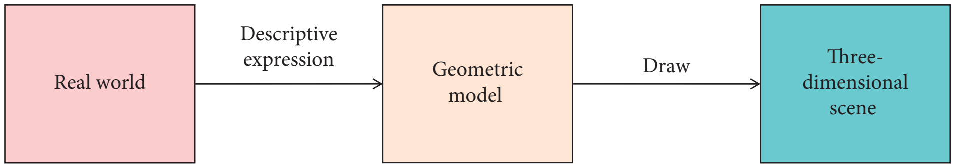

Figure 1: 3D scene construction process.

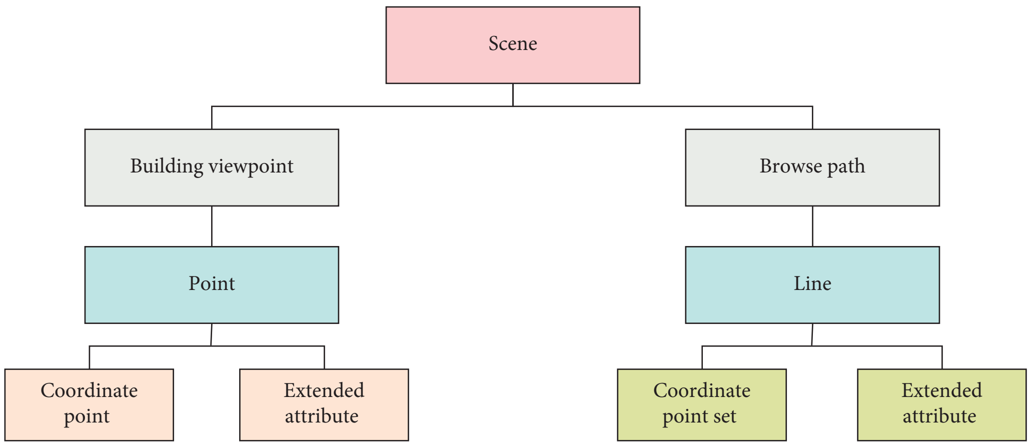

Figure 2: Object hierarchy in the vector data model.

the output device are carried out based on the observer's position, illumination, and blanking information, completing the roaming of the entire scene. Figure 3 depicts the modeling process.

With the appearance of 3D technology, the requirements of computer software and hardware are also improved. The improvement of computer hardware is not difficult, but the improvement of software technology is an arduous task, and there are always unsolvable problems. However, thanks to today's rapid advancements in science and technology, computer software and hardware technology have vastly improved, laying the hardware foundation for 3D landscape intersection technology and expanding its application field. The use of 3D landscape intersection technology in virtual reality, architectural performance, and film and television scenes reflects its importance as a display medium in the field of architecture. It deviates from previous plane renderings' simple plane layouts, combining high-tech animation techniques with gorgeous film and television special effects, vividly and concretely depicting the style of architectural buildings or unique urban buildings, and integrating people's rich life plots, the geographical location of buildings, and the beautiful environment. The rapid growth of China's economy has increased demand for real estate, and the continuous development of urban planning has given architectural animation significant market power. Its outstanding qualities make it a highly sought-after golden occupation field in the twenty-first century.

The relationship between urban status evolution and influencing factors is as follows:

$$Y = F(A, X). \tag{1}$$

Y is the change level of urban state, X is the influencing condition, A is the effect of the influencing condition, and F is the action function. Let us assume that there are n city states that have not been evaluated, the relative change of city states is y, and there are m influencing factors x. Among them, each influencing factor is X, the urban planning factor is x_p, the influence degree of each influencing factor is A, and the influence degree of urban planning factor is a_p. The formula can be expressed as,

$$y_n = f_n\left(a_1, a_2, \ldots, a_p, \ldots, a_m, x_1, x_2, \ldots, x_p, \ldots, x_m\right). \tag{2}$$

Taking into account the spatial and temporal dimensions, this relationship can be expressed as,

$$Y_k^t = F\left(A_k^t, X_k^t\right), \tag{3}$$

where k is the area ID and t is the time period. The area k has the city state $s_k^{t_s}$ at the start time of the time period t and the state $s_k^{t_e}$ at the end time, and then the city state changes $y_k^t = s_k^{t_e} - s_k^{t_s}$ of the area k at the time period t.

The inconvenient expression of architectural language and the designer's poor expression of perspective make it difficult for the masses to communicate and understand the design significance, and traditional architectural expression has significant limitations. We must mention the urban simulation system in the field of urban planning. Its significance lies in the application of virtual reality technology to urban landscape planning and design, with the goal of establishing a real model to reflect the urban environment and then realizing the real model through on-the-spot investigation and data capture into the computer. As a result, using 3D virtual technology and designers' creative ideas, we can fully express a single building, its material color, and our

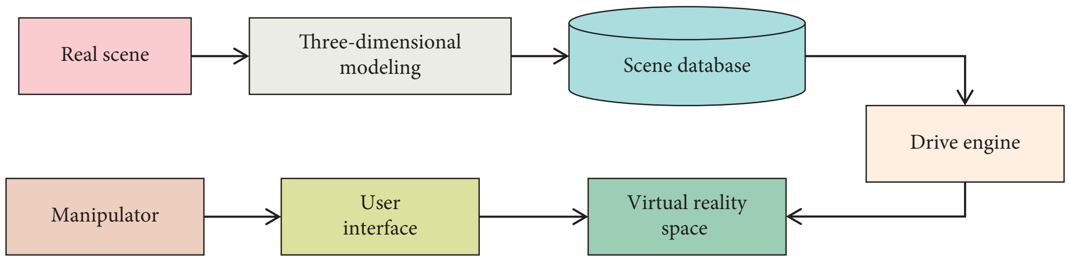

Figure 3: Flowchart of the modeling method.

own cultural information when we want to express all-round architectural information. People require more direct visual expression, and the intersection of three-dimensional landscapes has unquestionably become a necessary tool for people to enjoy the best visual experience. As a result, it is critical to incorporate 3D landscape intersection technology into the user participation design system, as traditional architectural performance is unmatched. It will be more widely used if 3D landscape intersection technology is applied to it.

4. Result Analysis and Discussion

4.1. Three-Dimensional Representation of Urban Landscape Commerce. Through the technical means of three-dimensional animation, artworks that show the vividness, aesthetics, creativity, and emotion of three-dimensional dynamic images from all angles [27]. The prospect of urban three-dimensional commercial performance in practical commercial application is still very broad. With the development of computer technology and technology, there will be more and more mature methods for building urban 3D landscape models, with higher modeling efficiency and better model quality. An important part of the three-dimensional landscape interaction is the three-dimensional animation of urban prospect landscape, which is essentially different from other kinds of animation. It mainly focuses on the prospect of future urban development and teaches intuitive three-dimensional deduction of future cities, showing the expression methods of urban development, urban rhythm, and urban image color. It can intuitively interpret the state of people's lives and the features of the city.

The physical attributes of objects are considered in the modeling of commercial complex. Fractal technology and particle system are typical physical modeling methods. Fractal technology can describe data sets with self-similar characteristics. Figure 4 shows the comparison results of algorithm performance before and after storage optimization.

Cultural Preservation in the City Landscape architecture performance is a form of cultural protection for urban landscapes based on the display of visible and intangible, static, and dynamic virtual reality technology. Today's cities are rapidly developing, but this rapid development has severely weakened the cities' original cultural atmosphere as well as their historical and cultural heritage. We should make a strong appeal to our people to protect our traditional urban culture and historical culture, using urban culture to protect landscape architecture animation, raise societal awareness, and deeply love our own urban history and culture; history is irreversible, so how can we strengthen awareness of inheriting our own history and culture, maximize protection, and make the city where we live have a good cultural atmosphere?

As a new business model, commercial complexes have not been in China for a long time, and there are basically no successful examples in China for reference. In fact, urban commercial landscape is to display the characteristics of the original architectural style in urban commercial complexes from the perspective of landscape designers and, at the same time, make these commercial buildings bring people a warm, comfortable, and relaxed shopping and leisure environment. Commercial landscape design should be combined with urban design, so that the landscape can reflect the humanistic and three-dimensional characteristics and better integrate with the city, thus providing important guidance for urban development. Landscape design can humanize the architectural space, at the same time, increase more added value of fine products, and also have a great impact on the lifestyle of residents. On the whole, the construction of business environment has certain forward-looking characteristics. Landscape ecology places special emphasis on maintaining and restoring the continuity and integrity of landscape ecological process and pattern, that is to say, maintaining the spatial relationship between residual green patches in cities and natural patches in wetlands.

The commercial building complex model created based on the task of three-dimensional landscape interaction can solve the possible design problems and quality problems of the project in advance through collision detection and other forms. Figure 5 shows the comparison of simulation of commercial building topology reliability optimization before and after optimization.

Three-dimensional landscape interaction measurement relationship is also widely used in planning results in the area statistics of planning land, the calculation of floor area ratio of different land types, the height and density of buildings, and the minimum distance between buildings with different heights. The approximate relationship between road width and building area is shown in Figure 6.

As a public place to provide consumption and leisure for urban residents, the landscape design of urban complex must strictly follow the principle of publicity. To a great extent, it has replaced urban public spaces such as city

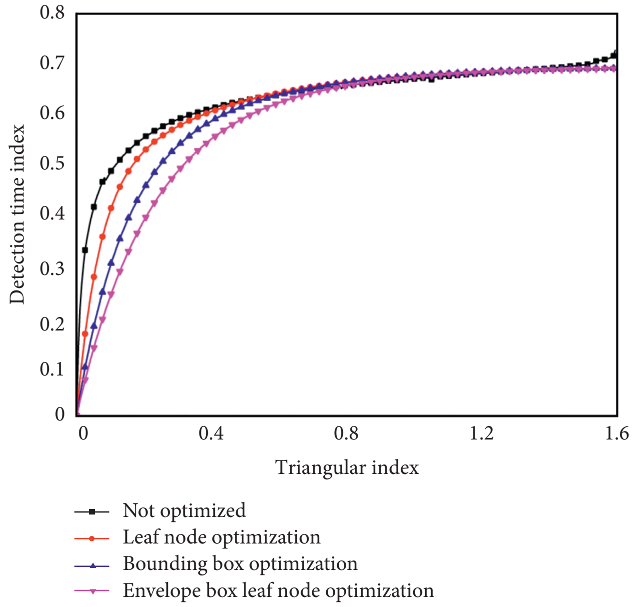

Figure 4: Comparison of algorithm performance before and after storage optimization.

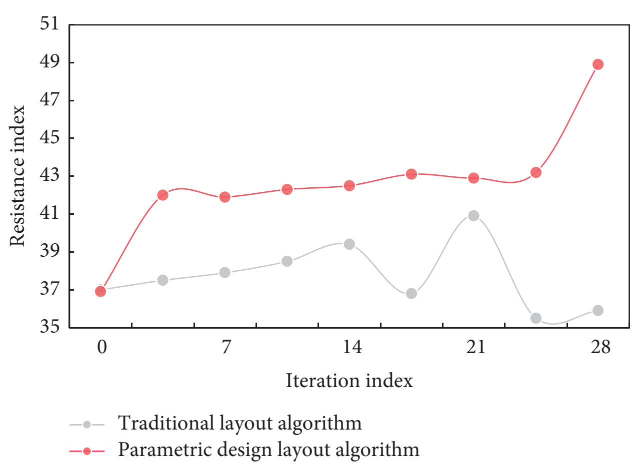

Figure 5: Simulation comparison of commercial building layout optimization.

streets and squares, and now urban commercial complexes have evolved into a main carrier of urban public activities. In the commercial landscape design of urban complex, the whole city should be regarded as a whole, and the construction should be based on it. In this case, the boundary between the city and the building becomes increasingly blurred. At the same time, designers should pay full attention to local historical and cultural traditions and pay attention to issues such as national personality, cultural customs, and religious beliefs, so as to show local characteristics by using various expression techniques in the design process.

4.2. Analysis of Building Characteristics. The method of building model includes the plane data and height data of the building. With the development of computer technology

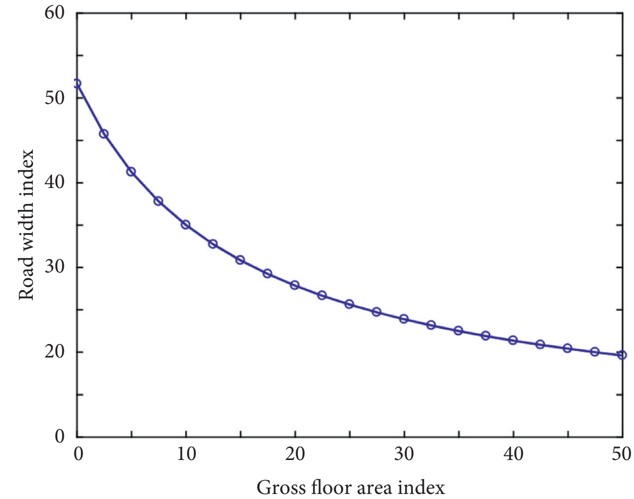

Figure 6: Relationship between road width and building area.

and graphics technology, some modeling software can be used to achieve finer and finer modeling to meet the basic visualization requirements into the three-dimensional modeling software and then directly stretch to the corresponding height to get the basic external surface model of the building. Through texture mapping, a complete building model can be obtained. Geometric modeling is the first development in the three-dimensional landscape interaction of commercial building complex layout. Analyze its path density, number of nodes, and central potential. The relationship between path density and node path is shown in Figure 7.

In terms of function, the close overlap between necessary space and auxiliary space improves the utilization rate of commercial landscape space and the vitality of space, thus strengthening space communication and strengthening commercial functional space. In terms of form, polysemy space revolves around the theme of complex landscape, and multidirectional guiding space is used in landscape nodes such as scenic spot transformation, so as to transform the space into nature, coordinate and strengthen the landscape theme as a whole, and promote the accessibility of the theme. Following the characteristics of people's public activities, the route layout considers the various route requirements of various formats in commercial complexes, and vertical traffic such as inevitable routes, horizontal passages, and landscape continuous routes is organized in a network to ensure high accessibility of major activity areas. Building texture is an important part of the 3D landscape. The majority of texture data comes from field photographs and is directly related to 3D scenes. As a result, texture data quality determines whether a more realistic expression effect can be achieved. Roads and their appendages, vegetation, the water system, independent features, and so on are examples of surface appendages. The 3D expression of plants such as flowers, trees, and other objects is an important part of the 3D landscape during the construction of the entire city 3D landscape, and it is also directly related to the fidelity of the 3D landscape expression.

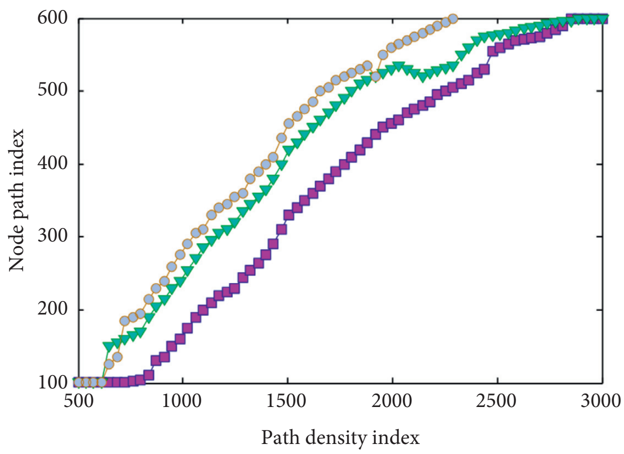

Figure 7: Path density and node path relationship.

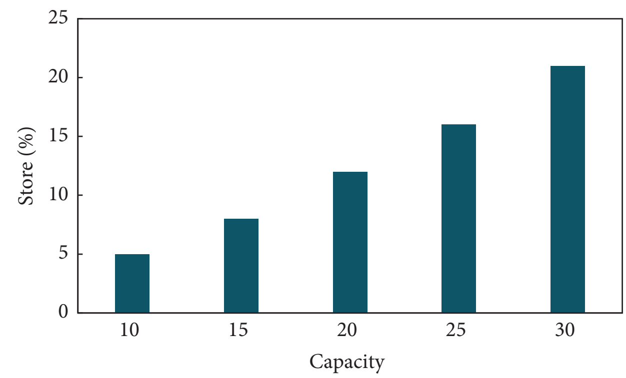

Figure 8: Excess cost ratio of single domain strategy.

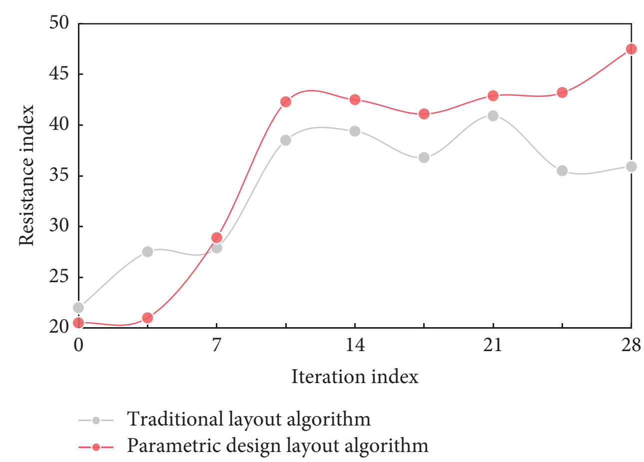

Figure 9: Simulation comparison.

The top texture of 3D building model cannot be directly obtained by field photography, so it can only be collected from orthographic images with original resolution, which can reduce workload and difficulty, and at the same time ensure the quality of texture data. Assume that the capacity of intradomain links is the capacity of interdomain links. The performance is illustrated by three different scenarios, as shown in Figure 8.

Fully consider the psychological factors of the active crowd, follow the changes of space and path, set the viewpoint, consider the attraction and guidance of the crowd's sight within the scope of sight, and consider the intensity and density of the sight direction and each attraction point within the visual threshold scale when arranging the landscape nodes. From the viewpoint, according to the sight demand of the active crowd, the scenic spots with different intensities and spaciousness are displayed in different sight scales, such as intimacy scale, etiquette scale, and public scale, so as to influence the diversified choices of user paths and make the experience interaction between each scenic spot and users. The simulation comparison of topology stability optimization is shown in Figure 9.

From the beginning of people's participation in the landscape experience, they have been actively or passively playing the role of interactive experiencer in the landscape, and their interaction mode is mainly direct expression, that is, active and direct participation in the landscape. Usually, when the landscape is represented by objective substances such as visual images, people tend to get close to nature actively and make automatic choices based on physiological reactions. The typicality of scenic spots and synaptic settings are the direct choice of human-landscape interaction. Effective arrangement of facilities and landscape nodes play a leading role in people's sense of participation and experience. Second, when the overall artistic conception of the environment is coordinated with the theme, the crowd's freedom will change the way they experience the world with the change of the path, be attracted by sound and shadow, be attracted by the gathered crowd, be attracted by unexpected events that have not been planned, and so on, all of which will have an impact on the interactive subject. The study of the interaction of commercial complexes and 3D landscape design can help to boost the economic benefits and vitality of urban commercial areas, as well as promoting the organic coexistence and development of people and the urban commercial landscape.

5. Conclusions

The development of history and civilization is not fast, and it will not have a long span, due to the city's constant expansion and construction. In general, once a city has reached a certain level of development, it is relatively stable. Modern cities have a large population, a large scale, and a complex functional structure, making commercial building complexes difficult to define and shape. This paper systematically examines related theories and methods in the construction of virtual cities, with a focus on comprehensive virtual city modeling, three-dimensional visual browsing and query, and so on. It has quickly spread throughout the city as a dynamic factor that can best promote urban economic development due to its development mode of maximizing land use. It is difficult for a single commercial structure to become a business gathering place. As a result, the commercial building complex has become an advantageous commercial carrier, allowing for increased attention to outdoor open space landscape design. The external space of an urban complex is systematically planned using modern landscape design knowledge, creating a landscape environment with intensive functions, high identification, and reasonable spatial combination, and jointly acting on a region to bring economic benefits. With the rapid advancement of science and technology, we must not only preserve our cultural heritage, but also begin to learn and receive new knowledge, as well as arming ourselves with new science and technology, in order to construct a better city and achieve faster development.

From the standpoint of visual elements, this article investigates the use of visual information technology in visual communication design. At this time, information visualization and data visualization are widely used to display visual form, which greatly facilitates people's use, provides a solid application foundation for visual communication design, and promotes its development. The image presentation of data is a common encoding process, and the reading of image content is the corresponding decoding process from the perspective of encoding and decoding. The combined efficacy of data encoding and image decoding determines the effectiveness of data visualization. It is worth noting that when it comes to "encoding and decoding," it has been established that the design mode of data visualization and visual communication is not a process of copying images but rather an external form of human thought. Then, there is the unmistakable presence of something unseen in the encoding and decoding processes. It also serves as the encoding and decoding key in the human brain. The image is as follows. From the standpoint of encoding and decoding, this article employs the data visualization self-encoder method to obtain visual data. Design pattern representation for perceptual communication can effectively support users' rapid motion analysis during the browsing process.

1. Introduction

The torrent of data conversion will become a trend as we move from Industry 4.0 to Industrial Internet and then to intelligent production. People are finding it more and more convenient to obtain information and data thanks to the rapid development of the Internet. Massive data quickly became a source of concern for the general public and the rate at which massive data were generated increased. This is a clear and beautiful topic in the field of visual communication [1]. Without a doubt, with the rapid advancement of technology, visual communication design will no longer be limited to a few well-known categories but will also include more related majors and make use of new science and technology to achieve a new level of separation. People's cognitive load can be reduced and a clear and intuitive visual expression can be formed using data visualization and graphical interface in an organic way [2]. Since the invention of cameras, televisions, and other tools, visual communication design has been in the process of image transformation, and interface design, as a subset of visual communication design, has also been in the process of image transformation. Vision has a significant impact on viewing data [3]. This article analyzes the application of visual information technology in visual communication design from the perspective of visual elements. At present, the display of visual form by information visualization and data visualization has been well applied, which greatly facilitates people's use, provides a certain application foundation for visual communication design, and promotes the development of visual communication design [4].

In this game, it is not a small step forward for human beings to consciously explore the rules and skills of coding from an unconscious coding, and it is also an aspect of human evolution without exaggeration. It is worth noting that when it comes to "encoding and decoding," it is affirmed that visual communication design is not a process of copying images but an external manifestation of human thought, so there is no doubt that there is something invisible in the human brain in the process of encoding and decoding, which is also the key to encoding and decoding. That is images [5, 6]. From the point of view of coding and decoding, the image presentation of data is a typical coding process, and the reading of the image content is a corresponding decoding process. The effectiveness of data visualization is the unity of the effectiveness of data coding and the effectiveness of image decoding [7, 8]. Coding shows the maximum amount of information in the shortest time and the least space, and the choice of a visualization method is very important [9, 10]. Coding and decoding are two different things. Data information can reduce the interference of a large number of visual noises in the process of visual coding with the help of the correct visualization method, which can lead to different mining attributes of data from many angles and discovering the important information hidden in the data [11]. The real position of the current voxel in the two code tables is determined using the two-layer code table index and the corresponding offset address, and the two texture coordinates are then used to obtain the decoded value in the corresponding code table. The reconstructed data value of the voxel is obtained by adding the two decoded values and the mean value [12, 13]. To determine the importance of data visualization in visual communication design patterns and make similar data adjacent to each other, data visualization and visual communication design patterns are coded [14].

Visual communication design under the coding and decoding theory can only take the road of diversified development, strengthen its own design, and differentiate development to participate in market competition. On this basis, it continuously interacts with, integrates, and continuously realizes innovation and improvement [15]. From the point of view of coding and decoding, the image presentation of data is a typical coding process, and the reading of the content in the image is a corresponding decoding process. The effectiveness of data visualization is the unity of the effectiveness of data coding and the effectiveness of image decoding. Simultaneously, it cultivates their desire to seek out differences, greatly improves their level of appreciation, aesthetic ability, and innovation ability, and lays the groundwork for cultivating skilled professional talents and innovative talents. To obtain the visual communication design pattern representation, a data visual self-encoder method based on the perspective of encoding and decoding is proposed, which can effectively support the rapid motion analysis of users in the browsing process. The proposed method's effectiveness is confirmed by the experimental results on the visual communication design pattern dataset.

2. Related Work

Literature [16] pointed out that a method of data visualization browsing uses KMeans to iteratively turn the visual communication design pattern in the data visualization set into a hierarchical tree and studies the data by specifying the starting and ending visual communication design patterns. In literature [17], using the big data analysis method and qualitative analysis of quadruple and maximum segmentation method, the visual communication design pattern is transformed into a systematic evolutionary tree, and better results of visual communication design pattern construction are obtained. Research in literature [18] showed that compared with tree organization, the visualization method of visual communication design pattern of scatter diagram based on SOM does not need to transform the relationship between nodes into a one-to-many parent-child structure. Literature [19] pointed out that the acquisition method of visual communication design pattern was introduced, and the application of data visualization in visual communication design was summarized. At the same time, the research approach of data visualization was discussed. In literature [3], through the big data analysis method, from the behavior angle of visual communication design pattern, based on the analysis method of data visualization, the characteristics of visual communication design pattern were studied, and the regularity of visual communication design pattern was excavated. Finally, the scope and demand situation of visual communication design patterns were studied. Literature [20] showed that users can finally get the desired visualization of target data by browsing. Compared with the retrieval method of example query, this method does not require users to provide query examples but also provides an important interface for users who are uncertain about the retrieval target or unfamiliar with the data field. Literature [21] pointed out that data visualization and related data are used to extract the amount of data in the process of design mode, which is used to predict the application of future visual communication design mode in data visualization and predict and analyze the visual communication design mode according to the amount of data. Literature [22] organized the analysis methods and ideas of visual communication design patterns from an application perspective using the big data analysis method, built the framework of a data visual listening system, explained the goals of data mining from the two perspectives of data and design, and explained the analysis process and mining methods of visual communication design patterns. According to literature [23], relevant methods for analyzing and studying visual communication design patterns are proposed after in-depth mining and analysis of data visualization, which aids in developing visual communication design patterns. According to literature [24], after analyzing the data of visual communication design mode, some methods for calculating the operation index of visual communication design mode are given based on data visualization. From the standpoint of encoding and decoding, this article investigates the design pattern of data visualization and visual communication. The image presentation of data is a typical coding process, and the reading of the image content is a corresponding decoding process in terms of coding and decoding. The combined effectiveness of data coding and image decoding determines the effectiveness of data visualization and visual communication design patterns.

3. Algorithm and Principle of Encoding and Decoding

The coding and decoding processes are asymmetric, and the propagation process is a circular circle rather than a line, with multiple interconnected but distinct links. Visual design and information transmission are the corresponding coding and decoding processes in the field of data images. Designers imbue images with inherent and intrinsic meanings. Although the decoding of data images based on images and visuality gives the impression that "seeing is believing," it leads to the delusion that image symbols are equivalent to real-world objects. The audio signal is first passed through an analysis subband filter bank, which is the first step in coding. With a reasonable time and frequency decomposition rate, the filter bank divides the input signal into 32 equidistant frequency subbands and extracts the subband sampling signal with a factor of 1/32. The extracted result from whole subband sampling is equivalent to the source signal, but there is some distortion. In a frame, there are 152 PCM audio samples, so each subband has 36 samples. The filter bank's output is calculated using the following equation:

$$St[i] = \sum_{k=0}^{63}\sum_{j=0}^{7} M[i][k] * (C[k+64j] * x[k+64j]), \tag{1}$$

where $St[i]$ is the sampling output of subband I at time t, $C[n]$ is the coefficient of 512-point analysis window defined in the standard, and $x[n]$ is the audio sampling input read from a 512-point sampling buffer. However, $M[i][k] = \cos[(2*i+1)*(k-16)*\pi/64]$ is the coefficient of the analysis matrix.

The above formula is transformed into an easy to understand convolution form to facilitate analysis:

$$St[i] = \sum_{n=0}^{511} x[t-n] * Hi[n], \tag{2}$$

where $x[t]$ is the audio sample $Hi[n] = h[n] * \mathrm{Cost}[(2*i+1)*(n-16)*\pi/64]$ at time t, and $h[n] = -C[n]$, when the integer part of $n/64$ is odd. $= C[n]$, when the integer part of $n/64$ is even; n is from 0 to 511.

In order to adapt to this change, the training sample set is updated by adding new samples and excluding old samples. A reasonable time interval T is selected. At time t, there is XR = XT... X (T-T). When new samples arrive, the training set has to be updated χ $T$and reestimate $\hat{p}(\vec{x}|XT, BG+FG)$. However, some values from old samples may belong to foreground objects, so we should use $p(\vec{x}^{\,t}, BG+FG)$ estimation to use GMM with m components. The corresponding formula is as follows:

$$p(\vec{x}^{\,t}|\mathrm{XT}, \mathrm{BG}+\mathrm{FG}) = \sum_{m=1}^{M} \hat{\pi}_m N\left(\vec{x}, \vec{\mu}, \hat{\sigma}_m^2 I\right), \tag{3}$$

where $\vec{\mu}_1 \ldots \vec{\mu}_M$ represents the average value estimated by the encoding and decoding component; $\vec{\sigma}_1 \ldots \vec{\sigma}_M$ represents the variance estimated by the encoding and decoding component; the covariance matrix is assumed as the diagonal unit matrix I; the weight is expressed by $\hat{\pi}_m$, and it is nonnegative and the sum of the weights is 1. Given a new sample at time t, the encoding and decoding model is updated using the following formula:

$$\begin{aligned}
\hat{\pi}_m &\longleftarrow \hat{\pi}_m + \alpha\left(o_m^{(t)} - \hat{\pi}_m\right),\\
\vec{\mu}_m &\longleftarrow \vec{\mu}_m + o_m^{(t)}\left(\frac{\alpha}{\hat{\pi}_m}\right)\vec{\delta}_m,\\
\hat{\sigma}_m^2 &\longleftarrow \hat{\sigma}_m^2 + o_m^{(t)}\left(\frac{\alpha}{\hat{\pi}_m}\right)\left(\vec{\delta}_m^{\,T}\vec{\delta}_m - \hat{\sigma}_m^2\right).
\end{aligned} \tag{4}$$

Usually, the invaded objects are represented by some clusters with a small weight, so the first B largest clusters are used to approximate the background model:

$$p(\vec{x}^{\,t}|XT, BG) \sum_{m=1}^{B} \hat{\pi} mN\left(\vec{x}, \vec{\mu}_m, \hat{\sigma}_m^2 I\right). \tag{5}$$

If the components corresponding to each pixel are arranged in descending order of weight, you can get

$$B = \mathrm{argmax}_b\left(\sum_{m=1}^{M} \hat{\pi}_m\left(1-c_f\right)\right), \tag{6}$$

where CF represents a maximum scale value that belongs to the foreground object but does not interfere with the background model. For example, if a new object enters the scene and remains stationary in the scene for a period of time, the object is likely to generate an additional stable cluster. Due to the occlusion of the background, the weight π_{B+1} of the additional cluster will continue to increase. If the object remains stationary for a long enough time, the corresponding weight will slowly exceed CF and it will be regarded as the background.

Given data x_1: T, x_i is the ith, t is the total number of data contained, and its corresponding hidden state is Z_1: t. In this article, z_i is the projection coordinate on the two-dimensional plane. Assuming the positive and negative directions, the conditional probability distribution of z_t about X can be expressed as $P(z_t|x_{1:t}, x_{t:T})$, where x_1:T is the time positive direction and X_t:T is the time reverse direction. According to VAE theory, we need to find a distribution $Q(z_t|x_{1:t}, x_{t:T})$ to approach cc by KL divergence $P(z_t|x_{1:t}, x_{t:T})$, and KL divergence is defined as q and p:

$$\begin{aligned}
D_{KL}(P,Q) = &\int Q(z_t|x_{1:t}, x_{t:T})\log\frac{Q(z_t|x_{1:t}, x_{t:T})}{P(z_t|x_{1:t}, x_{t:T})}dz_t\\
&+ D_{KL}(Q\|P(z_t)) - E_{zt\sim Q}\log P(x_t|z_t, x_{1:t-1}, x_{t+1:T}).
\end{aligned} \tag{7}$$

If the first term of equation (7) is a fixed term, minimize D and (P, q) can be transformed into maximization:

$$D_{KL}(P,D) = -D_{KL}(Q\|P(z_t)) + E_{zt\sim Q}\log P(x_t|z_t, x_{1:t-1}, x_{t+1:T}). \tag{8}$$

Equation (8) is also called the variational lower bound. Suppose that $P(z_t)$ obeys the distribution of $N(z_t{:}0,I)$ and $Q(z_t|x_{1:t}, x_{t:T})$ obeys the distribution of $N(z_t; \mu_t, \sigma_t)$, where $\mu_t = f_{\text{enc}}(x_t), \sigma_t = g_{\text{enc}}(x_t)$; then, $-D_{KL}(Q\|P(z_t))$ in formula (4) is

$$-D_{KL}(Q\|P(z_t)) = \frac{1}{2}\sum_{j=1}^{J}\left[1 + \log\left(\sigma_t^i\right)^2 - \left(\mu_t^j\right)^2 - \left(\sigma_t^j\right)^2\right]. \quad (9)$$

Equation (7) can be calculated by sampling from $Q(z_t|x_{1:t}, x_{t:T})$, z_t^l is the implicit vector of sampling, and the second term can be approximately as follows:

$$\begin{aligned} &E_{z_r \sim Q}\log P(x_i|z_r, x_{tz-1}, x_{l+1r}) \\ &\approx -\frac{1}{L}\sum_{j=1}^{L}\left\|x_t - h_{\text{dec}}\left(z_t^l, x_{1:t-1}, x_{t+1:T}\right)^2\right\| + c. \end{aligned} \quad (10)$$

According to the above analysis, the variational lower bound of equation (7) can be expressed by equations (8) and (9). In this article, fenc and genc are coding functions, and hdec are decoding functions, which are similar to those in the BiLSTM neural network. The network structure of the decoding algorithm is shown in the figure.

In order to better adapt to the change of environment, replace equation (4) with equation (6), and the updated formula of weight can be obtained as follows:

$$\hat{\pi}_m \longleftarrow \hat{\pi} + \alpha\left(o_m^{(t)} - \hat{\pi}_m\right) - \alpha c T. \quad (11)$$

Among them, $c\ T = c/T$, c corresponds to the number of samples supporting a Gaussian component; for example, $\alpha = 1/T$ can be selected, then at least $c = 0.01 * T$ samples are needed to support a component, and then $c\ t = 0.01$ can be obtained, and the specific flow corresponding to GMM is shown in Figure 1. The network structure diagram of the decoding algorithm is shown in Figure 2.

4. Methodology

4.1. Data Visualization and Visual Communication Design Pattern. The deeper reason for data visualization and visual communication design pattern lies in the mutual separation of "form metallurgy" and "content metallurgy." In the dimension of the visual design of data images, the content is deprived of form by strong governance, and designers have to go to great pains to find the most perfect form. In the dimension of data image content transmission, the audience has to strive to understand the content across the form, and the form realizes the separation of the content in a figurative manner. The development of data visualization and visual communication design pattern has gone through the process from static to dynamic and then to interactive presentation. The improvement of data visualization can obviously slow down the disharmony of visual communication design pattern, but it is still limited by the time period. Interaction in advance and interaction in the event are still needed; that is, analysis of the audience in advance and strengthening emotional communication in the event are needed. In order to verify the effectiveness of the coding and decoding model and algorithm, we first use the data visualization in the benchmark scene to train and test the model of our visual communication design pattern, compare the performance of network models at different depths, and compare it with the original GMM algorithm and the current advanced algorithm. Then, we further fine-tune and test the visual communication design pattern model in some new scenes. From the perspective of encoding and decoding, designers need to "design rationally"; specifically, based on data visualization, set design according to the purpose, highlight visual communication of design pattern information, match it with secondary information, and then present it aesthetically. "Reasonable" design is based on the fact that the visual communication design mode has at least the general level of image design ability. The "image garbage" and "image mediocrity" caused by "over-smelting" and "under-smelting" are not desirable. It should be noted that "reasonable" design does not require high data density image design or other high-level design, but it does not exclude the design for specific objects and specific purposes. Because there are many data visualization information and complex relationships, directly visualizing all data will lead to bloated graphics and difficulty of reading; simplifying data visualization will affect the completion of information performance, integrity, and accuracy. In the face of specific requirements, or focus on visual design, or focus on content communication and purpose, data visualization and visual communication design patterns can be finely designed to achieve specific effects. At the same time, based on the diversified needs of data visualization, visual communication design patterns can also be designed for specific data or nonspecific data. Firstly, this part analyzes the steps of data visualization and visual communication design pattern coding, which is described based on diagrams. Firstly, the input data visualization is based on a visual communication design pattern that divides the input signal into 32 equidistant frequency subbands. The sampled signal after this process is still in the time domain. Then, the sampled signal is mapped to the frequency domain by an improved discrete cosine transform. At the same time, the input PCM signal is transformed by FFT and then passed through a psychoacoustic model to judge the signal mask ratio of each subband, as shown in Figure 3.

The design pattern of data visualization and visual communication is a process of graphic simplification, which is a requirement for designers, and the information reading of data images is a complicated process, which is a requirement for audiences. Only when the requirements are clear can the problems to be solved be clearly defined and the design have an accurate direction. In the design mode of visual communication, many methods are widely used to analyze data visualization, such as interviews with users, situational investigation, auxiliary understanding of virtual objects' roles, and organizing targeted discussions among users. Referring to the training process of segnet, both models use the cross-entropy function as the loss function and use the random gradient descent algorithm to train on the Caffe framework. When training subnet-4, the

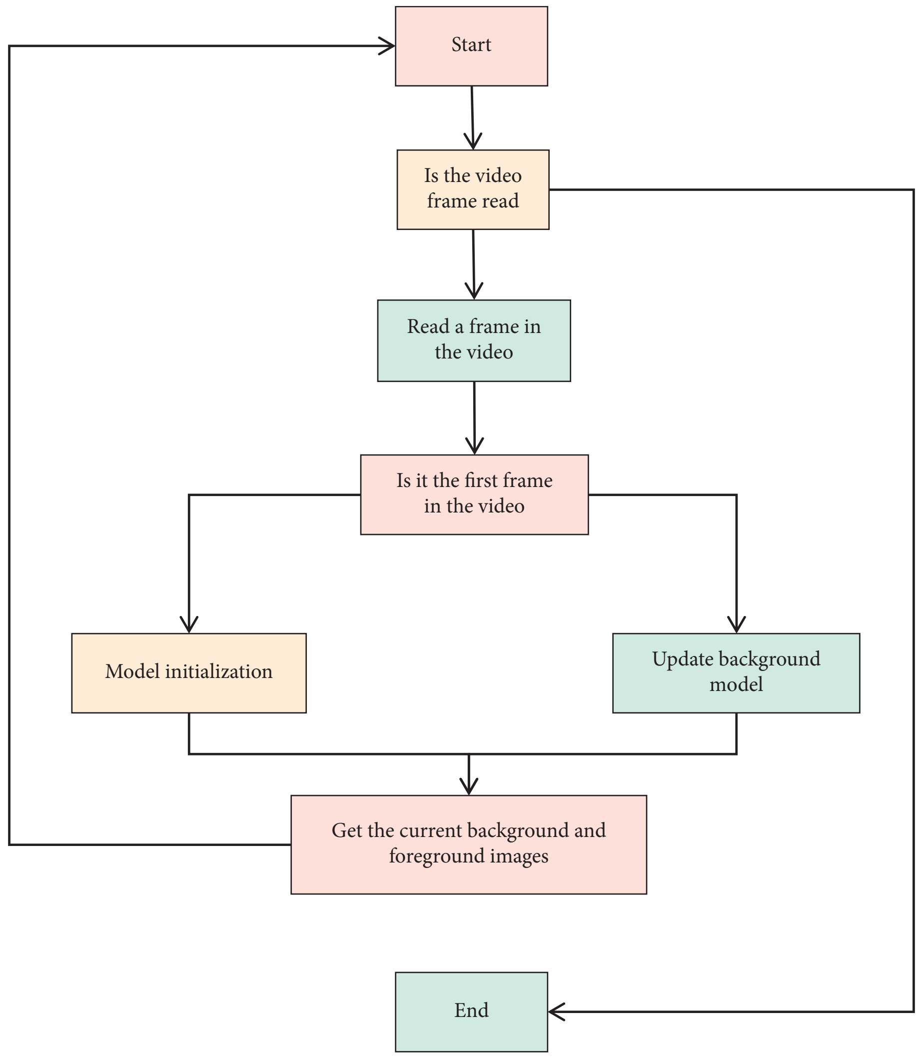

Figure 1: Flowchart of encoding and decoding model.

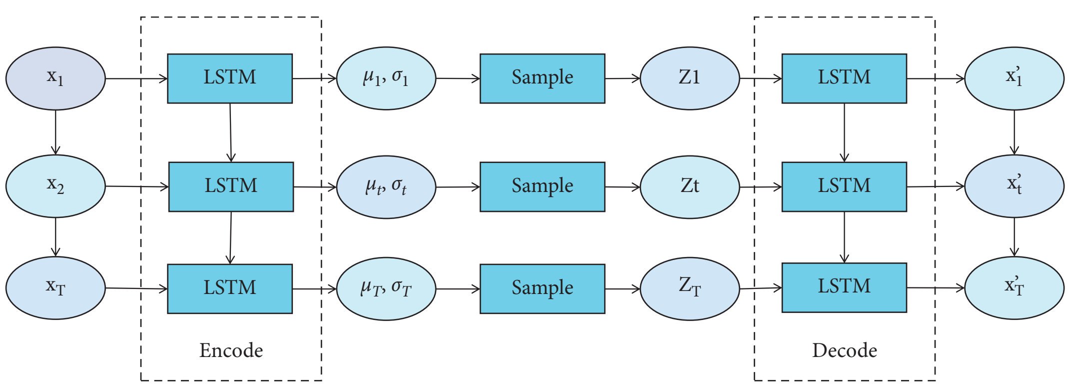

Figure 2: Network structure diagram of encoding and decoding algorithm.

learning rate is fixed at 0.01 and the batch size is set to 10 according to the actual hardware conditions; when training subnet-13, the learning rate is fixed to 0.001 and the batch size is set to 4. We observed that after about 15 training cycles (epoch, which means that all training data are trained once), the two visual communication design pattern models have basically converged. In order to compare the performance of models with different depths, we further trained the two visual communication design pattern models to about 30 cycles and then tested them on the resulting visual communication design pattern model. The visual change process of loss data during the training of two visual communication design pattern models is shown in Figure 4.

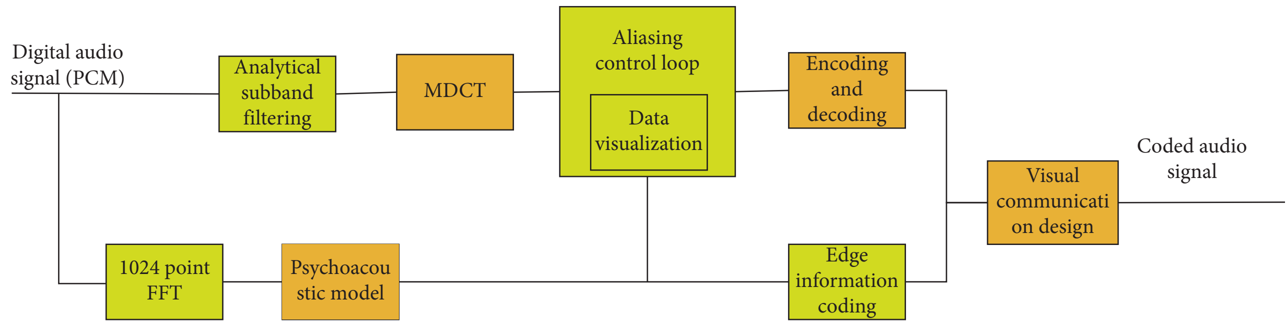

Figure 3: Block diagram of data visualization and visual communication design pattern coding.

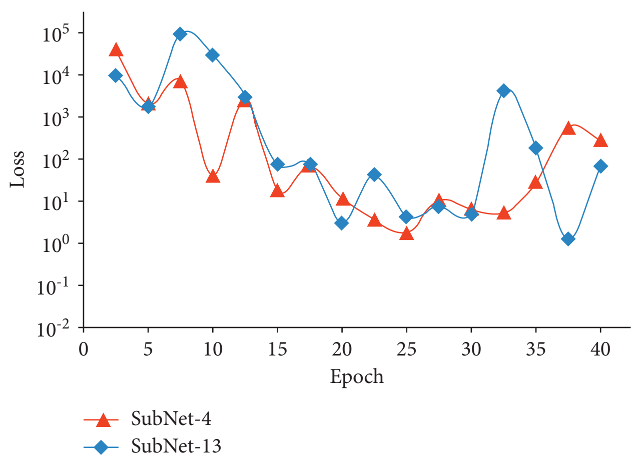

Figure 4: Numerical change curve of data visualization in visual communication design mode during training.

4.2. Experimental Results of Encoding and Decoding Algorithm in Data Visualization and Visual Communication Design Pattern. The coding and decoding algorithm performs similarly to the current top algorithms, and this is achieved without further optimization of the background modeling algorithm or the detection results (for example, DeepBS uses time median filtering to further process the results after obtaining the detection results), demonstrating that the coding and decoding algorithm is very competitive and has a lot of room for improvement. The advantages of data visualization and visual communication design patterns can complement and confirm each other by commenting on them or linking to the text content library. The look-up table simultaneously inputs the value of code length into an accumulator after a codeword is decoded. The accumulator serves two purposes: first, it indicates the position of the next word to be decoded in the buffer, which is calculated by adding the lengths of previous codewords; second, once all codewords have been decoded, the buffer is notified that new codewords are available from the bitstream. The look-up table's structure is made up of data pointers and memory, with the Huffman code table to be used in decoding already stored in memory. Because the encoding and decoding algorithm includes both Huffman encoding and scale factor in the main data, it can be assumed that a single-state machine can perform both Huffman and scale factor decoding at the same time. This can simplify the design code and save the hardware area, which can be realized by sharing the master data register by Huffman decoding and scale factor decoding. "We should be moderately skeptical about the reliability of the following information, cooperate with the data collection and processing personnel to check its authenticity, and then use it as the basis for making the data visualization and visual communication design mode." Regardless of the length of the codeword, the clock cycle required for decoding each codeword is the same, and the decoding time is relatively short, which is more suitable for requiring real-time decoding. Moreover, when Hoffman's code table changes, it only needs to modify the data in the look-up table, which is more convenient in terms of universality. In the interaction between data visualization and visual communication design mode, the designer has greater control because they are the supplier of image products. "The audience has no way of verifying himself." Whether or not data visualization is the source data information: first and foremost, it is not required. The image must be self-evident but separated from the visual communication design mode results in the loss of the reference object during verification; second, data visualization implies the conception and trade-off of the visual communication design mode, and restoring the source information is thought to be denying the designer's work and the value of the information map; third, it is a goal of data visualization; fourth, it is a goal of data visualization. The second goal is to encourage in-depth thinking and sublimation. We do not want the thinking to get stuck in the tangle of visual communication design mode after "understanding." The audience, on the other hand, is not taken for granted. The audience has the ability to read and understand basic judgments of image superiority and inferiority and the ability to "vote with their eyes"; that is, pay less attention to or ignore poorly designed data images. We conducted experiments and tests on other scenes of the CDnet dataset to further verify the generalization ability of the data visualization and visual communication design pattern model from the perspective of encoding and decoding. We only used subnet-4 to conduct related experiments here, based on the results of previous comparisons of different depth encoding and decoding networks. The performance of subnet-4 and subnet-13 is examined in each scene of data visualization, as shown in Figures 5 and 6.

We find that the algorithm performs well in the highway scenario but poorly in the office and pedestrian scenarios. Information transmission is realized through the encoding and decoding algorithm. There is no need to investigate

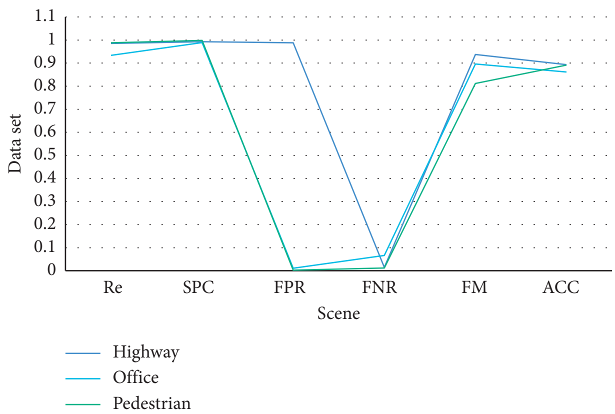

FIGURE 5: Performance of subnet-4 in various scenarios of data visualization.

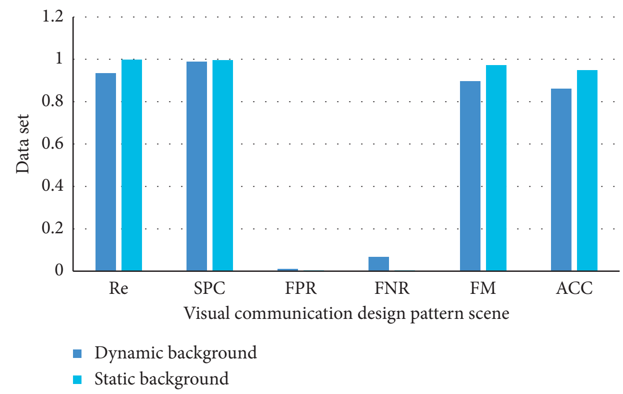

FIGURE 7: Performance of encoding and decoding in data visualization and visual communication design mode scenarios under different backgrounds.

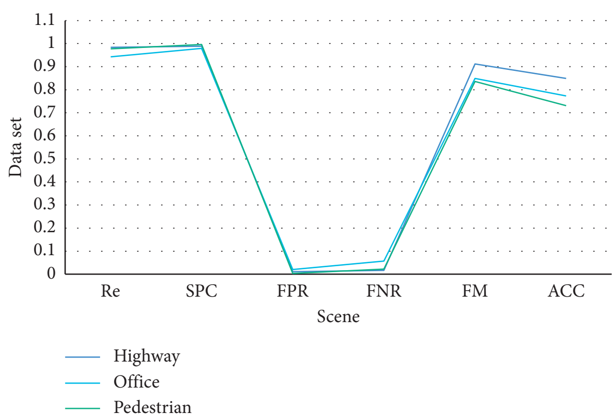

FIGURE 6: The performance of subnet-13 in various scenes in data visualization.

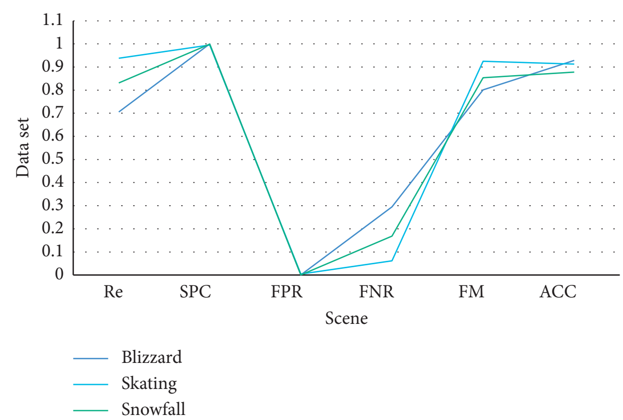

FIGURE 8: Performance of encoding and decoding algorithm in different scenarios of data visualization.

defects in the design process of data visualization. As long as the local visual communication design does not affect the beauty of the whole image and the audience can still understand the meaning of the image by bypassing defects, it is understandable. Of course, obvious errors are not allowed, which is related to the designer's own reasonable duty of care, including data visualization and visual communication design pattern comparison review, image ambiguity review, and aesthetic common sense review. The results show that our data visualization and visual communication design patterns are used to find the foreground object through the difference between the background image and the video frame; however, due to the shortcomings of the GMM model itself, the foreground object in the scene of data visualization and visual communication design pattern stays in the scene for a long time, which leads GMM to mistake it for the background. Considering that the design pattern of data visualization and visual communication is a scene with little background change, the subnet-4 model is used for testing, and the test results are shown in Figure 7.

First of all, we used some scenes of subnet-4 trained in data visualization dataset under the category of data visualization and visual communication design pattern dataset badWeather, and the results are shown in Figure 8.

The results show that the encoding and decoding algorithm performs well in skating scenes but not in other scenes due to the interference of fluttering snowflakes in bad weather scenes. We may not get good results based on the contrast between the background and video frames. Using an encoding and decoding algorithm, we can fine-tune and optimize the data visualization and visual communication design pattern. In particular, we randomly selected a portion of the data from the above scenarios, taking 10% of each scenario's data, for a total of about 2000 data, and then trained and fine-tuned subnet-4 for about 30 weeks. We tested the model in these scenarios after it converged. We also tested the average performance of the fine-tuned data visualization and visual communication design pattern model in the highway, office, and pedestrians scenes in the CDnet2014baseline category to see how fine-tuning affected the model. Figures 9 and 10 depict the test results.

It is clear from the results that the fine-tuning data visualization and visual communication design pattern model's performance in the new scene has vastly improved over the original model and that the average performance in the badWeather scene even outperforms the best existing algorithm. One of the more intriguing findings is that the fine-tuned data visualization and visual communication

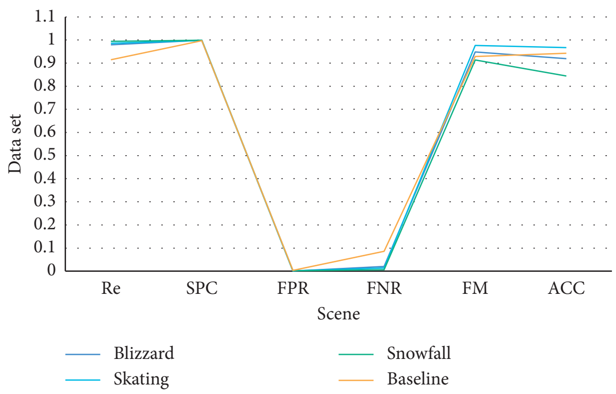

FIGURE 9: Performance of fine-tuned subnet-4 in various scenarios in data visualization.

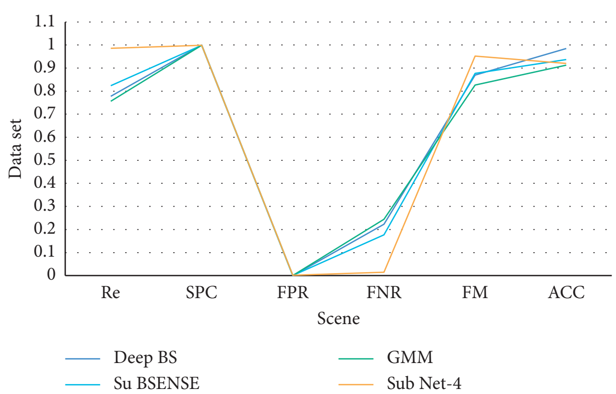

FIGURE 10: Average performance of different algorithms in some scenes of badWeather.

design pattern model's performance on the benchmark dataset has improved (the F score has increased from 0.9109 to 0.9284), implying that increasing the amount of data helps to improve the robustness of the data visualization and visual communication design pattern model. It is easy to see how much better the encoding and decoding algorithms are than the original GMM algorithm and how much better the antinoise ability is while effectively solving the "hole" problem.

5. Conclusions

Data visualization has taken off in this era of rapid advancement in computer technology and information technology, thanks to the power of science and technology. Traditional data charts have been transformed into visual communication design mode, which is of great benefit in guiding the general public to understand highly specialized data information and relieving data visualization resistance. The interactive operation mode is more user-friendly. The key to encoding and decoding is a thorough understanding of the design pattern of data visualization and visual communication, as well as the designer's improvement of drawing, the audience's adjustment, and the designer's interaction with the audience. The decoder's overall design is organized and divided into modules, with handshake signals defined. On this foundation, the decoding algorithm flow of data visualization and visual communication design pattern and the decoding system's hardware implementation scheme are thoroughly examined, and the majority of the modules are designed and simulated. The symmetry of the sine coefficient in data visualization and visual communication design pattern operation is used to improve the original algorithm, which can significantly reduce the times of addition and multiplication, based on careful analysis of the decoding algorithm of data visualization and visual communication design pattern.

Data Availability

The data used to support the findings of this study are included within the article.

The purpose of video key frame extraction is to use as few video frames as possible to represent as much video content as possible, reduce redundant video frames, and reduce the amount of computation, so as to facilitate quick browsing, content summarization, indexing, and retrieval of videos. In this paper, a method of dance motion recognition and video key frame extraction based on multifeature fusion is designed to learn the complicated and changeable dancer motion recognition. Firstly, multiple features are fused, and then the similarity is measured. Then, the video sequences are clustered by the clustering algorithm according to the scene. Finally, the key frames are extracted according to the minimum amount of motion. Through the quantitative analysis and research of the simulation results of different models, it can be seen that the model proposed in this paper can show high performance and stability. The breakthrough of video clip retrieval technology is bound to effectively promote the inheritance and development of dance, which is of great theoretical significance and practical value.

1. Introduction

With the continuous progress of multimedia technology and computer network, video and images show more positive significance in daily life, and the amount of video image data is increasing geometrically [1]. Therefore, for video data, how to index it and finally retrieve it quickly and accurately has become an urgent demand [2]. At first, the way of human communication was sound and language, and then words and graphics appeared [3]. In modern civilized society, the emergence of digital products such as digital cameras and digital video cameras has further made images and videos a popular way of information exchange [4]. Video has developed into the main carrier of information dissemination, enriching people's lives and bringing opportunities for the vigorous development of artificial intelligence and big data industry [5]. Among them, computer vision plays a vital role. Motion recognition is a very challenging subject in the current research field of computer vision. Its purpose is to analyze video data using image processing [6–8] and classification recognition technology [9,10] to recognize human motion [11]. Effective fragment retrieval of dance video can help dance teachers arrange dance and assist Dance Teaching [12]. The breakthrough of dance video retrieval technology will effectively promote the inheritance and development of dance.

Every day, a large amount of video data is generated, and digital video is becoming more widely used in all aspects. With the large increase in video data, video database management systems have received a lot of attention and have a lot of potential [13]. Due to the large amount of video data, the current standard practice is to first detect and segment the video and then select several representative still image frames, referred to as key frames, from the lens to represent the visual content of the entire lens [14]. On the basis of video segmentation into shots, key frame extraction analyzes the color, texture, and other characteristics of image frames in the lens and finds the image frame that best represents the lens content based on the relationship between frames [15]. There are several common key frame extraction methods available today, but most of them are only effective for specific videos and cannot be applied to other videos, and the extracted key frames do not always represent the video's main content [16]. Using the key frame as the index, extract the key frame set from the video sequence, summarize the original video content from high-level semantic information to low-level visual features, and retrieve the original video content. As a result, the number and quality of extracted key frames have a direct impact on the final search results' efficiency and accuracy [17]. Based on this, this paper proposes a multifeature fusion-based video key frame extraction method and applies it to dance action recognition.

Image retrieval is an early well-known video retrieval technology. It distinguishes the video by manually labeling some text descriptions or numbers. When retrieving the video, it uses the labeled label to search [18]. The content-based video retrieval method retrieves massive video data in the database according to the relationship between video content and context, in order to provide a visual feature algorithm that can automatically understand and recognize video in an unsupervised state [19]. Content-based video retrieval extracts the lowest level features to the high-level semantic features, analyzes and processes the video, automatically establishes an index of video data, and retrieves and browses according to the index [20]. The research results of motion recognition technology based on dance video not only are conducive to the analysis of dance video by dance professionals, but also can be used for teaching, protection, and excavation of artistic and cultural heritage. In addition, the research of motion recognition method based on dance video will also play a positive role in the research of human motion recognition in a large number of real and complex environments, enriching the application fields of motion recognition technology [21]. If the motion recognition technology is applied to the analysis of these music and dance videos, so as to obtain the organically related music and dance motion fragments, it can not only reduce the work intensity of dance professionals and facilitate the retrieval of music and dance video data, but also make the automatic dance arrangement system more efficient.

Firstly, this paper shows the feature extraction process and model in the key frame extraction method of music and dance video and then applies the feature fusion and recognition method to the key frame extraction of music and dance video. The simulation results show that the method proposed in this paper has high performance and accuracy.

2. Related Work

Literature [22] extracts the features of edge force field by Boosting classifier and designs a human posture estimation algorithm based on component detection. Literature [23] proposed an appearance model combining histogram and color features to estimate the pose of dance movements. However, due to the complexity of human posture changes, it is difficult for traditional methods to achieve effective posture estimation. Therefore, the method based on deep learning [9,24,25] is gradually used for human posture estimation. Literature [26] designed an hourglass-shaped neural network structure to extract multiscale features and identify dance movements. Literature [27] proposed a method to obtain human skeleton map by partial affinity domain. In addition, many dance movement recognition algorithms based on deep learning have been proposed one after another. Literature [28] takes out a fixed number of image frames at the first frame, the first frame, the second frame, or the equally spaced positions as key frames. Literature [29] selects multiple key frames according to the significant changes between frames. Firstly, the first frame of the shot is taken as the key frame, and then the difference between the previous key frame and the remaining frames is calculated. If the difference is greater than a certain threshold, another key frame is selected. Literature [30] proposed a method of extracting key frames based on shot activity. Firstly, the histograms of internal frames and reference frames were calculated, and then the activity marks were calculated. According to the curve of activity, the frame with local minimum is regarded as the key frame.

These methods often do not consider the change and complexity of the visual content in the lens. Most of the more complicated methods measure the similarity between any two frames in the shot by means of some underlying features such as color, texture, and motion information and divide all frames in the shot into different classes by combining threshold or clustering and then select representative frames from each class as key frames. Therefore, this paper proposes a method of dance motion recognition and video key frame extraction based on multifeature fusion, which is used to learn complex and changeable dance motion recognition. Through the steps of preprocessing, classifying, and indexing video data, a practical, convenient, and economical video retrieval system is developed, and the mechanism of video information retrieval and browsing scheme is improved.

3. Key Frame Extraction Method of Music and Dance Video

The relationship between video data units in terms of operation is unclear. The relationship between video segments is complex and difficult to define precisely, which introduces a slew of new issues into the setup and operation of a video database. It is difficult to process unstructured video data directly because it is difficult to measure the similarity between two unstructured data [31]. The successful application of motion recognition technology in other fields provides us with a sufficient theoretical foundation to apply it to dance video motion recognition. Currently, there are a large number of music and dance video materials, and professionals must spend a significant amount of time listening to and looking at these dance video materials, which is clearly inefficient. A specific action category is thought to have generated the image sequence in the video. As a result, the single-layer motion recognition method is primarily concerned with how to represent and match videos [32]. One or more frames of images that reflect the main information content in a group of shots and can express the shot content succinctly are known as key frames. Because each shot is taken in the same scene, each frame of images in the same shot contains a lot of the same information. Feature extraction is usually the first step in motion recognition research.

The feature extraction process mainly consists of three parts: the first part is to extract directional gradient histogram features by using the method of accumulating edge features; the second part mainly extracts the directional histogram features of optical flow from the dance data set; the third part extracts the corresponding audio stream files from the dance action videos and then extracts the audio signature features from the audio stream files. The specific feature extraction process is shown in Figure 1.

To achieve the data compression effect, only the key frames of the shot can be stored due to storage capacity. Second, key frames are used to represent shots, similar to keywords in text retrieval, so video shots can be processed by image retrieval technology. Key frame extraction has been made difficult by the variability of dance movements and the presence of too many redundant movements. This paper will calculate the optical flow of the image sequence of the dance action video after framing in order to extract a set of key frames with less redundancy and can summarize the video content. For smaller objects, this method can match movements with large displacement and estimate optical flow. At the moment, there is not much of a difference in the visual characteristics and content of the image frame.

When a video stream is segmented into a series of semantically independent shots, although the amount of data that needs to be analyzed and processed is segmented, the amount of image data in the shots is still huge. To reduce the amount of data in video index, it is more important to facilitate users to retrieve video information and improve retrieval efficiency. It is necessary to extract one or more key frames from a shot according to the complexity of the shot content [33]. Since the shot is composed of frame images that are continuous in time and highly relevant in content, the most irrelevant frames can be selected as the key frames of the shot to contain the most information. The specific algorithm is to let $f_i\,(i = 1, 2, \ldots, N)$ be the feature vector of the i-th frame of a shot with N frames of images and define the correlation coefficient between feature vectors f_i and f_j as

$$\rho_{ij} = \frac{C_{ij}}{\sigma_i \sigma_j}. \tag{1}$$

Here, $C_{ij} = (f_i - m)(f_j - m)$, $\sigma_i^2 = C_{ii}$, and m is the mean vector. Select the k frame $r_1, r_2, \ldots, r_k \in \{1, 2, \ldots, N\}$ with the smallest correlation as the key frame ($k << N$):

$$R\left(f_{r_1}, f_{r_2}, \Lambda, f_{r_k}\right) = \left\{\sum_{i=1}^{r_{k-1}} \sum_{j=1}^{r_k} \left(\rho_{r_i, r_k}\right)^2\right\}^{\frac{1}{2}}. \tag{2}$$

The main problem of the above method is that the amount of calculation is too large, because it is necessary to calculate the correlation for any two frames. The method is simplified, and 1 to 3 frames of images are automatically extracted as key frames according to the different characteristics of the lens.

Let f denote a frame of image and $S = \{f_m, m = 1, 2, \ldots, N\}$ denote a shot with N frames. Take image frames f_1, $f_{N/2}$, and f_N as candidate key frames. Define the distance between two images f_i and f_j as

$$D\left(f_i, f_j\right) = \sum_{x,y} \left| f_i(x, y) - f_j(x, y) \right|. \tag{3}$$

When extracting key frames, first calculate the distance between two candidate key frames, namely, $D(f_1, f_{N/2}), D(f_1, f_N), D(f_{N/2}, f_N)$. Compare them with a predetermined threshold T. If they are both smaller than T, it means that they are relatively close. At this time, take $f_{N/2}$ as the key frame. If they are all larger than t, it means that there is a big gap between them. At this time, all three frames are regarded as key frames. In other cases, take the two images with the largest distance as key frames.

Key frames are digital images that contain the most intuitive information summary for users of video retrieval systems. The summary should as much as possible express the main content of the shot, so that the user understands the content to be expressed in the video from the start. The envelope and music energy features of music will be extracted in this paper, and the music feature and entropy sequence will be fused to produce a music-related entropy sequence. Figure 2 depicts the main flow of video key frame extraction.

Use the optical flow calculation method to obtain the movement characteristics of dance videos:

$$\begin{aligned}
E(w) &= E_{\text{color}}(w) + \gamma E_{\text{grad}}(w) + \alpha E_{\text{smooth}}(w) \\
&\quad + \beta E_{\text{match}}(w, w_l) + E_{\text{desc}}(w_1), \\
E_{\text{color}}(w) &= \int_{\Omega} \psi\left(\left|\nabla I_2(x + w(x)) - \nabla I_1(x)\right|^2\right) \mathrm{d}x, \\
E_{\text{grad}}(w) &= \int_{\Omega} \psi\left(\left|\nabla I_2(x + w(x)) - \nabla I_1(x)\right|^2\right) \mathrm{d}x, \\
E_{\text{smooth}}(w) &= \int_{\Omega} \psi\left(|\nabla \mu(x)|^2 + \left|\nabla \nu(x)^2\right|\right) \mathrm{d}x, \\
E_{\text{match}}(w) &= \int \delta(x) \rho(x) \psi\left(\left|w(x) - w_1(x)\right|^2\right) \mathrm{d}x, \\
E_{\text{desc}}(w_1) &= \int \delta(x) \left|f_2(x + w_1(x)) - f_1(x)\right|^2 \mathrm{d}x.
\end{aligned} \tag{4}$$

Here, α, $ß$, and γ are adjustable weight parameters, and $E_{\text{color}}(w)$ is the assumption of brightness invariance, which is applicable to both color images and grayscale images. The influence of light is inevitable. Therefore, in order to reduce the influence of light, it is necessary to add gradient constraint $E_{\text{grad}}(w)$ on this basis and then smooth it through $E_{\text{smooth}}(w)$. The last two items are to construct descriptor matching and find its minimum value through variable models and optimizations.

Calculate the entropy value of the current optical flow diagram in chronological order:

$$S = -\sum_{k}^{m} p_k \log_2 p_k. \tag{5}$$

Here, p_k represents the proportion of pixels with a gray value of k in the image, m represents the gray level, and S is

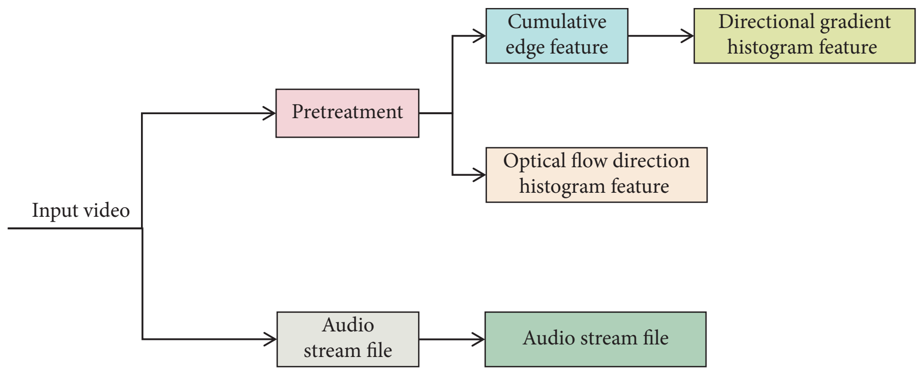

Figure 1: Feature extraction process.

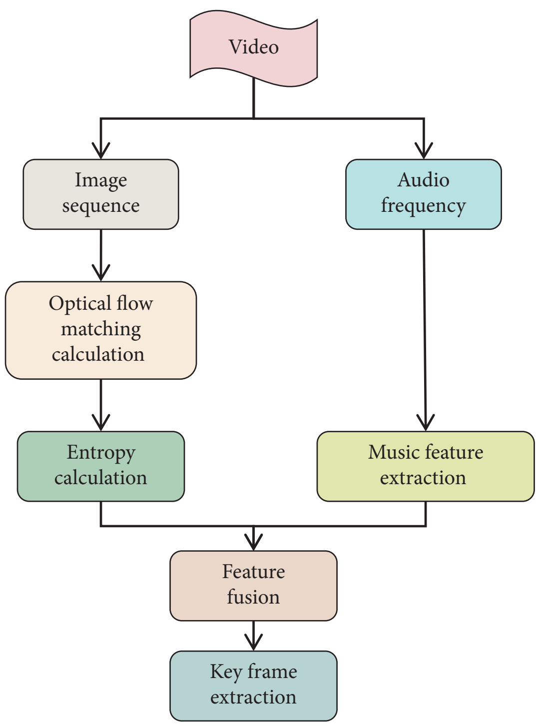

Figure 2: Dance key frame extraction process.

the entropy value. The greater the amount of information contained in the image, the greater the entropy value.

In the process of correspondence between audio and dance movements, the length of dance video, the frame number of images, and the frame rate of video are known. Then, the standard deviation is used to carry out interval operation to obtain the corresponding audio value per second, and the audio value and entropy value sequence are subjected to feature fusion.

4. Feature Fusion and Recognition

Although multiple key frames can more effectively describe the information expressed by shots than a single one, the likelihood of repeated or redundant video frames increases dramatically as the number of key frames increases. As a result, the focus and difficulty of key frame extraction technology is how to select the appropriate key frames that can not only represent the shot information, but also improve retrieval efficiency and reduce the amount of video index data. Optical flow directional histogram features are used to describe the motion information of dance movements, while directional histogram features are used to describe the local appearance and shape features of dance movements. Furthermore, the influence of music on dance should be considered when studying dance action recognition. All dancers perform with music playing in the background, and the type of music is related to the type of dance. Audio features, on the other hand, contain a lot of information, making them an important auxiliary feature that can help reduce the impact of self-occlusion on dance movements. Figure 3 depicts the multicore learning feature fusion process.

Suppose there are p dance moves $x_1, x_2, \ldots, x_p$ and category $y_1, y_2, \ldots, y_p$ in the dance data set. At the same time, the G kernel functions corresponding to the Histogram of Oriented Gradient (HOG) feature are defined as $k_g(x_i, x_j)$, the F kernel functions corresponding to the Histograms of Oriented Optical Flow (HOF) feature are defined as $k_f(x_i, x_j)$, $f = 1, 2, \ldots, F$, and the M kernel functions corresponding to the audio signature feature are defined as $k_m(x_i, x_j)$, $m = 1, 2, \ldots, M$. The linear combination of the kernel function combining the above three characteristics can be expressed by the following formula:

$$S = -\sum_{k}^{m} p_k \log_2 p_k. \tag{6}$$

Formula (6) satisfies $\beta_g \geq 0 \forall g, \beta_f \geq 0 \forall f, \beta_m \geq 0 \forall m, \sum_{g=1}^{G} \beta_g + \sum_{f=1}^{F} \beta_f + \sum_{m=1}^{M} \beta_m = 1$. β_g, β_f, and β_m are the weights of the corresponding kernel functions.

In order to express the content of the shot as completely as possible, conservative principles will be adopted when extracting key frames. When analyzing a video, if all the image frames at every moment are used, too many redundant image frames will be used. Therefore, people think of extracting key frames from thousands of image frames.

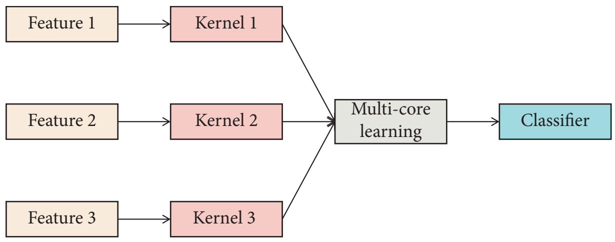

Figure 3: Multicore learning feature fusion process.

The use of key frames greatly reduces the amount of data in video index and also provides an organizational framework for searching and browsing videos.

5. Result Analysis and Discussion

In the past, motion recognition methods that relied on a single feature could only describe one aspect of human motion in video, but they could not effectively describe human motion. As a result, motion recognition research has turned to the multifeature fusion method. Combining different features can more comprehensively describe human motion in video, resulting in a better recognition effect. The dance video retrieval database is made up of key frames and video clips that have been summarized. Kernel functions play different roles in classification depending on the problem. The goal of multicore learning is to improve the classification effect by giving different kernel functions reasonable weights and combining multiple kernel functions to describe features more thoroughly. The data set is used to extract directional gradient histogram features, optical flow directional histogram features, and audio features for the dance motion recognition method described in this paper. Figure 4 shows the entire appearance feature of the audio signal as a result of envelope feature extraction from dance video accompaniment music.

The dance video is composed of a series of dance movements, and the coherent dance movements reflect more or less amount of movement. The motion information in the dance video is expressed by optical flow, and then the information in each optical flowchart is counted by entropy. Entropy sequence and music features are fused to obtain a music-related entropy sequence. Then, the key frames are selected by the threshold, and when the threshold is set, it will be compared with the key frame set selected by several users to select the best threshold suitable for the video. The matching of feature points starts from the first frame of the query segment, and the frames in the query segment are sequentially compared with the frames in the key frame set. Then select a key frame that is most similar to the frame of the query fragment. Video clips can be described by one or several key frames. No matter what level of similarity matching, if there are some dissimilar parts between the query segment and some subsegments, shots, or frames in the video segment, such segments are discontinuous. When this situation produces more dissimilarities, it indicates that the similarity between the two fragments is lower. Adaptive key frame extraction algorithm based on unsupervised

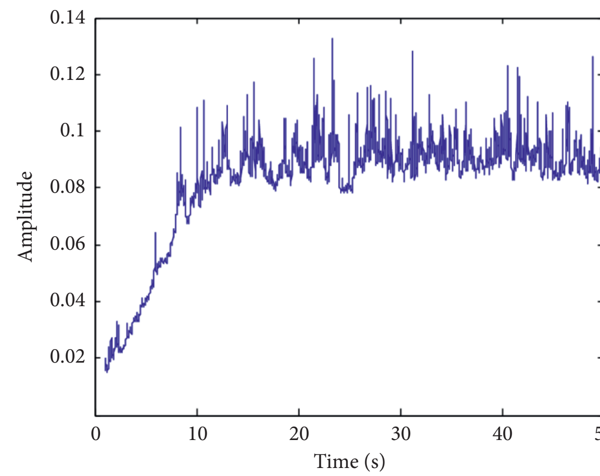

Figure 4: Envelope extracted from accompaniment music of dance video.

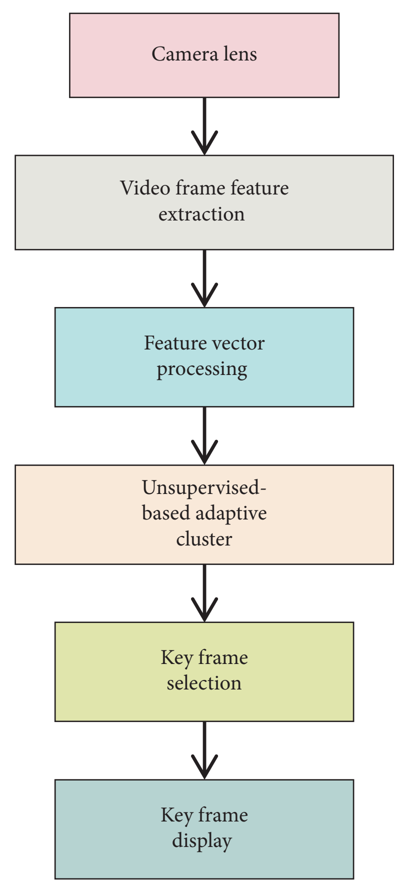

Figure 5: Algorithm implementation process.

clustering is used to extract key frames for different types of shots, as shown in Figure 5.

Different combinations of repetitive dance movements are frequently used to create dance videos. Similar dance movements will appear in various types of dance videos during this process, and eventually, everyone will follow this choreography pattern. We can discover that dance movements in dance videos are closely related to music through segment retrieval of dance videos. All of the video frames in the shot are treated as independent subclusters at the start of merging, and pairwise similarity is calculated. The two most similar subcategories, that is, the least similar, are chosen and merged into a new subcategory. Merge according to this cycle, then wait until an automatic merging stop rule is satisfied before getting the final clustering result. We should extract the features of the image frames in the video first, then process the features of the image frames with the algorithm, and finally extract the key frames, regardless of which algorithm we use to extract the key frames. Figure 6 shows a simulation comparison of image key frame extraction reliability optimization.

The motion features of video describing human motion information are often essential features in the research based on motion recognition, and the optical flow method is usually used to extract the features in some related motion recognition research at present. Texture is a value calculated from the texture image, which quantifies the features of gray scale changes inside the texture. Generally, texture features are related to the position, direction, size, and shape of the texture but have nothing to do with the average gray level. The purpose of feature extraction is to transform the spatial structure difference of random texture or geometric texture into the difference of feature gray value and use some mathematical models to describe the texture information of the image, including the smoothness, sparseness, and regularity of the image area. The linear regression curve is calculated according to the stepwise multiple linear regression equation, as shown in Figure 7.

FS denotes a method of searching that uses F7 layer features, HS denotes a method of searching that uses coarse searching, and HFS denotes a method of searching that goes from coarse to fine. Figure 8 depicts the effect of various algorithmic features on the retrieved video key frames. Clearly, HFS is the first to demonstrate good retrieval accuracy, implying that the video GIS data retrieval algorithm can obtain richer detail features of video GIS key frames. When retrieving more than 13 images, however, the retrieval effect of HS outperforms that of FS. This demonstrates that the binary code generated by this algorithm has a high level of discrimination and contains a lot of semantic information.

For a video containing multiple shots, the key frame fidelity is the average of the fidelity of each shot and the group of key frames. The purpose of extracting key frames is to use as few video frames as possible to represent as much video content as possible, so the higher the compression rate, the more effective this key frame extraction method. Make the estimate continuous at the threshold. The shrinking trend of the adaptive nonlinear curve is shown in Figure 9.

The purpose of key frame extraction is to replace the whole video with few image frames, so as to facilitate the viewer to quickly browse the content of the whole video and reduce the amount of video data, thus making the video processing more convenient and faster. Therefore, the effectiveness of the key frame extraction method should be considered first, and then its computational complexity and

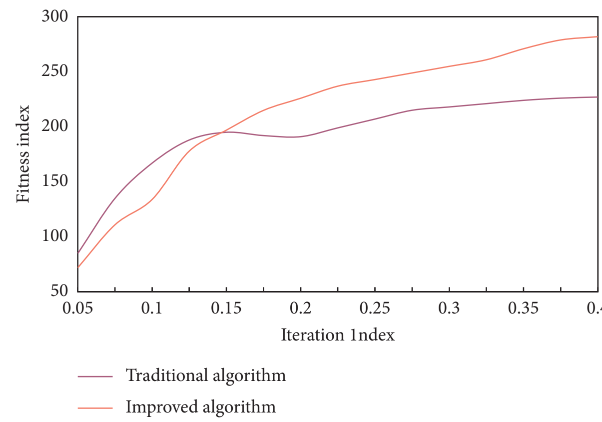

Figure 6: Image key frame extraction optimization simulation comparison.

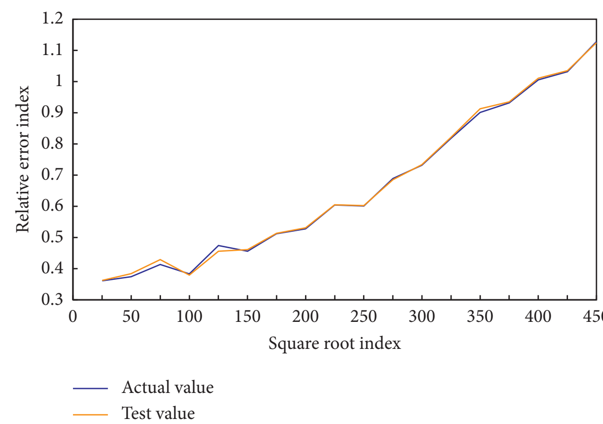

Figure 7: The relationship between the actual value and the calculated value of stepwise linear regression.

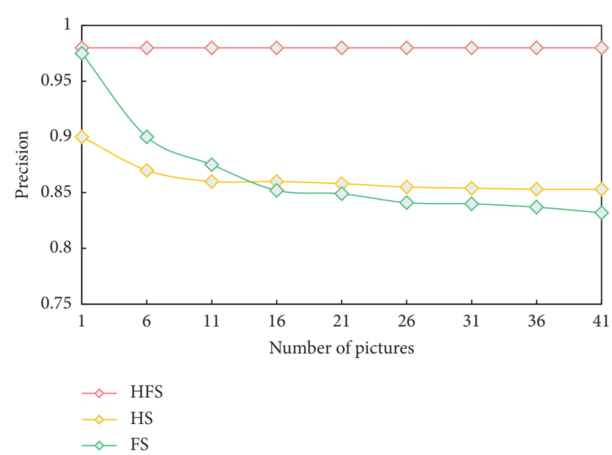

Figure 8: Retrieval effect of different network characteristics.

efficiency should be considered on the premise of effectiveness. The experimental results of the comparison between this method and the benchmark method in four dance combinations are shown in Figure 10. In the recognition of four dance combinations, the recognition rate of this method is higher than that of the benchmark method. The

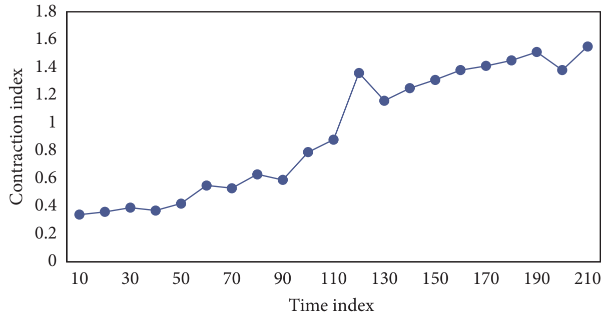

Figure 9: Adaptive nonlinear curve shrinking trend.

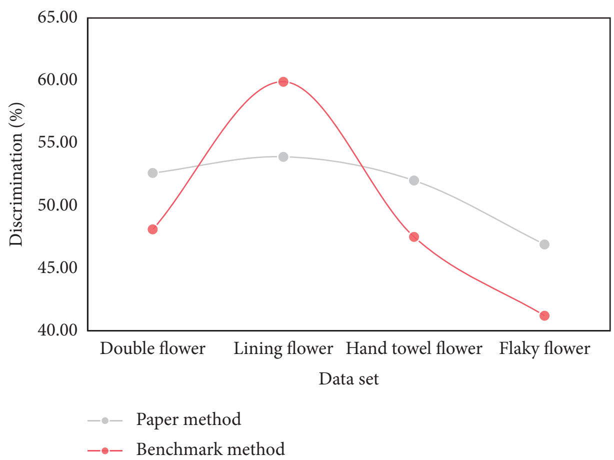

Figure 10: Comparison of the recognition rate.

recognition rate of this method is 53.9%, which is lower than 59.9% of the benchmark method. In other combinations, the performance of this method is better than that of the benchmark method, especially when the similarity of dance movements in the combination of towel and flower is too high.

When the dance movements are too complicated and there are similar movements and self-occlusion, the benchmark method based on trajectory feature fusion can not accurately represent the dance movements. The fusion algorithm in this paper can avoid the above influence to a certain extent, thus improving the recognition rate of dance, and it also verifies the effectiveness of the algorithm. The experimental results show that not only is the algorithm in this paper relatively simple in calculation, but also the extracted key frames can effectively summarize the main content of the video, realize video compression and storage, and lay a good foundation for video retrieval and video summarization. From the perspective of the future development trend of video data mining, the requirement for video data processing technology is getting higher and higher because of the contradiction between the large amount of calculation of video processing and the short retrieval time expected by users. Moreover, with the continuous development of information technology, it is more and more difficult to process video data with various features.

6. Conclusions

The dance contains far too many repetitive dance moves, which will slow down retrieval speed when searching. As a result, this paper proposes a method for extracting key frames from music and dance videos. First, the framed video's optical flow is calculated, and the video's motion features are extracted. Music and dance are inextricably linked. The corresponding audio in the video is then extracted, along with its features. This paper presents an unsupervised automatic video key frame extraction method. This method uses simple cyclic merging to cluster video frames and creates an automatic merging stop rule to stop merging when the clustering results are optimized. There is no need to set parameters or prior knowledge in advance for this video frame clustering process. The results of the experiments on multiple test videos show that the extracted key frames can effectively represent the video's main visual content.

Although some progress has been made in dance motion recognition research in this paper, the recognition rate of dance video motion recognition research is currently low, owing to the complexity of the dance motion and the inadequacy of existing methods for dance motion recognition. Because of the complexity of dance movements, the dance data set we created at this point only considers solo dance situations, ignoring changing stage scenes and other factors. More research will be done in the future on how to apply music theory-related content to create a more accurate mapping between music and dance movements, in order to improve dance movement recognition accuracy. In the field of computer vision, high-dynamic dance motion recognition is a difficult problem to solve. Its goal is to recognize human motion by analyzing video data using image processing and classification recognition technology. Video multifeature fusion has sparked a surge in research in a variety of fields. Several pixel points that can be distinguished and displayed in several adjacent images that can reflect their characteristics are referred to as multifeature fusion. It is responsible for a significant portion of the similarity results between the two video segments. Motion recognition relies heavily on video multifeature fusion, which has a direct impact on the robustness and accuracy of recognition results. The directional gradient histogram features, optical flow direction histogram features, and audio features extracted from dance video are used to characterize dance movements after all of the characteristics of dance movements have been considered. This paper focuses on the high-dynamic dance action recognition method based on video multifeature fusion, which aims to combine high-dynamic dance action recognition and video multifeature fusion.

1. Introduction

Video information has become widely used in many fields as a result of the development of computer vision and video image processing technology [1]. Computer vision is widely used in medical, transportation, and other fields as an auxiliary means of human vision and an important part of automation systems [2]. Users hope to retrieve and query specific action clips in high-dynamic dance video as easily and quickly as they retrieve and query text information and then obtain specific action clips of interest for playback and browsing [3]. Human posture estimation technology's application field of dance movement recognition is important. Dance movement recognition technology can assist dancers in identifying and correcting incorrect postures, as well as contributing to intelligent dance auxiliary training. Action recognition can help with game design in addition to dance learning and teaching [4]. Firstly, the actions in the dance image video are recognized, and then the action model is further established according to the recognition results to generate the character actions in the game, so as to greatly enhance the user experience effect. The research on human motion recognition in China started relatively late, but it developed rapidly. At present, many units are engaged in intelligent video analysis and research and have made some breakthroughs in related fields. Well known is the research on the key technology of intelligent surveillance video analysis carried out by the Institute of Automation, Chinese Academy of Sciences, which automatically analyzes the video captured from the camera, locates, tracks, and identifies the moving targets in it, realizes the management of daily surveillance, and makes timely response to abnormal situations. In the field of human motion recognition, some significant research achievements have been made after years of development. The research has also broadened from simple action analysis and recognition in a simple background to multiperson complex actions in a complex background. In the current research field of computer vision, motion recognition is a very difficult subject [5, 6]. Its goal is to recognize human motion [7] by analyzing video data [8] using image processing and classification recognition technology [9, 10].

In the research of motion recognition, video multifeature fusion is usually the first step [11]. After fully considering the characteristics of dance movements, the directional gradient histogram features, optical flow direction histogram features, and audio features extracted from dance video are used to characterize dance movements. Key frames are defined as some representative image frames with less redundancy in video. The directional gradient histogram feature is used to describe the local appearance and shape features of dance movements, and the optical flow direction histogram feature is used to describe the motion information of dance movements. In addition, the research on dance action recognition should also consider the impact of music on dance. Dance performers perform dance with the accompaniment of music, and the style of music is related to the type of dance. The key frame extraction has been made difficult by the variability of dance movements and the presence of too many redundant movements. This paper will calculate the optical flow of the image sequence of dance action video after framing in order to extract a set of key frames with less redundancy and can summarize the video content. This method can match large-distance actions and estimate optical flow for small objects. The accuracy of action recognition results and the robustness of action recognition methods are both influenced by the extracted features. Video multifeature fusion has sparked a surge in research in a variety of fields. Several pixel points that can be distinguished and displayed in several adjacent images that can reflect their characteristics are referred to as multifeature fusion [12, 13]. The directional gradient histogram features, optical flow direction histogram features, and audio features extracted from dance video are used to characterize dance movements after all of the characteristics of dance movements have been considered.

This fusion method produces new feature vectors with excessively high dimensions and redundant information. Although this method can improve classification effect to a degree, increasing the feature vector dimension increases computational cost, and the new features formed by fusion contain many features, resulting in the same weight of each feature [14, 15]. Such features with a poor classification effect are given the same weight as those with a good classification effect, affecting classification accuracy to some extent [16]. Video multifeature fusion plays a very important role in motion recognition, which directly affects the robustness and accuracy of recognition results [17, 18]. Video multifeature fusion is based on the trajectory formed by the connection of multiple feature points, and then extracting the trajectory based features is a good choice. It not only combines the global spatiotemporal volume features with local feature points, but also includes the temporal and partial spatial relationship between feature points, so that the extracted features can cover more abundant information of moving objects. The video multifeature fusion method can assign weights to each feature according to their contribution to classification through the decision-making mechanism, so it can let a variety of features give full play to their respective advantages, so as to improve the classification accuracy. Video multifeature fusion is a widely used fusion method in multifeature fusion.

2. Related Work

According to [19], some authoritative journals and important academic conferences in relevant fields around the world, such as IEEE Transactions on Pattern Analysis and Machine Intelligence (TPAMI) and International Journal of Computer Vision (IJCV), include motion analysis and recognition in video as one of the main research contents. A major visual monitoring project was established by the US Defense Advanced Research Projects Agency, which included many well-known universities. Its main research focus is on the intelligent analysis and comprehension of surveillance videos in a variety of settings, including battlefields and everyday settings. This study can achieve human motion region segmentation, multiperson tracking, and basic human motion analysis and recognition. Literature [20] shows that, by tracking the trajectory formed by several points on the human body, the recognition of simple actions such as walking and running is realized, which opens the door of action recognition research. Literature [21] points out that, in the process of learning and understanding content-based video retrieval, action video retrieval has become the mainstream and action video generally involves running, jumping, swimming, weightlifting, etc. Literature [22] shows that there is too little research on dance video because dance is a continuous and changeable limb movement, and different types of dance will have limb movements with different intensity changes. Literature [23] mentions that, through the big data analysis method, the main idea of content-based video retrieval technology is, given an image, similarity matching carried out according to the content in the image to find videos with the same or similar content. Literature [24] pointed out that image retrieval is a well-known video retrieval technology earlier. It distinguishes videos by manually marking some text descriptions or numbers, and when searching videos, it uses marked labels to search. Literature [25] reveals that, according to research, a large number of domestic and international scientific research institutions and related scholars are dedicated to the study of motion recognition based on video and have made significant contributions to the field's development. Domestic motion recognition research began relatively late, according to [26], using the big data analysis method. Many domestic universities and scientific research institutions have conducted motion recognition research as the application of motion recognition becomes more widespread. According to [27], features with a poor classification effect have the same weight as those with a good classification effect, which will affect classification accuracy to some extent.

3. Theory and Technology Related to High-Dynamic Dance Movement Recognition

3.1. Dance Movement Recognition Theory. Dance motion recognition has advanced to the level of motion recognition, as opposed to low-level motion recognition such as gesture recognition and simple body motion recognition. The term "flexible force sensor" refers to the material in which it is made. The force between irregular contact surfaces can be measured with a flexible force sensor. The flexible force sensor is an array of pressure sensitive points that can be seen from the outside. The first step in high-dynamic dance movement recognition was to use computers to perceive people's movements, and then it progressed to recognizing simple movements like walking, running, and jumping. High-dynamic dance movement recognition has evolved into video movement recognition, which recognizes human movements in videos as a series of simple movements. There will be multiple types of actions in each video frame sequence, and each type of action will contain multiple simple actions. Every simple action is made up of a variety of human body positions. The connection of transition actions between actions allows all types of actions to be coherent and smooth. The single step gait cycle's total pressure curve looks like a saddle curve during normal walking. The curve has three distinct points: xmax1 represents total pressure when the heel touches the ground, xmin represents minimum total plantar pressure when the entire foot touches the ground, and xmax2 represents total plantar pressure when the front foot steps off the ground. Figure 1 depicts this.

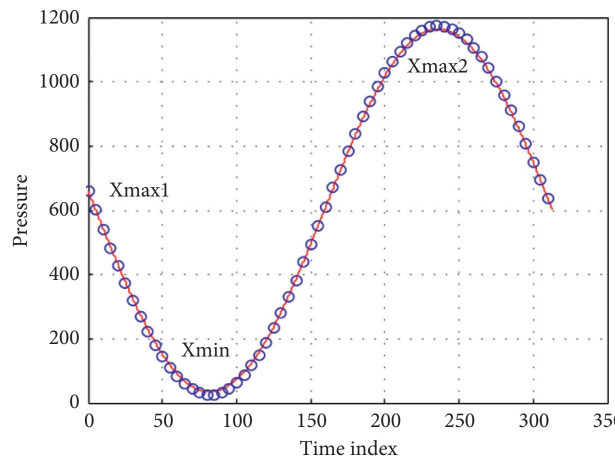

Figure 1: Characteristic points of total plantar pressure curve.

Therefore, it is difficult to obtain high recognition accuracy when a simple limb localization algorithm is used in dance movement recognition. It not only combines the global spatiotemporal volume features with local feature points, but also includes the temporal and partial spatial relationship between feature points, so that the extracted features can cover more abundant information of moving objects. In the stage of choreography, different forms of choreography should be carried out according to the characteristics of music. Similarly, in the soundtrack, it is necessary to match appropriate accompaniment music according to the rhythm and style of dance movements. The speed of dance movements is related to music. This paper will extract the accompaniment music from the video, read the accompaniment music in wav format, and then extract the envelope feature and energy feature of the music to prepare for the subsequent feature fusion, which is very helpful to the event detection of music. Dance movements usually have complex and large-scale changes, and recognizing dance movements requires a deep learning model [28, 29] to grasp the needs of each scale information when extracting features. Figure 2 is the result of envelope feature extraction for the accompaniment music of the dance video Theodora _ Africa _ wide. It shows the whole appearance characteristics of the audio signal.

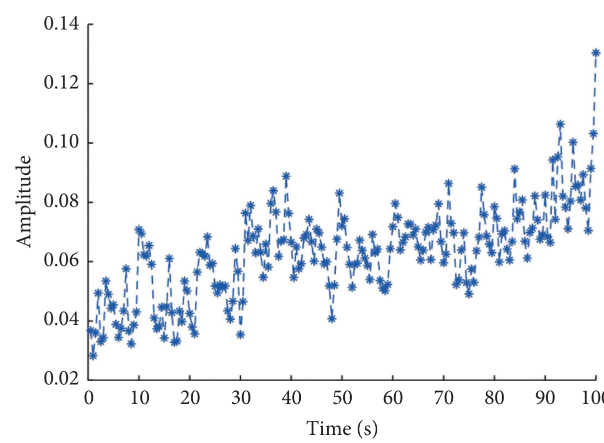

Figure 2: Dance video Theodora_ Afraid_ Envelope extracted from accompaniment music wide.

The plantar pressure data acquisition platform of the flexible force sensor designed in this paper dynamically acquires the plantar pressure information of the tester by using the characteristics of the flexible force sensor in real time. However, the high-dynamic dance moves are continuous and smooth, and it is difficult to accurately find the segmentation points, which is the main reason for the unsatisfactory segmentation of video motion sequences. Furthermore, the shortest data cannot contain the most human motion information simply by extracting key frames for motion sequence segmentation. A complete dance performance is made up of several groups of movements, each of which is made up of several simple movements such as flowers and pressing steps, and each simple movement is made up of several basic posture sequences such as raising hands and kicking legs.

3.2. Dance Movement Recognition Technology. The initial stage of high-dynamic dance motion recognition is to extract some features of images or video sequences and realize motion recognition through feature matching. Later, researchers found that the combination of low-level features and high-dynamic dance pose features can improve the accuracy of motion recognition. There are roughly two ways to obtain high-dynamic dance posture information. One is to accurately obtain the information of each joint coordinate, human skeleton, motion trajectory, and so on through motion capture equipment. Another method is to obtain the approximate joint positions and skeletons of the human body in images or videos by the method of human posture estimation. Dance movements usually have complex and large-scale changes, and recognizing dance movements requires a deep learning model to grasp the needs of each scale information when extracting features. According to the actual situation, the change trend of human posture joint position is basically the same, and there are obvious changes at the beginning and end of the action. At frame 600, i.e., after that, the curve changes disorderly, and the change cannot be accurately judged through the curve in the figure. It is necessary to obtain the concise and clear change trend of the whole pose sequence through further calculation. The position change trend of 30 joint points in human posture sequence is shown in Figure 3.

Although the change trend of human posture can be roughly seen in the figure, it is impossible to calculate and obtain the segmentation position, so it is necessary to obtain a curve that is visible and can calculate the segmentation position through further calculation. In this paper, the posture trend is expressed by calculating the average value of 30 joint positions.

$$\text{mean} = \frac{\left(\sum_{j=1}^{19} f_i\right)}{19}. \tag{1}$$

It has been discovered that using the mean value does not result in a significant change in the positions of the 30 joints in the video sequence frames but does result in a stable change trend for the regions with more chaotic changes. Figure 4 depicts the changing trend of the average position of the actor's 30 joint points over time.

Dancers often have obvious preparation time and stop time when performing dance movements. During this period, the dancers' posture basically does not change, and the distance between consecutive frames changes gently. However, most of the adjacent minima to maxima can only represent a simple movement, but not necessarily a complete dance movement. Because a complex dance movement is mostly composed of several simple movements, there are usually several extrema in a dance movement sequence.

Therefore, after finding each extreme value in the curve of continuous frame change trend, this paper uses cubic spline interpolation function to fit the curve. Firstly, the maximum value of continuous frame change data in video is obtained, and the upper envelope of data sequence is fitted by cubic spline function, and then the lower envelope of data sequence is fitted by cubic spline function. Finally, the mean value between the upper envelope and the lower envelope is calculated as the final fitting result of the current data series. The upper envelope, lower envelope, and final results of curve fitting are shown in Figures 5 and 6, respectively.

We can see the obvious segmentation points between various dance movements in a dance video after we get the fitting results. A simple action sequence can be determined by two adjacent minima, with the minima position indicating the segmentation position of the action sequence frame. Because the fitted curve may still have inaccurate segmentation positions, an action sequence must be determined using the dual control method of the difference between adjacent maxima and minima and the number of frames in the action sequence. According to statistics from

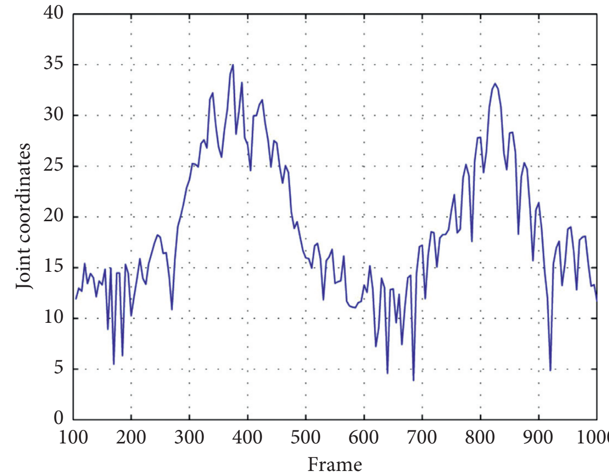

Figure 3: Trend chart of joint changes in continuous pose of actors.

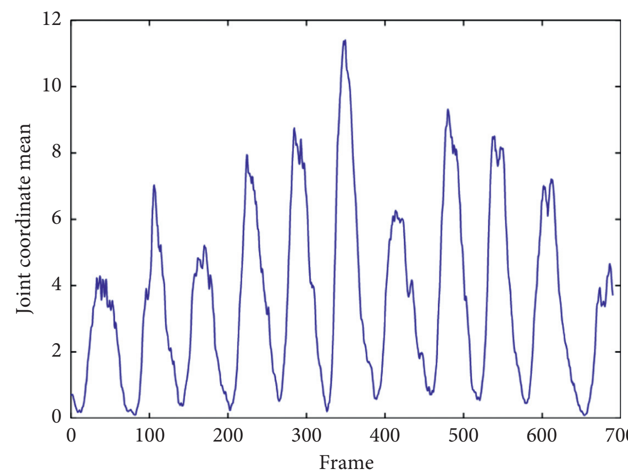

Figure 4: Average change trend of actors' continuous posture joints.

actual recorded dance situations, the dance action is a rhythmic action with a time limit of 10 seconds in the data collection process and a video frame rate of two eight beats per second, making it impossible to complete a dance action in one second at normal speed.

It is difficult to quickly and accurately retrieve specific action segments in high-dynamic dance video, and only the inherent video information contained in high-dynamic dance video data can be used to retrieve specific action segments temporarily. In order to realize the analysis and management of high-dynamic dance videos, it is necessary to study the design method of retrieval system for specific action segments in videos. People's orientation, the arrangement of limbs, and the relationship between adjacent joints all need to be inferred and identified from global context information, and local information can be accurately located. Motion recognition based on high-dynamic dance is also divided into two categories. One is to directly use the main joint information in human motion posture for similarity calculation and determine the action category by

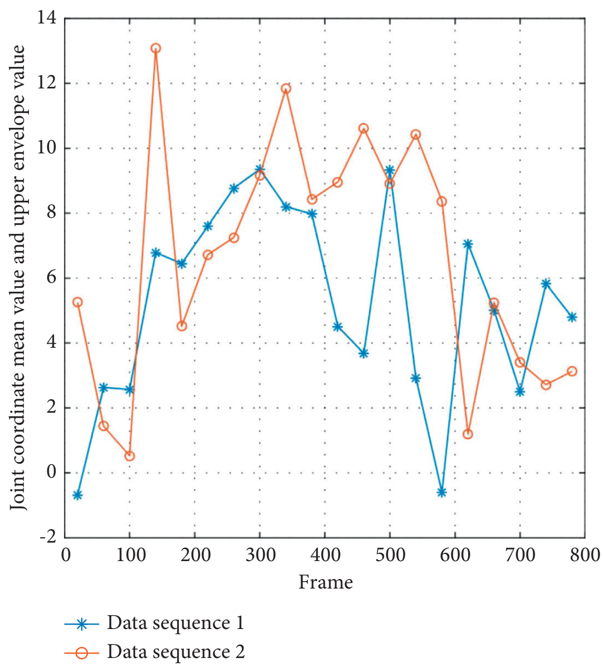

Figure 5: Curve fitting result diagram of envelope.

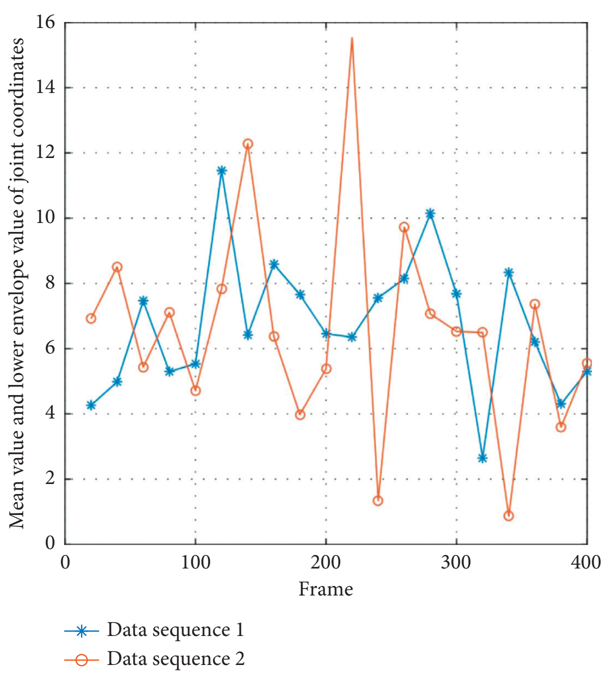

Figure 6: Lower envelope fitting results.

matching with the similarity between known actions, which is mostly used for human motion recognition in images. The other is to segment the human body in the image by using the obtained human posture, obtain the local image with each main joint position as the key, and then extract some features of the local image for recognition.

3.3. Action Recognition Method. At present, motion recognition methods are mainly divided into two categories: single-layer method and hierarchical method. Single-layer based methods usually regard actions as the characteristic category of video and use classifiers to identify actions in video. Image sequences in video are considered to be generated by specific action categories. The hierarchical method mainly identifies high-level actions by identifying simple actions or low-level atomic actions in the video. High-level complex actions can be decomposed into a sequence of subactions, which can continue to be decomposed as high-level actions until they are decomposed into atomic actions. The classification of action recognition methods is shown in Figure 7.

3.3.1. Single-Layer Method. There are two kinds of motion recognition methods based on single layer: spatiotemporal method and sequence model method. The main difference between spatiotemporal method and sequential model method is how to treat the time dimension. Different actions need to fully detect all kinds of actions, and the least crossing is better. When there are multiple types of human actions in the video, manual video editing shall be carried out and then processed according to the video containing single type of actions. Before collecting video data, most researchers choose to plan the type of action to be collected and the timing of various action videos. The sequence model method is usually better than the time and space method because it considers the sequence relationship of actions. In reality, the video cannot match the dataset's style during the research process. In most cases, the video contains a wide range of actions, and the human posture is consistent across all of them, with no discernible posture change interval. The contour feature based on the action energy map is used by the global feature, while the target cell is used by the local feature. Finally, the feature points are classified using the support vector machine's multiclass classification method.

3.3.2. Hierarchical Approach. Hierarchy-based methods usually use single-level or low-level subactions to identify high-level complex actions. A high-level complex action can be decomposed into several subaction sequences, and subactions can be decomposed as high-level actions until they are decomposed into atomic actions. At the same time, if manual video editing is used, it will take a lot of time to face professional dance movements, and nonprofessional researchers cannot guarantee the accuracy of video editing. The hierarchical method is closely related to the single-layer method to a certain extent. For example, the single-layer method can not only be used for low-level or atomic action recognition, but also be extended to the action recognition method of hierarchical model. Hierarchical methods are generally divided into three types: statistics based methods, grammar based methods, and description based methods. In addition, this paper also tested the recognition time within the range of 30 ~ 200 template images and found that the recognition time is directly proportional to the number of template images, ranging from 0.25 s to 1.75 s, as shown in Figure 8. Because the more the template images, the larger

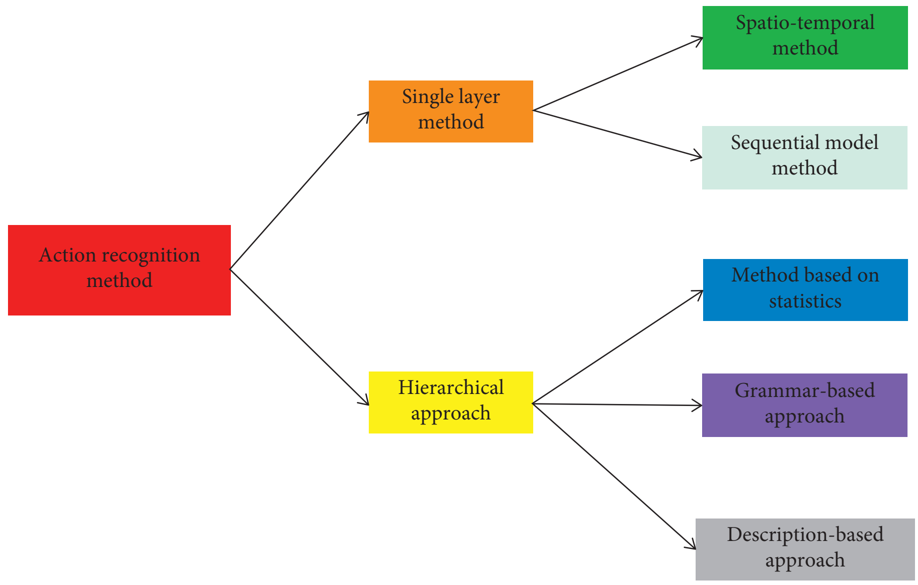

Figure 7: Classification of action recognition methods.

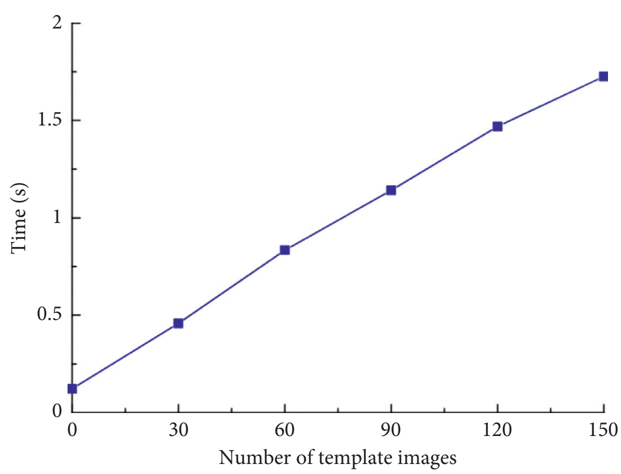

Figure 8: Identification time consumption diagram.

the scale of the template matrix, and the greater the amount of calculation during recognition operation, and the time required for calculating the distance vector between each row of the matrix and the test image is basically the same. Therefore, the recognition time increases linearly with the number of template images.

Build the model. Here, assuming that the value of a pixel at time t is XT, the probability of occurrence of XT can be obtained from

$$P\left(X_t\right) = \sum_{t=1}^{K} \omega_{i,t} \cdot \eta\left(X_t, \mu_{i,t}, \sigma_{i,t}\right), \tag{2}$$

where $\omega_{i,t}$ is the weight of the ith Gaussian distribution at time t, $\eta\left(X_t, \mu_{i,t}, \sigma_{i,t}\right)$ is the corresponding probability density function, $\mu_{i,t}$ is the corresponding mean, and similarly $\sigma_{i,t}$ is the variance. Meanwhile, the specific expression of $\eta\left(X_t, \mu_{i,t}, \sigma_{i,t}\right)$ is shown in

$$\eta\left(X_t, \mu_{i,t}, \sigma_{i,t}\right) = \frac{1}{\sqrt{2\pi\left|\sigma_{i,t}\right|}} e^{-(1/2)\left(X_t - \mu_{i,t}\right)^T \sigma_{i,t}^{-1}\left(X_t - \mu_{i,t}\right)}. \tag{3}$$

Firstly, the pixel values of the first frame of the video are assigned to the mean value of K Gaussian distributions; secondly, a larger value is assigned to their variance, and their weights are assigned the same value.

4. Video Multifeature Fusion and Recognition

4.1. Analysis of Related Problems. In the past methods of motion recognition, using a single feature can only describe one aspect of human motion in video but cannot describe human motion effectively. With the continuous evolution of dance types and forms and the increasing number of dance videos, how to browse dance videos quickly and effectively is the main problem. The movement of music and dance video is complex and changeable, and there are many repetitive movements, which brings trouble to the analysis and recognition of dance movements. The main difference between video multifeature fusion methods is the selected features and fusion strategies. Therefore, video multifeature fusion method has become a research direction of motion recognition. Fusion of different video features can describe human movements in the video more comprehensively, thus achieving better recognition effect. At present, video multifeature fusion can be divided into feature level fusion and decision level fusion.

4.1.1. Feature Layer Fusion. Feature layer fusion refers to the combination of various features to form new features; for example, there are two features $F1$ and $F2$, and a new feature vector $F3 = (f1, f2)$ is formed after feature layer fusion.

4.1.2. Integration of Decision-Making Level. The main idea of decision level fusion is to create corresponding classifiers for each feature, respectively, and then fuse the results of each feature classifier according to the selected decision mechanism to get the final classification result. The above two fusion strategies are facing certain problems. In recent years, scholars need to apply multicore learning to the research of multifeature fusion methods.

4.2. Dance Movement Recognition Method Based on Feature Fusion. The directional gradient histogram features, optical flow directional histogram features, and audio features extracted in this paper describe the characteristics of dance movements from the aspects of the appearance and shape of human dance movements in dance videos, the movement of human dance movements, and the assistance of audio features. Video clip retrieval entails locating a video clip that is similar to the query clip in the video and then determining the video clip's location in various ways. The Balletto dance video database will be used to test the effectiveness of the dance motion recognition algorithm based on video multifeature fusion. The feature fusion method has shown to be effective in the field of image classification, and it has since been applied to motion recognition research. Learning by using multiple kernel functions in training is a simple understanding. Multicore learning can effectively fuse various heterogeneous features by linear combination of kernel functions in the process of learning classifiers, so that different features can complement each other to improve recognition accuracy. Because the features used in our research contain heterogeneous features, multicore learning can effectively fuse various heterogeneous features by linear combination of kernel functions in the process of learning classifiers. The first step in high-dynamic dance motion recognition is to extract some features from images or video sequences and then match them to achieve motion recognition. Figure 9 depicts the multicore learning feature fusion process.

In practical application, according to the content and structure characteristics of the video, comprehensively measure the above points and allocate the weight. Based on this, we can find the video clip with high similarity to the query clip, as shown in Figure 10.

Therefore, it is assumed here that there are p dance movements $x1$, $X2$,..., XP and categories $Y1$, $Y2$,..., YP in the dance dataset. At the same time, the G kernel functions corresponding to the hog feature are defined as kg (Xi, XJ), $g = 1, 2, \ldots, G$, the f kernel functions corresponding to the HOF feature are defined as KF (Xi, XJ), $f = 1, 2, \ldots, F$, and the M kernel functions corresponding to the audio signature feature are km (Xi, XJ), $M = 1, 2, \ldots, M$. In this paper, the linear combination of kernel functions integrating the above three features can be expressed by the following formula:

$$\begin{gathered} k(x_i, x_j) = \sum_{g=1}^{G} \beta_g k_g(x_i, x_j) + \sum_{f=1}^{F} \beta_f k_f(x_i, x_j) + \sum_{m=1}^{M} \beta_m k_m(x_i, x_j), \\ \beta_g \geq 0 \forall g,\ \beta_f \geq 0 \forall f,\ \beta_m \geq \forall m, \quad \sum_{g=1}^{G} \beta_g + \sum_{f=1}^{F} \beta_f + \sum_{m=1}^{M} \beta_m = 1. \end{gathered} \tag{4}$$

β_g, β_f, and β_m are the weights of the corresponding kernel functions, respectively.

Arbitrarily select the two action sequences X and y after segmentation, and the lengths are L1 and L2, respectively. X and y are, respectively, expressed as

$$\begin{aligned} X &= \{x_1, x_2, \ldots, x_m, \ldots, x_{l1}\}, \\ Y &= \{y_1, y_2, \ldots, y_n, \ldots, y_{l2}\}. \end{aligned} \tag{5}$$

The mth frame of x is represented by xm, and nth frame of y is represented by yn. If $l1 = l2$, the interval between two action sequences will be calculated directly. If the two action sequences are not equal in length, the distance will be calculated after they are aligned by dynamic programming method.

In support vector machine based on multicore learning, the task of multicore learning model training stage is to learn to solve the weight β of each kernel function and the parameters α and B of support vector machine classifier. Based on the idea of simple MKL algorithm proposed by Palaiahnakote et al. introduced in the previous section, the objective function of the algorithm in this paper is defined as follows:

$$\begin{gathered} \begin{cases} \dfrac{\min}{\beta_g, \beta_f, \beta_m, a, b} & J = \dfrac{1}{2} \displaystyle\sum_{g=1}^{G} \beta_g \alpha^T K_g \alpha + \dfrac{1}{2} \sum_{f=1}^{F} \beta_f \alpha^T K_f \alpha + \dfrac{1}{2} \sum_{m=1}^{M} \beta_m \alpha^T K_m \alpha + C \sum_{i} \xi_i \\ \text{s.t.} & y_i \left[\displaystyle\sum_{G=1}^{G} \beta_g k_g(x_i) + \sum_{f=1}^{F} \beta_f K_f(x_i) + \sum_{m=1}^{M} \beta_m K_m(x_i) \right] \alpha + y_i b \geq 1 - \xi_i \forall i, \end{cases} \\ \xi_i \geq 0 \forall i, \quad \sum_{g=1}^{G} \beta_g + \sum_{f=1}^{F} \beta_f + \sum_{m=1}^{M} \beta_m = 1, \end{gathered} \tag{6}$$

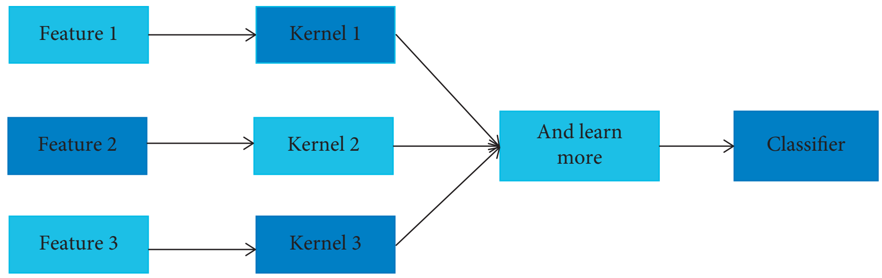

Figure 9: Schematic diagram of multicore learning feature fusion process.

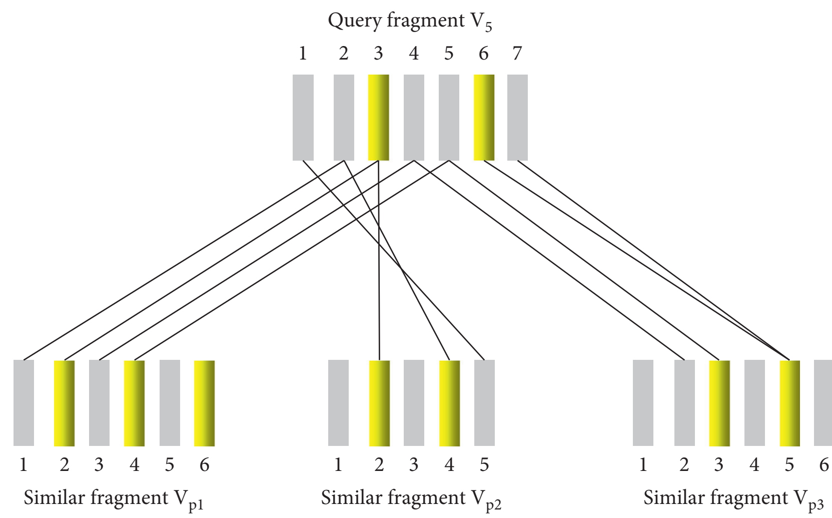

Figure 10: An example of video segment similarity matching.

where kg $(Xi) = [\text{kg}(Xi, X1), \ldots, \text{kg}(Xi, XP)]$, KF $(Xi) = [\text{KF}(Xi, X1), \ldots, \text{KF}(Xi, XP)]$, and km $(Xi) = [\text{km}(Xi, X1), \ldots$. According to the idea of simple MKL algorithm, the gradient descent algorithm is used to minimize the objective function and learn to solve the optimal parameters. The specific process is that, in each iteration, the classifier parameters α and B are calculated by giving the kernel function weight β; then, given α and B, a new kernel function weight β is calculated. Therefore, the classification function based on multicore learning support vector machine is as follows:

$$y = F(x) = \left[\sum_{g=1}^{G} \beta_g K_g(x) + \sum_{f=1}^{F} \beta_f K_f(x) + \sum_{m=1}^{M} \beta_m K_m(x)\right]\alpha + b. \quad (7)$$

In practical application, according to the content and structure characteristics of the video, comprehensively measure the above points and allocate the weight. Based on this, we can find the video clip with high similarity to the query clip.

5. Conclusions

The large amount of video data on the network is due to the wide range and fast speed of video transmission. The retrieval system improves precision and recall and has good practical performance, thanks to the density distribution, compactness, dispersion, and similarity between specific action segments in high-dynamic dance video. The diversity and repeatability of video become a difficult problem in the field of video retrieval when using content-based video retrieval. The related video retrieval research in this paper is focused on changeable dance videos. The single-layer method and hierarchical method are introduced first in terms of action recognition methods. Different actions must be fully detected in order to fully detect all types of actions, and it is preferable to cross at least once. When a video contains a variety of human actions, manually edit the video and then process it as if it contained only one type of action. Subaction sequences can be decomposed as high-level actions, and subactions can be decomposed as high-level actions until they are decomposed into atomic actions. As a result, motion recognition research has become increasingly popular in recent years, and it is now widely used in a variety of fields such as intelligent monitoring, human-computer interaction, and virtual reality. In a nutshell, human motion recognition research, particularly complex movement research, is still in its infancy, and many aspects such as methods and real time need to be improved. Despite the fact that an increasing number of researchers are working on this project, ongoing efforts are required to achieve the goal of advanced intelligent recognition and detection.

Data Availability

The data used to support the findings of this study are included within the article.

With the arrival of the mega data era, CET has developed a new teaching model based on mega data. This teaching requirement is met by a data-driven model based on mega data. By applying it to CET, students will be guided to explore and discover language rules and pragmatic features through quantitative analysis of data-driven technology, which will help compensate for the disadvantages of traditional English teaching and improve students' autonomous learning ability. The concept of data-driven language learning is introduced into teaching in this paper. Corpus is tried to stimulate students' autonomous learning in the teaching process, and the independent learning model of students is further improved in the teaching reform, based on educational theories of corpus linguistics and second language acquisition linguistics. Students' scores have improved, particularly in English listening, according to the findings. The data-driven CET-4 model improves students' learning ability and interest, as well as their ability to think creatively and critically.

1. Introduction

The advancement of computer and network technology has influenced not only people's daily lives but also traditional teaching methods, resulting in fundamental changes in people's methods and means of acquiring knowledge [1]. The deep integration of the Internet and IT has ushered in a new era of mega data, which presents both an opportunity and a challenge for current foreign language instruction. The teaching model has also undergone qualitative changes as a result of the inclusion of scientific and technological elements [2]. English instruction has progressed from a single computer-assisted method to a mixed method based on the Internet and derived mega data [3]. Learning resources, learning objectives, learning contents, and learning tools have all changed dramatically in the college English curriculum as a result of the digital and networked system [4]. People from all walks of life are becoming increasingly aware that whoever can take the lead in realizing mega data and who has a deeper understanding of mega data mining and application will seize the opportunity in the future. In the field of education, the penetration of massive data will inevitably lead to a high level of technological integration in the classroom. Developing smart classrooms, implementing data-driven learning (DDL) as a teaching model, and providing accurate decision-making will undoubtedly become a new trend in the future development of educational informatization, with a significant impact on profound changes in the field of education [5]. Under the tide of mega data, the DDL teaching mode method model, the DDL teaching mode method framework, and the practice of DDL teaching model are constantly emerging. The DDL teaching model has become an index to evaluate the effectiveness of any given teaching method [6].

The development of mega data technology provides new opportunities for the development of education and endows DDL teaching model with new connotations and missions. The wide application of data mining has brought rapid development to all fields of social life [7]. DDL model came into being in this situation and soon attracted people's attention, which will promote the development of foreign language teaching [8]. Applying it to college English teaching (CET) can create a real linguistic context for students and guide students to explore and discover language rules and pragmatic features through quantitative analysis of data-driven technology, so as to make up for the disadvantages of traditional English teaching model and improve students' autonomous learning ability [9]. DDL teaching model can improve our teaching efficiency and ensure our teaching quality. For the education industry, mega data is a major opportunity for traditional education research to move towards scientific demonstration. College English courses should use advanced IT to carry out English teaching based on computer and network so as to provide students with a good language learning environment and learning conditions [10]. This paper introduces the concept of data-driven language learning into teaching, based on the educational theory of corpus linguistics and second language acquisition linguistics; tries to use the corpus to stimulate students' autonomous learning in the teaching process; and further improves students' autonomous learning model in the teaching reform.

Through quantitative analysis of data-driven technology, it can be applied to CET to create a real linguistic context for students and guide them to explore and discover language rules and pragmatic features, thereby compensating for the disadvantages of traditional English teaching models and improving students' autonomous learning ability [11]. The corpus' rich and authentic corpus, as well as teachers' active assistance, not only stimulate English learners' interest in learning and cultivate their ability of active exploration, analysis, and induction but also greatly activate learners' innate language intuition and improve their cognitive and metacognitive skills [12]. The DDL method is a corpus-based discovery method for learning a foreign language that transforms the teaching space from closed to open. Learners are independent builders of knowledge, and the learning process is a knowledge construction process of self-creation and self-motivation. The DDL model, which is based on an English-driven decision-making model, has significant value and significance in encouraging empirical English teaching [13].

2. Related Works

Literature [14] points out that the most remarkable feature of DDL is that teachers do not know what rules learners will find in advance. DDL model is to enable English learners to actively explore the rules contained in the English corpus by analyzing the real and abundant data of the English corpus and to produce top-down discovery learning so as to cultivate English learners' autonomous learning ability. Literature [15] divides the research object into the control group and the experimental group. The experimental group adopts the DDL model for teaching, while the control group adopts the traditional way of teaching by teachers. Through pre-test, post-test and qualitative research, it is finally found that using DDL model for vocabulary learning is far better than the traditional teaching model. Corpus is widely recognized in language teaching, especially that language learning should be based on the abundant corpus. Therefore, the corpus-based DDL model becomes the best choice for teachers. Literature [16] indicates that DDL model is still more effective than the traditional language teaching method for language learners who have not received corpus operation training and primary level. In addition, it is far more beneficial to use keywords in a real and rich linguistic context for teaching than a long context composed of one or more sentences. Literature [17] shows that paper-based materials can eliminate the obstacles encountered in using corpus-based DDL model and make DDL model win more followers. This is because language learners at the primary level and those with lower qualifications do not have enough prior knowledge and patterns to follow, so they cannot learn effectively from a purely inductive teaching pattern. Literature [18, 19] holds that the transformation from DDL to demand-driven corpus should be completed. However, the DDL model cannot fully assume how to grasp the actual needs of learners. Literature [20] holds that the previous corpus-based DDL research ignored the differences of learners in the learning process. That is to say, the corpus-based DDL model only pays attention to the integrity of learners and ignores the particularity of learners.

The abundant corpus provided by the corpus can make up for the deficiency of the existing English textbooks to a certain extent and enrich the process of English teaching in form and meaning. At present, the application of the DDL model in teaching English to speakers of other languages is mostly limited to theoretical discussion but lacks systematic empirical investigation and research. Taking CET as an example, this paper studies the DDL teaching model of college English under the background of educational mega data and analyzes the operation process of this model.

3. Present Situation of CET

Although China's CET has been reformed in many aspects, the traditional classroom teaching model is still being followed, whether it is college English textbooks, teaching contents, or tests at all levels, including CET-4 and CET-6. Students rely more on vocabulary accumulation and grammar knowledge, focusing on various tests, rather than on the practice of communication in the real context. The combination of the corpus with computer and network makes its application in CET show us a new platform. In addition, corpus linguistics also plays an important role in foreign language teaching theory, content, and methods.

Our era is experiencing an information explosion due to the rapid development of the Internet and the emergence of cloud computing. The teaching model has also changed qualitatively as a result of the inclusion of science and technology elements. English teaching has progressed from a single computer-assisted method to a mixed method based on the Internet and mega data derived from it in the past. Corpus linguistics is a science of language analysis and research based on real corpora [21]. It is devoted to text retrieval, sampling, analysis, and statistics. The introduction of corpus linguistics into CET can merely compensate for the aforementioned flaws. Corpus linguistics has become increasingly linked to foreign language teaching as computers have advanced. The human-computer interaction-centered organization of classroom teaching is now the focus of the

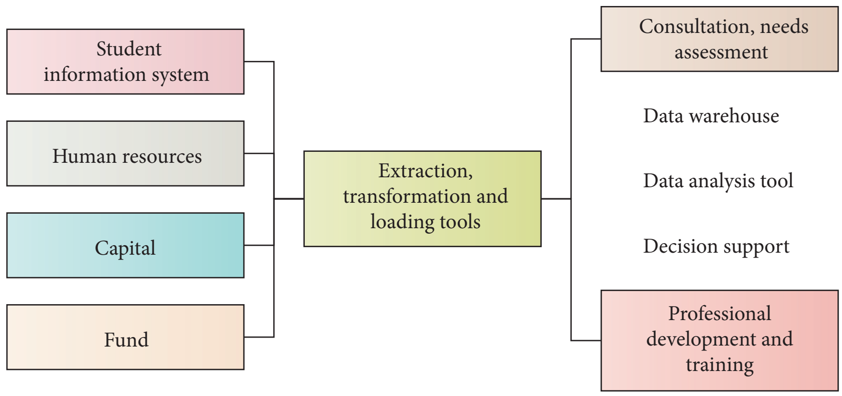

Figure 1: Data-driven decision model.

corpus-based data-driven CET model. After the teacher has compiled the language materials on the computer, students can read the materials on the computer and engage in student-centered learning. This model is only appropriate for the core educational viewpoint of today's college English reform, namely, the autonomous learning education model.

4. Construction of English-Driven Decision Model

4.1. Generation of Data-Driven Decision Model. Corpus is a new type of learning resource; it is essentially a warehouse for storing language materials, where many natural language materials of spoken and written languages are gathered. Corpus is a large-scale collection of written and spoken natural language materials that serve as a warehouse for storing language materials, also known as a language database. Because of the advancement and application of computers, the corpora we now use are essentially electronic corpora, which store a large number of language materials in the form of text via computers. The emergence of corpora provides more advanced technical means for linguistic research, as well as significant shifts in language research thought [22]. Knowledge acquisition, according to constructivism, is not a one-time event, and learners' social and cultural backgrounds and situations play a significant role in constructing the meaning of what they have learned. Learners are cognitive subjects, not passive recipients of knowledge. Learners benefit from learning in real or near-real situations because it allows them to explore the world based on prior experience and to build new knowledge on top of previous knowledge.

With the development of data mining technology, it is possible to make decisions by using various data analyses, which also enables the emergence and development of data-driven systems. The data-driven decision model is shown in Figure 1.

The learning process in DDL model is divided into three stages: pointing out problems, classifying materials, and summarizing. The target language in learning can be summarized as the process of data-driven language learning. Learners classify and search the corpus for context cooccurrence in order to collect a large amount of real information, which they then input into the materials for induction and summary in order to obtain the law of language. The following aspects of the corpus can be roughly summarized: systematicness, authenticity, flexibility, representativeness, and richness, among others. These characteristics help foreign language learners create complex and realistic task scenarios, which not only help them master more basic language skills but also boost their learning enthusiasm and initiative. The autonomous learning of students dominates the learning process [23]. Teachers typically serve as a guide, organizer, and negotiator in this process, assisting students in determining the overall learning direction. While students are the driving force behind the learning process, they must manage, monitor, and evaluate themselves, as well as further develop their autonomous learning ability, which can have a positive impact on other aspects of students' lives, forming a virtuous circle and promoting learning.

Language learning under corpus DDL model is the concrete practice of the core content of constructivism theory. With the increasingly mature corpus retrieval tools as the means, it observes and analyzes a large number of real language phenomena by learners themselves or in collaboration with others and sums up their language rules by combining the old information in their minds so as to realize the internalization of knowledge. Sustainability is used to measure the sustainability standard of quality evaluation reform and transformation system and the progress of each subsystem. The development speed of each subsystem is used as a measure as follows:

$$w = \left(w_{\max} - w_{\min}\right) \times \frac{I_{\max} - I_i}{I_{\max}} + w_{\min}. \tag{1}$$

Use clustering algorithm function method to find

$$Cr_{(t+1)} = k \times Cr_{(t)} \times \left(1 - Cr_{(t)}\right). \tag{2}$$

The calculated trend degree is as follows:

$$f_1(x) = \sum_{i=1}^{D-1} \left[100\left(x_{i+1} - x_i^2\right)^2 + \left(x_i - 1\right)^2\right]. \tag{3}$$

Large corpora have evolved into shared resources, with some corpus retrieval software available for download and

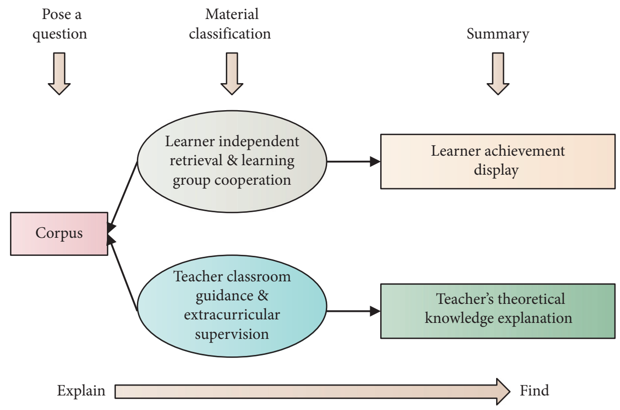

Figure 2: College English classroom teaching under the corpus DDL model.

use on computers. All of this provides a research foundation for implementing and developing DDL in foreign language instruction. DDL is a corpus-based language teaching model. Students' exposure to real language is generally limited in traditional teaching models, and the input of a large number of non-authentic languages causes various language errors, which has been fully verified in teaching practice. This is a problem that DDL excels at [24]. This is because all of the language data sources provided by the corpus for students are real communication activities, and they help students improve their language intuition and master a more pure language by creating a real linguistic context for them.

4.2. Construction of English-Driven Decision Model. The education industry has undergone significant changes and innovations as a result of the development of the Internet. The methods used to teach English are varied and innovative. Sources of teaching materials are becoming more diverse. Students and teachers can look up words on the Internet using online dictionaries, as well as use shared teaching resources created by other students. Teachers and students can use the Internet to discuss problems in the classroom and do supplementary learning after class by forming English learning groups or using the teaching platform. On the network platform, teaching is no longer limited to the classroom; it can now take place at any time and in any location. Teachers' lessons to students may be partially or completely uninteresting. This raises an important issue, namely, perception misalignment. As a result, perceived mismatch may be an important factor in causing unsatisfactory teaching results in second language teaching. Because of the traditional teaching model, the DDL model is no exception, and learner analysis is more influenced by test scores. Even though it involves a thorough examination of students' needs, motivations, and preferences, it is primarily based on teachers' intuition and experience. Learners' basic information, learners' learning motivation, learning preferences and needs, learners' vocabulary and grammar learning strategies, perceived mismatch between teachers and students, and teachers' beliefs are all sources of data in the English-driven decision-making system.

Teachers' beliefs largely determine the success of classroom teaching. Obviously, the DDL model based on the English-driven decision-making model not only takes into account learners' factors but also recognizes the importance of teachers' beliefs and perceived mismatch between teachers and students for data collection and analysis. Corpus DDL model of college English classroom teaching is shown in Figure 2.

Before using the DDL model for teaching English to speakers of other languages, in order to ensure the teaching effect, all factors that may affect the teaching process must be collected from learners' learning motivation, learning preferences, learning needs, teachers' beliefs, and learning strategies. The English-driven decision model is shown in Figure 3.

Students participate in the establishment of key and difficult points in the classroom through study groups, conduct corpus retrieval analysis on the problems discovered or to be solved, observe the retrieval results, discuss in groups, and present the discussion results in the classroom. The English-driven decision-making model incorporates basic learner information, and its foundation is a better understanding of learner characteristics. Differences in thinking and cultural beliefs, for example, caused by differences in nationalization, have a significant impact on learners' learning activities. Students and teachers are confronted with a plethora of data. How can science and technology be used to screen these data and determine their practical value? It's a problem that both teachers and students must work together to solve [25]. The fundamental premise of using the DDL model in English teaching is to analyze the learning needs of English learners. When analyzing the learning needs of English learners, we must take into account the learners' complex expectations and contradictions, as well as the language and cultural needs of the learners. In order to create more targeted teaching materials that meet the needs of students.

Positive indicators, then

$$X'_{ij} = \frac{\left[\max\left(X_j\right) - X_{ij}\right]}{\left(\max\left\{X_j\right\} - \min\left\{X_j\right\}\right)}. \tag{4}$$

Inverse indicators, then

$$X'_{ij} = \frac{\left[X_{ij} - \min\left(X_j\right)\right]}{\left(\max\left\{X_j\right\} - \min\left\{X_j\right\}\right)}. \tag{5}$$

In order to ensure that the logarithmic calculation is meaningful when calculating the entropy value, all the data is shifted by 0.5, $Y_{ij} = X'_{ij} + 0.5$, $Y_{ij} \in [0.5, 1.5]$, and the shifted value is subjected to a proportional transformation to obtain the normalized value of each evaluation index. The proportional transformation formula is as follows:

$$Z_{ij} = \frac{Y_{ij}}{\sum_{i=1}^{m} Y_{ij}}. \tag{6}$$

Teacher's input means that teachers subconsciously think that this is what learners should learn and master in

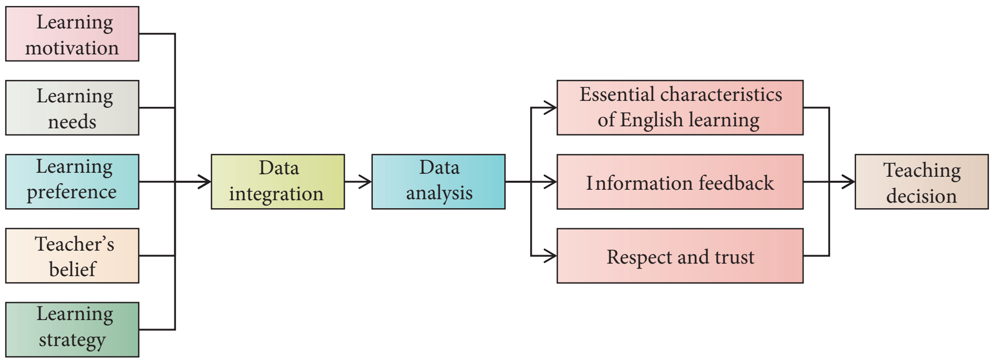

FIGURE 3: English-driven decision-making model.

this class by providing oral and written language materials or other forms of information. Learner acquisition refers to what learners get through personal participation or other learning methods in the course of the class, not just the ready-made information provided by language materials. In the multimedia classroom, teachers and students can experience this classroom teaching model together. However, attention should be paid to the proportion of online classrooms in the whole teaching system and the arrangement of class hours, which not only makes an attempt of classroom reform but also does not affect the normal learning progress of students.

5. Result Analysis and Discussion

It is the main carrier of language, and it is contained in culture, and culture is embodied in language. From the perspective of human beings, it is emphasized that the essence of culture is closely related to the essence of human beings. Culture fundamentally distinguishes human beings from animals, and the essence of culture is creation. Keyword list can be regarded as a common vocabulary or core word group that students often use to express a certain topic. This core word group is associated with other keywords in the thesaurus. Students have reduced semantic differences in the use of words. That is, some words sharing some semantic features are used alternately to express the same concept. This feature makes the students' vocabulary use focus on a few limited core words, and the concepts expressed are monotonous and vague.

Students may not have enough knowledge or confidence in words with more specific meanings, so they use words with broader meanings instead. When students use some fixed or semi-fixed collocations, their choice of collocations is free and changeable, unlike native English speakers, which have certain restrictions [26]. Therefore, to learn and use a foreign language, we must understand the culture closely related to the foreign language, and familiarity with the relevant culture is conducive to using a foreign language appropriately. A learning method that takes words or phrases as a unit and focuses on the sensory memory stage of memory is convenient for students to process vocabulary at a shallow level and memorize vocabulary. Select a number of students to test and compare the memory effect with that of traditional methods, as shown in Figure 4.

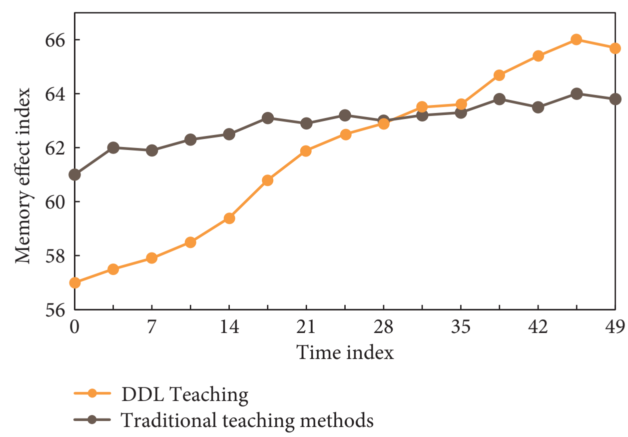

FIGURE 4: Comparison of memory methods.

Students' strong desire to pay attention to society and sense of participation is in sharp contrast with their vague understanding of social modeling. In the expression of students' theme, campus and society are divided into compulsory binary parts so that they can form semantic opposition in the use of words. Teachers should explain the teaching objectives and tasks of this class in class and at the same time conscientiously implement the teaching according to the teaching plan and lesson plan [27].

Set the related parameters of English learning resources distribution, reconstruct the constraint parameters of English learning ability evaluation, and get the time-domain curve of distribution as shown in Figure 5.

Teaching a language is a step-by-step process that progresses from simple to complex. As a result, the teaching of English culture should be done in stages and according to the principle of step by step. The content of culture instruction is determined by the students' language level, acceptance ability, and comprehension ability. Teaching should go from the easy to the difficult, from the simple to the complex, and from the phenomenon to the essence. Teachers should assist poor students in comprehending the cultural information provided by the text itself rather than introducing foreign content [28]. Within the same region, there are linguistic differences. Language has an impact on culture and can also be used to learn how to express culture.

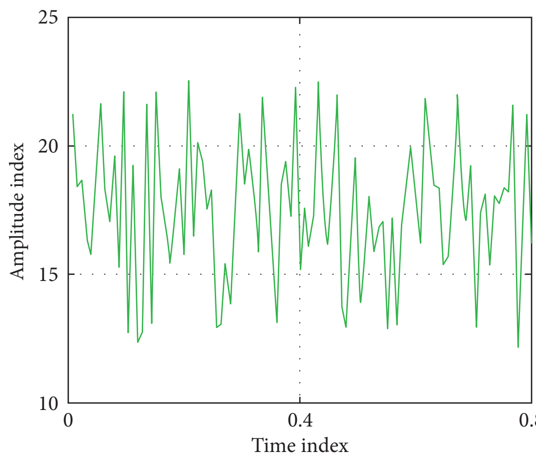

Figure 5: Time-domain distribution curve of mega data.

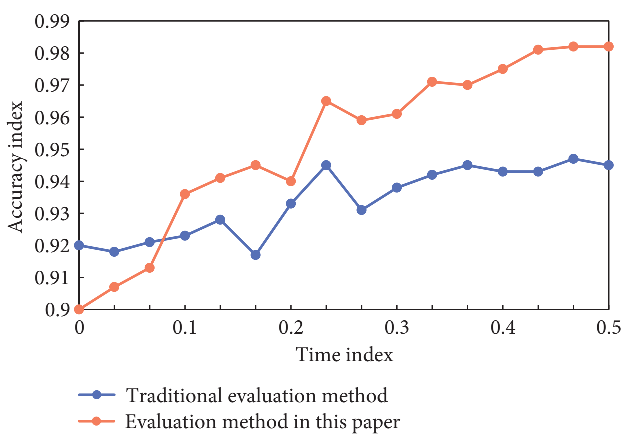

Figure 6: Comparison of accuracy data of two analysis methods.

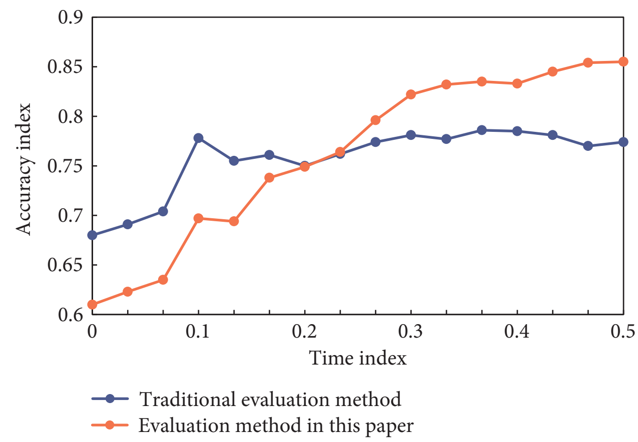

Figure 7: Comparison of utilization data of two analysis methods.

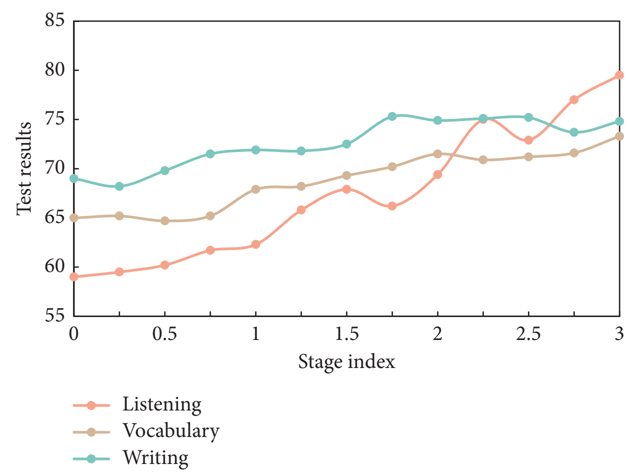

Figure 8: Comparison of achievements.

The accuracy of learning ability evaluation with this method is high, and the utilization rate of learning resources is good. A comparison of the two analysis methods is shown in Figures 6 and 7.

Language is not only a way of human communication but also a means of guiding the speaker's views. It provides people with idiomatic patterns for analyzing reality. Cultivating cross-cultural awareness in English teaching can better conform to the trend of globalization, so we must do this link well. The success of students' word use depends on whether they can build a word network around a theme, association, and word collocation. Its significance lies in that foreign language teaching, especially English teaching, centered on a certain topic and semantic association may be more effective than isolated and discrete vocabulary learning. If teachers do not care about the actual situation of students and the content of teaching materials, they will instill cultural knowledge into students, which is unacceptable to students with low English levels. Cultural diversity leads to linguistic diversity. Cultural differences are not only reflected in different regions. Many cultures will change with the passage of time and the influence of other cultures.

Using DDL model in English vocabulary and grammar teaching reflects the complexity of corpus retrieval, the diversity of corpus content, the dynamics of corpus selection, and the difficulty and time consumption of corpus analysis and collation. It also reflects the dynamics of learners' learning motivation, the complexity of cognitive strategies, the nonlinearity, and self-organization in the learning process. Learners' learning in DDL model, from curiosity and excitement at the beginning to joy at the middle stage to negative emotions at the later stage, fully shows that learners' learning motivation has changed. The test results are shown in Figure 8.

Students' scores have improved, particularly in English listening, according to the findings. There is a pedigree relationship between words when a person uses words to express his understanding of the real world. The semantic space is at the top of this hierarchical relationship. Language learners struggle to match the semantic field of their mother tongue to the semantic field of the target language. The learner's task is to match the mother tongue's semantic field to that of the second language. What they do not realize is that a second language semantic concept is realized as a word [29]. It may, however, be realized in its mother tongue as multiple words, or it may not be realized at all, or it may only be realized as mother tongue through difficult translation and interpretation. Different cultures are reflected in different languages. Language causes people to think and express themselves in a variety of ways. As a result, people act in different ways. There will be differences, while the globalization of education and the local foundation have an impact. Different thesaurus groups are divided according to semantic functions, and the statistical key thesaurus and thesaurus are grouped and analyzed according to composition topics. By connecting the analysis results with the composition topic and drawing, we can directly observe the basic words used by students to express a certain topic, as well as the relationship between these words.

6. Conclusions

Each teacher has his or her own approach to teaching, and each student has his or her own study habits. This personalized design is made possible by big data. Teachers can select their own teaching materials and develop their own teaching style. Teachers can pay close attention to each student's microscopic performance based on the data and adjust the education plan accordingly through the analysis of relevant student data, resulting in personalized education. With the help of abundant corpus materials and data-driven teaching methods, the corpus-based DDL teaching model of college English can effectively improve teachers' teaching level and students' autonomous learning ability, thus effectively improving the CET effect. The data-driven CET model improves students' learning ability and interest, as well as their ability to think creatively and critically. Students' overall scores have improved as a result of the new learning evaluation system. Students have a strong interest in learning physical education courses as a result of its implementation, and the new learning evaluation system has a positive impact on students' learning. This effect will be further enhanced if teachers can select and build a corpus of appropriate scale and suitable for students in our school from the actual level of students in our school and then carry out teaching activities on this basis.

Data Availability

Academic Editor: Tongguang Ni

In the future, the majority of PE (physical education) students in regular schools will become preschool teachers. As a result, these students' sports habits and feelings will have a direct impact on future preschool education and the training of preschool children's sports habits. As a result, PE curriculum in preschool normal schools must adapt to the future development of preschool education. This article develops a scientific, reasonable, and valuable children's PE curriculum by constructing the basic framework of modern children's PE curriculum. As a result, this research proposes two RNN-based models: one is a personalized recommendation model for children's PE curriculum—LSAPR (long short-attention point-of-interest recommendation) model, and the other is a recommendation model for children's PE curriculum sequence LSTM-RNNSR (long- and short-term memory-RNN sequence recommendation). The two models proposed in this paper have produced good off-line experimental results in various datasets, as well as a real-time personalized point-of-interest recommendation effect in practice.

1. Introduction

Children's sports have gradually become the focus of education practitioners, parents, and society in China, thanks to the Sunshine Sports Project's multilevel and all-around development [1]. The development of preschool education is directly influenced by the quality of preschool education. As a result, reforming the PE curriculum in preschool normal schools and improving students' attitudes toward physical activity are critical for exporting qualified preschool teachers, cultivating talents in line with social development, and improving preschool education quality.

At present, the research on curriculum teaching reform in general higher vocational colleges has changed from the traditional focus on technology, and teaching methods and means to all-round and multilevel research on teaching reform, such as teaching material construction, teacher team construction, teaching idea renewal, teaching mode, teaching organization form, teaching content, and teaching environment. [2] For example, some scholars have performed research on the reform of professional teaching in PE colleges; some scholars have performed research on fitness value development and other related aspects from their own point of view [3, 4]. Literature [5] writes that it is necessary to cater to students' main needs, create problem situations, stimulate students' interest in inquiry, and experience the happiness brought by success, thus breaking the competitive sports teaching mode that ignores students' psychological experience, changing the traditional organization mode, and closely combining school sports with social sports activity groups. Literature [6] found that the current mode of PE (physical education) courses in universities is mostly "three-stage," that is, the first-year basic PE class, the second-year optional courses, and the third-year and above elective courses. Literature [7, 8] makes a survey of the most popular sports among students in five universities, including table tennis, football, basketball, badminton aerobics, volleyball, and swimming. The results show that among the most popular sports in the universities surveyed, football actually ranks last, and the situation is not optimistic.

Preschool normal education in China has developed rapidly as the education system reform has progressed, and the educational concept and talent training mode of preschool normal education have changed dramatically, and the educational mode is becoming increasingly diversified [9]. However, there are still many issues to be resolved in terms of teaching mode and content in actual teaching. This study uses RNN (recurrent neural network) to assist and educate preschool teachers, develop more effective and sustainable preschool PE curriculum ideas, establish successful curriculum models, and provide high-quality educational services for young children.

At present, in the establishment of a teaching system, the school has established the PE teaching target system, which focuses on lifelong PE, supplemented by healthy PE and sports skills learning. However, it seldom involves the direction of sports culture shaping and sports appreciation, and the teaching evaluation methods are different. Therefore, this article applies the RNN model to the analysis of rationalization of preschool PE curriculum.

2. Related Work

DL (deep learning) usually uses the artificial neural network to learn the high-level data representation. By learning the depth model of a large amount of data, high-level data representations can be extracted from lower levels. For example, literature [10] proposed a method of processing a song as a group of 599 consecutive frames and trained CNN (convolutional neural network) [11, 12] to learn its sentences to solve the cold start problem in recommendation. Literature [13] proposed that the CNN (convolutional neural network) integrates product description into probability matrix decomposition. Compared with the topic model, it can capture context information of text. Because the size of convolution kernel is fixed during CNN training, the CNN with different convolution kernel sizes may be needed to improve the performance. A more common way to model text sequences is to use the RNN model.

Up to now, only a few recommendation methods based on the neural network have been proposed for POI (point-of-interest) recommendation, and the main network structure of these methods is the RNN structure and its variants. Literature [14–16] point out that both short-term preferences and long-term preferences of users cannot be ignored, but the traditional RNN structure is not designed to distinguish these two preferences at the same time. The popularization of literature [17] has brought some successful practices of model-based methods, which are based on MF (matrix factorization) technology. Literature [18] combines social influence with CF (collaborative filtering) model based on users and uses the Bayesian model to model geographical location context. Literature [19] shows how inner product linearly combines with potential features and limits the expressive ability of MF. Literature [20] proposed a latent model based on tensor, which considered the influence of users' latent behavior patterns on the recommendation results. The pattern was determined by context time and category information. Literature [21] uses the RNN to predict the click of online advertisements. At every moment, they train the RNN with the latest click of users and the previous state of the network and use the classification loss measure (cross-entropy loss) to predict the next click of users. Literature [22] proposes a context-adaptive method for constructing session-aware recommenders, which can deal with long-term (e.g., seasonal) and short-term changes of user preferences in the news field. In their work, the author put forward a semantic structural model of time depth, which combines the characteristics of users and projects with the characteristics of users' time into a joint model, in which the static characteristics are modeled by several feedforward neural networks and the time characteristics are modeled by a group of RNN.

3. Research Method

3.1. Curriculum Structure of Preschool PE. The definition of children's PE can be divided into different levels from a social standpoint. In a broad sense, it refers to children as the subject of sports activities, and in a more specific sense, it refers to the public's perception of kindergarten PE. Children's PE should follow the rules of children's growth and development, improve health, systematically teach children sports, health care, and a healthy lifestyle, cultivate children's interests and hobbies in sports, form the habit of exercising, and promote the all-round development of children's physical and mental personalities, according to this article. Curriculum development is a difficult and time-consuming task that encompasses not only the dominant curriculum idea, curriculum setting principles, and curriculum structure, but also the implementation and evaluation of curriculum. As a preschool teacher training institution, it is critical to establish clear training objectives, training modes, and principles for preschool teachers in today's society, as well as to train and adjust teachers' skills on a timely basis.

With the deepening of the educational system reform, the preschool normal education in China is developing rapidly. The educational concept and talent training mode of preschool normal education have been greatly improved, and the educational mode is becoming more and more diversified. However, in actual teaching, there are still \many problems to be solved in teaching mode and teaching content. In preschool normal PE, the ratio of male to female is seriously out of balance. If the teaching content of PE cannot be arranged reasonably. The teaching evaluation of PE is single, the evaluation method lacks scientificity, and the PE in preschool normal schools still focuses on physical quality assessment items, paying attention to the results and ignoring the differences of students' individual basis. This teaching mode lacks motivation and unfairness, which is not conducive to the development of quality education.

The theoretical basis of curriculum includes policy basis and academic basis. As a course, there must be a clear educational outline, including the requirements and indicators of educational tasks and objectives, educational principles, educational environment, and educational contents and methods. The basic framework of the course is shown in Figure 1.

There is explicit and implicit curriculum content in the curriculum. Explicit content in kindergartens refers to daily sports activities, whereas implicit content refers to material and spiritual content such as environmental creation, work

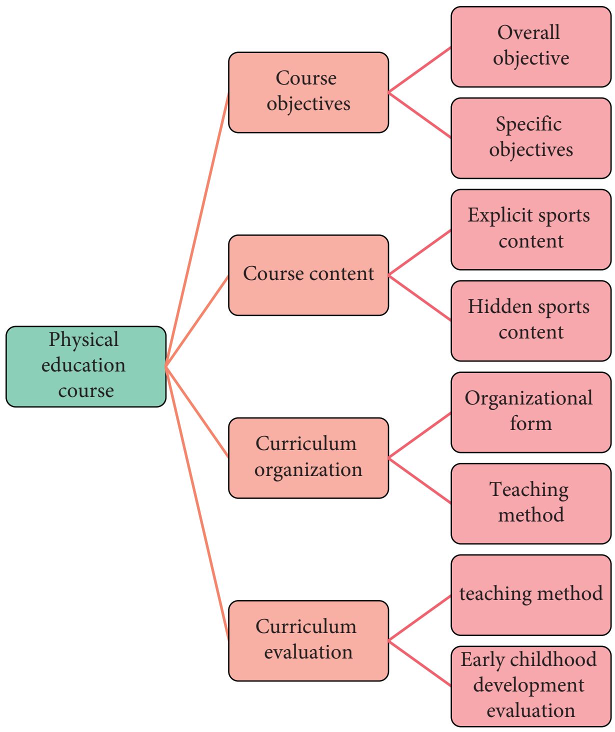

Figure 1: Basic framework of modern preschool PE curriculum.

and rest time, teacher-student relationships, good atmosphere, and home cooperation, among other things. The terms teaching methods and “teaching means” are used interchangeably. Individualized, group, and collective teaching methods are commonly used in preschool PE. Appropriate teaching methods and means should be used to improve children's interest in learning, taking into account the teaching objectives, children's abilities, and teaching resources.

3.2. Personalized POI Recommendation Model with AM. The formation of children's motor skills is the complementary connection of vision, hearing, vestibule, and other organs. Preschool teachers should use correct and graceful motor demonstration, and concise and neat oral instructions, and protect children in the teaching of difficult movements. It is difficult for children to fully understand and master what they have learned. Therefore, teachers require children to practice the actions they have learned repeatedly and attach importance to their active experience, independence, and innovation.

Among the means of curriculum evaluation, one is measurement-based evaluation, which aims at obtaining empirical data through strict measurement. The other kind of evaluation is based on speculation and logical inference, through rigorous analysis and demonstration at a higher theoretical level. Reveal the significance of the course and explain the value of the course. The evaluation of modern curriculum generally pays attention to the effective combination of the two.

In this chapter, an LSAPR (long short-attention point-of-interest recommendation) model is proposed, which uses all historical POISS of users to capture users' real long-term preferences and weights different times of the current POI sign-in sequence with AM (attention mechanism) [23].

RNN is a kind of artificial neural network modeled by sequence information. The structure of RNN is shown in Figure 2.

Specifically, given the sequence $x = (x_1, x_2, \ldots, x_T)$, the RNN updates the circular hidden state h_t by the following formula:

$$h_t = \begin{cases} 0, & t = 0, \\ \sigma(h_{t-1}, x_t), & t \neq 0, \end{cases} \tag{1}$$

where σ is a nonlinear function, such as tanh and sigmoid function.

Specifically, the hidden state update of the RNN in formula (1) is usually realized by the following formula:

$$h_t = g(Wx_t + Uh_{t-1}), \tag{2}$$

where g is a nonlinear function and W, U is a weight matrix.

An LSA algorithm using all user login sequences is proposed, which can dig out the user's long-term preferences from all the user's historical POISS (POI sign-in sequences) and pay attention to the short-term preferences in the current POISS. See the following formula for the specific forward propagation process:

$$\begin{aligned} \alpha_i &= Z_0 \sigma\left(Z_1 h_i^m + Z_2 h_t^m + Z_3 \overline{h}_t = b_\alpha\right), \\ h_{LSA}^m &= \sum_{i=1}^{t} \alpha_i h_i^m. \end{aligned} \tag{3}$$

Here, α_i represents the weight of the i th moment in the current POISS; h_{LSA}^m is the attention representation of the current POISS obtained by the AM; h_i^m indicates that the hidden state of the first moment in the current POISS represents the overall representation of the current POISS; h_t^m represents the user's long-term preference; and Z_*, b_α is the weight matrix and the deviation vector, respectively.

This article introduces the LSA mentioned above into the decoder of CAPR (context-aware point-of-interest recommendation), which can mine users' long-term preferences from all historical POISSs of users. Figure 3 is a schematic diagram of the network structure of LSAPR.

In this article, the general GRU structure is extended, the context information is integrated into the gating structure, and a CAGRU (context-aware gated recurrent unit) is proposed. Based on the natural geographical location attribute, time point attribute, and category information of POI, this expansion can make GRU structure more suitable for POI recommendation tasks.

It can be seen from Figure 3 that the LSAPR model first inputs the user's historical POISS into the CAGRU encoder to encode the whole sequence and at the same time uses the CAGRU. The encoder obtains the hidden state of each moment of the current sequence of the user. Then, input

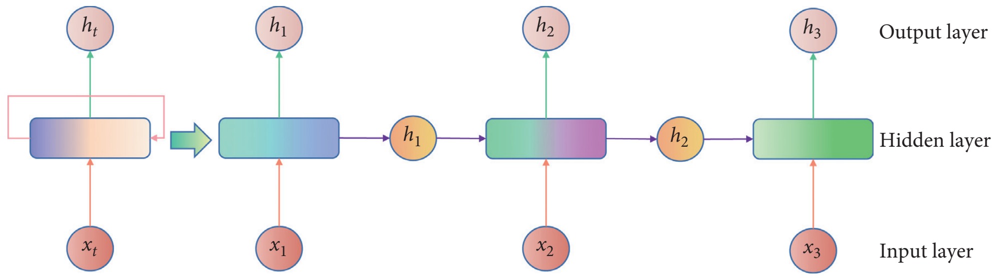

FIGURE 2: RNN structure diagram.

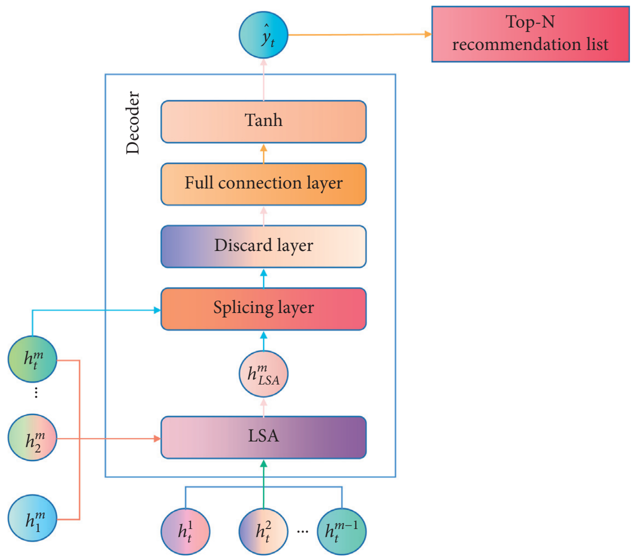

FIGURE 3: Schematic diagram of the LSAPR model structure.

these data into LSA to obtain the attention expression of the current POISS, which is given as

$$h^m_{LSA} = LSA\left(\left\{h^1_t, h^2_t, \ldots, h^{m-1}_t\right\}, \left\{h^m_1, h^m_2, \ldots, h^m_t\right\}\right). \quad (4)$$

It is necessary to train the data of each user separately during the LSAPR model training process in order to obtain personalized recommendation results for that user. Each user's POISS is sorted by starting time and then divided using the subsequence division method described in CAPR model training. To speed up the calculation of the attention score, the entire representation of the sequence before it is stored in memory for each POISS.

3.3. Sequence Recommendation Model Based on RNN. The learning evaluation system for PE courses in ordinary schools, as an important part of PE, lags behind in terms of reform and does not fully reflect its inherent function of guiding and encouraging people to grow up healthy and harmoniously. The goal of improving and perfecting the PE teaching content, teaching mode, and evaluation system is to meet the needs of society and comply with relevant requirements and norms, with the ultimate goal of "cultivating students' lifelong sports habits" and the specific goal of "enhancing students' physique, improving students' enthusiasm for participating in sports activities, and promoting students' physical and mental health development."

Today, with the increasingly severe social competition, the training objectives of school education are becoming more and more clear. How to make these technical applied talents who are fighting in the front line of society have good physical qualities and put them into the construction of society will become the development focus and development trend of school PE.

In this article, a new recommendation model LSTM-RNNSR (long- and short-term memory-RNN sequence recommendation) is proposed. The model consists of RNN attention module and item-item relationship module, which is integrated with the matrix decomposition model and optimized by Bayesian personalized sorting.

LSTM (long- and short-term memory) introduces gating mechanisms such as forgetting gate and input gate [24], which better solves the problem of gradient disappearance or explosion, so the LSTM-based model is widely used for text modeling, especially for long text modeling.

There are three gates in the LSTM unit to protect and control the state flow. For each time step t, given the input x_t and the current cell state c_t, the hidden state h_t can be updated with the previous cell state c_{t-1} and the hidden state h_{t-1}, and the update formula is as follows:

$$\begin{bmatrix} i_t \\ f_t \\ o_t \end{bmatrix} = \begin{bmatrix} \sigma \\ \sigma \\ \sigma \end{bmatrix} \left(W\left[h_{t-1}; x_t\right] + b\right),$$
$$\widehat{c}_t = \tan h\left(W\left[h_{t-1}; x_t\right] + b_c\right),$$
$$c_t = f_t \otimes \widehat{c}_{t-1} + i_t \otimes \widehat{c}_t,$$
$$h_t = o_t \otimes \tan h\left(c_t\right). \tag{5}$$

Here, i_t, f_t, o_t are the input gate, the forgetting gate, and the output gate, respectively, and the value range is $[0,1]$, σ is the sigmoid function, and $\otimes$ represents the element multiplication. The hidden state h_t represents the output information of the LSTM unit at time step t.

Because closely related project pairs may appear in L, T at the same time, different from previous studies, this article applies inner product between input item embedding and output item embedding to capture the item relationship between L, T:

$$\sum_{e_i \in S_{u,l}} e_i^T \cdot Q, \tag{6}$$

where $Q \in R^{d\times N}$ is the output item embedding, and the sum of inner product results captures the cumulative item-item relationship scores from each item in L to all other items.

Because the training data come from implicit feedback from users, this article optimizes the proposed model through Bayesian personalized sorting:

$$\arg\min \sum_{\left(u,L_u,i,k\right)\in D} -\log\, \sigma\left(\widehat{r}_{u,i} - \widehat{r}_{u,k}\right) + \Omega. \tag{7}$$

Here, L_u represents the continuous term of a user u in $|L|$, k represents the negative term of random sampling, and Ω is the regularization term to prevent overfitting. By minimizing the objective function, the partial derivatives of all parameters can be calculated by back propagation and gradient descent. At the same time, the Adam optimizer is used to automatically adjust the learning rate in the process of model learning.

Therefore, the PE teaching in preschool normal schools should constantly update the teaching content, so that students can lay a good foundation of knowledge. In teaching practice, it is necessary to provide students with opportunities for in-depth preschool education activities and practice, so that they have stronger social adaptability and at the same time can also integrate theory with practice and continuously improve their theoretical level in practice. In addition, the PE curriculum in preschool normal schools should reflect the characteristics of the school, add special courses in combination with the nature, characteristics, conditions, and personnel training objectives of the school, and provide more choices of courses to meet the diversified needs of students' future development.

4. Results Analysis and Discussion

4.1. Theoretical Results and Analysis. Following visits to and consultations with several schools, eight of the ten schools surveyed have developed their own PE curriculum in accordance with the National General Universities PE Teaching Guidelines, and some preschool normal schools have developed their own curriculum in accordance with their own operating conditions and actual teaching situation. Figure 4 depicts the statistical results of the selected public curriculum questionnaire in PE class.

The curriculum of the old syllabus finally determined by the questionnaire is basketball, gymnastics, track and field, volleyball, and so on. The final curriculum of the new syllabus is basketball, badminton, table tennis, yoga, physical training, sports theory, theoretical investigation, swimming, sports dance, gymnastics, track and field, and soft volleyball. The statistical results of the questionnaire selected for the test index of students' physical quality in preschool schools are shown in Figure 5.

The final test methods of students' physical fitness determined by the questionnaire are 30-meter run, shot put in place, shot put back, bench push, squat, and standing long jump.

Teachers must devise sports games and thoroughly explain the rules to children in accordance with the syllabus's requirements. Teachers only need to explain and emphasize the scope of the children's activities and the game rules when playing games. Teachers must re-explain the content of their lessons and determine the most effective teaching techniques. Recognize the parts that are difficult for children to master on a technical level. Children have already gained active experience and a new understanding of the teaching content as a result of this process. Teachers should also pay close attention to the standardization and details of the experience process, and set higher expectations for the children. Observe the children's experiences as bystanders and make a note of the characteristics of a few of the observations. For example, if a teacher needs to get closer to the students, he can squat and pass on the content of the lesson to the students.

4.2. Analysis of Personalized POI Recommendation Model of Preschool PE Curriculum. In order to accurately evaluate the performance of each model in POI recommendation tasks, this article adopts two evaluation indexes, Recall@K (recall rate) and MRR @ k (mean recall rank), which are widely used in recommendation systems. k represents the length of the recommendation list. In order to accurately evaluate the influence of different list lengths on recommendation results, this article selects the values of each evaluation index when the lengths of the report list are 2, 6, and 10.

In order to determine the appropriate hidden state dimension of the CAGRU structure in the model, this article uses the training set and the verification set to select the hidden state dimension parameters of the two models under the same other parameters. Take the experiment of CAPR model on Foursquare dataset as an example, and the results are shown in Figures 6 and 7.

It can be seen that with the increase in the hidden state dimension, the performance of the model gradually gets better, but under the condition that the number of

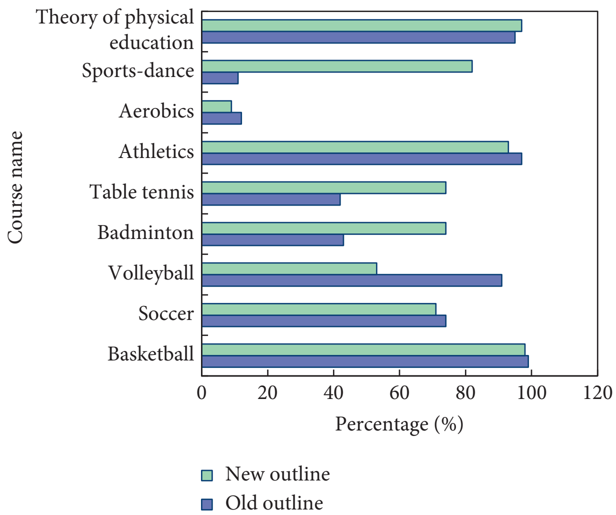

FIGURE 4: Questionnaire statistical results.

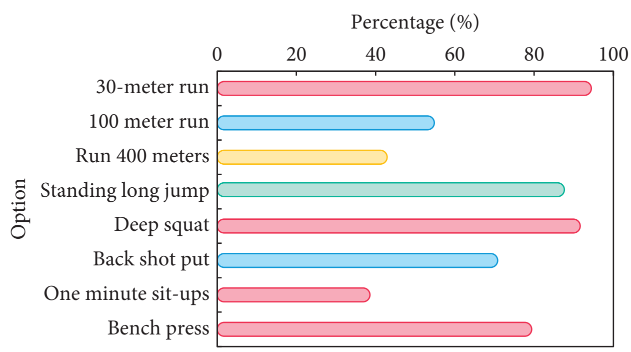

FIGURE 5: Test index selected questionnaire statistical results.

dimensions increases unchanged every time, the improvement speed of the model performance gradually slows down or even stops improving.

The increase in the hidden state dimension will not only bring greater computational complexity, resulting in higher training overhead, but also make the model structure very complicated, which is prone to overfitting problems when the existing data are insufficient. According to the above analysis, in order to balance the model performance and training cost, this article sets the hidden state dimension of the model to 240 dimensions.

When the learning rate of the optimization algorithm is too high, the model loss will drop rapidly at the beginning, but then it will fluctuate greatly, in which case it will not converge. When the learning rate of the optimization algorithm is small, the loss of the model decreases very slowly, and it will take many iterations to achieve the desired effect.

The comparison model mentioned above and CAPR and LSAPR models proposed in this article are trained and tested on two datasets, respectively. Figure 8 shows the statistics of experimental results of different models on two datasets, all of which are obtained by averaging multiple experiments.

The majority of the indexes of the two models on two real datasets exceed the currently popular POI recommendation model or sequence-aware recommendation model,

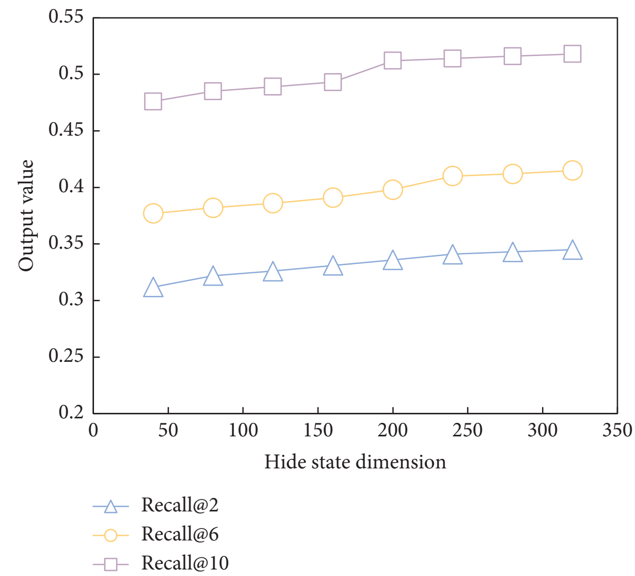

FIGURE 6: Hiding the experimental results of state dimension parameter selection (Recall@K).

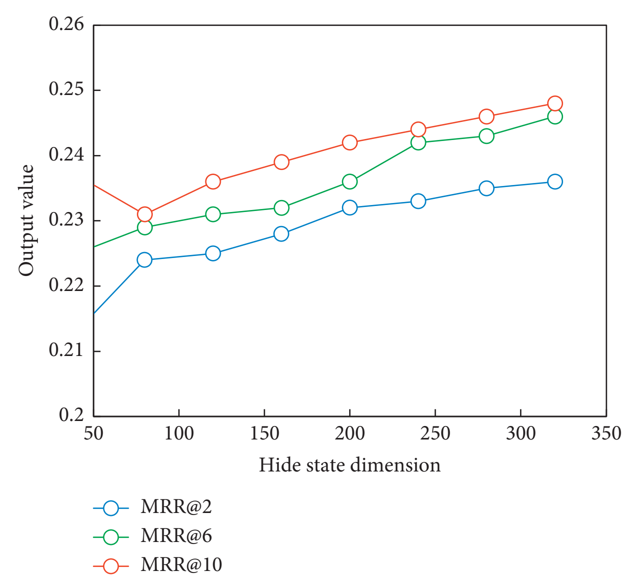

FIGURE 7: Hiding the experimental results of state dimension parameter selection (MRR@K).

according to the analysis of the experimental results in Figure 8. In general, as the length of the recommendation list grows longer, the model's performance on two evaluation indexes improves. Take the model's performance on a 10-item recommendation list as an example for analysis. In general, the CAPR and LSAPR models proposed in this article outperform the comparison model in each of the two datasets' indexes. The experimental results show that the CAPR and LSAPR models can more effectively capture users' long- and short-term preferences, and they can perform well in POI recommendation tasks regardless of whether the users are cold start or personalized recommendations.

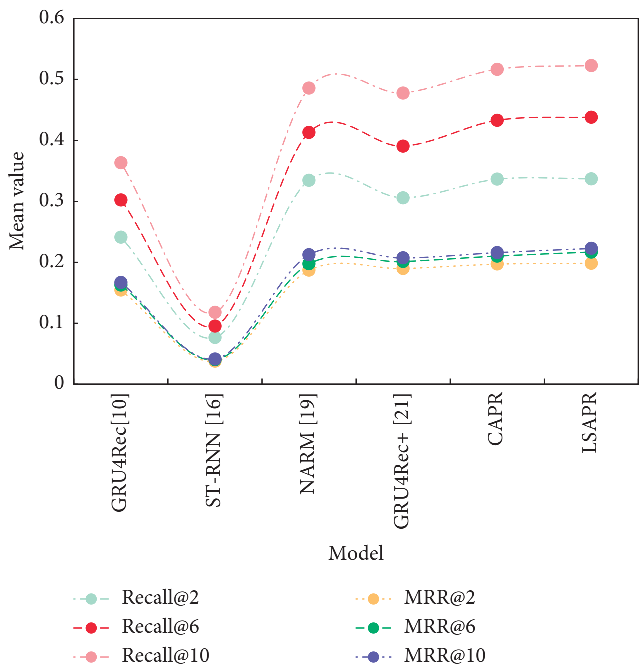

Figure 8: Foursquare comparative experiment results.

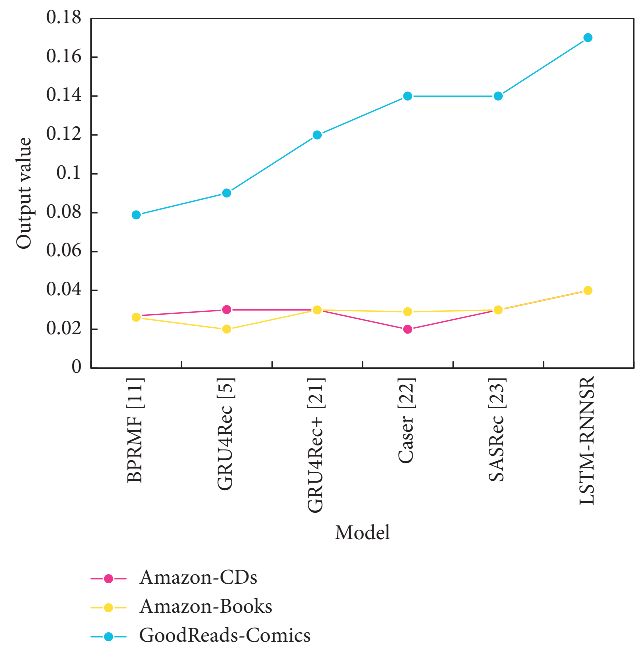

Figure 9: R@8 comparison of different recommendation algorithms.

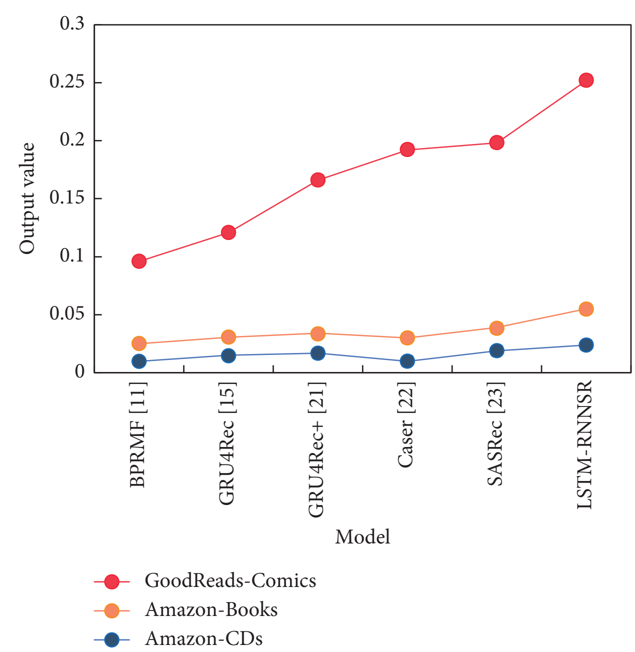

Figure 10: N@8 comparison of different recommendation algorithms.

4.3. Analysis of the Recommendation Model of Preschool PE Curriculum Sequence. In order to verify the recommendation performance of the model proposed in this article, the experiment will compare and analyze the LSTM-RNNSR model in this article with the commonly used recommendation models in three real datasets with different fields and sparsity.

In this article, Recall@k and NDCG@k are used to evaluate the recommendation accuracy of each model. For each user, Recall@k(R@k) represents the percentage of the first k recommended items that appear in the scoring items, and NDCG@k(N@k) is the normalized cumulative loss gain of the first k recommended items, taking into account the position of the correct recommended items.

In this article, six groups of algorithms are tested on Amazon-CDs, Amazon-Books, and GoodReads-Comics datasets, and the difference between the score prediction results of R@8 and N@8 is analyzed. The comparison results of the LSTM-RNNSR model with five comparison algorithms of R@8 and N@8 are given in Figures 9 and 10 respectively.

It can be seen from the table that the recommended performance of the LSTM-RNNSR model on Amazon-CDs, Amazon-Books, and GoodReads-Comics datasets exceeds all comparison methods.

The model LSTM-RNNSR in this article achieves better recommendation performance than SASRec. The main reasons are that SAREC only uses part of the user's historical interactive data, which may lead to the inability to fully learn users' long-term interests, and that SAREC does not explicitly consider the relationship between projects.

Based on BPRMF, this model uses the RNN and AM to capture users' short-term interest preferences and at the same time considers the relationship between users' historical interaction items and prediction items, thus making the model LSTM-RNNSR obtain better recommendation performance.

The effects of different values of item embedded dimension d on the model on Amazon-CDs dataset are shown in Figure 11.

It can be seen from Figure 11 that when the embedded dimension of the project is too small, the model recommendation performance is not good at this time, because the dimension of the project is too small to model the potential characteristics of the project. With the increase in the item embedding dimension d, the model performance gradually improves and becomes stable.

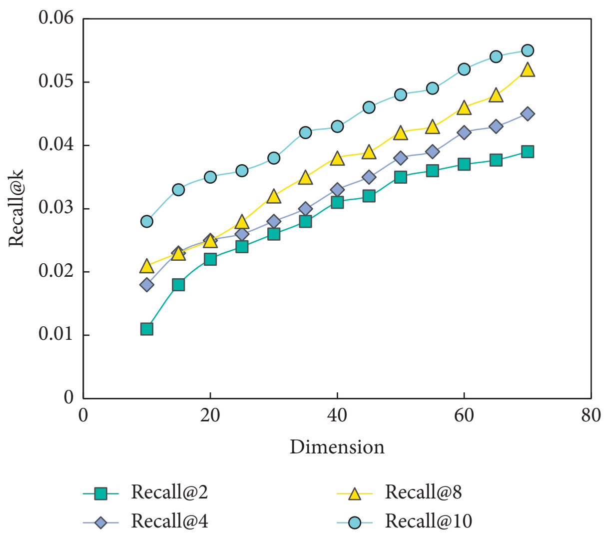

Figure 11: Change in embedded dimension.

5. Conclusion

The teaching status of preschool normal schools can be changed, and the teaching quality and effect can be improved, so that the PE curriculum in preschool normal schools can truly adapt to the future development of students, laying the foundation for cultivating more talents needed by society and improving the quality of preschool education. Based on the improved structure GRU of the RNN and the sequence nature of POI sign-in data, this article designs and implements two POI recommendation models: LSAPR and LSTM-RNNSR. To achieve the goal of personalization, the model uses all of the users' POISSs, as well as the long-term and short-term AM LSAs to more accurately capture the long-term and short-term preferences of users reflected in POISSs. The experimental results of the method proposed in this article on three real datasets with different categories and sparsity show that it outperforms the currently used sequence recommendation methods.

Because of the scarcity of data, the performance of the POI recommendation model may be severely limited. We hope to continue exploring the impact of data sparsity on model performance in the next step and to propose solutions to the problem of data sparsity.

Data Availability

The data used to support the findings of this study are included within the article.

Congestion and complexity in the field of highway transportation have risen steadily in recent years, particularly because the growth rate of vehicles has far outpaced the growth rate of roads and other transportation facilities. To ensure smooth traffic, reduce traffic congestion, improve road safety, and reduce the negative impact of air pollution on the environment, an increasing number of traffic management departments are turning to new scientifically developed technology. The urban road traffic is simulated by nodes and sidelines in this study, which is combined with graph theory, and the information of real-time changes of road traffic is added to display and calculate the relevant data and parameters in the road. On this foundation, the dynamic path optimization algorithm model is discussed in the context of high informationization. Although the improved algorithm's optimal path may not be the conventional shortest path, its actual travel time is the shortest, which is more in line with users' actual travel needs to a large extent.

1. Introduction

With the rapid development of global economy, the demand for transportation is becoming more and more urgent. However, the possibility of building and expanding roads in big cities is becoming smaller and smaller, and it is impossible to meet the traffic demand only by relying on the construction of infrastructure. Urban traffic congestion has become increasingly global [1]. In recent years, the congestion and complexity in the field of highway transportation are increasing day by day, especially the growth rate of vehicles has far exceeded that of roads and other transportation facilities [2]. More and more traffic management departments rely on today's scientific development of new technologies to ensure smooth traffic, reduce traffic congestion, improve road safety, and reduce the adverse impact of air pollution on the ecological environment [3]. In many cities, the road planning time is earlier, which cannot meet the requirements of modern traffic, resulting in some roads being very crowded. If there is a traffic accident on the main road or road renovation, it will cause long-term congestion and form a certain traffic vicious circle [4]. The intelligent transportation system (ITS) is to make full use of modern communication, positioning, sensors, and other information-related technologies [5] to reduce traffic congestion, improve road throughput, improve traffic safety conditions, and quickly realize the collection and transmission of traffic information, so as to achieve the purpose of reasonably allocating traffic resources and improving ground traffic conditions [6, 7]. Path optimization is the most basic and key part of the dynamic path guidance system. Its main function is to realize the path planning function for users before and during travel, guide vehicles to reach the destination along the optimal route, and realize real-time vehicle guidance based on urban road network information and real-time road traffic condition information [8, 9].

With the rapid development of information technology [10, 11], the development of urban motorization has been continuously promoted. The traffic development of large and medium-sized cities in the world gradually presents problems in road congestion, traffic congestion, and environmental pollution [12]. The resulting traffic accidents and environmental pollution not only inhibit the sustainable development of urban economy to a great extent but also affect the quality of life of urban residents [13]. Traffic jam has seriously affected the operation effect of the urban traffic system, affected the development speed of the city, and caused a great waste of social resources. Even the most advanced traffic system designed and deployed ten years ago cannot adapt to the current reality [14]. After entering the 21st century, due to the influence of geographical environment and historical factors, the available land area of the city continues to shrink, but the number of vehicles continues to surge, so it is impossible to increase the number of roads in the city indefinitely [15]. Traffic management departments increasingly rely on today's scientific development of new technologies to ensure smooth traffic, improve road safety, and reduce the adverse impact of traffic congestion and air pollution on the ecological environment [16]. Combined with graph theory, this study simulates urban road traffic as nodes and sidelines, adds the real-time change information of road traffic, and displays and calculates the relevant data and parameters in the road. To delete the network factors irrelevant to path selection, so as to save the storage space of road network simulation expression, establish the association of storage node elements and line elements, respectively [17].

As a complex system engineering, urban road traffic intelligent control mainly involves disciplines including automation control, engineering technology engineering, system engineering, and optimal dispatching [18]. Because it has many factors such as randomness, complexity, and uncertainty, people cannot establish an accurate mathematical model, so they must rely on intelligent methods [19]. In the transportation system, urban transportation is a very important part. The intelligent development of urban transportation is an important component of the whole intelligent transportation system and the primary task. At the same time, the intelligent development of urban transportation is also a hot spot in the field of traffic intelligent control [20]. The path optimization algorithm studied in this study is an essential and important part of the intelligent transportation system. Its role is to provide path guidance to travelers, and the provided path is the optimal path based on real-time traffic information. In this way, it can reduce the residence time of vehicles on the road, so as to avoid traffic congestion, congestion, and improve urban traffic.

The remainder of the study is laid out as follows. In Section 2, background study and literature review are elaborated. The methodology is discussed in Section 3, followed by experimental setup and results in Section 4. Finally, Section 5 concludes the study.

2. Related Works

The intelligent transportation system can effectively use existing transportation facilities or transform existing facilities and comprehensively use various modern technologies to integrate people, vehicles, roads, and related environments into a system, so that it can play an intelligent role, which can effectively alleviate traffic congestion, ensure smooth traffic, improve road capacity, and reduce the incidence of traffic accidents and a large amount of energy consumption [21, 22]. The urban road network model in the study by Yang and Daoyuan [23] was created using mathematical dynamic programming, which greatly simplified the calculation of the optimal path. Pan and Ma [24] proposed that historical data be added to optimal route selection based on predecessors and that historical data and current road traffic conditions be used to consider all problems in road transportation. Adjustments must be made when traffic conditions change dramatically in order to achieve the best route selection and calculation. However, due to the difficulty in obtaining historical data, this idea is limited and cannot be implemented in practice. In the study by Fulu et al. [25], the Dijkstra algorithm is proposed to realize the optimal route selection in an urban intelligent transportation system, based on the problem of urban traffic. However, selecting and setting parameters in this algorithm is extremely difficult, and traffic lights at road intersections are not taken into account. The use of closed-loop adaptive methods to solve the optimal path selection problem based on urban traffic system problems has been proposed in the study by Sanchez and Herrera [26], so that road traffic conditions can be accurately evaluated according to real-time road conditions, and the optimization calculation function can be used to calculate the optimal path. Calculate the best route. This method performs well in real-time. Because the objective function and linear programming are used in the calculation of the optimal path, the selection of the optimal path cannot achieve real-time effects when the weight of the linear programming changes, affecting the system's accuracy. A sequential algorithm for finding the average shortest path was proposed in the study by Xia [27]. This algorithm can reduce the computational complexity of optimal path selection while increasing its efficiency.

From the traveler's point of view, on the one hand, urban traffic construction gives them more choices in the choice of travel routes. On the other hand, better traffic conditions also reduce the incidence of urban traffic accidents, which not only improves the lives of residents but also improves the civilization of cities. On the basis of previous studies, this study first discusses the algorithm of static optimal path and its complexity, analyzes the traffic confidence and entropy, explains the complexity of traffic information and its complexity through the concept of entropy, and gives the influence of traffic information on traffic behavior. On this basis, it discusses the dynamic path optimization algorithm model under the condition of high informationization.

3. Route Selection Model Based on Real-Time Traffic Information

3.1. Road Network Model and Data Storage Structure. With the rapid growth of urbanization, urban traffic efficiency is becoming increasingly important, and path planning is becoming increasingly important in daily life. Path planning is the process of finding the best path through traffic by artificially designing the system, so that the destination can be reached in the shortest time or by driving the shortest distance. Because the starting point and destination of our travel are both from two nodes in this network and the optimal path can be selected through the search algorithm [28], we should first form a relatively complete network based on the conditions of urban roads, so that we can search for the optimal path in this network. Create a road network model that corresponds to the real-world road network. A road network model can be constructed as follows:

$$\begin{cases} G = (V, E, W), \\ V = \{v_i | i = 1, 2, \ldots, n-1\}, \\ E = \{\langle v_i, v_j \rangle | v_i, v_j \in V\}, \\ W = \{w_{ij} | \langle v_i, v_j \rangle \in E\}. \end{cases} \tag{1}$$

Among them, V represents the set of vertices, E represents the set of edges (sections), and sections $\langle v_i, v_j \rangle$ and $\langle v_j, v_i \rangle$ are the two different sections. W represents the weight set of the road section $\langle v_i, v_j \rangle$, and its attribute value can be selected according to different optimization goals. For the actual urban road network, the traffic information in two directions of the same road section is generally different, so the directed graph is used to express the actual road network. Directed graph increases the storage capacity of the road network, but it can express the real information of outlet network more comprehensively.

The unit for traffic volume is vehicles/h, and it refers to the number of vehicles passing by per unit time on a given road section. There are significant differences in traffic volume at different road sections or intersections due to differences in population density in different parts of cities. The ratio of the time spent by a car passing through a fixed road section to the total time is known as the time occupancy rate:

$$\theta_{ij}(t) = \frac{1}{T} \sum_{k-1}^{N} t_k, \tag{2}$$

where $\theta_{ij}(t)$ is the time required to travel on the road composed of node i and node j in the period t. T is the travel time interval, N is the total number of vehicles passing the road segment in the time period T, and t_k is the time for the vehicles to pass the test point.

There are many ways to calculate the travel time of the road section in path planning. Generally, the relationship between the three quantities of road traffic flow Q, speed V, and density K is used to calculate the average speed. $V = Q/K$, pass. The average speed can be calculated as the travel time $T = L/V$. In the model, the relationship between the time t and the traffic occupancy rate $\theta_{ij}(t)$ on the research section and the average traffic density $K_{ij}(t)$ of vehicle operation can be measured as

$$K_{ij}(t) = \frac{\theta_{ij}(t)}{L_e}. \tag{3}$$

In the formula, L_e is the length of the test vehicle, so the number of vehicles passing in this time, $S_{ij}(t)$, can be calculated as

$$S_{ij}(t) = L_{ij} \cdot K_{ij}(t), \tag{4}$$

where L_{ij} is the length of the road section connected by node i and node j.

In the route planning, the BPR function can be used to calculate the road travel time of the vehicle:

$$w_{ij}(t) = t_0 \cdot \left[1 + \alpha \left(\frac{Q_{ij}(t)}{C_{ij}}\right)^{\beta}\right], \tag{5}$$

where t_0 is the zero-flow impedance, that is, when the traffic on the road section is zero, it is the time required for the vehicle to travel, $Q_{ij}(t)$ is the traffic volume of the road section connected by node i and node j, and C_{ij} is the number of vehicles passing through the intersection in a unit time. C_{ij} can be regarded as a fixed value when traffic congestion occurs at an intersection due to control lights, but the actual traffic flow $Q_{ij}(t)$ is a dynamically changing amount, that is, C_{ij} has nothing to do with $Q_{ij}(t)$. α and β are the retarding functions. In the traffic flow allocation procedure, the values of α and β parameters are $\alpha = 0.15$ and $\beta = 4$, respectively.

The delay time of the road section can be measured by the detector in the system. At the same time, the occupancy rate $\theta_{ij}(t)$ and the traffic flow $Q_{ij}(t)$ of the road section can be measured, and the traffic density $S_{ij}(t)$ can be calculated according to the occupancy rate $\theta_{ij}(t)$. The length of the road segment to be solved is constant, so the number of vehicles EE can be calculated. Finally, $S_{ij}(t)$ and $Q_{ij}(t)$ are combined to solve the delay time $d_{ij}(t)$. Then, compare the delay time $d_{ij}(t)$ with all the green light times of the intersection to calculate the waiting time D_{ij}, so that the delay time of the road section can be calculated at the end:

$$d_{ij}(t) = \frac{S_{ij}(t)}{Q_{ij}(t)} = \frac{\theta_{ij}(t) \cdot L_{ij}}{Q_{ij}(t) \cdot L_e}, \tag{6}$$

where $Q_{ij}(t)$ is the traffic flow of the road section connected by node i and node j, and $Q_{ij}(t)$ and $\theta_{ij}(t)$ can be measured by the detector in the system. The delay time of the road section between different nodes i and j can be calculated by the following formula:

$$\begin{aligned} M &= \mathrm{int}\left[\frac{d_{ij}(t)}{t_u}\right], \\ C_{ij} &= \frac{t_u}{\lambda}, \end{aligned} \tag{7}$$

where C_{ij} is the entire signal period, λ is the green signal ratio, and $d_{ij} = M \cdot C_{ij}$.

Many factors influence actual traffic efficiency, such as traffic flow and road conditions, which directly limit vehicle traffic efficiency. As a result, these factors should be taken into account in the best route selection model, with traffic density and flow playing a key role. Because these two factors are random, unlike the length of a road section, they are fixed for a long time, and they can be factored into the optimal path selection to improve the system's accuracy.

3.2. Dynamic Path Optimization Algorithm. In the process analysis, first, the system administrator creates the station information database and inputs the number, name, longitude and latitude of the traffic station, and the distance between stations in the database. The system administrator is mainly responsible for maintaining the database [29]. After the database is generated, the relevant users can query the optimal path between sites in the query interface, and the users input the name of the starting site and the name of the target site [30]. The system calls the optimized optimal path algorithm to get the optimal path and displays the optimal path result on the display interface. Figure 1 shows the system flowchart.

Express the dynamic road network as $G = (V, E, W)$, where $V = \{V_1, V_2, \ldots, V_n\}$ is a finite node set, which corresponds to the road nodes of the road network. $E = \{V_i, V_j | V_i, V_j \in V\}$, corresponding to the actual road section between road nodes. $W = \{w_{ij}(t), d_{ij}(t) + D_{ij}\}$. Among them, $E = \{V_i, V_j \in V\}$, which means the time it takes for the vehicle to pass through section (V_i, V_j) at any moment.

$w_{ij}(t)$ is the travel time of the road section connected by node i and node j, and the delay time $d_{ij}(t)$ is the road section between nodes i and j, where D_{ij} is the signal waiting time between nodes, and t_u is the transit time at the intersection. $t_u = 30\text{s}$ when $u = 1$. $t_u = 60\text{s}$ when $u = 2$. $t_u = 90\text{s}$ when $u = 3$.

The objective function of the model is

$$\min T = \sum_{i=1}^{N} \sum_{j=1}^{N} x_{ij} \cdot \left\{ \delta w_{ij}(t) + (1 - \delta)\left[d_{ij}(t) + D_{ij} \right] \right\}, \tag{8}$$

$w_{ij}(t) > 0$, $d_{ij}(t) > 0$.

Decision variables are

$$\begin{cases} 1, & 0 < d_{ij}(t) \leq n \cdot t_u \\ 0, & d_{ij}(t) > n \cdot t_u, \end{cases} \tag{9}$$

$$\delta = \begin{cases} 1, & 0 < d_{ij}(t) \leq n \cdot t_u, \\ 0, & t_u < d_{ij}(t) > n \cdot t_u. \end{cases} \tag{10}$$

The formula (9) represents the duration of n green lights, and the size of n is determined by the driver. According to these relations, the time spent on different road sections can be well calculated, and the route is dynamically planned due to the change of the number of signal lights and the change of traffic flow, so as to select an optimal driving route [31].

Aiming at the problem of dynamic path selection, the specific execution steps are as follows. Step 1: initialization, setting the initial node and the destination node. Determine the time occupancy rate, the update time interval of traffic flow, and the size of n. Step 2: find the node adjacent to the starting point, record the node, and calculate the travel time $T_{ij}(t)$ of the road section connected to the node. Step 3: compare $T_{ij}(t)$, if $T_{ij}(t) < t_u$, the road section is relatively smooth, and $T_{ij}(t) = w_{ij}(t)$. If $t_u < T_{ij}(t) \leq nt_u$, then $T_{ij}(t) = d_{ij}(t) + D_{ij}$. If $T_{ij}(t) > nt_u$, the road section is relatively congested, discard the node, and return to Step 2. Step 4: when the next node selected is the destination node, the selection of a set of feasible paths is completed. Step 5: compare multiple groups of feasible paths and take the minimum value.

4. Result Analysis and Discussion

After entering the system, the system administrator first creates the database. Mark the distance values of traffic stations and traffic sections in the database and mainly set the distance values of traffic sections in a straight line way. After the database is created, the user can query the optimal path between traffic stations, input the initial station and the target station, calculate the optimal path according to the optimal path algorithm, and display the optimal path result [27].

During the training phase of the model, it will be tested on the verification set regularly. After continuous analysis and comparison, we finally chose 60 training times as the best training times under the condition that the batch size is 30. Figure 2 shows the trend of accuracy on the verification set along with the training process. Therefore, we can know that increasing the training times within a certain range can improve the performance of the model. On the contrary, too many training times will lead to overfitting, and the performance of the model will decrease.

It can be seen that the accuracy of the verification set of the algorithm is increasing with the convergence of the model, which verifies the correctness of the convergence of the network and the effectiveness of the network for feature extraction.

Adjust the initial model horizontally and vertically. Figure 3 shows the accuracy curve of the model, and Figure 4 shows the loss function curve; with the increase of training times, the accuracy of the network is increasing, and the loss function value is decreasing gradually, and the network basically converges after training 73 times.

During training, the loss function reflected by verification is gradually increasing rather than decreasing, which indicates that the algorithm training has entered the trap of local optimization. Figure 5 shows the relationship between iteration times and normal training and overfitting training.

Combined with the test results of test materials, the correlation between subjective evaluation results and objective evaluation results is 92.08%.

Figures 6 and 7 show the fitting diagrams of subjective evaluation results and objective evaluation results of training samples and test samples, respectively. Combined with the test results of test materials, the correlation between subjective evaluation results and objective evaluation results is 92.07%.

The iterative training is stopped when the training set's fitting degree reaches 98.55%. The test set has a fitting degree of 92.17%, indicating that the model's quality evaluation result is similar to the subjective quality score. When there is not much traffic, the travel time can be very short. When a vehicle approaches a particular road section, for example, it comes to a complete stop due to traffic congestion. The travel time is even longer than the traffic volume. As a result, in

order to effectively improve traffic efficiency, we should collect real-time traffic conditions on the road when planning routes.

5. Conclusions

A key component of an intelligent traffic system is the intelligent traffic management and control system. In order to improve and perfect the intelligent traffic management scheme, the urban intelligent traffic management and control system combines various signal monitoring methods to obtain real-time traffic information and constructs a scientific and reasonable intelligent traffic management framework. The optimal route planning algorithm is the core technology of the route guidance system in ITS, so it is of great practical significance to study it. The intelligent transportation system (ITS) is recognized as the best way to solve the three major problems in the field of international transportation. The intelligent traffic management and control system combines information transmission, allowing relevant management personnel and actual users of the intelligent traffic management and control system to obtain the traffic management scheme and real-time traffic road information in a timely and effective manner, maximizing the efficiency of intelligent traffic management. The main feature of the dynamic path selection problem is that the path selection conditions change over time. Because the majority of the traffic parameters used in the analysis are randomly changed, it is more appropriate to use a dynamic model when analyzing urban road congestion. These influencing factors should be taken into account when designing the road congestion analysis model to improve the accuracy of the analysis results.

Academic Editor: Tongguang Ni

In China, universities are important centers for SR (scientific research) and innovation, and the quality of SR management has a significant impact on university innovation. The informatization of SR management is a critical component of university development in the big data environment. As a result, it is crucial to figure out how to improve SR management. As a result, this paper builds a four-tier B/W/D/C (Browser/Web/Database/Client) university SR management innovation information system based on big data technology and thoroughly examines the system's hardware and software configuration. The SVM-WNB (Support Vector Machine-Weighted NB) classification algorithm is proposed, and the improved algorithm runs in parallel on the Hadoop cloud computing platform, allowing the algorithm to process large amounts of data efficiently. The optimization strategy proposed in this paper can effectively optimize the execution of scientific big data applications according to a large number of simulation experiments and real-world multidata center environment experiments.

1. Introduction

With unprecedented power, information technology is promoting the continuous change of thinking mode and behavioral habits recognized in human daily production and life [1]. Big data technology finds out the relevance of data and extracts valuable information through the correlation analysis of data resources such as SR (scientific research) management system, financial system, personnel system, large-scale scientific literature database, and patent database based on the Internet, which can provide an extensive and scientific theoretical basis for traditional expert qualitative decision management [2, 3]. Because most of this knowledge comes directly from inside the database, it is less restricted and influenced by external resources, has relative independence, and has great guiding significance for SR decisions.

Since university informatization is implemented at the end of the last century, many universities have established and operated various database systems. However, the database systems existing among various departments are not related; thus, a number of information islands are formed in the whole school, which not only lead to a large amount of resources and a serious waste of funds in the school but also bring difficulties to the intensive management of teaching and reasonable study. The SR management system also has its own characteristics [4]. The truly idealized university SR management system is a platform that fully realizes the networking of university SR management, and based on it, forms a data center and management communication platform that can be updated instantly, provides comprehensive and accurate SR information for schools, provides a powerful reference for school leaders to make relevant SR decisions, provides convenient, quick, and thoughtful services for all school teachers to carry out SR activities, and provides great convenience for SR managers [5–8]. With the increasing dependence of SR decision-making system on various data, it is very urgent to actively apply big data technology in university SR management informatization; therefore, more attention should be paid from all aspects, constantly explore and innovate, fully embody the role of big data, and provide assistance for the development of university SR management informatization.

First, A real-time SR business system is established in colleges and universities to improve SR departments' daily business efficiency. Second, an SR decision analysis system is created to ensure that a large amount of SR historical data and current operational data is effectively managed. Then, efficient algorithms are proposed to solve model problems, reduce data communication between data centers for scientific workflow tasks, and thus improve the execution performance of scientific big data applications.

The traditional data mining algorithm and its standalone environment have encountered performance bottlenecks, which can no longer satisfy the processing of massive data. Hadoop is a very simple distributed open-source computing platform, which has excellent advantages such as high efficiency, high reliability, high fault tolerance, and high scalability. Therefore, this paper has improved the NB classification algorithm, and based on the Hadoop cloud platform, it provides a parallel running environment for the data mining classification algorithm.

2. Related Work

Although managers can directly obtain clear information by using tools such as query, information such as relationships and trends hidden in a lot of data cannot be obtained from the data surface [9]. In literatures [10, 11], after analyzing the problems of the application method theory of the traditional management information system in the C/S mode, the idea of improvement is put forward. Literature [12] holds that the supervision of university research funds requires that each project team should have at least two supervisors. However, due to the great correlation between supervisors and research project personnel, supervision is difficult to achieve the expected effect. Literature [13] holds that there are some problems such as low utilization rate of fixed assets and insufficient protection of intangible assets.

Literature [14] holds that because there is no scientific budget accounting system at the national level, researchers and financial personnel have no calculation basis, so they can only calculate by experience, which leads to the incomplete and untrue content of budget preparation and cannot well reflect the research cost of the whole process of SR. Literatures [15, 16] hold that there are two problems in the performance of university SR projects: first, the lack of standards for performance evaluation of SR projects makes the overall performance evaluation unable to be effectively reflected; second, the lack of professionalism in SR content in the performance appraisal group leads to the lack of persuasiveness in performance appraisal results. Literature [17] holds that the person in charge of SR should establish the consciousness of budget management and attach importance to the role of budget in the management of SR funds. Literature [18] holds that internal control should be taken as the starting point to improve the management level of SR projects and the use efficiency of funds. Literature [19] holds that strengthening the performance evaluation of SR funds should start from two aspects: the use benefit evaluation of SR funds and the benefit of SR work. Paying attention not only audits compliance, legality, rationality, and authenticity of the income and expenditure of SR projects but also comprehensively evaluates their economic benefits, technical benefits, and social benefits. In the aspect of performance evaluation of research funding, literature [20] holds that the evaluation method combining individuals and teams can be adopted, which should pay attention to both the cultivation of individual abilities and the collective performance appraisal so as to realize the circular development of individual interests and teams.

With the help of data mining technology, the university SR management innovation information system studied in this paper has actually solved the problems of multilevel characteristics and weight distribution of indicators, uncertainty of evaluation results, and deep mining [21] of evaluation data in the process of establishing the evaluation system, which makes the evaluation system more scientific, reasonable, and reliable.

3. Research Method

Construction objectives and system functions of the university SR management information system are put forward, and the overall design scheme of the system is designed. The NB classification algorithms are analyzed, and based on their advantages and disadvantages, improvements are made, and the SVM-WNB classification algorithm, a combination algorithm of SVM and WNB classification algorithm, is proposed. The related models and algorithms of data layout and task scheduling are researched, and a scientific big data application workflow management system is implemented.

3.1. Overall System Design Scheme. It combines B/S with C/S to form B/W/D/C/S (browser/web/database/client/server) architecture [22], and users can access the database locally and remotely at the same time.

A real-time business subsystem of SR adopts the B/S mode. Users of other departments and Internet users access the database server of the network center to obtain the news released to the outside world, and the two servers make a differential copy at a certain time period to achieve the consistency of data.

According to the setting scheme of B/W/D/C architecture, the development platform of the system can adopt the following scheme, as shown in Figure 1.

Windows Server 2003 seamlessly integrates network management with the fundamental operating system, making the network simple to use and manage. Its internal architecture is entirely 32 bit, and there are multiple threads running at the same time, allowing it to support more powerful applications. At the same time, the system's stability is ensured by providing separate memory space for the operating system and application programs to avoid data conflict.

The system's database is SQL Server 2000, a relational database product with many features such as data query

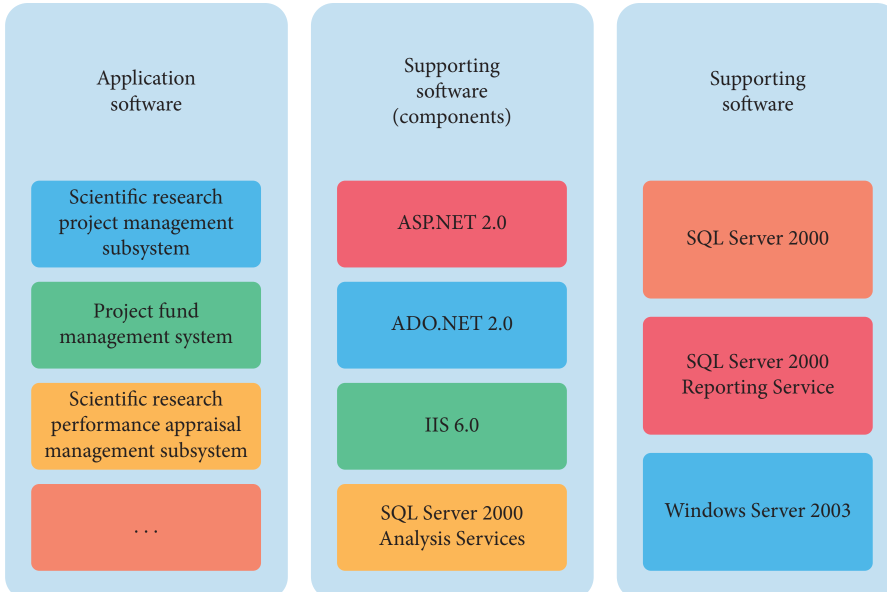

Figure 1: System development platform configuration.

diversity (SQL, XML), data integrity, high data access efficiency, concurrency control, transaction processing, data disaster protection, data diversification, security, and ease of use.

Our entire C/S mode SR decision analysis subsystem running platform is based on Visual Basic 6.0, which provides comprehensive component-based programming support, allows us to quickly build professional application systems for customers, reduces development and coding workload, and allows developers to focus more on communicating with users' needs.

3.2. Big Data Classification Algorithm. The basic idea of the NB (Naive Bayes) classification algorithm is simple and easy to understand, mainly assuming that the attributes between classes are independent of each other and they do not influence each other. Assuming that there are n classes $C_1, C_2, \ldots, C_n$, a sample X to be classified is given, then if and only if

$$P(C_i|X) > P(C_j|X), \quad 1 \le j \le n,\ j \ne i. \tag{1}$$

At this time, the sample X belongs to C_i; that is, the NB classification algorithm assigns the sample X to be classified to the class with the highest posterior probability.

Because the NB classification algorithm assumes that the attributes of classes are independent of each other, the classifier model of the algorithm is very simple, as shown in Figure 2, which is the structure diagram of the NB classifier model.

The NB classifier model structure is a tree-like Bayesian network, which includes a root node representing class variables and some leaf nodes representing attributes, among which attributes are independent of each other.

The NB classification algorithm also has its disadvantages. If the training sample set or the sample set to be classified has a very large scale, the cost of the NB classification algorithm will become very large.

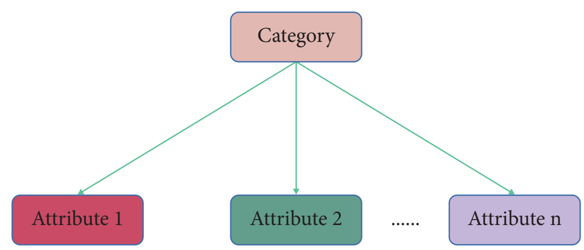

Figure 2: Structure diagram of NB classifier model.

The SVM (Support Vector Machine) algorithm often classifies samples incorrectly near the optimal classification hyperplane. For the NB classification algorithm, theoretically, the NB algorithm has very good efficiency and minimum error rate [23, 24], and the assumption of class condition independence reduces the computational cost of the algorithm. However, in practical application, such a hypothesis is impossible.

Based on the advantages and disadvantages of these two algorithms, the WNB (Weighted NB) classification algorithm can be obtained by improving the NB classification algorithm by weighting. Then, combining the two algorithms is considered to form a new algorithm, which is called the SVM-WNB (Support Vector Machine-Weighted NB) classification algorithm.

Assuming that w_k is the weight coefficient of attribute A_k, the WNB classification algorithm can be expressed by the following formula:

$$\underset{C_i \in C}{\operatorname{argmax}}\ P(C_i)\prod_{k=1}^{n} P(x_k|C_i)^{w_k}. \tag{2}$$

Here, two different methods are selected to calculate the weight coefficient w_k, and the average of w_{k1} and w_{k2} is obtained, respectively, and then, this average is taken as the final value of w_k, and w_k is put into the above formula for calculation. The following is a description of these two ways.

Assuming that the conditional attribute and decision attribute are X, Y, their mathematical expectations are $E(X), E(Y)$, and covariance, respectively:

$$\mathrm{Cov}(X,Y) = E(X,Y) - E(X)E(Y) = E[(X - E(X))(Y - E(Y))]. \tag{3}$$

The correlation coefficient ρ can be expressed as follows:

$$\rho = \frac{\mathrm{Cov}(X,Y)}{\sqrt{D(X)D(Y)}}. \tag{4}$$

The smaller the correlation coefficient ρ, the smaller the influence of condition attribute X on decision attribute Y. On the contrary, the larger the correlation coefficient ρ, the greater the influence of condition attribute X on decision attribute Y. Therefore, the correlation coefficient ρ can be used to weight the attributes, and w_{k1} can be expressed as follows:

$$w_{k1} = |\rho| = \left|\frac{\mathrm{Cov}(X,Y)}{\sqrt{D(X)D(Y)}}\right|. \tag{5}$$

The second method is relatively simple; that is, the weight coefficient is obtained by calculating the correlation probability, assuming that there is an attribute A_k, and a_k is the value of the attribute A_k. The number of attributes whose value is a_k can be expressed as $\mathrm{Num}(A_k = a_k)$. The attribute A_k takes the value of a_k, and the number belonging to class C_i can be expressed as $\mathrm{Num}(A_k = a_k \wedge C_i)$. w_{k2} can be expressed as follows:

$$w_{k2} = \frac{\mathrm{Num}(a_k \wedge C_i)}{\mathrm{Num}(A_k = a_k)}. \tag{6}$$

Two different methods are used to select the weight coefficient, and finally, the average value is taken, which makes the selection of the weight coefficient more reasonable. Different attributes and different weight coefficients effectively improve the accuracy of classification.

3.3. Scientific Workflow Scheduling. Scientific workflow scheduling is built on the foundation of scientific workflow and data center modeling, so the scheduling model must first model scientific workflow and data center and then consider the characteristics of scientific workflow scheduling and model workflow scheduling in a reasonable and accurate manner.

For the application of scientific big data, the DAG (Directed Acyclic Graph) model is usually used to represent the complex execution and data dependency among workflow tasks. In this study, the DAG model of scientific workflow is expressed as follows:

$$G = (V \leftarrow D \cup T, E, \omega, \theta), \tag{7}$$

where V represents the node set of the graph, including the dataset D and the task set T.

As shown in Figure 3, this study assumes that each task has an output dataset that can be used by many subsequent tasks.

At any level of coarsening l, in this paper, the optimized random connection weight matching method is used to aggregate the nodes of graph G_1. The nodes in the graph G_1 are randomly accessed. For each accessed node $v_i \in V^l$, if it has not been aggregated, the node v_j with the largest edge weight among the nodes connected to it and not aggregated is selected for aggregation.

If the edge connected with multiple nodes has the largest weight, the node with the best weight balance after aggregation is selected as follows:

$$f_{v_u} = (\tau(v_u) - \tau(k))^2, \tag{8}$$

where v_u is the vertex after aggregation, $\tau(v_u) = \omega_{cp}(v_u)/\sum_{v\in V}\omega_{cp}(v)/\omega_{st}(v_u)/\sum_{v\in V}\omega_{st}(v), \tau(k) = cp_k/\sum_{k\in K} cp_k/st_k/\sum_{k\in K} st_k$. The smaller the q f_{v_u} value, the better the balance.

In order to make the hybrid GA (genetic algorithm) search only the feasible solution space, the fitness function set by this algorithm is as follows:

$$\mathrm{fit}(I) = \frac{1}{2}\sum_{i=1}^{n}\sum_{j=1}^{n} c_{ij} * \sum_{k=1}^{K} Z_{ijk}. \tag{9}$$

The general idea of the algorithm is based on the concept of revenue, which is the reduction of the total division cost when the nodes are moved between the two divided parts. The benefits can be positive or negative, and the positive benefits indicate that the cost of mobile node division is reduced; it is consistent with the purpose of the study, which is the hope of this study; and negative returns need to be avoided.

$(G_t, G_{t'})$ denotes the two disjoint partitions, namely, $G_t \cap G_{t_l} = \varnothing$. The symbol $\mathrm{gain}(v_i, G_{t'})$ indicates the reduction of the division cost when the node $v_i \in G_{t'}$ moves to $G_{t'}$ gains; $\mathrm{gain}(v_i, G_{t'})$ can be calculated by the following formula:

$$\mathrm{gain}(v_i, G_{t'}) = g(v_i, G_{t'}) = g(v_i, G_t), \tag{10}$$

where $g(v_i, G_t)$ represents the sum of the weights of the edges connected with v_i in the partition G_t.

$v_i \in V_t$ iteration is moved to the appropriate data center according to the descending order of maximum profit until the partition meets the constraints of the corresponding data center.

4. Analysis and Discussion

4.1. Parallel Processing of Algorithm and Experimental Analysis. It is feasible to parallelize the SVM algorithm on the Hadoop cloud computing platform. In the NB classification algorithm, when the dataset or attributes is too large, the cost of storing samples and calculating probability is very huge, and the classification performance will be significantly reduced. However, because the data processed by the NB algorithm are mutually independent [25], and the process of calculating the probability of data is also mutually independent, the data

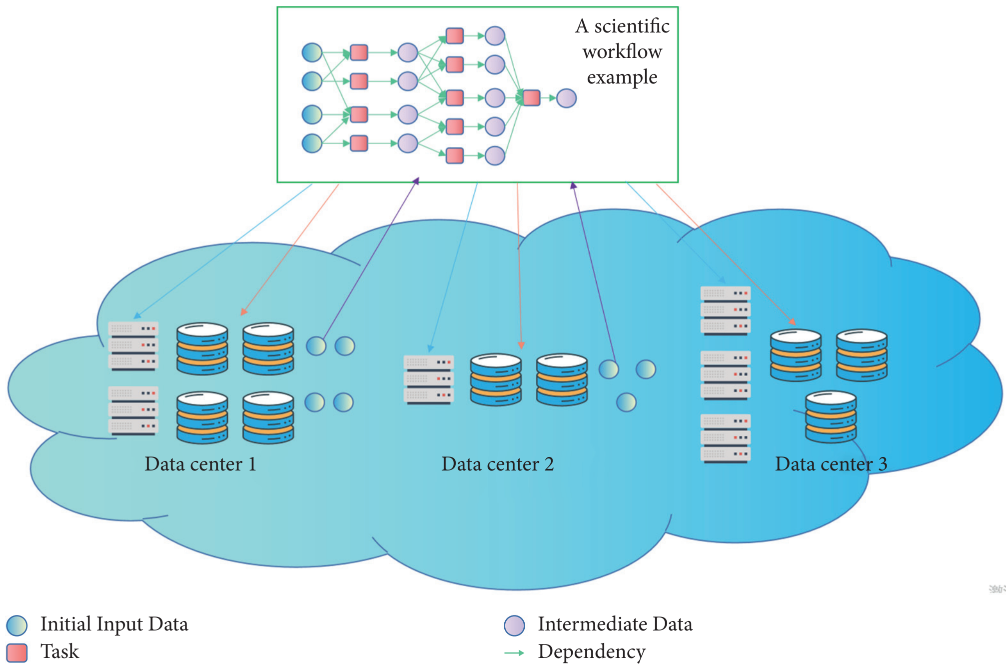

Figure 3: Schematic diagram of scientific workflow scheduling.

processed by the NB algorithm can be easily divided into balanced blocks. Through the above analysis, it is clear that the SVM-WNB classification algorithm is feasible.

In this experiment, the penalty parameter $C = 5$, the decision threshold $\xi = 0.6$, the radial basis kernel function parameter $g = 0.1$, and $K = 5$ in the nearest neighbor algorithm are selected, and mapred.map.tasks to 3 and mapred.reduce.tasks to 4 in Hadoop are set; that is, the number of maps is set to 3 and the number of reduce is set to 4.

For the multiclassification problem of the SVM algorithm, a one-to-one classification method is adopted (69), and $n(n-1)/2$ SVM classifiers are constructed for n categories.

The test sample set will be divided here in order to ensure the comprehensiveness and accuracy of the experimental results, and some samples will be randomly selected as experimental test data, and the final mean value will be taken as the result of many experiments.

The hSVM-WNB classification algorithm, NB algorithm, and SVM-WNB classification algorithm are compared after randomly selecting 10,000, 50,000, 100,000, 250,000, 500,000, 750,000, and 1 million test cases from the test sample set. The accuracy and processing time of these three algorithms are compared in Figures 4 and 5, respectively.

Figure 4 shows that the SVM-WNB classification algorithm is more accurate than the NB algorithm. On the one hand, it improves classification accuracy by optimizing the algorithm by weighting attributes in various ways; on the other hand, it selects and uses the optimized WNB algorithm to process near the classification hyperplane of the SVM algorithm. The hSVM-WNB classification algorithm maintains good accuracy even when the number of test cases is large due to parallel processing.

Figure 5 shows that the SVM-WNB classification algorithm requires two classifiers to be trained, whereas the NB algorithm is very fast, so the NB algorithm is faster than the SVM-WNB classification algorithm in terms of processing time.

4.2. Analysis of the University SR Management System. The workflow used for testing in this experiment was generated by the Pegasus workflow generator. The ratio between the amount of resources provided and the amount of resources required in this group of experiments is 1 : 2.

For each workflow task, the required computing resources are uniformly distributed among (1, 10), and the unit is the number of CPU cores. The size of each data obeys the uniform distribution of (1, 100) in GB.

It can be seen from Figure 6 that among the four candidate algorithms for Montage workflow, the hybrid GA algorithm (hybrid GA) has the best scheduling effect, reducing the data transmission by 40.1% and 30.4% compared with the RRLocality and KCut algorithm. Because the KCut algorithm is designed based on the maximum flow minimum cut theory, all parts of the workflow after division are extremely unbalanced, which shows that some divided parts contain most workflow tasks and data nodes.

However, due to the limitation of computing and storage resources in the data center, it is necessary to adjust the partition that does not meet the constraint conditions, which leads to the deterioration of the results.

From Figure 7, it can be seen that with the increase of data centers, the amount of data transmission across data centers also shows an increasing trend. If the workflow is dispatched to more data centers, more dependent edges will

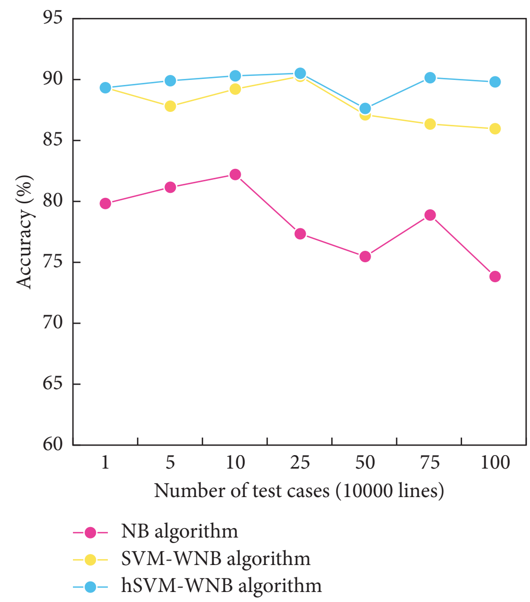

Figure 4: Comparison chart of classification algorithm accuracy.

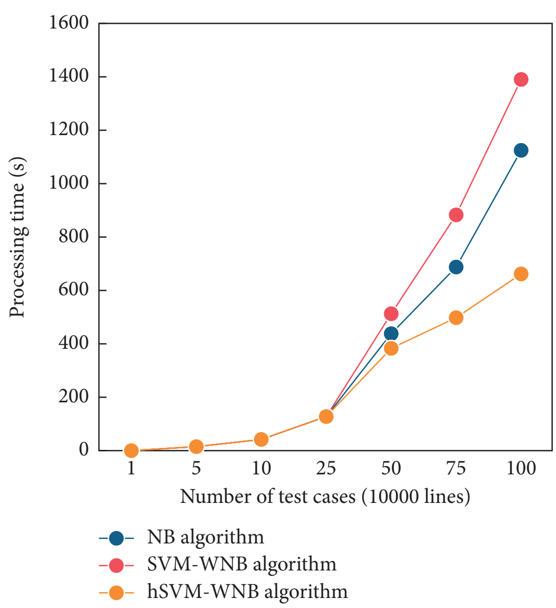

Figure 5: Comparison chart of classification processing time.

be divided, which will lead to the increase of data transmission across data centers.

Figure 8 shows a Montage workflow with 500 tasks that was sent to four different data centers to investigate the impact of changing data center capacity on data transmission across data centers. The ratio between the amount of resources provided by the data center and the amount of resources required in this experiment is set to gradually increase from 1.2 to 1.5, with a 0.05 increment.

As shown in Figure 8, for Montage workflow, the hybrid GA algorithm is the best candidate algorithm. It is not difficult to find that with the increase of data center capacity, the data transmission volume of workflow across data centers shows a downward trend. This is due to the increase

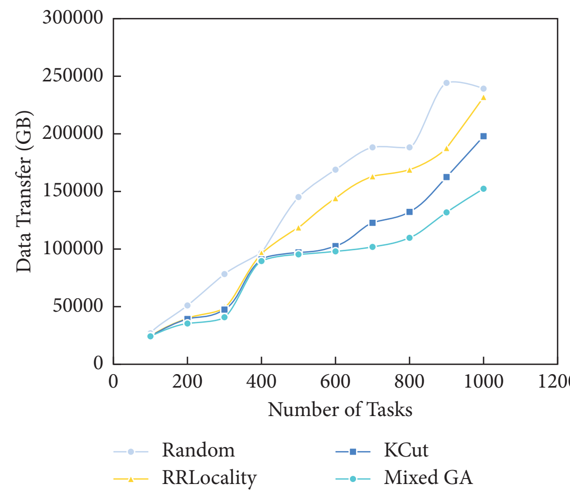

Figure 6: Influence of the number of workflow tasks on data transmission.

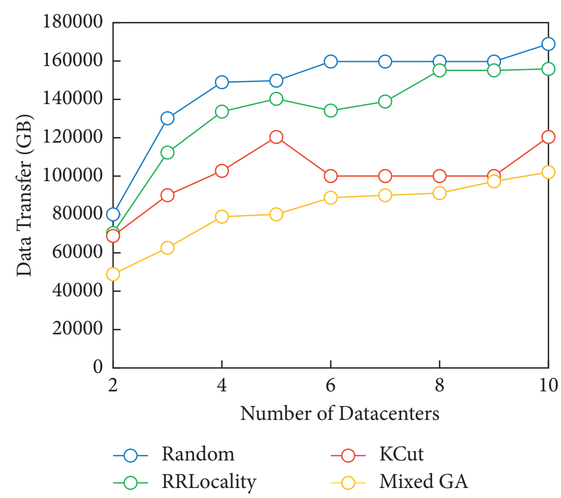

Figure 7: Influence of the number of data centers on data transmission.

of data center capacity, which greatly reduces the tasks or data that are forced to be placed in nonoptimal data centers due to data center capacity limitations, thus reducing the amount of data transmitted across data centers.

This system middleware is based on Globus Toolkit-6.0, which consists primarily of the following components: grid security of multidata centers is handled by GSI and MyProx; data management is handled by 2GridFTP; task management is handled by GRAM5, and grid infrastructure is built by a group of C language common libraries.

After the system middleware has been installed, the workflow management software must be installed on the submission node in order to complete the workflow definition, mapping, and submission for execution. This section of the function is based on the Pegasus system, an open-source workflow management software that implements the data layout and workflow scheduling strategy proposed in this paper. The Pegasus workflow management system includes an implementation interface for defining and

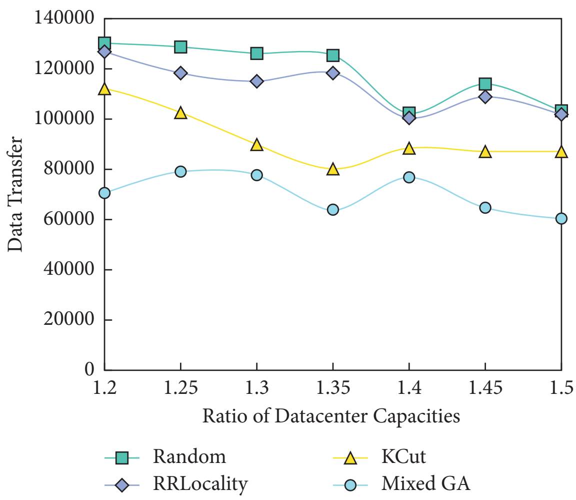

Figure 8: Influence of data center capacity on data transmission.

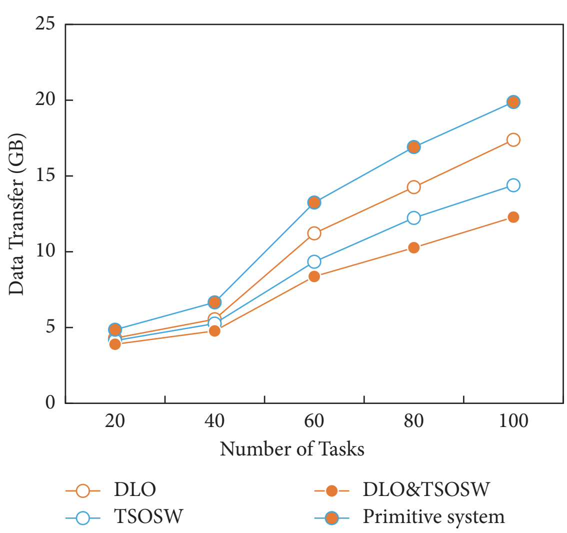

Figure 9: Influence of different policies on data transmission amount of AMS workflow execution.

analyzing workflows, as well as submitting them for execution in a multidata center environment.

In order to test the optimization efficiency of the scientific big data application implementation of the optimization strategy proposed in this article, this paper considers three optimization strategies: DLO (data layout optimization), TSOSW (task scheduling optimization of scientific workflow), and DLO and TSOSW (comprehensive optimization of two strategies), and the original system is compared.

The system execution environment consists of three data centers, namely, the cloud data center of a university, the dawning data center, and the data center built by several servers. The experimental data are AMS scientific data, which are distributed and stored in a multidata center environment. Due to the long running time of a large-scale scientific workflow and the huge data scale required, this

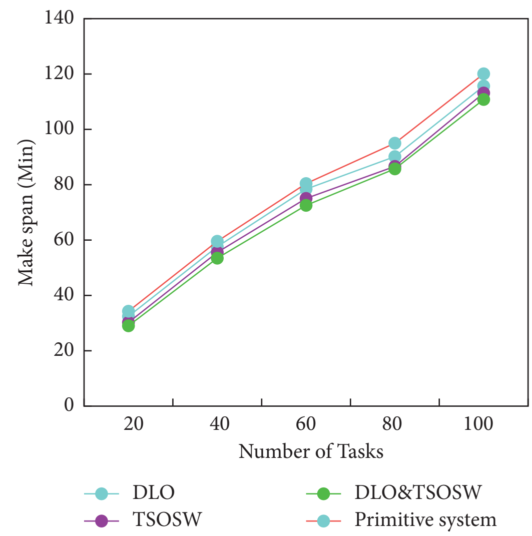

Figure 10: The effect of different policies on AMS workflow execution time.

paper uses small- and medium-scale scientific workflow to perform the test, and the number of workflow tasks ranges from 20 to 100.

Figures 9 and 10 are statistical charts of data transmission volume and corresponding execution time of AMS scientific workflows of different scales across data centers under different strategies.

Compared with the original system, DLO and TSOSW strategy reduces the data transmission by 34.1% on average and the execution time of workflow by 26.2%. Compared with TSOSW, the optimization effect of DLO is slightly worse. The reason may be that the execution position of the task has a greater influence on the data transmission. Only when the task is dispatched to the data center where the input data are located, the data transmission can be better optimized, and the execution efficiency can be improved.

5. Conclusion

SR is a source of national innovation and development, as well as a catalyst for scientific and technological progress and social progress. University SR management is a powerful guarantee for university SR's rapid development. In light of the rapid advancement of educational informatization, university SR management departments should introduce and utilize big data technology to provide an impetus for university SR's healthy and rapid development. This paper builds a comprehensive university SR management innovation information system using data warehouse and big data technology. The SVM-WNB algorithm is proposed, and attributes are weighted and improved. The hSVM-WNB algorithm was then transplanted to the Hadoop cloud computing platform for distributed processing. A series of experiments have shown that the parallelization of the new algorithm is possible, which could be very useful in practice. Using a special hybrid GA algorithm, a novel heuristic method is proposed that can effectively reduce data transmission across data centers during workflow execution.

The front end of the system does not provide good data mining functions for users because the data mining model is not included in the background design and development of the system. One of the next major tasks is to add a data mining function to this system so that it can function as a comprehensive decision support system.

This paper requires a lot of assumptions for financial risk, which cannot use all of the data and is often limited to financial data; and in the past, most early warning models for financial crises did not, so they could not track the fluctuation and change trend of financial indicators. A decision tree algorithm model is used to propose a financial risk early warning method. Enterprises have suffered as a result of the financial crisis, and some have even gone bankrupt. Any financial crisis, on the other hand, has a gradual and deteriorating course. As a result, it is critical to track and monitor the company's financial operations so that early warning signs of a financial crisis can be identified and effective measures taken to mitigate the company's business risk. This paper establishes a financial early warning system to predict financial operations using the decision tree algorithm in big data. Operators can take measures to improve their enterprise's operation and prevent the failure of the embryonic stage of the financial crisis, to avoid greater losses after discovering the bud of the enterprise's financial crisis, and to avoid greater losses after discovering the bud of the enterprise's financial crisis. This prediction can be used by banks and other financial institutions to help them make loan decisions and keep track of their loans. Relevant businesses can use this signal to make credit decisions and effectively manage accounts receivable; CPAs can use this early warning information to determine their audit procedures, assess the enterprise's prospects, and reduce audit risk. As a result, the principle of steady operation should guide modern enterprise management. Prepare emergency plans in advance of a business risk or financial crisis to resolve the financial crisis and reduce the financial risk.

1. Introduction

In the fierce market competition environment, many enterprises fall into financial difficulties or even bankruptcy due to poor management [1]. Enterprise financial risk means that enterprises may encounter some problems in the process of financial work, and the existence of these problems is likely to affect the normal operation and development of enterprises [2]. Enterprise financial risk early warning means that enterprises can alert these financial risks before encountering such problems, so as to help enterprises find the signs of possible risks in the process of financial work in advance [3]. In the process of enterprise financial work, financial risk early warning has always been the content that enterprise management leaders attach great importance to. Once an enterprise has financial risk, it is likely to cause serious losses to the enterprise's economy and seriously lead to the rupture of the enterprise's capital chain, making the enterprise face the risk of bankruptcy [4]. Therefore, it is important to strengthen the early warning of enterprise financial risk [5]. The quality of enterprises is related to the stability and development of the securities market. How to build an effective financial crisis early warning system for various interest groups of enterprises to help enterprises accurately predict financial risks and reduce losses is more important. In the economic field, some scholars have also done some research on financial risk early warning based on decision tree, but the data is simply balanced, and the research on algorithm is not comprehensive enough [6]. However, in the process of enterprise development, there is often a lack of effective risk early warning mechanism and risk control system scheme. Generally, financial risk problems are analyzed through post disposal, qualitative and static. At present, the research on financial risk early warning system is very lacking.

Decision tree algorithm is one of many data mining algorithms. With the rapid development of information technology [7], the related theory and application are becoming more and more mature. The decision tree does not need to assume a priori probability distribution and has good flexibility and robustness; not only discrete and continuous numerical samples, but also "semantic data" can be used. The generated rule set has simple structure, strong interpretability, and high computational efficiency. It can effectively suppress sample noise and attribute deletion. The disadvantages are as follows: the classification rules are complex and it has overfitting phenomenon.

This paper constructs a financial risk [8] early warning model based on the C4.5 algorithm of decision tree [9], uses the key financial indicators generated by the analysis of financial risk analysis system as the attribute set of decision tree, obtains the preliminary financial risk early warning model by analyzing the sample data of financial indicators, and then adds and integrates the representative branches of decision tree model by post-pruning, repeated experiments are carried out to verify the algorithm model, and final financial risk early warning model is obtained [10].

2. Related Work

Financial risk exposure is frequently the final stage of overall risk exposure, in which all potential problems manifest themselves as financial risk. In fact, data mining [11] can be used to retrieve data that can predict potential financial risks at an early stage. Because potential problems usually manifest themselves in nonfinancial or difficult-to-quantify indicators (such as moral hazard and agency cost), there are currently few studies of this type. In addition to financial indicators, the balanced scorecard concept is based on a set of theories [12].

According to consulting and analyzing a large amount of relevant literature on the occurrence, formation, harm, and treatment of financial risk, this paper makes a comprehensive analysis on the problems existing in the early warning management in the current financial risk management, in order to study the financial risk early warning through more scientific and practical research methods, and make the research results improve in practical application. In terms of processing methods, it mainly studies the theory and method system of financial risk early warning by using the algorithm of decision tree and other relevant methods on the basis of financial analysis theory, category unbalanced analysis theory, and early warning decision theory.

At present, there are many views on the definition of financial risk, and there is still no unified standard [13].

The literature holds that financial distress is the obstruction of enterprises in performing their obligations, which is embodied in four forms: insufficient liquidity, insufficient rights and interests, debt arrears, and insufficient funds [14].

According to the literature, companies in financial distress only include companies that have gone bankrupt, become insolvent, or have been liquidated for the benefit of creditors. It is considered that financial risk not only is defined as bankruptcy, but also includes debt default, bank overspending, failure to pay preferred stock dividends, and so on. The literature holds that bankruptcy is only a single event in a series of potential failures of companies with financial crisis tendency [15, 16].

Financial risk exposure is frequently the final stage of overall risk exposure, in which all potential problems manifest themselves as financial risk [17]. In fact, data mining [11] can be used to retrieve data that can predict potential financial risks at an early stage. Because potential problems usually manifest themselves in nonfinancial or difficult-to-quantify indicators (such as moral hazard and agency cost), there are currently few studies of this type. In addition to financial indicators, the balanced scorecard concept is based on a set of theories [12].

The document [18] is unable to pay the creditor's debts when due and is applied for bankruptcy by the creditor. The creditor's application for bankruptcy does not mean that the company is in fact bankrupt. Bankruptcy must be determined by the court's judgment. Before the court declares bankruptcy, the creditor and the debtor may reach a bankruptcy settlement agreement and reach a settlement agreement on the debtor's delay in paying off debts and reducing the amount of debts. After the court determines, the bankruptcy proceedings can be terminated [19].

The book net assets and shareholders' equity of the company are negative [20]. It shows that the company's assets are less than liabilities, and the risk of failure to repay debts is high; at least it is insolvent on the book. However, it does not mean that the company's financial crisis is serious, because many companies have some assets that have not been reasonably evaluated, and the actual value of these assets will greatly exceed the book value [21]. In any case, as long as the shareholders' equity is negative, it is considered that the company's operation is poor and the financial risk is large. The company is unable to perform the interest and principal repayment of the due contract. Once creditors apply to the court for bankruptcy, the company will fall into bankruptcy crisis [22].

In the application process of financial crisis early warning model, there are usually two kinds of errors: misjudging a crisis company as a healthy company and a stable company as a crisis company. The costs of these two errors are generally different. However, in the current domestic research, we usually assume that the cost of these two types of errors is the same, which will obviously affect the practicability of the model. This paper does not generally define a specific sign such as bankruptcy or financial risk, but classifies the financial risk of listed companies in different periods of operation and development into each link of the early warning chain according to the form of the early warning chain and selects the corresponding financial risk form as the early warning target according to the company's financial status and its specific link in the early warning chain [23].

3. Principle of Correlation Algorithm

3.1. Analysis of Financial Crisis Early Warning and Risk Control Based on Decision Tree. Generally speaking, financial risks include capital structure and cash flow risk, accounting and process risk, and accounting and financial reporting risk. The financial crisis studied in this paper only considers the capital structure and cash flow risk (or liquidity risk) [24]. More specifically, we will analyze from the perspective of the project. If the cash flow of the enterprise is less than a certain critical value, the enterprise is unable to obtain loans in time, or there is insufficient financing, we think the enterprise is in financial crisis. Decision tree is a typical machine learning classification algorithm. Each internal node represents the test of the input attribute, the branch derived from the node represents the output of the test, and each leaf node represents the category or class distribution [25].

Decision tree is a hierarchical structure composed of nodes and directed edges. It generally contains three kinds of nodes [26]:

(1) Root node: there are no in edges, but there are zero or more out edges
(2) Internal node: there is exactly one in edge and two or more out edges
(3) Leaf node or endpoint: there is exactly one in edge but no out edge

Starting from the root node of the tree, the test conditions are used to verify the records, and the appropriate branches are selected according to the test results. Follow this branch to another internal node, use new test conditions, or reach a leaf node. After reaching the leaf node, the class item name represented by the leaf node will be assigned to the inspection record.

3.2. Principle Overview of Decision Tree Algorithm. Using the decision tree information mining method, find the most representative attribute in the sample set [10], construct the node of the decision tree, then construct the node of the decision tree according to the attribute value, and analyze the type of the node. If it is an internal node, the node will continue to construct the next node of the decision tree. This is the establishment of decision tree. S sample data exists in set s, and M representative values are set for attribute standards of different categories. D has different categories Xi ($I = 1,\ldots,n$). Let Si be the number of samples in X. Then, for the sample category, the expected information required for differentiation can be expressed as

$$I(S_1, S_2, \ldots, S_m) = -\sum_{i=1}^{m} p_i \log_2(p_i). \quad (1)$$

In the above formula, PI is the probability that any sample belongs to a set and is expressed in Si/s. Let attribute y have v different values {A1,...,AV}. S can be divided into v subsets {S1,...,SV} by attribute y, in which the value of samples in special SJ on attribute y is AJ. Let SIJ be the number of samples of class Xi in subset SJ; then the entropy of attribute y is

$$E(Y) = \sum_{j=1}^{v} \frac{s_{1j} + \ldots + s_{mj}}{s} I\left(s_{1j}, s_{2j}, \ldots, s_{mj}\right). \quad (2)$$

The highest classification accuracy can be obtained by calculating the minimum value of information entropy. For a given subset SJ, $p_{ij} = s_{ij}/s_j$ is the probability that the sample in SJ belongs to Si. And the information gain on attribute y is

$$Gain(Y) = I(s_1, \ldots, s_m) - EY. \quad (3)$$

Therefore, the smaller the value of entropy, the greater the information gain. In terms of practical application, ID3 algorithm is a very valuable classification tool. As a typical case of machine learning in the field of artificial intelligence, it has the advantages of simple algorithm compilation and strong classification ability.

The amount of information I (XI) of the financial risk early warning event Xi can be measured as

$$I(x_i) = -\log_2 p(x_i), \quad (4)$$

where p (x, I) represents the probability of occurrence of event Xi.

Suppose there are m incompatible events $X = \{x_1, x_2, \ldots, x_m\}$. If only one event x occurs, the average information can be measured as

$$I(x_1, x_2, \ldots, x_m) = \sum_{i=1}^{m} I(x_i) = -\sum_{i=1}^{m} P(x_i)\log_2 p(x_i). \quad (5)$$

Assuming that x takes a finite number of variables (x1, X2,...,XM), the information entropy of X can be defined as

$$E(x) = -\sum_{i=1}^{m} P(x_i)\log_a p(x_i). \quad (6)$$

Among them, the logarithmic base a can be a positive task number, usually $a = 2$, and is specified.

The information gain gain (x) of attribute x for classification is

$$Gain(X) = E(S) - E(S|X). \quad (7)$$

Financial gain rate is formed on the basis of information gain. Suppose that attribute X has V different values x1, X2,...,XV, and the training sample s is divided into v subsets S1, S2,...,SV with attribute X. There is a training sample SJ with value XJ on attribute X. It is assumed that the training sample is segmented based on the value of attribute X. Split_Info is the concept of entropy, expressed as

$$Split\_Info(x) = -\sum_{j=1}^{v} p(x_j)\log_2 p(x_i). \quad (8)$$

Then, the information gain rate of the attribute can be expressed as

$$Gain\_Ratio(X) = \frac{Gain(X)}{Split\_Info(X)}. \quad (9)$$

The core of C4.5 algorithm is to generate corresponding test nodes in the decision tree and then divide samples according to attribute values.

4. Analysis of Financial Crisis Early Warning and Risk Control Based on Decision Tree

Table 1 shows the description of the simulated enterprise risk status. The sample data has been discretized based on the decision tree algorithm. According to the risk level of the financial indicators, each financial indicator is divided into four levels: excellent (RL-1), normal (rl-2), low risk (rl-3), and high crisis (rl-4).

It can be seen from Table 1 that the number of category attribute risk status, stability (s), and crisis (c), are 17 and 3, respectively, so the amount of information I (s, c) of the event can be measured as follows:

$$\begin{aligned}
I(s,c) &= -\frac{17}{20}\log_2\frac{17}{20} - \frac{3}{20}\log_2\frac{3}{20} = 0.6098,\\
E(AI) &= -\frac{5}{20}\left(\frac{4}{5}\log_2\frac{4}{5} + \frac{1}{5}\log_2\frac{1}{5}\right) - \frac{7}{20}\left(\frac{6}{7}\log_2\frac{6}{7} + \frac{1}{7}\log_2\frac{1}{7}\right),\\
&\quad -\frac{7}{20}\left(\frac{7}{5}\log_2\frac{7}{5} + \frac{1}{5}\log_2\frac{1}{5}\right) - \frac{1}{20}\left(1\ \log_2\frac{4}{5} + 0\right) = 0.3876,\\
Split_Info(AI) &= -\frac{5}{20}\log_2\frac{5}{20} - \frac{7}{20}\log_2\frac{7}{20} - \frac{1}{20}\log_2\frac{1}{20} = 1.8898,\\
Gain_Ratio(AI) &= \frac{0.6098 - 0.3876}{1.8898} = 0.1176.
\end{aligned} \quad (10)$$

Examine the cash flow ratio of the attribute. When the value is good, the stability is three, and the crisis is zero, the branch can obtain the leaf node stability directly. When the value is normal, the stability is 7, and the crisis is 0, the leaf node crisis can be obtained directly by the branch. The branch must be recalculated when the value is low risk, the stability is 7, and the crisis is 1. When the risk is high, the stability is zero, and the crisis is two, the branch can obtain the leaf node crisis directly. Figure 1 depicts a preliminary decision tree.

As can be seen from Figure 1, the attribute cash flow ratio is the root node, and the training sample data is divided into four subsets: excellent, normal, low risk, and high risk. When the cash flow ratio is low risk, the leaf node cannot be obtained directly. The result is to be determined and needs to be calculated again.

The following will use recursive algorithm to analyze the entropy and information gain rate of other attributes when the value of attribute cash flow ratio is low risk:

$$I(s,c) = -\frac{7}{8}\log_2\frac{7}{8} - \frac{1}{8}\log_2\frac{1}{8} = 0.5436. \quad (11)$$

Attribute financial income A1, and the number of instances with values of excellent, normal, low risk, and high risk is 2, 2, 4, and 0, respectively. When the value is excellent, the stability is 1 and the crisis is 1; when the value is normal, the stability is 2 and the crisis is 0; when the value is low risk, the stability is 4 and the crisis is 0. Then,

$$\begin{aligned}
E(AI) &= -\frac{2}{8}\left(\frac{1}{2}\log_2\frac{1}{2} + \frac{1}{2}\log_2\frac{1}{2}\right) - \frac{2}{8}\left(\frac{2}{2}\log_2\frac{2}{2} + 0\right),\\
&\quad -\frac{2}{8}\left(1\ \log_2\frac{7}{5} + 0\right) - \frac{1}{2}\left(1\ \log_2\frac{5}{5} + 0\right) = 0.2500,\\
Split_Info(AI) &= -\frac{2}{8}\log_2\frac{2}{8} - \frac{2}{8}\log_2\frac{2}{8} - \frac{4}{8}\log_2\frac{4}{8} = 1.5000,\\
Gain_Ratio(AI) &= \frac{0.5436 - 0.2500}{1.5000} = 0.1957.
\end{aligned} \quad (12)$$

Table 1: Simulated enterprise risk status.

Stock abbreviation	Financial income a1	Accounts receivable turnover a8	Quick ratio a19	Cash flow ratio a22	Risk status
Stock 1	Rl-3	Rl-2	Rl-2	Rl-2	Stable
Stock 2	Rl-2	Rl-3	Rl-3	Rl-2	Stable
Stock 3	Rl-1	Rl-3	Rl-2	Rl-2	Stable
Stock 4	Rl-2	Rl-3	Rl-3	Rl-3	Stable
Stock 5	Rl-1	Rl-4	Rl-3	Rl-4	Stable
Stock 6	Rl-3	Rl-4	Rl-4	Rl-3	Crisis
Stock 7	Rl-2	Rl-1	Rl-1	Rl-1	Crisis
Stock 8	Rl-1	Rl-3	Rl-1	Rl-2	Stable
Stock 9	Rl-3	Rl-4	Rl-3	Rl-3	Stable
Stock 10	Rl-2	Rl-2	Rl-2	Rl-4	Stable
Stock 11	Rl-1	Rl-3	Rl-2	Rl-2	Crisis
Stock 12	Rl-1	Rl-4	Rl-2	Rl-3	Stable
Stock 13	Rl-2	Rl-3	Rl-1	Rl-2	Stable
Stock 14	Rl-3	Rl-4	Rl-2	Rl-3	Stable
Stock 15	Rl-2	Rl-3	Rl-1	Rl-2	Stable
Stock 16	Rl-1	Rl-1	Rl-1	Rl-1	Stable
Stock 17	Rl-3	Rl-4	Rl-2	Rl-3	Stable
Stock 18	Rl-1	Rl-3	Rl-4	Rl-1	Stable
Stock 19	Rl-3	Rl-3	Rl-3	Rl-3	Stable
Stock 20	Rl-2	Rl-2	Rl-2	Rl-2	Stable

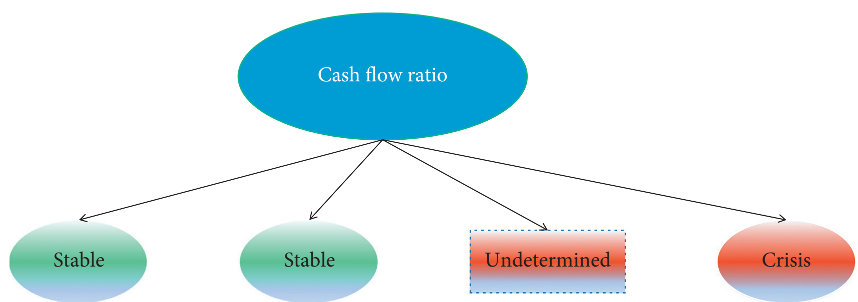

Figure 1: C4.5 algorithm initially forms a decision tree.

Through calculation, compared with the attribute information gain rate, it is obvious that the attribute financial income has the largest information gain rate. When the ratio of cash flow ratio is low risk, financial income is selected as the measurement attribute.

Examine the financial income ratio of the attribute. The branch must be recalculated when the value is good, the stability is 1, and the crisis is 1. When the value is normal, the stability is 2, and the crisis is 0, the leaf node crisis can be obtained directly by the branch. The stability is 4 and the crisis is 0 when the value is low risk. Figure 2 depicts the decision tree created in the second step.

As can be seen from Figure 2, the attribute EPS is the inner node, and the training sample data is divided into four subsets: excellent, normal, low risk, and high risk. When the financial income is excellent, the leaf node cannot be obtained directly, and the result is to be determined, which needs to be calculated for the third time.

Using the same method, the entropy and information gain rate of other attributes are analyzed when the value of financial income is excellent. The result is to select the quick ratio as the test attribute. When the value of the test attribute is low risk, the result is stable; for high risk, the result is crisis. Through the above steps, a complete decision tree is finally obtained, as shown in Figure 3.

The decision tree in Figure 3 uses a specific classification principle to test the data of an unknown mark. If stock *X* and financial income A1 are excellent, accounts receivable turnover A8 is normal, quick ratio A19 is high risk, and cash flow ratio A22 is low risk; then accounts receivable turnover A8 is normal, quick ratio A19 is high risk, and cash flow ratio A22 is low risk. The risk status is crisis, according to the classification of the constructed decision tree.

If the cash flow ratio is good or normal, the risk situation is stable, according to the decision tree. The risk situation is also stable if the cash flow ratio is low risk and the financial income is normal or low risk. Even if the financial income is excellent, if the cash flow ratio is low risk and the quick ratio is high risk, the risk situation is crisis; if the cash flow ratio is high risk, the risk situation is crisis.

5. Analysis of Experimental Results

In order to verify the classification performance of the decision tree model, first test the data set selected by the decision tree algorithm model, then batch calculate, and

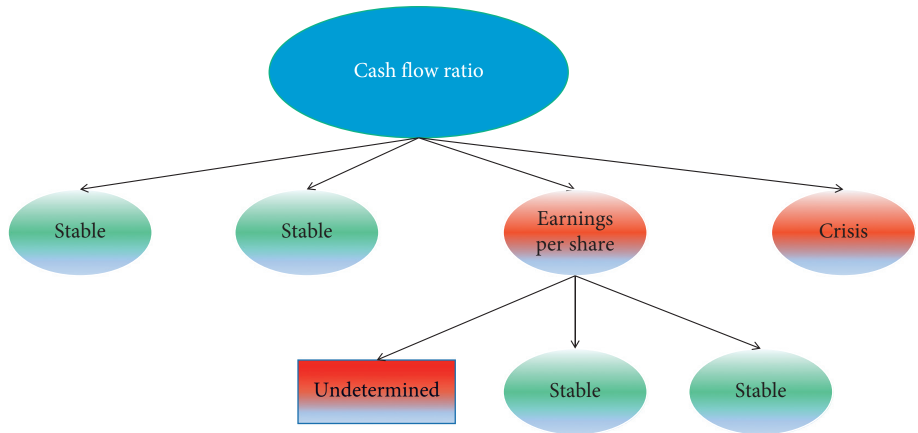

Figure 2: Decision tree formed in the second step of C4.5 algorithm.

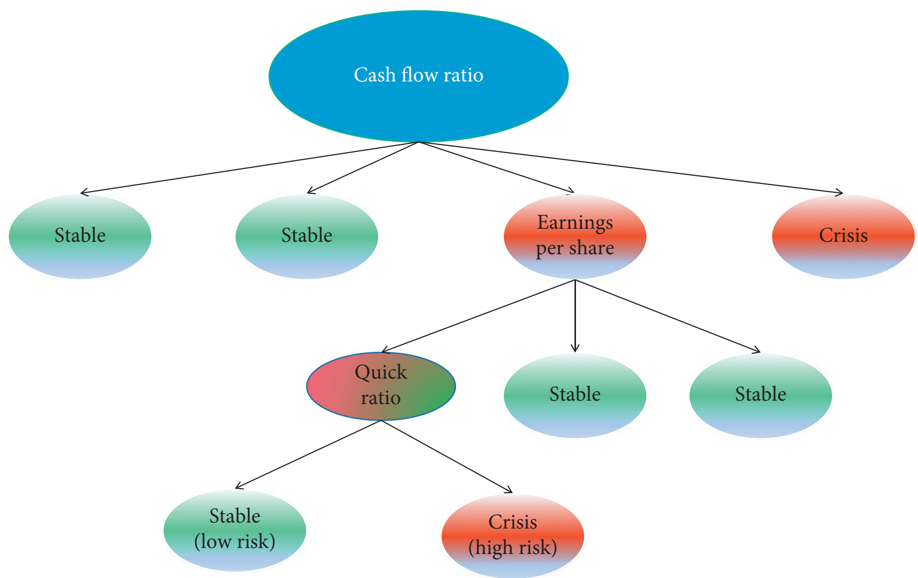

Figure 3: C4.5 algorithm forms a complete decision tree.

compare the test results of the combined classifier. The results of each model value of ratio are shown in Figures 4–10:

The statistical line chart of info value shows the split of the five models. Add a trend line to show the line's approximate trend and the mean value's approximate range. The number of experiments is represented on the horizontal axis, and the split obtained from each experiment is represented on the vertical axis. The lowest value of the longitudinal axis is set to 0.26 and the highest value is set to 0.34 to cover the split obtained by each model. For the info value and to make it easy to compare the linear distribution, the lowest value is set to 0.26 and the highest value is set to 0.34. The split of ID3 model: the average value of info is the lowest, only about 1.4, and its distribution is also the most dispersed among several models, according to the trend lines of the five figures. The split of the decision tree model has improved as the model has improved. The average value of information has increased slightly, but its distribution is similar to that of the ID3 model.

From the image, compared with the first two, the distribution of the broken line graph of the decision tree model is more concentrated, but its mean value has not improved. In contrast, graph (d) is the split obtained from the decision tree single classifier model. The average value of info (obtained by comparing the Split_Info value with the data obtained under all other sampling rates of the model at 100% sampling rate) is close to 0.32, which is the highest among the first four models, that is, the highest among single classifiers, but it still has little change compared with the dispersion of decision tree. Through the integration of classifiers, the decision tree combines the split of classifiers. The average value of info has been further improved, about 00.33. In terms of discreteness, the g value distribution of the model is very concentrated. It can be seen from the figure that the combined model is more stable. The classification effect of info model is the best, there is little difference between different entropy decision tree models, and the classification effect of

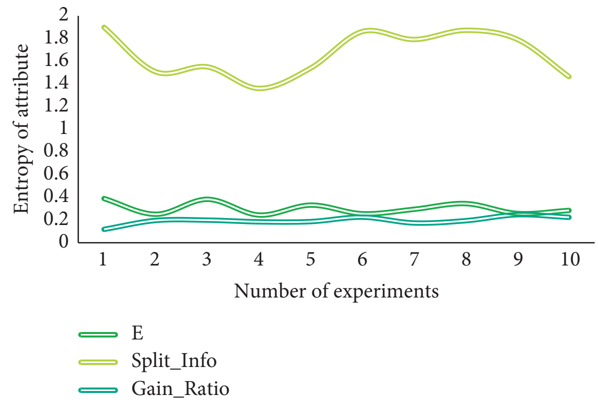

Figure 4: Entropy of decision tree model in the first experiment.

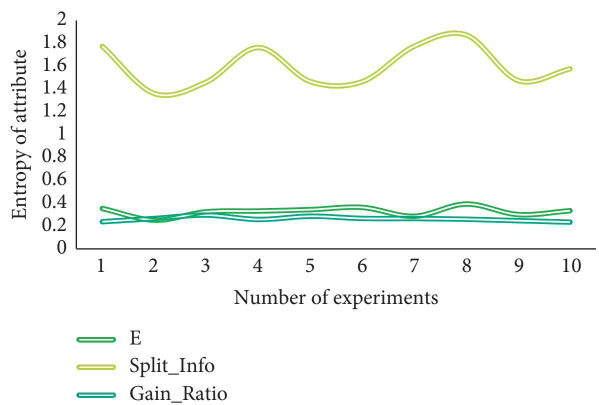

Figure 5: Entropy of decision tree model in the second experiment.

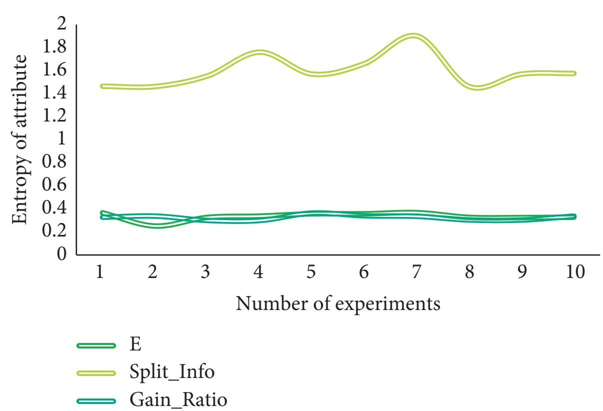

Figure 6: Entropy of decision tree model in the third experiment.

decision tree model is the worst. The integration of combined classifiers significantly improves the classification effect of decision tree model, which can show that the decision tree classifier for the classification problem of unbalanced data sets makes the classification effect better.

On the whole, the total classification accuracy of decision tree model is high, but the performance of other data is very poor, which is not ideal for the prediction of unbalanced bank credit risk [27]; although the distribution of decision tree model in single classifier is relatively concentrated and the classification effect is relatively stable, the low overall classification accuracy makes the model still not ideal. The decision tree combined classifier model of this problem shows great advantages in classification accuracy and stability and has a good effect on the research of credit risk early warning of class unbalanced banks [28].

The results are listed in Tables 2 and 3.

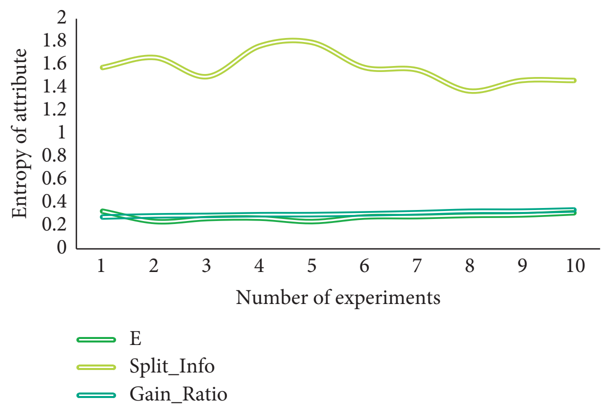

Figure 7: Entropy of decision tree model in the fourth experiment.

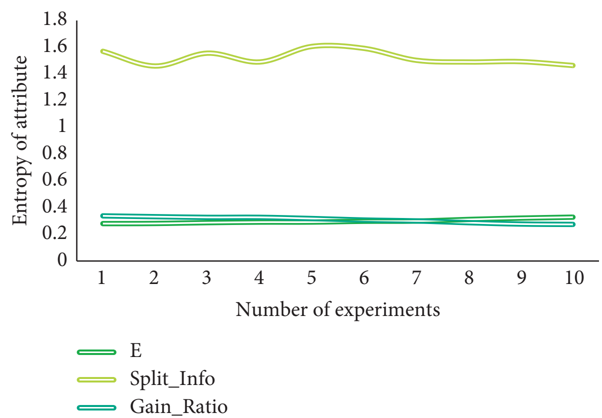

Figure 8: Entropy of decision tree model in the fifth experiment.

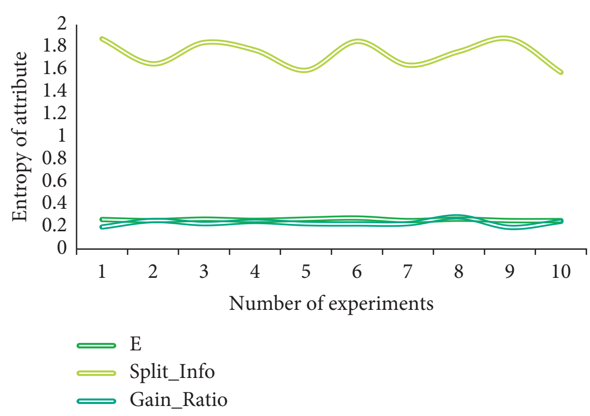

Figure 9: Entropy of decision tree model in the fifth experiment.

The mean difference of info is not significant, while the difference of e-means obtained by the decision tree model is not significant. Furthermore, the mean values of any pair of models differ significantly. The difference in info value is not significant, according to the analysis of each pair of models. The decision tree proposed in this paper is significantly different from other models, particularly the combined decision tree model, demonstrating that the decision tree model proposed in this paper has very superior performance for financial risk early warning data analysis.

OUS-ID3	Risk			0.000

6. Conclusions

People have been unable to use a ratio to obtain enough information to describe all the necessary characteristics of the enterprise, and a single ratio analysis is not only complex, but also difficult for analysts to digest and absorb this information to understand the overall financial situation of the enterprise. By applying the decision tree algorithm financial early warning model to the empirical analysis of enterprises, we can clearly see the effectiveness of the decision tree algorithm early warning model to the Chinese market. The importance of this model is to use multiple variables to obtain information about the financial situation of enterprises. Therefore, it is preferable to combine the financial ratios. In fact, the research on the deterioration of financial situation is not limited to the company. It is more difficult for the company to restructure or reform. It needs a substantial increase in profits to change the current situation. Timely and accurate prediction of financial distress is an essential alarm. Financial risk is the inevitable product of enterprise financial activities, which objectively reflects the operation of enterprises to a certain extent. In the market economy, financial risk exists objectively in every enterprise, especially when the economic system is not perfect, and enterprise financial risk becomes more complex, so the research on enterprise financial risk prevention becomes extremely important.

This paper proposes association rule mining algorithm to analyze enterprise financial risk and decision tree C4.5 algorithm to early warning enterprise financial risk. Although the financial early warning model still lacks a perfect economic theoretical basis and has some problems in methods, it has been highly valued by the practical and academic circles because it plays a good auxiliary role in the decision-making of actual economic activities, even in the current capital market, which is not perfect in all aspects [29].

In the future, the research content of this paper will conduct more in-depth research in the following three aspects:

(1) Explore more effective decision tree algorithm, and find out the data mining method of difficult-to-quantify indicators such as team cooperation and moral hazard
(2) Establish a dynamically maintained enterprise financial crisis early warning model according to the time series, mine the financial indicators for a period of time, adjust the desired mining results, find the frequent patterns and rules of financial crisis early warning indicators that meet the requirements, analyze the final mining results, and summarize the real root causes of enterprise financial crisis
(3) Looking forward to a public enterprise database, the basis of decision tree is to have enough data. Through

the verification of actual data, the research results of this paper will be more meaningful

Academic Editor: Tongguang Ni

Several unexpected behaviors may occur during actual treatment of clinical pathways, which will have negative impact on the implementation and the future work. To increase the performance of current deviation detection algorithms, a method is presented according to business alignment, which can effectively detect the anomaly in the implementation of the clinical pathways, provide judgment basis for the intervention in the process of the clinical pathway implementation, and play a crucial role in improving the clinical pathways. Firstly, the noise in diagnosis and treatment logs of clinical pathways will be removed. Then, the synchronous composition model is constructed to embody the deviations between the actual process and the theoretical model. Finally, $A*$ algorithm is selected to search for optimal alignment. A clinical pathway for ST-Elevation Myocardial Infarction (STEMI) under COVID-19 is used as a case study, and the superiority and effectiveness of this method in deviation detection are illustrated in the result of experiments.

1. Introduction

The data released by the seventh census show that China has gradually entered an aging society. Coupled with the impact of the coronavirus epidemic in recent years, the medical system is facing increasing pressure. Hence, the use of clinical pathway that can regulate medical behavior, improve medical quality, and control medical costs has become an inevitable choice for medical reform in China [1, 2]. With strong national support, the clinical pathway has entered the stage of large-scale promotion [3].

The essence of clinical pathway is to adopt standardized procedures for the diagnosis and treatment of a certain disease. However, in the actual implementation process of clinical pathway, there may be many unstable factors; for instance, patients do not understand the implementation standard of clinical pathway, medical staff are not positive about the process, etc. Factors mentioned above have greatly affected the promotion of clinical pathway. In addition, the imperfection of clinical pathway, including patient condition mutation, may lead to unexpected behaviors in the process of clinical pathway diagnosis and treatment. Such behaviors are all called deviations. Under various pressures, it is urgent to optimize and improve the clinical pathway. Process mining aims to mine and optimize the business process through effective data in event logs [4, 5], and the process mining methods can be used to detect the deviated behaviors, which is beneficial to predict the trend of the patient's diagnosis and treatment process, find the defects in the clinical pathway, and provide judgment basis for the intervention behavior in the diagnosis and treatment process, so as to improve the clinical pathway [6–8].

With the wide application of medical information systems, a large number of electronic logs are generated in the process of diagnosis and treatment, and electronic medical records are also widely used in hospitals. The method of mining deviation behaviors has also changed from a forward-looking method requiring manual recording to a retrospective method automatically processed by computers. This paper establishes the process model of clinical pathway and uses business alignment to detect the deviation between the business process and the execution records.

Lots of formal methods of process model description have been presented up to now, e.g., BPMN [9], C-net [10], EPC [11] and Petri net [12–15]. Petri net is the most mature and in-depth process modeling language, which can concisely and intuitively describe and analyze complex systems [16–27]. Hence, Petri net is selected as the process model description method.

Business alignment is one of the most advanced compliance checking methods at present. The use of business alignment can effectively detect the deviation of clinical pathway [28–30]. Compliance checking of complex models has always been a challenging research topic [31]. Adriansyah et al. [32] presented a technique which combines the process model and log model into a product model to get optimal alignment. Cook et al. [33] presented a means to obtain alignment results by comparing trace and process model with quantifying similarity. Song et al. [34] presented a heuristic trace replay method to align recorded traces and theoretical models, which reduces the search space.

By studying the existing methods, there is still something that can be improved in the efficiency of business alignment. Hence, a business alignment method is presented according to synchronous composition model of Petri nets, which effectively reduces the complexity of the model to improve alignment efficiency. A sequence of events recorded in the medical log of a case is called a trace. There may be some invalid traces in the log, which are called noise. Before the compliance check, it is necessary to filter the diagnosis and treatment logs by preprocessing to remove noise. Deviation detection is to find the optimal alignment based on the filtered treatment logs and locate possible problems in the traces. Since the efficiency of the optimal alignment computation is particularly critical, this paper uses A $*$ algorithm.

The remainder of this paper includes the following. The background knowledge is introduced in Section 2, including the concept of trace, Petri net, reachable graph, and alignment. A noise filter algorithm and an optimal alignment computation algorithm are presented in Section 3. The comparison of the experiments between our method and the classical one is shown in Section 4. Finally, Section 5 draws the conclusion and the ideas of follow-up research.

2. Basic Knowledge

A tremendous amount of data is stored in hospital information systems. We can extract a lot of medical events from them. A series of events in one case is organized as a trace, which is the basic element of logs.

Definition 1 (trace). Given a set A that includes activities, trace is a process instance, namely, a sequence of activities, denoted as $\sigma \in A^*$. If there is a trace of non-empty multiple set $L \in \beta\ (A^*)$, L is called a diagnosis and treatment log, and the set includes each finite sequence on set A, denoted as A^*; the set of all multiple sets on set A^* is denoted as $\beta\ (A^*)$.

Definition 2 (Petri net). Given a set A that includes activities, Petri net is a tuple on set A, denoted as $N = (P, T; F, \alpha, m_i, m_f)$. Set P contains all places, and set T contains all transitions, where $T \cup P \neq \varnothing$, $T \cap P = \varnothing$; set $F \subseteq (T \times P) \cup (P \times T)$ represents the directed arc set of the relationship between the place and the transition, which is called the flow relationship or arc relationship; $\alpha{:}T \longrightarrow A^\tau$ is the mapping function of transition and label, and τ is the invisible transition, that is, $A^\tau = A \bigcup \{\tau\}$; the state of Petri net is named as marking, which is a multiple set of the place set. $m_i \in \beta\ (P)$ stands for the initial state, and $m_f \in \beta\ (P)$ stands for the final state.

A simple Petri net example N_1 for clinical pathway of ischemic stroke is shown in Figure 1, and Table 1 shows the relationship of transitions, labels, and activities in model N_1.

For $\forall m \in \beta\ (P)$ and $\forall t \in T$, t can be fired under marking m iff $m\ (p) \geq \forall_{p \in P} F\ (p,\ t)$ holds, represented as $m\ [t>$; at this time, after the transition t occurs, the new state of the system denotes as m', and $\forall_p \in {}_P m'\ (p) = m\ (p) - F\ (p,\ t) + F\ (t,\ p)$, represented as $m\ [t > m'$. The set $R\ (m)$ contains all the markings which can be enabled under m.

The definition of Petri net's reachable graph can be constructed by the transition firing rule in Definition 2.

Definition 3 (reachable graph). Given a Petri net N, reachable graph of N is represented as $TS = (S, A', T')$, where $S = R\ (m_i)$, $A' = A$, $T' = \{(m_i,\ \alpha\ (t),\ m_j) \in (S \times A \times S) |\ \exists_{t \in T}\ (m_i [t > m_j])\}$.

Figure 2 shows the reachable graph TS_0 of N_1. Every node in the graph stands for a reachable marking of N_1, every arc means a transition that is enabled under its previous marking, and arrow points to the new marking after transition occurs.

When the trace in the diagnosis and treatment log is replayed on the model, the two may not be completely fitted. This unfit state is called deviation which can be detected by alignment.

Definition 4 (alignment) Given a set A including activities, a Petri net N, and a trace σ, the alignment between σ and A, namely, $\gamma \in (A{\gg} \times T{\gg})^*$ is a moving sequence (where $\gg$ denotes no movement and $A{\gg} = A \cup \{\gg\}$) which has the following rules:

(1) The projection of the first column elements in the ordered set of movements on A (ignoring $\gg$) is recorded as $\pi_1\ (\gamma)_{\downarrow A} = \sigma$.

(2) The projection of the second column elements in the ordered set of movements on T (ignoring $\gg$) produces a complete firing sequence, denoted as $m_i \longrightarrow^{\pi_2}\ (\gamma)_{\downarrow T}\ m_f$.

For every $(a,\ t) \in \gamma$, there are four possibilities:

(1) $(a,\ t)$ is named as log movement in case of $(a \in A) \wedge (t = \gg)$.

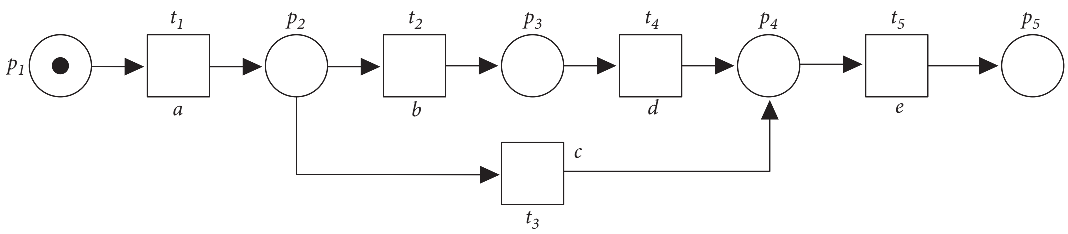

FIGURE 1: Petri net N_1 for clinical pathway of ischemic stroke.

TABLE 1: The relationship between transitions and activities of model N_1.

Transition	Label	Activity	Transition	Label	Activity
t_1	a	Initial inspection	t_4	d	Thrombolytic therapy
t_2	b	Meeting thrombolytic inclusion criteria	t_5	e	Hospitalization
t_3	c	Meeting thrombolytic exclusion criteria			

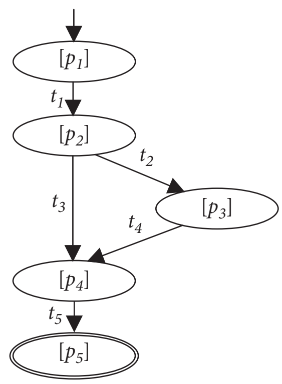

FIGURE 2: Reachable graph TS_0 for N_1.

(2) (a, t) is named as model movement in case of $(a = \gg) \wedge (t \in T)$.

(3) (a, t) is named as synchronous movement in case of $(a \in A) \wedge (t \in T)$.

(4) (a, t) is named as illegal movement.

Activity is an element of traces, and transition is an element of model. According to Definition 4, alignment is a sequence of movements, and movement reflects the correlation between the activities and transitions. For log movement, it means that an activity cannot be executed in the model; for model movement, it means that a transition is not observed in the trace; for synchronous movement, it means that the activity can correspond to the transition; for illegal movement, it will not occur in actual business process, so it will be ignored in this paper. Among them, (1) and (2) are the unfitness between trace and process model, which represent the deviations in alignment.

For a given trace and a process model, multiple alignment results may be computed. To get the best alignment result, a cost function needs to be introduced to compute the cost of each movement. Among all the alignment results, the alignment with the minimum total cost value is the optimal alignment.

For every $(a, t) \in \gamma$, the cost function is as follows:

(1) The value of $lc((a, t))$ is 1, when (a, t) is log movement.

(2) The value of $lc((a, t))$ is also 1, when (a, t) is model movement.

(3) The value of $lc((a, t))$ is 0, when (a, t) is synchronous movement.

(4) The value of $lc((a, t))$ is $+\infty$, when (a, t) is illegal movement.

3. Alignment Methods

3.1. Preparation for Alignment Computation

3.1.1. Removal of Noise. Before the implementation of synchronous composition, it is necessary to filter the traces in the diagnosis and treatment log, remove the noise, and retain effective traces.

There are generally two possibilities for traces with sequential deviation in event logs: ① the trace itself is noise and ② the activity which should occur in sequential relationship or selection relationship occurred in parallel relationship incorrectly. In the clinical pathway, it must be strictly in accordance with the implementation standards of clinical pathway, and the activities are mostly sequential or selective. Hence, traces with inverted sequence activities are considered as noise in this paper.

In Petri net, when a transition can occur before other transitions, there is a precedence relationship between this transition and its subsequent transitions, which is denoted by the symbol "⟶." When a transition cannot occur before others, there is no precedence relationship between this transition and others, which is denoted by the symbol "#." For the possible sequential deviation traces in the diagnosis and treatment log, this paper presents the concept of precedence relationship matrix as follows.

Definition 5. (precedence relationship matrix). Given a set A including activities and a Petri net N, the precedence relationship matrix is a matrix of $|T|\times|T|$, whose row and column labels are the activities, denoted as $M{:}\{\alpha(t_x)|t_x\in T\}\times\{\alpha(t_y)|t_y\in T\}\longrightarrow\{\text{"\#," "}\longrightarrow\text{"}\}$. The matrix contains the following elements:

(1) For any $\alpha(t_x)\in S$ and $\alpha(t_y)\in S$, if $\exists<t_1,\ldots,t_x,\ldots,t_y,\ldots,t_n>$, $m_{\mathrm{i}}\longrightarrow^{t_1}\ldots t_x\ldots t_y\ldots t_n\,m_{\mathrm{f}}$, then $M[\alpha(t_x)][\alpha(t_y)]=$ "⟶," denoted as $\alpha(t_x)\longrightarrow\alpha(t_y)$, where $1\le x$, $y\le n$.

(2) For any $\alpha(t_x)\in S$ and $\alpha(t_y)\in S$, if $\nexists<t_1,\ldots,t_x,\ldots,t_y,\ldots,t_n>$, $m_{\mathrm{i}}\longrightarrow^{t_1}\ldots t_x\ldots t_y\ldots t_n\,m_{\mathrm{f}}$, then $M[\alpha(t_x)][\alpha(t_y)]=$ "#," denoted as $\alpha(t_x)\#\alpha(t_y)$, where $1\le x$, $y\le n$.

Take N_1 as an example, and its precedence relationship matrix M_{pr} is shown in formula (1), where $a_x=\alpha(t_x)$ and $1\le x\le 5$.

$$M_{\mathrm{pr}}=\begin{array}{c}\\ a_1\\ a_2\\ a_3\\ a_4\\ a_5\end{array}\begin{array}{c}\begin{array}{ccccc}a_1 & a_2 & a_3 & a_4 & a_5\end{array}\\ \begin{bmatrix}\# & \longrightarrow & \longrightarrow & \longrightarrow & \longrightarrow\\ \# & \# & \# & \longrightarrow & \longrightarrow\\ \# & \# & \# & \# & \longrightarrow\\ \# & \# & \# & \# & \longrightarrow\\ \# & \# & \# & \# & \#\end{bmatrix}\end{array}. \quad (1)$$

To determine whether a trace is noise, it is necessary to check all activities in the trace one by one and compare the order between the current activity and its subsequent activities by the precedence relationship matrix. If not fitting, the comparison process is terminated, and the trace is regarded as noise, which should be removed from the log.

To store information of parallel activities, it is necessary to set a parallel activity set S as "current activity set" to compare with their subsequent activities, and the first activity in the trace is put into S before starting the traversal. Meanwhile, several variables are set as follows: let the current activity in traversal be activity *cur* and the subsequent activity in trace be activity *post*. The rules are as follows:

(1) If there is one or more activities that precedence relationship matrix allow to occur earlier than activity *post* in the set S and otherwise do not hold, remove these activities from the set S and place activity *post* in the set S.

(2) If all activities in the set constitute the parallel relationship with activity *post*, then put activity *post* in the set S without removing any other element.

(3) If there is an inverted sequence deviation between any activity and activity *post* in set S, this trace is regarded as noise and should be abandoned directly.

Algorithm 1 shows the pseudocode.

To filter the log, it is necessary to traverse the diagnosis and treatment log L and then gradually check the activities in the sequence σ, so two nested loops are required. $O(n^2)$ is its time complexity. The value of n is affected by the size of L and the length of the sequence σ. The space complexity is $O(n)$.

3.1.2. Synchronous Composition. For a given trace and its corresponding process model, a new model can be generated by the following operations: ① convert the trace into the log model described by Petri net; ② merge two corresponding transitions with the same activity label in two models; and ③ merge presets and postsets of the same transitions, respectively. Finally, the generated model is the synchronous composition model of trace and process model.

The log model transition and process model transition with the same label x will construct synchronous movement. For other synchronous movements, the transitions should be named according to Definition 4. Algorithm 2 shows the pseudocode.

The algorithm integrates the transitions, places, and arc relationships of process model N_{pm} and log model N_{lm} into synchronous composition model N_3. There are three loop structures, so $O(n)$ is the time complexity. The quantity of transitions, places, and the arc relationships affect the size of n, so space complexity is $O(n)$.

Taking N_1 as an example, trace $\sigma_1=<a, f, b, e>$ is given. Figure 3 shows the log model N_2 which is converted from σ_1. The synchronous composition model N_3 computed by Algorithm 2 from log model N_2 and process model N_1 is shown in Figure 4.

3.2. Computation of Alignment

3.2.1. Reachable Graph of Synchronous Composition Model. Since alignment is a sequence of movements, the transitions occur with the change of states and reachable graph can clearly express the changes of states and occurred transitions, and a weight can be given to every arc of a reachable graph to represent the cost of the occurred transition. The computation of optimal alignment can be converted to find the shortest path of a directed weighted graph, so the reachable graph of N_3 is then computed. The reachable graph TS_1 of N_3 is shown in Figure 5.

It can be inferred from Definition 4 that (t_1', t_1) is a synchronous movement, so $lc((t_1', t_1))=0$; $(\gg, t_3)$ is a model movement, so $lc((\gg, t_3))=1$; $(t_2', \gg)$ is a log movement, so $lc((t_2', \gg))=1$. By analogy, it can be obtained that the values of the other transitions in Figure 5 are $lc((t_3', t_2))=0$, $lc((\gg, t_4))=1$, $lc((t_4', t_5))=0$.

3.2.2. Search for Optimal Alignment. Considering the particularity of the clinical pathway model, the sequential and selective structure should be used as far as possible in this kind of model and the cyclic structure should be avoided. Hence, the cyclic structure in the reachable graph of the model will be ignored, and the graph can be easily converted into the form of relationship matrix. It can be seen that the optimal alignment computation is not complicated, and the efficiency is one of the key performance measures. Hence, it is necessary to select appropriate search algorithms to maximize efficiency.

As mentioned earlier, the optimal alignment problem is also the shortest path problem. Among the solutions to the shortest path problem, the basic search algorithms (e.g., the depth-first algorithm, the breadth-first algorithm, and the Dijkstra algorithm) are well known with simple structure and easy implementation. However, in dealing with this problem, it is necessary to traverse paths one by one, and the efficiency is poor. The intelligent algorithms (e.g., genetic algorithm, reinforcement learning algorithm, and ant colony algorithm) are too complex and need to be trained through a large number of datasets to adjust parameters, which is suitable for solving the tricky issues in complex scenes and is not suitable for solving this problem.

Since the weight of each arc is known, $A*$ algorithm is suitable for this problem, which is a famous heuristic algorithm. When solving the shortest path, $A*$ algorithm will estimate the distance between the current node and the target node. The accuracy of the heuristic function will affect the efficiency of $A*$ algorithm, and the accuracy represents the proximity between the estimated and the actual value. In addition, the code implementation of $A*$ algorithm is simple. Since the estimated value computed by the cost function used in this paper is basically equal to the actual value, the computational efficiency can reach the highest level. For reachable graph TS_1 obtained in Section 3.2.1, Algorithm 3 shows the pseudocode.

Considering that the algorithm uses the priority queue, assuming that it uses quick sort, $O\ (n\log_2{}^n)$ is the time complexity, and the quantity of reachable markings affects the size of n. In Algorithm 3, the frequency of iterations is affected by the complexity of the reachable graph, too. Hence, the time complexity is $O\ (n^2\log_2{}^n)$, and the space complexity is $O\ (n)$.

Taking reachable graph TS_1 as an example, formula (2) is the result of optimal alignment.

$$\gamma_1 = \begin{array}{|c|c|c|c|c|} \mathrm{a} & \mathrm{f} & \mathrm{b} & \gg & \mathrm{e} \\ \mathrm{a} & \gg & \mathrm{b} & \mathrm{d} & \mathrm{e} \\ t_1 & & t_2 & t_4 & t_5 \end{array} \qquad (2) \qquad (2)$$

Algorithm 3 finds the optimal alignment by calculating the minimum sum cost value of the occurred transition sequences. In the implementation of the algorithm, it is not necessary to generate reachable graph of synchronous composition model. The synchronous composition model can be directly used as the input to generate the search space, which can simplify the solving step, save the processing time, and improve the computational efficiency.

4. Experiment Analysis

4.1. Experiment Settings. This experiment will compare the scale of the model and the efficiency of alignment. There are three main elements to measure the scale of the model, including

(1) Quantity of places: how many places there are in the model. In general, the less the number, the lower the complexity.

(2) Quantity of transitions: how many transitions there are in the model. In general, the less the number, the lower the complexity.

(3) Quantity of arcs: how many arc relationships there are in the model. In general, the less the number, the lower the complexity.

The factors that measure alignment efficiency are the time consumed and the memory space occupied by the process of optimal alignment computation. In this experiment, the memory occupancy is measured by the quantity of reachable markings generated in the process of running Petri net. Hence, there are two main factors to measure the alignment algorithm:

(1) Quantity of reachable markings (quantity of queued nodes): how many reachable markings generated there are when the model is running. When calculating the optimal alignment, the number is equal to the quantity of the nodes queued in the priority queue, which is also called as the quantity of queued nodes.

(2) Computation time: the time consumed when computing the optimal alignment.

For a given process model, a log set, and a cost function, the computation process of the optimal alignment which presented by Adriansyah et al. can be divided into two steps: first, generate the search space; then, search for the optimal alignment. The reachable graph of the new-generated model is considered as the search space, whose complexity can be measured by the scale of the new model and basically determine the cost of the entire optimal alignment computation method. This experiment focuses on this part. Similarly, the method in this paper uses $A*$ algorithm for optimal alignment computation. Theoretically, this method reduces unnecessary transitions and arcs, so the quantity of reachable markings is less, and the efficiency should be better than the classical one when computing the optimal alignment.

Next, the clinical pathway of ST-Elevation Myocardial Infarction (STEMI) under COVID-19 is taken as an example for experimental verification. The model is manually established according to the natural language description of the diagnosis and treatment process. The specific clinical pathway is shown in Figure 6, and the relationship between activities and transitions is shown in Table 2.

The main work of this experiment is to compare the scale of the search space and efficiency of the alignment computation between the classical method and the method presented in this paper. All the fitting traces in logs are generated from the running process model, then noise is added in the proportion of the deviation number to the length of the trace from 0% to 30%, and each 5% is a group. Each trace is dealt with by Algorithm 3 and the classical algorithm for 10 times, respectively. The mean computation time and model scale parameters are obtained, so as to fully compare the differences between the two under the premise of control variables.

4.2. Experimental Environment. The experiment code adopts Java language, and Table 3 shows the hardware and software platform configuration.

4.3. Algorithm Superiority Verification. The results are shown in Figures 7–10. Among them, Figures 7 and 8 show the

```
Input: reachable graph TS of synchronous composition model N3;
Output: optimal alignment γ.
  //initialize a priority queue by (total cost value of m_i to m_f) + (total estimated value of the current node to the target node) in ascending order
  pqueue.create ();
  visitedNodesSet = Ø;
  pqueue.push (TS.initialmarking);
  while pqueue.size ()! = 0 do
    currenrNode = pqueue.poll ();
    if currenrNode == targetNode then
    //recursively search the predecessor node of currenrNode to get optimal alignment
    γ = getOptAlignment (currenrNode);
    return γ;
    else
      //visit all successorNodes of currentNode
      for all successorNode ∈ currentNode.getSuccessors() do
        //calculate the new total cost value of successorNode
        newcost = successorNode.calNewCost (currentNode);
        if successorNode ∈ visitedNodesSet then
          //for the visited node, if the new total cost value is smaller, update the total cost value of successorNode
          if successorNode.getTotalCost() > newcost then
            successorNode .setTotalCost (newcost);
            pqueue.push (successorNode);
          end
        Else
          visitedNodesSet = visitedNodesSet ∪ {successorNode};
          successorNode.setTotalCost (newcost);
          pqueue.push (successorNode);
        end
      end
    end
  end
```

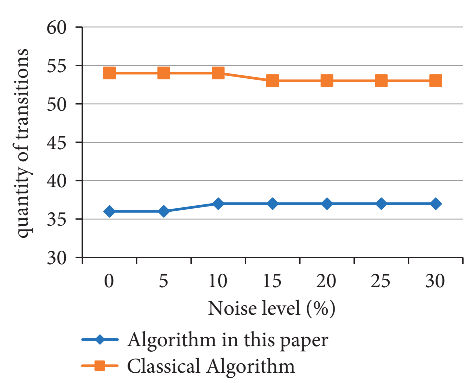

Figure 7: Comparison of the quantity of transitions with different noise levels between two models.

product model in classical algorithm and synchronous composition model in this paper, the quantity of places in the two models is equal to the element number of the union of places in the log model and process model.

Figure 7 compares the quantity of transitions between the two models. The number in the synchronous composition model is about 37, and the number in the product model is about 54. The synchronous composition model reduces some unnecessary transitions, which greatly decreases the scale of the model.

Figure 8 shows the comparison about the quantity of arcs between the two models. The number in the synchronous composition model is about 92, and the number in the product model is about 125. Arc is the flow relationship explained in Definition 2, which indicates the relationship between the transition and the place. The synchronous

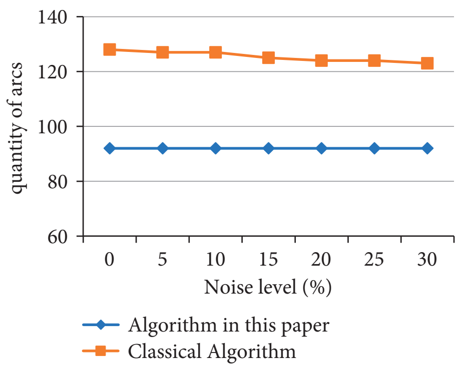

Figure 8: Comparison of the quantity of arcs with different noise levels between two models.

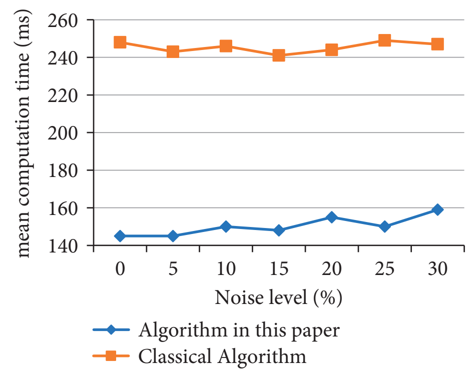

Figure 10: Comparison of the mean computation time with different noise levels between two algorithms.

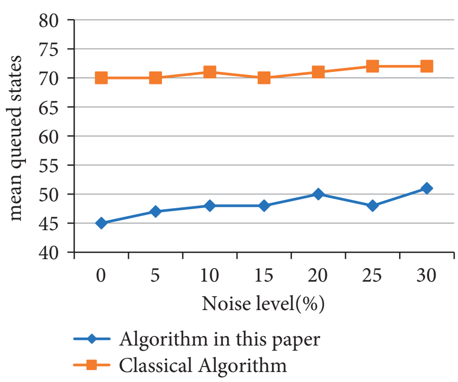

Figure 9: Comparison of the mean queued states (reachable markings) with different noise levels between two models.

composition model not only reduces transitions but also reduces some unnecessary flow relationships, so it reduces the complexity of the search space.

In the part of the optimal alignment computation, Figure 9 shows the quantity of reachable markings in reachable graphs of two models, i.e., mean queued nodes in the optimal alignment computation process. The number in the synchronous composition model is about 47, and the number in the product model is about 72. The quantity of reachable markings affects the time of iteration and sorting efficiency of A $*$ algorithm, as shown in Algorithm 3.

In Figures 7 and 8, the synchronous composition model reduces unnecessary transitions and arcs compared with product model, which makes the reachable graph closer to the real situation and reduces the unnecessary reachable markings.

Figure 10 compares the mean computation time of the two methods in finding the optimal alignment. The mean computation time of Algorithm 3 is about 150 ms, while the time of the classical algorithm is about 245 ms. It saves about 40% of the time and can complete the computation of optimal alignment faster than the classical algorithm at each noise level.

It can be seen from the data that the synchronous composition model used in this paper has lower complexity and higher computational efficiency. Next, the reasons are analyzed and explained.

First of all, the method presented in this paper preprocesses the log when generating the search space and removes noise. This step is also an indispensable step because this method is designed for clinical pathway, which can effectively filter unreasonable noise to prevent the algorithm from failure. Preprocessing is carried out for the log with low time complexity. Even if it cannot be directly reflected from the data, there is a subtle influence on the alignment efficiency and algorithm stability. The product model used in classical method has no need to do this operation because its higher complexity allows it to adapt to more situations at the cost of efficiency. Even if noise can be filtered by such preprocessing, it will not affect the stability of the classical algorithm and has little effect on the efficiency improvement.

Secondly, when generating the search space, the product model will keep the two kinds of original transitions, but the synchronous composition model will not. Assuming that the sum of the transitions in the log model and process model is t, the sum of the arcs is f, and the quantity of synchronous activities is s (assuming that the sum of the flow relationships associated with the log transition and the model transition corresponding to the i-th synchronous activity is f_i); in the product model, the quantity of corresponding transitions is $t+s$, and the quantity of arcs is $f + \sum_{i=1}^{s} f_i$; in the synchronous composition model, the quantity of transitions is $t-x$, and the quantity of arcs is f. That is, each synchronous activity will make product model have 2 more transitions and several arcs than the synchronous composition model. These additional transitions and arcs have no actual meaning. The preprocessing step of this method solves the problem in advance and simplifies the scale of the model as much as possible. Hence, the search space of this method is much smaller than that of the classical method. In addition, the higher the noise level, the lower the number of synchronous activities. Figures 7 and 8 show that with the gradual increase of the noise level, the scale of the two models is gradually close. However, the higher the noise ratio is, the closer the trace is to the real noise, the lower the significance of the analysis is, and the more it should be abandoned.

Table 4: The relationship between transitions and activities of trace σ.

Transition	Label	Activity
t_2	e	Exclusion of COVID-19 infection
t_8	c	CCU thrombolysis
	t	Transfer to isolation ward
t_{11}	r	Recanalization of thrombolysis in emergency patients

In the part of computing the optimal alignment, both methods use A $*$ search algorithm. The time complexity of A $*$ search algorithm in Algorithm 3 is $O\ (n^2 \log_2{}^n)$, and n is affected by the quantity of reachable markings. Even if the difference of the scale between the two models is not large, there will still be a large efficiency gap in the two methods. Figures 7–10 show that the quantity of transitions and arcs decreases less than 30%, and the mean queued nodes reduces by about 34%, and the mean computation time of optimal alignment reduces by about 40%.

According to the data and analysis in the experiments, when calculating the optimal alignment, since the efficiency of the optimal alignment increases geometrically with the model complexity, the selection of synchronous composition model can greatly improve the alignment efficiency.

4.4. Algorithm Effectiveness Verification. After the computation of the optimal alignment is completed, the optimal alignment results such as formula (2) are obtained. It can be clearly seen from the equation whether the activities of the patient's diagnosis and treatment process are normal and whether there are missing or multiple activities. Therefore, the medical staff can master the whole clinical pathway diagnosis and treatment process. An example in the diagnosis and treatment log is illustrated below.

Trace σ_2 = <. . ., exclusion of COVID-19 infection, . . ., CCU thrombolysis, transfer to isolation ward, recanalization of thrombolysis in emergency patients, . . .>, , and here, part of synchronous transitions are replaced by ellipses. The relationship between the activities and the transitions is shown in Table 4.

Trace σ_2 is denoted as <. . ., e, . . ., c, t, r, . . .> according to Table 4, and the optimal alignment result is shown in the following:

$$\gamma_2 = \left|\begin{array}{c|c|c|c|c|c|c} \ldots & e & \ldots & c & t & r & \ldots \\ \ldots & e & \ldots & c & \gg & r & \ldots \\ & t_2 & & t_8 & & t_{11} & \end{array}\right| \quad (3) \qquad (3)$$

According to the optimal alignment result of formula (3), it can be seen that the patient was excluded from COVID-19 infection at the beginning, but later transferred to the isolation ward which may be caused by many reasons. For example, as the epidemic situation intensifies, it is necessary to strengthen the protective measures for high-risk patients; or the patient contacted outside visitors with risk of infection during treatment, or the patient has concealed the travel information before admission to the hospital. The specific situation needs to be analyzed by the medical staff with the actual situation, which cannot be judged only from the logs.

The classical algorithm has been widely recognized and used for a long time, and its effectiveness is beyond reasonable doubt. Hence, the optimal alignments computed by the two algorithms need to be compared one by one. If all the results are the same, Algorithm 3 can be considered to be effective. Otherwise, if the results are different, it is possible that this algorithm be considered to be invalid.

Since the optimal alignment result is a sequence composed of nodes in the form of $(\alpha_2\ (t_x'), (\alpha_1\ (t_y), t_y))$, where t_x' corresponds to log model transition, $\alpha_2\ (t_x')$ is the activity corresponding to t_x', t_y corresponds to process model transition, and $\alpha_1\ (t_y)$ is the activity corresponding to t_y. Hence, after the optimal alignment is completed, the optimal alignment results obtained by the two algorithms are compared one by one to check whether the activity of the log model and the activity and the transition of the process model are exactly the same. According to the comparison results, it shows that all the optimal alignments are the same, which can illustrate that the algorithm is effective in deviation detection.

5. Conclusions

The deviation detection of clinical pathway is an important technology to standardize and study the diagnosis and treatment process and optimize the clinical pathway. The classical algorithm presented by Adriansyah et al. can synthesize the trace and process model and has a wide range of applications. Compared with the previous forward-looking methods, it has made a qualitative leap. However, with high complexity of search space, the efficiency in computing the optimal alignment is still unsatisfactory. Hence, this paper presents an optimization algorithm.

In this paper, the diagnosis and treatment log is preprocessed by the particularity of the diagnosis and treatment process. Considering that the alignment is logical based on the reachable graph to find the shortest path, even if the unnecessary transitions are only slightly reduced, the alignment efficiency can still be greatly improved. Hence, this paper uses the synchronous composition model for alignment computation, which greatly reduces the alignment time.

Finally, the clinical pathway of STEMI under COVID-19 is taken as an example for experimental analysis. It is illustrated that the newly proposed deviation detection method has the advantages of higher efficiency compared with the traditional algorithm, which can greatly shorten the time consumed in the deviation detection process. In the future work, this method can be applied to online deviation detection. Online deviation detection can timely detect the anomaly and remind patients of the deviation existing in the current completed diagnosis and treatment process. Meanwhile, it can predict the possible subsequent deviation and provide judgment basis for medical staff to carry out manual intervention to avoid adverse events. Online deviation detection requires higher efficiency, which can better reflect the advantage of the new method.

Academic Editor: Tongguang Ni

By constructing a complex network analysis model, this paper analyzes the data of 31 selected provinces in China from 2010 to 2019, summarizes China's provincial innovation chain development model, and then combined with the time series analyzes the evolution path of the model. The research shows that there is certain group proximity in China's provincial innovation chain in each year, and there are eleven models in ten years. The evolution path of the provincial innovation chain development model is mainly manifested in the development trend of low-level to medium-level and then high-level equilibrium model. Increasing investment and improving efficiency are the leading driving force for the development of China's provincial innovation chain. The medium-level equilibrium model runs through almost all years. Taking this as the node, the innovation driving force gradually changes from high investment to high efficiency.

1. Introduction

Discussing the mode and evolution of regional innovation chain is helpful to analyze the development direction of regional innovation chain and effectively optimize it and then has important theoretical and practical significance for the choice of the road of regional economic development. At present, the existing research on regional innovation mainly focuses on regional innovation system or regional innovation ecology. For the analysis of regional innovation development and its type differentiation, it has formed a variety of perspectives, such as efficiency perspective [1], system perspective [2], ecological perspective [3], and the perspective of regional innovation capability [4].

In terms of mode division and its development direction, it distinguishes China's high and low innovation capability aggregation areas from the perspective of innovation capability [5]. Several regional innovation models based on the manufacturing industry are compared and analyzed, and it is proposed that the Suzhou model is a better development direction [6]. Some researchers believe that different policies need to be formulated for different models to enhance their independent innovation ability [7]. Based on the analysis of innovation capability, it is found that the development shows the characteristics of agglomeration, especially in the eastern region (Wei Shouhua, 2021). Based on the comparative analysis of China's regional innovation models, it is proposed that the development direction should be the combination of technological innovation and non-technological innovation [8]. Some believe that regional innovation oriented to regional sustainable development should be established [9]. Based on the analysis of the distinctive regional innovation models of Jiangsu, Zhejiang, and Shanghai, it puts forward two basic construction ways, namely, the primary nature of market orientation and the late nature of government orientation [10].

In terms of research methods, in addition to some qualitative analysis combined with the original index data (such as [6]), quantitative analysis methods mainly focus on cluster analysis, such as Wu Yilin et al. [11]. Other quantitative methods, such as using factor analysis to measure the coupling degree of regional innovation [12], using Searle index and regional Gini index to discuss the spatial distribution and change trend of regional innovation capability [13], and using Moran analysis and spatial econometric model to analyze China's regional innovation capability [14], the application efficiency analysis distinguishes the differences and reasons of regional innovation [4].

In general, the existing studies, based on the distinction of types, do not fully discuss the development direction of its development model from the perspective of innovation chain, especially the development context and evolution path between models. In terms of methods, the existing common methods, such as factor and cluster analysis, can better distinguish various patterns, but they cannot analyze the internal similarity and external discrimination of types better, and their visual display is not explicit enough. The complex network modeling and analysis method can analyze the network relationship between objects by constructing point-to-edge mode and can deeply analyze the internal and external differentiation of patterns on the basis of pattern differentiation.

Therefore, based on the similarity perspective, this paper first comprehensively considers the regional innovation chain from the four dimensions of foundation, input, output, and achievement diffusion and constructs a comprehensive complex network model of 31 provinces and regions in mainland China from 2010 to 2019. Then, through community analysis, it divides subgroups, analyzes the characteristics of community agglomeration, and defines the model type of provincial innovation chain development. Then, combined with the time series, the evolution path of the model is found by analyzing the change of the type proportion of the provincial innovation chain development model in the time series.

2. Data and Methods

2.1. Regional Innovation Chain Index System. The relevant indicator systems of regional innovation are representatives, such as the "science, technology, and industry scorecard" of OECD, the national innovation capability index of the United States, and the Innovation Scoreboard of the European Union [15]. In addition, relevant studies have built an urban innovation support and input-output index system based on the theory of innovation vitality [16], emphasizing the importance of non-*R&D* indicators [17]. China's typical example is the report on China's regional innovation capability, which constructs an index system in five aspects: innovation environment, knowledge creation, knowledge acquisition, enterprise innovation capability, and economic benefits of innovation [18].

Based on the existing regional innovation evaluation index system, this paper constructs it from the perspective of innovation chain. In terms of index dimension, two dimensions of the main part of the regional innovation chain, innovation input (direct input of resources related to innovation) and innovation output (direct result output of innovation), as well as the postchain result part, innovation result diffusion dimension (transformation effect of innovation direct result), and the front chain foundation part, innovation foundation dimension, are considered. Therefore, the index system covers four links of the regional innovation chain: foundation, input, output, and application of achievements. In the selection of specific indicators, considering the respective contributions or influence of different innovation subjects (government, enterprises, scientific research institutions, and universities) in the innovation chain and drawing on the relevant rules of the EU Innovation Scoreboard, an index system including four dimensions, 12 primary indicators, and 24 specific indicators is constructed. For the selection of primary indicators, the regional innovation foundation includes the human and economic foundation, innovation service foundation, and innovation infrastructure, the regional innovation input includes the input of different innovation subjects (government, enterprises, scientific research institutions, and universities), and the regional innovation output includes the output of different innovation subjects (enterprises, scientific research institutions, and universities). The diffusion of regional innovation achievements includes the diffusion of innovation achievements of above designated enterprises and high-tech enterprises. In addition, this paper mainly considers the similarity between provinces, so the specific index data is mainly relative indicators. See Table 1 for details.

2.2. Data. This paper mainly uses the data from 2010 to 2019 from China Statistical Yearbook, China regional innovation capability report, China Science and technology statistical yearbook, and some local statistical yearbooks to collect and sort out the indicators of 31 provinces in China except Hong Kong, Macao, and Taiwan. Considering the data collection, this paper investigates the provincial innovation with enterprises above designated size instead of enterprises in the innovation subject. Since 2011, the statistical scope of industrial enterprises above designated size has been adjusted from French labor enterprises with an annual main business income of 5 million yuan and above to legal person industrial enterprises with an annual main business income of 20 million yuan and above.

2.3. Model Construction. This paper analyzes the complex network by constructing the complex network model. The complex network mainly analyzes the relationship between objects. This paper takes each province as a network node to form a complex network. By processing the index data, the cosine distance of each included angle is obtained, and the overall complex network diagram of 31 provinces is obtained by using UCINET(v6.5) software. Then, the complex network analysis method is used to analyze the community.

2.3.1. Distance Analysis between Provinces. Specifically, directed weightless network, directed weightless network, directed weightless network, and undirected weightless network belong to complex networks. At the same time, the setting of the relationship between network nodes affects the key core of the network. The interprovincial association complex network constructed in this paper is based on

Table 1: Construction of regional innovation chain index system.

Dimension	Primary index	Specific indicators
Regional innovation foundation	Humanistic economic foundation	Per capita GDP (yuan/person)
		Years of education per capita (years/person)
		Consumption level of residents (yuan/person)
	Innovation service foundation	Per capita technology market transaction amount (by flow direction) (yuan/person)
		Number of scientific research institutions per capita (10000 persons)
		Average amount of loans from financial institutions for scientific research expenditure of large and medium-sized industrial enterprises (10000 yuan/piece)
	Innovation infrastructure	Per capita road ownership (km/person)
		Average number of mobile phones per 100 households of households in various regions (department/100 households)
Regional innovation investment	Government investment	Proportion of government *R&D* expenditure in local GDP (%)
	Investment of enterprises above designated size	Proportion of *R&D* personnel of enterprises above designated size in employees of enterprises above designated size (%)
		Proportion of *R&D* expenditure of enterprises above designated size in local GDP (%)
		Proportion of total expenditure of technology purchase, introduction, absorption, and transformation of above designated enterprises in regional GDP (%)
	R&*D* organization investment	Proportion of *R&D* personnel in *R&D* institutions in each region (%)
		Proportion of *R&D* expenditure of *R&D* institutions in regional GDP (%)
	Investment in colleges and universities	Proportion of *R&D* personnel in colleges and universities in each region (%)
		Proportion of *R&D* funds of colleges and universities in regional GDP (%)
Regional innovation output	Output of enterprises above designated size	Average number of patent applications of industrial enterprises above designated size in each region (pieces/10000 people)
	Output of scientific research institutions	10000 people have an average of scientific and technological papers published by *R&D* institutions in various regions (articles/10000 people)
		Average number of patent applications of *R&D* institutions in various regions owned by 10000 people (pieces/10000 people)
	Output of colleges and universities	10000 people have an average of scientific and technological papers published by colleges and universities in various regions (articles/10000 people)
		Average number of patent applications of colleges and universities in various regions owned by 10000 people (pieces/10000 people)
Diffusion of regional innovation achievements	Diffusion of innovation achievements of enterprises above designated size	Proportion of new product output value of enterprises above designated size in total industrial output value (%)
	Diffusion of innovation achievements of high-tech enterprises	Proportion of output value of new products of high-tech industry in total output value (%)
		Proportion of new product export revenue of high-tech industry in new product sales revenue (%)

similarity distance and belongs to an undirected weighted network.

To build a complex network model, we must first standardize the index data used. In this process, the final 24 specific indicators are considered because they reflect the corresponding primary indicators and corresponding dimensions. And further, determine the relationship between provinces.

Let the index data of each province be $Y_{ij} = \left\{Y_{ij}, i = 1, 2 \ldots; j = 1, 2 \ldots\right\}$, y_{ij} represents the score of the *i*th province in the *j*th index, *i* Max 30, and *j* Max 24. For comparability, the original scores of all provinces under each indicator are divided by the square root of all original scores of the indicator as the standard score. The standard score matrix is

$$X_{ij} = \frac{Y_{ij}}{\sqrt{1/I \sum_{k-1}^{K} Y_{kj}^2}}. \tag{1}$$

$X_{ij} = \left\{X_{ij}, i = 1, 2 \ldots; j = 1, 2 \ldots\right\}$.

There are many ways to define the distance between provinces, which can reflect many differences between provinces. The included angle cosine distance between provinces R and S can be defined as

$$P_{rs} = 1 - \frac{\sum_{j-1}^{J} X_{rj} X_{zj}}{\sqrt{\sum_{j-1}^{J} X_{rj}^{2}} \sqrt{\sum_{j-1}^{J} X_{sj}^{2}}}. \quad (2)$$

The distance between R and S provinces is the cosine of the included angle of the vector composed of 24 indexes. All are nonnegative indicators, so [0, 1] is the value range of included angle cosine distance. The similarity of characteristics between provinces or the similarity of the development model can be expressed by this distance. Some provinces are economically developed, but the cosine distance between them and provinces with the same economic level is very large; the reason is that the two provinces have a different bias on a specific index, so the similarity between them is not high. This formula focuses more on similarity and difference in the analysis of provinces.

After setting the relationship between provinces, it is necessary to further set the edges in the complex network, that is, the connection relationship between nodes. Taking each province as the node and the relationship between provinces as the edge, a complex network of provincial innovation chain relationship can be established. For the distance matrix, there are two kinds of methods to establish edges. One is the threshold method; that is, according to the invariant topological properties [19], network connectivity [20], and the minimum spanning tree and event union (Wang *J*, Yang *h*, 2009) criteria, set a threshold, and the establishment of edges is set between node pairs whose distance is less than or equal to the threshold. The second type is the maximum edge restriction method; that is, specify a value to establish the maximum upper limit of each node connected to several nearest nodes [21]. This paper adopts the former method, that is, threshold method, and selects the maximum value of the minimum distance between each province and other provinces in the provincial distance matrix as the standard value. If it is less than or equal to this value, it will judge the similarity between the corresponding two provinces as the position and strength of each province in the whole provincial innovation network. Therefore, a complex network model of the provincial innovation chain is constructed.

2.3.2. Division and Analysis of Complex Network Communities in Provincial Innovation Chain. According to Newman's research on community structure, in the complex network of the provincial innovation chain, the provinces with a high degree of similarity include angle cosine distance from each community (subgroup). Therefore, the provinces are classified according to the community. On the basis of calculating the cosine distance of the included angle between provinces and determining the value of the distance matrix, the distance matrix is binarized. So the undirected binary relationship network diagram can be formed by the provincial innovation chain network, and then the community analysis of the provincial innovation chain can use the factional division method.

As for the division of communities, there are two methods: cliques and faces. According to the observation results of the complex network graph, it is forcibly divided into several most suitable groups (3–8 groups), so it is divided into various subgroups.

The extended subgroup density relation matrix can be obtained from the analysis of the combined block model [22]. The matrix describes the density relationship between the subgroup itself and the subgroup so that the similarity analysis between and within the subgroup can be carried out. It is also used to detect whether the above grouping is most appropriate.

This paper comprehensively analyzes the community division of provinces from four dimensions in order to find out the similarity of the innovation chain model among provinces. Combined with the time series, the development mode and path of the province are analyzed.

2.3.3. An empirical Analysis of China's Provincial Innovation Chain Model and Its Evolution Path. Based on the construction and analysis of the provincial innovation chain complex network model, combined with the data of 24 indicators in 31 provinces from 2010 to 2019, this paper uses UCINET (v6.5) software to analyze the provincial innovation chain complex network.

For the results processed by UCINET (v6.5) software community, we need to further combine the data analysis and then summarize the characteristics of each subgroup to obtain the innovation chain model of different years and provinces in China. Finally, through the comparison of time dimensions, this paper summarizes and refines the evolution path of the provincial innovation chain model.

2.4. Model Differentiation and Analysis of China's Provincial Regional Innovation Chain from 2010 to 2019. After the complex network analysis of the data, the complex network diagram is shown in Figure 1 (space limitation, only four annual graphs are shown).

Further, combined with the observation of the complex network diagram of each year, each year is divided into 4–5 subgroups by the mandatory method, and the similarity between subgroups and the appropriateness of grouping are analyzed by expanding the subgroup density relationship matrix. The division of complex network subgroups of provincial innovation chain in each year is shown in Table 2.

Analyze the original data of the relevant indicators of the four modules of each subgroup of the province in each year, and divide the data into five levels: poor, lower middle, middle level, upper middle, and better. Then, combined with the expert analysis method, 11 models are defined for all years. The first appearance and brief analysis of various models are as follows: in 2010, the first subgroup of provinces had poor innovation foundation, low innovation input, low innovation output, and less diffusion of innovation achievements. We defined it as the leading model of low input and low output. The provinces of the second subgroup have weak innovation foundation, medium innovation input, medium innovation output, and diffusion of innovation

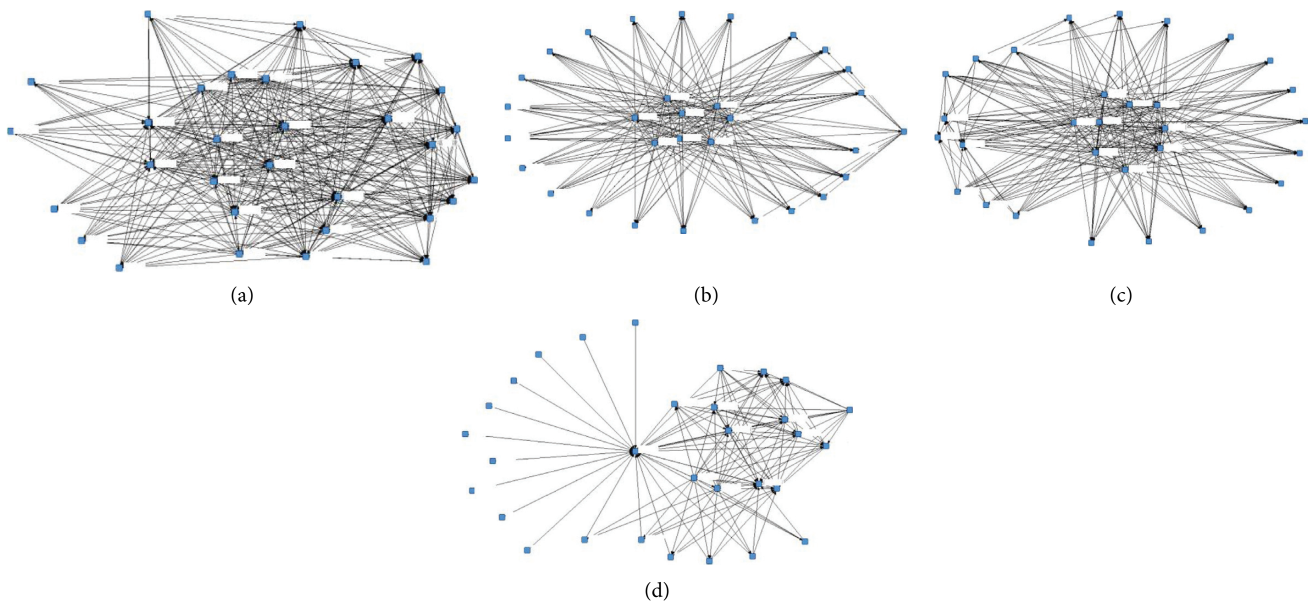

Figure 1: Annual complex network diagram of China's provincial innovation chain: (a) 2010 network diagram; (b) 2013 network diagram; (c) 2016 network diagram; (d) 2019 network diagram.

Table 2: Division of complex network subgroups of provincial innovation chain in each year.

Year	Subgroup	Province	Pattern
2010	First subgroup	Tibet and Qinghai	Leading mode of low input and low output
	Second subgroup	Heilongjiang, Guizhou, Inner Mongolia, and Shaanxi	CIC's weak equilibrium model
	Third subgroup	Beijing, Tianjin, Shanghai, Shandong, Fujian, Zhejiang, and Jiangsu	Higher-level equilibrium model
	Fourth subgroup	Hebei, Shanxi, Jilin, Anhui, Jiangxi, Henan, Liaoning, Hubei, Hunan, Guangdong, Guangxi, Hainan, Chongqing, Sichuan, Yunnan, Gansu, Ningxia, and Xinjiang	Low-level equilibrium model
2011	First subgroup	Xinjiang, Gansu, and Ningxia	Low-level equilibrium model
	Second subgroup	Hebei, Yunnan, Heilongjiang, Jiangxi, Sichuan, Guizhou, Tibet, Inner Mongolia, Jilin, Anhui, and Henan	CIC's weak equilibrium model
	Third subgroup	Beijing, Shanghai, Zhejiang, and Guangdong	Higher-level equilibrium model
	Fourth subgroup	Shanxi, Fujian, Shandong, Hubei, Hunan, Hainan, Shaanxi, Qinghai, Tianjin, Liaoning, Guangxi, Chongqing, and Jiangsu	Medium-level equilibrium model
2012	First subgroup	Sichuan, Yunnan, Tibet, Ningxia, Xinjiang, and Qinghai	High input and high diffusion mode
	Second subgroup	Shanxi, Inner Mongolia, Heilongjiang, Jiangsu, Shandong, Henan, Guizhou, Anhui, Hunan, Guangxi, and Chongqing	Medium-level equilibrium model
	Third subgroup	Beijing, Tianjin, Shanghai, Zhejiang, Fujian, Guangdong, Jiangxi, and Shaanxi	High-level equilibrium model
	Fourth subgroup	Hebei, Liaoning, Jilin, Hubei, Hainan, and Gansu	CIC's weak equilibrium model
2013	First subgroup	Hubei, Hainan, Chongqing, Sichuan, Tibet, Shaanxi, Qinghai, Ningxia, and Xinjiang	Leading mode of high investment and high diffusion
	Second subgroup	Hebei, Liaoning, Anhui, Jiangxi, Henan, Guangdong, and Gansu	Low-level equilibrium model
	Third subgroup	Beijing, Jilin, Heilongjiang, Shanghai, Zhejiang, and Fujian	Higher-level equilibrium model
	Fourth subgroup	Tianjin, Shanxi, Inner Mongolia, Jiangsu, Shandong, Hunan, Guizhou, Guangxi, and Yunnan	Medium-level equilibrium model
2014	First subgroup	Hebei, Jiangsu, Anhui, Shandong, Guangxi, Sichuan, Yunnan, Tibet, Gansu, and Xinjiang	Medium-level equilibrium model

Table 2: Continued.

Year	Subgroup	Province	Pattern
	Second subgroup	Shanxi, Liaoning, Jilin, Hubei, Hainan, Guizhou, Shaanxi, and Qinghai	Medium base weak equilibrium model
	Third subgroup	Beijing, Tianjin, Inner Mongolia, Shanghai, Hunan, Guangdong, and Chongqing	High-efficiency output leading mode
	Fourth subgroup	Heilongjiang, Zhejiang, Fujian, Jiangxi, Henan, and Ningxia	Equilibrium model in weak input
2015	First subgroup	Shanxi, Liaoning, Shanghai, Henan, Hunan, Guangxi, Xinjiang, Tibet, Gansu, and Ningxia	Medium-level equilibrium model
	Second subgroup	Jilin, Heilongjiang, Zhejiang, Anhui, Guizhou, Shaanxi, and Qinghai	CIC's weak equilibrium model
	Third subgroup	Beijing, Hebei, Jiangsu, Jiangxi, Shandong, Guangdong, and Chongqing	Higher-level equilibrium model
	Fourth subgroup	Tianjin, Inner Mongolia, Fujian, Hubei, Hainan, Sichuan, and Yunnan	Medium base weak equilibrium model
2016	First subgroup	Hebei, Jiangsu, Shandong, Guangxi, Yunnan, Tibet, and Xinjiang	Equilibrium model in weak input
	Second subgroup	Heilongjiang, Zhejiang, Fujian, Shaanxi, Qinghai, and Ningxia	Medium-level equilibrium model
	Third subgroup	Beijing, Tianjin, Inner Mongolia, Shanghai, Anhui, Hunan, Guangdong, Chongqing, and Gansu	High-efficiency output leading mode
	Fourth subgroup	Shanxi, Liaoning, Jilin, Jiangxi, Henan, Hubei, Hainan, Sichuan, and Guizhou	Medium base weak equilibrium model
2017	First subgroup	Heilongjiang, Fujian, Henan, Hubei, Hainan, and Guizhou	Equilibrium model in weak input
	Second subgroup	Zhejiang, Hunan, Chongqing, and Ningxia	Medium investment and high diffusion dominated model
	Third subgroup	Hebei, Jilin, Anhui, Shandong, Yunnan, and Xinjiang	Medium-level equilibrium model
	Fourth subgroup	Beijing, Tianjin, Inner Mongolia, Jiangsu, Jiangxi, Guangdong, Guangxi, Sichuan, Tibet, and Gansu	High-efficiency output leading mode
	Fifth subgroup	Shanxi, Liaoning, Shanghai, Shaanxi, and Qinghai	Leading mode of high foundation and high yield
2018	First subgroup	Tianjin, Inner Mongolia, Jiangxi, Hunan, Sichuan, Tibet, and Gansu	Equilibrium model in weak input
	Second subgroup	Hebei, Shanxi, Ningxia, Shandong, Guizhou, Yunnan, Shaanxi, Qinghai, and Xinjiang	Medium base weak equilibrium model
	Third subgroup	Jiangsu, Anhui, Hainan, and Chongqing	Leading mode of high foundation and high yield
	Fourth subgroup	Heilongjiang, Henan, Hubei, and Guangxi	Medium-level equilibrium model
	Fifth subgroup	Beijing, Liaoning, Jilin, Shanghai, Fujian, Zhejiang, and Guangdong	Higher-level equilibrium model
2019	First subgroup	Beijing, Guangdong, Zhejiang, Jilin, Shanghai, Jiangsu, Fujian, and Shandong	Higher-level equilibrium model
	Second subgroup	Tianjin, Inner Mongolia, Anhui, Jiangxi, Hebei, Guangxi, Sichuan, Tibet, and Gansu	Equilibrium model in weak input
	Third subgroup	Shanxi, Liaoning, Hunan, Chongqing, Shaanxi, Qinghai, Guizhou, and Yunnan	Medium-level equilibrium model
	Fourth subgroup	Heilongjiang, Henan, Hubei, Hainan, Ningxia, and Xinjiang	Medium investment and high diffusion leading model

achievements. We define it as the medium input weak equilibrium model. The third subgroup has a good innovation foundation, high innovation input, high innovation output, and good diffusion of innovation achievements. We define it as the high-level equilibrium model. The provincial innovation foundation, innovation input, innovation output, and innovation achievement diffusion of the fourth subgroup are in the lower middle position, which we define as the low-level equilibrium model. In 2011, the provincial innovation base and innovation output of the fourth subgroup were in the lower middle position, and the innovation input and innovation achievement diffusion were in the middle level. We define it as the medium-level equilibrium model. In 2012, the provincial innovation base and innovation output of the first subgroup were in the lower middle position, and the diffusion of innovation input and innovation achievements was good. We defined it as the high input and high diffusion model. In 2014, the provincial

Table 3: Summary of annual provincial innovation chain development model.

Year	Subgroup pattern and proportion										
	Leading mode of low input and low output (%)	Low-level equilibrium model (%)	CIC's weak equilibrium dominant model (%)	Medium base weak equilibrium model (%)	Medium-level equilibrium model (%)	Equilibrium model in weak input (%)	Leading mode of high investment and high diffusion (%)	Leading mode of high foundation and high output (%)	Medium investment and high diffusion leading model (%)	Higher-level equilibrium model (%)	High-level equilibrium model and high-efficiency output leading model (%)
2010	6.50	57.90	12.90							22.60	
2011		9.70	35.40		41.90					12.90	
2012			19.40		35.50		19.40			25.80	
2013		22.60			29.00		29.00			19.40	
2014				25.80	32.30	19.40					22.60
2015			22.60	22.60	32.30					22.60	
2016				29.00	19.40	22.60					29.00
2017					19.40	19.40		16.10	12.90		32.30
2018				29.00	12.90	22.60		12.90		22.60	
2019					25.80	29.00			19.40	25.80	

innovation base of the second subgroup was at the middle level, and the innovation input, innovation output, and innovation achievement diffusion were at the lower middle level. We defined it as the medium base weak equilibrium model. The innovation base, innovation output, and innovation achievement diffusion of the third subgroup are in the upper middle position, but the innovation output is very considerable, which we define as the leading mode of high-efficiency output. The provinces of the fourth subgroup belong to the innovation foundation, and innovation output and innovation achievements are at the middle level, but the innovation input is at the lower middle position. We define it as the medium equilibrium model of weak input. In 2017, the provincial innovation base and innovation output of the second subgroup were in the lower middle position, the innovation input was in the middle level, and the diffusion of innovation achievements was high, belonging to the dominant mode of medium input and high diffusion. The provinces of the fifth subgroup have a good innovation foundation, the diffusion of innovation input and innovation achievements is at a medium level, and the innovation output is high. We define it as the leading model of high foundation and high output.

2.5. Analysis of the Evolution Path of China's Provincial Innovation Chain Development Model. Further, we analyze the evolution path of China's provincial innovation chain development model and compare the number of provinces in each subgroup with the number of provinces in China to calculate the proportion of each model, so the provinces in China can be summarized as shown in Table 3.

Generally speaking, the main mode of China's provincial innovation chain is around innovation input and innovation output. From 2012, it began to pay attention to the innovation foundation and the diffusion of innovation achievements. In 2014, a high-level balanced development mode began to appear, slowly approaching the high-efficiency development mode. This shows that the development of China's provincial innovation chain is based on innovation input, pays more attention to innovation input and innovation output, and weakens the innovation foundation and the diffusion of innovation achievements. With the development of China's economy, the development of the two dimensions of input and output has affected or spread to other dimensions, showing a four-dimensional synchronous development trend, and began to pay attention to efficiency development and improve the quality of innovation.

At the same time, the annual scores and proportion of the eleven models in all years are quite different, and there are some main models, transition models, and edge models. From the overall trend of the development model of regional innovation chain from 2010 to 2019, the evolution of its main model is from low-level equilibrium model to medium-level equilibrium model and then to high-level equilibrium development. The medium-level equilibrium model runs through almost all years, taking this as the node innovation driving force, and gradually changes from high investment to high efficiency. In this trend, there are corresponding transition modes between the two stages of balanced development mode transformation, which are mainly started and driven by increasing investment or improving efficiency, such as medium input weak equilibrium mode, weak input medium equilibrium mode, and medium input high diffusion dominant mode. Therefore, it can be seen that the leading evolution path of the provincial innovation chain development model is to start with the low-level equilibrium model and develop from the medium-level equilibrium to the high-level equilibrium model. The auxiliary evolution path is investment enhancement path and efficiency improvement path.

3. Research Conclusion

Using the complex network model and the regional innovation-related data of 31 provinces in mainland China in recent ten years, this paper analyzes the four modules of China's innovation foundation, innovation input, innovation output, and innovation achievement diffusion, so as to investigate the development mode and evolution path of provincial innovation chain in China. The research findings are as follows: (1) Each year, the regional innovation chains of 31 provinces in China show certain group proximity. Each year, all provinces in China can be divided into 4 or 5 modes, and a total of 11 modes are shown in all years: low input and low output leading mode, low-level equilibrium mode, medium input weak equilibrium leading mode, medium foundation weak equilibrium mode, medium-level equilibrium mode, weak input medium equilibrium model, high input high diffusion leading model, high foundation high output leading model, medium input high diffusion leading model, high-level equilibrium model, and high-efficiency output leading model. (2) From 2010 to 2019, China's provincial innovation chain development model developed along the low-level-medium-level-high-level equilibrium model on the main model evolution path. The model evolution was mainly started and driven by increasing investment or improving efficiency. There were corresponding transition models between the two stages of balanced development model transformation, such as medium input weak equilibrium model, weak input medium equilibrium model, and medium input high diffusion dominant model. (3) The development model of China's provincial innovation chain shows a good trend: starting from innovation input, focusing on innovation input and innovation output, and then affecting or spreading to other dimensions, showing a four-dimensional synchronous development trend. However, the medium-level equilibrium model runs through almost all years. Taking this as the node, the innovation driving force gradually changes from high investment to high efficiency.

The enlightenment is as follows: for China as a whole, under the overall trend of the evolution path of China's provincial innovation chain development model, it is necessary to pay attention to the shortcomings of the simple promotion mode of high investment advocated all the time and turn to the high-efficiency promotion of quality and high yield and high diffusion of connotation, in order to more reasonably and effectively improve the development level of provincial innovation chain. In addition, for each province, it is necessary to correctly understand the development status of the innovation chain of the province and the previous evolution path and design the promotion ways and paths more in line with its own reality and historical situation.

In recent years, due to the rapid development of rural tourism, rural tourism has lost its unique rurality, which has led to a certain impact on the sustainable development of rural tourism. Primarily, based on the rural characteristics, the social environment development, population development, and economic development are taken as the research indexes, and the evaluation index system of rural tourism destination is constructed. Afterward, an empirical study on the spatial pattern of rural tourism is carried out with examples, and the model is simulated and analyzed by MATLAB software. Finally, the spatial autocorrelation method is used to analyze the evolution characteristics of the rural tourism spatial pattern. The results show that through the analysis of the evaluation error curve of the Back Propagation Neural Network (BPNN), the evaluation error and the actual error range are within 0.08%, which proves that the BPNN algorithm has good calculation accuracy. The BPNN rural tourism destination rurality evaluation model established here can make an effective evaluation of rural tourism space. The results show that the proportion of employees in the primary industry and the penetration rate of mobile phones are the decisive factors in the adjustment of industrial structure and social environmental factors, respectively. Rural per capita tourism income and the proportion of primary industry output value will also have a certain impact on rural evolution. Certain guiding significance is provided for the sustainable development of rural tourism.

1. Introduction

With the rapid development of information technology and Internet technology, the importance of big data technology is increasingly focused by various industries. Big data refer to massive and complex data that cannot be processed by traditional data processing methods. Both accurate analyzation of consumers' consumption behavior and decision-making can be realized through big data technology so that various business activities can be carried out in a targeted manner. With the rapid development of China's urbanization process, people's demand for rural and urban tourism is getting higher and higher. Meanwhile, China's rural tourism has developed very well in recent years [1]. However, problems in rural tourism have occurred during the rapid development of rural tourism, among which the most important one is the marketization of tourism destinations, which leads to the gradual weakening of the rural nature of rural tourism destinations and conflicts with the sustainable development of rural tourism.

Due to the rapid advancement and development of urbanization, the population flow between cities and villages has become increasingly frequent, thus strengthening the interaction of economic and social development factors cities and villages. The rural industrial structure and layout are constantly being adjusted. The fading of "homesickness" memory and rural spatial differentiation have made the rural research increasingly significant. Scholars from all walks of life have begun to pay attention to the study of rural nature [2]. At present, researchers all over the world have made a series of researches and discussions on the rural theory. Gao et al. [3] constructed the framework of rural spatial reconstruction driven by tourism. The changing process of rural spatial reconstruction was revealed by using geographic information system and participatory field investigation. The research showed that rural spatial reconstruction driven by tourism was the result of internal and external forces, while land consolidation was the direct way to trigger rural spatial reconstruction. Rural tourism can accelerate land consolidation and realize rural revitalization. Panzer-Krause et al. [4] conducted a standardized survey on tourists in Giant Causeway, the most visited scenic spot in Northern Ireland. The results showed that the awareness of sustainability had declined from individual tourists to long-distance tourists and then to cruise tourists, so it is necessary to manage sustainability in specific market segments. Rural tourism hot spots should be the hub to coordinate and promote the network of regional tourism providers, so as to realize their real integration into rural communities. Verma et al. [5] used data from the land satellite to conduct a survey on rural areas in Varanasi County. Also, results showed that the agricultural area (accounting for 50% of the land cover area) increased by 37% and the building area increased by 236% during 1993–2013 in Varanasi County. A relative rural development index was developed to understand the comparative development of rural blocks in the region. Qi et al. (2021) [6] took 169 villages in Jingyuan County as the research object, and the evaluation index system of rural development level was constructed from the perspective of factor structure function. The rural development level and spatial structure characteristics of Jingyuan County were analyzed by rural development index, regional function index, nearest neighbor index, and exploratory spatial data analysis, and the types and specific paths of rural development are determined. The results showed that the rural development level of Jingyuan County was low, which can be described as "high developing level in south areas but low developing level in north areas." Yang et al. (2021) [7] used multisource data, such as remote sensing images, building data, official websites, and field surveys to investigate the morphology and social evolution of rural communities from the perspective of tourism, and analyzed its driving factors.

Rural settlements are places where ancestors lived, and some unique landscape elements become the foundation of rural nature [8]. However, due to the rapid development of urbanization and rural tourism, rural development is facing new problems and challenges. One of the most important problems is that the development of some rural areas is disorderly and spontaneous. Urban characteristics, landscape construction, and the phenomenon in the process of rural tourism marketization are on the rise. Consequently, the original rural settlement landscape has been greatly negatively affected [9,10]. The originally good natural ecological environment in rural areas has been destroyed, and the problems in rural economic structure, villagers' culture, and lifestyle have become increasingly prominent. As a kind of rural tourism, its most basic charms have been seriously ignored in rural areas, and its rural nature is gradually losing in rural tourism areas [9]. The sustainable development of rural tourism will face severe challenges, and it is urgent to pay attention to rural development from a deeper and wider

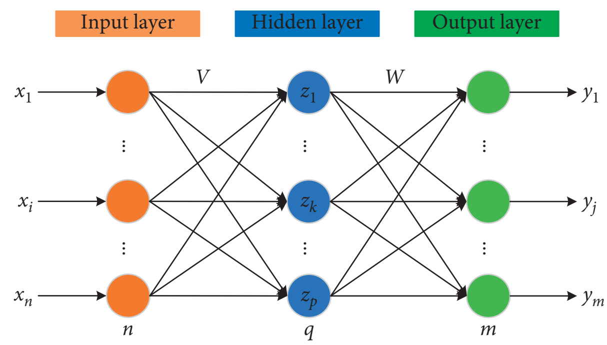

Figure 1: BPNN structure.

level. Tourism destinations must enhance their value cognition level and implement rural protection of tourism destinations. Therefore, the influencing factors of rural tourism destination are taken as the breakthrough point. An evaluation model of the rural tourism spatial pattern based on the neural network algorithm is implemented to evaluate the spatial pattern of rural tourism. Certain guiding significance is provided for the sustainable development of rural tourism.

2. Method

2.1. BP Neural Network. Back propagation neural network (BPNN) has become one of the most commonly used algorithms in the field of machine learning (ML) in recent years [11,12]. The artificial neural network (ANN) is composed of interconnected neurons. Also, each neuron receives the information sent by the neurons in the previous layer and transmits the received information through nonlinear transformation. The neural network can approach complex mapping relations through training and has wide applications in pattern recognition, function approximation, and classification prediction [13]. BPNN consists of three parts: input layer, hidden layer, and output layer. The hidden layer can have multiple layers, and each layer can contain different numbers of neurons [14]. When BPNN works, primarily, data samples are imported through the input layer. Then, through a series of mathematical calculations, the laws between the data are obtained. Finally, all prediction datasets are calculated by using these laws, and the prediction results are obtained. Figure 1 displays the structure of BPNN.

The specific expression of BP is as follows:

$$
\begin{aligned}
W_{R\times S} &= \begin{bmatrix} W_{0,0} & W_{0,1} & \cdots & W_{0,S-1} \\ W_{1,0} & W_{1,1} & \cdots & W_{1,S-1} \\ \vdots & \vdots & \vdots & \vdots \\ W_{R-1} & W_{R-1} & \cdots & W_{R-1,S-1} \end{bmatrix} \\
W_{S\times N} &= \begin{bmatrix} W_{0,0} & W_{0,1} & \cdots & W_{0,S-1} \\ W_{1,0} & W_{1,1} & \cdots & W_{1,S-1} \\ \vdots & \vdots & \vdots & \vdots \\ W_{R-1} & W_{R-1} & \cdots & W_{R-1,S-1} \end{bmatrix}.
\end{aligned} \tag{1}
$$

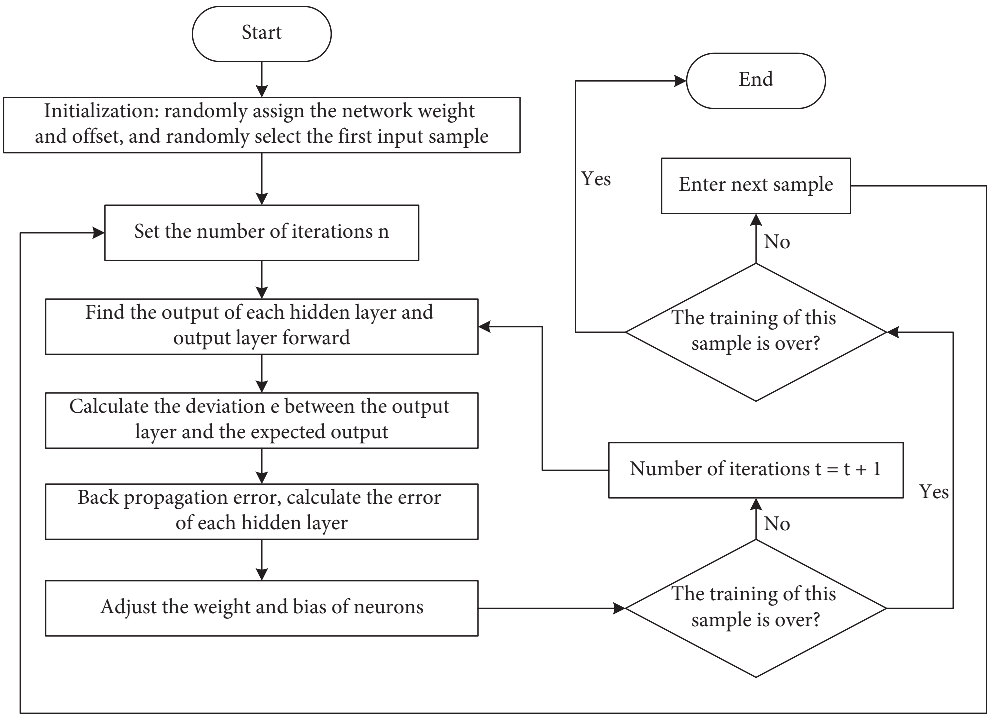

Figure 2: Algorithm flow of BPNN.

The matrices V and W are the connection weight matrices of the output layer and the hidden layer, and the connection weight matrices of the hidden layer and the input layer, respectively.

In the process of calculation, the data are propagated forward. In this process, the weights and deviations of hidden neurons are obtained randomly. The neural network is propagated forward to obtain the sum of each neuron, and the data on the neuron are transmitted to the next neuron through the activation function [15]. The neurons in the output layer also apply the activation function to complete the forward propagation of the neural network, and calculate the error between the output value and the actual output value of the output layer. The specific expression is as follows:

$$E = \frac{1}{2}(t - y)^2, \tag{2}$$

where E stands for the square of error, t refers to the expected value of the sample output, and y represents the actual output result.

Figure 2 signifies the algorithm flow of BPNN.

A “gradient descent method” is used to optimize the weights of neural networks, and the differential chain rule is mainly used to calculate the partial derivatives of error E relative to the weights of networks W_{ij} [16]. Utomo (2017) [17] proposed a gradient-based BPNN method to improve the optimization of stock price prediction. In the BPNN method, the gradient descent method is used to adaptively determine the learning rate, the training cycle, and other parameters, to obtain the best value in the stock data processing process, and to obtain the accuracy of the prediction during training. The calculation method is as follows:

$$\frac{\partial E}{\partial w_{ij}} = \frac{\partial E}{\partial o_j}\frac{\partial o_j}{\partial n\,et_j}\frac{\partial n\,et_j}{\partial w_{ij}}, \tag{3}$$

where j represents the neuron input and net_j refers to constraint neuron J. In the equation $o_j = y$, the derivative y is used to indicate the rate of change of the value, and the derivative or the slope is used to minimize the error. The partial derivative of the error term relative to the output of a specific neuron j is calculated as follows.

The method of expressing the neuron output partial derivative of the input neuron is as follows:

$$\frac{\partial o_j}{\partial n\,et_j} = \frac{\partial}{\partial n\,et_j}\varphi\left(net_j\right)\left(1 - \varphi\left(net_j\right)\right). \tag{4}$$

The partial derivative of the actual output value o_i is calculated as follows:

$$\frac{\partial n\,et_j}{\partial w_{ij}} = \frac{\partial}{\partial w_{ij}}\left(\sum_{k-1}^{n} w_{ij}o_k\right) = \frac{\partial}{\partial w_{ij}}w_{ij}o_k = o_i. \tag{5}$$

The weights of neurons in each layer of BPNN can be determined by a partial derivative and a learning rate. When using BPNN for calculation, it is necessary to repeat the above steps continuously until the error between the output value and the expected value reaches the allowable range or reaches the maximum times of iterations of NN. The advantage of using gradient descent method to improve BPNN is that the adjustment of weights and thresholds can further eliminate the instability in the neural network caused by the large variation of gradient value in the gradient adjustment process.

2.2. Study Area. Rural tourism refers to tourism activities that take nature, humanities, and cultures of villages as objects and attractions [18]. The meaning of rural tourism includes two features: the first feature is that the rural tourism destination is in the rural areas, and the second feature is the unique rural nature. These two points must be met in tourist activities at the same time to be called rural tourism [19,20]. Therefore, in the process of developing rural tourism, attention should be paid to the maintenance of rural images. Only by maintaining the original features of rural areas can urban people return to nature and the sustainable development of rural environment be ensured [21,22]. Rural nature is a restatement of the concept of rural regions. It is the harmony among human beings, architecture, and nature. It runs through rural history and is the result of harmonious coexistence between human beings and nature. Population characteristics and production scales are the basis of sustainable development and inheritance of human civilization.

Jiahu District of Hangzhou City in the north of Zhejiang Province is taken as the study area, which has been a land of fish and rice resources since ancient times, with flat terrain and beautiful scenery. The Zhejiang hinterland is a province with dense water resources, eutrophication of water bodies, and high degree of landscape ecology, which occupies a very important position in water resources and landscape ecosystem. A Hangzhou-Jiaxing-Huzhou region has a unique humanistic style and rich rural tourism resources, which provides conditions for the development of rural tourism. Based on local resources and existing farmers' production factors, a number of famous rural tourism brands have been created, which are identified as "Zhejiang Agricultural Villages" in small towns (villages) and "Hangjianghu agricultural areas." From the aspect of social and economic development, through the analysis of tourism resources, tourism level, geographical environment, and traffic location, results show that Jiahu District of Hangzhou is the largest rural tourism development zone in Zhejiang Province, with the highest management level and the largest scale. Zhejiang Province has become one of the first provinces to develop rural tourism in China. Taking the construction of beautiful villages as the carrier, it is one of the most abundant and mature areas of tourism resources in China. The Hangzhou-Jiaxing-Huzhou region gives a full play to the interactive role of new rural construction and rural tourism development. Through the development of rural tourism, the vast number of rural residents get employed, which strengthens the economic strength of rural areas and realizes the rapid development of rural economy. Significant changes have taken place in rural areas, and farmers' lives have also been greatly improved, which has become a classic example of urbanization of new rural cooperative economic organizations in China's ecological civilization construction. Therefore, it is a typical and representative problem to choose this area as the research object.

The data come from the statistical yearbooks of Hangzhou City, Zhejiang Province in 2010, 2015, and 2020, while other data are obtained through the compound calculation.

2.3. Construction of Rural Indicators of Rural Tourist Destinations Based on Neural Networks. The comprehensive description of rural development is the result of multifactors' integration, and the change of each factor determines the alternation of the direction of rural development. According to the research content on the concept and connotation of rurality in the rurality theory, rurality is the unique attribute of rural regions, including land use structure, industrial structure, infrastructure, and other factors. In addition, the current relevant research results usually display indicators from the population settlement, economic development, social development, land use, infrastructure, and other aspects, which are used to construct the rurality evaluation index system. Based on this, it is preliminarily proposed to construct the rurality evaluation index system of tourism destinations from the aspects of population development, economic level, social environment development, and infrastructure. Through the study of relevant literature, combined with the particularity of rural tourism destination, the representative, comparable, and easily accessible indicators are comprehensively selected. The four primary indicators of social environment development, economic level, population development, and infrastructure and the 15 secondary indicators after subdivision are taken as evaluation indicators. Figure 3 shows the rural evaluation index system.

2.4. Rural Tourism Evaluation Index Weight. The calculation method of rural index (RI) of rural tourist destination is a linear weighting method, and the method of determining index weight W_j is an entropy weight method. Because the dimensions of data are different, it will lead to inconvenient calculation. Therefore, the data should be standardized. The method used here is the range standardization, namely, using the maximum or minimum value according to the standard value of the index value. By calculating the difference between the current value and the maximum or minimum value of each index value, the ratio between each index value and each index value standardization is realized.

When parameter X_{ij} is a positive indicator,

$$A_{ij} = \frac{X_{ij} - \min\left(X_j\right)}{\max\left(X_j\right) - \min\left(X_j\right)}. \tag{6}$$

When parameter X_{ij} is a negative indicator,

$$A_{ij} = \frac{\max\left(X_j\right) - X_{ij}}{\max\left(X_j\right) - \min\left(X_j\right)}. \tag{7}$$

Among equations (6) and (7), X_{ij} indicates the value of the j_{th} index of the i_{th} county, A_{ij} represents the normalized index value, $\min(X_j)$ refers to the minimum value of item j, and $\max(X_j)$ stands for the maximum value of item j index.

Specific calculation steps are as follows.

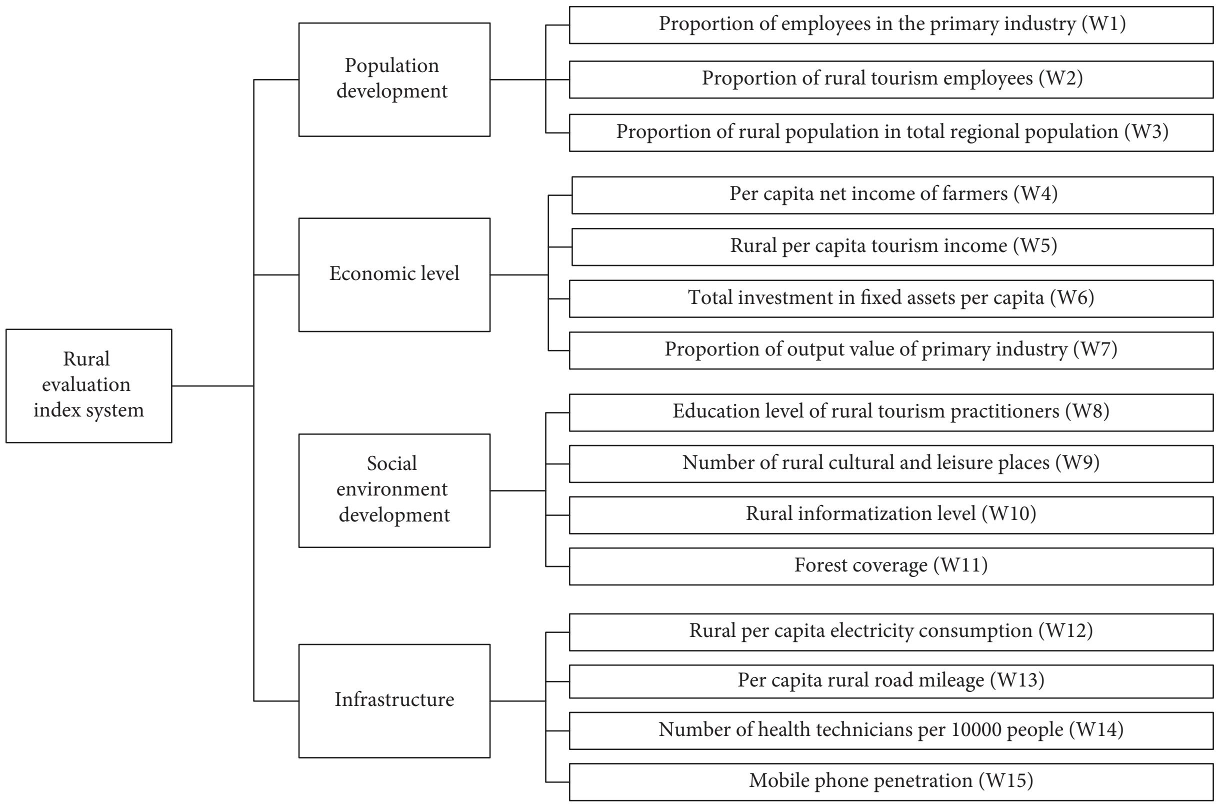

Figure 3: Rural evaluation index system of rural tourism destination.

Step 1. Calculate the specific gravity value.

$$B_{ij} = \frac{A_{ij}}{\sum_{i=1}^{m} A_{ij}}. \tag{8}$$

Step 2. Calculate entropy.

$$e_j = -K\sum_{i=1}^{m} B_{ij} \ln B_{ij}\left(\text{among them, } K = \frac{1}{\ln m}, \text{j} = 1, 2, 3 \ldots \text{n}\right). \tag{9}$$

Step 3. Calculate the weight of indicators.

$$W_j = \frac{1 - e_j}{\sum_{j=1}^{n}\left(1 - e_j\right)}. \tag{10}$$

The rural index of rural tourism destination can be calculated as

$$\text{RX}_i = \sum_{j=1}^{n} A_{ij} W_j. \tag{11}$$

Among equations (8)–(11), A_{ij} says the standardized index value, B_{ij} is the specific gravity value, m equals to the total amount of county units, W_j indicates the weight of j indexes, and RX_i represents the rural index of i county unit, where the rural index will change with the change of the value. E_j is the entropy value, and n stands for the total number of indicators.

2.5. Spatial Autocorrelation Analysis. Global spatial autocorrelation analysis can describe the spatial characteristics of attribute values of research objects in the whole region. It can also measure the overall spatial correlation between different regions and the degree of difference between them. The mathematical expectation of global Geary's C is constant 1, which is not affected by spatial weight, observation value, and sample size, resulting that the statistical performance of Geary's C is worse than that of global Moran's I. Only the distance-defined spatial proximity method can be adopted to form the weight matrix from Local Getis-Ord *G*, which performs poorly when identifying negative spatial autocorrelation. Moran's I index is a global index used to measure spatial autocorrelation, and its calculation is as follows:

$$I = \frac{n}{S_o} \frac{\sum_{i=1}^{n}\sum_{j=1}^{n} W_{ij} Z_i Z_j}{\sum_{i=1}^{n} Z_i^2}. \tag{12}$$

In equation (12), Z_i refers to the deviation between the attribute of element I and its average value, W_{ij} represents the spatial weight, n stands for the total number of elements, and S_o indicates the aggregation of all spatial weights. When the global Moran's I changes between 0 and 1, it means positive spatial correlation; otherwise, it means negative spatial correlation.

The local Moran's I index, also known as clustering and outlier analysis, is different from the global Moran's I. The global Moran's I index is only used to judge whether the global elements have spatial correlation, but the local

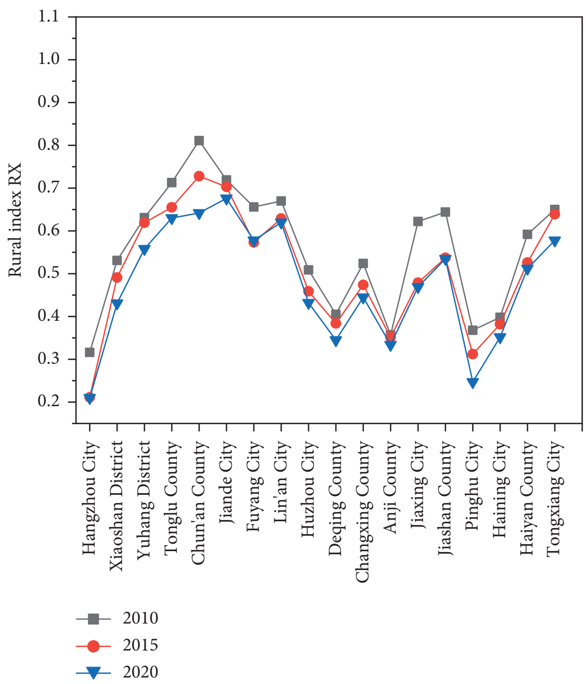

Figure 4: Rural index of counties in “Hangjiahu area,” Zhejiang Province (x: names of the counties in “Hangjiahu area,” Zhejiang Province; y: rural index).

Moran’s I can be used to show the spatial correlation among various elements. The calculation is as follows:

$$I = Y_i \sum_{i=1}^{n} W_{ij} Y_j. \tag{13}$$

In equation (13), Y_i and Y_j are the standardized values of the observed values of spatial unit *i* and unit *j*, respectively, and W_{ij} indicates the spatial weight. Local spatial autocorrelation can analyze the relationship between a certain point and the surrounding points of the cluster, including high-high clustering, high-low clustering, and low-high clustering.

3. Results

3.1. Overall Evaluation of Rural Tourism in “Hangjiahu Area”. Figure 4 shows the calculation of the rural index of “Hangjiahu area” in Zhejiang Province in 2010, 2015, and 2020.

Figure 4 reveals that from 2010 to 2020, the overall trend of rural index of all county units included in the “Hangjiahu area” of Zhejiang Province is decreasing year by year, and the rural differences among these county units are also gradually weakening. The rurality index of 18 counties in the “Hangjiahu area” of Zhejiang Province is the highest in Chun’an County during 2010–2015, with values of 0.811 and 0.728, respectively. Also, the lowest indexes are all in Hangzhou City, with values of 0.316 and 0.211, respectively. The highest index in 2020 is in Jiande, with a value of 0.676, and the lowest is in Hangzhou. This indicates that the rurality index of Hangzhou is the lowest. In order to deeply analyze the regional differences of rural characteristics in the “Hangjiahu area” of Zhejiang Province and the evolution of polarization degree in time sequence in these areas, a descriptive statistical analysis is made on the rural characteristics index, as Figure 5.

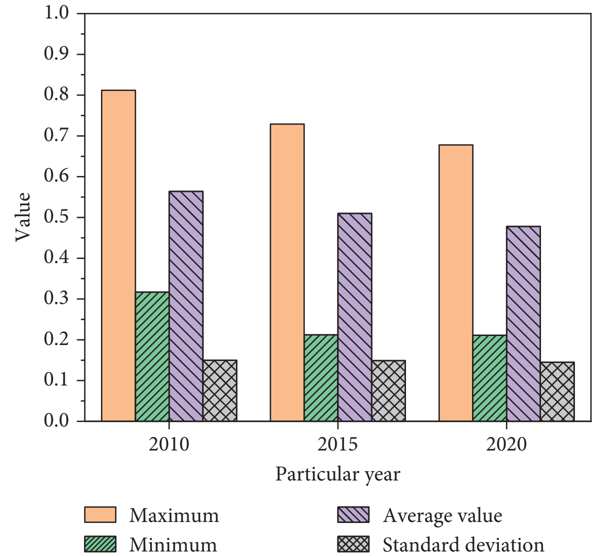

Figure 5: Evolution of regional difference of county rural index in the “Hangjiahu area,” Zhejiang Province (x; particular year; y: the values of maximum, minimum, average, and standard deviation of rural index).

Figure 5 indicates that from 2010 to 2020, the maximum value of rural index of all county units in the “Hangjiahu area” of Zhejiang Province decreased from 0.812 in 2010 to 0.678 in 2020, the minimum value decreased from 0.317 in 2010 to 0.211 in 2020, and the average value decreased from 0.564 in 2010 to 0.478 in 2020. Therefore, the results show that the impact of rural tourism development on rural economy and society is increasing. The standard deviation of rural index of each county unit is also decreasing year by year, from 0.15 in 2010 to 0.145 in 2020, which indicates that the rural difference in the “Hangjiahu area” of Zhejiang Province is decreasing and the difference is weakening year by year.

In order to further analyze the spatial differentiation and spatial pattern evolution of rural areas in the Hangzhou-Jiaxing-Huzhou region of Zhejiang Province from 2010 to 2020, a global Moran’s I statistical test was carried out on the rural indexes in the Hangzhou-Jiaxing-Huzhou region in 2010, 2015, and 2020. Figure 6 reveals the results.

Figure 6 notes that the Moran’s I indexes of rural areas ranged from 0.038 to 0.052 from 2010 to 2020, all of which were positive, and the overall trend was increasing year by year, and the significance level of *z* test was $P < 0.5$. The research results showed that the rural index of the Hangzhou-Jiaxing-Huzhou area in Zhejiang Province appeared with an aggregation distribution state in space. From 2010 to 2020, with the continuous development and advancement of rural tourism and urbanization, the differences between counties and cities in the Hangzhou-Jiaxing-Huzhou area of Zhejiang Province are shrinking year by year.

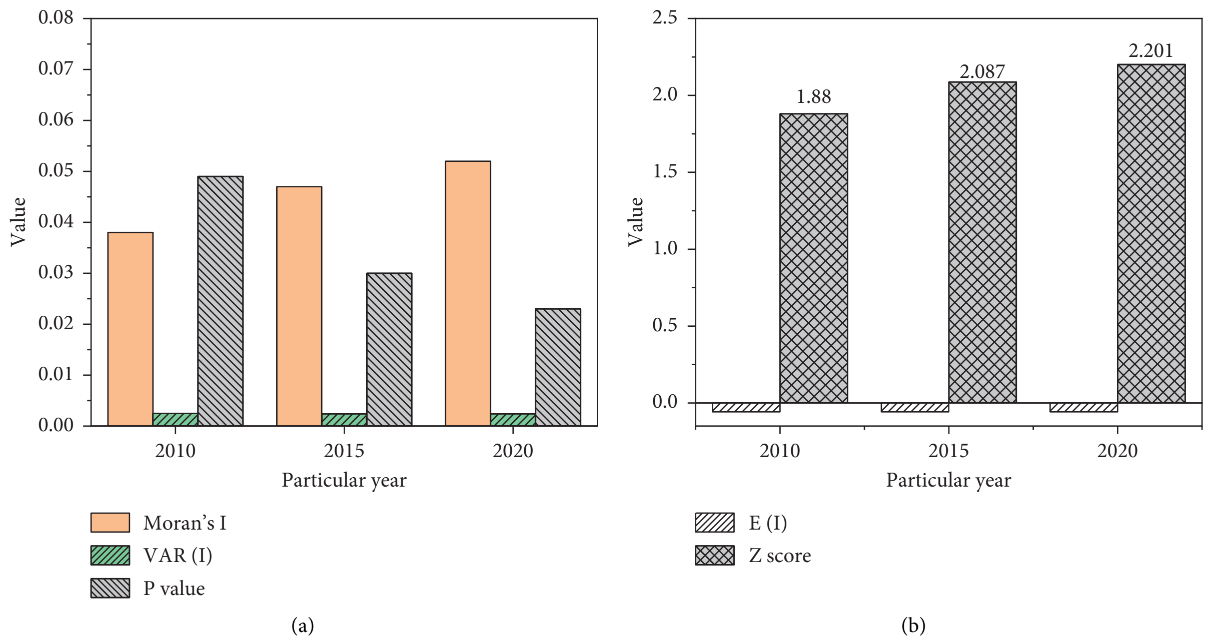

Figure 6: Global Moran's I statistical test results. (a) Correlation test results (x: particular year; y: values of global Moran's I statistical test); (b) significant test results (x: particular year; y: values of Z-score).

3.2. Index Weight Results of Neural Network Model. When using the ANN model to evaluate the spatial pattern of rural tourism, it is necessary to calculate and sort the weights of each index. Table 1 presents the weights of each index.

Table 1 indicates that the weight of employees in the primary industry (W1) is 0.523, that of rural tourism professionals (W2) is 0.462, that of rural per capita tourism income (W5) is 0.464, that of primary industry output value (W7) is 0.394, that of rural informatization level (W10) is 0.467, that of rural road mileage per capita W (13) is 0,431, and that of mobile phone population rate (W15) is 0.412. Also, the weight values of these eight indicators are relatively large, which shows that these eight indicators have a great influence on the rural nature of rural tourist destinations.

Table 1: Weight value of rural evaluation index of rural tourism destination.

Evaluating indicator	Weight
W1	0.523
W2	0.462
W3	0.281
W4	0.181
W5	0.464
W6	0.192
W7	0.394
W8	0.123
W9	0.178
W10	0.467
W11	0.242
W12	0.518
W13	0.431
W14	0.139
W15	0.412

3.3. BPNN Simulation Results. After the completion of the network training, the feasibility of the established evaluation system of rural tourism in the "Hangjiahu area" of Zhejiang Province is simulated by using the neural network toolbox in MATLAB software and 10 groups of samples. Figure 7 shows the comparison between the evaluation results obtained by the network and the actual evaluation results.

After the BPNN evaluation model for rural tourism destination being verified and tested, Figures 7 and 8 indicate that the actual value output is basically consistent with the expected value, and the difference between them is very small. By analyzing the BPNN evaluation error curve, it is found that the evaluation error and the actual error range are within 0.08%, which proves that the BPNN algorithm has good accuracy. Therefore, the BPNN evaluation model for rural tourism destination implemented here can make a good evaluation of rural tourism space.

3.4. Analysis of Influencing Factors of Rural Tourism Spatial Pattern Evolution

3.4.1. Factor Analysis of Industrial Structure Adjustment. Correlation analysis is made between the proportion of employees in the primary industry (W1), the proportion of rural tourism professionals (W2), the per capita tourism income in rural areas (W5), the proportion of the output value of the primary industry (W7), and the rural index in each county and city. Table 2 lists the results.

Table 2 and Figure 9 signify that Pearson correlation coefficients of rural per capita tourism income (W5) and rural index in 2010, 2015, and 2020 are −0.582, −0.654, and −0.703, respectively, and the test results of significance level are 0.012 (less than 0.05), 0.005 (less than 0.01), and 0.01,

Table 2: Correlation and significance analysis of rural index.

Age	Evaluating indicator	Pearson correlation	Significant (bilateral)
2010	W1	0.752^{**}	0.002
	W2	-0.529^{*}	0.021
	W5	-0.582^{*}	0.012
	W7	0.711^{**}	0.001
2015	W1	0.746^{**}	0.000
	W2	-0.604^{**}	0.006
	W5	-0.654^{**}	0.005
	W7	0.681^{**}	0.003
2020	W1	0.725^{**}	0.000
	W2	-0.609^{**}	0.003
	W5	-0.703^{**}	0.000
	W7	0.676^{**}	0.001

Note. *means a significant correlation at 0.05 level (bilateral); **means a significant correlation at 0.01 level (bilateral).

respectively. In addition, Pearson correlation coefficients of rural tourism professional ratio (W2) and rural index in 2010, 2015, and 2020 are -0.529, -0.604, and -0.609, respectively. The test results of significance level are 0.021 (less than 0.05), 0.006 (less than 0.01), and 0.003 (less than 0.01), respectively. Pearson correlation coefficients of the proportion of primary industry output value (W7) and rural index in 2010, 2015, and 2020 are 0.711, 0.681, and 0.676, respectively, and the test results of significance level are 0.001 (less than 0.01), 0.003 (less than 0.01), and 0.001 (less than 0.01), respectively. Pearson correlation coefficients of the proportion of employees in the primary industry (W1) and rural index in 2010, 2015, and 2020 are 0.752, 0.746, and 0.725, and the test results of their significance levels are 0.002, 0.000, and 0.000, respectively. There is a significant positive correlation between the proportion of employees in the primary industry (W1) and the rural index. From 2010 to 2020, the per capita rural tourism income (W5) and the proportion of rural tourism professionals (W2) in every county and city in the Jiahu area of Hangzhou are also increasing year by year. Moreover, the growth of surrounding counties with Hangzhou as the core is most obvious. This fully shows that the development of the primary industry is not paid enough attention to, so it has become one of the important factors that restrict the rural level in the Hangzhou-Jiaxing-Huzhou area. Results indicate that the development process of urbanization can be directly promoted by the tourism industry, but it will also be accompanied by the decline of the rural level.

3.4.2. Analysis of Traffic Factors. Correlation analysis is made between the per capita rural road mileage (W13) and the rural index in each county and city. Table 3 displays the results.

Table 3 presents that the Pearson correlation coefficients of the evaluation index of rural road mileage per capita (W13) and rural index in 2010, 2015, and 2020 are -0.474, -0.573, and -0.672, respectively, and the significance level test results are 0.048, 0.015, and 0.013, respectively, which are all less than 0.05. From 2010 to 2020, the per capita rural road

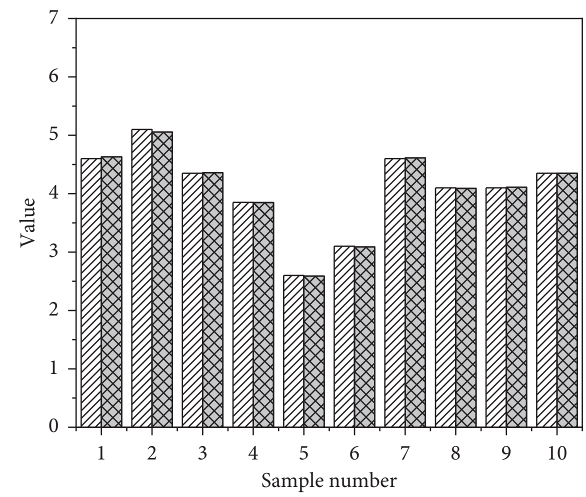

Figure 7: Performance comparison of BPNN algorithm (x: the orders of the samples; y: values of output and actual evaluation).

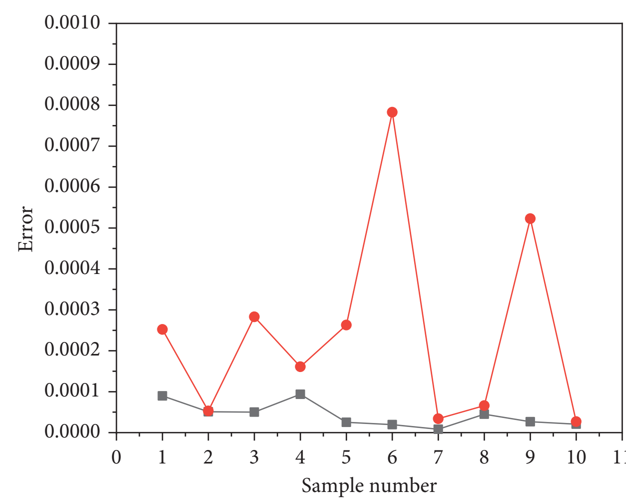

Figure 8: BPNN model training and error comparison (x: the orders of the samples; y: errors in training and test).

mileage (W13) of all counties and cities in this region showed a trend of increasing year by year, and the most obvious increase was in the surrounding counties with Hangzhou as the center. The rural index in this region showed a declining trend and an agglomeration distribution trend, which forms a cold spot with Hangzhou as the center. This fully shows that the accessibility of road traffic can promote the development of commercial and economic activities to a certain extent, so as to lower the rural level. Therefore, the improvement of traffic factors has a significant impact on the rural level.

3.4.3. Analysis of Social Environment Factors. The correlation analysis is made between the three factors of mobile

Table 3: Correlation and significance analysis of rural index.

Evaluating indicator	Age	Pearson correlation	Significant (bilateral)
W13	2010 years	−0.474*	0.048
	2015	−0.573*	0.015
	The year of 2020	−0.672*	0.013

Note. *indicates a significant correlation at 0.05 level (bilateral).

Table 4: Correlation and significance analysis of rural index.

Year	Evaluating indicator	Pearson correlation	Significant (bilateral)
2010	W10	−0.470*	0.047
	W12	−0.498*	0.035
	W15	−0.562*	0.014
2015	W10	−0.552*	0.013
	W12	−0.502*	0.039
	W15	−0.688**	0.003
2020	W10	−0.658*	0.016
	W12	−0.598*	0.035
	W15	−0.706**	0.001

Note. *means a significant correlation at the 0.05 level (bilateral); **means a significant correlation at the 0.01 level (bilateral).

phone penetration rate (W15), rural per capita electricity consumption (W12), and rural informatization level (W10) and the rural index. Table 4 and Figure 10 display the results.

Table 4 and Figure 10 signify that the Pearson correlation coefficients between the three factors of mobile phone penetration rate (W15), rural per capita consumption (W12), and rural informatization level (W10) and the rural index are -0.470, -0.552, -0.658; -0.498, -0.502, -0.598; and -0.562, -0.688, -0.706. The test results of significance level are 0.047, 0.013, 0.016; 0.035, 0.039, 0.035; and 0.014, 0.003, 0.001, respectively, all of which are less than 0.05. Rural informatization level (W10) is negatively correlated with rural index, and the negative correlation tends to increase. Rural per capita consumption (W12) is negatively correlated with rural index, and the negative correlation tends to increase. The mobile phone penetration rate (W15) is negatively correlated with rural index. Also, this negative correlation shows a growing trend. From 2010 to 2020, the rural informatization level (W10), mobile phone penetration rate (W15), and rural per capita electricity consumption (W12) in all counties and cities are increasing year by year. Conclusion is drawn that a strong modern civilization can strengthen a region's commercial awareness and the concept of market economy. It can also promote the presentation of more capital, technology, and talent advantages, to lower the rural level. Therefore, social and environmental factors will have a significant impact on the rural level.

In the future development of rural tourism, more attention should be paid to the construction of rural ecological environment and the protection of rural cultural characteristics. Therefore, creating an upgraded version of beautiful countryside is a policy that helps to protect rurality. In the process of creating an upgraded version of the beautiful countryside, the government should establish a sense of

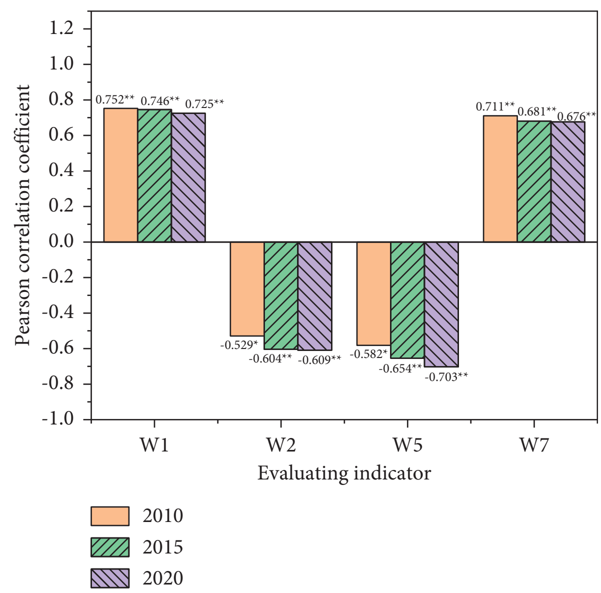

Figure 9: Correlation trend of rural index from 2010 to 2020 (x: evaluating indicator; y: Pearson correlation coefficient).

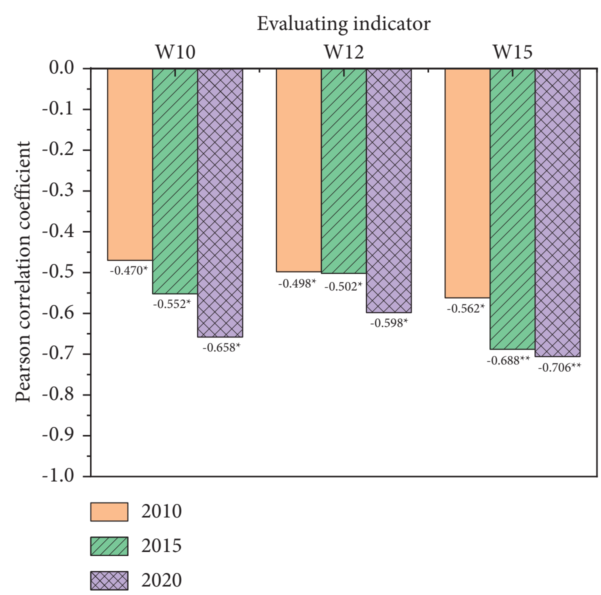

Figure 10: Correlation trend of village index from 2010 to 2020 (x: evaluating indicator; y: Pearson correlation coefficient).

regulation, scientifically formulate rural construction plans, fully demonstrate the connotation of the countryside, realize the unification of the economic value, social value, and ecological value of the countryside, and make "green" as the main tone of beautiful countryside. In the process of constructing the beautiful countryside, the green development is always the main line. The transformation should be gradually realized in the agricultural production mode, rural construction mode, and farmers' lifestyle. Meanwhile, the basic principle should keep still, which is adhering to the organic combination of local characteristics and ecological environmental protection requirements and carrying out differentiated construction according to local conditions.

Based on maintaining the landscape and pastoral scenery and historical and cultural characteristics of each village, the pattern of "one village, one product, one industry, one village, one rhyme" is formed to realize the sustainable development of the countryside. Besides, in the process of construction of beautiful countryside, the government should change its role, from the leader of rural construction to the guide and the coordinator, and the government should constantly strengthen the propaganda and education of all levels of society and improve the cognitive level of all levels of society on rural value according to the local traditional history, cultural accumulation, resource endowment, ecological environment, and other characteristics through various forms, using various platforms and carriers.

4. Conclusion

With the rapid development of urbanization and rural tourism, great changes have taken place in the traditional rural structure and lifestyle, followed by the gradual disappearance of the original unique rural nature and importance of the countryside. Based on rural characteristics, factors such as social environment development, population development, and economic development are taken as the research indicators, and the evaluation index system of rural tourism destination is constructed. The spatial pattern of rural tourism is empirically studied with examples, the rural index of the region in 2010, 2015, and 2020 is calculated, and the model is simulated and analyzed by MATLAB software. Finally, the spatial autocorrelation method is used to analyze the evolution characteristics of rural tourism spatial pattern. The research results show that by analyzing the evaluation error curve of BPNN, the evaluation error and the actual error range are within 0.08%, which proves that the BPNN algorithm has good accuracy. The BPNN evaluation model for rural tourism destination implemented here can make a good evaluation of rural tourism space. From 2010 to 2020, the proportion of employees in the primary industry and the penetration rate of mobile phones are the decisive factors in the adjustment of industrial structure and social environment, respectively. Rural tourism income per capita and the proportion of the output value of the primary industry also have a certain impact on the rural evolution. A certain guiding significance is provided for the sustainable development of rural tourism, but the deficiency lies in that only each county and city in Hangzhou Jiahu District is taken as the research object due to the availability of data. Some internal differences among county-level administrative regions have not been fully studied. In the future improvement research of BPNN, the variable coefficient method can also be used to modify the connection weight to accelerate the convergence speed of the network.

With the advancement of technology represented by artificial intelligence, art creation is becoming increasingly rich, and content expression is intelligent, interactive, and data-driven, making the relationship between technology, art, and people increasingly close and bringing opportunities for the development of emerging interaction. Artificial intelligence technologies aim to perfectly replicate the human mind by enabling natural responses based on the surrounding environment, decoding emotions, and recognizing human traits within the energy range. Driven by AI technology, interactive art no longer focuses on a single audiovisual sensory experience but rather on integrated artistic expressions that are highly interactive, kinetic, and emotional, based on the study of natural human behavior and integrated senses, combined with intelligence. In this paper, we first sort out the intersection of AI technology development and interactive art expression streams on the timeline based on historical development and analyze the deconstructive relationship between the two from the macroperspective of the historical development of technology and art. First, based on the conceptual connotation, development history, technical application, and singularity outlook of AI, we identify the current characteristics and development trends of interactive art; second, based on exploring the advantages of AI technology, we propose the impact of AI on the creative thinking, creative mode, and artistic experience of interactive art and establish the paradigm of interactive art creation in the context of AI. It solves the problem that experts are unable to quickly locate the category of painters when facing different styles of unsigned digital Chinese painting images in the authenticity identification task.

1. Introduction

In the Internet era, digital museums, digital libraries, and some related websites of Chinese painting and art have developed. As an important art relic, digitized Chinese paintings are slowly becoming known for their advantages of easy preservation and fast retrieval. Moreover, it is simple to digitize the Chinese paintings made on Xuan paper and turn them into digital Chinese painting images [1]. Therefore, the digitization of Chinese paintings is gradually becoming a new way to protect Chinese paintings. However, experts are unable to quickly locate the category of painters in the face of unsigned digital Chinese painting images of different styles in the task of authenticity identification, which affects the efficiency of identification [2]. Therefore, the classification of Chinese painting painters, as an important branch of digital Chinese painting authenticity-assisted authentication, has gradually become a hot spot for research in terms of its classification accuracy as well as automation. On the contrary, the prevalence of Chinese painting digitization has led to the difficulty of controlling the quality of digital Chinese paintings in Chinese painting databases [3]. Moreover, in the era of big data, the sources of digitized Chinese paintings have increased, and the authenticity of their contents has gradually become a focus of attention. Traditional identification methods mainly rely on the rich experience of identification experts [4]. Due to the subjectivity of traditional identification methods and the lack of objective referenceable indicators, there are limitations in the efficiency and accuracy of their identification in the face of the new generation of information technology forgery methods [5]. Therefore, a digital Chinese painting authenticity-assisted identification tool with a high degree of automation and accuracy is particularly necessary. At the beginning of the twentieth century, the great development of photography, communication, and other media technologies hit Western art, which was based on realism at that time and brought an unprecedented sense of crisis to art workers, and more and more artists realized that the only way to establish a new artistic status was to innovate, thus giving birth to numerous art schools [6].

Interactive art is rooted in the artistic trends of Cubism, Futurism, and Dadaism, which confronted traditional art and laid a solid foundation for the development of contemporary digital interactive art [7]. The relationship between artificial intelligence and interactive art can be traced back to the birth of the concept of "artificial intelligence" in 1956. Both interactive art and artificial intelligence technology are based on computer technology, and their inherent connection between technology and art has established the inevitability of their development and integration since their birth [8]. In the early stage of interactive art development, interactive artists customized the rules of interaction through technical research and attracted participants into the art world they created by changing the physical form, emphasizing the satisfaction of form and technical application and ignoring the experience and cognitive mode of participants. In the 1980s, computer psychology gradually developed into a cognitive discipline, artificial neural network research developed rapidly, and breakthroughs in speech recognition and machine vision technology brought artificial intelligence research into its formative years [9]. The research concept of experience formally entered the sight of artists and technology workers, and focusing on human interaction experience became the key point of interactive art expression. Therefore, as people pursue the sense of experience and entertainment in interactive art, the object of interactive art creation shifts from the study of objects to the study of human behavior, and the connection between science and art becomes closer. In the twenty-first century, with the development of deep learning technology of artificial intelligence, artificial intelligence research has entered a golden period of application, and human-computer interaction technologies such as intelligent voice interaction, machine recognition, and virtual reality based on artificial intelligence technology have advanced by leaps and bounds, which is pivotal to the development of human-centered interactive art [10]. Intelligence, nature, learning, and abiotic intelligence are new technologies and concepts carried by the development of artificial intelligence, which support the creation of contemporary digital intelligent interactive art and influence the aesthetic trends of the public and the creative thinking of artists. This paper focuses on how intelligent technology under the domination of artificial intelligence changes interactive art expression from the level of thinking, means, and experience logic and proposes a paradigm of interactive art expression under the influence of artificial intelligence technology [11].

The fusion of artistic creativity and technologically advanced productivity provides the creative impetus for the sustainable development of art and HCI technology in the future. Overall, artificial intelligence is much more than a simple technical means for art creation; it is more of a reshaping of art creation thinking and an impact on human cognition. We collect materials related to artificial intelligence, film and television creation, film and television market management, and film and television consumer experience, including books, newspapers and magazines, dissertations, theoretical works related to artificial intelligence, and film and television to provide comprehensive theoretical support for the dissertation, draw on and absorb research results from sociology, psychology, management, law, film, television, information technology, etc. The paper combines macro- and microanalysis to provide a more profound interpretation of the topic. This paper innovatively sorts out the influence of AI on interactive art expression through deconstruction and reconstruction thinking, analyzes how AI deconstructs the original model of interactive art creation in terms of technology and thinking, then analyzes the influence of AI on interactive art expression in terms of time, space, and natural logic, and establishes its application paradigm. This paper provides a new practical direction for interactive art creation. By selecting appropriate statistical methods, different external environmental factors are analyzed to understand the changes in the shape and quantity of the distribution, the relationship between variables, etc. This research method has a very obvious indirectness and it is less disturbed and easier to implement. Mainly through the analysis of statistics, statements, data, and other information published by relevant departments, we understand the development status of the film and television industry under the influence of AI, including the status of AI companies, products, and technology development related to the film and television industry and the status of AI applications in the film and television industry, and anticipate its future direction. The contributions of this work can be summarized as follows:

(1) We first sort out the intersection of AI technology development and interactive art expression streams on the timeline based on historical development and analyze the deconstructive relationship between the two from the macroperspective of the historical development of technology and art
(2) Based on exploring the advantages of AI technology, we propose the impact of AI on the creative thinking, creative mode, and artistic experience of interactive art and establish the paradigm of interactive art creation in the context of AI
(3) The proposed method can be used to quickly locate the category of painters when facing different styles of unsigned digital Chinese painting images in the authenticity identification task

2. Related Work

Global research on artificial intelligence has been carried out long before, and AI cannot be called a new science. In the early development of AI, with the later development of new technologies, AI technology in recent years has made new breakthroughs in a number of areas and empowered various industries [12]. Due to the increasing frequency of AI in public life and practical applications in recent years and the gradual maturation of the technology development, the literature research is mostly focused on journal reports, and the research content involves the application of AI as a film content element and the impact of AI on the production, market management, and consumer experience in the film and television industry chain [13]. The features of Chinese paintings are used as the direct basis for intelligent classification, and the amount of information they contain directly affects the classification results. Among the features of Chinese paintings, wavelet features are used for classification [14]. The feature values that can express the characteristics of paintings are proposed as the basis of classification using the information theory. The local and global features of the paintings are used to study the authors of Chinese paintings. With further research, the artistic style of the painter becomes an important factor in the identification of the painting [15]. Features describing the painter's artistic style such as color, texture, and brushstroke also gradually became an important basis for the classification of painters. Semantic classification is achieved using the image color and shape features of the target. Color histograms, color coherence vectors, and autocorrelation texture features are used and classified into two categories according to brushwork and painting [16]. The ink color features of brush strokes and brushwork of Chinese paintings are extracted as the basis of classification. A multiscale grayscale covariance matrix method is proposed to extract texture features and complete the classification recognition of Chinese paintings [17]. Although the image content-based features such as color, texture, and brushstroke can better express the artistic style of the painting and improve the classification accuracy, the pure underlying features, again, directly lead to unsatisfactory classification results and have limitations. In addition, there are relatively few existing research works on the fusion of multidimensional features based on image content, fusing the underlying color and shape features of Chinese paintings and using the fused features as the basis of Chinese painting research [18]. The above studies fuse fewer underlying features and cannot provide a sufficient basis for analysis.

In addition to feature merit affecting intelligent classification results, the classification method and its treatment of features are also the key to intelligent classification [19]. A Monte Carlo convex packet model is used to achieve the classification of Chinese paintings. The abovementioned classification methods based on statistical models depend on the goodness of features, and the cumbersome process of tuning parameters reduces the automation of classification. They extracted wavelet features of Chinese paintings and completed the classification of Chinese paintings using support vector machines. The above machine learning-based classification methods improved the parameter tuning process, but the feature quantification was not accurate enough. With the study, it was found that deep learning-based classification methods not only provide high-level semantic representation of image features, but also the end-to-end design of this class of methods improves the automation of classification. Picasso's brushstroke features are quantified using recurrent neural networks (RNNs), and painterly classification is achieved. Deep convolutional neural networks (DCNNs) are used to achieve the description of texture features of ancient paintings and the classification of ancient paintings. CNN is used to extract the brushstroke features in ink painting to quantify the style of ink painting and complete the classification [20]. Deep aggregation structure is used to improve the recognition ability of CNN models. The residual mechanism is proposed to increase the depth of the network by the jump connection and residual mechanism to improve the network classification performance. The feature rescaling module is proposed to emphasize the importance of different image feature channels. The convolutional block attention mechanism module (CBAM) is proposed to enhance the ability of CNN models to extract features. Therefore, it has become an important trend in the intelligent classification to introduce enhancement modules to improve the learning ability of the network based on deep learning networks.

In the 1960s and 1970s in the Western art field, research on theories related to artificial intelligence and interactive art had already begun, and many new artistic concepts were proposed, such as "artificial life art," "cyber art," and "natural intelligence" [21]. For the first time, it explores artists and their works who are working at the frontiers of scientific research and emerging technologies. The book is organized according to scientific disciplines and technological categories, discussing the in-depth relationship between art and science and technology, such as artificial intelligence and robotics, and exploring new possibilities for uncovering artists' work. It boldly predicts the next stage of artificial intelligence during the technological singularity, when human intelligences will merge with machine intelligences that greatly enrich the human brain with a faster, more accurate, larger storage, stronger memory, and efficient data-sharing capabilities. It explains the disruption of production, life, and even art by approaching singularity AI technologies, nano-life technologies, etc. It summarizes the history of the intertwining of art and technology, outlines the evolution of digital art since the 1980s, and provides a vision of future artistic expression, raising questions about audience interaction, artificial intelligence, politics, and social behaviorism through an analysis of artists' digital artworks. The third edition of this work, in 2015, expands the practice of digital art in the fields of virtual reality, augmented reality, and interactive public installations. The evolution of art forms such as interactive art-making, techno-intellectual art, and the art of dry computer and wet bio-fusion is discussed in detail. The way artificial and technological systems merge and the impact of future intelligence on artistic creation are explored, and the future evolution of biological self-evolution and the fate of art under the evolution of technological intelligence are looked into.

3. Artificial Intelligence-Based Art Design Feature Extraction

3.1. Image Features. Analysis for images is complicated by mathematical tools alone and requires finding feature values that can quantify the image information. Therefore, extracting image features and combining them with the feature learning capability of computers can improve the efficiency of image analysis. In this paper, the concepts and extraction methods of image stroke, texture, and color features are described in detail in the context of the research. Stroke features of an image are the lines that make up the content of an image, and lines are the primitives that make up the content of an image. In the image, the variation of lines can express the pose and outline of the image content. And the thickness and fiction of the lines can also convey different information. By studying the characteristics of lines on the surface of an image, a deeper meaning can be obtained. Edge detection algorithms are often used to detect line features of images. Therefore, applying edge detection algorithms to detect Chinese paintings can highlight the brushstroke features of Chinese painters. The edge detection algorithm usually relies on the edge detection operator, which is often used as the core operator for edge detection.

The detection principle is to detect the edges of an image by finding the absolute gray magnitude of the grayscale image. A series of grayscale vector information is generated when the edges of an image are detected using the reform operator. The Sobel operator usually computes two directions, horizontal and vertical, each with a convolution matrix of size 3×3, and any of the convolution matrices can be obtained by rotating another matrix by 90°. The expression is given in the following equation:

$$\widetilde{E}(n) = \sum_{i=1}^{I_k} \sum_{P \in Q}^{n} (\lambda t)^{n+1} e^{\lambda t} \log_n \frac{N_v}{N_n}, \tag{1}$$

where P is the original image and Gx and Gy are the convolution matrices in horizontal and vertical directions, respectively. The specific calculation formula is shown in equation where $f(x, y)$ is the grayscale value of the pixel point.

$$X = \frac{X_i - X_j}{\left(\sum_{i=1}^{n} \left(X_i - X_j\right)^2\right)}. \tag{2}$$

The calculation steps are as follows: (a) calculate the brightness difference of the image in different directions using two 3×3 matrices; (b) calculate the gradient value G of the pixels in the image at Gx and Gy, and the formula is shown as follows:

$$\begin{aligned} Q(x) &= \frac{\sum_{i=1}^{n} p\left(X = x_i\right)}{\log_2 (p(x))}, \\ Q(Y[X]) &= \frac{\sum_{i=1}^{n} p\left(X = x_i\right)}{q(x)}, \end{aligned} \tag{3}$$

and (c) calculate the gradient direction with the following equation:

$$\mathrm{Dis}\left(x_i, x_j\right) = \left(\sum_{i=1}^{n} \left(X_i - X_j\right)^q\right)^{1/q}. \tag{4}$$

In summary, the Sobel operator cannot distinguish between objects and backgrounds, and the image edges are intermittent, leading to its inaccurate results. If you want to improve the detection effect, you can increase the size of the convolution matrix, but such an operation will increase the computational effort. Usually, the image processed by the Sobel operator is not a grayscale image, which will make the image and the background not easily distinguishable. The Canny operator uses Gaussian filtering to remove image noise during edge detection, which makes the operator less susceptible to noise interference and can be applied to different scenes by setting different parameters. The Canny operator can fully reflect the strength of line edges in an image, making its detection fast and accurate.

3.2. Texture Characteristics. Texture features are surface attributes that describe an image or an image region. Regarding the extraction methods of texture features, as shown in Figure 1, they are divided into four main categories as follows:

(1) Statistical-based methods: texture features are random in the image region, but some regular characteristics of texture features can be mined using statistical methods. Statistical-based methods mainly study the grayscale distribution within the image region. Among them, the grayscale co-occurrence matrix is the most applicable, and the method uses the statistical feature values output from the grayscale co-occurrence matrix to represent the texture features of the image. The disadvantage is that it is not applicable to pixel-level texture classification tasks.

(2) Model-based methods: this class of methods considers that textures can be arranged according to some model distribution, and the relationship between texture primitives can be represented by the parameters of the model. The representative methods are mainly the random field method and fractal method. However, the disadvantages are obvious, as it does not match the actual image situation, and the texture is not adequately expressed. The fractal method mainly uses the relationship between image spatial location information and image grayscale to extract texture features of the image. The texture features extracted by this method have a

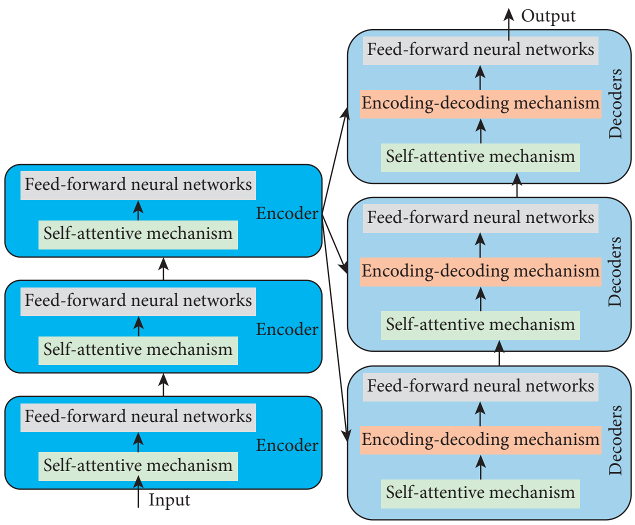

Figure 1: Texture feature extraction.

characteristic that different fractal dimensions are obtained when different image regions are extracted. Therefore, applying the fractal dimension to regional texture feature extraction can easily distinguish different image regions.

(3) Spectrum-based methods: this method is mainly based on spectral characteristics and multiscale analysis of texture features. The representative method is the wavelet transform, which was first proposed in the 1990s for the texture feature extraction, and then various improved methods based on wavelet transform were applied to various tasks of image processing.

(4) Structure-based method: the basic idea of this method is to analyze the texture primitives that make up the texture features so that the regularity of the texture features can be obtained.

Color features are important visual features in image processing. Among them, red, green, and blue (RGB), hue, saturation, and lightness (HSV) are the two most commonly used color spaces. The HSV color space is more intuitive than the RGB color space in color representation and is widely used in image processing tasks. The next part of this paper focuses on the commonly used color feature extraction methods.

(1) The color histogram is the proportion of each color in the image but ignores information about the spatial distribution of colors. This method is suitable for images without segmentation tasks. The color histogram is often calculated based on the HSV color space. First, the colors in the image are divided into different regions. Then, the number of pixels of different colors in each region is counted.

(2) The color set is proposed by Smith and is similar to the color histogram. First, the HSV color space needs to be transformed and the color space quantized into a histogram. Then, an index is created between the color space and the color components. This method has an advantage in retrieval speed when facing large-scale datasets.

(3) Color moments were proposed by Stricker et al. to express the color feature information in paintings by calculating the color first-order moments, second-order moments, and third-order moments of images, using the property that the color information is mainly concentrated in the lower-order moments.

(4) The color entropy is proposed by Zachary according to the definition of entropy mentioned by Shannon in the information theory, which combines the information entropy with the color histogram. The normalized color histogram can be set as h, and then the entropy of the image is expressed as

$$E(n) = \sum_{i=1}^{k} \sum_{P \in Q}^{n} (\lambda t)^{n+1} e^{\lambda t}. \quad (5)$$

3.3. Artificial Intelligence Deep Learning Models. Deep learning is a new research hotspot in the field of machine learning. Deep learning mainly emphasizes two points: (1) the depth of the model and (2) the mapping of feature information learned from shallow layers to a new feature space by reasonably increasing the number of network layers, which makes the classification more accurate. The VGG deep learning model, known as Visual Geometry Group, is a deepened version of AlexNet, designed by the Department of Science and Engineering at the University of Oxford, and is often used for tasks such as image classification and face recognition. Initially, the model was designed to clarify the relationship between the depth of the network and the accuracy of large-scale classification and recognition. The VGG model is composed of a convolutional layer, a pooling layer, and a fully connected layer. The basic computation of the convolutional layer is convolutional computation. Usually, the convolution operation requires setting parameters such as step size and padding. After the convolution operation, an activation function is usually introduced. The activation function is used to increase the ability of the network to fit various kinds of data by adding nonlinear capabilities. The following activation functions are commonly used (ReLU, Sigmoid, and tanh).

In addition, after the convolution operation of the input feature map using a large number of convolution kernels, the information of the feature map needs to be filtered, and the pooling is mainly operated using the maximum and average values. The main role of the fully connected layer is to fuse the feature information, which is usually connected in descending order. The commonly used VGG models have 16 and 19 layers, respectively, as shown in Figure 2.

The performance of the VGG network is positively correlated with depth, but increasing the depth of the network will reduce the learning ability of the network and cause a lot of parameters to reduce the efficiency. GoogLeNet is designed with twenty-two layers, but with one-twelfth of the parameters of AlexNet and one-fourth of VGG. The

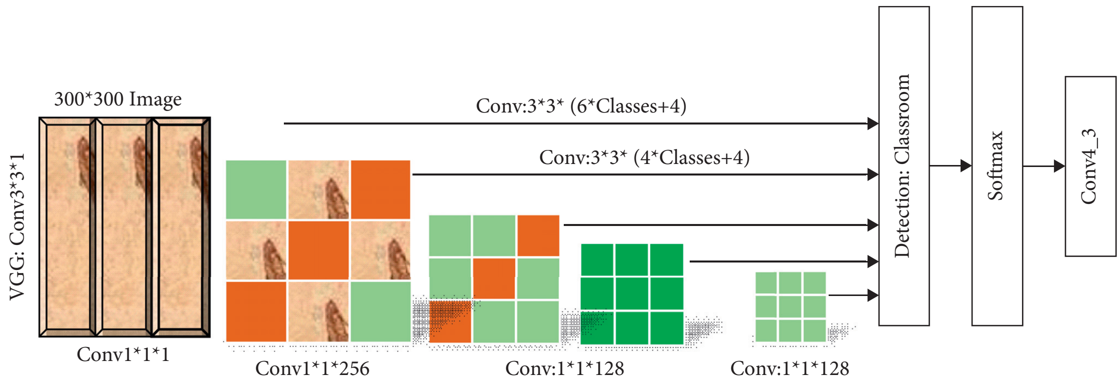

FIGURE 2: VGG-16 and VGG-19 network structures.

sparse network structure consists mainly of small convolutional kernels and 3×3 pooling layers, which can increase the network performance and ensure the efficient use of computational resources. In fact, after the network reaches a certain number of layers, the performance is negatively correlated with the number of layers, which leads to slow convergence and poor dataset performance. The residual mechanism in the residual network solves this problem by using multiple parameter layers to learn the residual representation between the input and output, that is, each learning depends on the previous learning result, preventing the performance of the network from degrading and making its learning incremental, instead of learning the mapping relationship between inputs and outputs in the ordinary order of the network structure. The advantage of the residual mechanism is that it largely solves the problem of network performance caused by increasing the number of layers. The structure of the residual mechanism is shown in Figure 3. The actual role of this layer is a nonlinear combination of features, which does not contain feature extraction and feature learning capabilities. In image processing, the number of parameters is reduced by using a small size of convolution kernels.

4. Analysis of Experimental Results

The experiments in this paper are based on the PyTorch deep learning framework for training and testing, with a NVIDIA GTX 1060 GPU, 8 GB of video memory, and Cuda version 10.1. The programming language is Python 3.6. Figure 4 shows the main parameters of the network training, and these parameters are used as the basic settings for the comparison experiments. To verify the performance of the proposed network classification in the context of Chinese painting classification, a five-fold cross-validation method is used, where the entire dataset is first divided into five disjoint subsets, and then four of them are randomly used as the training set and one as the test.

In the image block rejection process, the artistic target of the painting occupies a certain proportion of the whole frame, and there are blank and meaningless image blocks in addition to the artistic target because the blank image blocks and the image blocks containing a small number of artistic targets can provide less information and have the characteristic of low threshold. Therefore, the optimal contrast threshold is selected among [20, 60, 100, 140, 180, 220] using the grid search method. Among the random field methods, Markov random field models are very common, and they are used to establish a connection between textures and two-dimensional image fields. As can be seen from Figure 5, when the threshold value is 20, the presence of image blocks with invalid information leads to a low accuracy rate. As the contrast threshold value increases, the accuracy also increases. This is because blank image blocks and image blocks containing little invalid information are eliminated and image blocks containing valid information are retained. The accuracy is highest at the threshold value of 180. When the threshold value is 220, the accuracy starts to decrease because the blocks containing valid information are incorrectly rejected, which affects the network classification results. Therefore, the threshold is set to 180, and the specific effect of the image contrast-based image block rejection method on different subjects and images of different frame formats. From the results, it is shown that the method is good at removing blank and meaningless image blocks from paintings and retaining their artistic target details.

From Figure 5, it can be seen that the check-all rate and check-accuracy rate of color features are low among the four painters, which is because the color features are extracted with a single color variety in the paintings, and the color richness of the dataset is poor, making it difficult to achieve good classification results. This phenomenon is more obvious in Xu Beihong's paintings. As can be seen from the figure, the check-all rate and check-accuracy rate of Xu Beihong's paintings are obviously low, and the color features in Xu Beihong's paintings are not sufficiently characterized. Xu Beihong's paintings are mainly ink and wash, that is, black and white, lacking rich color expressions, which leads to lower check-all and check-accuracy rates. Thus, it can be seen that color features have a certain characterization ability, but the low color richness of traditional ink paintings and the little feature information available lead to the limitations of color features in the classification. Compared with the color features, the texture features have better characterization ability, and the texture features have better performance in two indexes, the check-all rate and the

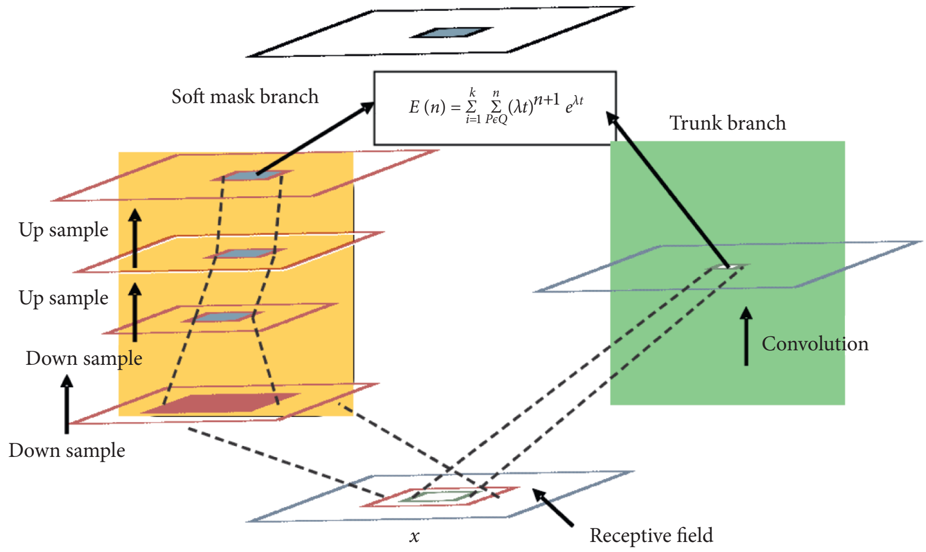

Figure 3: Residual mechanism structure diagram.

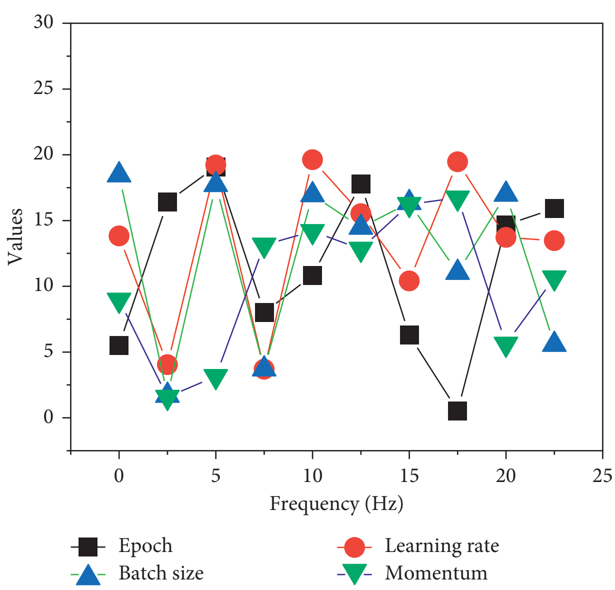

Figure 4: Network parameter data.

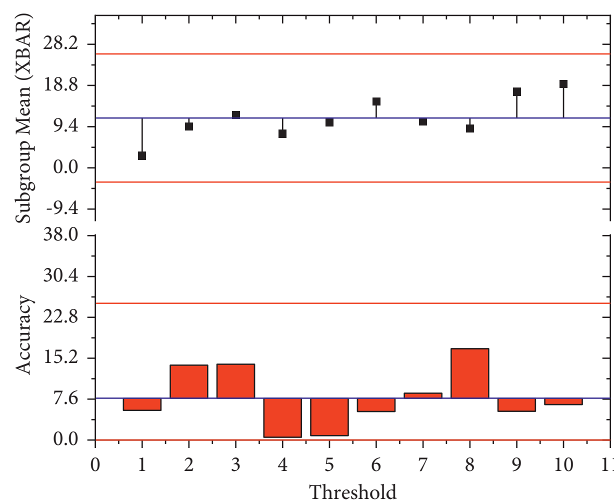

Figure 5: Different contrast thresholds.

check-accuracy rate. The texture feature map processed by the local binary mode algorithm removes the interference of the color feature of the painting itself, and the rotation invariance also reduces the influence of the different forms of the painting. In the four-painter classification experiments, the brushstroke features have better performance in two technical indexes, namely, the detection rate and the accuracy rate, compared with the color and texture features. It indicates that the brushstroke feature map processed by the edge detection algorithm can quantify the painter's artistic style by detecting the edge contours of the painter's brushwork. Finally, after fusing the three features, the check-all rate and check-accuracy rate of the four painters are significantly improved. It indicates that the fused features can make up for the deficiency of the color features' characterization ability; they have a deep semantic expression of the texture features; they retain the stroke features that can express the painter's artistic style. In summary, the fusion features are more suitable as the basis for the network classification. Furthermore, we discuss the effectiveness of the proposed network, and first argue whether the convolutional attention mechanism enhances the performance of the network. In the deep convolutional network, the commonly used attention mechanism modules are the SE module and CBAM module, and the experiments are mainly focused on these two modules to verify. The specific experimental results are shown in Figure 6.

From the figure below, it can be seen that the CBAM module slightly outperforms the SE module in terms of the average accuracy metric. It indicates that the SE module emphasizes the relationship between network channels but ignores the spatial information of the feature map. The natural logic expressed by intelligent interactive art follows the knowledge given to human beings by the natural human system. The social nature of human beings determines the

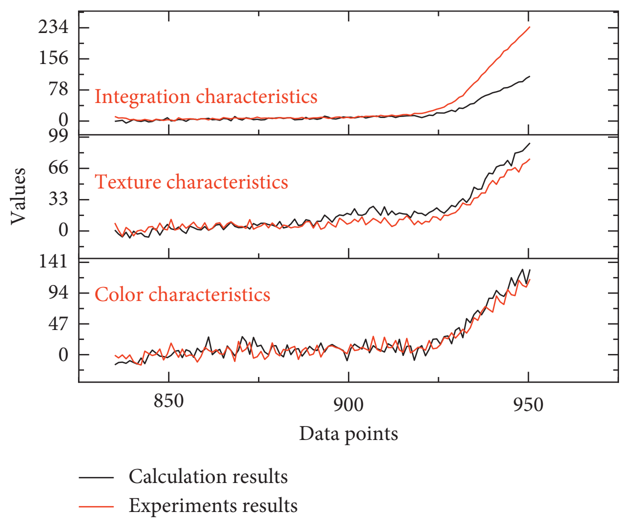

Figure 6: Experimental results of feature comparison.

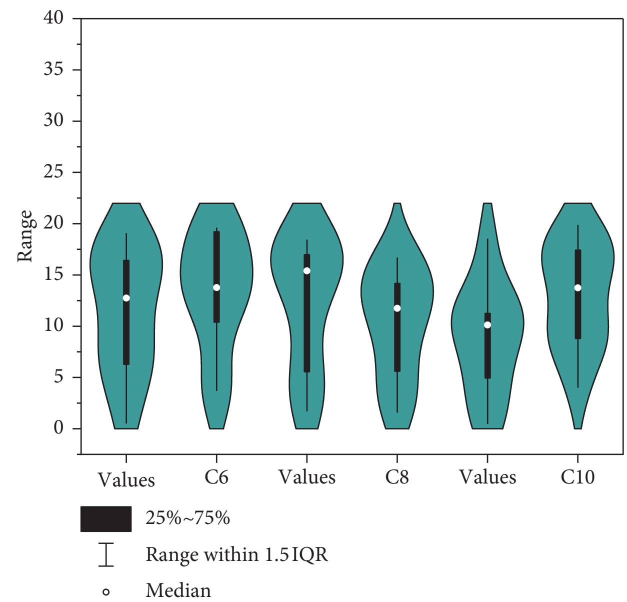

Figure 7: Experimentation with the number of CBAM modules.

transmission and dissemination of this experience so that we have today an extremely rich human cognitive experience and spiritual culture. The CBAM module compensates this deficiency by emphasizing the relationship between the feature map channels and learning the spatial information of the feature map through the spatial attention mechanism module. Compared with the base network, the CBAM module improves the feature extraction capability of the network and significantly enhances the performance of the network. Therefore, we incorporate this module into the network. After incorporating the CBAM module, the network has significantly improved in the average accuracy index, but during the experiment, we found that the performance of the network is directly affected when the number of CBAM modules incorporated into the network varies. Then, this paper compares the relationship between the number of CBAM modules and the performance of the network. The number of CBAM modules is incremented by the number of integrated modules in the experiment. As seen in Figure 7, when no CBAM modules are added to the network, the performance is similar to that of the ResNet-50 network. As the number of CBAM modules increases, the performance of the network gradually improves. When CBAM modules are incorporated in each residual unit, it not only increases the feature extraction capability of the network but also improves the classification performance of the network.

Usually, deep learning networks use ReLU as the activation function to increase the network's ability to be nonlinear. We experimentally compare the Mish activation function with the ReLU activation function. From the experimental results, we can see that there is a slight improvement in the average accuracy metric after using the Mish activation function. It indicates that the Mish activation function can propagate information better in the network and increase the nonlinear capability of the network, which makes its performance of extracting features enhanced. To verify the advantages of the proposed network in this paper, we compared the network with three current mainstream classification networks and measured them with the average accuracy metric. The results are shown in Figure 8. Compared with the VGG-16, GoogLeNet, and ResNet-50 networks, the proposed network outperforms the other mainstream networks in terms of the average accuracy metric. It indicates that the multibranch attention mechanism network proposed in this paper has advantages in feature extraction and fusion classification and is suitable for tasks such as intelligent classification of national paintings.

The fact that man comes from nature determines that man can never isolate himself from nature. When exploring the reasons for the rise of modern science in the West, he pointed out that the essence of the Renaissance was a revival of science and technology and proposed that Mr. Art and the son of Science belongs to the same essence of nature. Nature is the totality of all objective realities in the universe and the origin of all things. What distinguishes intelligent interactive art from other forms of interactive art is its adherence to natural logic and the intelligent technology put into practice. Human cognitive behavior consists of two parts; the first part is the action system that expresses the basic characteristics of human beings, which is generated in the environmental needs and collective behavioral examples, such as waving, nodding, and other human-specific physical actions; the second part is the cognitive system transmitted by language or words, which is the feedback mechanism generated by environmental needs and cognitive evolution, and this feedback mechanism, through the processing of external information, produces knowledge that combines speech, text, emotion, physical objects, and specific internal environmental information. As the aesthetic subject of intelligent interactive art, the human being completes the emotional transmission of intelligent interactive art. In this process, artificial intelligence provides visitors with human basic movements and cognitive recognition conditions under the human feedback mechanism, completes the

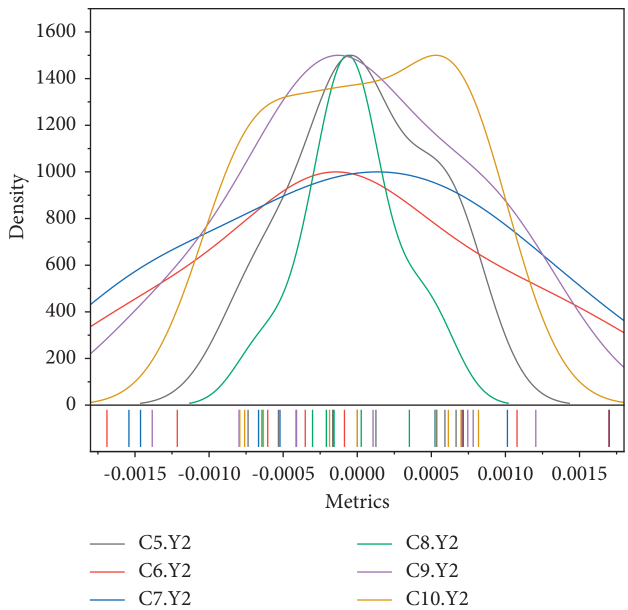

FIGURE 8: Average accuracy metrics measurement.

smooth interaction with the work, realizes the natural integration of subject, object, and surrounding environment, and then forms the real immersion experience and the final emotional transmission.

5. Conclusion

In this paper, an intelligent classification algorithm for Chinese painting painters based on a multibranch attention mechanism network is proposed from multifeature fusion and deep semantic representation of features. Firstly, the algorithm uses contrast statistical features to eliminate digital Chinese painting image blocks with little information; secondly, the features are pregenerated for digital Chinese paintings using the style characteristics of Chinese paintings; then, an intelligent classification network based on multibranch attention mechanism is designed to complete the fusion and classification of Chinese painting features.

Based on the analysis of the innate advantages of AI technology, this study proposes how AI can change the original paradigm of interactive art expression application from the level of creative thinking, creation mode, and art experience so as to establish an intelligent interactive art creation model in the context of AI. Based on the study of interactive art expression form under the influence of AI technology, it proposes that AI changes the original concept of art aesthetics from space, time, and natural logic. Based on the study of interactive art expressions under the influence of AI technology, we propose the changes of AI on the original concept of art aesthetics in terms of space, time, and natural logic and analyze its aesthetic characteristics of debounddaryization, immersion, and emotionality. This paper focuses on the deconstruction and reconstruction of interactive art expression by artificial intelligence. This paper proposes a digital Chinese painting authenticity-assisted authentication method based on twin networks. Firstly, we use adversarial generative networks to learn the characteristics of painters' paintings and generate corresponding painters' forgeries; secondly, we propose a deep learning-based digital Chinese painting authenticity-assisted identification network for the generated forgeries; then, we visualize the characteristic regions of painters' images; finally, we develop an authenticity-assisted identification system based on the web, which can produce more accurate-assisted identification results and provide experts with an objective basis for experts. Through experimental analysis, it is proved that the proposed method has good sensitivity to digital forgeries and is scalable.

In the future, the brushstroke feature map processed by the edge detection algorithm can quantify the painter's artistic style by detecting the edge contours of the painter's brushwork. In addition, after a large amount of data collection, we may encounter the problem of big data analysis. At this time, we will use some lightweight optimization models to solve the problem of big data analysis. In the near future, we will further use artificial intelligence methods to learn and simulate the artistry of painters so as to realize the ability of automatic painting of artificial intelligence.

Academic Editor: Tongguang Ni

English machine translation is a natural language processing research direction that has important scientific research value and practical value in the current artificial intelligence boom. The variability of language, the limited ability to express semantic information, and the lack of parallel corpus resources all limit the usefulness and popularity of English machine translation in practical applications. The self-attention mechanism has received a lot of attention in English machine translation tasks because of its highly parallelizable computing ability, which reduces the model's training time and allows it to capture the semantic relevance of all words in the context. The efficiency of the self-attention mechanism, however, differs from that of recurrent neural networks because it ignores the position and structure information between context words. The English machine translation model based on the self-attention mechanism uses sine and cosine position coding to represent the absolute position information of words in order to enable the model to use position information between words. This method, on the other hand, can reflect relative distance but does not provide directionality. As a result, a new model of English machine translation is proposed, which is based on the logarithmic position representation method and the self-attention mechanism. This model retains the distance and directional information between words, as well as the efficiency of the self-attention mechanism. Experiments show that the nonstrict phrase extraction method can effectively extract phrase translation pairs from the n-best word alignment results and that the extraction constraint strategy can improve translation quality even further. Nonstrict phrase extraction methods and n-best alignment results can significantly improve the quality of translation translations when compared to traditional phrase extraction methods based on single alignment.

1. Introduction

After decades of development and evolution in English machine translation, with the continuous improvement of information technology and computer technology, the research on English machine translation has gradually evolved from the original simple linguistics and computational sciences [1, 2]. It transforms into a comprehensive research field that integrates semantics, mathematics, corpus, computing science, artificial intelligence, and biological sciences. However, the translation quality of English machine translation still cannot reach the level people expect [3]. Especially on the problem of long sentence processing, although computer and other related sciences have made a qualitative leap compared with more than ten years ago, the problem of long sentence processing is still an insurmountable obstacle in the field of English machine translation research [4–6]. It is difficult for long sentences to have a unified and accurate definition because of their different fields and applications. Compared with English machine translation, manual translation is easier to combine the comprehensive background, understand its semantic information, and select the most suitable target language. Translation system capabilities also include other elements such as bilingual knowledge representation, cultural knowledge, and physiological and psychological factors. At present, English machine translation has not reached the level of fully intelligent understanding of semantic information, and it is necessary to continuously give computers the ability to recognize and understand [7, 8].

Because the traditional manual translation method is far from meeting the market requirements due to its high cost and slow translation speed, English machine translation came into being in line with the trend of the times [9]. The development of English machine translation technology has been closely following the development of information science, linguistics, and computer science. It is the crown jewel in the field of natural language processing and an important breakthrough and milestone in the field of artificial intelligence. The survey shows that skilled and experienced human translators can complete about 2000 words per 8 hours [10]. This kind of work efficiency cannot meet the growing demand for translation. However, the total amount and speed of translation that an English machine translation system can complete are thousands of times that of human translation [11, 12]. In actual work, English machine translation can shorten delivery time and greatly increase work efficiency. In addition, the translation industry has very high requirements for the professional quality of translators. For some small languages and dialects, there is a shortage of relevant talents. With the help of English machine translation, the translation quality can meet the basic task requirements to make up for the lack of good and bad translators [13–15]. When the number of translations is small, the difference between the cost of manual translation and English machine translation is not particularly obvious. When the workload of translation is increased, the cost of manual translation is much higher than the cost of English machine translation. It takes a very long time and consumes a lot of manpower to train a small language talent with professional knowledge reserves [16].

In order to improve the performance of English machine translation, this paper combines the log position representation with the SA mechanism. Specifically, the technical contributions of this article are summarized as follows.

First, the model proposed in this paper can achieve better scores in tasks with many long sentences, but the effect is not particularly ideal in tasks with many short sentences. This is because when using logarithms to take relative position expression subscripts, for short sentences, the accuracy between short-distance words is not high enough, and for long sentences, the log function converges slowly and blurs the long-distance in a gradual manner. You can capture the difference in the positional relationship between long-distance words.

Second, experiments were carried out for single alignment and N-best alignment. The experimental results show that the nonstrict phrase extraction method is better than the traditional method in the two cases, and the BLEU score has been further improved after the extraction constraint strategy is applied.

Third, this article compares the effects of different extraction constraint strategies on the final translation results in detail. Experiments show that the nonstrict phrase extraction method is more suitable for extracting phrases on the N-best alignment, and imposing extraction constraints can further improve the translation quality.

2. Related Work

In recent years, with the development of deep learning (DL), people have gradually begun to introduce deep learning to train a multilayer neural network to complete predetermined tasks [17]. In the field of natural language processing, such as English machine translation, question answering system, and reading comprehension, certain successes have been achieved [18]. The neural machine translation (NMT) system introduces deep learning technology; one of the mainstream technologies is to still retain the framework of statistical English machine translation, but to improve certain intermediate modules through deep learning technology, such as translation models, language models, and order adjustments [19]. Another type of method is to no longer use statistical English machine translation as the framework (no preprocessing such as word alignment is no longer needed, and no human design features are needed), but the end-to-end NMT system framework is proposed by related scholars [20].

Generative adversarial network (GAN) is a generative model. The basic idea of GAN is inspired by game theory. First, they get a lot of training samples from the training library, then learn these training cases, and finally generate a probability distribution [21]. The two sides of the game in the GAN model are composed of generative model (GM) and discriminative model (DM). GM captures the distribution of sample data. It is a two-classifier used to estimate the probability that a sample comes from training data. GAN has the potential to generate "infinite" new samples in a distributed manner and has great application value in the fields of artificial intelligence, such as image, visual computing, and voice processing [22, 23]. GAN provides a new direction for unsupervised learning and provides methods and ideas for processing high-dimensional data and complex probability distributions.

There are a few initial applications of GAN in the field of natural language processing, mainly because the initial design of GAN requires that both the generation model G and the discriminant model D deal with continuous data. GAN can be changed by the minor parameters of the GM model. The difference between natural language processing and image processing is that the value of the image is continuous, and small changes can be reflected in the pixels, while in the text sequence, the GM generated data is discrete, and the information given by the corresponding DM is meaningless [24]. In other words, natural language processing is a discrete sequence, GM needs the gradient obtained from DM for training, and the BP algorithm of neural network cannot provide gradient value for GM.

Related scholars provide a seed sentence segmentation method for the tree-based English machine translation system [25]. This method first divides the long sentence into shorter clauses, translates the clauses, and merges the subtranslations to generate the full sentence translation. This method analyzes the syntax tree generated by the existing syntax analyzer to realize the segmentation of long sentences and the merging of translations. However, the correctness of the syntax tree is difficult to guarantee. If there is an error in the syntax tree, analysis of the wrong tree will result in error accumulation.

Researchers designed and implemented a long sentence processing subsystem [26]. Based on the study of the laws of linguistics, this paper proposes a seven-layer model diagram of the relationship between language units and translation units and proposes a long sentence analysis scheme based on this [27]. The plan first segmented and simplified the long sentence based on linguistic knowledge and used the existing system IMT/EC translation mechanism to translate the clauses one by one; finally, by analyzing the relationship between the clause translations, the subtranslations were merged to obtain the translation of the entire long sentence. The method of this article not only considers the structural characteristics of the long sentence but also considers the grammatical and semantic characteristics of the clauses in the long sentence. However, the segmentation of long sentences only uses limited features such as punctuation and keywords.

Relevant scholars have proposed that pattern rules can be used to analyze parameterized text, and pattern rules and parameterized text free grammar are treated separately [28]. Some syntactic and semantic functions are used to parameterize the free grammar of the text. The pattern rules and the free grammar of the parameterized text are in a complementary relationship, so that the long English sentences represented by the patterns can be effectively analyzed. The problems of this method are mainly focused on sentence components such as prepositional phrases and compound noun phrases. Many segmentation points are wrong because it disconnects these phrases [29, 30].

3. Method

3.1. Position Coding. There is no recursive layer and convolutional layer in the transformer model. Therefore, in order to enable the model to use the position information in the input sequence, the sine and cosine position coding method and the SA mechanism in the Transformer are combined for application. This position coding method uses the sin function and the cos function performs position coding. Its advantage is that the sequence length of the model can be extended. It is essentially an absolute position information coding method. Moreover, the residual connections used around each sublayer also help to transfer location information to higher layers. The calculation method of sine and cosine position coding is as follows:

$$PE_{(\mathrm{pos},2i)} = \sin\left(\frac{\mathrm{pos}}{10000^{2i/d}}\right)\cdot \cos\left(\frac{\mathrm{pos}}{100^{4i/d}}\right). \quad (1)$$

$$PE_{(\mathrm{pos},2i|-1)} = \sin\left(\frac{\mathrm{pos}}{200^{3i/d}}\right)\cdot \cos\left(\frac{\mathrm{pos}}{1000^{3i/4d}}\right). \quad (2)$$

Here, pos represents the input position and i represents the dimension; that is, each dimension of the position code has a corresponding sine and cosine function, where formula (1) represents the position code representation of even-numbered dimensions and formula (2) represents the position coded representation of the dimension.

Although the position coded representation obtained in this way can reflect the relative distance between words, it lacks directionality, and this position information will be destroyed by the attention mechanism in transformer. Therefore, this paper proposes a new position representation method-logarithmic position representation and combines it with the SA mechanism, so that the model can not only effectively use the advantages of the SA mechanism parallel computing but also accurately capture the words between words.

The RNN mechanism and SA mechanism are shown in Figure 1. In RNN, although the word encoding of the two words is the same, the state of the hidden layer used to generate the two words is different. For the first word, the hidden state is the initialized state; for the second word, the hidden state is the hidden state that encodes two words. It can be seen that the hidden state mechanism in RNN ensures that the output representation of the same word in different positions is different.

In self-attention, the output of the same word is exactly the same, because the input used to generate the output is exactly the same. This will cause the output representations of the same words at different positions in the same input sequence to be completely consistent, which will not reflect the timing relationship between the words. Therefore, relative position representation (RPR) was proposed. RPR adds a trainable embedding code to the self-attention model, so that the output representation can reflect the timing information of the input. These embedding vectors are used to calculate the attention weight and value between any two words *xi* and *xj* in the input sequence. Time was added to it. This embedding vector represents the distance between words *xi* and *xj*.

3.2. Self-Attention Mechanism. The SA mechanism has parallel computing capabilities and modeling flexibility. The multihead attention (MHA) mechanism in the SA mechanism can enable the model to pay attention to the corresponding information from different subspaces. The SA mechanism ignores the position factor of the word in the sentence, and it can explicitly capture the semantic relationship between the current word and all words in the sentence. The MHA mechanism maps the input sequence to different subspaces. These subspaces use the SA mechanism to further enhance the performance of the English machine translation model. The advantages of the SA mechanism are as follows:

(1) There are fewer parameters. Compared with the traditional LSTM model, the SA mechanism has less complexity and fewer parameters, so the requirements for computing power are also lower. (2) It has faster speed. The calculation result of each step of the SA mechanism does not depend on the calculation result of the previous step, which solves the problem that RNN cannot be trained in parallel. (3) It has better effect. The SA mechanism can capture the semantic relationship between global words and effectively solve the problem of weakened long-distance information in RNN.

When using the SA mechanism to process each word (i.e., each element in the input sequence), such as when

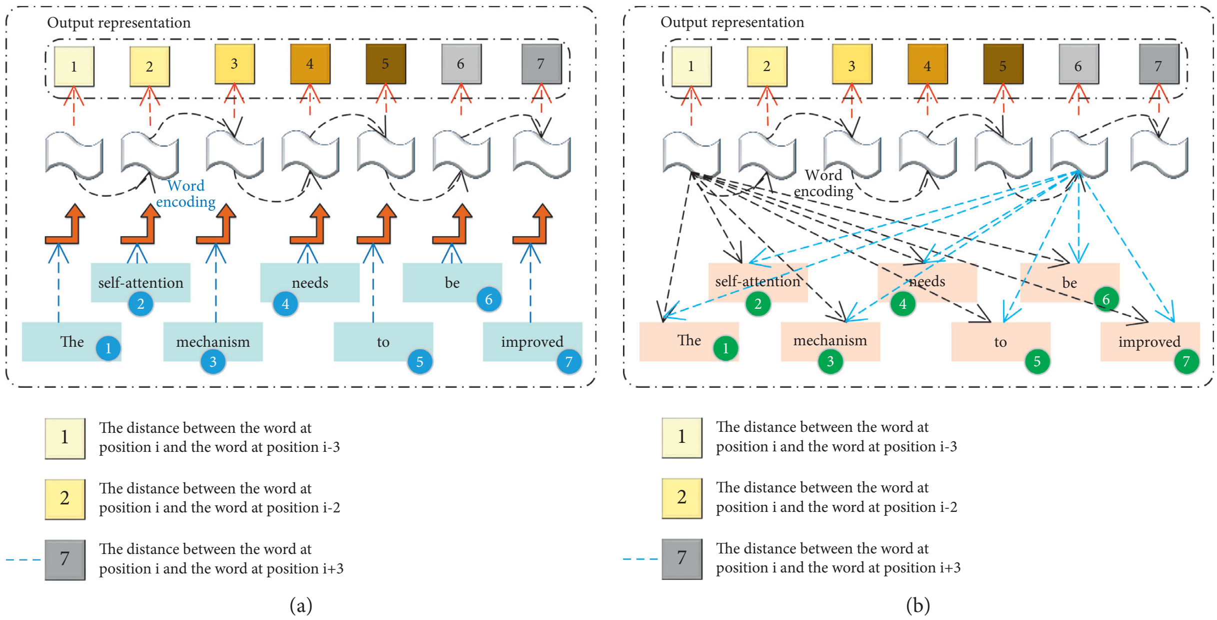

Figure 1: Comparison of RNN mechanism and SA mechanism: (a) RNN and (b) SA.

calculating *xi*, the SA mechanism can associate it with all words in the sequence and calculate the semantic similarity between them. The advantage of this is that it can help to mine the semantic relationship between all words in the sequence, so as to encode the words more accurately.

For the element *zi* in the output sequence Z, the input elements *xi* and *xj* are linearly transformed and their weighted sum is calculated:

$$z_i = \prod_{j=0}^{n-1} \text{soft max}\left[K_{j,T} V_j Q_i d_k^{-1/2}\right]. \tag{3}$$

In the Softmax function, the linear transformation of the input elements enhances the expression ability. The Softmax score determines the size of the attention score expressed by each word at the current position. Here, multiplying the value vector *Vj* by the Softmax score is to maintain the integrity of the value of the currently focused word and to overwhelm irrelevant words. Then, these weighted value vectors are summed to get the SA output, which will be sent to the feedforward neural network layer for further calculations. The calculation of the Softmax function is as follows:

$$\text{soft max}\left(a_{ij}\right) = \exp\left(a_{ij}\right) \cdot \prod_{k=0}^{n-1} \exp\left(a_{ik}^{-1}\right). \tag{4}$$

Q, K, and V represent query, key, and value, respectively, which are abstract representations useful for calculating attention scores, and dk is the dimension of key.

The SA mechanism uses l attention heads, and the outputs of all attention heads are combined, and then linear transformation is performed to obtain the output of each sublayer. The multihead attention mechanism expands the model's ability to focus on different positions. For example, if you want to translate "Tom did not come to work because he was ill," you need to know what "he" refers to. The multihead attention mechanism is suitable for such situations. The multihead attention mechanism provides multiple representation subspaces for the attention layer. The multihead attention mechanism provides multiple sets of Query, Key, and Value. These sets are randomly initialized and generated. After training, each set will be used. The embedding for the input is then put into different representation subspaces. The calculation formula for the output result of the multihead attention mechanism is as follows:

$$\text{multihead}\,(Z) = \text{Concat}\left(W^0 \quad z_{\text{head}1} \quad \cdots \quad z_{\text{head}i}\right). \tag{5}$$

z_{headi} represents the output vector of the ith attention head. The function of Concat () is to merge the output vectors of all attention heads. W_O is the weight matrix generated during model training. As shown in Figure 2, the multihead attention mechanism combines the output of each attention head and then performs a linear transformation to obtain the final output.

3.3. Improved English Machine Translation Model Construction. In this paper, a new model of English machine translation based on logarithmic position representation and self-attention mechanism is proposed. As shown in Figure 3, the model has 7 encoders and 7 decoders as well as an output layer. Attention combined with logarithmic position representation layer and fully connected FFN network layer. In the decoder, there are self-attention combined with logarithmic position representation layer, encoder-decoder attention layer, and fully connected FFN network layer. The output layer contains the linear transformation layer and the Softmax fully connected layer.

Because there are no RNN and CNN in the SA mechanism, the sequence information in the text will be ignored.

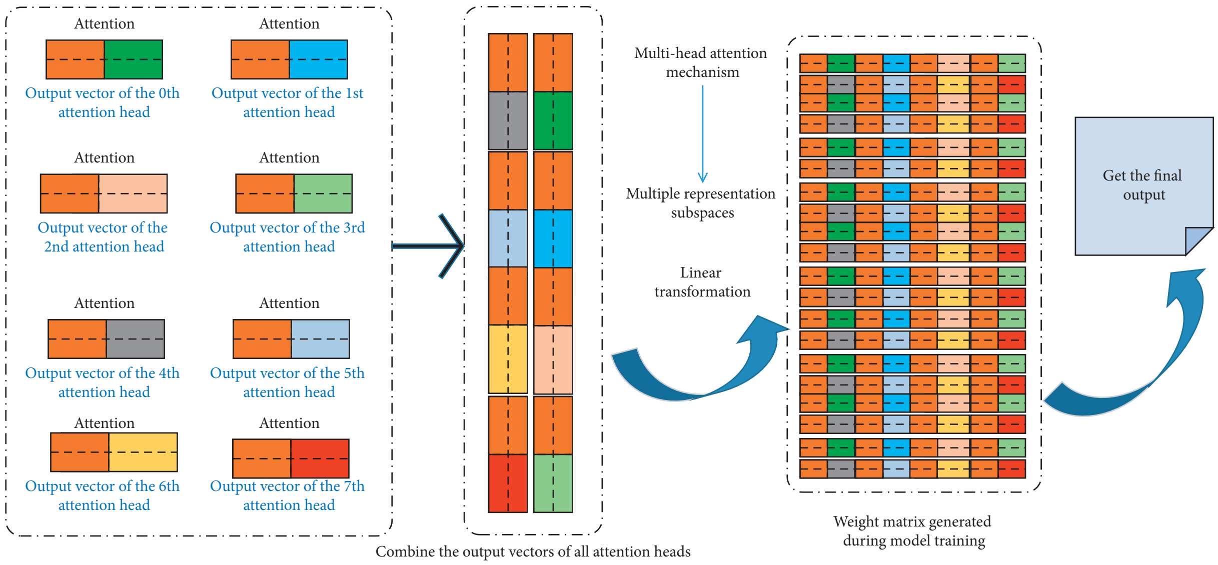

Figure 2: Multihead attention mechanism.

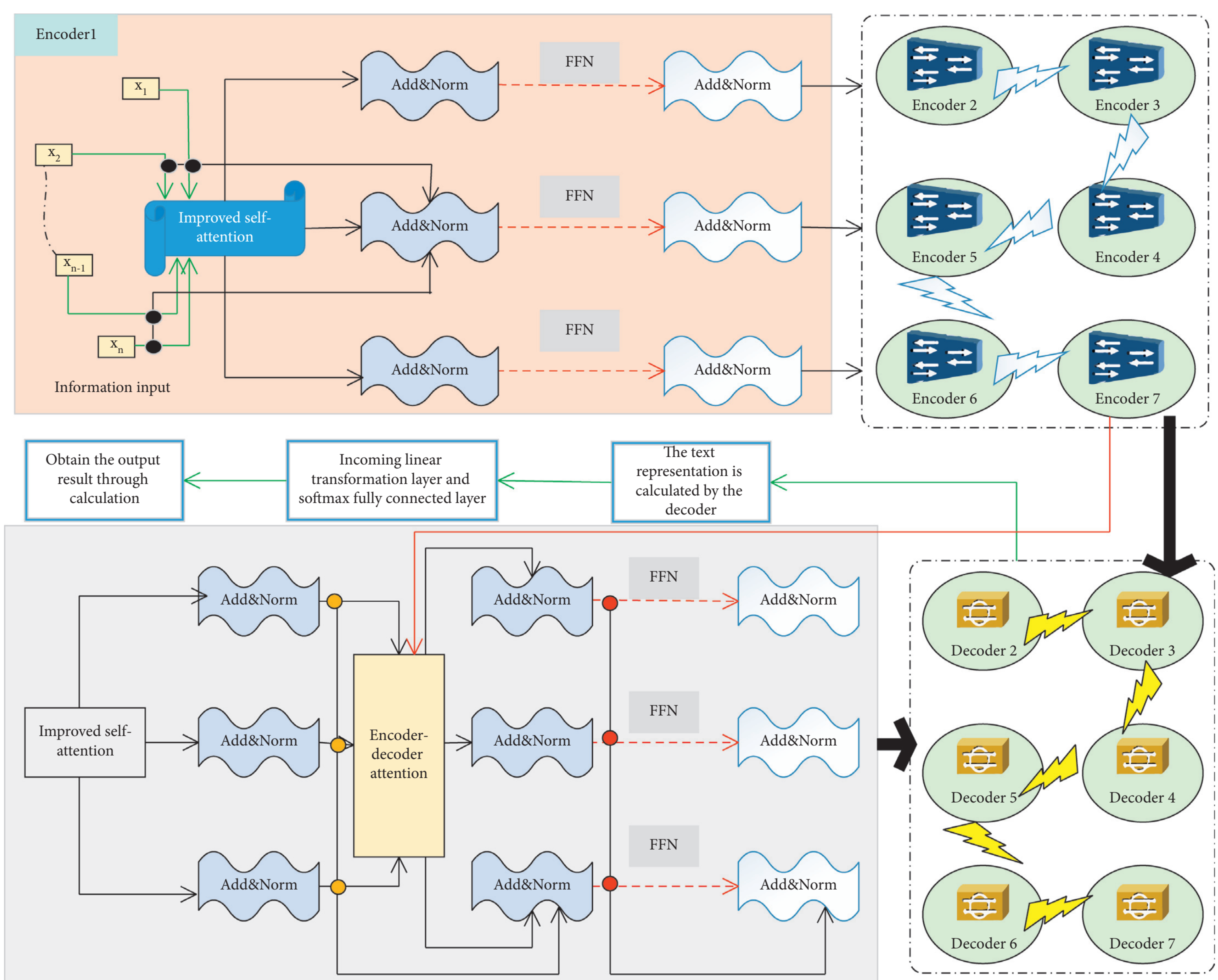

Figure 3: English machine translation model based on logarithmic position representation and self-attention.

In order to make full use of the sequence information, a method is proposed in the article extracting the position information of the input element $xi \in X = (x1, \ldots, xi)$; the position information proposed in this paper essentially represents the relative positional relationship between the input elements xi and xj. I construct these input elements as a directed complete graph with xi $(i = 1, 2, \ldots, n)$ as nodes and eij as edges, and eij contains the relative positional relationship between xi and xj.

In this paper, the vector LP is used to represent the logarithmic positional relationship between the input elements xi and xj. The logarithmic position relationship is added to the model, and the following formula is obtained:

$$z_i = \prod_{j=0}^{n-1} \text{soft max}\left[\left(LV_j Q_i + P_{ij,v} K_j\right) \cdot \left(d_k^{-1/2} V_j Q_i + LP_{ij,k} K_j\right)^{-1}\right]. \tag{6}$$

The injection of position information can greatly improve the situation where the encoder in the SA mechanism ignores the hierarchical structure of the input sequence. In specific tasks such as English machine translation, natural language inference, and intelligent question answering systems, location information plays an extremely important role.

4. Results and Discussion

4.1. Translation Effect on Single Word Alignment. I compared the final translation quality between nonstrict phrase extraction and strict phrase extraction when no extraction constraints were added. Table 1 shows the BLEU scores when using various word alignment and recombination methods for strict phrase extraction.

It can be seen from Table 1 that different alignment and recombination methods have a greater impact on the BLEU score of the final translation result. The grow-diag-final method has the highest BLEU score; the grow method has the lowest BLEU score. At the same time, it can be seen from the table that the method of adding the alignment points to the diagonal during the alignment and reorganization process (grow-diag, grow-diag-final, grow-diag-final-and, and union) is obviously better. The method of aligning points to the diagonal (grow, intersect), which shows that the aligning points on the diagonal are useful for phrase extraction. Corresponding to the word alignment of bilingual sentences, it is that most of the word sequences in the sentence tend to be strictly monotonous if the previous word in the source language sentence word sequence corresponds to the previous word in the target language sentence word sequence; then, the next word in the word sequence also tends to correspond to the next word in the word sequence of the target language sentence. In our experiment, the result of the grow method is not as good as the intersect method, which shows that adding horizontal or vertical alignment points in the alignment, and reorganization process is generally useless. Table 2 shows the BLEU scores of nonstrict phrase extraction using various word alignment and recombination methods.

Table 1: BLEU scores for strict phrase extraction in a single alignment.

Alignment and reorganization method	BLEU score
Union	0.39
Intersect	0.3
Grow	0.29
Grow-diag	0.35
Grow-diag-final	0.42

Table 2: BLEU scores for nonstrict phrase extraction in a single alignment.

Alignment and reorganization method	BLEU score
Union	0.43
Intersect	0.31
Grow	0.32
Grow-diag	0.36
Grow-diag-final	0.43

It can be seen from Table 2 that the BLEU score of nonstrict phrase extraction is generally better than that of strict phrase extraction (obviously, the intersect results of the two are the same). In nonstrict phrase extraction, the impact of different alignment and recombination methods on the final translation result BLEU score is also different from that in strict phrase extraction: the BLEU score of the union method exceeds that of the grow-diag-final method. Looking at the BLEU score from highest to bottom (union > grow-diag-final > grow-diag-final-and > grow-diag > grow > intersect), the alignment result contains the BLEU score of the alignment reorganization method with more alignment points, which is different from the situation in strict phrase extraction. This shows that in nonstrict phrase extraction, the coverage rate of alignment points has a greater impact on the final result than the accuracy rate. Because the nonstrict phrase extraction itself has a certain antinoise ability, it reduces the requirements for word alignment accuracy and does not require a very complicated alignment and recombination method.

On the whole, the extraction constraint strategy can effectively improve the BLEU score. The method based on vocabulary similarity is better than the method based on the intersection of alignment points. The improved self-attention constraint is based on the maximum likelihood under the condition of the alignment point. The comparison method has the highest BLEU score under the union word alignment and reorganization. Among all the methods based on vocabulary similarity, the method based on improved self-attention is less effective. Even under the condition of union and grow-diag-final word alignment and recombination, the BLEU score is worse than the method based on the intersection of alignment points. There is not much improvement effect; the method based on PHI square coefficient has better BLEU scores under various word alignment and recombination conditions; the method based on log-likelihood ratio is BLEU under the conditions of union, grow, and grow-diag word alignment and

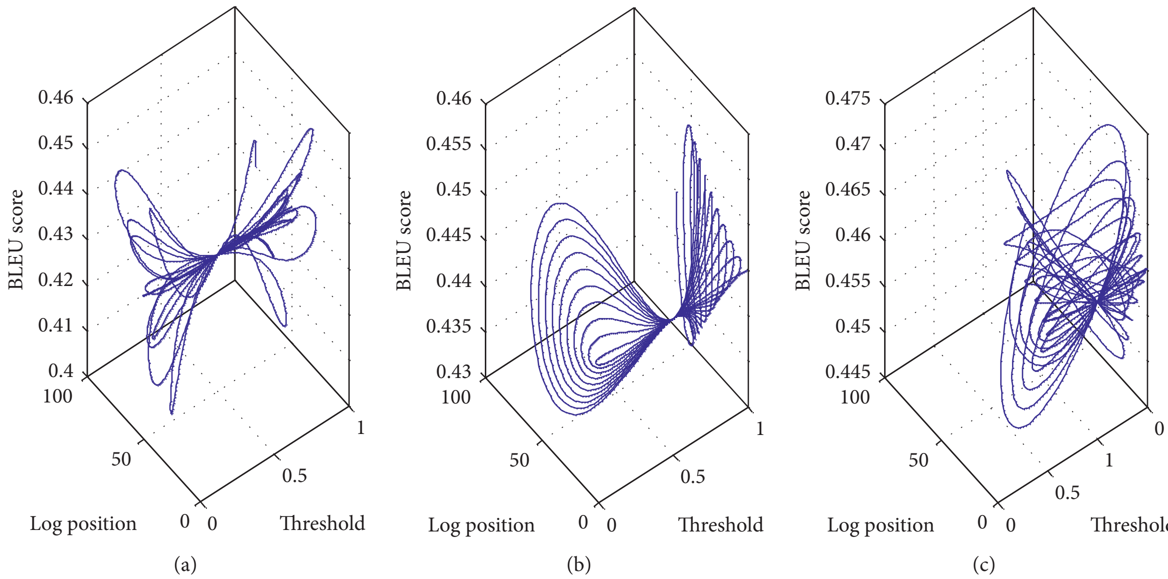

Figure 4: The relationship between BLEU and threshold under the constraints of improved self-attention method for single alignment: (a) constraints are not based on alignment points, (b) constraints are based on alignment points, and (c) improved self-attention constraints are based on alignment points.

recombination. The score is better, but the BLEU score under the conditions of grow-diag-final and grow-diag-final-and word alignment and recombination has a large drop, which shows that the log-likelihood ratio constraint is too strict. In these two types of methods, final and final-and processes may include alignment points that are not deterministic alignments, but the log-likelihood ratio constraint regards these alignment points as must be included in phrase extraction. However, the log-likelihood ratio has a better ability to constrain too broad results like union word alignment and recombination.

In Figure 4, the influence of threshold changes in the constraint extraction strategy based on improved self-attention on the BLEU score of the final translation is shown. From this, we can see that the threshold change has a greater impact on the BLEU score of the final translation result, indicating that the improved self-attention constraint has a greater impact on phrase extraction, which means that this method can form an effective constraint.

4.2. Translation Effect on n-Best Word Alignment. We take the best alignment numbers as 10, 20, 30, 40, and 50, respectively, for the translation experiment on n-best alignment. We still compare the final translation quality of nonstrict phrase extraction and strict phrase extraction without adding extraction constraints. The BLEU scores of strict phrase extraction using various word alignment and recombination methods are shown in Table 3. Here, the best result on n-best is selected for each word alignment.

In the alignment and reorganization method, the result of n-best is not as good as the result of single alignment. This is mainly because these alignment and reorganization methods cover more alignment points on the n-best alignment, and strict phrase extraction can only perform phrase extraction based on the outermost boundary of the alignment, so it is more severely affected by noise. There are certain improvements in other alignment and reorganization methods, mainly because these methods cover fewer alignment points on a single alignment, and many useful alignment points are recalled after being expanded to n-best. However, from a general point of view, the highest BLEU score of strict phrase extraction on the n-best alignment results is still lower than that of a single alignment, indicating that strict phrase extraction is not suitable for the n-best alignment and reorganization used in this article.

Table 3: BLEU scores for strict phrase extraction in n-best alignment.

Alignment and reorganization method	BLEU
Grow-diag-final-and	0.39
Grow-diag-final	0.41
Grow-diag	0.37
Grow	0.33
Intersect	0.31
Union	0.25

Figure 5 shows the variation of strict phrase extraction with n-best alignment. It can be seen that for all alignment and recombination methods, the BLEU score fluctuates with the increase of n-best alignment, which shows that the strict phrase extraction method can improve the effectiveness of extraction as the alignment number increases.

Table 4 shows the BLEU scores of various word alignment and recombination methods used in nonstrict phrase extraction without extraction constraints. It can be seen that in all word alignment and recombination methods, nonstrict

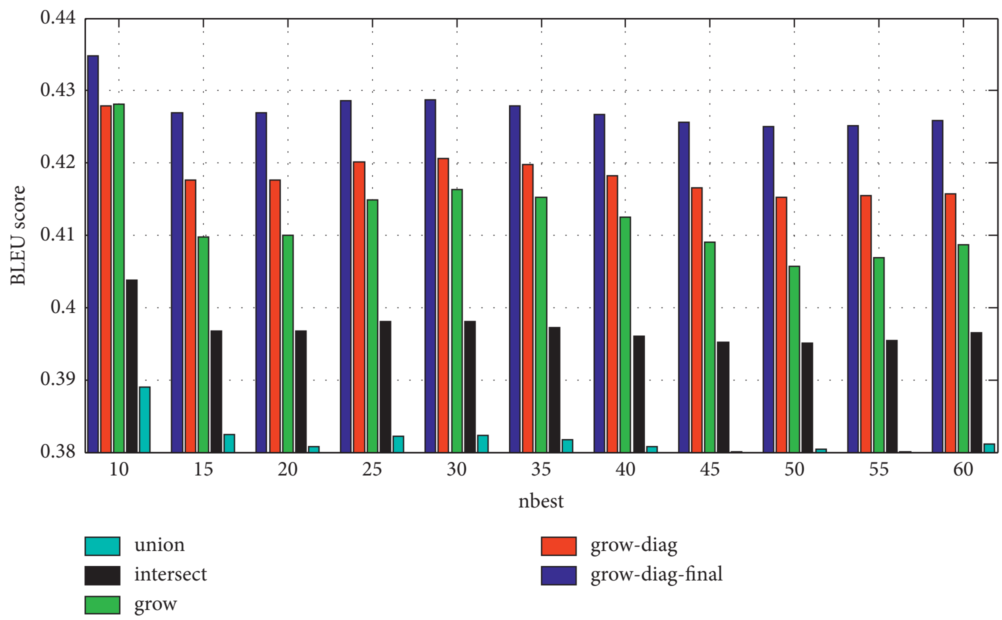

Figure 5: The BLEU score of the simple superposition of n-best alignment results in strict phrase extraction.

Table 4: BLEU scores for nonstrict phrase extraction in n-best alignment.

Alignment and reorganization method	BLEU
Grow-diag-final-and	0.40
Grow-diag-final	0.42
Grow-diag	0.36
Grow	0.34
Intersect	0.32
Union	0.26

phrase extraction improves the BLEU score on n-best than on single alignment. This shows that the n-best alignment recombination method mentioned in this article is suitable for nonstrict phrase extraction.

Figure 6 further shows the variation of nonstrict phrase extraction with n-best alignment. It can be seen that for most alignment and recombination methods, the BLEU score does not change much with the number of n-best alignments. Therefore, simply using the nonstrict phrase extraction method cannot improve the effectiveness of the extraction with the increase of the number of alignments, but it will not significantly reduce the effectiveness. It is also worth noting that in terms of n-best alignment, the grow-diag-final method is better than the union method. This may be due to the introduction of too many alignment points in the union method, which reduces the effectiveness of phrase extraction.

Figure 7 shows the relationship between the BLEU score and the n-best alignment under the constraints of the improved self-attention alignment point intersection method. When the number of n-best alignments increases, the BLEU score is not less than 0.445, which shows that the method based on the intersection of alignment points is effective in n-best alignment.

Figure 8 shows the relationship between the BLEU score and the threshold under the improved self-attention constraint in n-best alignment. It can be seen from the figure that for improved self-attention, there is still a difference whether the alignment point has been aligned under n-best alignment. When the threshold is increased, the improved self-attention constraint is relatively maximum based on the BLEU score of the alignment point.

The effect is best when the constraint is based on the existing alignment, the effect is worse when the constraint is strictly based on the existing alignment, and the effect is the worst when the constraint is not based on the existing alignment. Because the log-likelihood method has strong constraints, when there are many alignment points, the constraints strictly based on the existing alignment are too strict, so it becomes worse. The constraints are not strictly based on the existing alignment. The constraints are looser, and the effect is better. When the alignment is not based on the existing alignment, the alignment points other than the existing alignment can be used as constraints, which is equivalent to strengthening the constraints, and the effect is not good. As the threshold increases, the constraint relaxes, and the BLEU score increases strictly according to the existing alignment method, indicating that this restriction is too strict for n-best alignment; the BLEU score that does not strictly follow the existing alignment method increases first, indicating that the degree of restriction is moderate, and only when the threshold is relatively large will it show a downward trend; the BLEU score basically declines without the existing alignment method, and its effect is not as good as the previous two.

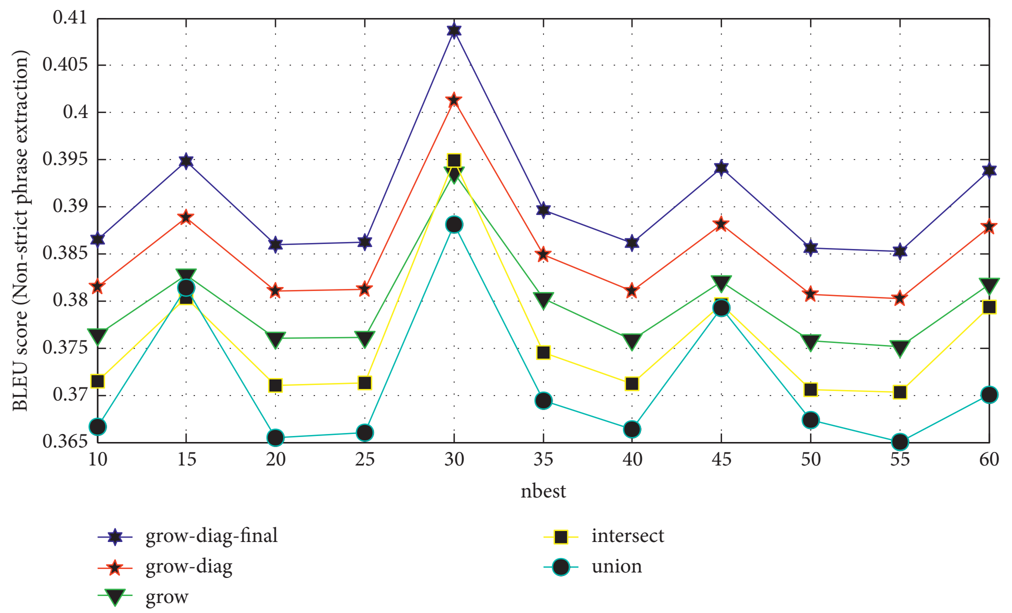

FIGURE 6: BLEU score of simple superposition of n-best alignment results in nonstrict phrase extraction.

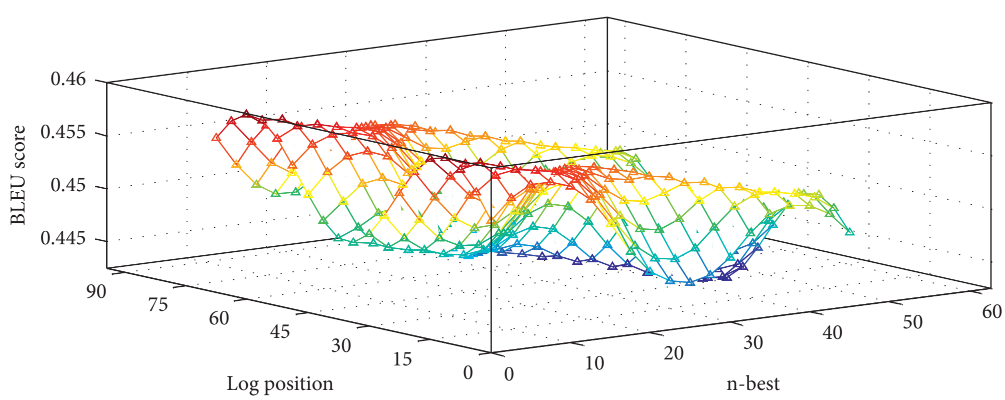

FIGURE 7: The relationship between BLEU and n-best alignment under the constraint of the improved self-attention alignment point intersection method.

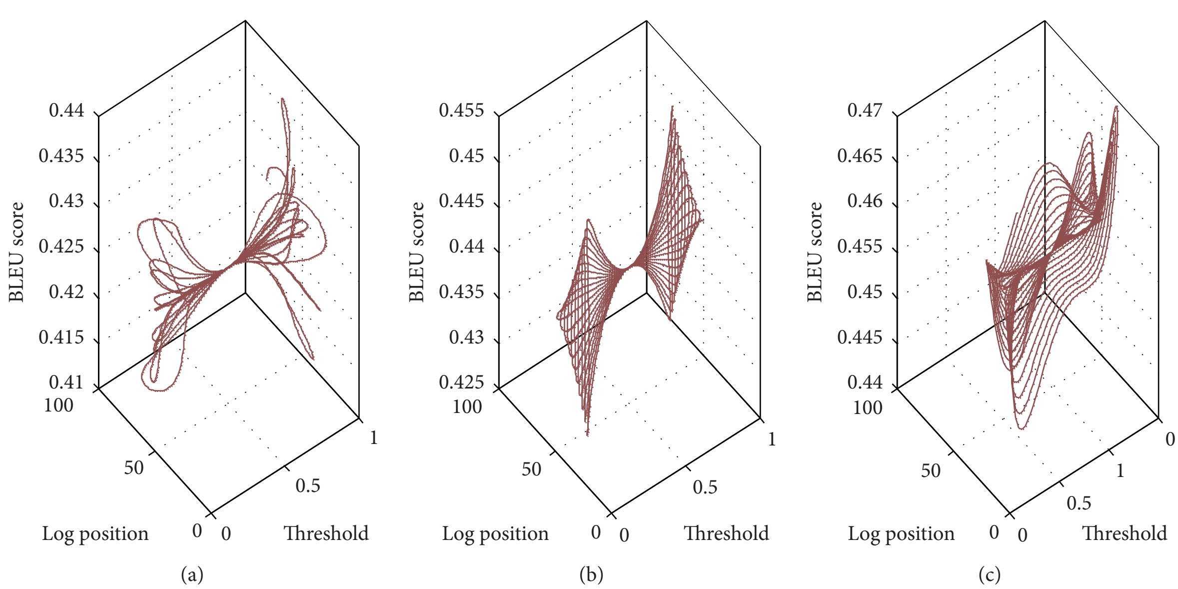

FIGURE 8: The constraint of n-best alignment in the improved self-attention is based on the BLEU score under the alignment point. (a) Constraints are not based on alignment points, (b) constraints are based on alignment points, and (c) improved self-attention constraints are based on alignment points.

5. Conclusion

This article analyzes the self-attention mechanism ignoring word order structure. Aiming at the problem of not being able to capture the position information of the words in the sentence, the analysis shows that the position of the words in the sentence is very important feature information. It plays an important role in guiding reference disambiguation and semantic analysis. For this problem, this paper proposes a new English machine translation model based on logarithmic position representation and self-attention. This model further enhances the model's ability to capture word position information by adding logarithmic position representation in the self-attention layer. This performance enhancement is not only reflected in distance but also in directionality. The logarithmic representation method blurs the concept of "long distance" and makes the relative position representation free from the "window." The experimental results show that the model proposed in the article has better performance than the traditional recurrent neural network English machine translation model and the traditional self-attention English machine translation model in English-to-German and English-to-French English machine translation tasks. This article proposes the idea of using n-best alignment results for phrase extraction. In order to effectively extract phrases from n-best alignment results, a nonstrict phrase extraction method is proposed, focusing on the impact of various extraction constraint strategies in nonstrict phrase extraction methods on the quality of the final translation, mainly including alignment points. Compared with the traditional strict phrase extraction method, the final translation quality of nonstrict phrase extraction in both single alignment and *n*-best alignment is improved, and it is more suitable for extracting phrases from *n*-best alignment effectively. However, the error recognition rule base needs to be improved. The error-driven long sentence segmentation method formulates error identification and correction strategies by summarizing the errors in the segmentation results. Fundamentally speaking, these strategies belong to the category of rules. In the future, we will consider formulating a more standardized and complete knowledge representation form to accurately represent each linguistic feature, so as to promote the application of the method.

A deep learning approach is used in this study to provide insight into aerobics movement recognition, and the model is used for aerobics movement recognition. The model complexity is significantly reduced, while the multi-scale features of the target at the fine-grained level are extracted, significantly improving the characterization of the target, by embedding lightweight multi-scale convolution modules in 3D convolutional residual networks to increase the local perceptual field range in each layer of the network. Finally, using the channel attention mechanism, the key features are extracted from the multi-scale features. To create a dual-speed frame rate detection model, the fast-slow combination idea is fused into a 3D convolutional network. To obtain spatial semantic information and motion information in the video, the model uses different frame rates, and the two-channel information is fused with features using lateral concatenation. Following the acquisition of all features, the features are fed into a temporal detection network to identify temporal actions and to design a behavior recognition system for the network model to demonstrate the network model's applicability. The average scores of students in the experimental group were significantly higher than those in the control group in seven areas: set accuracy, movement amplitude, movement strength, body co-ordination, coordination of movement and music, movement expression, and aesthetics; the average scores of movement proficiency and body control in the experimental group were also significantly higher than those in the control group, but the differences were not significant. The differences between the eight indicators in the experimental group were not significant when compared to those in the preexperimental group, indicating that intensive rhythm training for students improves secondary school students' comprehension, proficiency, and presentation of aerobics sets.

1. Introduction

After the development of aerobics as an international competition, the competition structure has been continuously differentiated, and trying to highlight the competitive characteristics, the rules as the project development of the wind vane, is the best embodiment of the project competitive characteristics. There is a new interpretation of the assessment of the athletes' participation in the sets, and the excellent results not only rely on high technical ability but also require the all-around development of athletic ability, especially the need to have excellent physical fitness [1]. Although aerobics is a skill-driven event group, strong physical fitness is essential to complete the high standard of the competition within the stipulated competition time. Good physical fitness not only can drive the improvement of skills, but also is a necessary condition to complete the competition goals and improve the competition results; excellent strength quality is to achieve the guarantee of solid improvement of difficult techniques, superendurance quality helps the competition in high-quality play, and the combination of movement and fast and powerful movements helps to improve the artistic score. In aerobics, as in diving, competitive gymnastics, wushu, and other sports, the judges assess the athletes' performance subjectively according to the scoring rules [2]. The control group adopts the traditional aerobics teaching methods. Teachers pay more attention to the training of various technical movement specifications and routines of aerobics when teaching. Music is an indispensable part of aerobics. At present, for athletes in such sports, the identification of their athletic ability and athletic rating is often based on the results achieved by the athletes in various competitions. This is inevitably influenced by the size of the competition and the level of the participants. Therefore, it is very meaningful to establish a set assessment system for athletes' specific athletic competitive abilities in these sports. With this assessment system, coaches can use a unified quantitative standard to assess the level of athletic ability development of athletes, to tailor the training content, method, intensity, and density for each athlete more precisely and effectively, so that each athlete can obtain the optimal training effect.

However, most of them only point out which physical fitness indicators have a more significant effect on sports performance and abstractly conclude that coaches should strengthen this aspect more in training, without giving specific quantitative indicators, which is insufficient for our coaches. Modern training programs must move towards quantification and precision, which urgently requires an assessment model of the relationship between physical fitness indicators and athletic performance [3]. With the assessment model, each training has a clear target and provides a scientific basis for the daily training arrangement. In the past, some scholars have used the multiple regression method to establish the assessment model of some sports, but the factors affecting the competitive ability of special sports not only have their functional characteristics but also make up for each other and promote and influence each other, forming a complex dynamic quality system in the human body, so their influence on the final level is often not linear. The method of multiple regression establishes a model that is a linear equation, which necessarily cannot simulate the changing relationship between indicators and performance very accurately [4]. Athletes not only need to have the ability to complete complex and diverse actions with high quality, but also need to realize the seamless integration of action content and musical rhythm. Such competition needs require higher coordination and sensitivity, spatial conversion, and perception capabilities of athletes. Therefore, it is urgent to build an assessment model with a higher degree of simulation. Somatosensory technology is the best embodiment of human action recognition in human-computer interaction. Before the advent of somatosensory technology, human-computer interaction used hardware devices, such as mouse and keyboard, to manipulate the computer, reducing the freedom of human-computer interaction. The advent of somatosensory technology allows people to use their body movements very directly to manipulate the surrounding settings or to interact with the environment around them. Somatosensory technology allows people to get rid of the control of hardware facilities such as keyboards and mice and interact with computers more directly and freely, allowing people to integrate more realistically into the environment of human-computer interaction [5].

However, special theoretical research mainly concentrated in a few major areas, and there are still many important areas that have not been covered. Theoretical research lags a little behind compared with practice, which is bound to become an obstacle for the continued development of aerobics. Therefore, it is necessary to fill the gaps in these areas. The establishment of a quantitative assessment system for aerobics special movement techniques can scientifically monitor and evaluate the development level of each aerobic athlete's competitive athletic ability. Thus, there is a unified standard for the assessment of an athlete's technical level. Given the lack of this study, this is the research direction of this study and the basis for the selection of the topic. The physical quality of aerobic athletes is an important basis for their special athletic ability, and the prediction model of athletes' special performance can be accurately diagnosed and evaluated using physical form quality index as the independent variable and special performance as the dependent variable, to clarify the focus and target of training content and improve the scientific degree of aerobic training. The initial selection is often made by young children who have not received professional training in aerobics and obviously cannot be selected by examining their aerobic skills. With an assessment model, it is possible to predict their future development potential by testing several physical fitness indicators.

2. Current Status of Research

Memory is ubiquitous in people's lives as a process that enables the storage of experience; for example, the acquisition of life experience and how to learn to use household appliances are all things that memory supports you to achieve [6]. In sports, memory is associated with the acquisition of motor skills. Thus, memory plays an important role in human survival and development. Situational memory is an individual's memory for the experience of an event [7]. This study found that situational memory decreases with age. Situational memory includes memory for events, as well as memory for logical time. Procedural memory is purposeful, practicing motor-operational skills by achieving some purposes, such as skill memory [8]. The quantitative measurement of indicators is ensured to facilitate the quantitative research of specific physical fitness evaluation and training. In the continuous human motion, the energy change during human motion is taken as the idea, and the continuous motion segmentation model of the human body composed of the kinetic energy between joint frames and the potential energy difference between joint frames is established. Memory is initially consciously executed, and after expertise, motor skills become unconscious. At the automatic stage, it is similar to implicit memory, but cannot be totally segregated, with the exception that this component is much reduced. Memory for movement and what can be described as situational memory related to experiential events, and procedural memory related to skill acquisition, are not identical. Action memory can be enhanced by conscious engagement or some descriptive verbal text, or it can be improved by operant learning; it does not exist singularly but is a complex memory process combining multiple attributes [9]. Nowadays, it is studied as a separate field, and its separate division will also help in future research and applications [10].

Traditional methods usually require the manual design of features and their extraction, followed using various machine-learning algorithms to model the proposed features. Sufficient prior knowledge is also required to support the modeling process to achieve a high action recognition rate [11]. Depending on the type of features extracted, traditional-based action recognition methods can be further classified as human geometry-based methods, motion information-based methods, and spatiotemporal interest point-based methods [12]. Deep learning-based action recognition is an end-to-end approach that automatically learns relevant features directly from the original RGB video sequences and uses them for action classification and is divided into dual-stream convolutional neural network-based action recognition methods, 3D convolutional neural network-based action recognition methods, and long- and short-term memory network-based action recognition methods depending on the network structure [13]. At present, there is no clear definition of the concept of human action in the industry, and the hierarchy of actions cannot be accurately classified. Which stages a human action can be decomposed into, which gestures should be included in each stage, and how to determine the start and end time of each gesture are urgent problems to be solved in the future [14].

In competitive aerobics, the flexibility of the joints of the whole body has its specific role in each movement, and anyone movement that is not in place will slow down the process of the full set of movements, making it difficult for athletes to play the technical level. Good flexibility quality can increase the amplitude of the action, make the action more stretching, posture shape more beautiful, and more artistic expression is the basic guarantee of high quality to complete the action. At the same time, good flexibility quality can also effectively prevent sports injuries and extend the life of the sport. Therefore, in the training of competitive aerobics flexibility quality has been an important training content.

3. Analysis of Deep Learning Recognition and Evaluation of Aerobic Movements

3.1. Deep Learning Action Recognition Algorithm. Based on the construction of human action recognition features, the design uses classifiers to recognize and classify human actions based on the features [15]. In recent years, due to the development of deep learning technology, it has many advantages in the field of human action recognition that traditional methods do not have, so it has been widely used, and currently, the field of human action recognition mainly uses two kinds of convolutional neural networks and recurrent neural networks. LSTM neural network solves the gradient disappearance problem of recurrent neural networks and can remember more long-term states. Using a classifier for human action recognition classification is essential to classify the serialized data that have been constructed. In human action recognition, each frame in a sequence corresponds to a moment [16]. To complete the recognition of an action depends not only on the data in the present moment, but also has a strong relationship with the data before this moment, and the whole sequence needs to be analyzed to make a judgment. The emergence of recurrent neural networks solves the serialization problem that traditional neural networks cannot handle. In recurrent neural networks, the output depends not only on the current input but also on the output of the previous layer, and the combination of both determines the final output. The frame interval between the two energy values must be greater than 30 frames, so that the acquisition is completed in sequence. In the end, the frames corresponding to the obtained energy values are arranged from small to large, which is the center of the ten actions obtained by the energy method. There is signaling between the nodes of the hidden layer in a recurrent neural network, and the output of the hidden layer is transformed into a part of the next input; i.e., the output contains the current input and the last output. Having such a special structure allows the recurrent neural network to have the ability to handle sequential data well. Figure 1 shows a diagram of the recurrent neural network structure.

The input gates and the output gates are the control gates: the input gates determine the amount of information to be transferred to the memory cell and the output gates determine how much information from the memory cell will be transferred to the current output. The forgetting gate controls the memory unit and is used to decide between remembering and forgetting the memory unit, and the decision is how much data from the previous moment in the memory unit will be transmitted to the present [17]. Compared with the traditional recurrent neural network, LSTM by introducing a gating structure in it, this structure can well solve the gradient disappearance problem of recurrent neural networks during the training process. At the same time, LSTM can store information for a very long time through the memory unit, which is one of the biggest advantages that distinguish it from other networks. However, too long information will make the LSTM suffer from gradient loss, so it can only play its maximum performance in the appropriate range.

The network input is a fusion feature made by combining four features, and after the previous feature extraction and processing, each human action feature becomes 43-dimensional data, and the length of the data varies depending on the number of frames of each action. Before inputting into the network, each group of data used for training or testing is uniformly processed to equal length for ease of processing, and the remaining sequences are zeroed according to the sequence with the longest sequence in each group. In each period, the data input to the network is a 43-dimensional vector. Next, the intermediate values are fed to the output layer through the computation of the LSTM layer, and the output layer used is the softmax function, which judges the activities and outputs the probability of belonging to each action label, and the corresponding probability with the highest value is the final output class of the network.

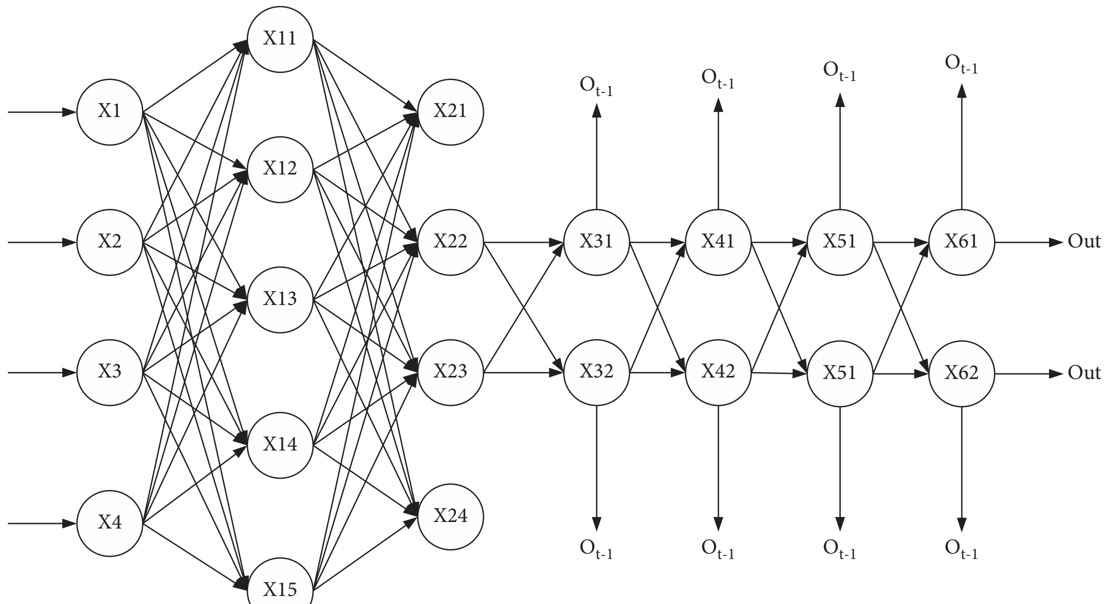

Figure 1: Structure of the recurrent neural network.

$$f_t = \sigma\left(W_f \cdot [h_t, x_t] - b_f\right),$$
$$a_{tn} = \frac{\exp(\mathrm{ent})}{\sum_{t=1}^{T} \exp\left(e_n^t\right)}. \tag{1}$$

In the process of network training, the parameter setting in the model is an important factor that affects the recognition effect of the model. In this chapter, to facilitate the accurate determination of parameters in the network, the grayscale-processed video frames are input into the network for training. Since the grayscale data and the original data are identical in terms of video length, dataset size, and action type except for the single image pixel data, the grayscale images were chosen to initially determine the training parameters for the network structure. Therefore, in this subsection, the number of samples and iterations of the batch data for the network training process will be determined through grayscale graph experiments. The dataset has a significant impact on the effectiveness of the convolutional neural network. Since the duration of human action is not only related to the action, but also related to the active performer, an action lasts from a few frames to tens of video frames, and even for the same action, the number of video frames that the action lasts is inconsistent due to the different action executors. Then, this will also have a great impact on the recognition effect. In the process of recognition, the processing of a different number of frames will also occupy the different sizes of computing resources. To reduce the use of computational resources, before training the network again, the key region of human motion is first detected using the target detection method, and this region is cut out and added to the network as new data for training. Think of it as another action category in addition to all individual action categories. All these individual action categories and transition action categories are used to train the neural network.

$$c_t = f_t c_{t-1} + i_t \tanh\left(W_f \cdot [h_t, x_t] + b_f\right),$$
$$o_t = \sigma\left(W_o \cdot [h_{t+1}, x_{t-1}] - b_f^2\right). \tag{2}$$

In human behavioral movements, not all body movements are equally important, and there are often some that are not so important for the recognition of movements. For example, in the human hand waving action, the main change is concentrated in the upper arm part, and the main change part of the kicking action is in the lower limb part; only the action of this one part is needed to discriminate it, and the action of other parts of the body does not have much influence on the determination of the category. Introducing attention to the human action model, so that it looks for key limb and joint points and gives more attention to them, can be more effective for human action recognition. The main principle of the attention mechanism can be understood as that when humans observe a thing, they do not give equivalent attention to the whole thing, but tend to focus most of their attention on a certain part of the observed thing, which helps humans to use their limited attention to quickly obtain valuable information from a huge number of resources [18]. Because of the presence of attention, it makes human processing of image information very efficient and easy. The attention mechanism is to assign different weights to different parts of things so that they play different importance in the final decision, which is generated through the learning process in the network and is constantly updated. In this study, the attention mechanism is combined with Bi-LSTM neural network for human action recognition, compared with the previous LSTM neural network to make a comparison; adding the attention mechanism to the neural network can calculate the weights of the feature vector output in the network at different time points, find out the important features in the whole human action sequence, and finally improve the accuracy of the whole human recognition network.

$$\begin{aligned} \text{Score}_i &= f\left(Q_t^2, h_i^2\right), \\ \alpha_i &= \text{soft min}\left(\text{Score}_i\right). \end{aligned} \tag{3}$$

First, some neurons in the hidden layer of the neural network are randomly removed, but the neurons in the input layer, as well as the output layer, remain unchanged. Next, the data of human action features are input on top of this network and the data are propagated forward through the neural network, and eventually, the loss values of the network are back propagated after a part of all the training samples are performed in this process and this part of the samples are updated with the parameters on the retained neurons. Finally, this process is kept repeated to recover the previously removed neurons and again some neurons are randomly selected from the hidden layer for deletion, but to record the parameters of the deleted neurons in the training of some of the samples, as shown in Figure 2. According to the athlete's current level, the coach can predict the athlete's possible performance peak according to the prediction model. The coach can calculate the athlete's current physical fitness and the corresponding sports performance and perform the exercise on the athlete according to the athlete's physical function potential and the coach's experience.

Strong attention differs from soft attention in that strong attention considers that every point in an image may be extended to attention, while strong attention is a powerful stochastic prediction process where the system samples randomly from implicit states rather than decoding using all implicit states, with more emphasis on dynamic changes. The bottom line is that strong attention is non-microscopic attention, and the training process is often done through augmented learning. Since the gradients in the network are computed directly and not estimated by a stochastic process, we choose the soft attention mechanism. A temporal attention model is added to the extracted feature model, using a layer of LSTM network with updated weight values.

3.2. Aerobic Movement Evaluation Design. In the process of testing using the metronome after the experiment, the experimental group was able to judge the correct beat of the music faster than before the experiment, and the students' ability to hear and recognize the rhythm of the music was strengthened, and there was a great improvement in their ability to grasp the rhythm of the music, while the control group used the traditional aerobic teaching method, and the teachers paid more attention to the training of the specification of each technical movement of aerobics and the completeness of the set movements [19]. The music is an indispensable part of aerobics, and in the teaching methods and means for the strengthening of rhythm practice, some teachers still do not pay enough attention to the teaching of the early stage of simply teaching the action, so that students are only in the over and over again skilled, and in the late direct use of music practice, the teacher did not teach the process to effectively establish the relationship between

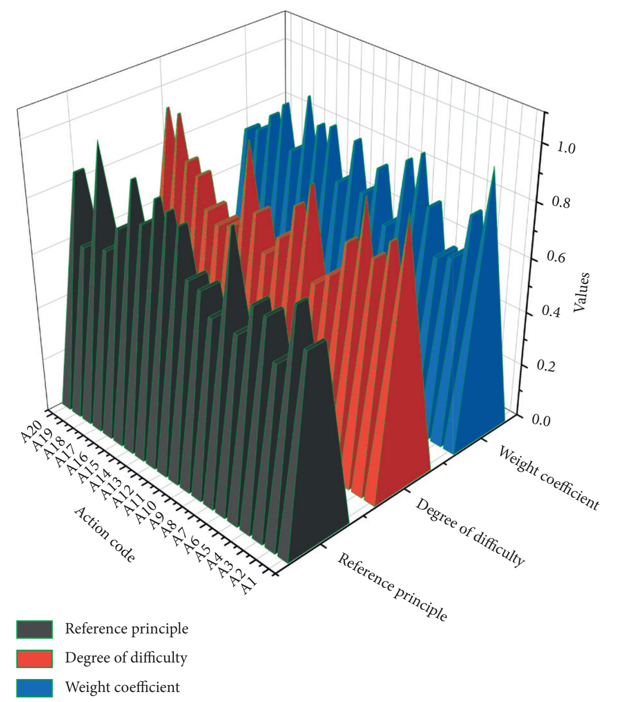

FIGURE 2: Movement indicators for assessing the technical level of specific movements of bodybuilders.

music and sets of movements, so that students lack understanding of music and cannot establish the music. Therefore, the traditional teaching method is not obvious for students to improve their ability to hear and identify music beats, so the experimental group students' music beat reaction time test scores are better than the control group, which has a significant teaching effect.

Physical fitness is the basic athletic ability expressed through the qualities of strength, speed, endurance, coordination, flexibility, agility, etc. It is the core element of competitive ability, and the external form and internal function have an impact on physical fitness. Each project has different requirements for physical fitness. Good physical fitness is the prerequisite for systematic and scientific improvement of performance; it is the necessary guarantee to continuously increase the load and maintain the training efficiency; it is the necessary foundation to improve the competitive state and ensure the level of participation; it is the key to effectively avoid trauma and prolong the training life. The core task of physical training is to improve physical quality and improve external form and strengthen internal functions according to the competitive needs of the project. From the viewpoint of competition time, the set time of aerobics is 80 (±5) seconds, in which athletes need to carry out high-intensity exercise without interval and make endurance adjustments through the action of main content; from the viewpoint of energy supply mode, glycolysis system is the main source of energy of aerobics; and from the viewpoint of action technology, aerobic technology is diverse, and the mastery and play of technology is the key element that dominates the result of participation. In summary, aerobics is a skill-driven sport with short duration, high load intensity, and no intervals, as shown in Table 1.

The external shape consists of length, circumference, density, etc., while internal components are mainly muscle, fat, and body fluid components. The morphological characteristics of athletes vary and differ at different ages. The development of body shape is to some extent the result of quantitative changes in training, which is conducive to the improvement of function and quality, and its changes have an impact on the training effect. For the aerobic program, which is dominated by the judges' subjective judgments, good morphological indicators can enhance artistic expression. To better summarize the morphological characteristics of aerobic athletes, measurements were taken on the athletes participating in the study.

The average height of the participating athletes was 176 cm, with no athletes too tall and no athletes too short. Complexity, variety, and innovation are among the requirements for judging all movement content in the rules of aerobics. Athletes not only need to have the ability to complete complex and varied movements with high quality but also need to have the ability to achieve seamless integration of movement content and music beat, which requires high coordination and agility as well as spatial transformation and perception ability. Good physical fitness can not only lead to the improvement of skills, but also a necessary condition to complete the competition goals and improve the competition performance; excellent strength quality is the guarantee for the realization of the stable improvement of difficult skills. Athletes who are too tall have certain disadvantages in agility and coordination, and they have difficulty in completing large and varied movements, which is not conducive to training and competition; while athletes who are too short have the innate advantage of better agility and coordination, those who are short have a certain disadvantage in artistic aesthetics due to their small range and poor expressiveness in the expression of movement content. Therefore, considering the needs of competition and movement expression, athletes of moderate height are more conducive to aerobic training and competition (Figure 3).

There are many special fitness indicators and complex structures, and different indicators have different effects on the level of special fitness of high-level aerobic athletes in China, and the complexity and operation methods vary in the actual test. Which indicators can reflect the current situation of athletes' special fitness in a comprehensive and representative manner, which indicators are more convenient to obtain data, and which indicators are more conducive to the development of special fitness of aerobic athletes are all indicators of the key elements that need to be considered comprehensively in the selection of indicators. Therefore, before constructing the index system, the principles that need to be followed for index selection should be determined first to guide the selection of the indexes. Firstly, we should consider the representativeness of the indicators, and the indicators with high representativeness can reflect the competition demand more intuitively. This will inevitably be affected by the scale of the competition and the level of the participating players. It is very meaningful to establish a set of evaluation systems for athletes' special sports competence in these sports.

The availability of indicator data is a prerequisite for the scientific conduct of the evaluation.

It is required that the selected or designed indicators can obtain the corresponding data in practical application, avoiding the indicators for which data are not available or accurate data cannot be obtained and ensuring the quantitative measurement of indicators for the quantitative research of special physical performance evaluation and training. In human continuous action with the idea of energy changes during human movement, a human continuous action segmentation model consisting of kinetic energy between joint frames and the potential energy difference between joint frames is established [20]. After visualizing the recognition effect, the recognition results of the single-channel network and the two-speed channel network have the same trend, the difference is that the action recognition changes more smoothly when recognizing the video action after using the two-speed channel, and the overall recognition probability is slightly smaller than the recognition result of the single-channel network, as shown in Figure 4.

To make the evaluation process more objective and accurate, it is necessary to develop a unified evaluation standard that can provide a more intuitive and clear understanding of the differences in the special physical abilities of high-level aerobic athletes. To ensure the objectivity of the evaluation criteria, 16 high-level aerobic athletes were selected to test the index system, and all the athletes selected had the title of the athlete with the rank of general and had won the top 3 places in the authoritative Chinese aerobic events in recent years to ensure the representativeness of the test sample. The data of the athletes were obtained for each index for the follow-up study. This is obviously not enough for our coaches. Modern training programs should be developed in the direction of quantification and accuracy, which urgently needs to establish an evaluation model of the relationship between physical fitness indicators and sports performance.

4. Analysis of Results

4.1. Deep Learning Action Recognition Results. According to the energy model established earlier for the segmentation of continuous action recognition, the energy difference before and after all frames in human continuous action is calculated. Figure 5 is a schematic diagram of the energy of a continuous action obtained after the calculation, the energy between the different two frames has a large difference, and the energy method is based on this for the segmentation of continuous actions. Based on the overall idea that the energy value between two frames when the action occurs is higher than that when the transition action occurs, the segmentation of the continuous action is performed according to the energy value. All the frames of this continuous action are sorted according to the energy value, and the ten frames with the largest energy values are taken to correspond to the ten actions in the continuous action. To avoid that, some individual actions have higher energy values in general, which

Table 1: Body morphometry.

Height	Weight	Leg length	Shoulder width	Chest circumference	Waistline	Hip circumference
Average value	70.3	75.6	41.7	72.5	53.4	44.5
Standard deviation	55.8	82.6	62.7	92	58.2	90.7
Minimum	91.5	60	76.8	58	50.6	50.4
Maximum value	41	42.6	88.9	71.6	94	76.5

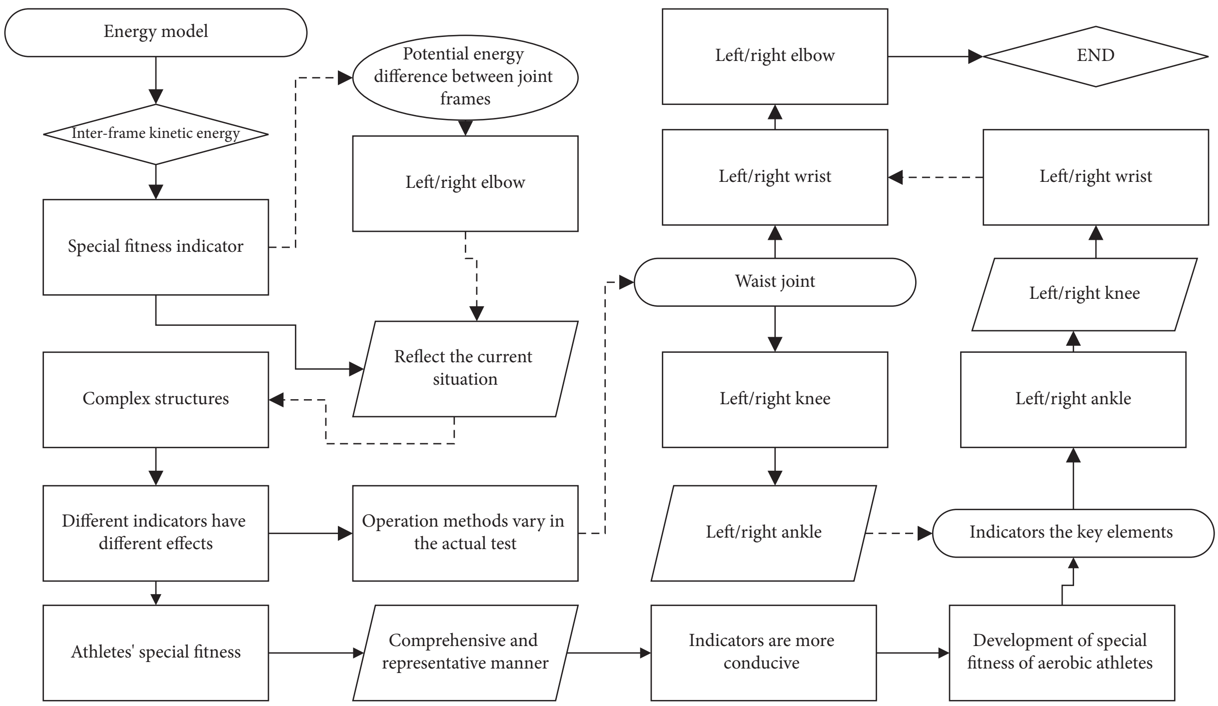

Figure 3: Energy model node composition.

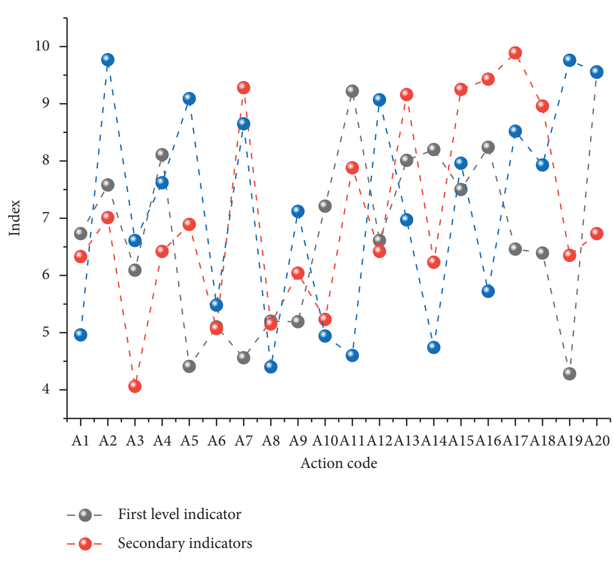

Figure 4: Evaluation indicator system and weighting factors.

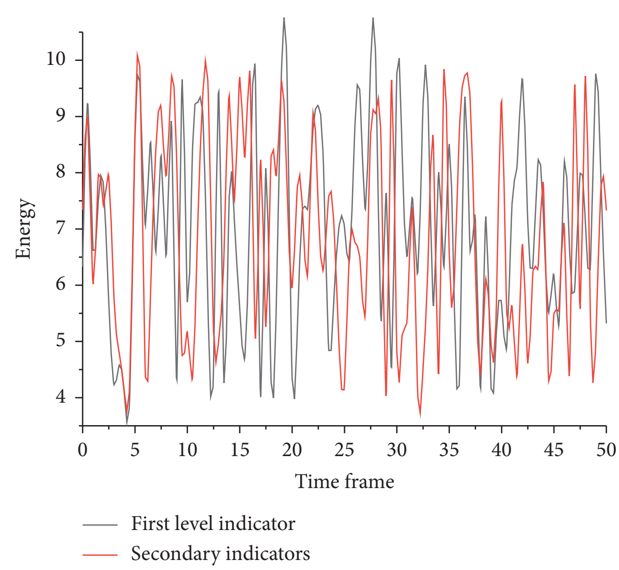

Figure 5: Schematic of continuous action energy.

affects the acquisition, and the interval between two energy value frames must be greater than 30 frames, so that the acquisition is completed in turn. Eventually, the frames corresponding to the obtained energy values are arranged from smallest to largest, which is the center of the ten actions completed by the segmentation obtained by the energy method. The arrows point to the locations of the centers of the actions segmented using the energy method, and the lower line segment is the correct segmentation interval for successive actions. Some of them were effectively segmented, but some of them could not be effectively identified. This is mainly because jitter occurs from time to time during the acquisition of a human continuous action data point, which can cause a dramatic change in the energy value between a certain two frames, causing some degree of interference to the energy method segmentation.

For a human continuous action sequence, the sliding window combined with a neural network classifier has the theme idea of identifying the segmentation while sliding. The neural network classifier is needed in the segmentation process of the human continuous action, and for the training set of the neural network classifier in addition to using the manually segmented individual action sequences in continuous action, there should be transitional action sequences between individual actions and the first and last interspersed action sequences as another action category in addition to all individual action categories. A complex dynamic quality system is formed in the human body, so their influence on the final level is often not linear, and the model established by the multiple regression method is a linear equation. These all individual action categories, as well as the transition action categories, are used to train the neural network. Finally, the segmentation of sequential action sequences of the human body is completed using the trained neural network. In conjunction with a sliding window, the action data are collected at a fixed window size in certain steps, and the neural network classifier completes the recognition segmentation of the actions in the window at that moment and then continues to the next moment window, and when the results of the action categories recognized in the first two moments do not agree, it is determined that the boundary of that action category is reached. When the recognition segmentation of the whole human continuous action is completed, the segmentation result of the continuous action is finally determined after using the screening mechanism to filter and evaluate the segmented actions in the whole human continuous action, as shown in Figure 6.

In the segmentation model of human continuous action recognition based on sliding window combined with the neural network classifier of this study, four of the continuous action sliding window recognition results obtained are shown in Figure 6 below, and a total of ten action classes and one transition action class are recognized. In the recognition experiments of ten actions based on sliding window combined with the neural network classifier of this study for all continuous actions, different step lengths may have an impact on the segmentation recognition of continuous actions, combined with the continuous action database used in this study, the minimum action sequence frame number is below 10 frames, and using a larger step length will cut or jump a certain complete action. Somatosensory technology allows people to get rid of the control of keyboard and mouse and other hardware facilities, and interact with computers more directly and freely, allowing people to integrate into the human-computer interaction environment more realistically. The overall effect of the sliding window on the recognition rate is that the recognition rate decreases as the

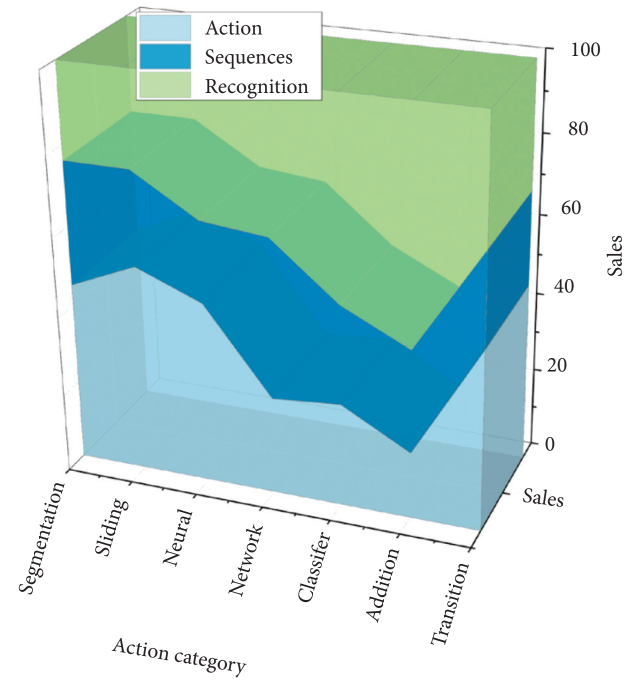

Figure 6: Continuous motion sliding recognition results.

window increases, mainly because the length of each action sequence in a continuous action is mostly concentrated around 30 frames, and using a larger window tends to include transitions outside the boundary, resulting in a lower recognition rate. The maximum recognition rate is obtained at 15 frames mainly because when recognizing an action, the important features tend to be concentrated in a few frames, and the action can be recognized and classified by a few frames.

In this database segmentation problem, two continuous action segmentation methods are given, the energy-based segmentation method and the sliding window-based method combined with the neural network classifier in this study. In the energy-based continuous action segmentation method, an energy model consisting of the kinetic energy between joint frames and the potential energy difference between joint frames is established, and the energy at the time of action is higher than the energy at the time of transition action as the general idea for the segmentation of continuous actions, and the obtained action centers are given time windows of different sizes for experimental simulation. Then, the sliding window combined with the neural network classification built in this study is used to identify the segmentation of human continuous actions, and the initial boundary points obtained are evaluated using a screening mechanism to select the final action boundary in the experimental simulation.

4.2. Results of the Evaluation of Aerobic Movements. The completion of difficult movements and the level of physical training is not a simple superposition of sports qualities, but the result of the comprehensive role of the qualities. Each quality not only has its own functional properties but there is also a complicated interaction between them that not only makes them up but also influences and restricts them. In the human body, a complicated dynamic quality system is formed that affects the overall functional effect. The final score of the difficult action technique is closely related to the structure of physical qualities. The question of what level of each quality should be reached to achieve the ideal score for difficult movements is related to whether the athletes' physical quality potential can be fully utilized and brought into play. Therefore, it has been widely used. Currently, convolutional neural networks and recurrent neural networks are mainly used in the field of human action recognition. Therefore, the development of evaluation criteria for the final score of difficult movement techniques and the level of physical quality development plays a crucial role in the development of training plans to improve the final score of difficult movements. The difference in the difficulty score itself gives a different value to the difficult movements. The higher the difficulty score, the higher the technical and physical requirements of the athlete to complete the movement. If the difficulty factor is too low, it will not be possible to open the gap between the technical levels of the movements of individual athletes. Therefore, we should try to choose the movements with a higher difficulty coefficient as the evaluation index, as shown in Figure 7.

Usually, the development of a professional-level aerobic athlete is long-term and requires the selection of potential recruits starting at a young age. In early selection, we can test the six basic quality indicators of the prospect, which can predict the potential that the prospect has in the sport of aerobics through the prediction model, and combined with the coaches' own accumulated experience in selection, we can make the early selection more justifiable. LSTM can store information for a long time through the memory unit, which is the biggest advantage that distinguishes it from other networks. However, too long information will cause the LSTM to lose the gradient, so it can exert its maximum performance only in an appropriate range. Based on the existing level of the athlete, the peak performance that the athlete may reach can be predicted by the coach based on the prediction model to calculate the existing physical quality of the athlete and the corresponding athletic performance and make a judgment on the athlete based on the potential of the athlete's physical function and the coach's experience to accurately predict what height the athletic performance of the athlete can reach after a certain period of training. The coaches can measure the changes in the athletes' physical quality indicators and sports performance regularly, compare the measured values with the expected values calculated by theory, and check the sports training effects in stages to make timely adjustments to the training plan so that the whole training process is under control. Coaches should determine the content of training according to the two situations of athletes: for athletes with unbalanced physical quality development, to effectively improve the overall level of physical quality, strengthening the weak links in their physical quality should become the focus of training. For athletes with a balanced level of physical quality development, the content of sports training should be arranged according to the principle of priority development of physical quality.

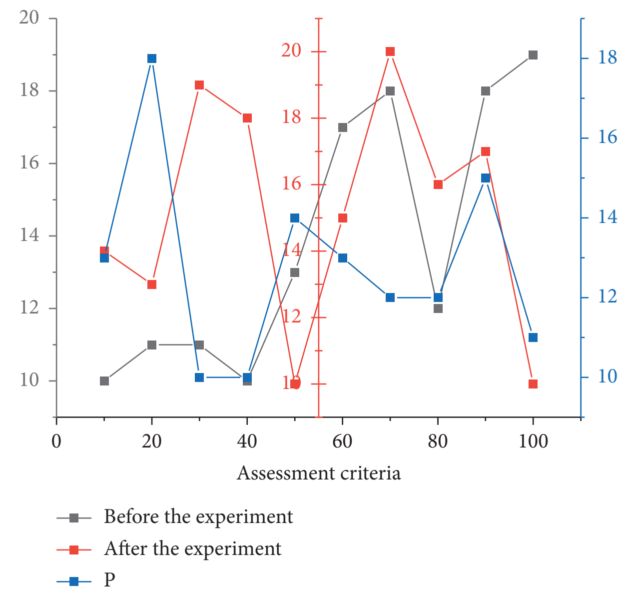

Figure 7: Intragroup comparison of the 8 items of aerobic set performance of the experimental group before and after the experiment.

5. Conclusion

Based on the improved C3D model, a deep convolutional neural network extracts per-frame-based features in the input video. After feature extraction, these features are fed into a temporal attention subnetwork. The temporal attention subnetwork assigns the relevance weight of the features in the recurrent neural network based on the relevance of each feature to the action topic in a positive correlation. This weight is constantly updated during the training iterations of the network during the activity recognition process. The product of superimposed weights and features is used in the temporal attention model to derive the action state information at the current moment, and finally, the decision classification is added to obtain detection results based on the motion state information. This helps humans use limited attention to quickly obtain valuable information from massive resources. Because of the existence of attention, the processing of image information by human beings is very efficient and convenient. In this study, 12 difficult action indicators were selected from 307 movements to reflect the movement skill level of aerobic athletes, and the evaluation table of special movement skill level was developed using the weighting method, and the reliability test results showed that the established evaluation table can accurately reflect the movement skill level of aerobic athletes. The prediction model was established using the method of the neural network, and the reliability and error of this model were analyzed. The error test showed that the evaluation model of body form and quality of aerobic athletes established by the neural network can predict aerobic sports performance and assess the development level of physical quality more accurately.

With the rapid development of computer big data technology, online education in the form of online courses is increasingly becoming an important means of education. In order to objectively evaluate the teaching quality of online classroom, a teaching quality evaluation system based on facial feature recognition is proposed. The improved (MTCNN) multitask convolutional neural network is used to determine the face region, and then the eye and mouth regions are located according to the facial proportion relationship of the face. The light AlexNet classification based on Ghost module was used to detect the open and close state of eyes and mouth and combined with PERCLOS (percentage of eye closure) index values to achieve fatigue detection. Large range pose estimation from pitch, yaw, and roll angles can be achieved by easily locating facial feature angles. Finally, the fuzzy comprehensive evaluation method is used to evaluate students' learning concentration. The simulation experiments are conducted, and the results show that the proposed system can objectively evaluate the teaching quality of online courses according to students' facial feature recognition.

1. Introduction

Online education, as a brand new education model, has been gradually welcomed by students and parents due to its characteristics of openness and diversity [1]. Online education market has also ushered in a vigorous development, while there are still numerous shortcomings in the actual use process. The biggest deficiency lies in the poor supervision effect of teachers on students in the classroom [2]. In the traditional teaching process, teachers and students are in a limited space. The position of the podium is very good for quick observation of the whole classroom. In the course of class, teachers can control the whole room and effectively supervise students with just a glance. But in online education, the limits of space are broken down. Most of the teacher's attention is paid to the lecture; thus, the rest of the attention cannot effectively control the state of all students, let alone play a supervisory role. For students, online education offers many choices and flexible hours, while the degree of self-discipline is very high. The analysis results of the statistical data of some online education platforms show that there is an obvious phenomenon of learners' poor autonomy in online classroom. This results in a high enrolment rate but a low course pass rate for all kinds of courses [3, 4]. During the COVID-19 pandemic in 2020, some parents reported that the learning effect of their children's online classes at home was very low. This not only causes many students to waste valuable learning time, but also undermines teachers' control over teaching progress and quality.

The COVID-19 pandemic is the first large-scale use of online education to replace traditional education in a short period of time, though it cannot completely replace traditional education at present [5]. However, with the emergence and application of 5G technology, online education has gradually become an important development trend that complements traditional education. Therefore, considering that online education teachers cannot effectively supervise students, the exploration of online classroom teaching quality evaluation system has become an important task of online education development.

Online education has the characteristics of loose structure and open distance teaching environment, in which online learning effect evaluation is an important part. It is very difficult to objectively evaluate the teaching quality of the course via these characteristics [6]. Literature [7] discusses how to improve the learning effect and efficiency of learners through positive emotion and positive emotion in online education. Literature [8] analyses how teachers channel and dissolve students' negative emotions through positive emotions, so as to improve students' learning enthusiasm. Literature [9] builds an emotional interaction model of social learning network, which can identify learners' emotional states in online education. Emotional states include six categories: pleasure, pain, tension, calm, surprise, and disgust. Literature [10] designs a teaching feedback strategy construction method based on emotion learning ontology. In the current research environment, quantitative analysis of student behaviour is an important link of online education. Based on the hybrid teaching mode combining online and offline, paper [11] established online evaluation and offline evaluation systems. The evaluation system focuses on the learning process and teachers can take intervention measures according to the early warning situation.

This paper presents an online classroom teaching quality evaluation system based on facial feature recognition. The innovations and contributions of this paper are listed below.

(1) Face regions are determined by an improved multitask convolutional neural network, and then eye and mouth regions are located according to the facial proportion relationship of the face. The light AlexNet classification based on Ghost module was used to detect the open and close state of eyes and mouth and combined with PERCLOS index values to achieve fatigue detection.

(2) Complete the face pose estimation from pitch, yaw, and roll angles in a wide range through easily located facial feature angles.

(3) Finally, the fuzzy comprehensive evaluation method is used to quantitatively evaluate students' learning concentration.

The simulation results show that the system can effectively evaluate students' concentration in class according to the results of face detection, so as to evaluate the teaching quality of online education.

The chapter structure of this paper is as follows. Section 2 focuses on the proposed algorithm model in this paper. Section 3 is experiment and analysis. Section 4 is the conclusion.

2. The Proposed Model in This Paper

2.1. Fatigue Detection Model. Fatigue detection based on human facial features usually needs to determine the location of the face and eye-mouth and detect the opening and closing state of the eye-mouth. In order to achieve the above functions, this paper uses the improved MTCNN (Multitask Cascaded Convolutional Networks) to complete face detection and key point positioning. Then, the improved AlexNet was used to identify the open and closed state of the eyes and mouth. Finally, the fatigue discrimination was performed according to PERCLOS and PMOT parameters. The fatigue detection process is shown in Figure 1.

2.1.1. Key Point Positioning Based on Improved MTCNN. MTCNN is a face detection and alignment algorithm based on deep learning, which uses image pyramid to detect faces at various scales [12]. Different from multitarget face detection, fatigue detection only needs to precisely locate the human face region. Therefore, the image pyramid part of MTCNN network is improved to achieve face detection and key point location quickly and accurately. Then, after locating the key points, the eye and mouth regions are obtained by using the proportion relation of three courtyards and five eyes of human face. Three courtyards here refer to the length of the face proportion, and the length of the face is divided into three equal points. Five eyes here refer to the proportion of the width of the face, and the width of the face is divided into five equal parts with the length of the eye as the unit.

MTCNN is made up of Proposal Network (P-Net), Refine Network (R-Net), and Output Network (O-Net). The idea of candidate frame plus classifier is used to detect face quickly and efficiently. In order to detect faces of different scales, MTCNN reduces the original image to different sizes to generate image pyramids. The original image is compressed to a certain scale, and the image is traversed with a candidate box of fixed size 12 pixels by 12 pixels. Loop until the reduced image is smaller or wider than the side length of the candidate box. At this point, a picture with a size of 12 pixels $\times$ 12 pixels and channel number of 3 is obtained as the input of P-Net. P-Net uses a convolution kernel with a size of 3×3 to extract image features through convolution operation. Maximum pooling operation was used to remove redundancy. Face classification is used to determine whether the region is a face. Face regions were initially located using bounding box regression and a facial landmark localization. These fields are inserted into R-Net, which will repeat the operations of P-Net. Most of the interference is filtered out; then the reliable face area is retained and input into O-Net. P-Net takes advantage of the feature that the full-convolution output size is 1 pixel $\times$ 1 pixel and the number of channels is 32. R-Net uses a 128-dimensional full connection layer after the last convolutional layer, which preserves more image features. O-Net performs more refined face discrimination, border regression, and key point positioning and finally outputs the coordinates of the face region and 5 feature points. The five characteristic points are left eye midpoint, right eye midpoint, nose tip, left corner of mouth, and right corner of mouth.

The image pyramid constructed by MTCNN contains a large number of images. Sending it into the network to detect all the face areas in the image would take a lot of time. In the

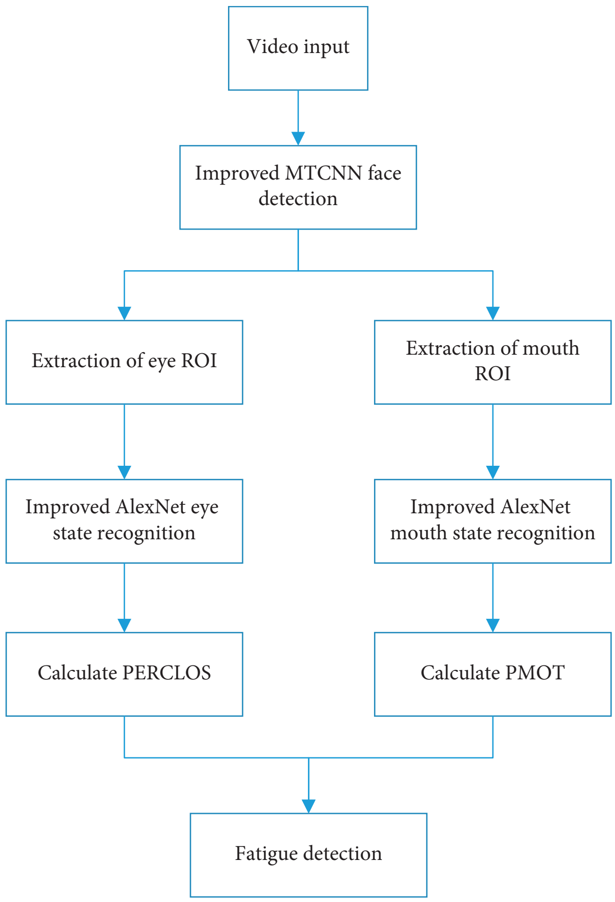

Figure 1: Fatigue detection process.

fatigue detection scene, it is necessary to eliminate the interference of redundant faces and accurately locate human faces. Considering that the human face region occupies a large proportion of pixels in the video frame, this paper amplifies the minimum face size in MTCNN network according to the proportion of human face in the image. The fixed reduction scale is reduced and the first reduction and traversal are skipped. This allows the improved MTCNN network to accurately locate human facial areas. At the same time, it can filter out irrelevant faces in the background and greatly reduce the face detection time.

It is assumed that the coordinate of the left eye obtained by MTCNN is $t_1(\alpha_1, \beta_1)$ and the coordinate of the right eye is $t_2(\alpha_2, \beta_2)$. With extraction of human eye region according to face proportion relationship, its corresponding relationship is shown as

$$\begin{cases} f_1 = \sqrt{(\alpha_1 - \alpha_2)^2 + (\beta_1 - \beta_2)^2}, \\ \omega_1 = 0.5 f_1, \\ \varphi_1 = 0.5 f_1, \end{cases} \quad (1)$$

where f_1 is the distance between the eyes. ω_1 is the width of the eye area. φ_1 is the height of the eye area.

It is assumed that the coordinates of left and right corners of human mouth obtained by MTCNN are $m_1(\alpha_1, \beta_1)$ and $m_2(\alpha_2, \beta_2)$, respectively. The mouth region of human is extracted according to the proportion relation of face, and its corresponding relation is

$$\begin{cases} f_2 = \sqrt{(\alpha_1 - \alpha_2)^2 + (\beta_1 - \beta_2)^2}, \\ \omega_2 = f_2, \\ \varphi_2 = f_2, \end{cases} \quad (2)$$

where f_2 is the distance between the left and right corners of the mouth. ω_2 is the width of the region of interest of the mouth. φ_2 is the height of the mouth area.

Key points were located for the examples in NTHU-DDD dataset [13], and the regions of interest of eyes and mouth were obtained according to the proportion of three courts and five eyes, as shown in Figure 2.

2.1.2. Eye and Mouth State Recognition. The method of eye and mouth state recognition based on manual feature extraction is affected by the shooting angle, shooting distance, and individual differences and has poor robustness. In this paper, the improved AlexNet is used to recognize the open and closed state of the eyes and mouth, which avoids the complex preprocessing operation of the image and has strong robustness.

Ghost module [14] is a lightweight neural network unit. In order to make the fatigue detection model obtain better real-time performance at the edge end, Ghost module is used in this paper to replace all convolution operations in AlexNet. Due to the redundancy of feature images output by deep convolutional neural network, these similar feature images make the feature extraction ability of convolutional neural network stronger. Therefore, Ghost module uses a simple linear operation to obtain more similar feature graphs to improve CNN performance. Ghost module uses a small amount of conventional convolution to get eigen features and then the obtained eigen features through depthwise convolution such a simple linear operation to generate Ghost features. Finally, the intrinsic feature graph and Ghost feature graph are spliced to get the final output. Compared with the direct use of conventional convolution, Ghost module, in the guarantee of accuracy at the same time, greatly reduces the amount of calculation.

AlexNet [15] showed excellent results in image classification based on 8-layer network structure. AlexNet is improved in this paper to classify the open and closed state of eyes and mouth. Since the image of eyes and mouth occupies fewer pixels, the input size of AlexNet is compressed from 224 pixels × 224 pixels and channel number 3 to 24 pixels × 24 pixels and channel number 3. Modify 11 × 11 and 5 × 5 convolution kernels to 3 × 3 convolution kernels. The stride of maximum pooling operation was optimized to avoid too small size of feature graph. AlexNet is only used for eye-mouth state 4 classification, and only the first full connection layer in AlexNet is retained in the model. The output dimension of the full connection layer is changed from 2 048 to 128. Finally, Softmax regression function is used to output the probability that the sample belongs to the open mouth state. The model retains the first layer of traditional convolution to extract image features

Figure 2: ROI positioning of eyes and mouth. (a) Normal state. (b) Yawning state. (c) Slow blink with nodding. (d) Sleepy state.

comprehensively. The other convolution operations are replaced by Ghost module, making the network lightweight. The improved AlexNet architecture is shown in Figure 3.

2.1.3. Fatigue Detection. When a person is in a state of fatigue, there will be a series of physiological reactions, such as long closed eyes, yawning and so on. By calculating PERCLOS and PMOT parameters of continuous video frames, the improved AlexNet model can judge the fatigue state of human with threshold value.

PERCLOS is a physical quantity proposed by Carnegie Mellon Institute to measure fatigue. The correlation analysis of 9 fatigue parameters, including PERCLOS parameters, blinking frequency, and yawning parameters, shows that the correlation between PERCLOS parameters and fatigue state is the highest [16]. PERCLOS parameter represents the percentage of eye closure time in unit time, and the calculation equation is shown as follows:

$$p_{\mathrm{PERCLOS}} = \frac{\sum_x^M h_x}{M} \times 100\%, \tag{3}$$

where M is the total number of video frames per unit time. h_x is the number of closed frames. $\sum_x^M h_x$ is the total number of frames closed per unit time. In the normal state, the value of the PERCLOS parameter is small. When people are in fatigue state, the number of closed eye frames increases, and the value of PERCLOS parameter increases.

The PMOT parameter is similar to the PERCLOS parameter and represents the percentage of open mouth time per unit time. Its calculation equation is as follows:

$$p_{\mathrm{PMOT}} = \frac{\sum_x^M h_x}{M} \times 100\%, \tag{4}$$

where M is the total number of video frames per unit time. h_x is the number of open mouth frames. $\sum_x^M h_x$ is the total number of open mouth frames per unit time. In normal process, the value of human PMOT parameter is small. When a person yawns, the number of open mouth frames increases and the value of PMOT increases.

2.2. Face Pose Estimation Algorithm. Face deflection axis is shown in Figure 4. Among them, the deflection around the X axis is called pitch, the deflection around the Y axis is called yaw, and the deflection around the Z axis is called roll.

In this paper, Adrian Bulat face feature point locator is used to complete face feature point positioning [17], as shown in Figure 5. The positioner is suitable for feature location of rotating face in plane. In addition to the visible feature points, those blocked or invisible face feature points can also be located.

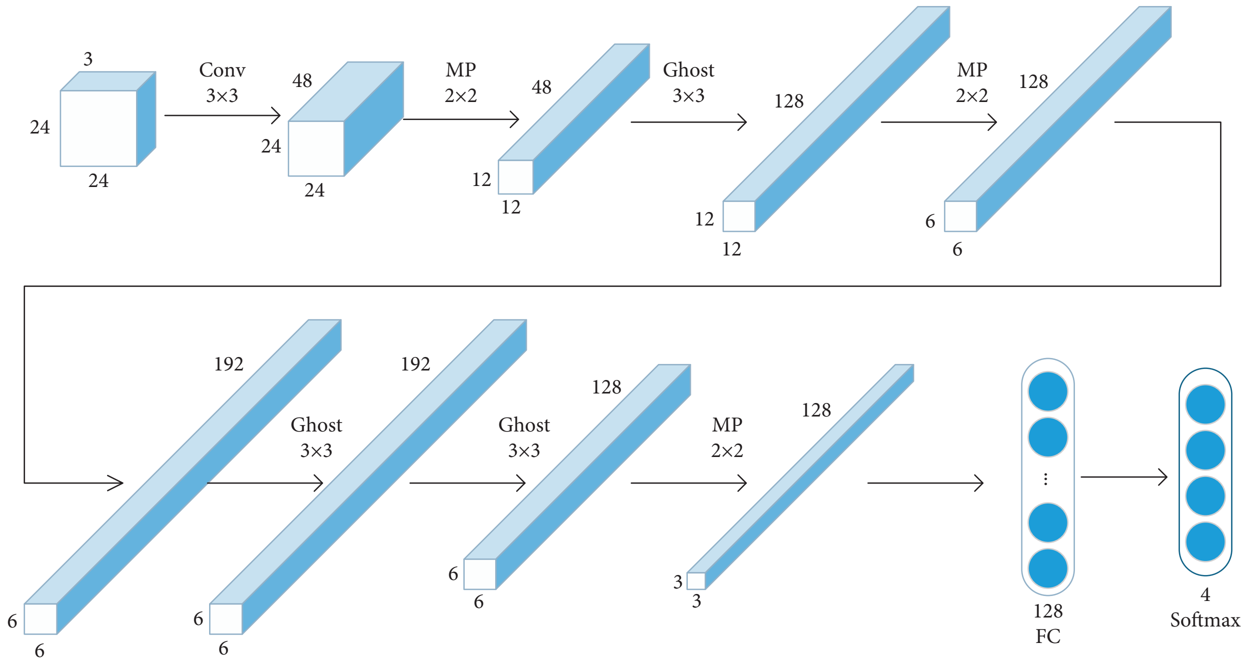

Figure 3: Improved AlexNet architecture.

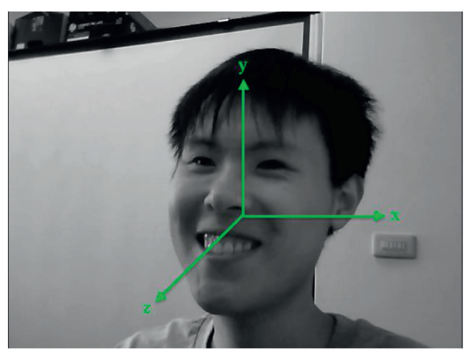

Figure 4: Face posture and its coordinate axes.

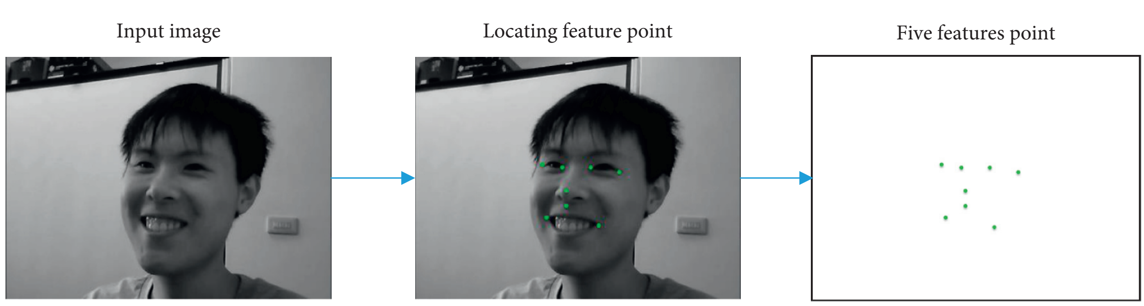

Figure 5: The process of obtaining facial feature points.

Based on facial features, the face pose estimation process adopted in this paper is shown in Figure 6. In order to reduce the estimated parameters in the loss function, the algorithm transforms the process of estimating face rotation around three axes into the process of searching the best rotation angle around X and Y axes within a certain rotation range around Z axis of sparse model. Thus, the roll angle parameter in the loss function is eliminated.

By aligning the subnasal point on the 3D model with the subnasal point on the image, the constraint model can only rotate around the subnasal point to eliminate the translation parameter in the loss function. This makes the loss function retain only the scaling factor, pitch angle, and yaw angle.

Let s be the global dimension parameter of the 3D model; w_α and w_β are the translation parameters in the X and Y directions of the 3D model after the parallel projection to the

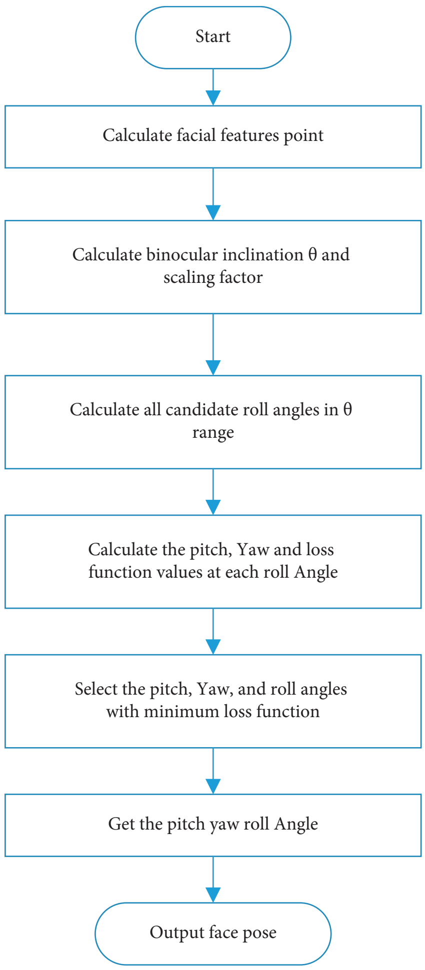

Figure 6: The process of face pose estimation.

XY plane. If face roll angle γ is known, the following method is used to estimate face depth direction deflection angles α and β. The subnasal points of 3D model v were recombined and fixed with the subnasal points of human face on the image. Then, s, α, and β were adjusted to align other feature points on the image with corresponding points on 3D model v after 2D projection (meeting the minimum sum of squares of distance). The equation for the sum of the squares of the minimum distance is as follows:

$$\min h(s,\alpha,\beta) = \min\left(\sum_{x=1}^{t} p_{3\,D} R_{3\,D} S_{3\,D} v_x^{3\,D} + W_{2\,D} - v_x^{2\,D2}\right), \quad (5)$$

$$\begin{cases} W_{2\,D} = v_u^{2\,D} - p_{3\,D} R_{3\,D} S_{3\,D} v_u^{3\,D}, \\ s > 0, \\ \alpha, \beta, s \in R, \end{cases} \quad (6)$$

where t is the number of alignment points, and $v_x^{2\,D}$ is the alignment point on the face image.

$$v_x^{2\,D} = \left(\alpha_x^{2\,d}, \beta_x^{2\,d}, 0\right)^T, \quad (7)$$

$v_x^{3\,D}$ is the corresponding alignment point on model v.

$$v_x^{3\,D} = \left(\alpha_x^{3\,d}, \beta_x^{3\,d}, \gamma_x^{3\,d}\right)^T. \quad (8)$$

$v_u^{2\,D}$ and $v_u^{3\,D}$ are the subnasal points on the face image and v, respectively. $W_{2\,D}$ is the translation vector after the projection of v. $p_{3\,D}$ is v orthographic matrix. $R_{3\,D}$ is v rotation matrix. $S_{3\,D}$ is v global scaling matrix.

Substitute equation (6) into equation (5), and construct the augmented objective function (loss function) using the interior point penalty function method; then it can be obtained as follows:

$$\min H(s,\alpha,\beta) = \min\left(\sum_{x=1}^{t}\left\| \mathrm{P}_{3\,D} R_{3\,D} S_{3\,D}\left(v_x^{3\,D} - v_u^{3\,D}\right) + \left(v_u^{2\,D} - v_x^{2\,D}\right)\right\|^2\right) + \frac{r_z}{s}. \quad (9)$$

$r_z > 0$ is the barrier factor. The modified Newton method [18] is used to calculate the deflection parameters α and β of pitch and yaw of the image face satisfying equation (9) at the specified γ angle, as well as the scaling coefficient s of 3D face model v.

In this paper, the estimations of face in-plane rotation angle and out-plane deflection angle were combined, and the final estimation of face deflection angle around each coordinate axis was obtained by searching for the best deflection angles α and β are within the range of $\theta \pm 90^\circ$ based on the angle θ of the two-eye center line.

2.3. Fuzzy Comprehensive Evaluation. In practical problems, objective decision is often a comprehensive decision of many factors. Some attributes are ambiguous, cannot be quantified, and cannot be judged simply by “good” or “bad.” Fuzzy comprehensive evaluation decision is a comprehensive evaluation method based on fuzzy mathematics [19]. The basic idea is to use fuzzy linear transformation principle and maximum membership principle. Fuzzy attributes are quantified by membership function and evaluated by traditional quantitative evaluation method. In this way, the quantitative and qualitative factors in the problem can be uniformly dealt with, and the differences between fuzzy attributes can be taken into account.

The evaluation objective of this paper is learning concentration. It cannot be quantified in the academic world and belongs to the fuzzy goal. Facial orientation and fatigue degree are also fuzzy in evaluation, so fuzzy comprehensive evaluation is adopted in this paper. The mean value of horizontal facial deflection angle, vertical facial deflection angle, times of eye closure, and times of yawn per unit time are the first level factors. Facial orientation and fatigue were the second factors. Therefore, this paper adopts fuzzy comprehensive evaluation oriented to multilayer factor evaluation, that is, multilevel fuzzy comprehensive evaluation.

2.3.1. Factor Evaluation of the First Layer. The head posture score was divided into turning head score and raising head score, and the minimum value was taken for the comprehensive score. Firstly, the mean of left (right) head turn angle θ_1 and the mean of raised (low) head angle θ_2 were calculated. According to the left and right rotation range of human cervical vertebra joint is $\pm(60^\circ \sim 80^\circ)$. 70° is taken as the maximum left (right) head rotation angle in this paper. The smaller the angle θ_1 is, the higher the score is.

$$z_1 = \begin{cases} 1 - \dfrac{|\theta_1|}{70^\circ}, & 0^\circ \leq |\theta_1| \leq 70^\circ, \\ 0, & |\theta_1| > 70^\circ. \end{cases} \tag{10}$$

The angle of raising (lowering) head of human cervical vertebra joint is $-60^\circ \sim +60^\circ$. When the angle is greater than 0°, it is judged as the head, and when the angle is less than 0°, it is judged as the head. The closer the angle θ_2 is to 0, the closer the head is to the ground, indicating that the learner is looking straight ahead. So the closer the angle θ_2 gets to zero, the higher the score is.

$$z_2 = \begin{cases} 1 - \dfrac{|\theta_2|}{60^\circ}, & 0^\circ \leq |\theta_2| \leq 60^\circ, \\ 0, & |\theta_2| > 60^\circ. \end{cases} \tag{11}$$

The comprehensive score takes the minimum value as

$$\rho_1 = \min(z_1, z_2). \tag{12}$$

In this paper, a comprehensive score of PERCLOS value [20], average length of eye closure, and yawning frequency was used to evaluate fatigue. The comprehensive evaluation of concentration included τ times measurement of eye closure, yawn, and head rotation. The total time of τ times detection is W. PERCLOS value t_1 was calculated according to the number of eye closure T1 and detection τ.

$$t_1 = \frac{w_1}{\tau}. \tag{13}$$

The average closed eye duration (t_2) was calculated from the total time (W) of τ times detection.

$$t_2 = \frac{W}{w_1}. \tag{14}$$

Yawning frequency t_3 was calculated according to the number of yawns w_2.

$$t_3 = \frac{w_2}{\tau}. \tag{15}$$

The weights of the three parameters are determined according to their importance. Take the weights of the three as 1, 0.8, and 0.5, respectively, and the comprehensive fatigue score ρ_2 can be calculated as

$$\rho_2 = t_1 + 0.8t_2 + 0.5t_3. \tag{16}$$

2.3.2. Second Factor Evaluation. The multilevel comprehensive evaluation model of fuzzy comprehensive evaluation model was used to calculate the comprehensive score of concentration. The scores for the first tier of factors have been calculated. Facial orientation score and fatigue score were grouped into evaluation factors $p = [\rho_1, \rho_2]$. Analytic hierarchy process was used to calculate the weight of each factor.

The eigenvector is $\Omega = [0.653, 0.347]^T$. The comprehensive score of concentration is the sum of the scores of the two factors and the weight product, and the equation is as follows:

$$\rho = P \cdot \Omega. \tag{17}$$

3. Experiment

3.1. System Development. The computer development system of this system is Win10. The programming language for development is Python. The development tool uses Pycharm. The programming environment is Python 3.8. The system is set to perform a test every one second. Every five times is a detection period.

3.1.1. Image Preprocessing. This system uses OpenCV's own function to open the computer camera and obtain images. If the fetch fails, it is fetched again. To judge the resolution of the successfully obtained image, if its length (width) is greater than 700, the image is reduced to 1/3 of the original image. Grayscale processing of image can reduce the complexity of subsequent calculation. The face feature points of the image are detected using the preloaded DLIB library. If the detection is successful, 68 feature points and ash images are returned. If the detection fails, obtain the image again and perform the above steps again.

3.1.2. Head Posture Assessment. This module firstly obtains face feature points outputted by image acquisition and preprocessing module. The feature points of canthus of both eyes, corners of the mouth, tip of the nose, and subnasal points were selected. Binocular inclination, scaling factor, and all candidate roll angles were calculated. The pitch, yaw, and loss function values at each roll angle were calculated using the modified Newton iteration method. Select the pitch, yaw, and roll angles corresponding to the minimum loss function. Finally, the evaluation value of face pose is output.

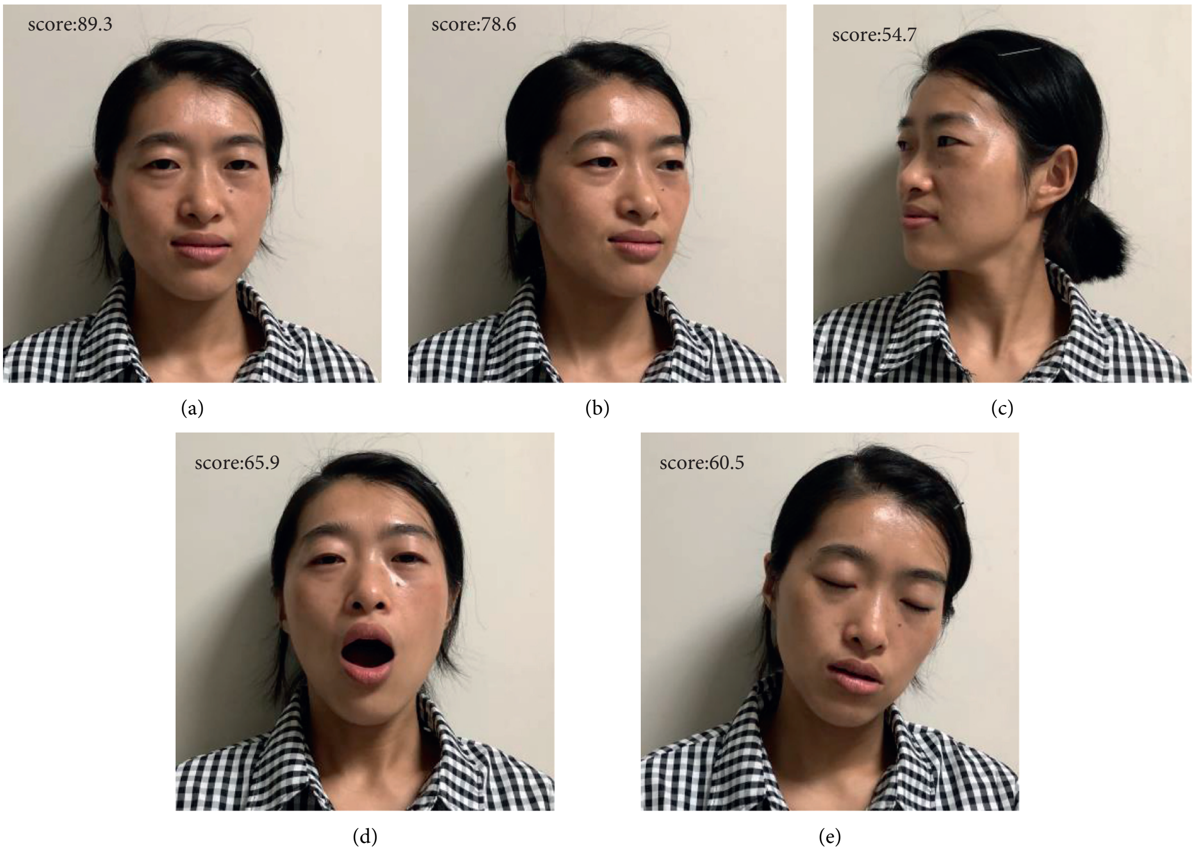

Figure 7: Five learning states of learners. (a) Normal state. (b) Mild head deflection. (c) Severe head. (d) Yawning. (e) Being asleep.

3.1.3. Eye Closure Test and Yawn Test. This module firstly obtains image acquisition and preprocessing module outputs face feature points. Select the feature points of left (right) eye and mouth. The mean value of left (right) eye closure was calculated. Check whether the closure is less than or equal to the threshold. If the condition is met, the number of eye closures is increased by 1. The mouth closure is calculated according to the characteristic points of the mouth to determine whether the closure is greater than or equal to the threshold. If the condition is met, the number of yawns is increased by 1.

3.1.4. Fuzzy Comprehensive Evaluation. The fuzzy comprehensive evaluation module firstly determines whether the detection cycle is over. If not, continue monitoring. At the end, the head posture score and fatigue score were, respectively, calculated according to the detected head raising angle, head left-right turning angle, PERCLOS value, average eye closing duration, and yawn frequency. Then the learning concentration score was calculated based on fuzzy comprehensive score.

3.2. System Experiment. In order to objectively evaluate the teaching quality of online classroom, a teaching quality evaluation system based on facial feature recognition is proposed. The effectiveness of the scheme needs to be tested in practical application. Therefore, a detection scheme is designed in this paper. The subjects were watching a 40-minute teaching video on the computer while the detection system started working. During this process, subjects randomly simulated normal state, nodding state, yawning state, mild head deflection state, and severe head deflection state. It can be seen as Figure 7.

The detection system calculates the mean value of the learning concentration score given by the system to learners in different states. The experimenters were divided into four groups with 20 people in each group. The experimental results are shown in Table 1. For the same learning state simulated by different experimenters, there was no significant difference between the scores given by the system to learners. Compared with the normal state, the scores of learning concentration in other states all decreased to different degrees. In the severe head deflection state and the sleepy state, the decrease of learning concentration score was greater. Combined with the actual situation, severe head deflection and drowsiness will have a very negative impact on learners' concentration. When the head is slightly tilted, it indicates that the learner's attention has shifted to a certain extent, but to a small degree. Therefore, at this time, the system score has decreased relative to the normal state, but the decrease is small. Yawning indicates that the learner's mental state shows fatigue, which will have a great negative impact on their learning concentration. Therefore, the score of the system at this time has a large decrease compared to the normal state.

Table 1: System scores of learner groups in different states.

Learner groups	Normal state	Mild head tilt	Severe head deviation	Yawn state	Sleepy state
1	88.2	81.6	56.2	67.2	59.9
2	87.8	81.7	53.5	66.5	52.7
3	93.1	79.3	55.6	57.9	63.3
4	89.9	79.8	53.9	61.4	63.6

It shows that the system can realize the detection of learners' learning concentration to a certain extent through the simulation experiment of the system designed in this paper. The quality of online course teaching can also be evaluated through this system. At the same time, the teacher can obtain students' online learning concentration in real time at the remote end and master the classroom status. In order to improve the quality of teaching, teachers can adjust the teaching plan to help students learn better.

4. Conclusion

As a new education model, online education is gradually welcomed by students and parents because of its openness and diversity. Aiming to objectively evaluate the teaching quality of online classroom, a teaching quality evaluation system based on facial feature recognition is proposed. Firstly, the improved MTCNN network is used to obtain key points of face. The eye and mouth regions were obtained according to the proportion of three courtyards and five eyes. The improved AlexNet based on Ghost module is used to classify the state of eyes and mouth and make fatigue judgment. Then, the face pose estimation is completed by associating Adrian Bulat face feature point locator. Finally, the effectiveness of the system is verified by simulation experiments. The experimental results show that this system has a good effect on the evaluation of learning concentration and can objectively evaluate the teaching quality of online courses. The analysis and optimization of algorithm efficiency is the content of future work.

Academic Editor: Tongguang Ni

In this paper, we proposed an improved 2D U-Net model integrated squeeze-and-excitation layer for prostate cancer segmentation. The proposed model combined a more complex 2D U-Net model and squeeze-and-excitation technique. The model consisted of an encoder stage and a decoder stage. The encoder stage aims to extract features of the input, which contains CONV blocks, SE layers, and max-pooling layers for improving the feature extraction capability of the model. The decoder aims to map the extracted features to the original image with CONV blocks, SE layers, and upsampling layers. The SE layer is implemented to learn more global and local features. Experiments on the public dataset PROMISE12 have demonstrated that the proposed model could achieve state-of-the-art segmentation performance compared with other traditional methods.

1. Introduction

Prostate cancer has become a high incidence cancer among men. Early medical detection and diagnosis of cancers could substantially improve the cure rate among patients. Currently, radiation therapy which uses medical ionizing radiation to kill cancer cells is a very common procedure to treat prostate cancers [1]. However, the worst disadvantage of the procedure is that the radiation may damage the cells of surrounding tissue when it kills prostate cancer. For the sake of raising the accuracy of radiation therapy and reducing the side effect in surrounding tissue such as bladder and rectum, more delicate prostate cancer diagnosis and more accurate prostate cancer localization methods are required.

At present, there are two main types of artificial and automatic to achieve prostate cancer segmentation on MRI (magnetic resonance imaging) [2]. The former, however, is gradually being displaced by the latter. Manual segment by radiologists is a time resuming work, and there are subjective differences among radiologists' diagnoses. For example, a radiologist may get a segmentation image differently, and different radiologists may obtain to different results on the same image.

Automatic segmentation methods can help radiologists achieve prostate cancer segmentation result faster with higher accuracy. There are two main methods usually utilized: atlas-based methods and deformable model-based methods [3]. As for the atlas-based method, training images accompanied with their corresponding manual labels are mixed together; then, through nonrigid registration (NRR), a reference image named as an Atlas and labeled Atlas is formed [3]. The Atlas is a trained image which represents the prostate and its surrounding tissue while its corresponding labeled Atlas shows the probability of a voxel being a part of the prostate [2, 3]. In model-based methods, the model can use the atlas-based segmentation for its initialization and use the grey-level information of the image to be deformed to match the boundaries of the prostate [4]. Then, a distance metric is utilized, usually the Mahalanobis distance to match the contour of the feature model with the contour extracted from the case images [3]. Both methods can be time-consuming since they require a good initialization to display better effects on prostate cancer segmentation [2].

Currently, the deep learning-based methods have made a remarkable performance in medical image segmentation. There are some research studies based on deep learning methods that have obtained accurate results in the segmentation, which prove that a well-trained deep learning model can improve the accuracy and velocity in medical image segmentation [5–7]. Karimi et al. put forward a two-step segmentation method which contains two convolutional neural networks (CNNs), where the first CNN determines a prostate bounding box and the second CNN provides accurate delineation of the prostate boundary [5]. Guo et al. designed a deformable MR prostate segmentation method by integrating deep feature learning with sparse patch matching [6]. Cheng et al. presented a supervised learning framework which merges the atlas-based active appearance model (AAM) and support vector machines (SVM) to achieve a high segmentation result of the prostate boundary [7]. However, all the methods mentioned above have a common disadvantage in which it is difficult to achieve a pixelwise level segmentation with high accuracy.

Fully convolutional networks (FCN) proposed by Long et al., where the last fully connected layer of regular CNN is replaced with a convolution layer, can obtain the classification information of every pixel; therefore, it solves the problem of pixelwise level segmentation [8]. Roneneberger et al. made a further optimisation based on FCN and presented a symmetric structure called U-Net, which is a regular CNN with an upsampling operation, where deconvolutions are utilized to increase the size of feature maps [9]. At present, FCN or U-Net becomes the most popular backbone network in the medical image segmentation field. There are many new structures derived from the FCN or U-Net model after that time. For example, Zhou et al. modified the skip connection between encoder layers and decoder layers based on U-Net and then designed a new model called U-Net++ [10] and Milletari et al. put forward a variant model named as V-Net which can realize 3D segmentation [11]. However, these methods have a common disadvantage that the similar low-level features are extracted by the model repeatedly which results in unnecessary waste of computational resources.

In order to solve the problems above, in this paper, we proposed a more effective model, which utilizes the U-Net as the backbone of our network, and a squeeze-and-excitation layer is added to every convolution operation to select the emphasize the features which are contributed to the prostate cancer segmentation.

2. Related Works

There are many research studies [5, 6, 10–12] took the deep learning method the same with as to achieve prostate cancer segmentation on MRI because it comes to more remarkable performance in the field compared to the traditional method. The idea of making an optimisation based on U-net has attracted much attention in recent years; many related research studies have made good results. For examples, the U-Net++ was proposed by Zhou et al. which modifies the skip connection between the encoder and the decoder to achieve an optimisation [10], and the 3D U-Net called V-Net was put forward by Milletari et al. based on 2D U-Net [11].

The application of the SE layer took much inspiration from the channel attention utilized in a biattention adversarial network designed by Zhang et al. [12], which proves to have a positive effect on improving model performance.

3. Background

3.1. Structure. Our proposed model refers to the U-Net model and fully convolutional network (FCN), which divide the model into the encoder stage and the decoder stage (autoencoder). The overall structure of our model can be seen in Figure 1. The encoder (also called the contraction path) is used to capture the context in the image, and the decoder (also called the symmetric expanding path) is used to enable precise localization. U-Net and FCN are actually very similar and both of them are published in 2015; however, U-Net is a little bit later than FCN. However, there are still some differences between them. Compared with FCN, U-Net is completely symmetrical whose encoder stage and decoder stage are similar while FCN's decoder stage structure is simpler which only uses one deconvolution operation and no more convolution structures such as U-Net. The second difference is about skip connection, FCN uses summation operation while U-Net uses concatenation operation.

3.2. The Activation Layer. An activation layer is always used after a convolution layer to choose if a particular neuron should be activated or not to be activated in U-Net. There are two most common activation functions used in U-Net. The first is rectified linear unit (ReLU) and the second is leaky rectified linear unit (Leaky ReLU). We are going to introduce these two functions in this section.

The ReLU formula is as follows:

$$f(x) = \begin{cases} 0, & \text{if } x \leq 0, \\ x, & \text{if } x > 0. \end{cases} \tag{1}$$

For the Leaky ReLU,

$$f(x) = \begin{cases} x, & \text{if } x < 0, \\ cx, & \text{if } x \geq 0. \end{cases} \tag{2}$$

Compared to the traditional activation function, such as logistic sigmoid, tanh, and other hyperbolic functions, the rectified linear function has the following advantages:

(1) Imitation of biological principles: brain studies have shown that the message encoding of biological neurons is relatively scattered and sparse [13]. There are about 1–4% of neurons working in the brain at the same time. With linear rectification and regularization, we can know the detailed activities in the machine neural network. The logic function reaches 12 at input 0, which is already half full and stable

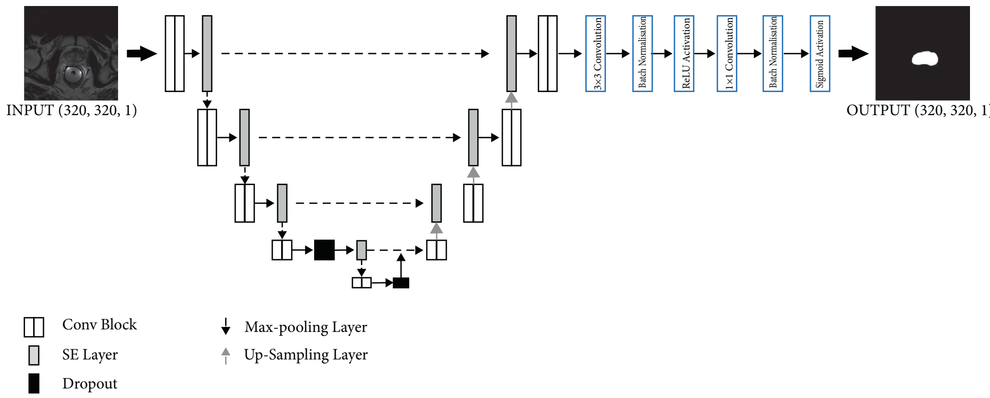

FIGURE 1: Overall structure of the segmentation network. The network includes the encoder and decoder stage connected with skip connection operation. The base components are Conv Block, SE layer, max-pooling layer, and upsampling layer. The first two components will be introduced later.

which is not the same as the expectation of the scientist who think a simulated neural network is the same as the real biology [14].

(2) More efficient gradient descent and backpropagation.

(3) Simplify the calculation: ReLU function can prevent the influence of complicated function, for example, exponential functions, and reduce the total computing cost of the model.

3.3. Dropout Layer. Dropout is a popular way to prevent overfitting in neural network training. In the training process of deep learning network, dropout temporarily discards neural network units from the network with a certain probability, which causes each batch to train a different network model. Use the average to improve the generalization ability of the model. In addition to overfitting, dropout also alleviates the problem of long training time for large-scale neural networks.

3.4. Skip Connections. Skip connection is an operation that skips some of the layer of the network and then takes the output of the layer to feed to the next layers. In U-Net, skip connections were used to fight the vanishing gradient problem and learn pyramid level features [9]. The main idea of skip connections in U-Net is to have the pretrained features and reuse them in the later layer to improve the performance. The features are transferred from the encoder layer to the decoder layer by skip connections which are combined with concatenation instead of summation.

4. Proposed Methods

In this paper, we proposed an improved 2D U-Net model integrated squeeze-and-excitation layer which is used to segment prostate cancer automatically. We are going to introduce our proposed model and the main blocks.

4.1. Model Structure. We did some improvements to the traditional U-Net. Inspired by [8, 9], we added some squeeze-and-excitation (SE) layers, which will be introduced later, based on U-Net. Our model is divided into the encoder stage and the decoder stage; on the encoder stage, the model can effectively extract the input image feature by continuous convolution layer and pooling layer; on the decoder stage, the model will step by step map the extracted features to the original image by the continuous upsampling layer and output predicted mask eventually. Figure 2 is our proposed model, which is more complex than the traditional U-Net. In particular, we added a SE layer before each encoder's pooling layer and after each decoder's upsampling layer.

4.2. CONV BLOCK. We use skip connection operation to concatenate two continuous convolution layer and activation layer and consist of a block and put them into a block which we named as CONV BLOCK. Figure 3 is its inner structure.

4.3. SE Layer. Inspired by [10], calculating the importance weights of each channel and then marking the more useful features, referring to Se-Net's [15] practice, we implemented a method which can extract important features from channels and named it the SE layer; Figure 4 shows its detailed structure.

First of all, we assume feature $F \in R^{H\times W\times C}$, H, W, and C represent the height, width, and channel and number of features is F, respectively, and the function of F is

$$F = [F_1, F_2, \ldots, F_i, \ldots, F_C]. \tag{3}$$

F_i is the i_{th} feature of the channel. For feature F, we use a global average pooling layer (GAP) to generate a vector and named it z_i whose function is

$$z_i = \frac{1}{H \times W} \sum_{x}^{H} \sum_{y}^{W} F_i(x, y). \tag{4}$$

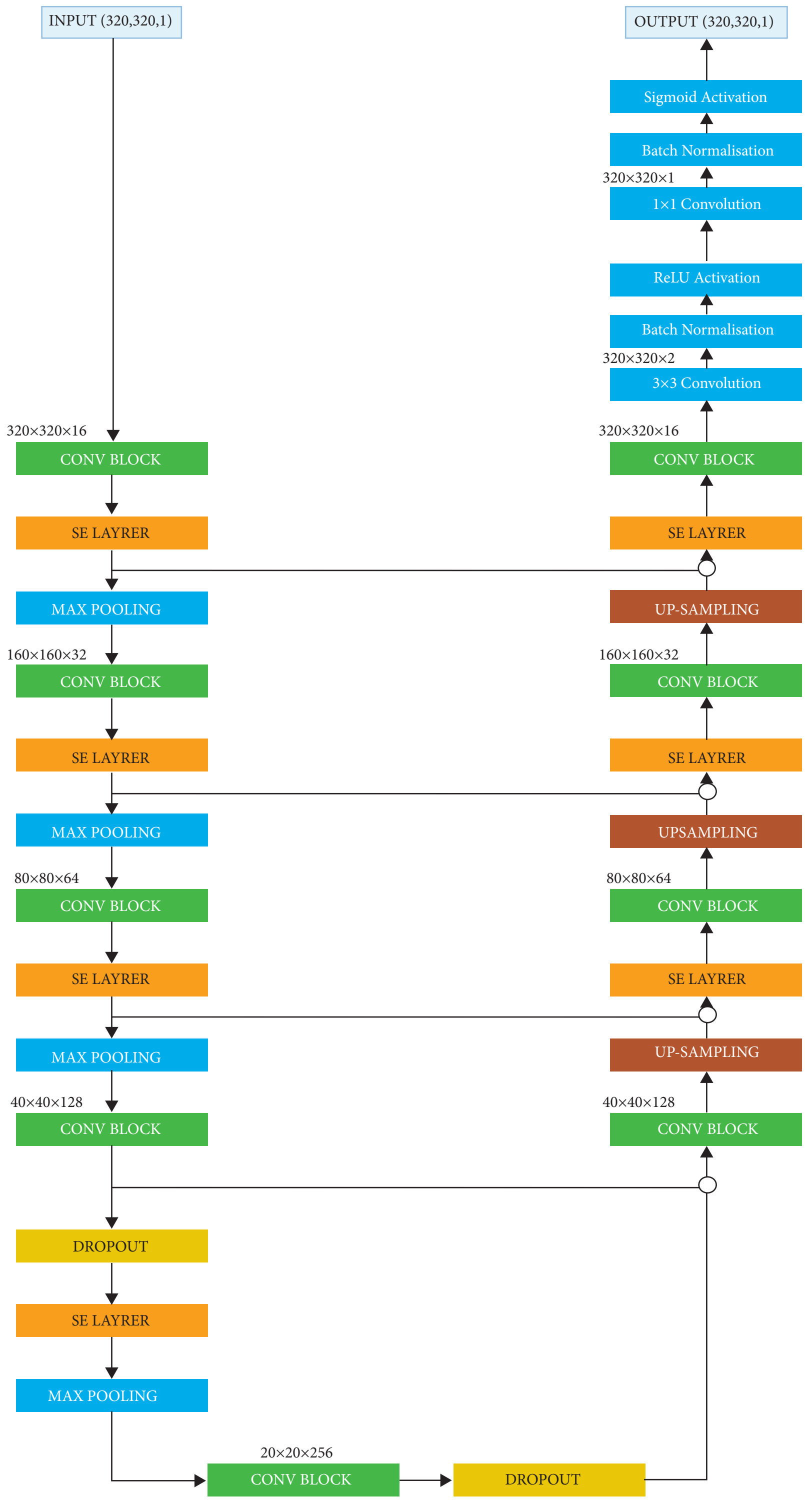

FIGURE 2: Our proposed model structure. The input size is 320×320. And the encoder consists of a series of CONV BLOCK, SE layer, max-pooling layer, and two dropout layers. The decoder consists of a series of CONV BLOCK, upsampling layer, and SE layer. In order to get a 320×320 output, the tail of the decoder consists of two convolution layers, two batch normalisation layers, a ReLU function, and a sigmoid.

z_i is the i_{th} global averaged channel. After that, we use a ReLU activation layer and a sigmoid activation layer to achieve information aggregation as

$$z' = \sigma(W_2\delta(W_1 z)), \tag{5}$$

where σ refers to the ReLU function, $W_1 \in R^{C\times C/r}$ and $W_2 \in R^{C/r\times C}$ refer to the two fully connected layers, and r is a ratio parameter to reduce the dimensional complexity which is set to 4. The importance of each feature channel can be learned and named as z'.

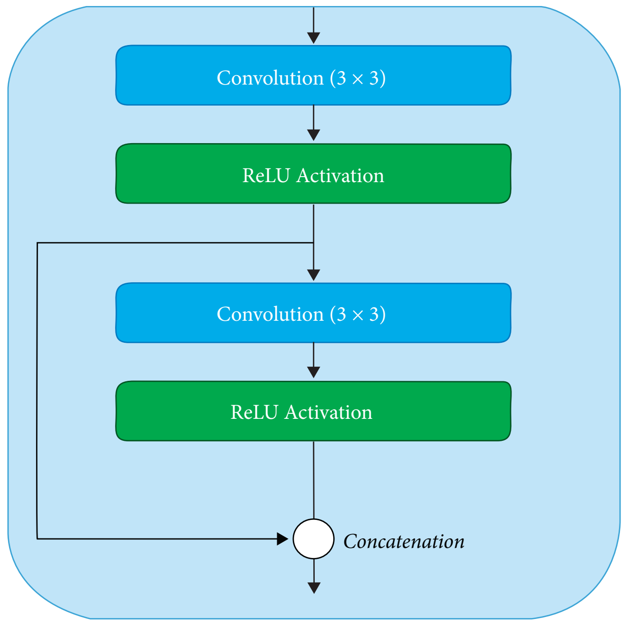

Figure 3: The inner structure of the CONV BLOCK. It consists of two continuous convolution layer and activation layer using concatenate operation.

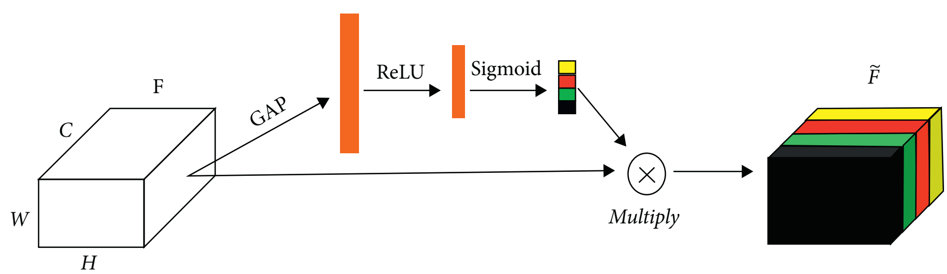

Figure 4: The structure of the SE (squeeze-and-excitation) layer, including a GlobalAveragePooling layer, a ReLU activation, and a Sigmoid activation. F will select important features by a multiply operation as $\tilde{F}$.

We can extract important features by multiplying F with z', and it can be described as

$$\begin{aligned}\tilde{F} &= F * z' \\ &= [F_1 * z_1', F_2 * z_2', \ldots, F_i * z_i', \ldots, F_C * z_C'].\end{aligned} \tag{6}$$

The SE layer is a good way to enhance the ability to learn globally of the model, which is proved to be correct and valid in [15], by strengthening more important features. We use it in both the encoder stage and decoder stage; the detailed location is described in Section 3.1.

4.4. Evaluation Function. We choose Dice similarity coefficient (DSC) as our evaluation function according to [16]. Denote P the predicted mask and GT the ground truth:

$$\mathrm{DSC} = \frac{2|P \cap \mathrm{GT}|}{|P| + |\mathrm{GT}|}. \tag{7}$$

In addition to this, we also choose accuracy (AC), Jaccard index (JA), and sensitivity (SE). TP, FP, TN, and FN represent true positive, false positive, true negative, and false negative, respectively. Their functions can be described as

$$\begin{aligned}\mathrm{AC} &= \frac{\mathrm{TP} + \mathrm{TN}}{\mathrm{TP} + \mathrm{FP} + \mathrm{TN} + \mathrm{FN}}, \\ \mathrm{JA} &= \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FP} + \mathrm{FN}}, \\ \mathrm{SE} &= \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN}}.\end{aligned} \tag{8}$$

5. Results

5.1. Dataset. The performance of the model is evaluated on a public dataset, PROMISE12 dataset, which includes 50 training sets and 30 continuous T2 weighted MR images in each set. We will resize the original image to 320×320 as the input of the model after loading the origin images.

5.2. Training. The designed model is based Tensorflow-Keras library. Our test set and training set all run on 6 GB

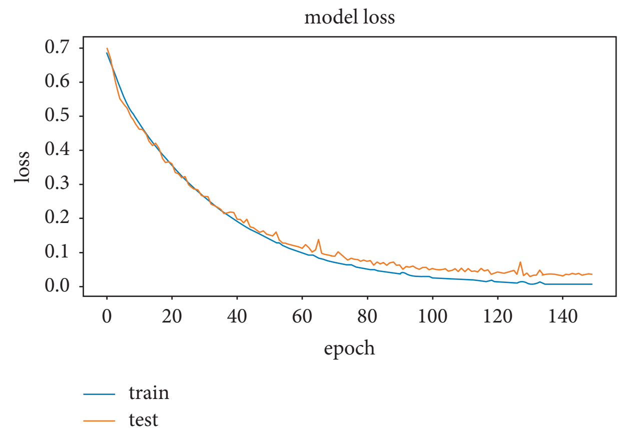

FIGURE 5: The loss curve of the model. The train loss curve dropped gradually to 0.05 and lower until 150 epochs.

NVIDIA GTX 1660TI GPU with Intel (R) Core (TM) i7-9750H CPU @ 2.60 GHz 16RAM. The initial learning rate is 10^{-4}, and the epoch is 150. Before training, we use random flip, rotation, and cropping to augment our training sets to get better training results.

We use an Adam optimizer [17] with a 10^{-4} learning rate as we mention above and a binary cross-entropy loss function [18], given by

$$\text{Loss} = -\left(y_i \log f(x_i, \theta) + (1 - y_i)\log(1 - f(x_i, \theta))\right), \quad (9)$$

where $f(x_i, \theta)$ is the prediction of the network on sample i in a range between 0 and 1 and y_i is the ground truth of sample i in binary 0 or 1.

5.3. Results and Discussion. After the training of 150 epochs using five folds to pick each train set and test set, we can get the model loss and accuracy curves.

As can be seen in Figures 5 and 6, both the loss and accuracy curves perform well, and the effectiveness of the training was preliminarily proved. Two curves remain stable in dozens of epochs, which showed the model is not overfitted. And the gradual decline of the curve demonstrates good convergence of the model.

To show the effectiveness of our model, we implemented three traditional prostate segmentation methods [8, 9, 19]. The work in [8] is fully convolutional networks (FCN), [9] is traditional U-Net, and [19] is a multiatlas method. We will compare our model results to the other three model results mentioned above.

After examining the score in the whole dataset using five-fold cross validation, our model performed well compared to the other three models whose mean DSC is 0.87 and median DSC is 0.89. And the remaining three were also higher than the others.

The detailed five-fold cross-validation results can be seen in Figure 7.

As can be seen in Figure 7, our model performed well on five-fold cross validation. Most of its DSC scores are in the range of 0.70 to 0.95. On the first fold, the median DSC score is above 0.90 and the mean DSC score is a little lower in the range of 0.85 to 0.90. And the second, fourth, and fifth folds are almost like the first fold whose median DSC is around 0.9. And the mean DSC of all five folds is 0.87 which can be seen in Table 1.

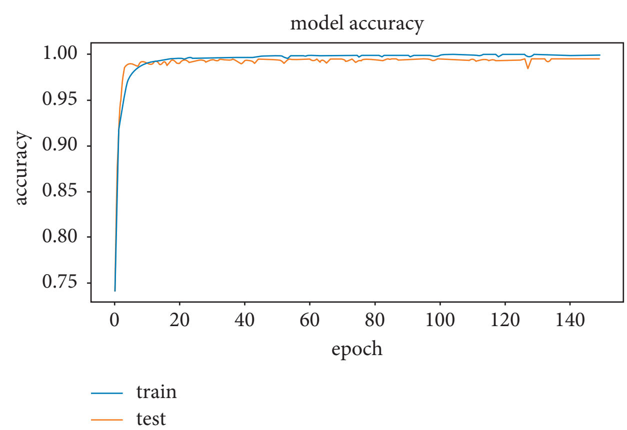

FIGURE 6: The accuracy curve of the model. The train accuracy curve increased gradually to about 0.95 until 150 epochs.

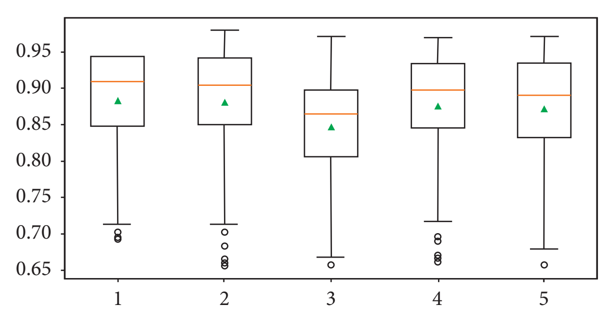

FIGURE 7: Five-fold cross-validation Dice's similarity coefficient (DSC) scores plotting with box-and-whisker. The orange line represents the median DSC score and the green triangle icon represents the mean DSC score on the first fold, the median DSC score is above 0.90, and the mean DSC score is about 0.88. The other folds performed well like the first fold, whose median DSC score is above 0.90 and the mean DSC is in the range of 0.85 to 0.90, except the third fold whose median DSC score is above 0.85 and mean DSC score is a little lower than 0.85.

Table 1: Performance comparison between our model and the traditional methods.

Method	Mean DSC	Median DSC	Mean AC (%)	Mean JA (%)	Mean SE (%)
FCN	0.79	0.81	84.6	72.5	90.6
U-Net	0.81	0.82	85.8	74.0	92.7
Multiatlas	0.80	0.82	85.0	73.5	90.1
Our model	0.87	0.89	87.3	75.3	93.2

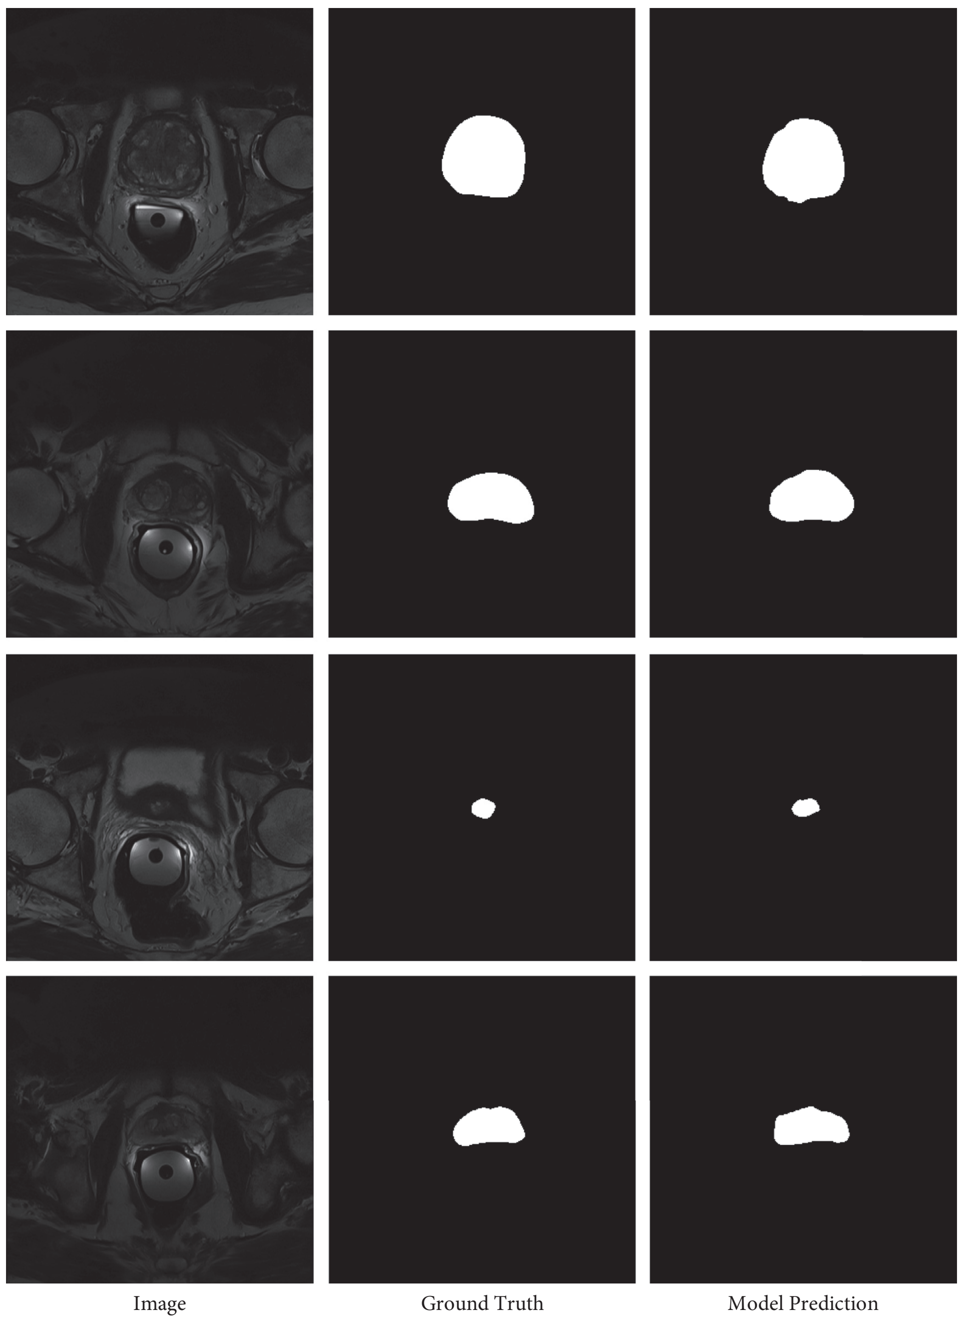

Figure 8: The visualization of some segmentation results in test sets.

6. Conclusion

In this paper, we develop an improved 2D U-Net model integrated Squeeze-and-excitation layer for prostate cancer segmentation. We divided two important components: SE layer and CONV BLOCK. With the SE layer, our model can learn more global and local features. In the CONV BLOCK, we combined feature maps and skip connection with a concatenation operation to bring further improvement in the model performance. In future work, different MRI modalities are going to be tried on our model to segment prostate cancer automatically.

Data Availability

The prostate MRI image dataset can be downloaded from the website (https://promise12.grand-challenge.org/Download/).

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors' Contributions

The authors contributed equally to this paper.

Cross-border e-commerce of the Internet of Things is affected by international situations and political factors. Supply chain interruption and returns will cause violent fluctuations in commodity inventory, making the inventory control of cross-border e-commerce very difficult. The TRIZ principle is utilized to solve the problem of the difficulty to evaluate the suppliers comprehensively in e-commerce warehouse management. The Markov algorithm is used to describe the change of inventory level. The cyclic expected time and cost function are constructed by the horizontal crossing method, updating the process and Martingale theory. The effect of the correlation between the demand and supply interruption on the optimal inventory control strategy is studied by simulation. The change of the optimal control strategy under the different interrupt and return types is analyzed, and the validity of the management system is verified.

1. Introduction

The accelerated evolution of cross-border Internet of Things e-commerce has become a new trend of international trade development and a novel engine of national economic growth [1]. To promote the development of cross-border e-commerce, the government encourages the establishment of a comprehensive service system for cross-border e-commerce. At present, the Internet of Things technology is developing rapidly, and the market scale is also in a good situation of expanding. The Internet of Things has turned into an important development strategy for countries around the world. The government has made many policies and plans to promote the in-depth development of the Internet of Things technology so that the industrial system of the Internet of Things constantly improved.

The environment of cross-border Internet of Things e-commerce is increasingly complex, which can be summarized as influenced by three factors. Firstly, the international situations and political factors result in supply disruptions [2]. Secondly, it is affected by the international epidemic, bad weather, and traffic jams [3]. Moreover, the new consumer-related laws and regulations require "seven days without reason to return goods," resulting in a large number of returned goods. These factors interact to create wild swings in inventories. Consequently, the companies increase the costs while reducing the quality of service. Therefore, how to effectively control the inventory under this environment has become a research hotspot in recent years.

Literature [4] studies the joint order decision of retailer optimal pricing when the order demand is out of stock due to price changes. Literature [5] studies the optimal pricing and ordering of the supply chain and its members when the market demand of the products depends on the price and consumers' time preference. Literature [6] constructed a multivariety-combined replenishment inventory model with the demand dependent on the deterioration time based on the characteristics of the nonimmediate deterioration of the products. In the above literature on perishable inventory strategy, the price decision alone was considered, while the replenishment cycle was out of consideration. In some inventory systems, such as the fashion goods inventory, when the goods are out of stock, the length of waiting time for each replenishment will directly affect whether the consumers can accept the delayed arrival of goods. Some scholars have conducted in-depth studies on the combination of the replenishment cycle and pricing. Literature [7] considers the demand dependence of nonimmediate perishable products on the price and product quality and studies the joint decision of the optimal price and replenishment cycle. Literature [8] assumes that price is a time-varying function of the discount rate and initial price, and the demand rate depends on the price and product quality. It studies stock replenishment and pricing decisions for perishable products. The above literature does not consider the impact of the price changes of perishable products during the sales period. Literature [9] analyzes the impact of price discount before product deterioration on unit profit. Others have studied retailers' promotional efforts on perishable goods. Literature [10] takes dynamic pricing, promotion efforts, and delayed payment of the perishable products into consideration and constructs a corresponding joint decision model of ordering and pricing. Literature [11] established a two-stage ordering decision model of dynamic perishable goods sellers to study the ordering decision of the sellers. Literature [12] studies the joint pricing and replenishment of nonimmediate deterioration products on the basis of considering the promotion efforts, price-sensitive random demand rate, and partial delayed order.

People often adopt the inventory defense strategy [13] in addition to the combination of multisource ordering [14] and other means to cope with supply interruptions. Literature [15] evaluated the defensive effects of various strategies. Literature [16], after summarizing the achievements made in the past 20 years, points out that the interruption problem related to the demand and supply state needs to be solved urgently. In this regard, literature [17] studied the use of product substitution strategy to alleviate the panic buying caused by interruptions. To deal with the impact of returned goods on inventory, researchers also put forward many effective measures. Literature [18] studies the inventory control problem in an unrelated environment of return and supply interruption. In addition, for special returns, literature [19] studied the design of the closed-loop supply chain network under the interruption of supply facilities.

Supplier selection is one of the main contents of e-commerce warehouse management. When choosing the suppliers, it is easy to be influenced by the emotional factors of the decision makers. Therefore, there is no quantitative standard for supplier evaluation, and it is difficult to achieve reasonable, objective, and comprehensive evaluation. If e-commerce warehouse management is to continue to develop efficiently and reliably, it is necessary to establish a set of scientific and effective evaluation systems for supplier selection and decision-making. The innovations and contributions of this paper are listed below.

(1) Based on the TRIZ (theory of the solution of inventive problems) theory, this paper makes an in-depth analysis of the e-commerce warehouse management supplier selection to solve the inventory control problem in the environment related to demand and return and supply status.

(2) TRIZ principle is used to solve the problem that it is difficult to evaluate suppliers comprehensively in e-commerce warehouse management.

(3) As the parameters of the Markov modulation model depend on the Markov chain, they are changeable. It allows the pricing models to change with market conditions for better reflecting the objective reality. Thus, Markov is used to describe the change of the inventory level, and the horizontal crossing method and multidimensional martingale theory are used to study the construction of the model. On this basis, the new environment of inventory management enlightenment is put forward by the analysis of the influence of key factors.

The chapter structure of this paper is as follows: the TRIZ theory is described in the next section. The third part mainly introduces the algorithm model proposed in this paper. The fourth part is experiment and analysis. The fifth part is the conclusion.

2. TRIZ Theory

TRIZ is the theory of creative problem solving. It is a set of invention and creation theories put forward by the former Soviet Union's Achishuler and his colleagues in 1946 [20]. For this reason, Achishuler is also known as the "Father of TRIZ." After years of continuous research by enterprises and scholars, the TRIZ theory has formed a systematic theory to solve invention problems, which is shown in Figure 1.

The content system of TRIZ theory mainly includes the following contents.

2.1. Theoretical Basis

(a) Technical systems: It refers to anything that performs or performs a function. A technical system generally has multiple subsystems, and each subsystem is a technical system in its own right. The subsystems of a technical system interact with each other, and changing one subsystem will inevitably affect the whole system.

(b) Conflict is a contradiction: It is another core concept of the TRIZ theory. The TRIZ theory holds that creative problem solving must solve at least one pair of conflicts. In the TRIZ theory, conflict is divided into three categories, namely technical conflict, physical conflict, and management conflict. Technology conflict refers to the deterioration of another feature or parameter when one feature or parameter is improved. Physical conflict refers to two opposite states of a technical system at the same time on a certain characteristic or parameter. Managing conflict is when something needs to be done to achieve certain results or avoid certain phenomena. However, not knowing how to do that means not being able to distinguish between technical conflict and physical conflict.

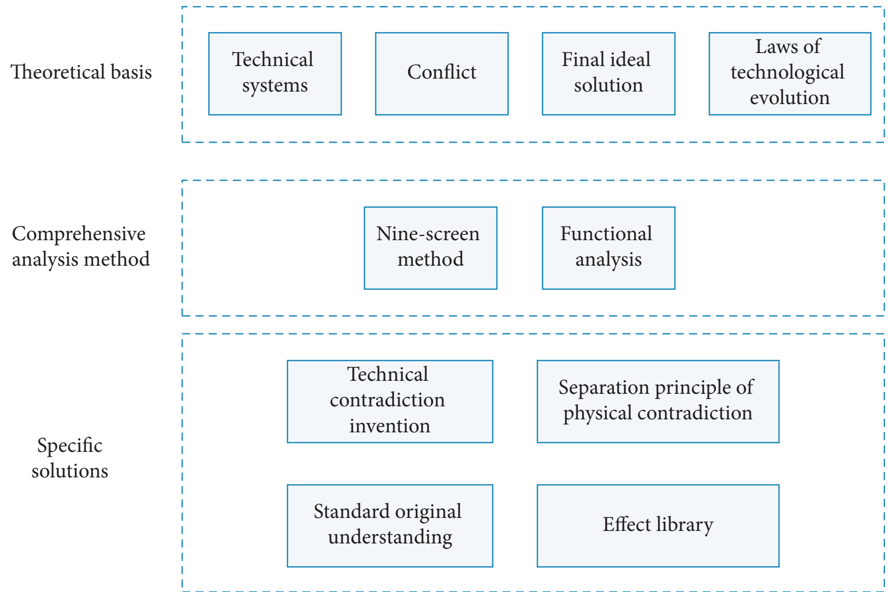

Figure 1: TRIZ system of theory.

(c) Final ideal solution: It refers to a technical system. If it tends to use fewer resources, more features will be provided with fewer side effects. It is a state that tends to be more ideal. The TRIZ theory holds that there is no perfectly ideal technology system. However, the desired end result can be a signpost for innovation. It makes the “ideality” of the technical system increase continuously and gets closer to the final ideal solution state.

(d) The laws of technological evolution: Every technological system is in a state of evolution, in the sense that things are constantly evolving and changing. Achishuler proposed eight rules of evolution. These evolutionary laws can predict the evolution of technological systems, effectively increasing our predictability and moving in their direction.

2.2. Comprehensive Analysis Method

(a) Nine-screen method: It refers to considering not only the current system but also its supersystems and subsystems when analyzing and solving problems. The past and future of the current system are considered. Also, the past and future of the hypersystems and subsystems are taken into account.

(b) Functional analysis: It refers to the technical system as a unit from the perspective of realizing the functions and fully analyzes the system, subsystem, super system, and their internal relations or functions.

2.3. Specific Solutions

(a) Technical contradiction invention principle: It refers to the 40 principles of creation summarized by Achishuler according to the categories of technological contradictions. After the main contradiction is obtained based on the contradiction analysis, it can be solved according to the creation principle corresponding to the contradiction matrix table. There are four main steps to define a technical contradiction. Step one is to know what the problem is. Step two is to know what the existing solutions are. The third step is to identify the shortcomings of the existing solution. The fourth step is to know what is improved and what is worsened, i.e., a pair of technical contradictions are formed.

(b) Separation principle of physical contradiction: It mainly has four separation principles to solve the physical contradiction problems. The four separation principles are space separation principle, time separation principle, conditional separation principle, and whole and part separation principle.

(c) Standard original understanding: It is a construction rule for combining and reorganizing the technical systems. Two functions are contained. One is to help improve an existing system or synthesize a new system. The second is the most effective method to establish the graphical model of the problem, namely the object-field model.

(d) Effect library: In the process of analyzing patents, Achishuler used the principles for many of his existing inventions borrowed from the other fields of scientific knowledge. Therefore, one of the methods proposed in the TRIZ theory to solve the problem is the knowledge base. It means applying the relevant laws of the field, especially in other fields, to solve problems.

3. e-Commerce Warehouse Control System of Internet of Things

3.1. Supplier Selection Model. There are many factors influencing the selection of e-commerce warehouse management suppliers. Combined with the general characteristics of e-commerce warehouse management, this paper chooses factors that are easy to measure to evaluate suppliers according to the extraction principle in the 40 invention principles of the TRI billion theory system. Supplier evaluation is mainly carried out from five aspects: product quality, product price, supplier's technical ability, supplier's management ability, and supplier's service ability. Associated with the invention principles of the TRIZ theory system, the evaluation indexes of the five aspects of the supplier selection are determined, and the supplier selection evaluation model is constructed.

Firstly, according to the universal invention principle of the TRIZ theory, the judgment matrix G of the supplier selection evaluation system is constructed. The product quality H1, product price H2, supplier's technical ability H3, supplier's management ability H4, and supplier's service ability H5 of the four suppliers (C1~C4) are compared in pairs. Their relative importance is judged, and the values of each parameter of the judgment matrix G are listed according to the judgment results. The same method is applied to construct the judgment matrix of H1~H5. Taking the judgment matrix G of the supplier selection evaluation system as an example, the judgment matrix has the following characteristics:

$$\begin{aligned} G_{xx} &= 1, \\ G_{yx} &= \frac{1}{G_{xy}}, \\ G_{xy} &= \frac{G_{xz}}{G_{yz}}, \quad (x, y, z = 1, 2, \ldots\ldots t). \end{aligned} \tag{1}$$

The maximum feature roots and feature vectors of G, H1, H2, H3, H4, and H5 of the supplier selection evaluation system are determined by the combined invention principle of the TRIZ theory. The vector of the judgment matrix G of the supplier selection evaluation system is normalized as follows:

$$G_{xy} = \frac{G_x}{\sum_1^t G_y}, \quad (x, y = 1, 2, \ldots, t). \tag{2}$$

Each column of the supplier selection evaluation system judgment matrix is normalized, and the judgment matrix is obtained.

$$X_x = \sum_1^t G_{xy}, \quad (x = 1, 2, \ldots, t). \tag{3}$$

Divide the vector after adding the judgment matrices of the supplier selection evaluation system by n to obtain the weight vector.

$$M = \frac{X_x}{t}. \tag{4}$$

The calculation will judge the maximum characteristic root $\lambda_{\max}$ of the matrix.

$$\lambda_{\max} = \sum_1^t \frac{(\mathrm{HX})_x}{tX_x}. \tag{5}$$

Combined with the homogeneity invention principle of the TRIZ theory, the consistency test of the judgment matrix of the supplier selection evaluation system is carried out. If the test fails, the model should be rebuilt or the judgment matrix should be reconstructed.

The consistency index CI of the judgment matrix is

$$\mathrm{CI} = \frac{\lambda_{\max} - t}{t - 1}. \tag{6}$$

$\mathrm{CI} = 0$ indicates that the judgment matrix has complete consistency. CI is close to 0, indicating that the judgment matrix has a satisfactory consistency. The larger the CI, the more serious the inconsistency of the judgment matrix.

Calculate the consistency ratio CR of the judgment matrix of the supplier selection evaluation system.

$$\mathrm{CR} = \frac{\mathrm{CI}}{\mathrm{RI}}. \tag{7}$$

When $\mathrm{CR} < 0.1$, it indicates that the judgment matrix of the product quality has a satisfactory consistency.

When $\mathrm{CR} \geq 0.1$, it indicates that the judgment matrix of the product quality should be rebuilt.

Using the feedback invention principle of the TRIZ theory, the optimal scheme is selected by calculation. Furthermore, synthesize the pros and cons of the last level of the order.

$$W = \sum_g^h X_x \times X_x^x. \tag{8}$$

The final calculation result is the comprehensive score of the evaluation of the supplier in five aspects: product quality, product price, technical ability, management ability, and service ability. The supplier with the highest score is the best supplier choice.

3.2. Warehouse Control System

3.2.1. Problem Description. Assume that a retailer sells a product and accepts returns. Set return without defect after repackaging into the stock as new products to meet the needs of users. The supply state change is described by the state transition of irreducible continuous time Markov chain $Y = \{Y(n), n \geq 0\}$. Here, Y has two states. $Y(n) = 1\,(Y(n) = 2)$ indicates that the time t supplier is in the supply (interrupted) state. Its duration obeys the exponential distribution of $\theta_1\,(\theta_2)$. To obtain the analytical solution, the user demand rate during this period is set as $\mu_1\,(\mu_2)$. The return is a compound Poisson process with the arrival rate $\lambda_1\,(\lambda_2)$, and the batch size follows an exponential distribution with the independent parameter $q_1\,(q_2)$.

Continuous inventory (r, C) strategy is adopted for ordering, i.e., start ordering when the inventory reaches r

level. Assume that the lead time is 0. If $Y = 1$, then the supplier immediately replenishes the inventory to level C. If $Y = 2$, the retailer needs to wait until the supplier outage ends before replenishing the inventory to level C. During the operation of the system, if the inventory level is 0, the demand is lost, resulting in out-of-stock costs. If the return exceeds the limit of the inventory capacity C, the retailer will exceed the part of the discount, and the processing time will be ignored. The return fee (including product cost and packaging replacement fee), handling fee, out-of-stock fee, and inventory fee per unit time are c_r, c_d, c_π and c_a, respectively. The fixed and variable costs of the order are c_f and c_o, respectively. Determine r and C to minimize the retailer's long-run average total expense ratio.

3.2.2. Model Construction. According to the problem description, the inventory level $I(n)$ is a Markov-modulated Levy process starting from C.

$$\begin{aligned} I(n) &= C - Q(n) \\ &= C - \sum_{y=1}^{2} \int_0^n Q_y(\tau) 1_{\{Y(\tau)=y\}} \mathrm{d}\tau, Q_y(\tau) \\ &= \mu_y - \sum_{t=1}^{T_y(\tau)} D_t^y, \end{aligned} \tag{9}$$

$T_y(\tau)$ is a Poisson process, indicating that it returns to the batch at time τ. $D_1^y, D_2^y, \ldots$ is the independent exponential distribution sequence of the q_y parameter and represents the quantity of the returned goods in each batch.

To facilitate the determination of the amount of returned goods, the remaining inventory space process $M(n)$ is analyzed below. Since the returns beyond C are processed, W can be represented as a Markov-modulated Levy process reflected at 0.

$$\begin{aligned} M(n) &= C - I(n) + L(n) \\ &= Q(n) + L(n). \end{aligned} \tag{10}$$

Here, the local time process L_y gives us the amount of returned goods processed up to time T. Obviously, the process in state J is zero.

$$L_y(n) = \int_0^n 1_{\{Y(s)=y\}} \mathrm{d}L(s), \tag{11}$$

where $L(n) = L_1(n) + L_2(n)$. It can be seen from the strong Markov property of Levy process that M is a renewal process. Update the optional interrupt end point at which the supplier completes replenishment.

If M_1 is defined as a subloop running from level 0 to level C, then a loop of M_1 may have multiple subloops embedded in it. If the number of subcycles is T, it can be known from the strong Markov property of Levy process that N follows geometric distribution. Let the running time of the subcycle be τ_1 and the probability that process M_1 reaches the level C corresponding to a state y be u_y.

$$\begin{aligned} &\tau_1 = \inf\{n > 0: M_1(n) = \overline{C} | M_1(0) = 0, Y(0) = 1\}, \\ &u_y = U(Y(\tau_1) = y), \quad y = 1, 2. \end{aligned} \tag{12}$$

The expected number of subcycles is $E[T] = 1/u_2$. The expected time of the M_1 cycle is as follows:

$$\begin{aligned} E[N_1] &= E[\tau_1] E[T] \\ &= \frac{E[\tau_1]}{u_2}. \end{aligned} \tag{13}$$

In addition, let the cycle time of M_2 be N_2, and it can be seen from the description of the problem that N_2 follows an exponential distribution with parameters θ_2. Thus, the expected time of a cycle of process M is as follows:

$$\begin{aligned} [N] &= E[N_1] + E[N_2] \\ &= \frac{E[\tau_1]}{u_2} + \frac{1}{\theta_2}. \end{aligned} \tag{14}$$

The cost function of building the system according to the operation of M is as follows:

(1) Inventory cost function: According to the limit theorem of the renewal process, the stationary distribution function of M_1 and M_2 exists and is set as $M_{1,e}$ and $M_{2,e}$, respectively. The expected inventory cost of a cycle is as follows:

$$E[\mathrm{CB}] = c_b \left\{ \left(C - E[M_{1,e}]\right) \frac{E[\tau_1]}{u_2} + \frac{\left(C - E[M_{2,e}]\right)}{\theta_2} \right\}. \tag{15}$$

(2) Return cost function: since return is a compound Poisson process, the amount of return per unit time is equal to the sum of the product of the amount of return per state and the corresponding state's long-range time. The expected return cost of a cycle is as follows:

$$E[\mathrm{CR}] = c_r \left\{ \frac{\lambda_1}{q_1} \frac{\theta_2}{\theta_1 + \theta_2} + \frac{\lambda_2}{q_2} \frac{\theta_1}{\theta_1 + \theta_2} \right\} E[N]. \tag{16}$$

(3) Deal with the cost function: For phase 1, the desired return processing amount for state y is ℓ_y. For phase 2, where the amount of returned goods is $E[\Gamma]$, the expected return processing the cost for a cycle is as follows:

$$\begin{aligned} E[\mathrm{CD}] &= \& c_d \{E[L(\tau_1)] E[T] + E[\Gamma]\} \\ &= c_d \left\{ \frac{(\ell_1 + \ell_2)}{u_2} + E[\Gamma] \right\}. \end{aligned} \tag{17}$$

(4) Shortage cost function: Shortages occur only in stage 2, and given $E[\Pi]$ as expected shortages, the expected shortage costs for a cycle are as follows:

$$E[\mathrm{CS}] = c_\pi E[\Pi]. \tag{18}$$

(5) Replenishment cost function: The replenishment amount of stage 1 subcycle is $\overline{C}$. Assume that the inventory level before the end of stage 2 is $M_2(N_{2^-})$. Then, the replenishment quantity is $E[M_2(N_{2^-})]$. The expected replenishment cost for a cycle is as follows:

$$E[\mathrm{CO}] = \frac{c_f}{u_2} + c_o\left\{\frac{\overline{C}u_1}{u_2} + E\left[M_2(N_{2^-})\right]\right\}. \tag{19}$$

Based on the renewal reward theorem, the long-term average expense ratio model is constructed as follows:

$$\mathrm{NC}(r, C) = \frac{E[\mathrm{CB}] + E[\mathrm{CR}] + E[\mathrm{CD}] + E[\mathrm{CS}] + E[\mathrm{CO}]}{E[N]}. \tag{20}$$

3.2.3. Determination of Functions in the Model. Since M_1 and M_2 are Markov-modulated Levy processes, it is difficult to obtain the undetermined functions by traditional methods. Kella–Whitt martingale is an effective tool for solving the Levy process problems.

Let Q(n) be a Markov-modulated Levy process. If $K(n) = Q(n) + J(n)$, the equation obtained is as follows:

$$W(\alpha, n) = \int_0^n e^{\alpha K(s)} 1_{Y(s)} \mathrm{d}s F(\alpha) + e^{\alpha K(0)} 1_{Y(0)} - e^{\alpha K(n)} 1_{Y(n)} + \alpha \int_0^n e^{\alpha K(s)} 1_{Y(s)} \mathrm{d}J(s). \tag{21}$$

It is the 0 mean (row) vector martingale, where 1_Y is an N-dimensional row vector whose y$^{\text{th}}$ component is 1 and remainder is 0. $F(\alpha) = V + \mathrm{diag}(\varphi_1(\alpha), \ldots, \varphi_n(\alpha))$ is the matrix exponent of Q(n). V is the state transfer rate matrix of y. $\varphi_1(\alpha)$ is the Levy index of $Q_y(n)$.

For this problem, if $J(n) = L(n)$, then $K(n) = M_1(n)$. The process L(n) only changes when $M_1(n) = 0$, and hence, it is simplified as follows:

$$W(\alpha, n) = \int_0^n e^{\alpha M_1(s)} 1_{Y(s)} \mathrm{d}s F(\alpha) + e^{\alpha M_1(0)} 1_{Y(0)} - e^{\alpha M_1(n)} 1_{Y(n)} + \alpha \int_0^n 1_{Y(s)} \mathrm{d}L(s). \tag{22}$$

Therefore, we can get,

$$\begin{aligned} V &= \begin{bmatrix} -\theta_1 & \theta_1 \\ \theta_2 & -\theta_2 \end{bmatrix}, \quad \varphi_y(\alpha) \\ &= \mathrm{loa} E e^{\alpha Q_y(n)} \\ &= \mu_y \alpha - \frac{\lambda_y \alpha}{\left(q_y + \alpha\right)}. \end{aligned} \tag{23}$$

The matrix exponentials are as follows:

$$F(\alpha) = \begin{bmatrix} -\theta_1 + \varphi_1(\alpha) & \theta_1 \\ \theta_2 & -\theta_2 + \varphi_2(\alpha) \end{bmatrix}. \tag{24}$$

The Kella–Whitt martingale described above is used to determine the function to be solved. Firstly, the optimal sampling theorem for τ_1 is obtained from equation (22).

$$E \int_0^{\tau_1} e^{\alpha M_1(n)} 1_{Y(n)} \mathrm{d}n F(\alpha) + E e^{\alpha M_1(0)} 1_{Y(0)} - E e^{\alpha M_1(\tau_1)} 1_{Y(\tau_1)} + \alpha E \int_0^{\tau_1} 1_{Y(n)} \mathrm{d}L(n) = 0. \tag{25}$$

By $\det(F(\alpha)) = 0$, four roots α_w can be obtained, satisfying the right column vector $F(\alpha_w)h^{[w]} = 0$ right column vector. In equation (25), take $\alpha = \alpha_w$ and multiply with $h^{[w]}$.

$$b_1^{[w]} - e^{\alpha_w \overline{C}}\left(u_1 b_1^{[w]} + u_2 b_2^{[w]}\right) + \alpha_w\left(\ell_1 b_1^{[w]} + \ell_2 b_2^{[w]}\right) = 0, \tag{26}$$

where $w = 1, 2, 3, 4$. To solve this equation, it can be obtained as follows:

$$\left[u_1, u_2, \ell_1, \ell_2\right]^N = H^{-1}\phi. \tag{27}$$

Among them,

$$\begin{aligned} \phi &= \left[b_1^{[1]}, b_1^{[2]}, b_1^{[3]}, b_1^{[4]}\right]^N, \\ H &= \begin{bmatrix} b_1^{[1]} e^{\alpha_1 \overline{C}} & b_1^{[1]} e^{\alpha_1 \overline{C}} & -\alpha_1 b_1^{[1]} & -\alpha_1 b_2^{[1]} \\ b_1^{[2]} e^{\alpha_2 \overline{C}} & b_2^{[2]} e^{\alpha_2 \overline{C}} & -\alpha_2 b_1^{[2]} & -\alpha_2 b_2^{[2]} \\ b_1^{[3]} e^{\alpha_3 \overline{C}} & b_2^{[3]} e^{\alpha_3 \overline{C}} & -\alpha_3 b_1^{[3]} & -\alpha_3 b_2^{[3]} \\ b_1^{[4]} e^{\alpha_4 \overline{C}} & b_2^{[4]} e^{\alpha_4 \overline{C}} & -\alpha_4 b_1^{[4]} & -\alpha_4 b_2^{[4]} \end{bmatrix}. \end{aligned} \tag{28}$$

Then, using the obtained u_y and ℓ_y, simplified for (25), it can be obtained as

$$E\int_0^{\tau_1} e^{\alpha M_1(n)} 1_{Y(n)} \mathrm{d}nF(\alpha) = [\psi_1(\alpha), \psi_2(\alpha)]. \tag{29}$$

Substitute $F(\alpha)$ given in equation (22) into equation (29) and obtain

$$E\int_0^{\tau_1} e^{\alpha M_1(n)} 1_{\{Y(n)=y\}} \mathrm{d}n = \frac{\psi_y(\alpha)\varphi_x(\alpha) - \theta_x(\psi_1(\alpha) + \psi_2(\alpha))}{\varphi_1(\alpha)\varphi_2(\alpha) - \theta_1\varphi_2(\alpha) - \theta_2\varphi_1(\alpha)}. \tag{30}$$

Let $\alpha \longrightarrow 0$ in equation (30), and apply L'Hopital's rule on the right side of the equation.

$$E\int_0^{\tau_1} 1_{\{Y(n)=y\}} \mathrm{d}n = \frac{\theta_x(\overline{C} - \ell_1 - \ell_2) - (-1)^y u_2(\mu_x - \lambda_x/q_x)}{\theta_1(\mu_2 - \lambda_2/q_2) + \theta_2(\mu_1 - \lambda_1/q_1)}. \tag{31}$$

It can be obtained from equation (31).

$$E[\tau_1] = E\int_0^{\tau_1} 1_{\{Y(n)=1\}} \mathrm{d}n + E\int_0^{\tau_1} 1_{\{Y(n)=2\}} \mathrm{d}n = \frac{(\theta_1 + \theta_2)(\overline{C} - \ell_1 - \ell_2) + u_2(\mu_2 - \mu_1 + \lambda_1/q_1 - \lambda_2/q_2)}{\theta_1(\mu_2 - \lambda_2/q_2) + \theta_2(\mu_1 - \lambda_1/q_1)}. \tag{32}$$

In addition, the number of M_1 subcycles in time τ_1 obeys geometric distribution.

$$E\int_0^{N_1} e^{\alpha M_1(n)} \mathrm{d}n = \frac{E\int_0^{\tau_1} e^{\alpha M_1(n)} \mathrm{d}n}{u_2}. \tag{33}$$

Using the ergodic theorem and equation (33), it can be obtained.

$$E\left[e^{\alpha M_{1,e}}\right] = \frac{E\int_0^{N_1} e^{\alpha M_1(n)} \mathrm{d}n}{E[N_1]} = \frac{\sum_{y=1}^{2} E\int_0^{\tau_1} e^{\alpha M_1(n)} 1_{\{Y(n)=y\}} \mathrm{d}n}{E[\tau_1]}. \tag{34}$$

The value can be determined by substituting equations (30) and (32) into (34). On this basis, it can be obtained.

$$E\left[M_{1,e}\right] = \frac{\mathrm{d}}{\mathrm{d}\alpha}\left\{E\left[e^{\alpha M_{1,e}}\right]\right\}\Big|_{\alpha=0}. \tag{35}$$

Equation (35) is easy to be obtained using equation (34), however, the result is long and tedious. Considering space limitation, it is omitted here.

Process M_2 is a Levy process that starts from level C and runs in interval [0, C]. The expectation of steady-state M_2 is zero. It can be obtained as follows:

$$\begin{aligned} E\left[M_{2,e}\right] &= U_0 C + \int_0^{\overline{C}} i f_2(i)\mathrm{d}i + \int_{\overline{C}}^{C} i f_1(i)\mathrm{d}i \\ &= U_0 C + \sum_{y=1}^{2}\left\{\left[\left(C - \frac{1}{\omega_y}\right)e^{\omega_y C} - \left(\overline{C} - \frac{1}{\omega_y}\right)e^{\omega_y \overline{C}}\right]\frac{G_y}{\omega_y} + \left[\left(\overline{C} - \frac{1}{\omega_y}\right)e^{\omega_y \overline{C}} + \frac{1}{\omega_y}\right]\frac{H_y}{\omega_y}\right\}. \end{aligned} \tag{36}$$

4. Experiment

4.1. Simulation Experiment of Supplier Selection. The four alternative suppliers of commodity Z are C1, C2, C3, and C4. The relative weight of each indicator is given by experts according to the importance scale. Construct the judgment matrix of supplier choice A, product quality H1, product price H2, supplier's technical ability H3, supplier's management ability H4, and supplier's service ability H5. Construct the judgment matrix of C1, C2, C3, and C4 relative to the product qualification rate H11, raw material supply condition H12, product production equipment, and product inspection equipment condition H3. The judgment matrix of the supplier choice G and its weight are shown in Table 1. The judgment matrix of product quality H1 and its weight are shown in Table 2.

The supplier selection judgment matrix and its weight are calculated, and the consistency of the constructed judgment matrix is tested. By the analysis of the calculation results, the values of CI and CR are less than 0.1. It shows that the constructed judgment matrix has a satisfactory consistency. According to the calculation, the total score of supplier C1 is 0.2623. The total score of supplier C2 was 0.3044. The total score of supplier C3 was 0.2074. The total score of supplier C4 was 0.2259. Therefore, the four suppliers of commodity A should be selected in priority order: (1) C2, (2) C1, (3) C4, and (4) C3. Therefore, supplier C2 should be selected as the supplier of commodity Z.

Table 1: Supplier selection judgment matrix G and its weight.

G	H1	H2	H3	H4	H5	M1
H1	1	2	3	3	4	0.4033
H2	1/2	1	2	2	3	0.2458
H3	1/3	1/2	1	1	2	0.1384
H4	1/3	1/2	1	1	2	0.1354
H5	1/4	1/3	1/2	1/2	1	0.0771

Table 2: Product quality judgment matrix H and its weight.

H	H11	H12	H13	H14	M1
H11	1	2	3	1	0.3523
H12	1/2	1	2	1/2	0.1898
H13	1/3	1/2	1	1/3	0.1078
H14	1	2	3	1	0.3501

4.2. Simulation Experiment of Supplier Selection. Using the function obtained above, the system optimization model is constructed as follows:

$$\min \mathrm{NC}(r, C) = \frac{E[\mathrm{CB}] + E[\mathrm{CR}] + E[\mathrm{CD}] + E[\mathrm{CS}] + E[\mathrm{CO}]}{E[N]}, \tag{37}$$

where $E[\mathrm{CB}] \sim E[\mathrm{CO}]$ can be calculated by equations (15) to (19). Obviously, the above equation is a nonlinear optimization function with constraints, and its optimal solution can be determined by Matlab.

The purpose of the simulation is to analyze the influence of the system parameter variation on the optimal control strategy r^* and C^* and cost NC^* under the new environment. Referring to the commonly used model of demand and price multiplication, the relationship between the demand rate and supply interruption is defined as follows:

$$\mu_2 = \mu_1 e^{\delta\rho/(1+\rho)}, \tag{38}$$

where δ represents the correlation between the demand and supply interruption. ρ is the interruption intensity (i.e., the ratio of mean interruption time to supply time (θ_1/θ_2). Similarly, the return rates and supply disruptions are defined as follows:

$$\gamma_2 = \gamma_1 e^{-\varepsilon\rho/(1+\rho)}, \tag{39}$$

where ε is the correlation between the returned goods and supply interruptions. Obviously, if δ and ε are 0, then $\mu_1 = \mu_2$, $\gamma_2 = \gamma_1$. It means that the demand and returns are independent of supply disruptions.

The influence of the change of the interrupt intensity and type is studied in the case of demand and interrupts. Here, the change of interrupt type is realized by adjusting the value of recovery rate θ_2 for a given interrupt intensity $\rho = 1$. Other parameters take the basic values, and the optimal results of the system are shown in Figures 2 and 3, respectively.

As can be seen from Figure 2, r^*, C^*, and NC^* increase with the increase of δ or ρ. The reason is that the increase of δ and ρ leads to the increase of the demand rate μ_2. To avoid

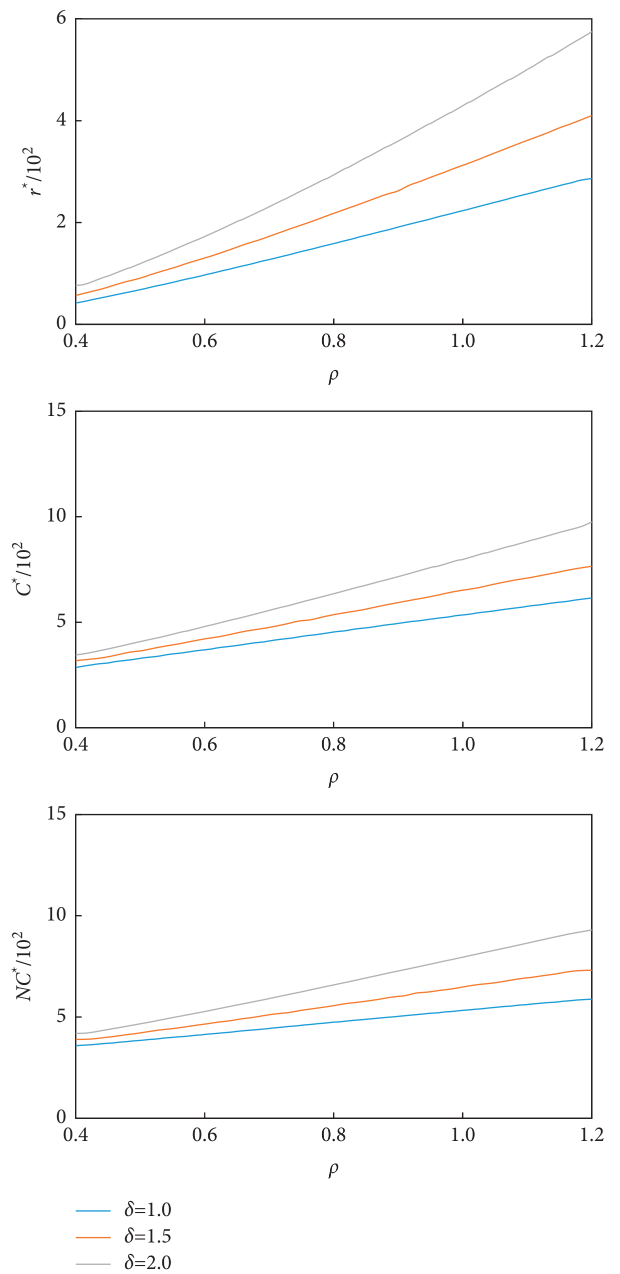

Figure 2: Optimal inventory strategy and cost corresponding to δ and ρ changes.

large shortages and order costs, the retailers raise r^* and C^*, resulting in higher NC^*.

By comparing Figures 2 and 3, it can be seen that the change of interrupt type does not change the influence trend of δ on r^*, C^*, and NC^*. However, with the increase of θ_2, r^*, C^*, and NC^* tend to decrease. The reason for this is that as θ_2 changes from small to large, the interrupt type changes from low frequency with long duration to high frequency with short duration. Suppliers can recover more quickly from disruptions, and retailers do not need to keep high inventories to guard against shortages caused by disruptions. Therefore, both r^* and C^* decrease gradually, and NC^* also decreases.

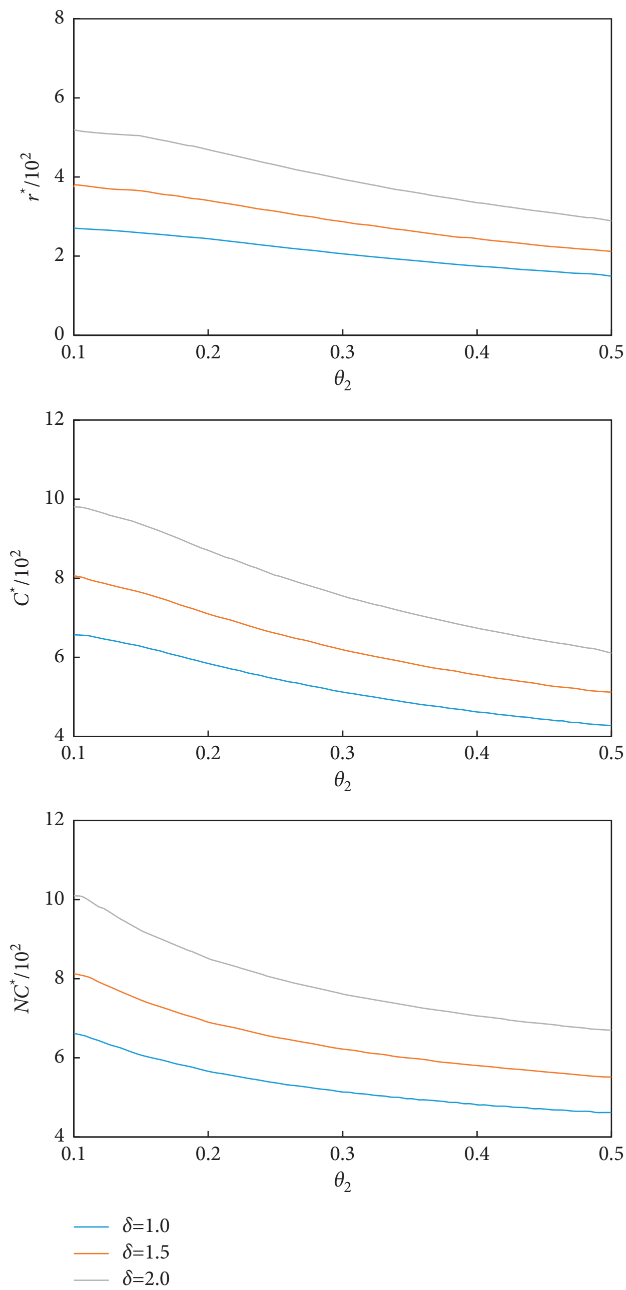

FIGURE 3: Optimal inventory strategy and cost corresponding to δ and θ_2 changes.

5. Conclusion

Cross-border Internet of Things e-commerce is developing rapidly and has become an important development strategy for countries all over the world. However, the environment of cross-border Internet of Things e-commerce is becoming more and more complex, which is influenced by international factors, transportation, policies, and other factors. The supplier selection of e-commerce warehouse management is deeply analyzed based on the TRIZ theory, aiming to improve the rationality of inventory control. With expressing the change of the inventory level as a Markov-modulated Levy process, the model of the system's long-range average total cost ratio is constructed using the horizontal traversal, updating process, and multidimensional martingale theory. The feasibility of the system is verified by a simulation experiment. Future work will add the international trade situation, the climate, and other real-time change factors into the influence factors of the algorithm to make the model more consistent with the objective situation. The efficiency of the algorithm will be analyzed in future work.

With the development of information communication and satellite positioning, crowd logistics has gradually emerged as a popular urban distribution mode for logistics enterprises. Trust and synergy between the crowd workers and the crowd logistics enterprises have become key issues in urban logistics development. Based on commitment-trust theory and logistics synergy, this paper developed a theoretical model exploring ability trust, goodwill trust, logistics synergy, and crowd logistics operational performance. We used SmartPLS software to analyze the questionnaire survey from 50 senior managers in crowd logistics enterprises. The results show that ability trust has a significant positive impact on logistics synergy and operational performance. Logistics synergy was also found to increase the operational performance of crowd logistics enterprises and plays a mediating role in the impact of ability trust and goodwill trust on operational performance. We recommend that logistics enterprises evaluate their crowd workers' service abilities, promote trust relationships with them, strengthen the construction of crowd logistics mechanisms, and invest in crowd worker training and development.

1. Introduction

With the rise of the sharing economy, many new business forms have developed, including crowd logistics. Crowdsourcing is a collaborative operation that integrates external knowledge and resources with enterprise technology to generate innovation [1]. With the crowdsourcing mode, logistics enterprises can gather scattered and idle external resources [2] and outsource the distribution activities originally performed by their employees to non-fixed social groups through the internet platform [3]. Given logistical difficulties, such as shortages in terminal logistics distribution resources and large fluctuations in market demand, crowd logistics provides an innovative solution to ameliorate delivery efficiency and reduce operating costs [4]. Dada Express, for example, has more than 4 million registered crowd workers on the platform, covering more than 1,400 cities across the country with over 40 million active users [5]. The emergence of crowd logistics has effectively solved the issues of delivery warehouse bursting, difficulties in resource integration, and low-efficiency distribution, resulting in huge economic benefits to enterprises [6]. Meanwhile, advances in information and communication technology, satellite location, and navigation [6] have opened up further opportunities for the crowd logistics development. The platformization and intellectualization of crowdsourcing logistics also match the industry 4.0 era's development needs. As a result, crowdsourcing logistics is becoming increasingly popular in urban distribution.

From the perspective of resources, enterprises regard crowd workers as external resources, achieving resource integration through crowdsourcing [7]. When internal and external synergies are transformed into synergies of enterprises, enterprise performance can be elevated [8]. However, while crowd logistics can promote cost reduction and increase efficiency, problems such as consumer information leakage and mishandled or damaged parcels occasionally happen. Some major reasons for these problems include immature development of the practice, weak stickiness of the public, and non-employment of crowd workers [6]. In particular, trust issues between the enterprise and crowd workers are prominent [6, 9], affecting enterprises' synergy efficiency, service quality, and operational performance.

At present, studies on the impact of trust in the operational performance of logistics enterprises have mostly focused on the integration of third-party logistics and related fields (e.g., Zaheer et al., 1998 [10]; Luo et al., 2015 [11]; and Wang et al., 2009 [12]), largely overlooking trust issues at the crowdsourcing level [9]. Some studies have discussed the impact of trust on crowdsourcing performance from the perspective of the overall crowdsourcing environment (e.g., Yao et al., 2019 [7] and Ye and Kankanhalli, 2017 [9]), and very few have explored the impact of trust on operational performance particularly in crowd logistics. The trust issue between crowd workers and logistics companies has produced a slew of social problems. There is also a study on this topic gap. Therefore, our study motivation is to make up for this gap in the literature and provide practical implications for crowd logistics participants. The questions to be tackled in this paper are: how does logistics synergy and trust between crowd workers and crowdsourcers impact the operational performance of the crowd logistics enterprise? On a micro level, resolving this issue aids in enhancing the synergistic efficiency of the crowd worker and the enterprise; on a macro level, it promotes the long-term development of urban logistics.

This study addresses some of these research oversights. To ensure the depth of analysis, this study focuses mainly on physical crowd logistics. By applying theories in commitment, trust, and logistics synergy, a research model was developed exploring the impact of trust and the mediating role of logistics synergy on enterprises' operational performance. The main contribution of our research is the construction of a theoretical model of the relationship between trust and crowd logistics enterprise's operational performance. The results of this study can help promote cooperation between the enterprises and crowd workers, improve operational performance, and enhance the service level of crowd workers. Customers, meanwhile, can profit from increased trust between crowd workers and businesses. Because crowd workers who have a high level of trust may be better able to follow delivery standards and preserve the privacy and information of clients. Thus, the practical value of our study is that our research findings may benefit crowd workers, crowdsourcers, customers, and crowdsourcing platforms.

The rest of the paper is arranged as follows. Section 2 is the literature review, while Section 3 provides the theoretical background and research hypothesis. Section 4 discusses the research method and empirical results. Section 5 presents the discussion of results, while Section 6 provides the conclusion, limitations, and future research directions.

2. Literature Review

2.1. The Origin and Role of Trust. Trust, which refers to an individual's dependence on a partner in the presence of risk, first appeared in the field of psychology [10] and was later applied in relationship marketing research [13]. With the growth and expansion of the market economy, trust issues between enterprises have become more prominent, and research on trust has grown significantly. For example, McAllister [14] divided trust between organizations into cognitive and affective. He defined cognitive trust as believing that the other party has enough ability, including technology, capacity, and knowledge, to achieve the desired results. Affective trust emphasizes the emotional interaction between two parties, focusing on the duration of cooperation when the external environment fluctuates and is driven by emotions and relationships [14]. Inkpen and Tsang [15] pointed out that trust is crucial in organizational relationships and is an important predictor of organizational performance. Fynes et al. [16] concluded that trust between enterprises could reduce opportunistic behaviors in both parties and reduce transaction costs.

In recent years, the relationship between trust and enterprises' operational performance has been the focus of numerous studies. Many scholars have explored the promoting effect of trust on enterprise operational performance from the perspective of third-party logistics integration (e.g., Hofer et al., 2009 [17]; Lai et al., 2013 [18]; and Dai et al., 2015 [19]). Studies have found that the trust between logistics outsourcing enterprises and service providers can promote integration among third-party logistics and boost the operational performance of logistics enterprises [17, 18]. Developing trust between partners would reduce erratic and uncertain behaviors, reduce supervision costs for both parties, and improve operational performance [19]. The positive effect of trust has been proven to be effective in internet technology (IT) outsourcing enterprises and enhance innovation among enterprises [20, 21].

For crowdsourcing, Blanchard and Markus [22] found that trust in the crowdsourcing platform affects participation behavior, impacting crowdsourcing performance. Similarly, Bauer et al. [23] concluded that trust has an important influence on participants' online social behavior. Norat [24] pointed out that increasing trust among crowd workers is conducive to the continued completion of tasks, reduces the number of abandoned packages in the distribution process, and improves crowdsourcing performance. Analyzing the relationship between trust and crowdsourcing performance, Meng [25], Tu [26], Pang [27], and Yao et al. [7] found that the degree of mutual trust among principal parts (e.g., crowd worker, enterprises, and platforms) can, directly and indirectly, impact crowdsourcing performance.

2.2. Trust in Crowd Logistics. The crowdsourcing operation mode is based largely on the concepts of the sharing economy and open distribution and is driven by the emergence of smartphones, global positioning system (GPS), WLAN, and information and communication technology. This operation mode has been absorbed by the logistics field [6], resulting in a new group of crowdsourcing logistics enterprises (e.g., JD-dada, FlashEx, and MyWays). While some have argued that scholarly research on crowd logistics has significantly lagged behind its current practical applications [28, 29], a number of studies have been conducted investigating particular aspects of crowd logistics. For example, Chanal [2] argues that crowd logistics can be used to tap idle social resources to solve distribution needs and mitigate shortages in human resources. Carbone et al. [29] believe that crowd logistics can make full use of people's idle time, abilities, and other logistics resources to develop logistics services. Wang et al. [30] proposed applying crowd logistics to solve the last-mile delivery problem, realizing the optimization of real-time logistics distribution. Lin et al. [31] argue that crowd logistics has the advantages of low distribution costs and environmental friendliness.

Numerous scholars have also researched the influencing factors, behavioral decisions, and legal governance issues of crowd logistics. For example, from the perspective of crowdsourcer, Bin et al. [32] explored the main factors influencing the implementation of crowd logistics and concluded that logistics operation mode, external incentives, internal benefits, and security of transformation significantly affect the willingness of enterprises to implement crowd logistics. Liang et al. [33] built a theoretical model, studying the effects of participation motivation, subjective norms, perceived behavior, and satisfaction on crowd workers' continued participation. Guo and Wang [34], using the theory of UTAUT (unified theory of acceptance and use of technology), applied a structural equation model to empirically analyze the influencing factors of crowd workers' participation behavior in crowd logistics. Sun et al. [35] identified risk factors in crowd logistics through literature research and used Fengniao (a crowd logistics application) to conduct an empirical analysis on factors affecting consumer satisfaction. Peng [36] studied the multiple legal risks in crowd logistics and made recommendations, including the establishment of a credit system and information protection mechanisms.

Most studies on crowd logistics largely involve concept definitions, influencing factors, behavioral decisions, and the positive effects of the new logistics mode. Few have explored its negative effects (see Mladenow et al. [6] for a notable exception). Although the current research on crowd logistics involves identifying risk factors, few have analyzed trust and its associated risks generated in this process (see Huang et al. [37] for a notable exception). In particular, how trust between the crowd worker and the logistics enterprise can be further encouraged requires further investigation. In third-party logistics, trust is considered a pivotal factor in enhancing the operational performance of enterprises. However, the cooperative relationship under the crowd logistics mode is generated based on the task, with short timelines, weak stability, and poor sustainability. Building trust between the crowd worker and the crowdsourcer and promoting cooperation and synergy are critical to reinforcing the operational performance of crowd logistics enterprises.

3. Theoretical Background and Hypothesis

3.1. Theoretical Background

3.1.1. Commitment-Trust Theory. Commitment-trust theory is a fundamental theory in relationship marketing. It was first proposed by Morgan and Hunt and is regarded as an important mechanism to promote customer relationships [13]. According to Morgan and Hunt, commitment and trust are crucial to competitive advantage. Trust determines commitment. It can push the customer to rely on the transactional relationship with the marketer and be willing to make a personal effort to maintain that relationship. The relationship capital between trust and commitment also helps reduce misunderstanding and customer concerns on particular uncertainties and transactional risks [13].

In recent years, this theory has been applied in numerous management studies. For example, Zhu [38] applied commitment-trust theory to empirically analyze the influence of trust on user participation in social media. Yao [39] verified that trust has a positive impact on supply chain performance through the mediating role of synergy. Cui et al. [40] also used this framework to study the influence of trust on online participation willingness and satisfaction in cross-border mobile commerce. These studies show that the commitment-trust theory provides a positive theoretical reference to study participatory behavior in the sharing economy. Since trust is crucial between the crowd worker and the crowdsourcer in the crowd logistics network, we used this theory to explore the influence of trust on the crowd logistics enterprises' operational performance.

3.1.2. Logistics Synergy Theory. Logistics synergy was first analyzed in the United States and has since been studied from different perspectives. Sacaluga [41] posits that logistics synergy mainly refers to the efficient and coordinated operation among various functions, including logistics, to maximize customer demand. Cao and Yang [42] studied the influence of supply chain synergy on enterprise performance. Chen et al. [43] expounded the necessity of enterprise knowledge chain innovation and forwarded corresponding innovation countermeasures using the logistics synergy theory. Zhang et al. [44] applied this theory to the coordinated development mode of rural e-commerce and rural logistics. Based on this theory, Zhang [45] constructed the cross-border e-commerce and cross-border logistics synergy mode and raised a series of measures to promote the value of enterprises. With the continued application of this theory, logistics synergy has increasingly presented the trend of interdisciplinary sharing.

Crowd logistics is mainly supported by internet information technology, where enterprises outsource delivery tasks to the public [6]. The two parties cooperate to share logistics information, technology, and human resources, thus increasing resource allocation efficiency, reducing logistics costs, and enhancing enterprise performance. Crowdsourcing system includes not only enterprises, platforms, and crowd workers but also information, capital, human resources, technology, and other resource elements [37]. Since the synergy of elements within the system has a significant impact on crowdsourcing performance, we first discuss the theory of logistics synergy in studying crowd logistics enterprises' operational performance.

3.2. Research Model Construction. We separate the factors affecting the operational performance of the crowd logistics enterprise into trust (goodwill trust and ability trust) and logistics synergy using commitment-trust theory and logistics synergy theory. We propose that goodwill trust, ability trust, and logistics synergy can significantly impact crowd logistics enterprises' operational performance and that logistics synergy plays a mediating role on goodwill trust and ability trust in affecting operational performance. On this basis, a theoretical research model is developed and is presented in Figure 1.

3.3. Hypotheses. Based on literature review and theoretical analysis, this study presents several hypotheses on the relationship between trust, logistics synergy, and crowd logistics enterprises' operational performance.

3.3.1. Trust and Crowd Logistics Enterprises' Operational Performance. Trust is considered the foundation of effective cooperation [46]. Trust between enterprises can reduce opportunistic behaviors to maintain long-term benefits with existing partners and obtain specific performance results [47]. Early studies on the integration of third-party logistics found the role of a solid, trusting relationship as crucial in elevating the operational performance of logistics enterprises [17, 18]. Feller et al. [48] concluded that trust is a critical factor affecting the crowd worker's continued participation and can also determine crowdsourcing success. Bauer et al. [23] also found that trust affects the crowd worker's social behavior. Norat [24] further pointed out that enhancing users' trust in crowdsourcing enterprises can boost the enterprises' operational performance.

Trust can be divided into different dimensions in various ways. In this study, trust is divided into two dimensions, based on the studies of Jonathan and Kankanhalli [9], McAllister [14], and Mayer et al. [48]: goodwill trust and ability trust. In the sharing economy, the demand side is largely concerned with whether the resource supplier has the skills and ability to meet its needs and whether it has essential qualities of kindness and integrity [49]. Numerous scholars (e.g., Meng and He, 2020 [49]; Wang, 2011 [50]; Li and Yu, 2011 [51]) have found that ability trust and goodwill trust are key factors driving consumer's behavioral intention in the sharing economy.

In goodwill trust, the enterprise believes that the crowd worker can keep the qualities of honesty and trustworthiness amidst fierce market competition, safeguarding the company's interests [49]. Goodwill trust focuses on the sense of moral obligation and responsibility, which can significantly impact the individual's attitude and behavior and affect the performance of enterprises [50]. Goodwill trust focuses on the quality and intentions of partners, which are conducive to reducing transaction costs and opportunistic tendencies and raising the stability of cooperative behavior and the operational performance of supply chain enterprises [51].

Crowd logistics adopts the idea of the sharing economy in its operation mode, maximizing idle labor resources to perform urban logistics services. However, in actual practice, the loose cooperative relationship between crowd logistics enterprises (crowdsourcer) and the crowd worker is highly uncertain [52]. Crowd workers, for example, are often penalized by companies due to complaints from consumers. When receiving first-time complaints, enterprises often forego investigation and directly blame the crowd worker, at a time when goodwill and trust have not been formed between the two parties. This behavior reduces enthusiasm among crowd workers to participate in crowd logistics, affects their service quality, and adversely impacts the enterprise's operational performance. Accordingly, this study offers the following hypothesis:

> H1a: Goodwill trust has a positive impact on crowd logistics enterprises' operational performance

Ability trust refers to the enterprise's belief that crowd workers can achieve their own needs and expectations and perform their duties smoothly. In practice, delivery risks (e.g., vandalizing parcels and revealing customer information) are widespread, given the absence of professional training for crowd workers [53]. If the enterprise, as the demander, chooses to trust the crowd workers' professionalism that they will not harm the interests of the enterprise for their own interests, a healthy cooperative relationship can be formed between the parties, which will improve the performance of the enterprise. Morgan et al. [13] argue that ability trust helps partners not have to repeatedly explain each other's abilities, which helps promote high-quality cooperation, reduces unnecessary supervision and incentives, and advances the response speed of the supply chain. Therefore, the ability trust of the enterprises to connect with crowd workers can help increase their continued willingness and participation, significantly reduce management costs, and raise the company's operational performance. Based on these arguments, we put forward the following hypothesis:

> H1b: Ability trust has a positive impact on crowd logistics enterprises' operational performance

3.3.2. Logistics Synergy and Crowd Logistics Operational Performance. Synergy results from one party choosing to interact and cooperate with another, given the difficulties of accomplishing its goal by itself [54]. With the growing application of synergetics theory in various disciplines (e.g., economics and engineering), its use in logistics has also increased [55]. Research on logistics synergy mainly focuses on the supply chain, emphasizing cooperation between supply chain functions from multiple dimensions to maximize overall efficiency. Research has shown that logistics synergy in the supply chain positively affects the enterprise's operational performance and that strengthening information resource coordination among enterprises helps improve operational performance [56, 57]. Wang et al. [8] concluded that logistics synergy is a crucial factor affecting enterprise performance.

In crowd logistics activities, enterprises and crowd workers carry out flexible logistics synergy through advanced management and information technology to achieve common goals. The logistics synergy between the crowdsourcer and the crowd worker through the original boundary of enterprise capital specificity realizes cross-organization sharing and resource allocation. This synergy significantly boosts the operational flexibility of third-party logistics enterprises and improves the level of customer

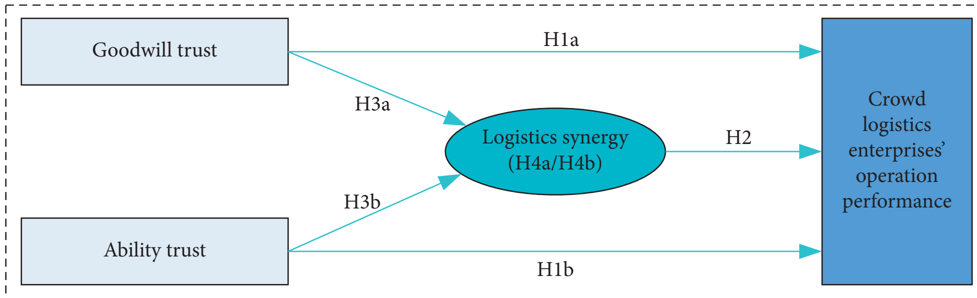

Figure 1: Research model.

service. This means logistics synergy is a critical force to promote the crowd logistics enterprises' operational performance. Hence, we propose the following hypothesis:

> H2: Logistics synergy has a positive impact on crowd logistics enterprises' operational performance

3.3.3. Trust and Logistics Synergy. Trust is the basis of effective collaboration and plays a positive role in promoting cooperation between enterprises [45, 58]. Crowd logistics offers delivery invitations to a large group of people in a collaborative way. In this process, trust between the crowd worker and the crowdsourcer may affect the logistics synergy. Saenz et al. [59] found that organizations that lack trust are more likely to reject logistics collaboration. Zhang et al. [60] found that trust is a critical factor that can restrict horizontal logistics synergy. In other words, enterprises that trust each other are more likely to carry out synergistic activities for particular logistics businesses [61].

In the crowd logistics system, the moral level of the crowd worker is a major factor for enterprises to measure synergy. The goodwill trust of the enterprise recognizes that the crowd worker has a moral character of loyalty and integrity and trusts the cooperative behavior of each other [62]. Therefore, we propose the following hypothesis:

> H3a: Goodwill trust has a positive effect on logistics synergy

Ability trust encourages enterprises to believe that crowd workers have the strength and ability to complete the task and achieve the targets. This enhances information sharing and promotes cooperative behavior between parties, further improving the degree of synergy [63]. Crowd logistics enterprises pay attention to service quality and delivery efficiency and are likely to choose qualified, competent, and experienced crowd workers [7]. This kind of ability trust can help enterprises reduce synergy costs and enhance crowd logistics synergy with crowd workers. Hence, we propose the following hypothesis:

> H3b: Ability trust has a positive effect on logistics synergy

3.3.4. The Intermediary Role of Logistics Synergy. Trust can be a significant factor restraining opportunistic behavior and promote the development of synergistic activities. Efficient synergistic activities have been shown to reduce operating costs and improve customer service quality [16]. In the crowd logistics market, enterprises' trust in crowd workers can help reduce the need for formal contracts, decrease unnecessary logistics links, and increase logistics response speed [12]. Developing trust also promotes the transfer and sharing of information, technology, and other resources between crowd workers and crowdsourcers, thus lowering transaction costs and positively impacting operational performance. Based on these arguments, we propose the following hypotheses:

> H4a: Logistics synergy plays a mediating role in the influence of goodwill trust on crowd logistics enterprises' operational performance
>
> H4b: Logistics synergy plays a mediating role in the influence of ability trust on crowd logistics enterprises' operational performance

4. Research Methodology and Results

The research method of this paper consists of five steps: (1) questionnaire design, (2) questionnaire pretest, (3) data collection, (4) selection of control variables, and (5) data analysis [37, 64].

4.1. Questionnaire Design. The questionnaire consists of two parts. The first part includes the basic information of the crowd logistics enterprises, including the ownership, annual sales, and the number of years of operation. The second part consists of four latent variables: ability trust, goodwill trust, logistics synergy, and operational performance. The observation items for each latent variable were based on measurement scales developed and verified in previous studies and adjusted according to the practical background of crowd logistics. Table 1 provides the summary of latent variables and observation items used in the study. We used a Likert five-point scale to quantify each observation item ranging from: strongly disagree, disagree, neither agree nor disagree, agree, and strongly agree [65].

4.2. Questionnaire Pretest. Before the actual survey, we pretested the questionnaire and sent it to 12 senior managers of crowd logistics enterprises by e-mail. The managers were from Changsha city, Zhuzhou city, and Xiangtan city. The

Table 1: Observation items for each latent variable.

Latent variables	Observation items	References
Goodwill trust (GT)	H1a-a1: I believe that when the market changes, the crowd worker will not be inclined to transfer costs to the enterprise H1a-b1: I believe that the crowd worker pays close attention to the needs of the enterprise and sincerely cares about the success of the enterprise H1a-c1: I believe that the crowd worker has sacrificed for the enterprise in the past	Levin and Cross [66]; Ganesan [67]
Ability trust (AT)	H1b-a2: I believe that the crowd worker has strong working skills, and working with them can enhance the enterprise's operational performance H1b-b2: I think most of the crowd workers are reliable in terms of their business capability H1b-c2: In my opinion, the crowd worker meets the task requirements of the enterprise and can complete the delivery task with high quality	Mcallister [14]; Anderson and Narus [68]
Logistics synergy (LS)	H2-a3: Our enterprise keeps regular feedback and communication with the crowd worker H2-b3：I think when the customer demand change, the enterprise and the crowd worker can negotiate to develop a flexible workflow H2-c3: To my way of thing, the enterprise and the crowd worker can share crowd logistics information in a timely manner	Sinkovic and Roath [69]; Story et al. [70]
Crowd logistics enterprises' operational performance (CLEOP)	H-a: In my opinion, crowd logistics enterprises can provide excellent customer service quality H-b: I think crowd logistics enterprises can respond to customer needs in a timely manner H-c: I think the delivery speed of crowd logistics enterprises is fast, and the delivery reliability is strong	Zhao et al. [71]

pretest was to identify possible errors, confusing statements, or ambiguous language in the questionnaire. The work took two weeks to finish and was conducted in August 2020. Based on the feedback, modifications were made accordingly.

4.3. Data Collection. The respondents to the actual survey were senior managers of crowd logistics enterprises from the cities of Changsha, Zhuzhou, and Xiangtan in Hunan Province, China. These cities form the "Chang-Zhu-Tan Urban Agglomeration" (see Figure 2). In 2007, the urban agglomeration was approved by the State Council as a national comprehensive reform pilot area for resource efficiency and environment friendliness [72]. Adhering to the concepts of green and shared development, this urban agglomeration has been encouraging crowdsourcing business development in recent years. Crowd logistics is characterized by both sharing and green development [6], and thus, this business mode has been strongly supported by the local government.

The survey was conducted both offline and online (via e-mail, WeChat, and other social software) and was conducted for nearly 3 months, from September to November 2020. On average, the respondents were able to finish the survey in about 7 minutes. While we did not offer material rewards to the respondents, we promised that the participating enterprises would be given priority to cooperate with our team in future logistics experiments and studies. This was received positively by many crowd logistics enterprises. Among the 63 questionnaires sent out, 56 were recovered, equivalent to an overall recovery rate of 88.9%. Fifty questionnaires were valid, resulting in an effective recovery rate of 89.3%. The characteristic distribution of valid sample enterprises is shown in Table 2. In terms of ownership structure, private enterprises accounted for 64.36%, while state-owned enterprises accounted for 23.27%. More than 90% of the sampled enterprises have been operating for more than 10 years, and nearly 60% have annual sales of more than 100 million yuan.

4.4. Selection of Control Variables. The factors that remain unchanged or are not evaluated during the experiment are referred to as control variables [73]. To eliminate the potential influence of certain factors, we used some basic information on the respondent's enterprise as control variables. These include the ownership structure of the enterprises, the number of years it has been in business, and its annual sales. The control variables used in this study are listed in Table 2.

4.5. Data Analysis. Partial least squares (PLS) [74] structural equation modeling was used for data analysis and hypotheses testing. PLS is a component-based estimation method widely used in social science research to analyze quantitative data [75]. Compared with LISREL, AMOS, and other methods, PLS is more applicable for quantitative analysis of structural equations with small sample sizes and can process non-normally distributed data samples and test higher-order structural equation models [76]. In this paper, trust was used as a second-order latent variable, and PLS modeling can more accurately reflect the relationship between higher-order model variables. Furthermore, trust

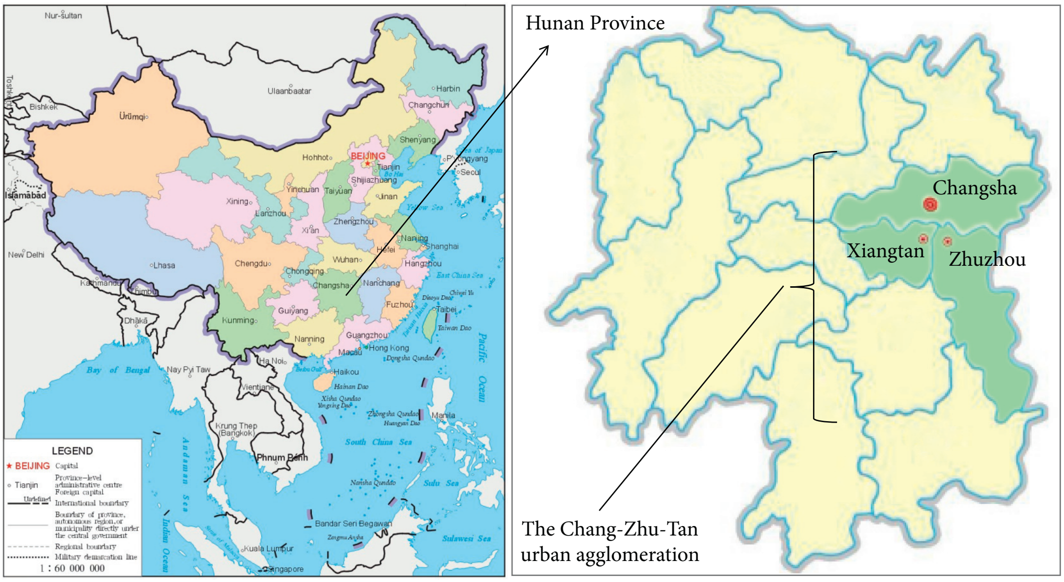

Figure 2: The cities where the data were collected.

Table 2: Descriptive statistical information of crowd logistics enterprises.

Category	Item	Ratio (%)
Ownership structure	The private enterprise	64.36
	Wholly foreign-owned enterprise	4.47
	Sino-foreign joint venture	7.90
	State-owned enterprises	23.27
Business years	< 10 years	9.41
	10–19 years	37.62
	≥20 years	52.97
Annual sales (yuan, CNY)	< 1 million	1.98
	1 million–5 million	4.95
	5.01 million–10 million	1.49
	10.01 million–50 million	6.44
	50.01 million–100 million	25.25
	≥100 million	59.9

between crowd workers and logistics companies is difficult to assess in the usual sense. SEM-PLS is well suited to analyze survey data in such complicated scenarios [76].

4.5.1. Reliability and Validity Tests. Reliability and validity tests are used to verify whether the measured scale is scientific [74]. In this study, Cronbach's alpha (CA) and average variance extracted (AVE) values were used. The lowest CA value was 0.814 (≥0.7), and the lowest CR value was 0.889 (≥0.7), indicating good reliability in the study's scale design [77]. The outer loading values for all observed variables were greater than 0.7 (the minimum is 0.807), as shown in Figures 3–5. The calculated AVE values were greater than 0.7 (the minimum is 0.729), as shown in Table 3, indicating that the indicator data had good convergence validity [77]. In addition, the AVE square root was greater than the correlation coefficient between latent variables. This suggests no collinearity among the latent variables and good discriminative validity for the model (as shown in Table 4) [77].

Considering that common method bias (CMB) may adversely affect the results of the study [78], a method of procedural control was used [46]. We first conducted a pretest before the formal questionnaire survey, which eliminated the problems caused by semantic deviations or difficulty of respondents to understand the questions. Then, we informed the respondents before the survey that their personal and business information will be kept confidential throughout the study [37].

4.5.2. Hypothesis Testing. Three models were constructed using SmartPLS3.0 software to analyze the following: the influence of goodwill trust and ability trust on logistics synergy (model 1, see Figure 3); the influence of goodwill trust, ability trust, and logistics synergy on the crowd logistics enterprises' operational performance (model 2, see Figure 4); and the mediating role of logistics synergy in the process of trust influencing crowd logistics enterprises' operational performance (model 3, see Figure 5). The first two models were compared with model 3 to determine whether logistics synergy plays a mediating role.

In the three validation models, the minimum R^2 value was 0.667, indicating good explanatory ability for the constructed research model had [77]. Based on the results shown in Table 5, H1b, H2, H3b, H4a, and H4b passed the hypothesis test (p-value ≤ 0.05 [77, 79]), while H1a and H3a (the path coefficient is negative, contrary to our hypothesis) did not pass the hypothesis test (p-value > 0.05 [77, 79]).

4.5.3. Findings

(i) Confirmed hypothesis

The results suggest that ability trust positively affects the crowd logistics enterprises' operational performance (H1b passed the hypothesis test), similar to the

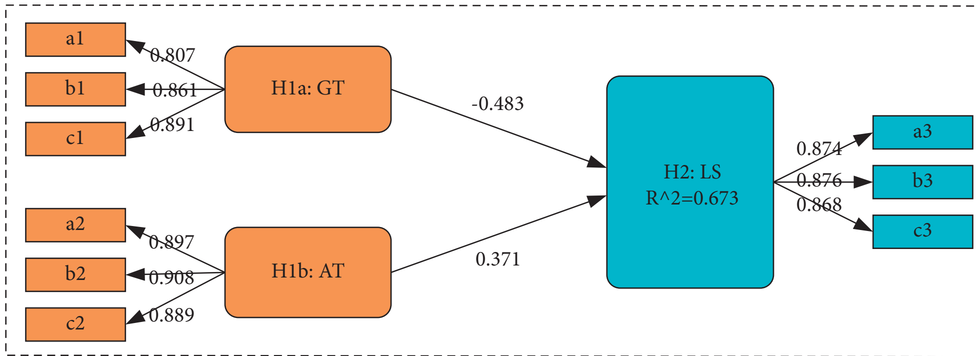

Figure 3: The model 1 results.

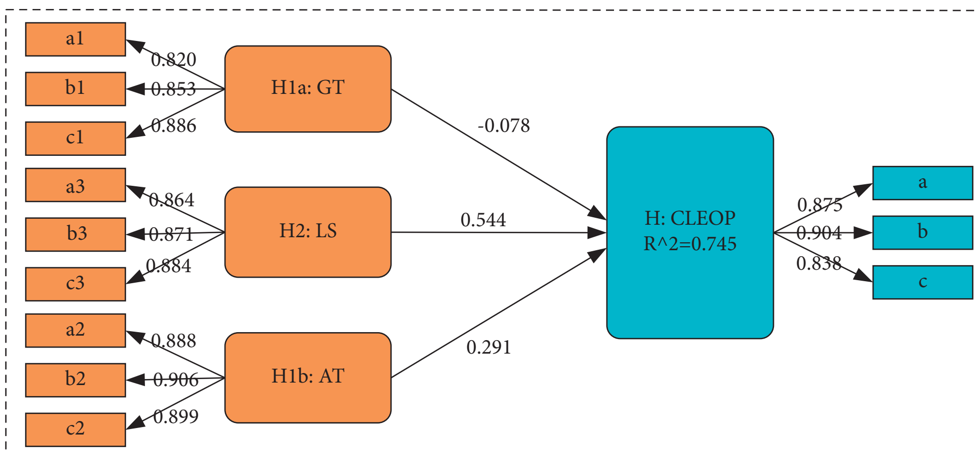

Figure 4: The model 2 results.

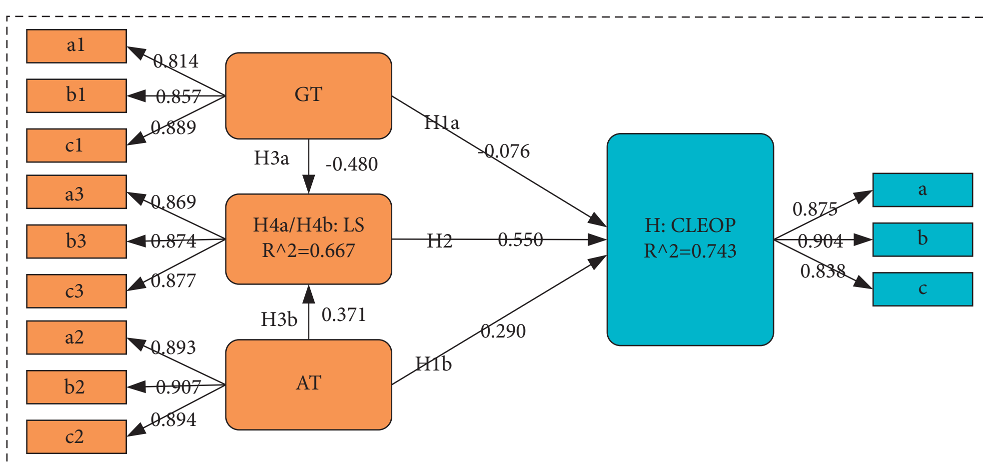

Figure 5: The model 3 results.

conclusions of some previous studies (e.g., Luo et al. [11], Hofer et al. [17], and Cheng et al. [80]). This means that if an enterprise has trust in its crowd workers' abilities to complete the delivery work, it will have a positive impact on the company's operational performance. Therefore, enterprises can improve the effectiveness of cooperative relationships and increase operational performance by developing and cultivating trust with their crowd workers.

Ability trust positively affects logistics synergy (H3b passed the hypothesis test). If the crowd logistics enterprise trusts that its crowd workers have the skills to complete the delivery task with high quality, it will help promote synergistic activities. Previous studies have

Table 3: Reliability and validity test results.

confirmed the positive effect of trust on synergy. For example, Wang et al. [8] found that mutual trust between suppliers and crowd workers can enhance their degree of synergy, provide enterprises with a competitive advantage, and help meet consumer needs.

Logistics synergy positively influences crowd logistics enterprises' operational performance (H2 passed the hypothesis test), and logistics synergy plays a mediating role in how ability trust positively affects operational performance (H4b passed the hypothesis test). This conclusion is similar to the findings of Erik [56] and Frank et al. [57]. Lu and Gao [81] believe that a good synergistic relationship between employees and enterprises is crucial for the success of supply chain operations. When traditional logistics enterprises carry out promotional activities on various e-commerce platforms, they often face multiple problems, such as overcrowded express warehouses and insufficient transport capacity. Through logistics synergy with crowd workers, enterprises can promptly share workforce, logistics, information, and other resources. This considerably reduces the costs of purchasing special delivery vehicles and recruiting formal employees. And with timely feedback, this system can flexibly respond to the fluctuations in customer needs, greatly improving service quality and customer satisfaction. The results show that ability trust not only affects the enterprises' operational performance directly but also has an indirect effect through the intermediary variable of logistics synergy. To promote the positive effect of ability trust in operational performance, logistics enterprises should build a good synergistic relationship with their crowd workers and regularly implement synergistic activities.

The results also show that logistics synergy plays a mediating role in how goodwill trust affects operational performance (H4a passed the hypothesis test). The results show that logistics synergy amplifies the inhibitory effect of goodwill trust on operational performance, which may be caused by the maturation of the crowdsourcing market and the increasing diversification of crowd workers. In the sharing of information, technology, and resources, goodwill trust between enterprises and crowd workers can be established relatively quickly. This trust may lead to a relaxed environment for synergy, leading crowd workers to take advantage and have opportunistic behaviors. These outcomes would not be conducive to the improvement of the crowd logistics enterprises' operational performance.

(ii) Unconfirmed hypothesis

Goodwill trust was found to have no significant effect on the crowd logistics enterprises' operational performance (H1a did not pass the hypothesis test). This conclusion is similar to the findings of Ganesan [67]. One possible explanation for this finding is that enterprises are mainly concerned with task completion when selecting crowd workers. Goodwill trust depends largely on the quality and intentions of partners and is a soft resource that gradually develops over long-term communication and collaboration. Since crowd workers are external temporary hires, enterprises are not compelled to have long-term communication, mutual familiarity, and identification. Moreover, goodwill trust is not as easily perceivable as ability trust. These could explain why goodwill trust did not significantly affect the operational performance of crowd logistics enterprises.

Goodwill trust negatively affects logistics synergy (H3a did not pass the hypothesis test), which is contrary to the research hypothesis of this paper. In most cases, the goodwill trust of the enterprise to the crowd worker can only be obtained by short-term emotional perception, which can easily lead to subjective wrong judgment. Some crowd workers who do not have the goodwill quality enter the enterprise, while some with excellent qualities are unjustly expelled from the market. If this goes on for a long time, the wrong goodwill trust cannot support the continuous development of logistics synergy between the two parties. Besides, in the absence of legal contracts, the crowd worker may take opportunistic behavior in the complex external environment, for example, the disclosure of some hidden, critical, and valid information (e.g., consumer's address and preference) shared by the enterprise. This will seriously violate consumer privacy and reduce customer satisfaction. Therefore, it may inhibit the positive effect of logistics synergy.

5. Discussion

In this paper, we proposed a total of seven research hypotheses, five of which have been verified. These five hypotheses are about the impact of trust on the crowd logistics enterprises' operational performance. The findings suggest that ability trust and logistics synergy are significant variables that directly impact crowd logistics enterprises' operational performance. Ability trust is positively correlated with logistics synergy; the more ability-trust logistics enterprises have in the crowd workers, the more conducive it will be to the collaborative operation of logistics enterprises. Logistics synergy was also found to play a mediating role between trust (both goodwill trust and ability trust) and operational performance. These findings largely support the conclusions of existing literature. These findings are similar to those of some previous studies (e.g., Ye and Kankanhalli, 2017 [9] and Huang et al., 2020 [37]), and we expect that these findings will be echoed in other contexts. The following are some theoretical and practical implications based on the results of this study.

5.1. Theoretical Implications. First, this study adds to the growing literature about the role of trust in crowd logistics. Crowd logistics has become a major research topic, with numerous studies being conducted from varying perspectives. For example, studies have been made analyzing the influencing factor affecting continued participation in crowd logistics, from the perspective of crowd workers (e.g., Ye and Kankanhalli [9], Liang et al. [33], and Huang et al. [37]). Several studies have investigated the influencing factors of implementation from the perspective of enterprises or platforms (e.g., Yao et al. [7], Bin et al. [32], and Bin et al. [64]). Some have explored the environmental sustainability of crowd logistics (e.g., Mladenow et al. [6], Rai et al. [28], and Lin et al. [31]). This paper focuses on the issue of trust, which provides a new insight for establishing a good cooperative relationship between the enterprise and the crowd worker.

Second, this study comprehensively investigates the impact of logistics synergy on the operational performance of crowd logistics enterprises. The perspectives of crowd workers and crowd logistics enterprises are taken into account and integrated into a theoretical model and analysis, as well as factoring in the effects of logistics synergy [41]. The addition of logistics synergy factors significantly improves the discussion on the relationship between the crowd worker and the enterprises, providing new insights into the subject matter.

Finally, this paper expands the application of commitment-trust theory in crowd logistics research. Informal cooperation between the crowd worker and the crowd logistics enterprises requires more trust to maintain the relationship between the two parties. This suggests that this theory can be used and expanded to other related disciplines (e.g., Zhu [38], Yao [39], and Cui et al. [40]). In particular, there is no legal, contractual relationship between the two parties.

5.2. Practical Implications. First, enterprises and platforms should scientifically evaluate the abilities of crowd workers and promote trust relationships with crowd workers. The results show that ability trust has a significant positive impact on the operational performance of crowd logistics enterprises. Therefore, enterprises should establish an assessment method in selecting experienced and skilled crowd workers to ensure that the crowd worker can fulfill their work on time [37] and provide high-quality delivery service [32]. Enterprises should also construct a personal credit system and a service quality evaluation system in their operations and adopt an elimination system for crowd workers with low distribution efficiency, high credit risk, and poor service levels. These measures can help enterprises reduce their distrust against opportunistic behavior when the environment is changing or unpredictable (e.g., the emergence of peak orders and the appearance of bad weather).

Second, enterprises should strengthen crowd logistics mechanisms that enhance synergistic efficiency. The results show that logistics synergy is a significant mediating variable increasing the operational performance of enterprises. In crowd logistics, enterprises and crowd workers have broken through the traditional boundaries of enterprise capital specificity, raising higher requirements on cross-organizational sharing, resource allocation, and collaborative logistics operations [6, 28]. Therefore, enterprises should maintain open communication with their crowd workers, sharing timely internal and external logistics information and quickly responding to changes in the external environment. Building sound information feedback and sharing mechanism is essential to ensure that logistics information can be sent and received accurately, timely, and efficiently and raise the speed and reliability of delivery services.

Finally, enterprises should invest in skills training for crowd workers. This study found that most crowd workers registered on the crowdsourcing platform are part-time personnel who have not received standardized professional training. This has resulted in the uneven quality of services, affecting enterprises' operational performance [6]. Enterprises should conduct systematic training for part-time staff, particularly those involved in crowd delivery operations [37]. Enterprises should also regularly carry out skills development on safety management and risk prevention and provide other relevant training to their crowd workers to improve their professional skills and minimize risk concerns.

6. Conclusions

With the emergence of the sharing economy, huge demands for logistical services have created the distribution mode of crowd logistics [82]. In route selection and optimization, the use of information communication, satellite location, and navigation provides crucial technical support for the development of crowd logistics. Trust and synergy between crowd workers and the crowdsourcer, however, have become essential challenges in the growth and development of crowd logistics in day-to-day operations. To address some of the current knowledge gaps on the subject matter, this study analyzed the impact of trust between crowd logistics enterprises and crowd workers on operational performance and integrated logistics synergy into the theoretical model. The results indicate that ability trust and logistics synergy are significant variables, directly increasing the operational performance of crowd logistics enterprises. Ability trust was also found to be positively correlated with logistics synergy. The results also show that logistics synergy plays a mediating role between trust (both goodwill trust and ability trust) and operational performance. This work focuses on the examination of the trust relationship between the crowd worker and the crowdsourcer, which is beneficial to promoting the sustainable development of urban logistics.

Based on the results, we recommend that logistics enterprises and platforms evaluate their crowd workers' capabilities and promote trust relationships with them. Enterprises should strengthen crowd logistics mechanisms that stimulate collaborative efficiency. Enterprises must invest in training and developing their crowd workers to boost their abilities and encourage trust, which would eventually enhance their operational performance.

There are some limitations to this study. First, the conclusions may have some regional characteristics. The study area was the Chang-Zhu-Tan urban agglomeration, and some of the results may have been affected by local factors. Future studies can focus on other regions and other scales and compare the results of this study. Second, this paper focused on the influence of trust on operational performance and did not consider other factors that could have affected the results, such as incentive mechanisms and satisfaction. Future research should consider the impact of other factors on the operational performance of crowd logistics enterprises. Third, the commitment-trust theory and logistics synergy theory are applied to this study. Different theoretical foundations may necessitate different factors to be examined, and additional research would be required. Fourth, this study surveyed mainly senior managers. Future studies should consider surveying crowd workers and compare the results of this study. Finally, as part of the industry 4.0 development process, we must continue to pay close attention to and investigate the relationship between crowd workers and logistics companies. Crowd workers are mostly managed by platform algorithms rather than actual managers in the context of the rapid growth of computer algorithms. Therefore, how enterprises handle the balance between managers and platform algorithms has a big impact on how crowd workers and logistics companies trust each other.

Academic Editor: Tongguang Ni

In this paper, a 9-layer convolutional neural network with 4 convolutional layers, 4 pooling layers, and 1 fully connected layer is designed to recognize the emotions of digital learning images in the era of big data. The convolutional neural network is trained using digital learning images that have been labeled with emotions, and the final test shows that the network has good recognition results. This in turn causes the information overload problem to arise. And combined with the questionnaire results and interviews, it was found that there are problems of technology for technology's sake, teaching for teaching's sake, and in multimedia teaching, and these will add to the psychological and visual sensory burden of students and easily cause the information overload problem. The types of information overload problems in multimedia-assisted teaching are summarized as follows: unreasonable presentation of information, which causes audiovisual redundancy; too much teaching irrelevant information, which increases the external cognitive load; and an uncoordinated audiovisual environment, which increases the external cognitive load. Starting from the perspective of the integration of preservice to in-service art teachers' new media art curriculum design and teaching ability development, three representative teacher education cases were studied using a combination of teaching practice and case tracking methods to summarize the successful experiences and effective ways of art teachers' new media art curriculum development and teaching ability development, which will provide future art teacher training and in-service teachers' professional development. Both are below 5%. The types of funny emotions are mainly distributed in animation teaching methods. Animation resources are generally well designed in color and layout and can convey good visual emotional characteristics. In other types of images, the emotional distribution level of funny is less than 10%. It is worthwhile to learn from this experience.

1. Introduction

After entering the era of big data, human beings will face more impacts between big data and culture, artificial intelligence is developing rapidly, the world culture, technology, and art are facing new challenges, and images are flooding our lives like never before. However, the private demolition of cultural and historical buildings to build mansions, the piracy of famous Parisian architectural communities, the construction of rehashed Egyptian pyramids, and the placement of indecent public sculptures, all these ugly cultural images reflect the lack of people's aesthetic level, cultural respect, and creative consciousness, repeatedly becoming an obstacle to the development of civilization [1]. The development of civilization cannot be reduced to the sacrifice of science and technology. The aesthetics and inner cultural beliefs of human beings are the important force of the development of the times. In contrast, the current situation of art museum education in China is that art museum education activities are in various forms, but they lack the depth and extension of education and do not play a role in improving the visual literacy of citizens [2]. This study aims to explore the current situation of art museum education, understand the impact of art museum education on students' visual literacy, explore how art museum education should promote the improvement of students' visual literacy in the context of the big data era, cultivate a generation of citizens with good artistic cultivation, and promote the development of a generation of civilization progress [3]. The advent of the big data era has exposed a large amount of information to life, impacting modern human attitudes of thought and visual perception. Two hot zone comparison pictures with very strong synthesis, very weak sequence type, very weak synthesis type, and very strong sequence type are referred to as comprehensive type and sequence type hereinafter. The large volume and varying quality of information affect human cognition while testing modern humans' discernment and aesthetic ability of current information. The rapid development of social civilization is often hindered by the level of human's aesthetic cognition, such as the out-of-place urban sculptures and the high ratings of vulgar films and TV shows, which reflect the lack of quality of life and the pursuit of "beauty" in the current impetuous and fast life of human beings. This is the downside of the rapid development of material civilization and the difficulty of the public's visual literacy and civilizational awareness to keep up with the development of civilization.

The rapid development of information technology has not only revolutionized our work, study, and life but has also had a profound impact on the field of education and teaching, greatly contributing to the improvement of the efficiency of teaching and learning in schools [4]. In recent years, the way of teaching and learning in schools has also undergone major changes with the advancement of technology. With the continuous reform and innovation of technology, we have achieved a change from the early days of using audiovisual and auditory media such as slide projectors, video visualizers, tape recorders, radios, and other teaching devices to the present-day application of interactive whiteboards, multimedia computers, and network teaching platforms. The application of these devices and related teaching software in teaching has not only changed the effect of face-to-face teaching but also made it possible to realize distance network teaching across the limitation of space and distance. Based on the characteristics of the Internet itself, online network teaching is more informative, richer in learning resources, and more interactive in real time [5]. The comprehensive learning style is more interested in graphic information. When studying, he can integrate graphic information more closely, and the reading time is shorter. Participants with strong sequence type basically followed their logic when reading text. And with the continuous advancement and innovation of artificial intelligence, big data, cloud computing, and other information technologies, the impact of technology on the traditional classroom and changes to the field of education will grow, thus benefiting more schools and teachers and students [6]. Special emphasis is placed on the important role of the modern media arts curriculum in developing students' core literacy in the subject. Accordingly, how to give full play to the teacher's role in achieving effective teaching and better development of subject core literacy within the limited class time also becomes an important issue that must be properly addressed in teaching. In this study, the author tries to put the unit teaching "zero into whole" design concept throughout the modern media art course and strives for more focused teaching objectives, more optimized teaching content, and more comprehensive student abilities [7].

In today's booming modern information technology, the human scientific process is developing at an unprecedented speed, and the power of increasingly advanced information technology for film and television art is also more profound. As the seventh category of art, film and television art is different from painting, music, theater, and other ancient art forms, it has been accompanied by the process of science and technology since its birth, and film and television have a high degree of integration with modern information technology and tacit understanding. Modern information technology has pushed film and television art to take a big step towards industrialization, and it is also under the high degree of integration and interaction between information technology and film and television art that digitalization, virtualization, high speed, technology, specialization, and internationalization of film and television art have been realized, and information technology has had a profound impact on the creation, dissemination, and consumption of film and television, as well as on the aesthetics of film and television. This is the most favorable era for the development of the film and television industry, and modern information technology is also in the era of becoming the strongest development, which is the best era in human history, but at the same time the worst era. Under the influence of modern information technology, does film and television art grasp the most essential form of realization of film and television art? Without the help of modern information technology, will film and television art lower its level, or even lose its audience and box office? Film and television art as the seventh category of art forms has been in the form of cutting-edge and rapid performance. As the audience, we are undoubtedly experiencing great changes, and this change is also happening under the influence of modern information technology. The closer the combination of the two, the greater the mutual force will be. The content of both sides is constantly changing, the form is changing as well, and the audience's experience is also changing. The film and television art both technically and artistically has produced great fluctuation and impact.

2. Current Status of Research

Research on blended learning is much earlier abroad than at home. At present, the research on blended learning is mainly reflected in the concept and how it is applied. It is a local theory born and grown in China, and the research is still in the initial stage [8]. After the theory was proposed, a seminar on multimedia picture language was held at Tianjin Normal University. Since picture art design before that mostly applied to other disciplines of art theories, Lande et al. proposed a multimedia picture language art theory, which solved the problem of borrowing other disciplines of art theories [9]. After that, Li combined multimedia picture art theory with cognitive psychology to study the cognitive law of multimedia picture language and explored the cognitive law that should be followed in the design of multimedia teaching resources [10]. Patel and Sharma further developed multimedia picture language in "Research on the Construction of the Theoretical System of Multimedia Picture Linguistics," drawing on other linguistics, psychology, educational technology, and other related achievements, which provides a reference for multimedia picture language subsequent research providing a referenceable research framework as well as ideas and methods [11]. The strategy emphasizes three major educational resources, namely, educational policy and planning, teacher development and information and communication technology, and four priority development areas, namely, literacy, vocational and technical education and training, higher education, and learning process and outcome enhancement, and three major learning activities, namely, global citizenship education, education for sustainable development, and health education, intending to promote quality and comprehensive lifelong learning and thus fostering creativity and responsibility [12]. How to use multimedia to facilitate human learning is a central question in the study of multimedia learning. Ramsgaard Thomsen et al. divides the study and development of multimedia teaching and learning into two categories: the first category is technology-centered, and the second category is learner-centered [13].

Some foreign language colleges and universities began to have more advanced e-teaching equipment, such as simple language laboratories, and with the rapid development of e-education, e-education equipment was gradually applied to multimedia-assisted teaching. After entering the nineties, China's information technology developed rapidly, and since then, multimedia-assisted teaching has also been developed significantly. The research on multimedia teaching in this period is also more in-depth than that in the previous period, and there are researches on how multimedia teaching is used in specific subjects in colleges and universities and further analyses on how multimedia teaching is used in teaching practice [14]. 51.59% of the students said that the background color matching of the text in the multimedia courseware is relatively reasonable, which will not cause visual disturbance or redundancy, but 48.41% of the students said that the multimedia courseware has unreasonable places in the color matching; this will also disturb the learning and cause visual redundancy for students. Along with the increasing progress of education informatization, the use of multimedia-assisted teaching as a modern teaching tool has become increasingly common in the teaching of colleges and universities and has gradually become an important teaching tool in colleges and universities. The educational content in modern media art is provided, but it has certain problems, such as the prevalence of low attention, fragmented teaching content, single teaching method, fewer research results, and lack of relevant knowledge of teachers [15]. In response to these problems, this study uses literature method, questionnaire survey method, and comparative method to study the current situation and problems of the modern media art curriculum, and after analyzing the reasons, based on postmodern curriculum theory, constructivist teaching theory, theory of unified curriculum and interdisciplinary teaching, evaluation theory, multiple intelligence theory, and visual culture theory to compile and program design for new media art in secondary schools [16]. The birth and development of the art of cinema and the evolution of the art of cinema were accomplished in an integrated way with the role of technology: for the emergence and invention of the film camera and projector before the emergence of film as real art, due to technological improvements in the art of film and television added the element of sound, and the development of film technology contributed to the journey of color film, with the technology of film stunts, the Electricity Bureau could produce fantasy. The spectacle nature of cinema only then discovered, and cinema was further released on a deeper level.

In the context of a rapidly developing information society, the development of modern media art has grown rapidly and has fully penetrated all aspects of life, providing a favorable environment and excellent technology for the development of modern media art curriculum and teaching in schools. For the current generation of high school students, their social background and living environment have also resulted in greater interest and enthusiasm for digital products and video art than traditional art media, which is also an intrinsic motivation for the continuous development of modern media art learning modules.

3. Optimization Analysis of Hybrid Multimedia Art and Design Teaching Mode under Big Data

3.1. Multimedia Art Design Big Data Design. As one of the main manifestations of multimedia learning resources, the design of digital learning screens and their related research should be based on a theory that is consistent with human learning styles and should be explored and practiced in conjunction with the cognitive theory of multimedia learning. Richard E. Mayer of the University of California proposed a cognitive theory of multimedia learning based on three views of cognitive science and pointed out that multimedia-based learning activities should include three assumptions, namely, the dual-channel assumption, the limited capacity assumption, and the active learning assumption, to explain the cognitive tendency of learners when using multimedia resources for learning. The dual-channel hypothesis refers to the fact that people have separate information processing channels for materials with visual and auditory representations [17]. Paying attention to result evaluation, process evaluation is relatively lacking, and so on. The author also started thinking and researching and believes that modern media art curriculum learning evaluation tools should be developed, and learning evaluation dimensions should be established. In the evaluation, modern media art creation and appreciation capabilities should be integrated, and students should be clear that modern media art is not just creation of works. When visual information such as on-screen text and images containing knowledge, content is delivered to the learner's eyes, and the acquired information is processed in the visual-image channel; when narration, background music, and other information are presented to the learner's ears, the acquired information is processed in the auditory-verbal channel. Meyer argues that although the acquired information enters the information system through one channel, the learner can change the processing channel through a switch in representation. For example, when a learner looks at a text, he or she first represents the information through the visual-image channel, but a learner with the ability to read text can convert the information received through the visual into audio information, and the relationship between the two can be transformed through different representations.

The active processing hypothesis refers to the idea that learners actively engage in cognitive processing to build a coherent mental representation of their experience, meaning that learners' activities in processing multimedia information are active rather than passive. Meyer states that the three processes of active processing involve selection, organization, and integration. Selection means noticing multimedia information and creating discourse and picture material; organization means establishing intrinsic connections between the selected knowledge information; and integration means establishing extrinsic connections between the organized verbal model and image model and prior knowledge, thus facilitating meaningful learning to occur. Multimedia images should be composed in a way that is consistent with the subject matter to be represented and with certain artistry, like the art of speaking and presentation. Having a certain art is, for example, aesthetic, but more important is the effectiveness of its expression, which can be explored at the content level, the cognitive level, and the picture structure level in terms of its logical laws. Xiaofeng described the 12 multimedia design principles, which include the multimedia cognition principle, spatial proximity principle, time proximity principle, always principle, channel principle, redundancy principle, and personalization principle [18]. Thereby, this strengthened the harmonious interaction between learner's emotion and picture emotion in the smart learning environment. The coding of the digital learning screen can help users understand the attributes of the screen from the side. However, it is macrolevel, difficult to play a practical role, not yet able to solve the actual problems faced. Multimedia screen language has initially formed its unique design methods and rules based on the rules of interpretive information design, explored the logical main line of screen representation content, and made multimedia design followable from the relationship between media, between media and content, and between media and surrounding environment. The basic framework of big data multimedia screen linguistics theory is shown in Figure 1.

Things are universally connected and are organically linked to each other, interdependent and mutually constraining; there are no things that exist in isolation from the surrounding things and conditions. Therefore, in home education statistics, in a particular study not only the thing itself, but also other things that interconnected with it, and find the connection that exists between them through reasonable ways and means. The interdependence between things or phenomena can be broadly divided into two kinds: one is the function relationship, which is a kind of deterministic relationship; that is, when the value of a thing changes, the value of its related things or phenomena will also change accordingly. There is also a correlation, which means that there is a certain relationship between things, which cannot be described by a fixed causal relationship, and at the same time, although the correlation is not definite, it is regular.

Both regression analysis and correlation analysis can be used to describe correlations, and both can measure the relationship between two or more variables to determine the relationship between them. This is what regression analysis and correlation analysis have in common. However, broadly speaking, regression analysis is subordinate to correlation analysis, and strictly speaking, there is a difference between the two. The purpose of correlation analysis is to measure the closeness of the relationship between two random variables. Regression analysis, on the other hand, is more oriented towards changes between variables, describing their relationship through mathematical expressions and thus determining the extent to which a change in one or several variables affects another identified variable [19]. Using multidistance regression analysis, it is possible to determine how closely one independent variable and the dependent variable are related and to detect factors that are less well related, but whether to discard the worst independent variable or whether that independent variable is at all users cannot be simply based on the results of the mathematical treatment and should be considered holistically based on expertise. The current study established the effect of the blended learning experience as the dependent variable and the corresponding independent variables constructed from the blended classroom process experience and closely related to the multimedia screen, and the equation of the multiple regression was expressed as follows:

$$\begin{aligned} Y &= b_0 - b_1 x_1 - b_2 x_2 - \cdots - b_i x_i, \\ Y_i &= X_i \beta - u_i. \end{aligned} \tag{1}$$

Multiple linear regression can use ordinary least squares, maximum likelihood, or distance to estimate the parameters, provided the underlying assumptions met. After the regression function is obtained with the data, statistical tests need to be performed on the sample regression function to determine the reliability of the estimates, and the statistical tests that need to be performed include goodness-of-fit tests, tests of overall linearity of the equations for significance, and tests of significance of the variables:

$$R = \sqrt{\frac{\mathrm{ESS}}{\mathrm{TSS}}}. \tag{2}$$

The prediction of user ratings can be viewed as an act of filling in missing values for a residual user-item rating matrix; that is, given a sparse matrix where the rows are items, the columns are users, and the specific values of the matrix are user-item ratings, the matrix is constructed to fill in the remaining vacant parts to obtain the user-item ratings, assuming a low-rank matrix, the user-item rating prediction is transformed into a minimization problem.

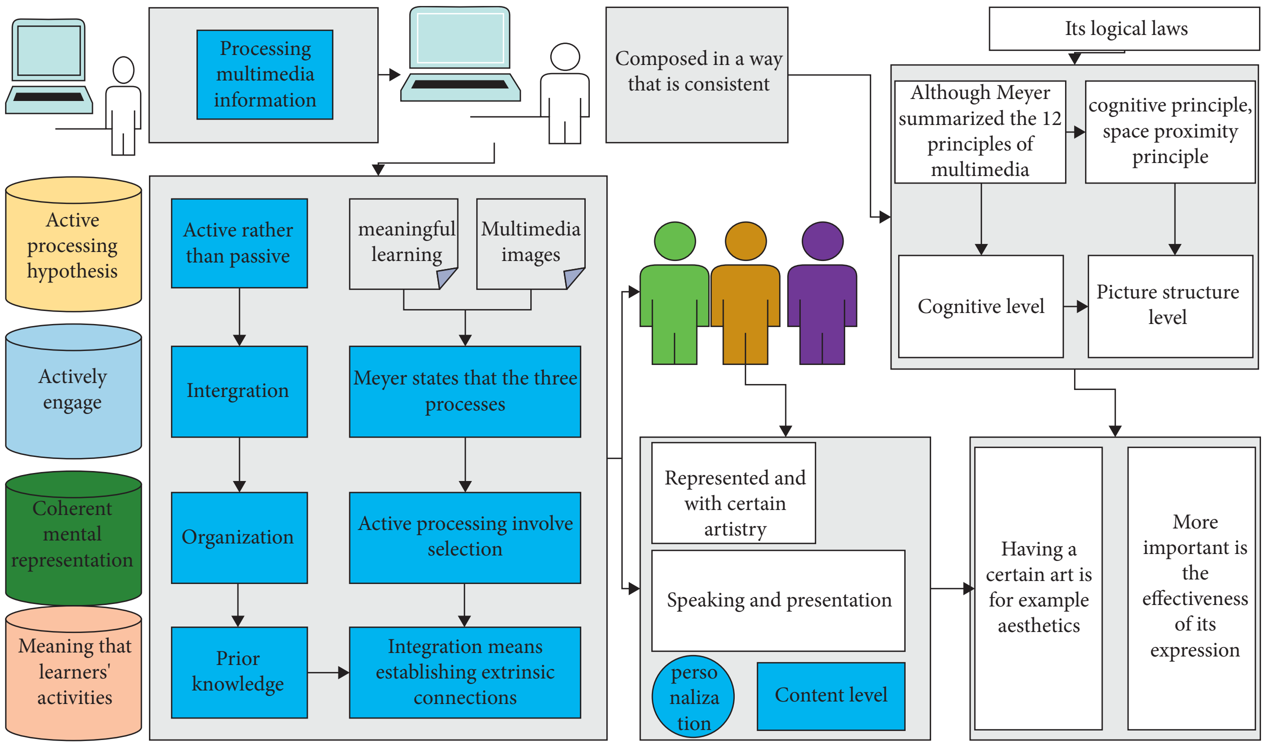

Figure 1: Multimedia art and design big data framework.

$$\arg\max \left\|X_i\right\|^e - \left\|X_i\right\|^2 + \frac{a}{2}\|w(X+Y)\|^e,$$
$$\arg\max \left\|X_i\right\|^2 + \left\|X_i\right\|^2 - \frac{a}{2}\|w(X+Y)\|^e. \tag{3}$$

Large classes are the main form of teaching in China at present, with an average of fifty students per class in primary and secondary schools, and as many as fifty to sixty in colleges and universities, and as few as twenty to thirty, so it is difficult to realize that only one student plays the role of lecturer in each class, but it is possible to work together in small groups to teach a topic. At the same time, conditions should be created for the subordinate information management system to be extended and refined based on this classification system. When students choose a topic, due to the limitations of their knowledge and ability, they need to ask the teacher for advice or learn systematically through the Internet, and so on. Therefore, the hybrid teaching mode needs to be combined with other teaching modes, and collaborative learning and peer-administered teaching can effectively support the hybrid teaching model.

$$\delta = \sum_{i\in U, j\in U}^{R} \sqrt{p_i(r)p_j(r)}. \tag{4}$$

To ensure the accuracy and comprehensiveness of the prediction scores, the prediction results of the blending steps are mixed to obtain the final prediction score matrix.

$$\varphi_i = \frac{1}{1-e^{-\pi i}}. \tag{5}$$

Teaching and learning can be counterproductive. Therefore, teachers need to do a lot of preparatory work when implementing blended learning models. First is that the peer-administered content should be selected considering both the ability level of the giver and the recipient. Second, they should be good at identifying students' strengths and weaknesses. Third is to determine the means of instruction based on the class specifics and the instructional goals of the course. Fourth, the teacher should monitor and guide the entire process, and after assigning tasks to the students, he or she should frequently learn about their progress and guide and supervise them. Fifth is to conduct reasonable teaching evaluation, not only to complete the dissemination of knowledge, but also to focus on the process of comprehensive ability improvement so that this evaluation should serve to check the effectiveness of teaching, but also protect the students' motivation, as shown in Figure 2.

The personalized recommendation method based on potential factors incorporates methods such as matrix decomposition complementation, which not only considers the potential factors of users and items but also considers the respective neighbor information sets of users and items when performing matrix complementation. First, the user rating matrix is constructed, and the user potential factor information and the project potential factor information are modeled and stored in the HBase database, and the user neighbor information set and the project neighbor information set are derived using the similarity calculation formula and stored in HBase; then the original user project rating matrix is matrix-decomposed to obtain the preliminary prediction rating matrix

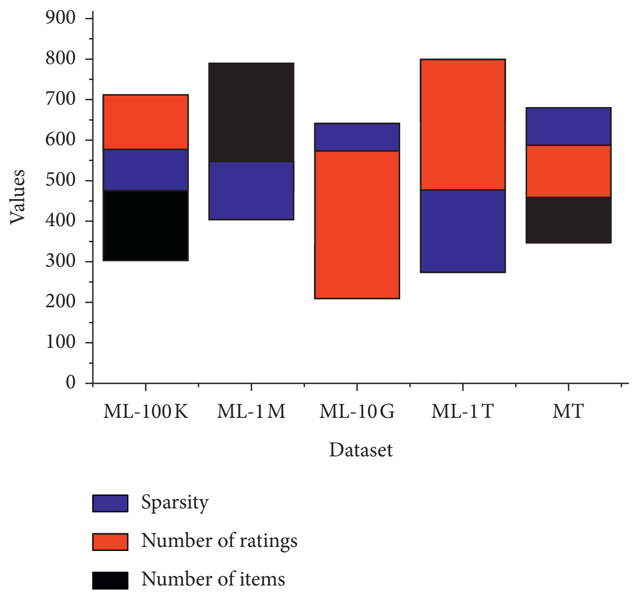

Figure 2: Big data dataset characteristics.

and the true prediction rating error value and stored in the database table. The scoring error values are stored in HBase as database tables.

3.2. Hybrid Multimedia Art and Design Teaching Mode Optimization Design. The principle of systematicity requires that when classifying digital learning images, it is necessary to determine their different subordination and order according to the relevant links of their essential properties so that all digital learning images form a reasonable, orderly, and hierarchical classification system among themselves. The classification of digital learning screens guided by the principle of systematicity helps teachers and researchers to clarify the hierarchical relationship between different screens and their essential properties, which helps to improve the efficiency of classification. The improvement of visual literacy can promote the faster and better development of civilization. Extensibility means setting up shelter categories to ensure that when new things or concepts are added, the established classification system is not disrupted, and it should also create conditions for the lower-level information management system to extend and refine based on this classification system. In other words, the classification of digital learning screens is changed after the design is completed, and small-scale adjustments and changes should be made to the classification rules promptly when there are screens whose essential properties are completely different from the previous classification system or have subordinate relationships.

Practicality requires that the classification criteria for digital learning screens should be such that the actual needs of all relevant units in the system are met as much as possible while meeting the total tasks and requirements of the system. In this study, the classification of digital learning screens developed should first meet the organization and arrangement of all screens based on local disks. The second is to support the subsequent work of this study to achieve accurate identification of digital learning screen emotions, thus enhancing the harmonious interaction between learner emotions and screen emotions in the intelligent learning environment. The encoding of a digital learning picture can help the user to understand the attributes that the picture possesses from the side. For example, a simple encoding can identify the characteristics of the subject to which the screen belongs, the school section to which it belongs, and so on, and facilitate quick retrieval and classification in the computer. In addition, as the database of digital learning screens becomes larger and larger, the need for coding comes to the fore; for example, a standard and stable coding strategy helps to improve the accuracy of classification, the speed of retrieval, and the depth of the database, as shown in Figure 3.

With the rapid development of the Internet, the total amount of digital learning resources has also shown exponential growth. In the research process, it is difficult to manage such many learning images efficiently without a stable and reasonable coding method. With the support of coding, digital learning images with the same properties can be quickly categorized using regular expressions. In addition, when using deep learning to train classification for emotional features of images, the input data can be automatically labeled during the data preprocessing stage to improve training efficiency. Promoting the development of a generation of civilization and progress, the advent of the era of big data has exposed a large amount of information in life, impacting modern people's thinking, attitude, and visual perception.

Sentiment estimation of digitally learned images relies on many digitally learned images as training data, and the amount of training data and labeling accuracy can have an impact on the level of sentiment prediction. In this study, a supervised learning convolutional neural network is used, so image preprocessing such as sentiment labeling of the training data is required before training. According to the previously mentioned emotion-type classification criteria, this study needs to annotate 17,433 digitally learned images according to 14 emotion types: warm, cheerful, lively, funny, exaggerated, humorous, funny, bleak, boring, dull, tedious, unreal, thrilling, and scary, and the annotation intensity is divided into 4 levels, where 0 indicates the lowest intensity and 3 indicates the highest intensity [20]. In this study, 17,433 digital learning images were annotated utilizing paid recruitment of annotators. Except for the necessary training required before the annotation process began, the emotional value of each digital learning image and its intensity calibration depended on the subjective experience of the annotator and was not influenced by the subjective consciousness of the researcher. However, the researcher conducted strict supervision throughout the annotation process to ensure that the entire work was carried out smoothly.

In the modern media course learning, the evaluation link is relatively lacking, and there are also some problems; for example, the evaluation criteria are vague, and the evaluation content is not detailed and clear; the focus on the results of the evaluation, the process of evaluation is lacking. The

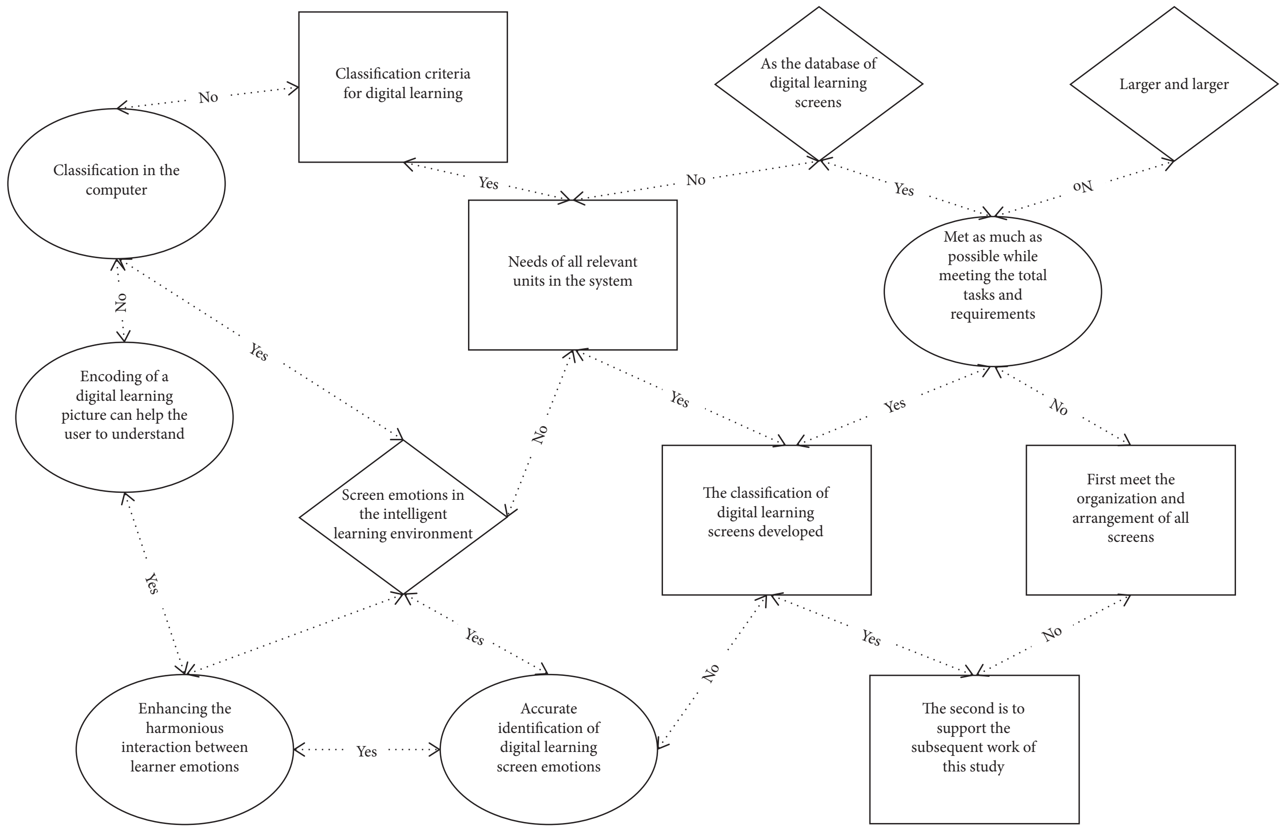

Figure 3: Steps to optimize the hybrid multimedia art and design teaching model.

author also started to think and research that modern media art course learning evaluation tools should be developed, set up learning evaluation dimensions, in the evaluation of modern media art creation and appreciation ability into one, guide students to clarify the fact that modern media art is not only the creation of works media, technical changes, but also learning, creation ideology is subversion and innovation of the concept, and advocate a tiered evaluation. The learning assessment rules for the Truth Modern Media Art learning ability level are shown in Figure 4.

Interesting content in multimedia courseware is designed with the initial intention of attracting students' attention in the hope that they can focus on classroom learning. After investigating the interesting but irrelevant content in multimedia courseware, it was found that 31.21% of the students in this study thought that there was no such irrelevant content that would disturb students' learning [21]. Based on the characteristics of the Internet itself, online network teaching has more information, richer learning resources, and stronger real-time interaction. However, 63.38% of the students believe that there is content in multimedia courseware that disturbs students' learning. Thus, it seems that the content in multimedia courseware needs to be filtered and not interesting for the sake of being interesting.

51.59% of the students said that the matching of text and background colors in multimedia courseware is reasonable and does not cause visual disturbance and redundancy, but 48.41% of the students said that the color matching of multimedia courseware is unreasonable, which also disturbs learning and causes visual redundancy for students. This shows that beautiful multimedia courseware can attract students' attention, but too much pursuit of gorgeous decoration and neglect of the integration with the content of the courseware will also cause visual disturbance and redundancy; or the courseware is too "plain," the content of the courseware is all words, lack of artistry and technicality of the courseware, which will make multimedia teaching. This will make multimedia teaching too dull so that the courseware programming board or the electronic version of the lecture notes will not be able to reflect the advantages of multimedia.

4. Analysis of Results

4.1. Multimedia Art Design Large-Database Design. The total gaze time for the different modules of the multimedia screen represents the sum of the duration of all gaze points within the subject's area of interest, and these data can reflect the extent to which the learner is processing the knowledge. It has become an important issue that must be properly resolved in teaching. In the research of this subject, the author tries to integrate the design concept of unit teaching "disintegrating into a whole" through the modern media art curriculum and strive to focus on teaching goals, optimize teaching content, and make students more comprehensive. A longer gaze time means that the area is more likely to attract the learner's attention or to be more difficult to process. Information that receives more

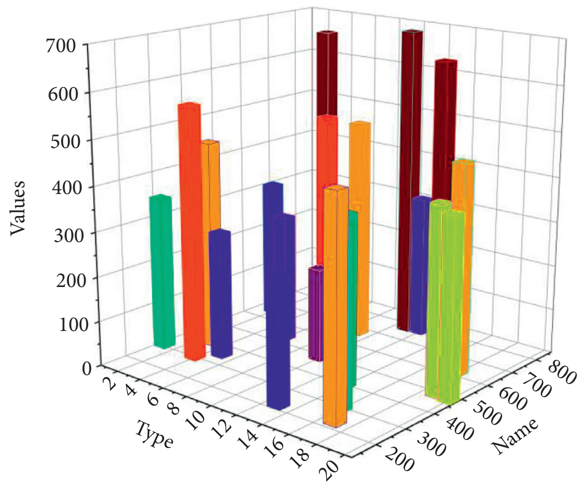

Figure 4: Clarity of instructional information presentation.

attention is more likely to be transmitted for further processing, as shown in Figure 5 below for the total gaze time data for the graphic area. It can be found in the statistics that the average total gaze time in the text area of the whole multimedia screen is significantly longer than the total gaze time of the diagram, which shows that the learners take significantly longer to process the knowledge information described in the text, but it does not mean that the diagram information is not important because the two kinds of information have different characteristics in themselves. Linear, abstract, and comprehensive are the distinctive features of textual language, which is a step-by-step complete expression of the complete content through an idea, requiring a strong logic, and therefore takes more time to read. Diagrams are three-dimensional and visual, and good diagrammatic information can be understood briefly, but it is condensed information and inevitably misses something about what is being expressed. The integrative learning style is more interested in diagrammatic information, and it can combine diagrammatic information more closely and take less time to read when studying.

Subjects with a more sequential style read the text following its logic as well as in step, and the overall time spent is relatively long, as will be reflected in the statistics of the hot-zone data later. As a result, when designing multimedia images, we should ensure that the images and texts are well combined, as this can produce better visual effects and aid readers' memory.

To further explore how students with different learning styles allocate their attention in multimedia screens, this eye-movement experiment was conducted to compare eye-movement hot zones based on four dimensions of learning styles. The digitalization, virtualization, high-speed, technology, specialization, and internationalization of film and television art have been realized. Information technology has also had a profound impact on film and television creation, dissemination and consumption, and film and television aesthetics. The hotspot diagram allows us to visualize the subjects' gaze, revealing differences based on the size, location, and some color areas displayed in the hotspot zones in the diagram. Two hot-zone comparison images with integrated very strong and serial type very weak and integrated very weak and serial type very strong are used, after which they are referred to as integrated and serial type. Integrated students had a slightly smaller gaze range than sequential students and significantly fewer hot zones than sequential subjects. The eye-movement data for the two learning styles were extracted, the average dwell time and the proportion of the two areas in the graphic text, and the average number and proportion of gaze points, as shown in Figure 6.

From Figure 6, it can be found that the total gaze time differs between the two types of students on the same screen, but the ratio of the gaze time on the picture to the time on the text is similar, and a similar pattern can be found by counting the other three dimensions of learning styles. When the narration, background music, and other information are presented to the learner's ears, the acquired information will be processed in the auditory-speech channel. Thus, different learning styles have a similar degree of relative processing of knowledge on the same picture, no picture would differentially affect different learning styles, and therefore multimedia pictures should have regular uniformity rules. Firstly, reference was made to existing questionnaires related to blended learning and multimedia screens, and Professor You Sewing's literature related to the language of multimedia screens and blended learning was also consulted and studied and then analyzed with due characteristics, and 13 variables were established from three aspects. After that, it was sent to the tutor and the students of educational technology to collect feedback for modification.

4.2. Results of the Optimization of the Hybrid Multimedia Art and Design Teaching Model. The distribution of positive emotions in both the university and social education levels showed a significant downward trend compared to the other segments, while emotions such as dull and dreary showed a significant increase, and the level of the distribution of negative emotions in these two segments was already higher than the level of positive emotions. There is a certain degree of art such as aesthetics, but more importantly, the effectiveness of its expression and its logical laws can be explored from the content level, the cognitive level, and the picture-structure level. Among the other emotion types, the distribution of emotions such as tedious, thrilling, and scary does not differ significantly from the distribution of the above three academic periods, except for unreal, which has increased. From the distribution of emotions, the design of teaching resources at the university and social education levels focuses more on the transmission of knowledge content, and the images are boring and have a single layout, which makes it difficult to convey positive emotions to learners in terms of visual characteristics. Figure 7 provides a visual representation of the distribution of emotions in each digital learning screen by school level.

The warm emotion type of digital learning screen is mainly present in teaching methods such as playing sound, animation, multimedia PPT, image, drawing, classroom, etc.

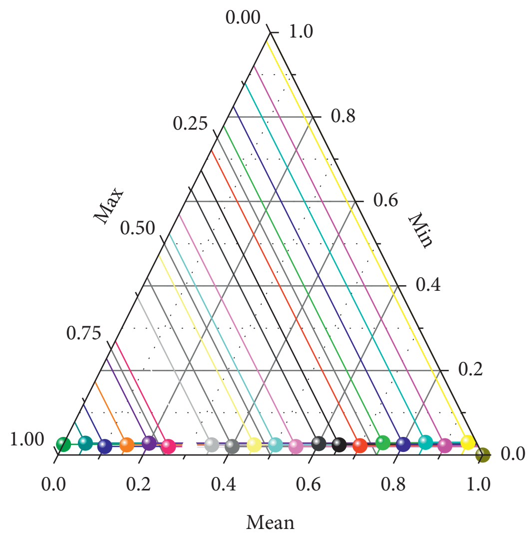

Figure 5: Description statistics of attention time.

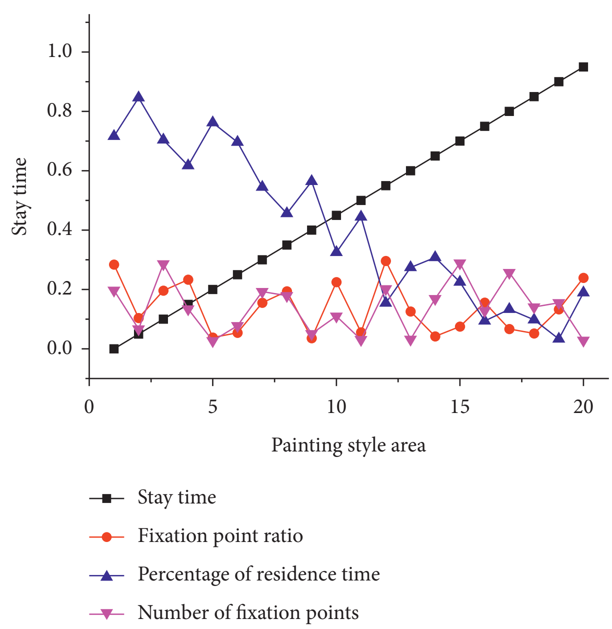

Figure 6: Description of learning style interest area differences.

The level of warm emotion distribution of other types of resources is below 20%. The distribution of warm emotions in videos and web pages is 6.25% and 1.68%, and the lowest distribution of warm emotions in human-computer interaction is only 0.15%. The cheerful emotion type is mainly found in the two teaching methods of animation and playing sound, and the distribution of other types of resources is also lower than 20%, especially in the teacher and teaching content, video, web page, human-computer interaction, and classroom, the distribution level of cheerful emotion is less than 5%. The lively emotion type is mainly found in the text-based teaching approach, probably because text-based resources enhance the visual characteristics of the resource due to a well-designed typographic layout and color scheme, which enhances the level of positive, lively emotion on the screen. The distribution of lively emotion in resources such as teacher's single lecture, teacher's teaching content, human-computer interaction, experimental training, and web page is low, all below 5%. The funny emotion type is mainly distributed in the animation teaching method, and the animation-type resources are usually well designed with color and layout, which can convey good visual emotion characteristics. In contrast, the level of distribution of funny emotions is below 10% in all other types of images. The three emotions of exaggerated, humorous, and funny are not distributed high in all types of images, with the distribution of both humorous and funny emotions below 1%, and most of the images have difficulty in reflecting the metaphorical characteristics of these two emotions.

Multimedia-assisted teaching in colleges and universities should start by changing the traditional teaching concept, establishing the teaching concept of students as the main body of the classroom, and carrying out classroom teaching from the perspective of facilitating students' learning and teachers' teaching while suggesting that teachers can apply a variety of teaching aids for diversified knowledge exchange. At the same time in the actual multimedia-assisted teaching teachers in addition to updating the concept of education and teaching, it should be clear that multimedia technology is only an auxiliary technical tool for teaching, rather than teaching. Multimedia-assisted teaching in colleges and universities should start by changing the traditional teaching concept, establishing the teaching concept of students as the main body of the classroom, and carrying out classroom teaching from the perspective of facilitating students' learning and teachers' teaching while suggesting that teachers can apply a variety of teaching aids for diversified knowledge exchange. Meanwhile, in the actual multimedia-assisted teaching, teachers should make it clear that multimedia technology is only an auxiliary technical tool for teaching, not teaching, in addition to updating the concept of education and teaching, as shown in Figure 8.

Modern information technology is an important manifestation of science and technology, but today's society is a society in which economic capital occupies a major position. The main reason modern information technology has been promoted to such a high position and why it has been continuously improved and developed also lies in its value and the needs of the market, as well as the pursuit of profit, or the value orientation of contemporary society and film and art, which puts forward the information technology to a higher level of pursuit. When the value of a thing changes, the value of the thing or phenomenon related to it will also change accordingly. There is also a correlation, which refers to the fact that there is a certain relationship between things, which cannot be described by a fixed causal relationship. At the same time, although the correlation is not certain, it is regular. Thus, the face of technology or the manifestation of modern information technology is essentially a technology of the economy, even profit-oriented technology. The technology of economy or capital with science and technology, as the main means of benefiting the most, pushes technology to the center of the art of film and television. The

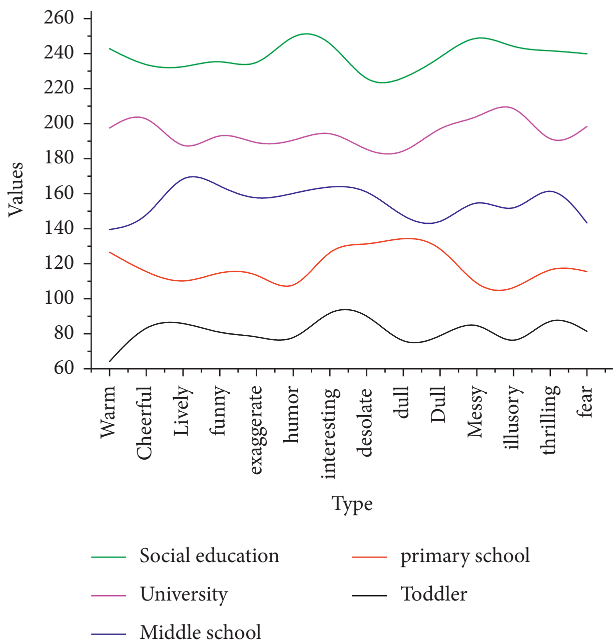

Figure 7: Distribution among school segments.

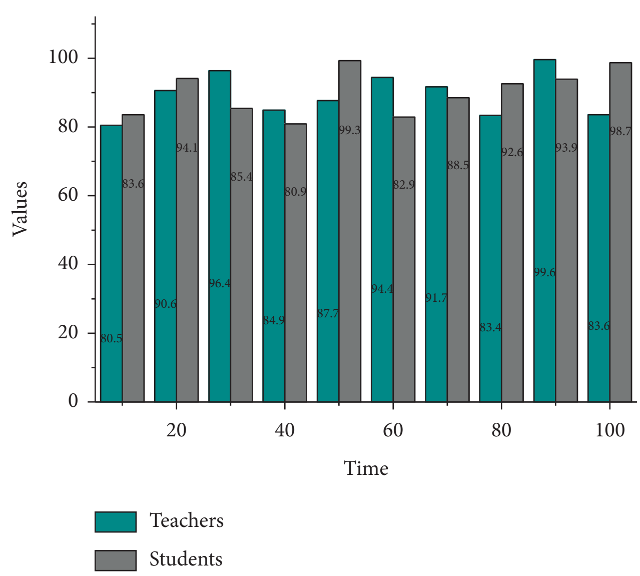

Figure 8: Evaluation results.

character of modern information technology, then, depends not only on the profitability of film and television art but also on the rational needs of modern film and television art that permeate the ultimate modern information technology, especially the scientific rationality of the needs of film and television art under mass aesthetics.

5. Conclusion

Art museum education in the context of the big data era faces more challenges and opportunities and opens a new chapter of development for art museum education. The booming development of big data has changed people's way of accessing information from active to passive, and in this transformation process, recommendation system has a crucial role. Recommendation algorithm is the key technology of recommendation system; the traditional recommendation algorithm still has the problems of cold start, high data sparsity, and so on. The prediction accuracy of the recommendation algorithm is an important criterion to measure the goodness of a recommendation system. Modern information technology has brought a great impact on the development of modern society because of its wide, fast, and technological communication, and for the development of film and television art, information technology not only makes its creative field and subject matter selection more extensive, but also it does limit the content of creation to reality. Modern information technology has broken the traditional time and space pattern, expanding the space and time of film and television production, making the impossible possible, and creating more infinite space and time possibilities through computerized postproduction of special effects. Modern information technology will also make the dissemination of film and television art more diversified and multichannel and obtain more infinite possibilities of film and television art, and the influence of film and television art will also be accompanied by the development of modern information technology and break through the traditional means of creation and expression so that the impossible becomes possible and dreams become reality.

Academic Editor: Tongguang Ni

The Kubuqi Desert is the seventh-largest desert in China. Under the leadership of the central, autonomous region and local governments, the ecological situation has undergone historic changes. In this paper, we select Hangjin Banner and Dalate Banner, which have the most widely distributed deserts and use 347 households as the research perspective to construct the evaluation index system of the government's ecological environment governance effect. The entropy method is used to evaluate the governance effect, and the ordinary least squares and quantile regression are used to compare the evaluation differences of different publics. The research found the following. (1) The public believes that the government's ecological governance measures have achieved good results in the third-level index analysis. The ecological environment in the desert area has been significantly improved; that is, the survival rate of trees has increased, the area of vegetation coverage and vegetation types have increased, and the frequency of sandstorms has decreased. However, the intensity of sandstorms and the flow of water sources did not change significantly. The various types of public income have increased significantly compared to before the governance. The public takes the ecological priority as the concept and actively participates in the government's governance implementation, which means that the ecological awareness and behavior are higher. (2) Among the second-level index, the weights and scores in descending order are public economic characteristics: 45.53% and 0.4840, public ecological behavior: 25.62% and 0.1682, public ecological effect perception: 18.35% and 0.1240, and public ecological awareness: 10.51% and 0.0291. The comprehensive evaluation result is 0.8054, which is in the first grade, and the effect is excellent. (3) The public comprehensive evaluation results of the two regions are similar. Hangjin Banner is 0.8209 and Dalate Banner is 0.8557, both in the first grade. The effect is excellent. (4) In the OLS regression results, gender has a significant positive impact on evaluating the government's ecological environment governance effect. Age, ethnicity, and occupation have a significant negative impact. As the quintile increases, the influence of gender, age, and ethnicity first increases and then decreases. The maximum regression coefficient of gender at the 50% quantile is 0.714, which has a significant positive effect. Age has a significant negative impact at each quantile. The regression coefficient of ethnicity at the 50% quantile is the highest -0.357, which has a significant negative impact. Occupation only has a significant negative impact at the low quintile.

1. Introduction

In today's increasingly severe ecological environment problems, countries worldwide are actively exploring ways to realize the rational development and utilization of environmental resources. Over the years, the Inner Mongolia Autonomous Region, as one of the provinces with more severe ecological and environmental problems in China, has made some gratifying achievements and valuable experience in environmental governance. In particular, the ecological environment management of the Kubuqi Desert has become a representative case in environmental environment management, sand prevention, and control in the Inner Mongolia Autonomous Region, China, and even the world. In a broad sense, environmental governance refers to the management of human social and economic activities through the extensive use of financial, technological, legal, and administrative means within the scope of environmentally permitted capacity, following the scientific guidance of environmental theory. In a narrow sense, to achieve the expected environmental goals, managers should prevent and control the pollution impacts produced in social and economic development to achieve the unity of economical, social, and ecological benefits [1]. The United Nations Development Program (UNDP) and the United Nations Environment Program (UNEP) pointed out how to make environmental decisions and who makes decisions. This process is called environmental governance [2]. That is to say, environmental governance is the exercise of power over natural resources and the environment, including the decision-making process of laws and public institutions such as government agencies and village committees to make power specific. As the primary embodiment of national or local existence, government agencies occupy the core position and leading role in the governance of many fields [3], including the area of ecological environment governance.

Relying on the natural resources and climatic characteristics of the Kubuqi area, the government formulated a "focus on forest and animal husbandry, diversified management" from the end of the 1970s. Comprehensive management of the Kubuqi Desert began in the 1980s. The construction of "planting three and five small" (planting trees, planting grass, planting Caragana korshinskii, small watershed, small water conservancy, small fenced pasture, small economy, small farming, and animal husbandry machinery). Simultaneously, the desolate sand, empty beach, slope, desolate ditch, and desolate mountain are allocated to households to encourage planting trees and grass, managed by farmers and herders. In the 1990s, vegetation construction was regarded as the most significant infrastructure construction. During this period, the Kubuqi region implemented various ecological and economical projects following "resource development and environmental protection" principles, adapted to local conditions, classified guidance, regional implementation, and gradient promotion [4]. By 2000, the policy of "grazing prohibition, rest grazing, rotation grazing, stall-feeding and half-feeding, and transfer of farmers and herdsmen" will be implemented. The Kubuqi Desert is designated as a prohibited development zone. They are carrying out ecological immigration, guiding enterprises to join environmental governance, and building ecological industries of desert tourism, desert medicine, and circular desert economy [4, 5]. After 2012, the Kubuqi region has practiced Xi Jinping's ecological civilization thought, incorporated desertification into the overall national economic and social development plan, and implemented a local administrative leadership responsibility system. And encourage the whole society to participate in ecological construction and increase the application of science and technology in environmental governance. The ecological situation has achieved a historic change. The international community has highly recognized Kubuqi's ecological governance achievements and experience. In 2014, the United Nations Environment Program established the Kubuqi Desert Ecological Management Zone as a "Global Desert Ecological Economic Demonstration Zone." In 2015, the United Nations Climate Conference in Paris shared Kubuqi's desertification control as a "Chinese sample." In 2017, the United Nations released the world's first desert ecological wealth report and the world's first case of China's ecological civilization construction recognized by the United Nations and the international community [5].

Scholars are concerned about the macrolevel natural environment of the Kubuqi Desert [6], governance process, governance policies and measures, governance effectiveness (Qi Hailin, 2017) [5, 7], and empirical enlightenment [8, 9]. The microlevel government-led ecological environment governance [10, 11], the effect of ecological migration [12], land use under governance policies [13, 14], and other aspects are less content. In particular, the research on governance effects based on the public's perspective is relatively lacking. The methods, indicators, and corresponding evaluation results are different based on evaluating the ecological environment governance effects of different subjects [15]. At present, the evaluation of ecological governance effects from the public's perspective includes analytic hierarchy process (AHP) decision analysis method [15], analytic hierarchy process (AHP)-fuzzy comprehensive evaluation (FCE) method [16], entropy method [17, 18], etc. Different methods have their advantages and disadvantages. In this paper, the entropy method is used to evaluate the governance effect. At the same time, the ordinary least squares regression and quantile regression are used to compare the evaluation differences of different publics. In this way, we provide help for follow-up governance.

2. Materials and Research Methods

2.1. Overview of the Research Area

2.1.1. Geographical Distribution Overview. The Kubuqi Desert is located on the northern edge of the Ordos Platform, on the southern bank of the Yellow River, facing the Mu Us Sandy Land in the south. It is 360 kilometers long from east to west and 40 kilometers wide from north to south. They are distributed in Hangjin Banner, Dalate Banner, Zhungeer Banner, Yijinhuoluo Banner, and Dongsheng District of Ordos City. However, they are mainly distributed in Hangjin Banner and Dalate Banner. Therefore, choose Hangjin Banner and Dalate Banner for analysis. In the mid-1990s (Table 1), the total area of the Kubuqi Desert was 18,500 square kilometers. The results of the 5th China National Desertification and Sandification Inventory Monitoring show that the total area of the Kubuqi Desert is 14,100 square kilometers. Among them, the desert area in Hangjin Banner is 10,600 square kilometers, accounting for 75.37% of the total desert area. Dalate Banner covers an area of 2,386 square kilometers, accounting for 16.92%. The two places account for 92.29% of the whole desert area.

Table 1: Kubuqi Desert in the mid-1990s and the 5th China National Desertification and Sandification Inventory Monitoring and distribution data comparison (unit km^2).

Statistical unit	Desert area	Mobile dune/ land	Accounted for the total desert area (%)	Semifixed dune/land	Accounted for the total desert area (%)	Fixed dune/ land	Accounted for the total desert area (%)
Mid-1990s	18517.85	9074.26	49.00	1675.28	9.05	7768.31	41.95
The 5th China national desertification and sandification inventory monitoring	14111.52	5331.33	37.78	2532.59	17.95	5125.89	36.32
Hangjin Banner	10635.85	4669.67	33.09	2342.84	16.6	2975.89	21.1
Dalate Banner	2386.93	638.65	4.52	148.41	1.05	1331.53	9.43

Note. The data comes from Yang Wenbin, The natural environment and comprehensive management of Kubuqi Desert [M], Inner Mongolia University Press, 2005 and data obtained from the survey.

2.1.2. Socio-Economic Overview. **Agriculture and animal husbandry production:** the total output value of farming, forestry, animal husbandry, and fishery in Hangjin Banner increased from 28.05 million yuan in 1978 to 4.020 billion yuan in 2020, an increase of 99.3%; the total number of livestock and total grain output increased by 55.5% and 94.1%, respectively, at the end of the year (Figure 1). The total output value of farming, forestry, animal husbandry, and fishery in Dalate Banner has increased from 36,47million yuan in 1978 to 753,603.97 million yuan in 2020, an increase of 99.52%; the total number of livestock and total grain output increased by 75.6% and 91.1%, respectively, at the end of the year (Figure 2). **Regional economy:** Hangjin Banner's GDP increased from 26.31 million yuan in 1978 to 12883.26 million yuan in 2020, an increase of 99.8%; public finance budget revenue, public finance budget expenditure, and per capita net income of farmers and herdsmen increased by 99.6%, 99.8%, and 99.2%, respectively (Figure 3). Dalate Banner's GDP increased from 53.63 million yuan in 1978 to 31969.72million yuan in 2020, an increase of 99.8%; public finance budget revenue, public finance budget expenditure, and per capita net income of farmers and herdsmen increased by 99.8%, 99.7%, and 98.9%, respectively (Figure 4).

2.2. Data Sources

2.2.1. Questionnaire Survey. From October 2019 to August 2021, the author selected 10 Sumu and towns (Table 2) in Hangjin Banner and Dalate Banner to conduct a random household questionnaire survey. A total of 405 questionnaires were issued, with 347 valid questionnaires, and the efficiency is 85.68%.

2.2.2. Basic Information of the Sample. There are more males in the sample (69.16%), and 60.81% of the interviewees are over 41 years old, and they have participated in the management of the Kubuqi Desert and the construction of desert-crossing highways. Among them, the Han nationality accounted for 62.54% and the Mongolian nationality accounted for 37.46%. The education level of technical secondary school and above accounted for 50.72%, and the overall educational level was relatively high. Half-agricultural and half-pastoral households accounted for the largest proportion of households, accounting for 23.63%. "3–4 persons" accounted for the largest proportion of the family population, at 66.29%. In terms of total household income and per capita net income, the proportion of each income segment varies greatly (Table 3).

2.3. Research Methods

2.3.1. Entropy Method. The entropy method can transform Kubuqi's public's subjective, long-term, and qualitative continuity judgments of the governance process into quantitative data [18]. The main steps of the entropy method to determine the weight coefficient:

(1) Construct the original data matrix:

$$A = \left(x_{ij}\right), i = 1, 2, \ldots, 347, j = 1, 2, \ldots, 22, \quad (1)$$

where i represents the number of citizens participating in the evaluation and j represents the number of evaluation indexes.

(2) Data standardization: the standardization basis for positive indexes and moderate indexes:

$$x = \frac{x_{ij} - \min x_{ij}}{\max x_{ij} - \min x_{ij}}. \quad (2)$$

The proportion of income from crops and the proportion of income from farming, which are moderate indexes, are standardized based on the average value within the group:

$$x = \frac{|x_{ij} - avgx_{ij}|}{|avgx_{ij} - \min x_{ij}|}. \quad (3)$$

(3) Unified quantification of indicators, calculating the weight of the jth index,

$$P_{ij} = \frac{x_{ij}}{\sum_{i=1}^{n} x_{ij}}. \quad (4)$$

(4) Calculate the entropy value of the jth index:

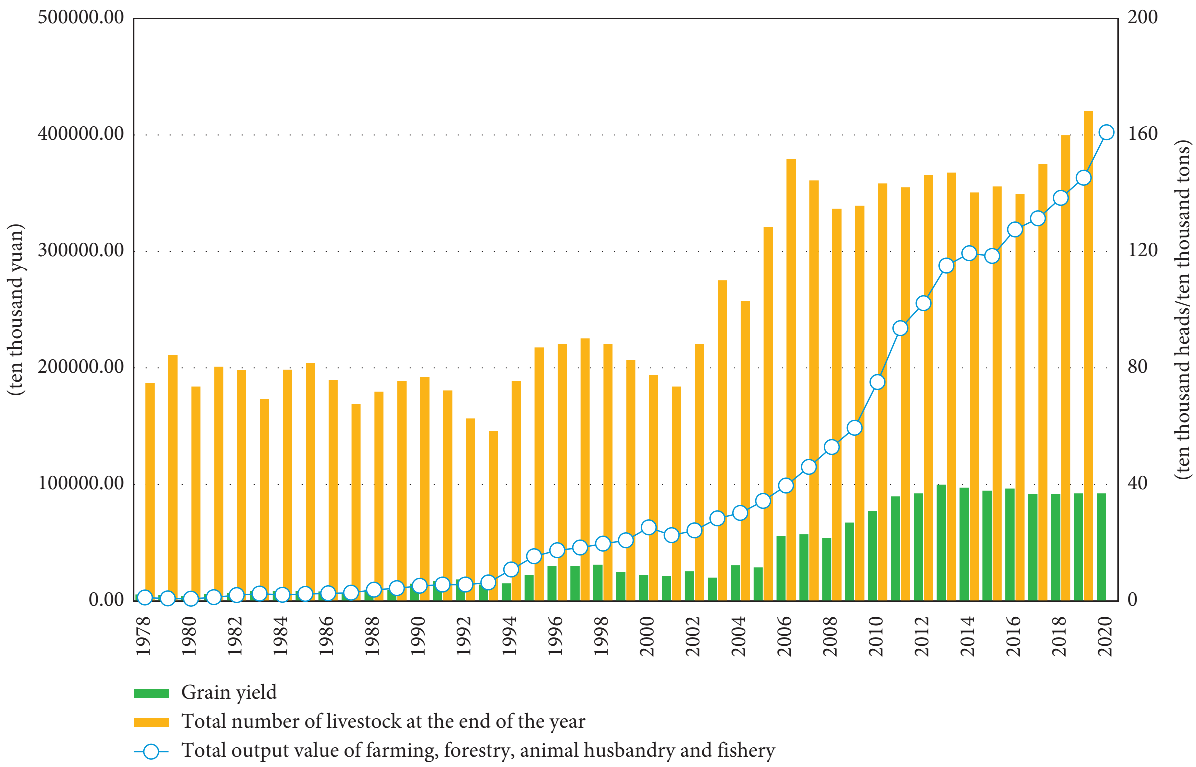

Figure 1: Main agricultural production statistics index of Hangjin Banner.

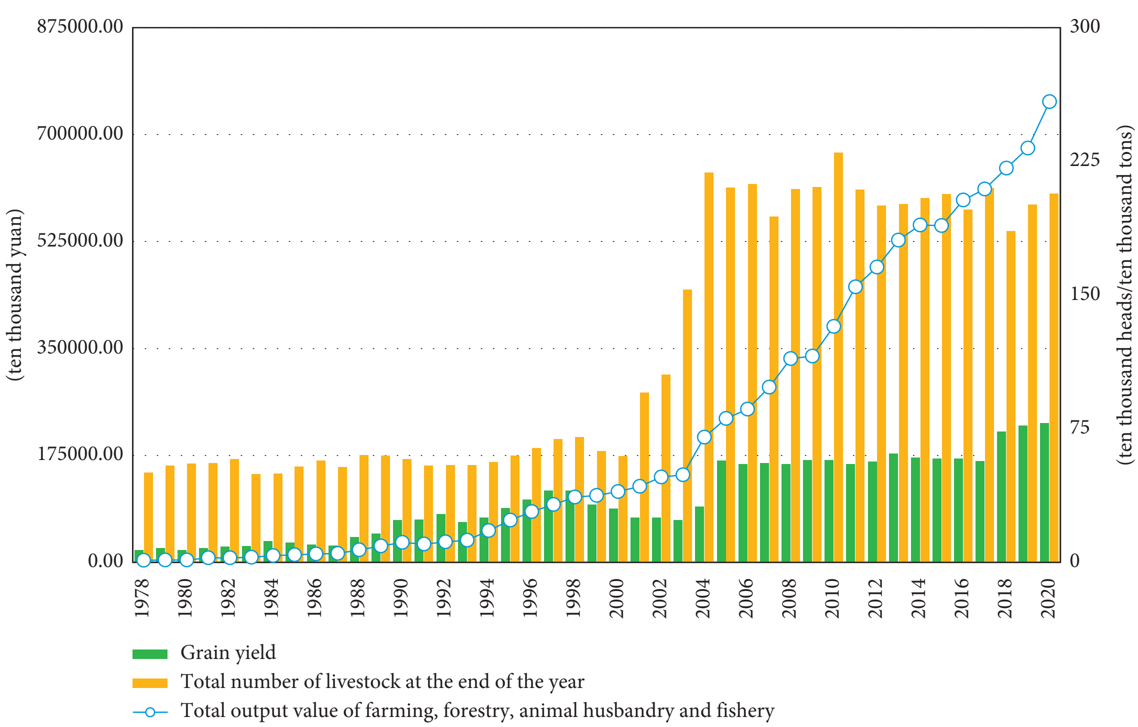

Figure 2: Main agricultural production statistics index of Dalate Banner.

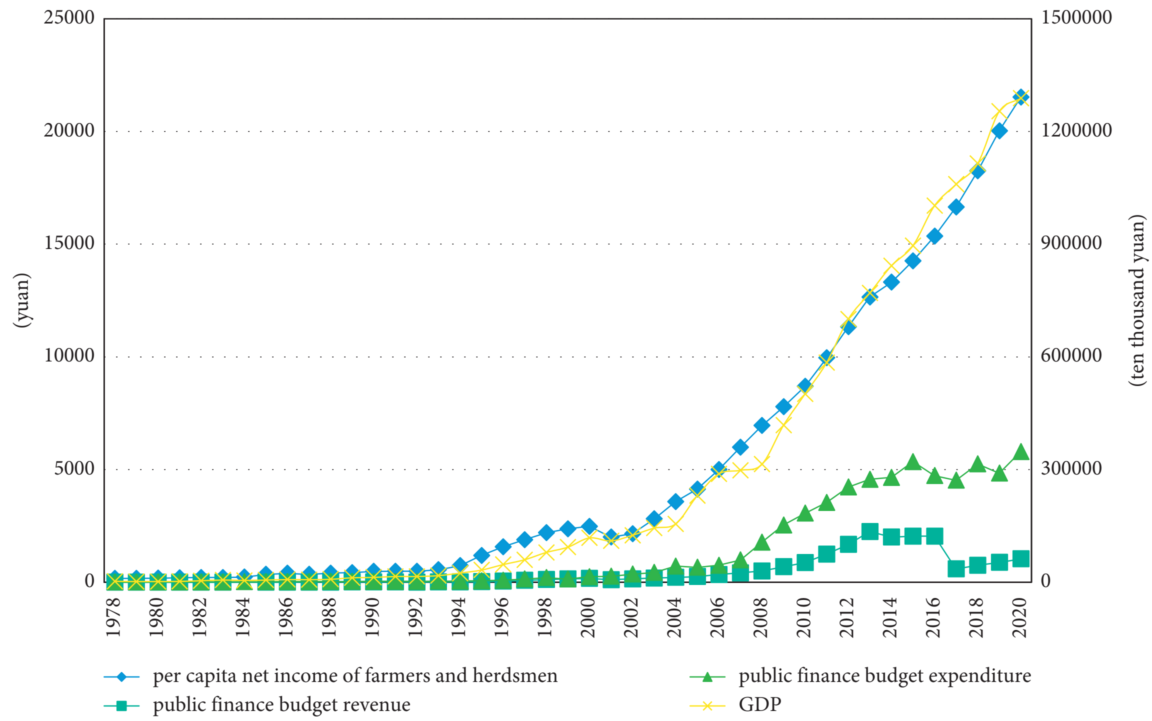

FIGURE 3: Main regional economic statistical index of Hangjin Banner.

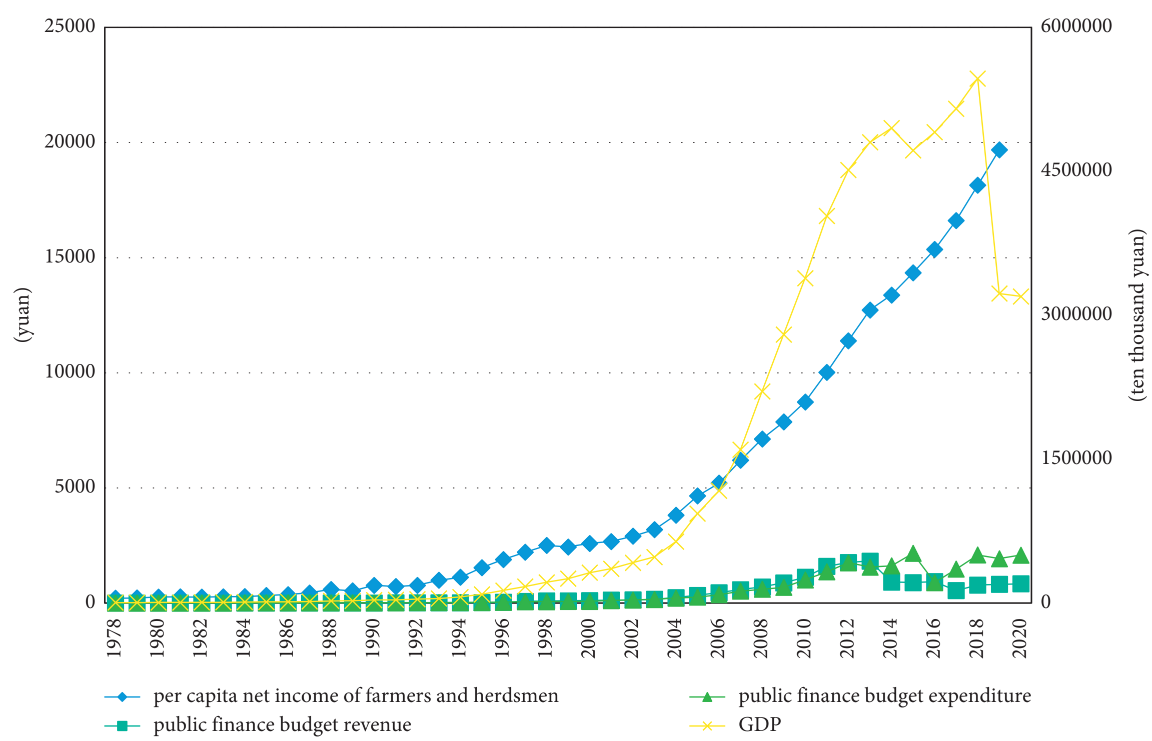

FIGURE 4: Main regional economic statistical index of Dalate Banner. *Note.* The data are derived from the “Inner Mongolia Statistical Yearbook,” “Ordos Statistical Yearbook,” and the statistics of the National Economic and Social Development Bulletin of Hangjin Banner and Dalate Banner in 2020.

Table 2: Distribution of the sample area.

Banner county name	Sumu (town)
Hangjin Banner	Jiri Galangtu Town, Duguitala Town, Yihe Wusumu, and Xini Town
Dalate Banner	Engebei Town, Zhandanzhao Sumu, Shulinzhao Sumu, Wangaizhao Town, Bainijing Town, and Zhonghe West Town

Table 3: Descriptive statistics of sample data.

Population characteristics	Attributes	Number of people	Proportion (%)	Population characteristics	Attributes	Number of people	Proportion (%)
Gender				Nationality			
	Male	240	69.16		Han nationality	217	62.54
	Female	107	30.84		Mongolian	130	37.46
Age				Family household			
20 years old and below		1	0.29		Pure animal husbandry	54	15.56
21–30 years old		62	17.87		Pure farmer	61	17.58
31–40 years old		73	21.04		Half-agricultural and half-pastoral	82	23.63
41–50 years old		90	25.94		Other	150	43.23
50–61 years old		69	19.88	Occupational situation			
Over 60 years old		52	14.99		Farming	124	35.73
Education					Nonagricultural and animal husbandry self-employed	53	15.27
Elementary school and below		20	5.76		Students	13	3.75
Primary school		48	13.83		Inability to work	13	3.75
Junior high school		68	19.60		Public officials	144	41.50
High school		35	10.09	Total household income			
Technical secondary school		18	5.19		Less than 5,000	156	44.96
Junior college		32	9.22		5,000–20,000	18	5.09
Undergraduate		108	31.12		20,000–50,000	19	5.38
Postgraduate and above		18	5.19		50,000–100,000	26	7.49
Family population size					More than 100,000	129	37.08
1 person		12	3.46				
2 person		77	22.19	Per capita income			
3 person		129	37.18		Less than 5,000	79	22.77
4 person		101	29.11		5,000–20,000	156	44.96
5 person		9	2.59		20,000–30,000	39	11.24
6 person and above		19	5.48		More than 30,000	73	21.04

$$e_j = -k \sum_{i=1}^{n} P_{ij} \ln P_{ij}, \text{where k is equal to} \frac{1}{lni}, k > 0. \quad (5)$$

(5) Calculate the difference coefficient of the jth index:

$$g_j = 1 - e_j. \quad (6)$$

(6) Calculate the weight of the jth index:

$$w_{j=}\frac{g_j}{\sum_{j-1}^{m} g_j}, \quad (7)$$

w_j is the final weight of each quantified third-level evaluation index. According to the principle of additivity of the index at the same level [17], the second-level index weight is the sum of the corresponding third-level index weights and can be obtained the first-level index weight in the same way.

(7) Calculate the public's evaluation of the effect of ecological governance:

$$E_j = \sum w_j x_j. \quad (8)$$

According to the principle of the additivity of the statistical index scores of the entropy method [17], the second-level index score is the weighted summation of the corresponding third-level index scores and can be obtained the first-level index score in the same way.

2.3.2. Quantile Regression. Quantile regression has strong robustness for outliers, normality of dependent variables, or heteroscedasticity problems [18]. The model is as follows:

$$y_q(x_i) = x_i\beta_q, \quad (9)$$

where y is the evaluation result of the public's ecological governance effect, x_i is the factor that affects the public evaluation result, and β_q represents the q-quantile regression coefficient, and its value is

$$\beta_q = \min \sum_{i:\ y_i \geq \beta_q x_i}^{n} q\left|y_i - \beta_q x_i\right| + \sum_{i:\ y_i < \beta_q x_i}^{n} (1-q) + \left|y_i - \beta_q x_i\right|. \quad (10)$$

3. Results and Analysis

3.1. Construction of the Evaluation Index System. Based on the principles of systematicity, pertinency, stability, discrepancy, and measurability [17, 18], we refer to relevant domestic and foreign literature [18]:

(1) The public's perception of the ecological effects of governance
(2) Influence the effects of ecological governance
(3) The level of public economic development is affected by or related to ecological governance
(4) The public's willingness to participate in ecological governance and environmental awareness, respectively, correspond to the four second-level indicator standards

That is the public's perception of ecological effects, ecological behavior, their economic level, and ecological awareness. Under each second-level index, several third-level indexes are set as the scheme layer. See Table 4, for specific indicators and connotations.

3.2. Overall Evaluation Results. To directly reflect the effect of ecological environment governance, scholars divide the evaluation index of government ecological environment governance effect into five grades [17, 18], see Table 5.

3.2.1. Third-Level Index Result. In the third-level index (Table 6), the index factor value is the average value of the same sample data as the evaluation value. C1, C2, C4, and C5 are positive indicators with evaluation grades ranging from 1–5. Their factor values are all greater than 4, indicating that the public perceives that the ecological environment of the Kubuqi area under the government's leadership has significantly improved, that is, the survival of trees has increased, the area covered by vegetation, and the types of vegetation have increased. At the same time, the frequency of sandstorms has decreased a lot. Still, the intensity of C3 sandstorms and the flow of C6 water sources have not changed significantly. 96.25% of the people in the questionnaire believe that the environment in the sandy area has been significantly improved. As of 2016, the governance area of the Kubuqi Desert reached 6,460 square kilometers and a green area of more than 3,200 square kilometers. The forest and vegetation coverage has increased from 0.8% and 16.2% in 2002 to 15.7% and 53% [5]. Among them, the artificial afforestation area of Hangjin Banner and Dalate Banner in 2019 was 10.41 thousand hectares and 5.17 thousand hectares, an increase of 76.4% and 19.7% over 2018. Dust weather decreased from more than 50 times in 1988 to one time in 2016, rainfall increased from less than 100 mm to 456 mm, and biodiversity increased to more than 530 types [5].

C8, C20, and C22 indicate that the public believes that the government's ecological governance measures have achieved specific results, with high satisfaction and confidence in sustainable governance. An average of 93.85% of the respondents in the questionnaire also agreed that the Kubuqi Desert governance is a scientific and successful governance case, and it will have better development in the future. C13 is the weight and score of the channel type for obtaining ecological policy information are the second, occupying the central position, indicating that getting governance policy information is one of the public's evaluation criteria for the effectiveness of government governance. If the public information is not comprehensive enough, not transparent enough, and asymmetrical, it will make the overall government governance become water without a source and a tree without roots. C14, C15, C16, and C17 are the rate of change and satisfaction of various incomes before and after ecological governance. The weights and scores are all the top 5, indicating that multiple revenues such as agriculture, animal husbandry, labor, and government subsidies have increased significantly compared to before the governance. The government's ecological migration policy provides a monthly social security subsidy of 350 yuan per person in addition to cash and housing subsidies for herders in sandy areas. Guide enterprises to transfer more than 1.5 million acres of sandy land to farmers and herdsmen in sandy areas, and farmers and herdsmen also earn income through land entering agriculture. Since 2017, 12 villages and towns around Kubuqi have more than 5,500 people through the traditional Chinese medicinal planting model represented by licorice have been benefited. C9 and C10 indicate that taking others as the reference object, the respondents believe their sand area activities are significantly less than others. This result may be due to the external expected pressure brought by the questionnaire to the respondent. There may be a self-perception bias, which will eventually lead to biased results. C19, C21, C11, C12, and C18 indicate that the public prioritizes ecology, which means they have higher ecological awareness and behavior.

3.2.2. Second-Level Index Results. In the second-level index results (Table 6), the weights and scores in the descending order are B3 public economic characteristics 45.53% and 0.4840, B2 public ecological behavior 25.62% and 0.1682, B1 ecological effect perception 18.35% and 0.1240, and B4 public ecological awareness 10.51% and 0.0291. It shows that the government should prioritize economic construction and ecological behavior in the process of governance. 93.65% of the people said that the ecological environment governance has significantly improved the region and their economy. Also, 92.5% of the people felt that the governance had brought positive social benefits. In recent years, the economy of Kubuqi has continued to develop, creating a desert economy with the integration of the tertiary industry and complementing each other, which has driven 102,000 people out of poverty. Their income has increased from less

Table 4: Evaluation index system of government ecological environment governance effect.

First-level index	Second-level index	Third-level index	Index value description
Evaluation index system of government ecological environment governance effect	Public ecological effect perception B1	C1 tree survival rate	5 = *a* lot of increase, 4 = *a* minor increase, 3 = no change, 2 = *a* minor decrease, and 1 = *a* lot decrease
		C2 sandstorm frequency	5 = decrease a lot, 4 = decrease some, 3 = no change, 2 = increase some, and 1 = increase a lot
		C3 sandstorm intensity	5 = weaken a lot, 4 = weaken a little, 3 = no change, 2 = enhance a little, and 1 = enhance a lot
		C4 vegetation coverage area	5 = *a* lot of increase, 4 = *a* minor increase, 3 = no change, 2 = *a* minor decrease, and 1 = reduce a lot
		C5 vegetation type	Same as above
		C6 water flow changes	Same as above
		C7 oasis blocks the effect of wind and sand	Same as above
		C8 whether government governance meets expectations	4 = good governance effect has been achieved, 3 = there is ecological governance effect, but the governance effect is not up to expectations, 2 = there is no governance effect, and 1 = unclear
	Public ecological behavior B2	C9 types of economic activities of others in the sand area	5 = no activity, 4 = 1–2 activities, 3 = 3–4 activities, 2 = 5–6 activities, 1 = 7 activities, and above
		C10 types of economic activities in the respondent's sandy area	
		C11 whether to stop other people from destroying the ecological environment of the sandy area	3 = stop, 2 = report to relevant government organizations or departments, and 1 = don't care
		C12 frequency of participating in collective desertification voluntary labor	3 = participate often, 2 = participate occasionally, and 1 = never
		C13 types of channels for obtaining ecological policy information	1–5 represent the number of ways to obtain information
	Public economic characteristics B3	C14 the ratio of crop income to total income	The ratio of grain and cash crops to total income (%), comparison before and after treatment
		C15 the ratio of aquaculture income to total income	The income ratio from raising cattle and sheep to total income (%), the same as above
		C16 the ratio of other income to total income	Other income includes labor, self-employment, wages, financial subsidies, and land lease, the same as above
		C17 satisfaction with current household income	5 = very satisfied; 4 = satisfied; 3 = fair; 2 = not very satisfied; 1 = not satisfied
	Public ecological awarenessB4	C18 whether to consider sustainable production and lifestyle	2 = yes and 1 = no
		C19 the importance of economy and environment	3 = it is necessary to protect desert vegetation, 2 = the two are equally important, and 1 = it is important to develop the economy
		C20 the future ecological environment of the Kubuqi area	3 = the ecological environment will be restored, 2 = it is hard to say and it depends on the specific measures of governance, and 1 = the oasis disappears
		C21 whether to support the state or related organizations to implement governance policies and projects in the Kubuqi area	2 = yes and 1 = no
		C22 satisfaction with the various governance policies implemented in the Kubuqi area	3 = satisfied; 2 = dissatisfied; 1 = unclear

Table 5: The grading standard of the government's ecological environment governance effect evaluation index.

Grade	1	2	3	4	5
Evaluation index	0.8–1.0	0.6–0.8	0.4–0.6	0.2–0.4	<0.2

than 400 yuan to the current 14,000 yuan. The government benefits farmers and herdsmen through comprehensive measures such as letting farmers and herdsmen circulate sand to plant grass and trees, build infrastructure, government support, employment assistance, and education and training. Three new immigrant villages in Hangjin Banner, Yanhaizi, Daotugacha, and Hangjinnaoer have been built successively, with 333 households and 840 people of ecological immigrants [19]. The ecological behavior of the public in the sandy areas started in 1980 with the government's decision of "vegetation construction is the largest infrastructure construction" and the "decision to plant trees, grasses, and caragana korshinskii with 1 million mu each year." At this stage, numerous professional afforestation households have emerged.

By the end of the 1990s, under the guidance of the government, the public began to participate in the construction of the "desert-crossing highway" (Hangjin Banner Desert-Crossing Highway, also known as the Poverty Alleviation and Development Highway from Xini Town to Wulashan Town), with a total length of 115 kilometers. After entering 2000, the government-supported and encouraged farmers and herdsmen to carry out joint-stock development, taking the form of operation or participation of enterprises + bases and companies + farmers and herdsmen, extending the land contract period and service life, and auctioning them at low prices. The government also adopted free allocation of sandy land to large households for governance, exempted 3-5 years of fees, and allowed inheritance and transformation of sandy land after development. It also implements regular tax reductions and exemptions for the agricultural and sideline products processing industries of the people in the sandy area to guide the public become the main participants in the governance of Kubuqi. Only during the Tenth Five-Year Plan of China period, 713 large households with more than 500 acres of sand control and afforestation were formed, including Wurigendalai and Feng Zhiting. These people have afforested an area of 1.02 million mu, accounting for 20% of the total afforestation area in Ordos City (Qi Hailin, 2017) [5]. Based on consolidating the achievements of economic and ecological behavior construction, we should strengthen the perception of ecological effects. The ecological awareness weight and score are the lowest 10.51% and 0.0291. The research team found that farmers and herdsmen living in desert areas participated more in governance, while the public participation far from the desert areas was less.

3.2.3. First-Level Index Results. The comprehensive evaluation result is 0.8054 (Table 6), which is in the first grade, and the effect is excellent. In general, under the guidance of the ecological projects and policies of the central, autonomous region, and local governments, the ecological conditions of the Kubuqi Desert have achieved historical changes. In particular, since 2012, practicing Xi Jinxing's ecological civilization thought and the idea that "clear waters and green mountains are as good as mountains of gold and silver," we promote green transformation and development and implement the policy of giving priority to conservation, protection, and natural restoration, providing necessary conditions for governance.

3.3. Evaluation Results of the Public in Different Regions. The public comprehensive evaluation results of the two regions are similar (Figure 5). Hangjin Banner is 0.8209 and Dalate Banner is 0.8558, both in the first grade with excellent results. From their respective composition, the evaluation of each part of Dalate Banner is relatively balanced. In terms of public ecological behavior and public ecological awareness, the public in Hangjin Banner is slightly higher than the public in Dalate Banner, which is related to the main distribution of the Kubuqi Desert in Hangjin Banner. As a result, the public has an intuitive comparison and more active participation in increasing various incomes before and after governance.

3.4. Evaluation Differences of Different Public Heterogeneity

3.4.1. Independent Variable Diagnosis. Ten public attributes such as gender, age, and educational level are selected as independent variables. The public's evaluation of the government's ecological environment governance effect is used as the dependent variable. After the stepwise regression of the above indicators, the explanatory power of education level, household population, household category, annual crop income, annual breeding income, and annual other income is weak and not significantly so eliminated. R^2 in Table 7 is 0.223, meaning that gender, age, ethnicity, and occupation can explain 22.3% of the change in the public's evaluation of the government's eco-environmental governance effect. The model passed the F-test ($F = 24.559$, $p < 0.001$). The VIF values are all less than 5, there is no collinearity problem, the D-W value is near the number 2, there is no autocorrelation, and there is no correlation between the sample data.

For heteroscedasticity, two methods of the White test and the BP test are used to test. The null test hypothesis is that the model has no heteroscedasticity, which shows that both tests accept the null hypothesis ($p > 0.05$), and there is no heteroscedasticity problem (Table 8).

3.4.2. OLS Regression Results. In OLS regression (Table 9), the regression coefficient value of gender is 0.552 and passes the significance of 0.01, producing a significant positive correlation. It shows that gender has a greater impact on the public's evaluation of ecological governance results. Compared with female respondents, male respondents have a higher evaluation of governance effects. It may be that men are more sensitive to and concerned about policies than women and have a more objective judgment on implementing policies. In contrast, women often rely on intuitive feelings. The age passes the significance of 0.01, and the coefficient is negative, indicating that the older the age, the lower the evaluation of the effect of ecological governance. The national regression coefficient value is −0.308; through the significance of 0.05, there is a significant negative correlation. The regression coefficient value of occupation is −0.113, passing the significance of 0.01, which produces a significant negative correlation.

3.4.3. Quantile Regression Results. In quantile regression (Table 9), the regression coefficient of gender at the 50% quantile is the highest at 0.714. The quantile 25% and 50% pass the 0.01 significance test, and the 75% quantile pass the 0.05 significance test. The regression coefficient of age is the highest at the 50% quantile −0.357, and each quantile passed the significance test of 0.01. The regression coefficient of nationality is the highest at the 50% quantile −0.357, which passes the significance test of 0.05, and the other quantiles pass the significance test of 0.01. The regression coefficient of occupation rose from −0.200 to −0.000 and only passed the significance test of 0.01 at the 25% quantile, while the other quantiles were not significant.

4. Discussion

The research results in this article show that the ecological awareness weight and score are the lowest. Therefore, even in advanced new technologies, the ecological environment is essential for human coexistence and development. This is "too rich nature makes people inseparable from the hands of nature, just like children cannot do without the lead belt." [20] To resolve this contradiction, it is necessary to strengthen the ecological consciousness of the people in it, that is, environmental problems originate from the behaviors caused by people's misconceptions and consciousness, and the ecological environment governance is actually the governance of people. The public is the micromain body of Kubuqi governance and the driving force to promote sustainable environmental governance. However, according to research findings, Kubuqi's ecological governance is still in an embarrassing situation where the majority of people benefit from government-led support and a few people participation. First of all, farmers and herdsmen living in the desert area are doing their best for the management of the Kubuqi Desert, while the public far away from the desert area lacks the awareness and enthusiasm to participate in the ecological environment management and even thinks that it has nothing to do with them, which leads to the overall governance efforts are not enough. Secondly, governance activities are formalized and the channels through which the public can participate in governance are relatively simple. For example, civil servants and enterprise employees of the local government administration department of Hangjin Banner participate in tree planting and greening every year only through the tree planting day and tree planting week organized by the local government or party organizations' day activities. It is inevitable to be absent from time to time in the governance process, and the ecological awareness and

sense of responsibility are weak. Therefore, the government should conduct targeted and dynamic propaganda against these groups [21], cultivating personal ecological consensus and reshaping ecological concepts.

In addition, obtaining governance policy information is an important criterion for the public to evaluate governance. Therefore, an open and transparent information-sharing mechanism should be embedded in the policy system to break the information "islands" between different subjects and different fields for "sharing governance" and two-way communication [22]. Moreover, it has a smooth information dissemination system to ensure the objective authenticity of its dissemination of information. There should also be a mechanism for other subjects' normal participation and institutional guarantees for classifying, solving, and responding to problems based on multiparty induction and integration. This can encourage the establishment of an institutional trust system between environmental information among various subjects and enhance the effectiveness of environmental governance.

Furthermore, suppose the government increases the transparency of its operations and allows other subjects to express policy preferences and dissatisfaction through various channels. In that case, people will increase their confidence in the political system's fairness, stability, and predictability. In turn, confidence in the system can enhance people's sense of trust in each other [23]. "The role of trust is like a lubricant; it makes the operation of groups or organizations more effective [24]," thereby promoting Kubuqi ecological governance affairs.

5. Conclusion

(1) The analysis of the third-level index shows that the public believes that the government's ecological governance measures have achieved good results. The ecological environment in the desert area has been significantly improved. The survival rate of trees has increased, the area of vegetation coverage and vegetation types has increased, and the frequency of sandstorms has decreased. However, the intensity of sandstorms and water flow is not a significant change. The various types of public income have increased significantly compared to before the governance. The public takes the ecological priority as the concept and actively participates in the government's governance implementation, which means that the ecological awareness and behavior are higher.

(2) In the second-level index, the weights and scores in the descending order are public economic characteristics 45.53% and 0.4840, public ecological behavior 25.62% and 0.1682, ecological effect perception 18.35% and 0.1240, and public ecological awareness 10.51% and 0.0291. The comprehensive evaluation result is 0.8054, the grade is 1, and the effect is excellent.

(3) The public comprehensive evaluation results of the two regions are similar, with Hangjin Banner being 0.8209 and Dalate Banner being 0.8557.

(4) In the OLS regression results, gender has a significant positive impact on evaluating the government's ecological environment governance effect. Age, ethnicity, and occupation have a significant negative impact. As the quintile increases, the influence of gender, age, and ethnicity first increases and then decreases. The maximum regression coefficient of gender at the 50% quantile is 0.714, which has a significant positive effect. Age has a significant negative impact at each quantile. The regression coefficient of ethnicity at the 50% quantile is the highest -0.357, which has a significant negative impact. Occupation only has a significant negative impact at the low quintile.

Academic Editor: Tongguang Ni

With cloud computing's powerful computing power, many end users can create a variety of effective network applications using the cloud's services without having to worry about computing technology or access methods. Based on CC technology's on-demand service characteristics and unlimited dynamic expansion capability, this article designs and implements a shared network examination system. In the Web mode, the functions of receiving and distributing examination data, identity verification, online examination, and examination result collection can be realized using the SaaS deployment structure, MVC three-tier architecture, Java modeling language, XFIE, JSON, web service, DES, and other technologies combined with MySQL database. At the same time, the improved parallel genetic annealing algorithm (IPGAA) is proposed as a CC resource scheduling strategy. The IPGAA has better adaptability in the CC system with various cloud resources because it combines the fast global search ability of the genetic algorithm (GA) with the local search ability of the simulated annealing algorithm. Simulation tests show that the IPGAA is effective.

1. Introduction

With the application of various modern information technologies and the rapid development of network technology, many schools or institutions have gradually replaced the traditional paper examinations with online examination systems, thus improving the examination efficiency and the examination quality, and making the examinations no longer restricted by places and regions [1]. The existing online examination system structure modes mainly include client/server (C/S) structure and browser/server (B/S) structure [2, 3]. For the examination system with the C/S structure, the examination center is independent. During the examination, the administrator pushes the examination questions and examinee information down to the examination center, and the examinee takes the examination at the examination center. This kind of structure is mainly distributed in the local area network, and candidates can only take exams in the prescribed environment, which is limited to a certain extent in time and space. In addition, this kind of system has limited carrying capacity, is not easy to expand, and is easy to cause candidates' answers to be lost in emergencies, and there are some phenomena such as disconnected examination systems and difficult data synchronization, which makes it difficult for examination systems based on the B/S structure to be widely used. Therefore, a new technology is urgently needed to improve this dilemma [4].

Cloud computing (CC) is the product of the rapid development of the new generation Internet technology and is a new neural computing mode [5–7]. CC makes computing distributed on a large number of distributed computers, instead of local computers or remote servers. CC is the product of the integration and development of distributed computing, utility computing, virtualization technology, web services, grid computing, and other technologies. Its goal is that users can use virtual resource pools to the maximum at any time and any place through the network to deal with large-scale computing problems [8]. SaaS (software as a service) is one of the services provided by CC, which is a software application mode that provides software services based on the Internet, and represents the latest trend of software technology development [9, 10]. At the same time, double cache technology and adapter technology are used to help solve the problems of the examinee's answer loss and data synchronization among the examination systems under unexpected circumstances. Therefore, CC provides a technical solution for the design of the current online examination system.

The design of an online examination system based on CC in this article refers to the actual needs, given the rapid advancement of CC technology and the rapid development of the economy. The system can help enterprises enjoy high concurrent examination services at a lower cost, and distributed examination services can be configured at any time according to the needs of examination scale, reducing the pressure on the main system, increasing the concurrent number, and providing a stable and reliable platform for large-scale online examinations, thanks to CCs unlimited dynamic expansion capability.

The main innovations of this article are as follows:

(1) According to the functions of the system, aiming at the problems that the traditional random algorithm has weak control ability on knowledge points and difficulty in generating test papers, and low efficiency caused by a large number of repeated invalid test questions, an improved random test paper generating algorithm based on knowledge points and difficulty is proposed for job generation.

(2) A cloud computing resource scheduling strategy based on IPGAA is proposed. It solves the problems of single-point failure, high communication overhead, and relatively low efficiency of scheduling algorithm in existing resource scheduling.

2. Related Work

CC and its applications are rapidly developing and expanding as a result of the academic and industrial communities' understanding of it, affirmation of its role, and joint promotion of its technology. Literature [11] connects data in a new way, adjusting and improving them at the same time, ensuring their independence, addressing user and cloud security, and integrating resource usage, which is a secure new cloud security technology. Literature [12] demonstrates that through Hadoop, "cloud" can execute parallel applications on huge datasets in a reasonable time, thus supporting computation-intensive services. Literature [13] studies the secure storage of CC and proposes a recoverable proof model to ensure the recoverability and error correction performance of data. Literature [14] puts forward a method to integrate the virtual machine model into the existing resource management framework. Using a two-level scheduling method, virtual machine management will be integrated into batch scheduling to provide better scheduling services for cloud users. However, at present, reservation services for virtual resources are not supported. Literature [15] puts forward a method of automatically and quickly deploying context, which is mainly realized by analyzing the context environment of a virtual cluster, such as IP address of a virtual machine and security information. In addition, a virtual private network provides a customizable network environment for cloud users.

Because system parameters such as CPU time and virtual machine memory size are not independent of one another in a CC system, the impact of system parameters on performance is frequently nonmonotonic. Classic optimization algorithms are rarely used in online parameter configuration because of their high time complexity. Literature [16] automatically manages resources based on self-management strategy and describes how to coordinate according to policies and messages. Literature [17] proposes a CC virtual resource allocation algorithm based on the ant colony algorithm. The algorithm gets better quality and response time, but it can only be used to search computing resources and is limited in the simulation stage. Literature [18] studies the application of CC technology in smart grid, introduces CC technology into traditional smart grid technology, puts forward the idea of intelligent cloud, and makes in-depth research along with the construction of intelligent cloud, resource management, and corresponding security mechanism. Literature [19] puts forward a resource allocation and pricing strategy based on particle swarm optimization. Literature [20, 21] suggests that the feedback control method can be used in the CC system to complete the adaptive configuration and dynamic resource allocation of virtual machines.

3. Research Method

Based on CC technology, the university online examination system studied in this article uses the algorithm for generating test papers. At the same time, a genetic annealing algorithm with double fitness is proposed, which enables the cloud computing system to dynamically formulate cloud resource scheduling solutions to meet the cloud resource requirements of different cloud users and ensure the response time of the cloud computing system to cloud user requests.

3.1. Overall Design of the System

3.1.1. Overall Business Architecture of Cloud Examination System. Cloud examination system is based on CC service, aiming at realizing "on-demand" subscription. Its design and development require scalability and foresight, and it must be able to exchange data with other existing systems. As an independent system, the cloud examination system will provide multiple interfaces to obtain reference personnel and examination information. Besides feeding back the examination results to external systems, it can also provide comprehensive examination information. The overall business structure is shown in Figure 1.

The external subsystem, examination subsystem, examination information input interface, examination login interface, examination result feedback interface, and monitoring information query interface are shown in Figure 1. The entire business architecture is divided into two subsystems and four interfaces: external subsystem, examination subsystem, examination information input interface, examination login

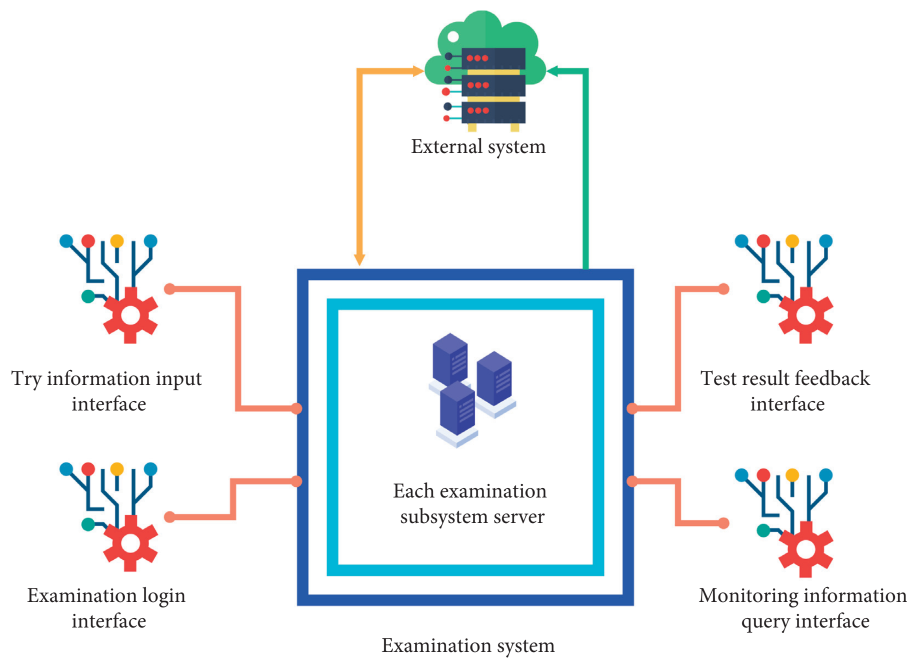

Figure 1: Overall business architecture diagram of the cloud examination system.

interface, examination result feedback interface, and monitoring information query interface. A detailed description of the subsystems and interfaces is given as follows:

(1) *External system:* Peripheral subsystem refers to all systems that need examination services. The number of these subsystems is unlimited and can be expanded as needed to achieve the purpose of customizing examination services.

(2) *Examination system:* Examination system is a system that provides examination services for the periphery. The examination server uses distributed deployment, adopts the shortest path principle to route and forward the examination service request of the external system, and obtains the nearest normal server to process the request.

(3) *Examination information input interface:* The examination subsystem obtains the basic information of the examinees, examination papers, and so on through the examination information input interface.

(4) *Test result feedback interface:* The test result feedback interface is that the test system feeds back the test results to the peripheral system.

(5) *Examination login interface:* The login interface is a separate entrance of examination service provided by the examination system, through which reference personnel can directly enter the examination system for examination without logging into the peripheral system.

(6) *Monitoring information query interface:* The information query interface is an internal interface of the examination system, which is mainly used to monitor the running status of each server of the examination system and provide reference for routing and forwarding.

3.1.2. System Function Module Design. According to the demand analysis of the online homework and examination system, the whole system is divided into two subsystems: homework system and examination system. The Homework subsystem is composed of student module and teacher module, which mainly completes three functions: students' independent training, online work, and test paper generation.

The periodic examination function is performed by the examination subsystem. For example, a teacher may send out an examination notice instructing students to complete a paperless mid-term examination with the specified difficulty coefficient, number of questions, and time limit. Teachers can dynamically understand students' weak links in the course learning process, strengthen students' training on weak knowledge points, and realize intelligent guidance of autonomous learning based on homework feedback.

Figure 2 shows the design of the total functional modules of the system.

3.1.3. Design and Implementation of Database. Online homework and examination system is an application system based on database, in which user information, question bank information, and test paper information are stored. In fact, the database design of this system is to design the structure of every two-dimensional table stored in the database. The system includes two subsystems: homework and exam. It is necessary to design a table for storing exam information, as well as a table for each user's homework information, exam information, and score information. Because the system has

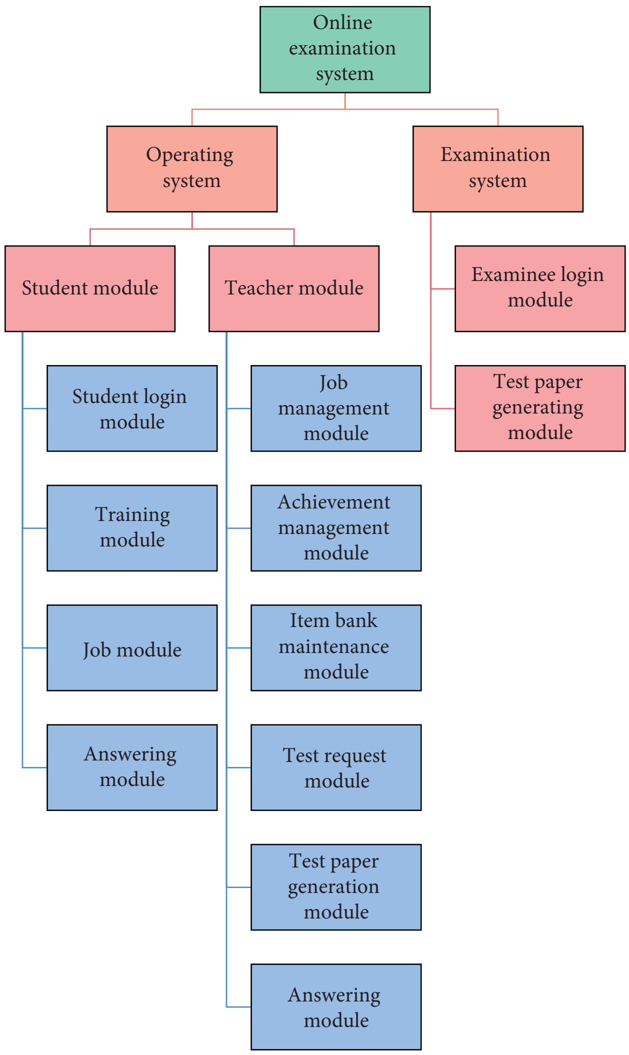

Figure 2: Total functional modules of the system.

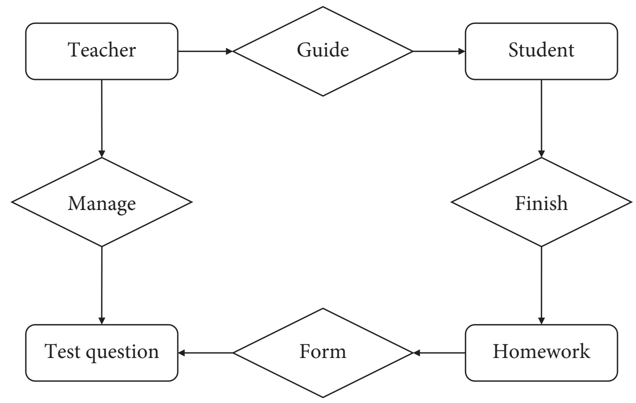

Figure 3: Entity relation diagram.

the function of answering questions online, it is necessary to design a table for storing questions and replies.

According to the results of requirement analysis, conceptual design uses conceptual data model to express the relationship between data and requirements. This model has nothing to do with the database management system, is universal [22], is independent of computer software and hardware systems, and is very convenient to communicate with users. Through the analysis of system requirements, the entities such as students, teachers, test questions and assignments, and their relationships are designed. The E-R diagram of the relationship among students, teachers, homework, and test questions is shown in Figure 3.

3.2. Research on Key Technologies of System Development

3.2.1. System Development Environment. This system adopts MVC (model-view-controller) three-tier architecture mode (namely, presentation layer, business logic layer, and data access layer logic) and is written in the Java language. As Java is an object-oriented cross-platform language, this system can be applied to many operating systems such as Windows and Linux. During the development of the system, the following key technologies are involved:

(1) ActiveMQ is Apache's open-source message stack. The system mainly uses ActiveMQ to share some data transmission and relieve the pressure on the database. Data enters the queue first and then the queue stores the data in the database.

(2) Encryption technology of DES (data encryption standard). It is used to transmit important data, and all passwords of users in the database are encrypted by DES, which improves the security of the system.

(3) XFire is the Java web service engine. It can easily publish the web service interface for other programs to call.

(4) MyBatis is the persistence layer framework. It can easily map Java objects into database records by annotation, write SQL code in XML (Extensible Markup Language), and separate it from Java code, which is beneficial to the maintenance of the system.

(5) JSON (JavaScript Object Notation) is a lightweight data interactive format, which is easy for programmers to read and write, and also easy for computers to parse and generate.

3.2.2. Test Paper Generation Algorithm. The users of online homework and examination system are students and teachers. For students, the purpose of homework and examination is to test their mastery of knowledge, while teachers judge students' mastery of course content through students' training and submitted homework, and adjust teaching plans appropriately. The algorithm for generating test paper should be reasonable, fair, and scientific.

The process of generating test papers is to select appropriate parameters, and according to a certain strategy of generating test papers, select the test questions that meet the requirements from the test question bank to form a test paper. The process of volume formation has the following steps, as shown in Figure 4.

Explain the process of generating test paper as follows:

(1) Because this strategy is used for homework and test paper generation, the requirements of these two

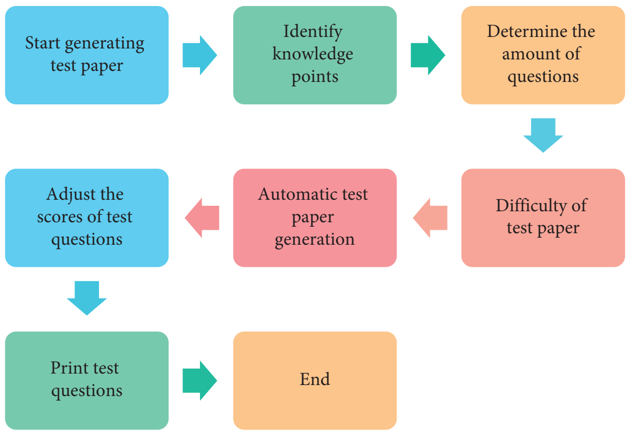

FIGURE 4: Basic steps of volume formation.

operations are different. When the job is generated, the score is not determined and adjusted.

(2) When determining the number of questions, considering that the examination time is limited, an appropriate number of questions should be arranged.

(3) The purpose of adjusting test scores is to make the test scores more reasonable. Teachers can adjust the test scores slightly according to the difficulty of the test questions when the total score is 100.

Test paper is the process of making the selected test attributes meet these conditions according to the constraint conditions. Specifically, it can be understood that the test paper consists of m test questions, and each question has 7 attributes to meet, which are represented by a $m * 7$ matrix:

$$S = \begin{bmatrix} s_{11} & s_{12} & \cdots & s_{17} \\ s_{21} & s_{22} & \cdots & s_{27} \\ \vdots & \vdots & \ddots & \vdots \\ s_{m1} & s_{m2} & \cdots & s_{m7} \end{bmatrix}. \quad (1)$$

In the above matrix, each line represents a test question, and $s_{i1} - s_{i7}$ corresponds to the attributes in the test question attribute table, namely, question number s_{i1}, question type s_{i2}, chapter s_{i3}, difficulty coefficient s_{i4}, discrimination s_{i5}, test question score s_{i6}, and secondary knowledge point s_{i7}. The matrix should satisfy the following Jordan conditions:

Knowledge point constraint:

$$Z_j = \sum s_{i3} * c_{1i}, \quad c_{1i} = \begin{cases} 1, & s_{i3} = j, \\ 0, & s_{i3} = 0. \end{cases} \quad (2)$$

The test questions belong to the first j knowledge point, the chapter points plus 1.

Question constraint:

According to the characteristics of the course of communication electronic circuit, the types of test questions are set as selection, filling in the blanks, short answers, and calculation. In the process of grouping questions, the structure of test questions is fixed. $T = (T_1, T_2, T_3, T_4)$ is used to represent, where T_i is the number of different types of questions, and the calculating formula is

$$T_i = \sum s_{i2} * c_{2i}, \quad c_{2i} = \begin{cases} 1, & s_{i2} = i, \\ 0, & s_{i2} \neq i. \end{cases} \quad (3)$$

Total score constraint:

The total score of a test paper can be expressed as $ZF = \sum s_{i6}$, and the default full score is 100.

Difficulty constraint:

The difficulty factor G is expressed as

$$G = 1 - \frac{\sum s_{i4}}{m}. \quad (4)$$

The problem of creating test paper is essentially a multi-constraint combinatorial optimization problem. Many constraints, such as question type, knowledge point, and difficulty, must be met in order to generate a reasonable and scientific test paper. These issues are intertwined. When creating test paper, different weights are assigned based on the importance of each attribute, in order to meet as many constraints as possible.

Define the overall error $F(x)$ of the test paper, which is equal to the error value $e_i(x)$ of each index multiplied by their weight value W_i, and the final ideal result is that the error value is simplified to the minimum value problem of $F(x)$ as much as possible, that is,

$$\min F(x) = \sum_{i}^{4} W_i e_i(x). \quad (5)$$

3.2.3. CC Resource Scheduling. The distribution, heterogeneity, and dynamics of CC resources determine the complexity of the CC resource scheduling system. Therefore, the research on cloud resource scheduling has become another key issue in the CC system. To solve the above problems, this study proposes a CC resource scheduling strategy based on the improved parallel genetic annual algorithm (IPGAA). Figure 5 shows the specific algorithm flow. It enables the CC system to dynamically formulate cloud resource scheduling solutions to meet the cloud resource requirements of different cloud users, while ensuring the response time of the CC system to cloud user requests.

According to the optimal solution scheme, cloud users can request effective scheduling of available cloud resources in the CC system, which makes the resources of the whole CC system be scheduled in a balanced way and effectively improves the efficiency of the whole system.

A virtual machine resource can be described by a sextuple, as shown in the following formula:

$$V = \{\mathrm{ID}, \mathrm{CPU}, \mathrm{Ram}, BW, F, P\}. \quad (6)$$

The type, ID represents the virtual machine's unique identifying number; CPU represents the number of virtual CPUs in the CC system; Ram represents the memory size of virtual machines in the CC system; BW represents the maximum bandwidth allowed by virtual machines in the CC system; F represents the failure rate of virtual machines in the CC system; and P represents the price of using virtual machines per unit time in the CC system.

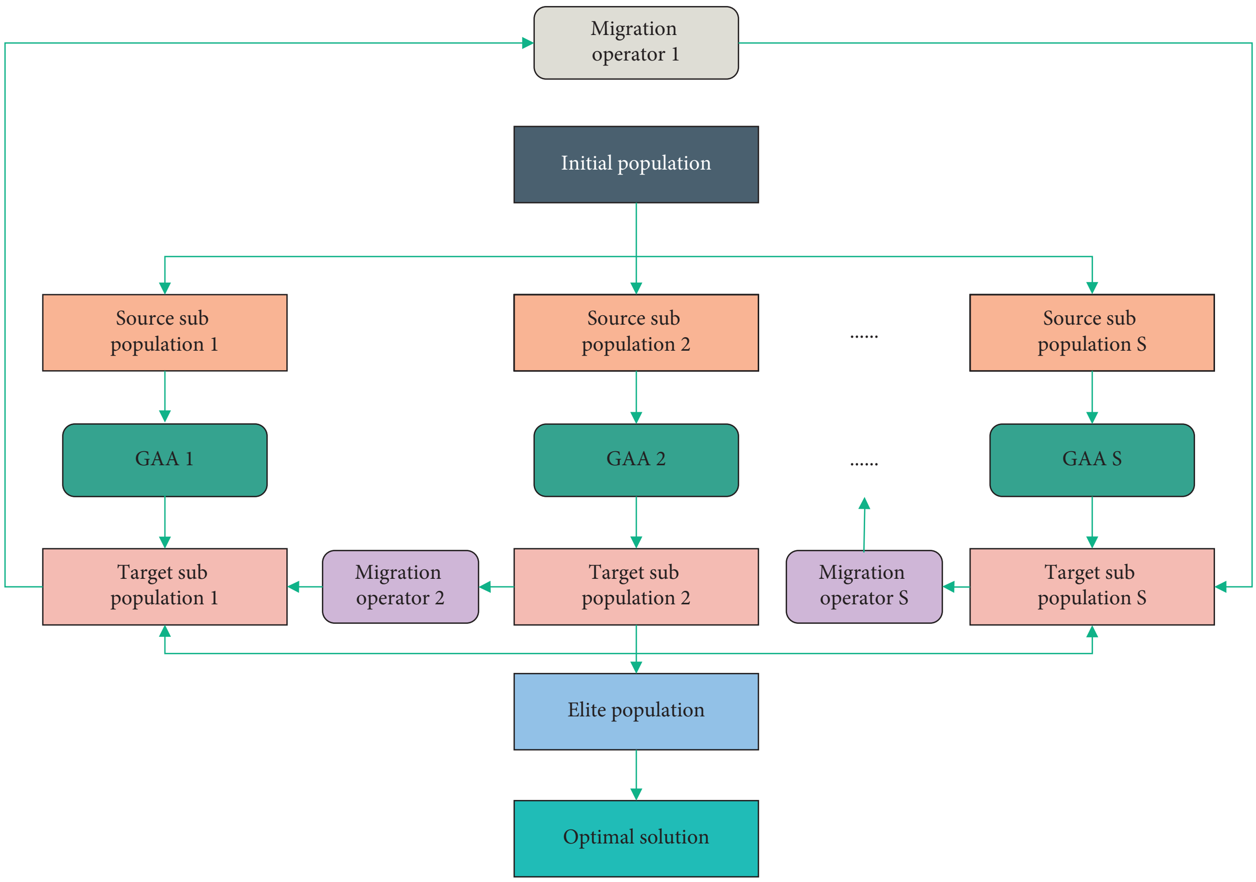

Figure 5: Parallel genetic annealing algorithm process.

According to the characteristics of resource scheduling in the CC system, this study proposes to encode the available cloud resources occupied by each cloud user's subtasks by indirect encoding. Figure 6 shows the coding method used in this study, and its specific coding scheme is as follows: the position number of each bit of chromosome indicates the number of cloud user subtasks; chromosome represents the number of available resources occupied by cloud user subtasks, which is represented by the positive integer value of each bit.

In Figure 6, T_i represents the number of cloud user subtasks and R_i represents the number of available cloud resources occupied when executing the cloud subscriber subtask T_i.

The total completion time of all cloud subscriber request tasks running on a virtual machine is the virtual machine's cloud subscriber task execution time. As a result, the total completion time required to run all cloud user tasks in the entire CC system is equal to the maximum running time of all virtual machines running cloud user tasks, that is,

$$F(x) = \operatorname*{Max}_{m=1}^{M} \sum_{i=1}^{n} \mathrm{Time}(m, t). \tag{7}$$

In the above formula, $\mathrm{Time}(m, t)$ represents the time required to execute the t-th cloud user task on the virtual machine with the identification number of m; n represents the number of cloud user tasks running on the virtual machine labeled m; and M indicates the total number of running virtual machines in the CC system.

T_1	T_2	T_3	...	T_n
R_1	R_2	R_3	...	R_n

Figure 6: Coded system.

The operation of the selection operator of the IPGAA algorithm proposed in this study is realized by roulette model; that is, the selection probability of each individual is proportional to the value of its fitness, and $P(i)$ is used to represent the selection probability of individuals; then,

$$P(i) = \frac{F(i)}{\sum_{i=1}^{\text{popsize}} F(i)}. \tag{8}$$

It should be pointed out that in the IPGAA algorithm proposed in this study, the crossover probability P_c and mutation probability P_m are dynamically changed, and the P_c function and P_m function are

$$P_c = \begin{cases} \dfrac{k_1 (f_{\max} - f')}{(f_{\max} - f_{\min})}, & f' \geq f_{\text{avg}}, \\[2ex] \dfrac{k_2 (f_{\max} - f'')}{(f_{\max} - f_{\min})}, & f'' \leq f_{\text{avg}}, \end{cases}$$

$$P_m = \frac{k_3 (f_{max} - f)}{(f_{max} - f_{min})}. \tag{9}$$

The maximal fitness value of chromosomes in a modern evolutionary population is represented by type k_1, k_2, k_3, which is a constant; f_{max} represents the maximum fitness value of chromosomes in contemporary evolutionary population; f' indicates that the fitness of two chromosomes crossing in the contemporary evolutionary population is larger; f_{min} represents the minimum fitness value of chromosomes in contemporary evolutionary population; f_{avg} represents the average fitness value of all chromosomes in the contemporary evolutionary population; f' indicates that the fitness of two chromosomes crossing in contemporary evolutionary population is small; and f represents the fitness value of variant chromosomes in contemporary evolutionary population.

From the above analysis, it can be concluded that the IPGAA algorithm proposed in this study uses the indirect coding mode of "resource-task," and the process of redistributing cloud resources occupied by cloud users' tasks corresponds to the process that chromosomes in the population are operated by crossover and mutation operators to generate new chromosomes in the IPGAA algorithm. Therefore, the IPGAA algorithm is adopted to solve the resource scheduling problem in the CC system, which combines the characteristics of both, and provides an effective method for the resource scheduling problem in the CC system.

4. Result Analysis and Discussion

4.1. Test Paper Generating Results and Analysis. In order to test the improvement of GA on the performance of generating test paper, the following groups of experiments were performed, each experiment was conducted 20 times, the successful running time was averaged, and the algorithm success rate and knowledge points were counted.

Experiment: 6 multiple-choice questions, 7 fill-in-the-blank questions, 8 short-answer questions, and 5 calculation questions, with a difficulty coefficient of 0.55. Chapters: all chapters, select all secondary knowledge points, and the amount of question bank: 600;

Experiment 2 : 12 multiple-choice questions, 14 fill-in-the-blank questions, 15 short-answer questions, and 10 calculation questions, with a difficulty coefficient of 0.55. Chapters: all chapters, select all secondary knowledge points, and the amount of question bank is 600.

Experiments were conducted 20 times, and the results are shown in Figures 7 and 8.

Figures 7 and 8 show that, while the GA takes much longer than a random algorithm to generate test papers under the same conditions, its success rate has greatly improved, especially as the number of test banks and questions grows larger. It is worthwhile to sacrifice time for system applications in order to improve the success rate.

4.2. Map/Reduce Model Performance Analysis. Due to the limitation of experimental conditions, one Hadoop distributed platform is selected as the main server, and the remaining seven are node servers. Make relevant verification under the Linux environment. This study gives full consideration to the computing performance of each different computing node, the distance between map tasks, and the distance between the node and the master node. Map/reduce considers load balancing, but balanced allocation cannot. By taking the first 10 tasks in an average of 20 tests, we compare the accuracy of data results retrieved by one map/reduce model and two map/reduce models, as shown in Figure 9.

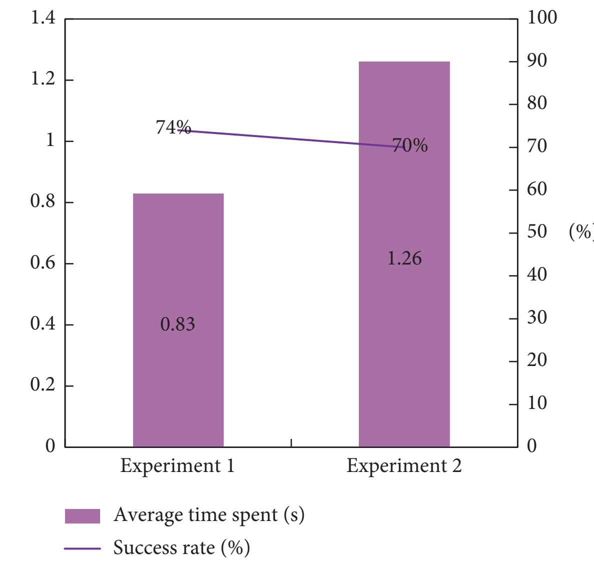

Figure 7: Success rate and time consumption of random test paper generation.

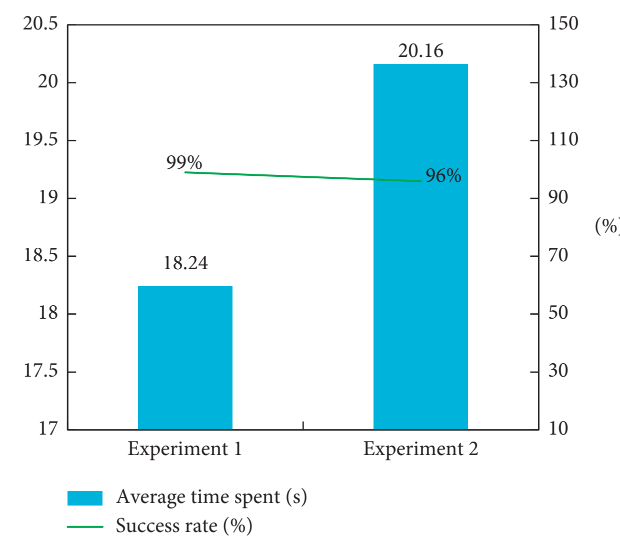

Figure 8: GA test paper generation success rate and time consumption.

While the secondary map/reduce classified storage ensures the time efficiency of tasks, its index retrieval effect in the secondary classified storage is obviously better than that in the primary map/reduce model. The reason for this is that the primary map/reduce has too much data and too many

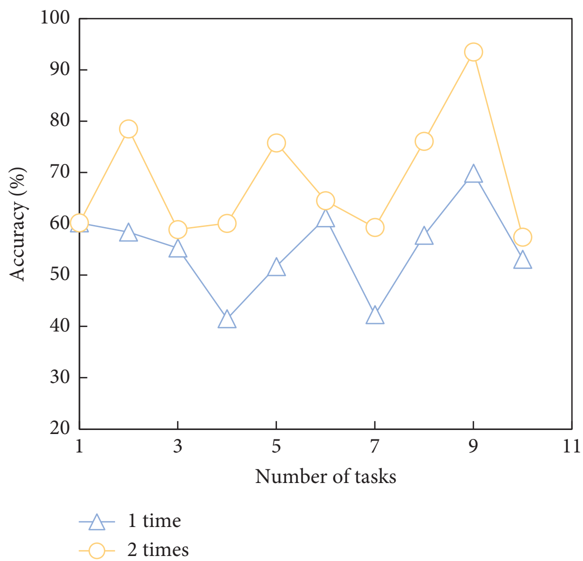

Figure 9: Search graph based on secondary map/reduce classified storage.

returned results, and the data results are often incomplete and inaccurate, resulting in a decline in users' interest.

However, the secondary map/reduce classified storage reduces the number of searches , improves the accuracy of returned results and the user satisfaction, and is more targeted.

4.3. Simulation Analysis. In order to prove the effectiveness and efficiency of the IPGAA algorithm proposed in this article, this article uses CC simulation tool CloudSim to conduct simulation experiments and chooses Cloudsim-3.0.2 version software. In the Cloudsim working model, cloud information service is responsible for allocating appropriate CC resources for user requests. Among them, the data center agent is responsible for the assignment of tasks to virtual machines. The virtual machine allocation control policy is responsible for completing the mapping between virtual machines and hosts. A virtual machine scheduler is an abstract class that implements host components and simulates the allocation and scheduling strategy of virtual machines.

This simulation is mainly an extension of DatacenterBroker, in which the IPGAA is introduced to realize the deployment of Task to the virtual machine.

There are t tasks $\text{Task} = \{\text{Task}_1, \text{Task}_2, \ldots, \text{Task}_t\}$ and m virtualized resources $VM = \{VM1, VM2, \ldots, VM_m\}$. The experiment simulates two groups of resource scheduling scenarios: the first group simulates 20 resources and 30/70/100 tasks, and the second group simulates 30 resources and 30/70/100 tasks. When the population size is set to 300 and divided into 6 subpopulations, the size of each subpopulation is $N = 50$.

Through a large number of simulation tests, Figure 10 shows the specific experimental results. In Figure 10, the algorithm completion time and algorithm evolution algebra

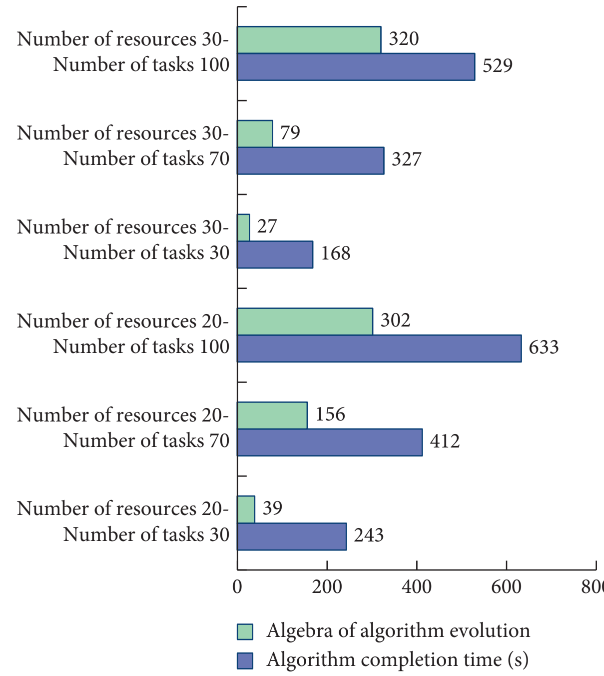

Figure 10: Simulation experimental results.

of the IPGAA algorithm are the average values obtained by running the algorithm 50 times.

It can be concluded from Figure 10 that when the number of cloud user tasks remains unchanged, for example, when the number of cloud user tasks $n = 30$, as the number of available cloud resources increases from 20 to 30, the completion time of the IPGAA algorithm decreases; when the number of cloud user tasks $n = 70$, with the increasing number of available cloud resources, that is, when the number of available resources increases from 20 to 30, the completion time of the IPGAA algorithm decreases greatly.

At the same time, Figure 10 shows that the number of cloud user tasks has increased from 30 to 70 and 100, and the algorithm completion time of the IPGAA algorithm shows an overall upward trend. However, the completion time of the algorithm did not increase exponentially with the number of cloud user tasks; on the contrary, it was a process in which the growth ratio was relatively reduced, which showed an optimization trend in essence. Similarly, when the number of available cloud resources is set to $m = 30$, a similar conclusion can be obtained.

Figure 11 lists the simulation execution results of the IPGAA algorithm under the conditions that the number of resources is $m = 20$ and $m = 30$, and the number of scheduled cloud user tasks is $n = 30$.

It can be concluded from Figure 10 that when the number of available cloud resources is set to $m = 20$ and the number of cloud user tasks is set to $n = 30$, the IPGAA algorithm converges to the global optimal solution around the 38th generation, and the solution of the average completion time of the IPGAA algorithm in each generation after the 38th generation is the same as that around the 38th

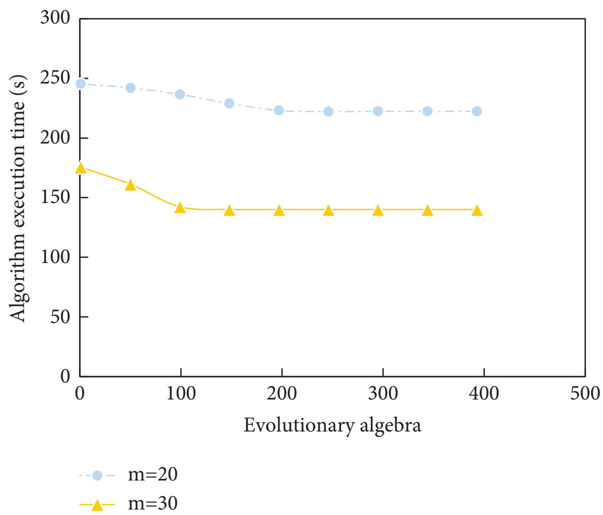

Figure 11: Algorithm simulation results.

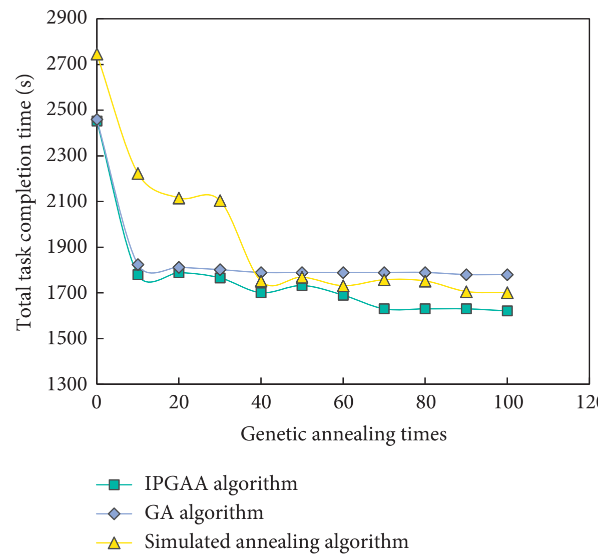

Figure 12: Comparison of total task completion time.

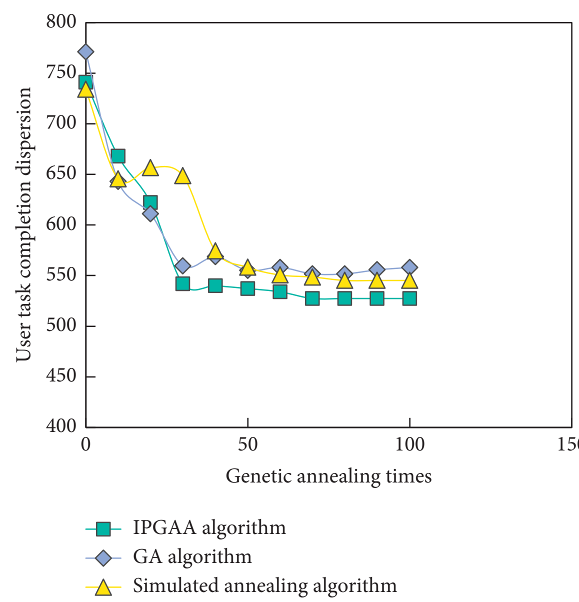

Figure 13: Cloud user task completion dispersion.

generation. Therefore, it can be concluded that the IPGAA algorithm is convergent and has good stability.

When the number of available cloud resources is set to $m = 30$ and the number of cloud user tasks is set to $n = 30$, the IPGAA algorithm converges to the global optimal solution when it runs to the 28th generation or so. And in the generations after the 28th generation, the solution of the average completion time of the IPGAA algorithm is the same as that in the 28th generation or so, and it can also be concluded that the IPGAA algorithm is convergent and has good stability.

In order to further verify the efficiency of the IPGAA algorithm proposed in this article, this article compares the IPGAA algorithm, simple GA algorithm, and simple simulated annealing algorithm, and compares the performance of these three algorithms in total task completion time and cloud user task completion dispersion. The performance comparison results of the above two aspects are shown in Figures 12 and 13.

It can be concluded from Figure 12 that for the total completion time of all cloud user tasks in the CC system, the final task completion time of three scheduling algorithms, that is, IPGAA algorithm, GA algorithm, and simulated annealing algorithm, is almost the same. However, compared with simulated annealing algorithm, the IPGAA algorithm shows that its convergence is better and faster.

This fully shows that IPGAA algorithm can not only get less total completion time of cloud user tasks, but also accept nonoptimal solutions with a certain probability, thus effectively avoiding local convergence caused by fast convergence of GA and greatly improving the performance of the cloud user task scheduling algorithm.

From Figure 13, it can be concluded that the convergence speed of the IPGAA algorithm is slower than that of GA because it can accept the nonoptimal solution of the IPGAA algorithm according to a certain probability.

In addition, the IPGAA algorithm can effectively prevent local convergence, and its final cloud user task completion dispersion is smaller than simple GA and simple simulated annealing algorithm. The smaller the dispersion of cloud user task completion, the higher the cloud user satisfaction, indicating that the IPGAA algorithm has achieved higher cloud user satisfaction than the other two algorithms.

5. Conclusion

Due to the closed, scattered, and uneven distribution of resources in the network examination system's application in enterprises, CC technology was introduced into the network examination system, which solved the problem of dynamic distribution of examination resources on demand, and successfully designed and implemented an online examination system based on CC. There were two subsystems created: online homework and online exams. The online homework module gives students the ability to do online practice and homework, which makes it easier for teachers to keep track of their students' homework and spot any leaks or gaps in their instruction. The IPGAA algorithm has better adaptability in the CC system with various cloud resources, as it introduces the basic idea of the genetic annealing algorithm, fully combining the fast global search ability of the GA and the local search ability of the simulated annealing algorithm.

Cloud technology requires a large number of users to participate, and privacy problems inevitably arise. Users' participation means collecting some user data, which leads to the worry about the safety of user data. Many users are worried that their privacy will be collected by cloud technology. For this reason, when joining the cloud plan, many vendors promise to avoid collecting user privacy as much as possible, and even if they do, they will not disclose or use it.

This paper provides an in-depth study and analysis of big-data-driven data visualization and visual communication design models. The characteristics of new media and the definition of traditional media are analyzed; the importance of the new media environment is derived through comparison; and the successful cases of new media integration today are analyzed. In this process, we will optimize the traditional science and technology intelligence service model, optimize the various components that make up the science and technology intelligence wisdom service, achieve model optimization and reflect the four characteristics of science and technology intelligence wisdom service, and reconstruct the science and technology intelligence wisdom service using the literature research method. The design based on imagery schema theory is manifest, inclusive, and somewhat innovative and at the same time has a high degree of consistency and internal logical relationship with the visual representation of multidomain heterogeneous data at the cognitive level and displays purpose. This internal logical relationship is systematically organized and deeply analyzed, and the methodology from subpattern extraction and visual interaction design to the deep integration of visual representation is proposed in combination with specific application scenarios and cases.

1. Introduction

In the twenty-first century, digital information technology is the main media way. The major mode of communication in the new media environment of visual communication design is network communication, which is used to lead people to a new visual direction while connecting the orientation of consumerism culture, as the country continues to progress, in enhancing the hard strength of culture while also enhancing the soft power of culture. Therefore, under the continuous change of market economy, the transformation form of visual communication performance to meet the market is also particularly important, especially the expression form of visuals in the new media environment and the innovation of design style. This paper will also examine people's mainstream ideologies on the research and analysis of visual performance, as well as the audience group's psychological change features, popular aspects, and other varied factors [1]. In the market economy, we design to meet the consumer's psychology and activate the desire to buy, thus boosting the gross domestic product [2]. So this article will also analyze the research and analysis of people's mainstream ideology on visual performance that is very important and, at the same time, study various factors such as the psychological changes of the audience and popular elements. In the international design arena, design works not only follow the international fashion trend in the form of expression but also understand different aspects of domestic regional culture, customs, and folklore to regionalize to centralize the extraction of design works representing Chinese regional elements to the world. We should pay attention to both the embodiment of its value, but also should pay attention to the timeliness of the delivery of information published, the time of delivery, delivery efficiency, communication carriers, and the feelings of the audience [3]. In the digital information technology progress today, the form of design expression should also have the mass type. The cost of dissemination in new media operations is much more than the audience (which refers to the news media dissemination object as well as a variety of cultural and artistic works of the recipient) brought about by its dissemination itself and by economic benefits, so it cannot be formed for the effective value of the media.

In recent years, the rapid development of new media stage, the emergence of many new communication companies, but in the baptism through the media storm, few companies can survive; without understanding the core of the new media communication design expression form, blindly copying and borrowing other works leads to failure, or the design concept is too far beyond people's basic cognitive aesthetics which leads to design failure, such examples abound [4]. While choosing the essence and the dross, it is also important to grasp the timeliness, interactivity, and interactivity of new media. With the aid of technology and information technology, it is also important to reflect the transformation of visual performance in an innovative way. Therefore, designers should profoundly analyze the ideology of consumers and the psychology of the audience before designing works and should not impose difficult design concepts on the design performance, leading to the failure of design works and market inconsistency and disproportionate input and outcome. In the data-driven era, the data resources faced by scientific and technological intelligence services show multidimensional, heterogeneous, and massive trends. These trends make it difficult for traditional data analysis methods, techniques, or tools to cope with the current situation of multiple and heterogeneous data sources, which is one of the challenges faced by science and technology intelligence agencies. According to the task division of S&T intelligence services defining the time, scope, format, and processing techniques of multisource data, there are five key categories of S&T intelligence tasks such as identification tasks, tracking tasks, comparison tasks, evaluation tasks, and prediction tasks. Cartography plays an important role in geographic research, where the main use is for the scientific exploration of geographic laws. Initially, it was used as a visualization product for abstract thinking [5]. With the transformation of cartography from traditional paper maps to computer hardware facilities such as screens, the information-carrying capacity of maps and the accuracy of information expression are also increasing, and the ways of human interaction with maps for data analysis are also enriched. And with the continuous development of Internet technology, the public openness of geographic information services is getting higher and higher. The communication of web map information has also faced a variety of different user needs. The tools and workflows produced by online mapping platforms, as well as the interactive features that can be implemented, are categorized and summarized in a series of case studies of maps from government, academia, and research institutions. It is concluded that overall, the technical difficulty of online mapping is decreasing due to open data distribution, open-source software, and cloud service innovations. These new technologies are enabling increasingly powerful data exploration capabilities and are an important part of big data and open data. However, online analytics capabilities for the web are currently less mature and can have promising applications in areas such as urban analytics.

Process-based assessment with big data will record and analyze all data about the student learning process. It is the fusion of information related to learning outcomes that will aid in decisions about instructional improvement. Although teacher excellence is outcome-oriented, if the process is ignored, it is difficult to reproduce the growth process of teaching excellence and replicate more of them. The commercial benefits brought by the communication itself cannot be formed into the effective value of the media. For example, evaluating the computer technology and information literacy abilities of computer science majors and teacher education majors by testing their computer application skills showed that the computer application skills of computer science majors were significantly higher than those of teacher education majors, which is an outcome evaluation. Based on the outcome evaluation alone, it is easy to overlook the fact that computer science majors take more computer-related courses during their training. It cannot be simply assumed that increasing the number of computer courses taken by teacher-training students will improve their information literacy; it is important to consider that students enrolled in computer science programs are generally more interested in software, electronic technologies, and products, and differences in logical thinking between students in teacher training programs and nonteaching students exist.

2. Current Status of Research

Two attributes, timestamp and geographic location, are the characteristics that distinguish spatiotemporal data from other data. The rapid spread of mobile terminal devices and sensor devices monitor and track the massive behavioral data generated by research subjects on the Internet in real time. Foreign scholars are committed to applying spatiotemporal big data for mining and analysis to reveal regular conclusions [6]. For example, in the field of urban research, it can be used to study the spatial structure of cities and residents' behavioral patterns and so on. At the same time, many scholars are interested in how to represent these new types of data and visualize the results of the analysis [7]. Visualization is an important expression method for big data analysis, which takes advantage of human's cognitive ability for visualized information and organically combines the respective strengths of humans and machines with the help of human-computer interaction analysis methods and interactive technologies, assisting people to gain more intuitive and efficient insight into the information, knowledge, and wisdom behind big data [8]. Since spatiotemporal data carries spatial geographic information, it is often combined with geographic cartography to express, and the key is how to visualize and map the spatial dimension, the temporal dimension, and the corresponding attribute dimension [9]. The spatiotemporal cube visualizes time, space, and events in the form of a 3D coordinate system. A stacked map can also be used to fuse 2D and 3D to expand the space for displaying multidimensional attributes in the space-time cube. However, the display of a 3D coordinate system also has its limitations, especially when the spatiotemporal information objects have more dimensions, so it is often fused with multidimensional data visualization methods to assist the expression [10]. The rapid development and mature application of artificial intelligence technology and big data bring opportunities and challenges to scientific and technological intelligence work, and systematic review and improvement of scientific and technological intelligence service research systems in the data-driven era can provide development ideas for scientific and technological intelligence intelligent service mode [11].

Faced with the trend of intelligent technology and the trend of multisource heterogeneity of massive data, the science and technology intelligence service model faces serious challenges. For example, in the face of massive data resources such as scientific and technical literature and patent literature, the traditional human-driven model cannot realize the semantic extraction of massive multisource heterogeneous data resources, and the characteristics of literature resources such as multilingual and multidomain for accurate extraction of data resources corresponding to scientific and technical intelligence tasks, which requires the development of semantic extraction tools with more enhanced capabilities [12]. The research and application of schema theory in the field of foreign language teaching are dominant, and the research direction is subdivided into the application of schema theory in reading comprehension, listening comprehension, translation, and corpus, but the mainstream of research and application is still limited to its ontology: linguistics; the research of cognitive discipline begins to sprout, which is manifested in the application of schema theory to gain insight into the process and method of language acquisition and the systematic analysis of cognitive patterns, pathways, strategies, and representations in the process of foreign language learning [13]. The research on the reading comprehension process occupies the main position, and the research on cognitive disciplines is still not separated from the field of foreign language teaching; although psychology and philosophy have been involved in this field since the introduction of schema theory, scholars' research in this field is relatively rare and limited in depth.

The purpose of this paper is to construct a data-driven scientific and technological intelligence wisdom service model, improve and enrich the scientific and technological intelligence wisdom service research system, help scientific and technological intelligence service organizations better understand their advantages and defects, recreate the service process according to the scientific and technological intelligence wisdom service model, and develop a wisdom service plan that meets their characteristics. Firstly, the research on data-driven scientific and technological intelligence wisdom service has not been systematically analyzed in terms of its constituent elements and characteristics, and the systematic analysis of the constituent elements and characteristics of the data-driven scientific and technological intelligence wisdom service model on the existing research results is a key part of improving the scientific and technological intelligence wisdom service research system, establishing the correlation between the constituent elements of scientific and technological intelligence wisdom service and systematically cognizing each constituent element.

3. Analysis of Data-Driven Data Visualization and Visual Communication Design Patterns

3.1. Data-Driven Algorithm Design for Data Visualization. The design concept is too much beyond people's basic cognition and aesthetics, which also leads to the failure of design. Such examples are everywhere. Therefore, designers should deeply analyze the ideology of consumers and the psychology of the audience before designing works and should not deal with design concepts that are difficult to achieve. Multidomain heterogeneous data is a kind of big data; it is an important trend and direction that emerged at a certain stage of big data development, which is proposed by researchers or users for expanding data sources, domains, and complex data structures, and big data is an important source and basis for multidomain heterogeneous data generation. Before understanding multidomain heterogeneous data, a brief overview of big data is needed [14]. Compared with the traditional service model, the components of the scientific and technological intelligence service model in the era of big data should reflect the characteristics of intelligent service, and the scientific and technological intelligence service has shifted from the qualitative analysis service model such as expert experience judgment in the past to quantitative analysis based on scientific study big data service model, and the data-driven research paradigm will become the core paradigm of scientific and technological intelligence service. The intelligence service relies more on intelligent devices and technologies, sensing user needs through intelligent data services, using intelligent analysis technologies to obtain intelligence oriented by the concept of integration, and finally using big data on user behavior to push scenario-based services. Science and technology intelligence services are user-demand-oriented, data-driven, and highly knowledge-intensive, and the development and maturity of big data bring opportunities and challenges for intelligence services. The composition of the scientific and technological intelligence analysis process that integrates scientific research big data covers seven dimensions, such as data, users, technology, intelligent intelligence, scientific and technological intelligence workers, and intelligent service platforms and methods. In-depth analysis will be conducted from these seven dimensions, and on this basis, the theoretical and practical basis for the realization of data-driven scientific and technological intelligence services will be discussed, and then the demand sensitivity of scientific and technological intelligence services will be discussed. The theoretical and practical foundations of data-driven STI services will be discussed, and the four main characteristics of STI services, including demand sensitivity, data multisourcing, technical intelligence, and service scenario, will be explained.

Principal component analysis (PCA) is a commonly used method for dimensionality reduction. High-dimensional data is generally very sparse, with most data at the boundaries in a high-dimensional hypercube. This makes analyses such as clustering and outlier analysis, which focus on the distance between points and the degree of aggregation, meaningless. And high-dimensional data also suffer from data redundancy, which reduces the speed of processing data later and takes up storage resources [15]. Therefore, it becomes necessary to represent high-dimensional data with low-dimensional data with as little information loss as possible. PCA style is the simplest method of dimensionality reduction by taking random variables that are originally componential correlated.

$$\begin{aligned} X &= \left(x_1, x_2, \ldots, x_m\right)^2, \\ Y &= \left(y_1, y_2, \ldots, y_m\right)^2. \end{aligned} \tag{1}$$

Data identification is based on the definition of data scope, structure, and attributes, such as for data collection services, after data fusion to refine the available knowledge for data applications, after data identification for collection and organization, and then classification and storage to build the corresponding field of the thematic database, such as industrial technology database, thematic database, intelligence reports database, and research id database. The data will generate new data in the application stage, such as user behavior data (evaluation and feedback data) and so on, which can be used as data identification scope for recirculation. Overall, due to open data release, open-source software, and cloud service innovation, the technical difficulty of online mapping is declining. The construction of scientific and technological intelligence resources has become more prominent in the characteristics of "big data," and intelligent data have become a new orientation for the construction of scientific and technological intelligence resources. In this process, wisdom data service emphasizes semantic interconnection, which essentially improves the standard of data quality and value, and the construction and management of intelligence resources in the field of science and technology continue to innovate and rise, and the construction of various kinds of databases with special characteristics in the field are springing up, so how to reasonably embed wisdom data service, through the fusion of multisource heterogeneous data, correlation, and semantic analysis of data, and then realize the science and technology intelligence service. Intelligent data is the logical starting point of intelligent services; the quality and quantity of data determine the depth and breadth of scientific and technological intelligence intelligent services, as shown in Figure 1.

Small tree-like structures are often considered to be communities, despite their sparse structure. Considering the intrinsic meaning of communities, such a result is counterintuitive and raises the question: is community detection therefore unusable on mobile call graphs? Finally, user behavior big data are used to push scene-based services. Science and technology intelligence services are highly knowledge-intensive services that are user-demand-oriented and data-driven. The results may need to be considered with caution, but as community detection methods always do, this particularity of communities in mobile call graphs seems to be a special rather than a problem, regardless of the network used [16]. Although they may have a single shape, communities can provide important information when useful with external information.

$$\begin{aligned} D &= \frac{1}{m} Y Y_n^T, \\ w_i &= \frac{\lambda_i}{\sum_{j=0}^{k} \lambda_j^2}, \\ X &= \begin{pmatrix} p_{11} - p_1 & p_{12} - p_1 & \cdots & p_{11} - p_1 \\ p_{21} - p_1 & p_{21} - p_1 & \cdots & p_{21} - p_1 \\ p_{31} - p_1 & p_{31} - p_1 & \cdots & \cdots \\ p_{41} - p_1 & p_{41} - p_1 & \cdots & p_{41} - p_1 \end{pmatrix}. \end{aligned} \tag{2}$$

The human brain can process visual features such as curvature, color, and so on and will process this information much faster than it can process symbolic information. For example, an observer can easily find a blue dot in a mass of red dots mixed with a blue dot or even spot the blue dot without being prompted. Information visualization takes advantage of the developed nature of the human perceptual system to be able to process large amounts of data quickly. Good visualization can convey information more efficiently and directly, which is an advantage of the method used in this study. Visual analytics is a combination of automatic computer analysis capabilities and human cognition of visual graphics, based on which Lei Ren et al. analyze in detail the cognitive theory, information visualization theory and human-computer interaction, and user interface theory that support the analysis process and discuss information visualization techniques for mainstream applications of big data and human-computer interaction techniques that support visual analytics. They use pixels of different colors to represent different data attributes. The position and order of the pixels can be used to represent semantic information such as level of interest or item similarity, and this visualization design can be used well to represent large data sets. Many visualizations in this category are based on hierarchical aggregation techniques, and often such visualizations distinguish information details for scalability, so there is little visual clutter after the data is visualized [17]. There has been much excellent research in the field of visualization based on visualization design. A proper spiral layout design can make trends in periodic data more visible when the right period is chosen. This is a very much used method to reveal periodic patterns in temporal data along a spiral timeline by parameterizing the visual design.

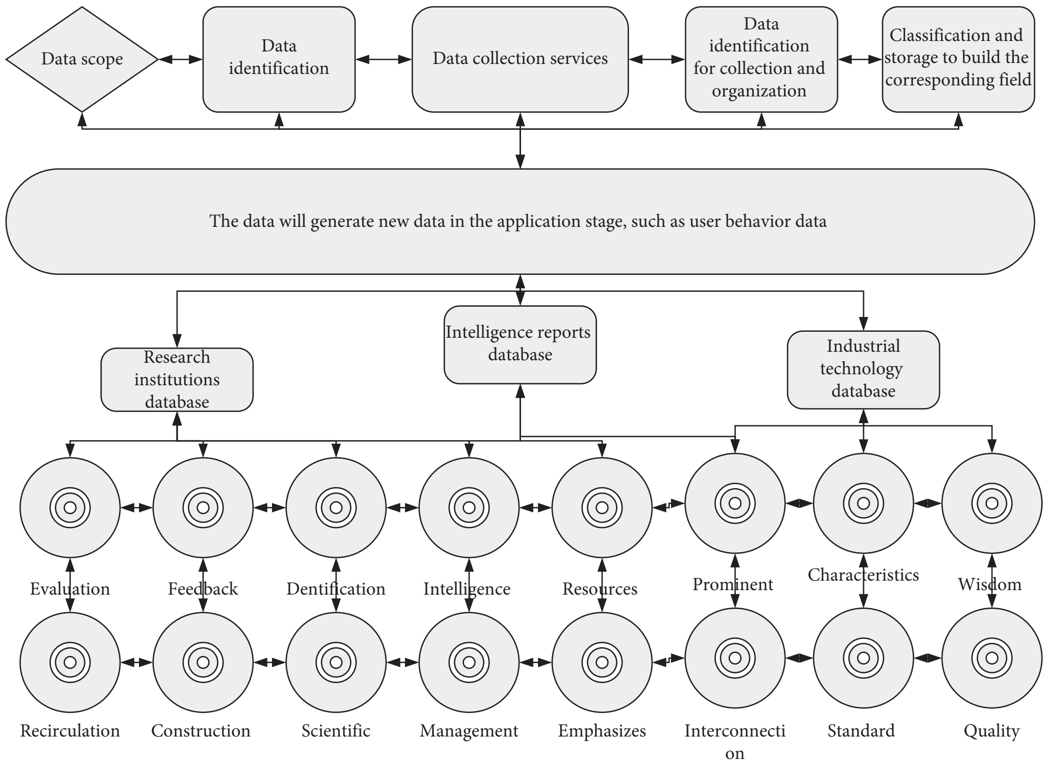

Figure 1: Data-driven framework.

$$p_{AB} = \frac{Cov(a, b)}{\chi_a \lambda_B},$$
$$A = \left[\sqrt{\lambda_1 \eta_1}, \sqrt{\lambda_2 \eta_2}, \ldots, \sqrt{\lambda_n \eta_n} \right]^{1/2}. \tag{3}$$

As an example of a diagrammatic reaction force, forces occur in pairs, and the action involves the active encounter of equally powerful physical or metaphorical opposing forces, which is the reaction force. The effects of reaction forces are more common in life, such as slapping a basketball or loosening a compressed spring. In design, proper use of reaction forces can receive good results, such as the proportional relationship between the length of time and the strength of pressing the cue in a billiards game; the game Jump a Jump also uses the same principle; pinball games and Angry Birds are typical applications of reaction forces in design, as shown in Figure 2.

Spatial schemas cover a variety of subgraphs that are closely integrated into human activities such as orientation and space and have a wide range of cuts in design and multidomain heterogeneous data visualization. User behavior data can be recirculated as the data recognition range. The construction of scientific and technological information resources has highlighted the characteristics of "big data," and smart data have become a new direction for the construction of scientific and technological information resources. Their prominent role is not only in the basic composition but also in close cooperation with Gestalt-based design methods, which play an important and prominent role in the visual representation and interactive operation of multidomain heterogeneous data. The original purpose of data visualization is to map a wide variety of multisource heterogeneous data sets into geometric elements through algorithmic design and then output graphical images to show the structure and insight into the laws in an intuitive, clear, and concise manner. Data is an asset, and data visualization is an important tool to revitalize this asset. The set graphical style for data sets of the same kind of homogeneous merging, link graphical style for related data sets of relationship mapping, and part-whole graphical style for complex data sets of the point surface are the outstanding embodiment of simplification. Appropriate use of these composite schemas in the design of visual representations can provide intuitive insight into patterns, facilitate knowledge acquisition, and maximize the value of information.

3.2. Visual Communication Design Model Design. After the data has been cleaned, there are still problems such as sparse information density, so the information contained in the data needs to be mined. Operators want to understand the communication patterns of user groups in the local network, including the distribution of local users under each characteristic, which characteristics of users should be the focus of attention; how to identify ordinary and prominent users through objective methods; and other information. This requires us to find objective and effective methods to be able to accurately mine user group information [18]. Traditional analysis methods are designed using line graphs and histograms, but in the analysis process, only two to three

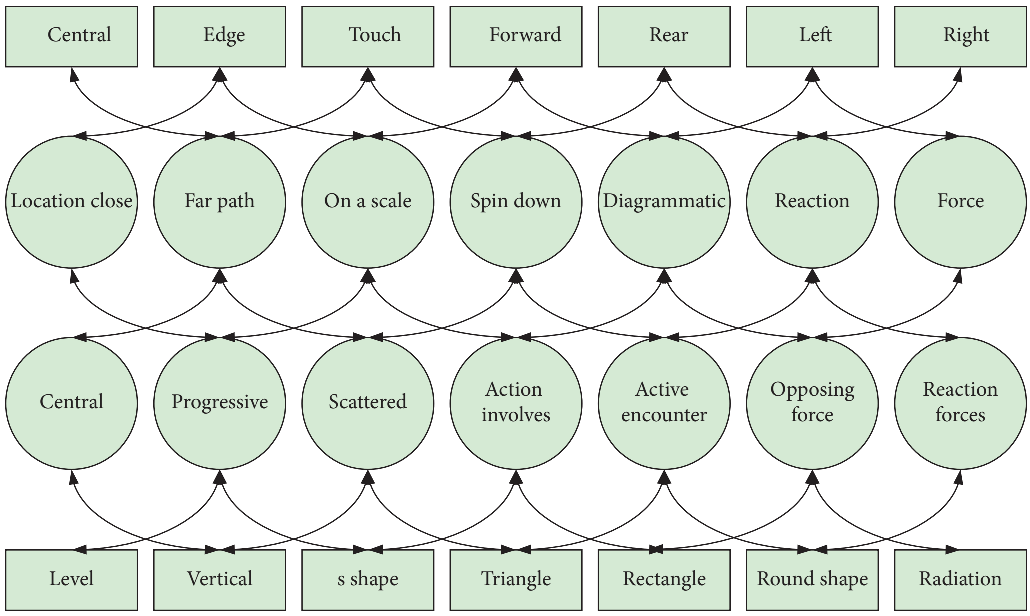

Figure 2: Data visualization steps.

dimensions of data can be selected for analysis, which greatly limits the depth of the information mined, making the information obtained in the analysis incomplete, and if a dimensionality reduction algorithm is adopted, the information displayed is also incomplete if the user is only interested in certain user characteristics. The user data density of call recording data is sparse, and there is the problem of incomplete analysis samples if only some of them are filtered for study. In terms of layout, the simplest way to represent a user is to take a point representation, but if the number of users is large, such as a shopping site with up to hundreds of millions of users, choosing to depict users with points would show points that are too dense for the display screen area to accommodate, as well as problems of visual confusion and occlusion coverage. Therefore, in this study, there is a need to abstract sparse user data records into machine-recognizable user features, with the aim of mining effective data information, improving the efficiency of the system in processing and drawing data information and designing clear and beautiful visualizations based on data analysis results to effectively communicate data information to users.

Due to the space limitation of the Cartesian product coordinate system, a few features are selected in this paper to analyze the distribution of users. The coordinates of intranet contacts and extranet contacts of users in the features are first selected for comparison, as shown in Figure 3. The horizontal coordinate is the number of intranet contacts, and by looking at the figure, we can roughly see that the order of magnitude of users' extranet contacts is larger than the order of magnitude of intranet contacts, which means that generally, users have more extranet contacts than intranet contacts. But from the graph also that shows the shortcomings of this depiction, most of the users still have some similarities, and the communication behavior pattern also has some similarities; at the same time, the data volume of this experiment is large; there are more data points; the situation of obscuring and covering is more serious; and the information cannot be displayed clearly and intuitively.

In this paper, we want to obtain specific feature data for each point, and we want the data points to be in such a way that they cannot be covered and obscured, and the data points are visible [19]. To this end, a checkerboard layout was adopted to plot each coordinate point, which was able to demonstrate the needs of this analysis task and confirmed the above observations clearly and unambiguously. After this, the limitations of the layout were still found, taking this layout, depicting the limited distance of the axes, and not being able to observe other users who are not within the coordinates. If the plotting is done by zooming or sliding to select the coordinates, the user needs to slide the coordinates several times to observe all the data points, which means that the user cannot view all the information in a short time, which is not compatible with the theory of visualization to convey information quickly. Visual analysis is a combination of computer automatic analysis capabilities and human cognition of visual graphics. On this basis, Ren Lei and others analyzed in detail the cognitive theory, information visualization theory, and human-computer interaction and user interface theory that support the analysis process. And information visualization technology for mainstream big data applications and human-computer interaction technology that supports visual analysis is also discussed.

Inverse thinking, which can also be called divergent thinking, is what people take for granted in the opposing mode of thinking expression so that the design state will give people a new visual impact. For example, in the process of visual expression, the same theme using cis-thinking is difficult to stand out in many design works; more will make the audience produce visual fatigue. Instead, reverse thinking will give the audience a sense of visual impact at first sight. In reverse thinking, it is necessary to consider the universality of simple elements in

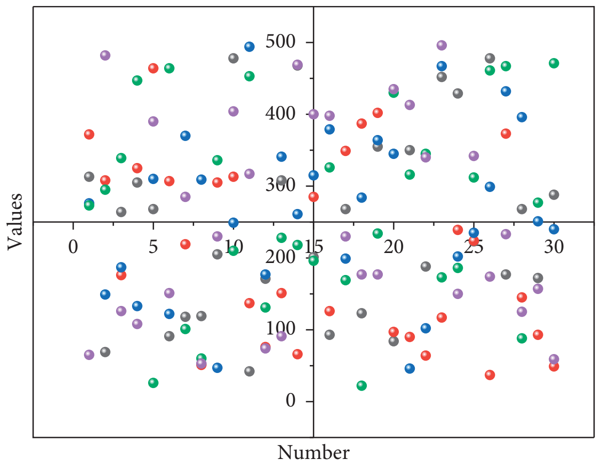

Figure 3: Distribution of intranet contacts and extranet contacts.

the audience's common design work, such as color changes, opposite sizes, or the choice of opposites, which can be the point of view of transformation. Using the design concept of guidance and challenge to observe the audience thinking blind, breaking the conservative design thinking concept, bold use of new elements and new composition methods, the audience often agrees with things in reverse thinking but has a critical point of view, which is also a breakthrough for the traditional way. This is where the designer needs to notice the novelty in reverse thinking, establish a new design concept, and focus on the sense of innovation, as shown in Figure 4.

The results of multisource data fusion are used to reveal different dimensions of an event or activity, showing facts or patterns side-by-side, where the same facts or patterns may be hidden in different forms in the data network and where the same form of data exists to show one or more dimensions of the same facts or patterns. If the dimensionality reduction algorithm is adopted, if the user is only interested in certain user characteristics, the displayed information is also incomplete. Multisource data fusion is the basis of computational intelligence and is the embodiment of quantification, automation, and fusion thinking [20]. The process of conducting decision research decomposes the task into different subtasks, constructs a multisource data fusion model for the data sources of the subtasks, and is oriented to the task context, and the process of data collection, processing, and analysis should be oriented to the context in which the subtasks are located, covering all the data sources required for the task. The development of data-driven thinking is gradually moving towards the development path of synthesis, multisource, and refinement, with data focusing more on the whole rather than traditional sampling data, more on precision rather than on efficiency, and better reflecting cause-and-effect relationships, overturning the previous model of intelligence task interpretation. Multisource data fusion places more emphasis on the complementarity between data, the ability to corroborate each other, and more emphasis on large and broad. At the level of data fusion algorithms, targeted data fusion algorithms are becoming more sophisticated in various fields.

4. Analysis of Results

4.1. Data Visualization Results. An important challenge in visualizing multidomain heterogeneous data is that the designer must control the amount of information in the visualization map; too much or too little information can cause some distress to the user in receiving the information. Visualizing too little data can be a waste of resources, typically data that contains only two opposing attribute values, such as the number of present versus absent, gender comparison, pass versus fail ratio, and other data that sum to 100% and can be derived from one attribute to the other, for which other more intuitive ways of displaying the data are available and have no visual value. In contrast to this is another situation where designers want to express too much information, believing that a visualization containing too much information not only increases the complexity of the visualization but also makes the visual schema confusing and difficult to interpret, making it difficult for end users to understand, obscuring necessary information, and causing problems for users to understand the data. The combination of attribute and composite schemas can alleviate this problem to a certain extent for designers. One way is to provide users with the operation of filtering and filtering data according to the size, density, and importance of the data so that users can select the data to be displayed in the current scene. Another way is to combine and divide the data in an orderly manner as proposed above, through multiple views or multiple screens and cross-screen to split the display according to user needs and relevance.

In multidomain heterogeneous data visualization design, color is second only to graphical layout in terms of expressiveness. However, in some cases, color has a communication effect that graphic layouts do not. The effect of color on human emotions in data visualization is not available in layout. The proper use of color can help users understand data structure more intuitively, detect data anomalies, focus their attention, and enhance their understanding of abstract data. If the graphic layout reflects the control of the designer's reason, then the color in visualization puts a warm coat on the cold data, which brings spiritual comfort to the viewer, and the impact of color on the user focuses on emotional experience. Color in current design practice is one of the more extreme elements of data visualization, either ignored or abused, as shown in Figure 5.

Users of data visualization systems also indirectly assume the role of evaluation, where the evaluators are mainly users who test and evaluate visual graphics and visualization systems. Users cannot view all the information in a short period of time, which is inconsistent with the visual theory of rapid information transmission. Evaluation is important to find out the shortcomings of the visualization system, improve the user experience of the system, and evaluate the advantages and disadvantages of technical solutions. Evaluators generally consist of two types of users: expert users and general users. Expert users are professional users who meet certain conditions of the visualization system (industry experts, technical experts, etc.). These users have a thorough understanding of the data or the goals to be achieved, have a

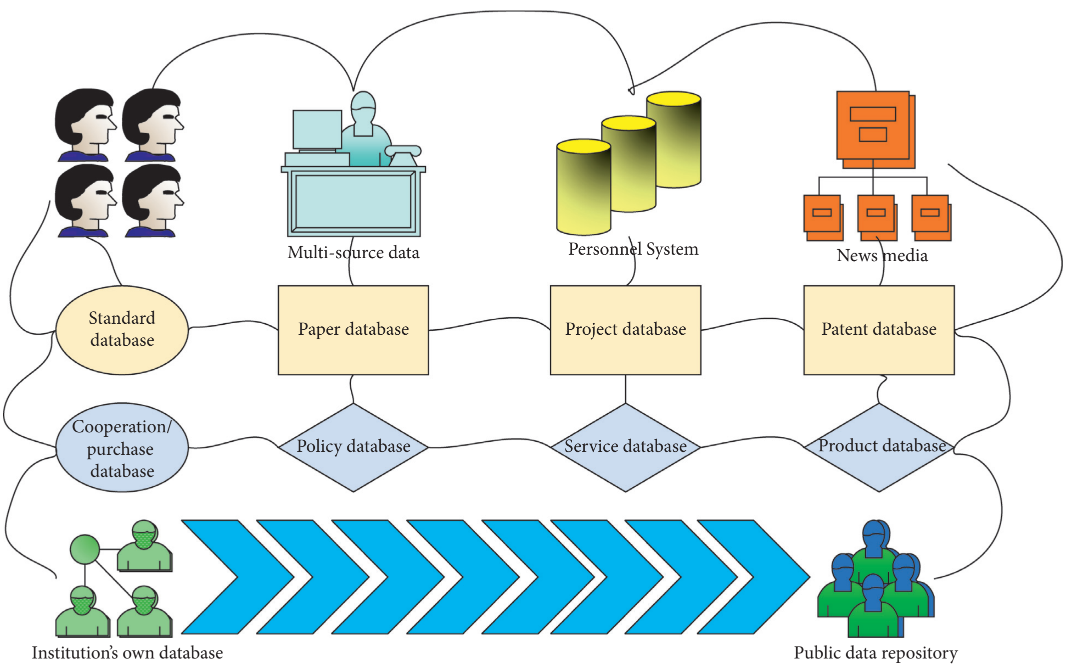

Figure 4: Visual communication design model.

clear judgment of the usability and ease of use of the system, and can provide quality suggestions for the iteration of the visualization system. General users generally evaluate the public-oriented visualization system, which has a greater uncertainty of users, and the main purpose of testing is to improve the compatibility, friendliness, and ease of use of the system for users, which is generally done through task execution analysis, eye-movement data analysis, or subjective evaluation, as shown in Figure 6.

At the same time, the difficulty of mining user needs, especially deep user needs, increased by the characteristics of partial expression, false expression, and abandonment of expression for various reasons. For this reason, the article tries to mine the deepest emotional needs of users from the perspective of data visualization. Emotional demand is the state and direct expression of human nature, the deepest demand of users, and a cultural trait based on the original rhythm of life and higher than life in a narrow sense. Whether the emotional demand of users can be accurately mined and fully satisfied is one of the important criteria to measure whether the multidomain heterogeneous data visualization system has an innovative spirit and humanistic care. Based on the effective mining of information about users' inner emotions in multidomain heterogeneous data visualization, we analyze them in depth and obtain insights about users' emotional differences and inner needs.

The extraction of imagery patterns requires a high degree of accuracy in user wording. In industry-oriented multidomain heterogeneous data visualization design, users are mainly professional and semiprofessional, and the extraction of imagery patterns in such visualization systems is based on structured interviews, which facilitate designers to directly extract subpatterns of high relevance. Data with a sum of 100% can be derived from one attribute to another attribute value. Such data can be displayed in other more intuitive ways without visual value. The public-oriented data visualization platform is based on scene observation, supplemented by semistructured interviews, which can extract relevant subpatterns efficiently and accurately.

4.2. Visual Communication Design Results. After understanding the new performance of visual communication in the new media environment, while focusing on dynamic performance and interactive performance, it is also necessary to have innovative performance on the basis. Inheriting the growth of traditional media visual communication performance based on the creation of new forms of expression, to improve the expansion of visual advertising design, is also the design of the place's connotation.

Through the dynamic form of visual expression that enables the audience more likely to accept the products marketed, the new media environment and the traditional media environment development of visual design development of different performance is also evolving, from the previous simple and easy-to-understand direct form of expression into a subtle performance; because the quality of today's nationals is continuing to grow, the level of thirst for knowledge is increasing day by day, making it simpler to float about the things brought in. This is a great breakthrough for the design form of advertising to reflect the change. In design, we can use simple elements around us to represent some spiritual feelings that want to express complex psychological states so that the scene can create emotions and resonate with visual psychology and other states. The visual symbolization of the product increasingly becomes the representative direction to attract the eyes of consumers, for the product of successful packaging design or advertising design is indeed the consumer impulse to

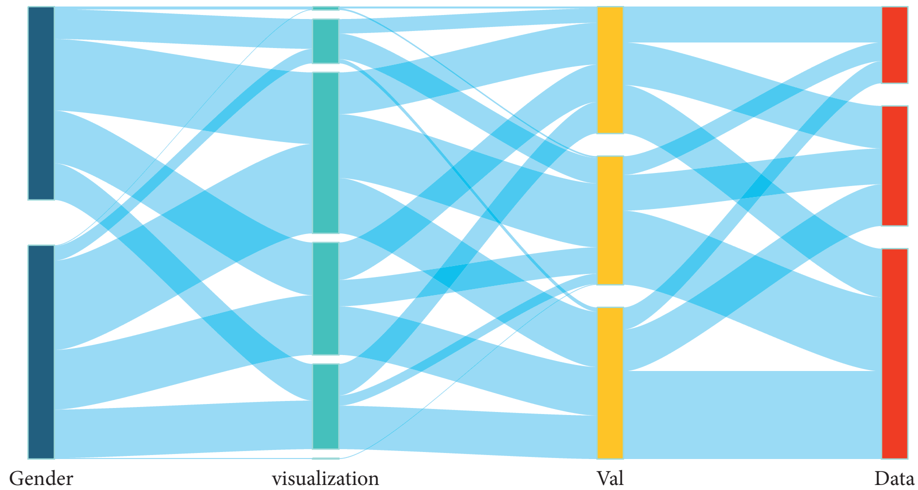

Figure 5: Data visualization assessment.

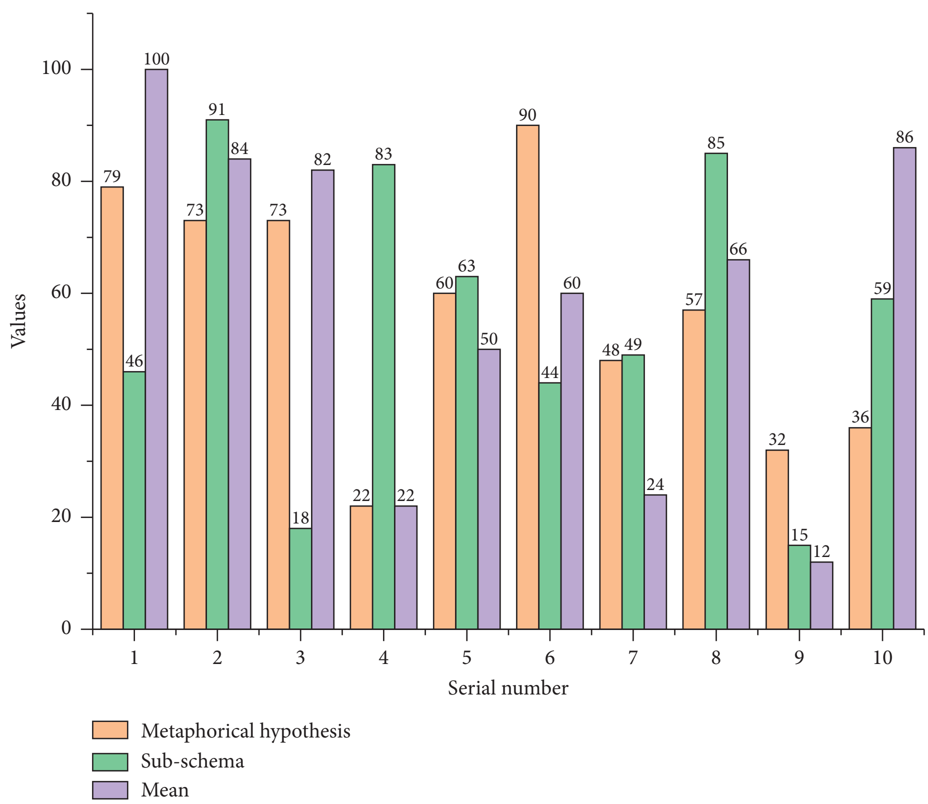

Figure 6: Validity measures.

produce consumer ideas. People must be visual product expressions of whether the consumer view resonates with the psychology of the consumer in order to grasp the product of the development of emotional consumption, as depicted in Figure 7.

If the product's external image is split, such as the product's shape, material, and color, the buyers can get an instinctive sensation able to make high-quality ideas for the visualization system's iteration. Ordinary users generally conduct evaluations on public-facing visualization systems. Users of this type of data visualization system have greater uncertainty. The main purpose of the test is to improve the compatibility of the system with users. The second is the behavior level for the experience of consumer behavior; seeing the product's first sense is also the psychological state whether there is a sense of pleasure. The third is about the experience of the consumer's emotional state, based on whether the consumer's inner state resonates with the product to promote the desire to buy the product. The fourth is about the consumer's associated

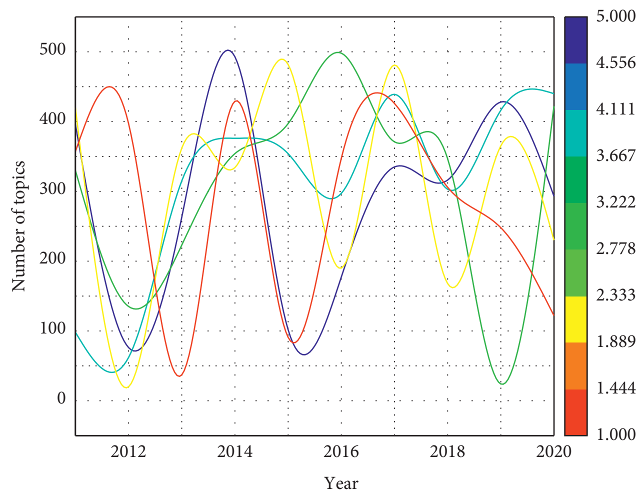

Figure 7: Structural drawing visualization layout design results.

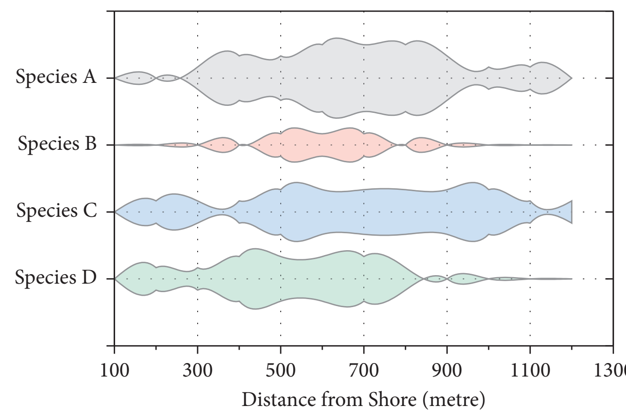

Figure 8: Visual communication design results.

experience, which also needs to be associated with the product's after-sales service, whether the consumer can feel at ease to buy the product after the experience is also key. Therefore, by analyzing the characteristics of consumer experience, we can learn that the first sensory experience mainly corresponds to the consumer's consumption state whether there is a sense of impulse to consume, the second experience corresponds to the emotional analysis of the consumer's purchase state and whether there is a positive level of aspects, the third experience is through the consumer's experience whether there is a psychological level and the establishment of emotions and whether the product has produced consumer trust, and the fourth experience is whether the consumer builds a cognition of the brand culture after understanding the product and whether he or she has the will to establish a long-term relationship to cultivate consumer consumption awareness, as shown in Figure 8.

Visual communication performance is to serve the audience, but there is still a very clear division of the audience; for different levels of consumption level, habitual acceptance of the media is clear, so more attention is paid to the commercial value of visual communication performance. The development of visual communication relies on digital technology in the form of expression, and the integration of design expression with the benefits of business is also an inevitable development trend. The gradual commercialization of visual communication performance has also become aesthetic and humanized. In the visual communication and the new media, the environment reflects the value of reciprocity; the performance form is closer to the market and integration in the economic development today. Because of the constant closeness to market requirements, visual communication performance has also changed qualitatively. For the audience, an examination of people's visual psychological state for visual development and the economic market can promote a more perfect integration.

5. Conclusion

In the process of designing multidomain heterogeneous data visual systems, imagery schema theory can inspire designers' creativity, improve design efficiency, and help designers find innovative design solutions, which can improve design efficiency and bring novel user interface designs to design works compared to other design approaches. The integration of visual communication in the new media environment has also led to the emergence of new visual models. For example, motion graphic design can provide the audience with a more intuitive understanding of the meaning of the expression. Secondly, interaction design allows the audience to interact with the visual work. The second experience is the emotional analysis corresponding to the consumer's purchase state and whether it has a positive level. The third experience is whether a psychological level and emotional establishment are generated after the consumer's experience. The design also pays more attention to the feedback link of the audience, so the direction of the design pays more attention to the "human-centered" design concept. The development of visual communication is promoted with the assistance of new media and Internet technology, and the concept of multisensory acceptance is adopted in the expression of design transformation forms. In today's era of rapid economic development, the conversion of visual communication expressions is increasingly developed in the direction of commercialization. This paper analyzes the consumer psychology, consumption patterns, and aesthetic trends of consumers so that we can accurately integrate the consumer market better in the form of design conversion.

Data Availability

The data used to support the findings of this study are included within the article.

This paper makes a detailed analysis of the integrated mining algorithm, analyzes the characteristics of curriculum big data, and analyzes the existing problems of the current association rule mining algorithm, as well as the defects and deficiencies when applied to the curriculum data. Aiming at the problem of mining the entire data set by the mining algorithm, this topic proposes the idea of using the K-means algorithm for clustering processing and uses the Ball-tree structure on the basis of the original K-means algorithm to improve the efficiency of the algorithm. The data set is separated into several clusters of an appropriate number. In the flipped classroom, the basic knowledge is put before the class for learning, and the further deepening and practical application of language knowledge is completed in the class. Teachers can give timely guidance when encountering unsolvable difficulties so that students' learning can be more effective. This new teaching model not only strengthens students' confidence in learning and increases their interest in learning, but also increases the opportunities for students to interact with teachers and classmates in the classroom, allowing them to construct the meaning of knowledge in the fun of interactive communication. The classroom has become relaxed, lively, and attractive, and students' sense of autonomy, self-learning ability, and collaborative inquiry ability have also been unknowingly improved. Among the main factors, the willingness to flip, emotional state, leadership role, and online learning input have a significant positive impact on collaborative learning performance, and the sense of competition has a partial negative impact on collaborative learning performance, of which positively affecting individual knowledge mastery. Among the nonmain factors, the degree of difficulty of the course, teacher-student interaction, teacher motivation, and evaluation mechanism have a significant positive impact on collaborative learning performance. Classroom assistive technology has a partial negative impact on collaborative learning performance. From the perspective of group performance, group-level performance considerations such as the quality of group conversations and the degree of group knowledge sharing in collaborative learning performance are more affected by nonsubject factors.

1. Introduction

With the integration and development of computer and communication technology, network infrastructure is becoming more and more perfect, equipment terminals are rich and diverse, and network applications are more extensive; the Internet has increasingly penetrated into people's social life, opening a new era [1]. Due to the characteristics of the Internet and computer digital processing, all behaviors of people in the process of popularizing the use of the Internet are transformed into data information [2]. These data and information are collected and stored into digital records through terminals, networks, and servers, forming a big data environment in which everything is digital and everything can be quantified. The real material world in the Internet age is transformed into the real data world. The comprehensive campus network infrastructure, extensive application of information systems, and the popular use of new technologies, new equipment, and new applications by teachers and students have formed a mature campus big data environment with good conditions for big data applications [3]. In the context of the era of big data, flipped classrooms were born and developed rapidly as a new teaching model. In recent years, the research and application of this model have been very hot in foreign countries [4]. Many domestic universities have applied this model to the teaching of different subjects and have gained successful experience [5]. The characteristic of flipped classroom is that it reverses the sequence of learning knowledge in class and completing homework after class in traditional teaching [6].

In traditional teaching, students acquire new knowledge in the classroom and consolidate knowledge by completing homework after class, while students in flipped classrooms acquire knowledge by watching videos made by the teacher before class and then resolve questions with teachers and classmates in class [2]. The introduction of flipped classrooms into college teaching will help promote the innovation and exploration of college teaching models and promote the transformation of college teaching models to informatization, high efficiency, individualization, and humanism. Related theories provide new ideas and theoretical references for the future application of flipped classrooms in college classroom teaching [7]. Flipped classroom teaching can fully stimulate students' potential for independent and active learning. Before the class, students can learn independently by watching microvideos or other learning materials anytime and anywhere, and control the pace of learning by themselves. In this process, students will gradually cultivate their independent learning ability and sense of responsibility for learning. In the classroom, there are learning activities such as problem discussion, group cooperation, and results display. In this process, students' interpersonal communication and cooperation ability, high-order thinking ability and independent learning ability are gradually cultivated [8]. Through case studies on the use of flipped classrooms in colleges and universities, it analyzes and summarizes the teaching ideas, teaching strategies, and teaching principles implemented by flipped classrooms in colleges and universities. The construction of a classroom teaching environment that respects the individuality of students in teaching provides a reference for operation.

According to the existing association rule mining algorithm, its advantages and disadvantages are analyzed and ideas for improvement are put forward. We analyze the characteristics of the curriculum data set, and we analyze the reasons for the inapplicability of the current algorithm, propose an integrated idea of combining multiple algorithms, analyze its advantages, and verify the experiment according to the above idea as well as realize the proposed integrated algorithm. We compare the efficiency gap with the previous algorithm. In the flipped classroom, students start collaborative learning in the classroom based on the knowledge and background of the relevant courses. This is also a point that is special in traditional classrooms. The source of student knowledge and experience is the flipped teachers on the online learning platform of "Chinese College Students MOOC" online learning platform. The learning tasks and learning resources released by teachers in Yu Classroom before class, the weekly course online test, and the knowledge review link in the classroom all emphasize the importance of learners' online self-study before class. At the same time, differences in the length and frequency of learners watching videos and completing exercises, as well as classroom test scores, also indicate differences in students' online learning input. Students with a higher level of input are aware of the knowledge reserves and strategies required to complete the task, and it is relatively easy to make tacit knowledge explicit in each link of collaborative learning. Therefore, the degree of learner's online learning input has a significant positive effect on both the individual learning performance of collaborative learning performance or the group learning performance.

2. Related Work

Flipped classrooms in Western countries (such as the United States, Australia, and the United Kingdom) have begun to be widely used in graduate and undergraduate teaching, and the teaching subjects and research fields involved include medical care, nursing, biochemistry, and materials science [9]. Their research on flipped classroom teaching methods is no longer limited to theoretical research and more turns to teaching practice. They have even used flipped classrooms to devote themselves to applications in other fields, such as using flipped classrooms to develop students' learning skills and self-reflection abilities.

The American education consulting company Class Window released a survey report that revealed the application value of flipped classrooms [10]. A total of 450 teachers participated in the survey. Among them, 88% of teachers said that their satisfaction had improved, 46% of teachers reported a significant improvement, and 99% of teachers said that they will continue to use flipped classroom teaching next year. Columbia University conducted a survey of 203 students from the United States [11]. The survey found that 80% of the students said that they have more frequent and active interactions with teachers and peers in flipped classrooms, and there are more course materials they need to read in flipped classrooms. There are also more opportunities to learn and practice according to their own time, and more opportunities to demonstrate learning results. Students are more willing to regard learning as an active and active process. Speak Up Survey surveyed 43,000 K-12 students, parents, and administrators [12]. Through a survey of managers, it was found that 25% of managers indicated that flipped classrooms are the most important change in teaching, which surpassed educational games. It can be seen that the flipped classroom teaching method has generally been recognized by foreign students, parents, and managers and has high feasibility.

Domestic scholars mainly conduct research on the teaching strategy, teaching process, and subject and object of the flipped classroom [13]. Based on the flipped classroom under the conditions of informatization, the teaching strategy is more flexible, the teaching process focuses on problem-solving, and students have more decision-making power [14]. Although the research on flipped classroom content is relatively broad, the research depth is not enough. Furthermore, a mature theory has not yet been formed, and many schools, especially basic education schools, often just try to flip classroom teaching [15]. It is difficult to do in-depth research only by completing a few demonstration classes on a certain topic. By trying several flipped classroom teachings with enthusiasm, the experience gained may not withstand the test of practice. Adhering to normalized flipped classroom teaching will greatly promote the research of flipped classroom teaching mode, and the practical experience gained is also worth learning. In the era of big data, the use of big data thinking to guide and optimize normalized flipped classroom teaching makes classroom teaching a new look. A middle school in Chengdu insists on normalized flipped classroom teaching, and it collects student learning process data, uses this data to guide and optimize flipped classroom teaching, and has gained some experience [16].

The University of Wisconsin-Madison used eTeach software to synthesize lecture videos and courseware simultaneously and successfully carried out the flipped classroom teaching reform [17]. Multimedia teaching technology creates necessary conditions for flipped learning and emphasizes the technical characteristics of flipped teaching mode [18–20]. In a teaching practice, related scholars helped students who were absent from the classroom make up lessons by recording videos of applying PPT in classroom teaching and then uploading them to the Internet for students to download and learn by themselves [21–23]. Through this teaching attempt, they found that the students' understanding and internalization of the video requires the guidance and help of the teacher, so they reversed the order of the classroom. Through this teaching experiment, the idea of flipped classroom teaching has been further disseminated in American primary and secondary schools [24].

3. Method

3.1. Characteristic Analysis of Course Data. English flipped classroom teaching has provided a good path and opportunity for our educational scientific research work. It has constituted a cross-ethnic, cross-cultural, cross-professional, and cross-social communication platform. By studying these educational data, we can discover new information hidden in the data. The English cloud education platform network assisted by big data is shown in Figure 1.

Curriculum big data, as a relatively common type of data in education big data, has the following characteristics:

(1) Wide range of data sources: the big data of the course has a wide range of sources and a large scale. English flipped classroom teaching has many advantages, such as unique convenience and high efficiency. More and more students choose English flipped classroom teaching to learn and supplement their own knowledge reserves. There are also more and more educators and schools starting to use the English flipped classroom teaching platform for online teaching. More and more managers begin to use the English flipped classroom teaching management platform for online data management. Therefore, the English flipped classroom teaching platform has a large amount of student selection data, school curriculum data, educator teaching data, and a large number of comment data, etc. The source of curriculum big data is very wide, and it is no longer limited to schools or education bureaus.

(2) Higher potential value: curriculum big data does not only come from students, so the analysis and application of curriculum big data is no longer limited to students who need to learn but can be expanded to more lecturers and education managers. Therefore, curriculum big data has a higher potential value.

(3) More relevant: there may be certain relationships between data, and the values of certain variables may affect each other, but this correlation is generally weak and usually not causal. Compared with other types of education data, curriculum big data has greater opportunities for each feature variable to influence each other and stronger correlation. For example, people who choose to learn front-end technology may be more willing to learn front-end-related technology; students who learn testing techniques are more willing to learn such as automated testing, black-and-white box testing courses, and so on.

(4) Larger amount of data: generally speaking, curriculum big data has the characteristics of large quantity and high dimensionality. Some courses will have multiple characteristics, and some courses will also belong to multiple course categories at the same time. For example, in the course selection data of students, each course of selection data will have its own category. These categories are diverse, and each student's course selection tendency is also different.

3.2. Problems in Association Rule Mining Algorithms and Improvement Ideas. Association rule mining algorithm is a mining algorithm that discovers frequent itemsets. It is an important subject in data mining. Its main function is to find hidden relationships between specific data sets and find valuable information from it. The process of association rule mining is roughly divided into two stages. The first part requires finding frequent itemsets in the original data set. The second part digs out association rules from these frequent itemsets through pruning and sorting.

Common association rule mining algorithms are mainly based on the corresponding association rules for the entire data set to mine. When the data set is very large, it will often produce massive amounts of redundant data and similar association rule mining results, which will also cause the final mining results of the association mining algorithm to be too accurate. For example, the Apriori algorithm finds frequent itemsets by frequently accessing the database. When faced with massive data sets, this frequent access to the database operation method will reduce the efficiency of the algorithm as the data set expands.

Although the FP-growth algorithm avoids a large number of database accesses by establishing the FP-tree, a large amount of data will also cause the FP-tree to be too

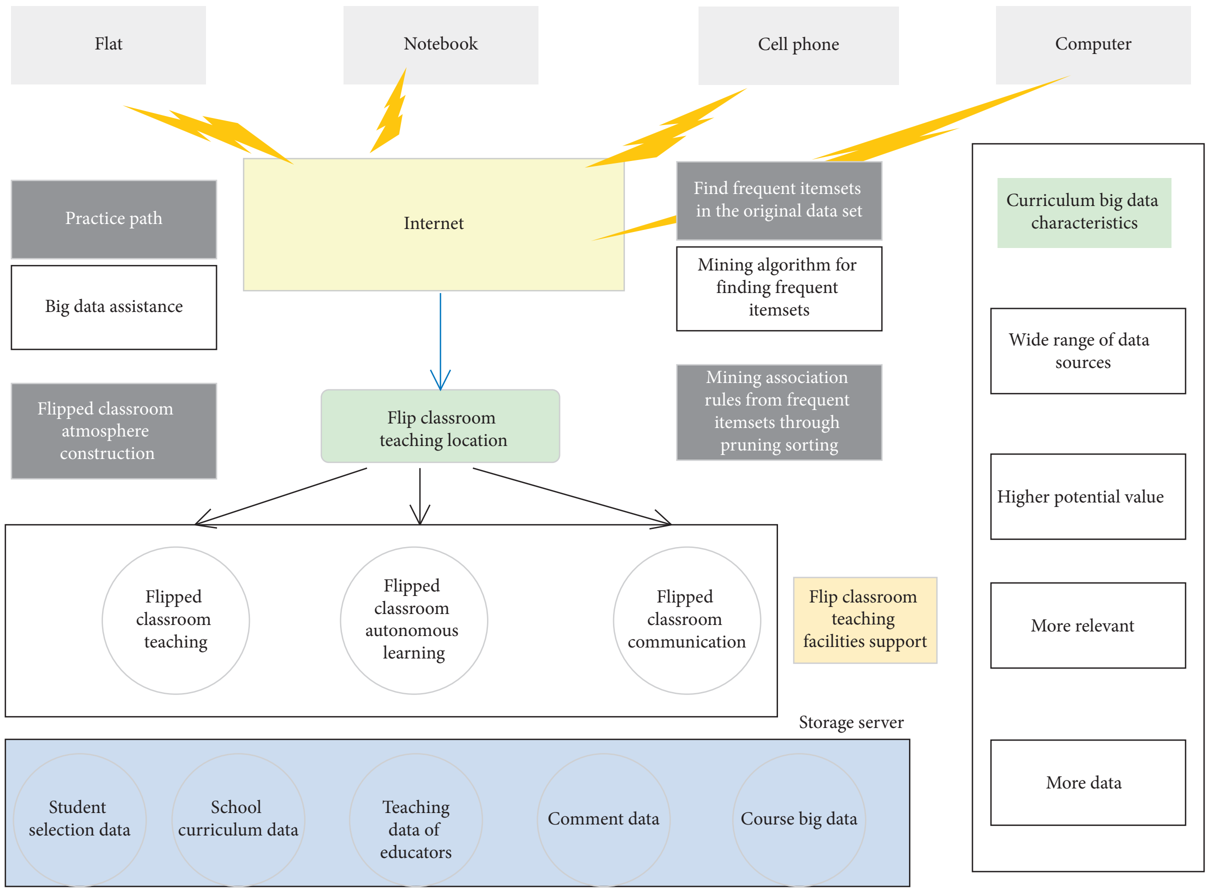

Figure 1: English cloud education platform network assisted by big data.

large. Therefore, this will greatly affect the overall efficiency of the algorithm and the accuracy of the mining results, which cannot be well adapted to the characteristics of curriculum big data.

Top-K is an association rule mining algorithm designed by Fournier-Viger. Compared with the traditional association rule mining algorithm, the advantage of this algorithm is that the user can specify the number of rules to be generated K, avoid generating too many rules, so the efficiency is higher than the traditional association rule mining algorithm.

In this topic, improvements are made on the basis of Top-K association rule mining algorithm, and correlation coefficients are added on the basis of Top-K algorithm to improve the accuracy of the algorithm and further improve the efficiency of the algorithm. In view of the large number of data sets and high-feature dimensions, the K-means algorithm is improved to adapt to the situation of high-dimensional data. The K-means algorithm can refine the data set into multiple small data sets, and each data set represents a category. With the collection of the same feature vector, the accuracy and efficiency of the mining results are improved through the idea of classification and mining. However, the traditional K-means algorithm is not very adaptable to high-dimensional data, and the KNN algorithm uses KD-tree and Ball-tree to optimize the processing methods of high-dimensional data and compares the similarities between the K-means algorithm and the KNN algorithm. Therefore, this topic uses the Ball-tree structure to optimize.

3.3. Analysis and Improvement of K-Means Algorithm. Cluster analysis is to group according to the information involved in the data contained in the description of the objects or the relationship between them. There are many kinds of clustering algorithms, but not all algorithms are suitable for this experiment. Considering the efficiency of the algorithm, we prefer to choose the clustering algorithm with high efficiency. One of the biggest advantages of clustering methods based on definition partitions is their fast convergence rate and convergence speed, and for some large data sets, they are simple and efficient, with low time and complexity. The K-means algorithm is a typical clustering algorithm based on the distance between targets. The distance between targets is used as an evaluation index for the degree of similarity between targets. That is, if the distance between two targets is closer, the possibility of them being the same cluster is greater.

First, we need to determine the size n of a known selected sample data set, and the feature dimension of each selected sample data set is m, recorded as

$$\xi = \left[X_{1i} \quad X_{2i} \quad \cdots \quad X_{mi} \right], \quad i = 0, 1, 2, \ldots, n-1. \tag{1}$$

Then, we need to set the required number of clusters K. And we need to randomly select the final cluster center point that is the same as the set number of clusters k in a data set.

$$\zeta = \left[\zeta_{1j} \ \ \zeta_{2j} \ \ \dots \ \ \zeta_{mj} \right], \quad j = 0, 1, 2, \dots, k-1. \tag{2}$$

For each point in the data set, we calculate the Euclidean distance between each centroid and each point. According to the criterion of the closest distance, they are divided into the corresponding classes closest to the cluster center (most similar), calculated as follows:

$$\xi(i, j) = \sqrt{\left(\zeta_{1j} - x_{1i}\right)^2 + \left(\zeta_{2j} - x_{2i}\right)^2 + \dots + \left(\zeta_{mj} - x_{mi}\right)^2}. \tag{3}$$

After putting all the data together, there will be K sets. If the distance between the newly calculated centroid and the original centroid is much smaller than the expected threshold, then we can be sure that the sample clustering does not reach the expected classification, and the algorithm may be terminated. If the newly appearing center of mass differs greatly from the original center of mass, it will change, and the above steps must be repeated again.

It can be clearly seen that the K-means algorithm achieves the goal of sample clustering through multiple iterative calculations. In each iteration of the calculation process, it is necessary to reset and calculate the center point of each sample cluster, and replace the previous sample center point, which is used as the sample center point for the next iteration. The final sample center point can be considered as the final cluster center.

The K value of the K-means algorithm affects the result of clustering. The original K-means algorithm uses a method of randomly selecting K values. This method is extremely unstable and cannot get stable and good results. The larger the K value of the cluster, the more detailed analysis and division of the data. When the K value is less than the number of clusters, since the increase in the K value will greatly increase the clustering degree of each cluster, the SSE (sum of square error) will also decrease. When the K value is greater than the number of clusters, increasing the value of K will increase the degree of polymerization, so the decline of SSE will also decrease sharply and then gradually flatten out. In other words, the K value corresponding to the inflection point of the relationship graph between SSE and K is the optimal number of clusters in the data set. This experiment uses SSE to determine the evaluation value. SSE is defined as follows:

$$\mathrm{SSE} = \prod_{i=1}^{k} \prod_{p \longrightarrow c_i} \left(m_i - p\right)^2. \tag{4}$$

Among them, C_i represents the ith cluster, p represents the sample point in C_i, m_i represents the center point of C_i, and SSE is the clustering error of all samples, representing the quality of the clustering effect.

The K value determined by the elbow method can basically be determined as the optimal number of clusters in the current data set. This is more stable and accurate than the original K-means algorithm that randomly selects the K value, which effectively avoids the randomness of the K-means algorithm itself and improves the stability of K-means.

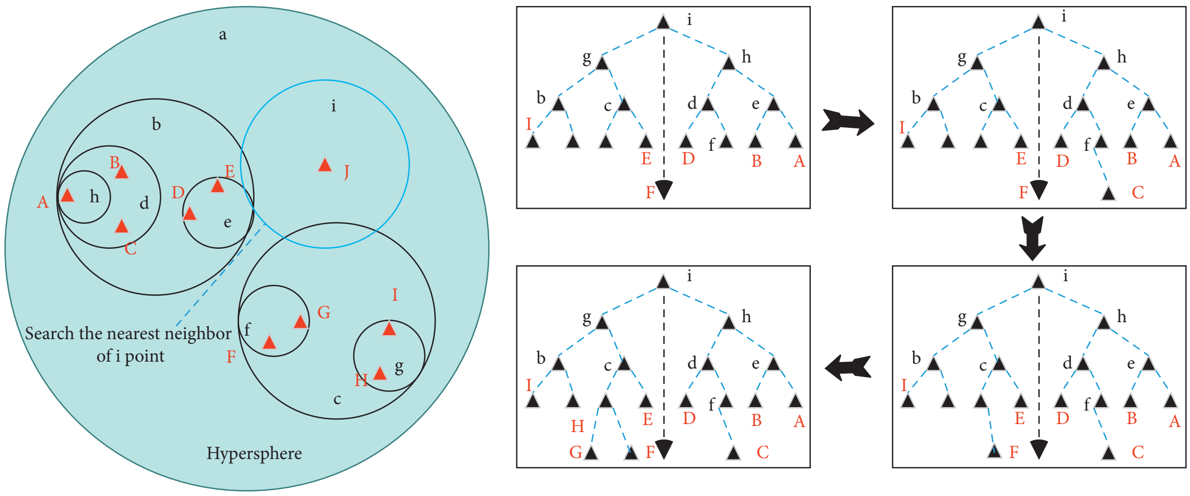
The KD-tree structure and the Ball-tree structure are used to improve the efficiency of the KNN algorithm and the processing power on high-dimensional data, and the K-means algorithm and the KNN algorithm also have the same ideas. Therefore, the KD-tree and Ball-tree structures can also be used in the K-means algorithm to improve the efficiency of the K-means algorithm value and the processing capacity of high-dimensional data.

If the K-nearest neighbors in the data set of a sample belong to a certain category, the sample also belongs to this category. The basic implementation of KNN is linear scanning. At this time, the distance between the current instance of the input and each training instance is calculated. When a training set is very large, the calculation duration is very long and time-consuming, and the efficiency of this method is very low.

The KD-tree model is a high-dimensional indexed tree data structure, which is often used to search the data in space. However, the K-means algorithm is similar to the KNN algorithm and has similarities in the idea of the algorithm; that is, it is necessary to find a point on the data set through this point to find the closest point to it. Therefore, KD-tree can also be used in the K-means algorithm.

Ball-tree is analogous to KD-tree's construction idea. KD-tree uses hyperrectangles for regional division, while Ball-tree uses hyperspheres for regional division. Although the construction process will take more time than KD-tree, performance on high-dimensional data sets will be more efficient. In the Ball-tree construction process, T represents the selected data set, and S represents the current data field. At the beginning of the creation process, the data set T and the data domain S need to be passed in. When there is only 1 data point in the data set, return to that node directly. Otherwise, first, we use the midpoint of all points as the center of the circle and use the distance from the midpoint to the farthest point as the radius to construct the initial circle, and we find the two points node 1 and node 2 with the furthest distance in the initial circle. If they are close to node 1, they are classified as clusters of node 1, and if they are close to node 2, they are classified as clusters of node 2, and then recursively construct small circles. Next, recursively we construct a smaller minimum circle from the solved current minimum circle, until there is only one node left, and it is stored as a leaf node. The structure and search process of Ball-tree are shown in Figure 2.

3.4. Rule Generation and Pruning. The original Top-K association rule mining algorithm is based on the traditional "support-confidence" model, but the traditional "support-confidence" model can only find strong association rules in frequent item sets but cannot filter out strong associations. For rule $A \longrightarrow B$ or $B \longrightarrow A$, the correlation coefficient is defined as



(a) (b)

Figure 2: Ball-tree structure construction and search process. (a) Schematic diagram of structure. (b) Structure search process.

$$\theta(A, B) = \frac{p(A \cap B)}{[P(A) \bullet p(B)]}. \quad (5)$$

The correlation coefficient θ can reflect how much influence "the appearance of item set A" has on the appearance probability of item set B. In practical applications, there are many problems in both positive and negative correlations that deserve our close attention. When θ is greater than 1, it indicates that the former term has a positive promotion effect on the latter term, and the larger the value, the greater the promotion effect. On the contrary, it is an inhibitory effect. When θ is 1, it can be seen from the formula that the occurrence of X has no effect on the occurrence of Y, so we need not consider the case where θ is 1.

$$\theta(A{:}B) = \begin{cases} > 0 & \text{positive correlation,} \\ = 0 & \text{independence,} \\ < 0 & \text{negative correlation.} \end{cases} \quad (6)$$

Therefore, on the basis of support and confidence, the correlation coefficient can only be used to determine the correlation between an item set. Correlation cannot be equal to causality, so the correlation coefficients of the two rules $A \longrightarrow B$ and $B \longrightarrow A$ are the same:

$$\theta(A, B) = \frac{p(A \mid B)}{p(A)} = \frac{p(A \cap B)}{p(A) \bullet [1 - p(B)]}. \quad (7)$$

3.5. Construction of Teaching Mode. Based on the theory of constructivism and blended learning theory, combined with the subject characteristics of English courses and their own teaching experience, this paper proposes an English teaching model based on flipped classrooms, as shown in Figure 3.

Starting from the two dimensions of teacher activities and student activities, this model divides the teaching process into three stages in chronological order: pre-class, in-class, and after-class, showing the relationship between the various links in the teaching process. The pre-class stage of the flipped classroom is mainly to realize the transfer of knowledge, which is mainly composed of the production and preparation of the teacher's teaching resources and the independent learning of the students. The in-class stage is mainly to realize the internalization of knowledge, and the task of English subjects is to complete the use of language. Therefore, in the classroom teaching stage, it aims to realize the application of language knowledge and divides teacher-student activities into answering questions and supplementing. Correction, creation of situations, group collaboration, display and communication, and evaluation feedback are four links, and students are included in the main body of evaluation. Teacher evaluation is combined with student self-evaluation and group evaluation to realize the diversification of evaluation subjects. After class, teachers should reflect on teaching and provide support and guidance for students' review activities to help them complete knowledge remediation or knowledge expansion.

4. Results and Discussion

4.1. Questionnaire Design and Test Results. This research has compiled a "Questionnaire on Collaborative Learning of Students in Flipped Classrooms in Colleges and Universities." The questionnaire is divided into two parts. The first part is mainly about the basic personal information of learners, including gender, grade, subject category, and the length of learning experience in the flipped classroom. It is not only to understand the relevant learning background of the learner, but also to prepare for the differences in these aspects of the influence of different factors in the subsequent data analysis. The second part is the main part of the questionnaire, which mainly reflects the collaborative learning performance of students in flipped classrooms and its influencing factors. Among them, the design of collaborative learning performance items is mainly based on the measurement indicators of collaborative learning performance in the flipped classroom in the previous chapter; the

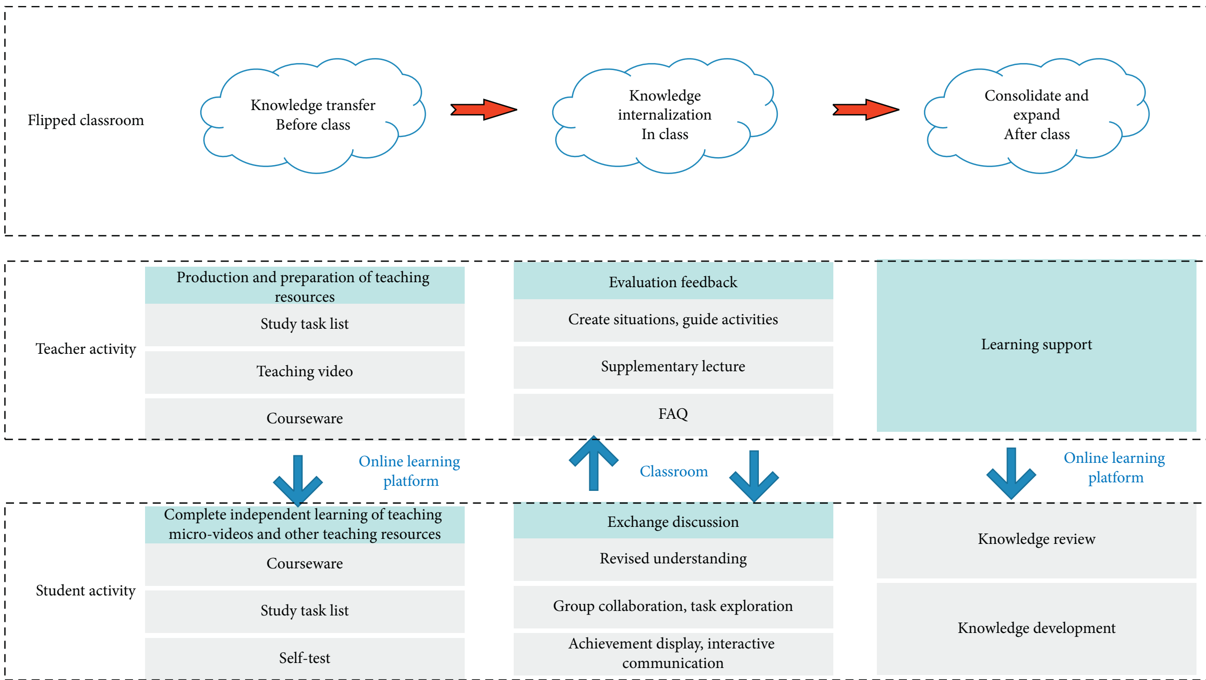


Figure 3: Structure diagram of English teaching model based on flipped classroom.

item design of related influencing factors is mainly based on the 13 influencing factors determined by the learner as the main dividing standard. The questionnaire items are based on the existing research thoughts, written records of classroom observations with the group, and student interviews and exchanges as the standard, and they are discussed with the instructor of the flipped classroom in the class and conceived, designed, and modified. The items in the questionnaire are all single-choice questions. Among them, there are 4 items in the first part of the questionnaire and 35 items in the main part of the questionnaire.

Before forming a formal questionnaire, first, we conduct a trial test. The test subjects of this questionnaire are all students in the class, a total of 50 people. The questionnaire was distributed through the form of online questionnaires, and 50 questionnaires were actually returned. At the same time, the reliability of the test results is analyzed, and the commonly used measurement method is the Cronbach α coefficient method. If the α coefficient is above 0.9, the reliability is very good; if it is above 0.8, the reliability is good; if it is above 0.7, the reliability is good; if it is above 0.6, the reliability can barely be accepted; if it is above 0.5, it indicates that the scale needs major revisions; and if the α coefficient is below 0.5, this indicates that it should be abandoned. The internal consistency of α coefficient in the reliability test result is 0.956, indicating that the overall internal reliability of the questionnaire is ideal. Finally, the test result of the correlation coefficient between the item and the total score is shown in Figure 4.

4.2. Reliability and Validity Test Results of the Questionnaire. Most of the items in the questionnaire of this research are compiled based on literature review, classroom observations, and student interviews. There is no overlap between the formal questionnaire and the test questionnaire. The Cronbach alpha coefficient is 0.953 in total dimensions, indicating that the overall reliability is ideal. The test coefficient of influencing factors is shown in Figure 5. The lowest value of α is 0.65, which is above 0.6 and is acceptable, so the questionnaire reliability is good.

In questionnaire analysis, the validity test is also indispensable. The higher the validity, the more it can reflect the function and purpose of the question to be researched by the questionnaire. Questionnaire validity testing generally includes content validity analysis and structural validity analysis. From the perspective of content validity, the questionnaire in this study is the result of comprehensive review of relevant literature, classroom and group observations, and student interview investigation and analysis. Coordinating the frontline to flip the opinions of teachers, after trial testing and modification, based on the questionnaire formed by enriching the preparation work, it can be trusted in terms of content validity. The structural validity adopts the factor analysis method. First, the KMO and Bartlett sphere test of the data are carried out, and then according to the factor load and cumulative contribution rate, it is considered whether it is suitable for factor analysis. The closer the KMO value ($0 < \text{KMO} < 1$) is to 1, the more common factors among variables and the more suitable for factor analysis. According to the data statistical analysis standard, the KMO value must be above 0.6 before the factor analysis can be done reluctantly, and it can be discarded if it is lower than 0.6. The KMO value is 0.822, which meets the index requirements. At the same time, the approximate chi-square of Bartlett's sphere test is 589.323 ($P = 0.000 < 0.050$), reaching a significant level. There is a correlation between various influencing factors, which is suitable for factor analysis.

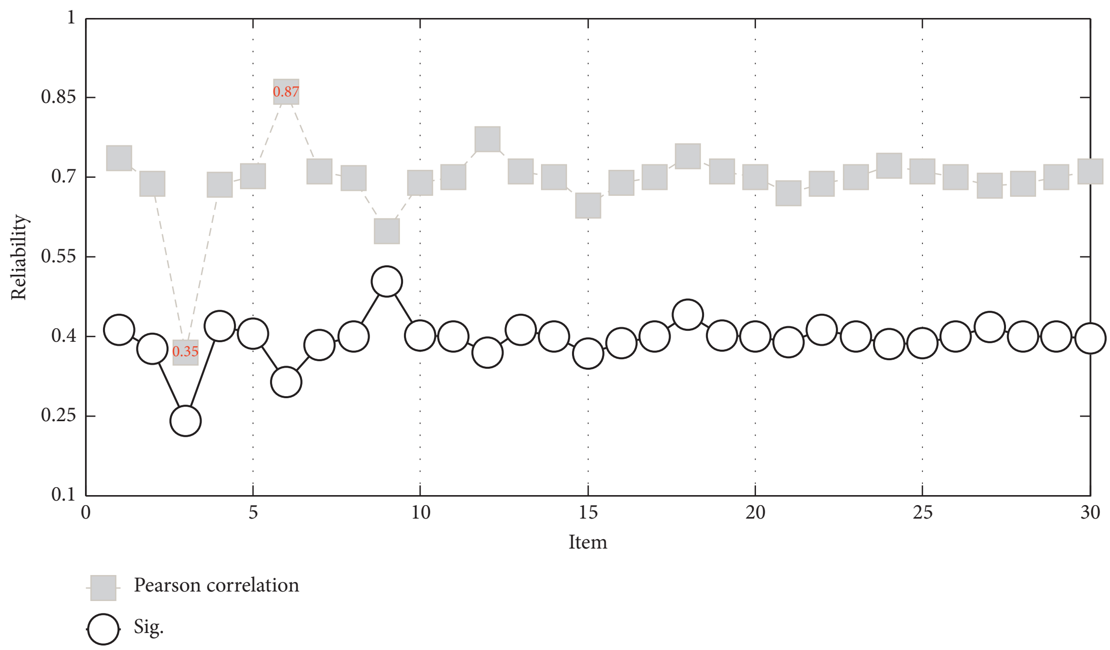

Figure 4: Reliability test of the test questionnaire.

4.3. Descriptive Statistical Analysis of Data. In order to grasp the survey questionnaire data as a whole, descriptive statistics are made on the collaborative learning performance and influencing factor variables in the questionnaire. The basic personal information of the students was learned from 62 valid questionnaires. Among them, 54 boys and 8 girls were first-year university students. Investigators are the first time to come into contact with flipped classroom teaching. The questionnaire uses the Likert five-point scale, and 3 is divided into the middle value. As shown in Table 1, the average value of the observed indicators of collaborative learning performance is greater than 3, which indicates that in flipped classrooms in colleges and universities, the collaborative learning status of students is generally good. Among them, the average value of "individual learning attitude," "group collaborative learning atmosphere," and "group conversation quality" are above 4 points, which is also consistent with the data in the classroom observation record table. There are specific behavioral performances in other aspects, which also reflect the positive attitude of students to the assignment of tasks in collaborative learning.

4.4. Main Effect Test of Data. Using the method of multiple linear regression to determine the mathematical relationship between variables, we determine the path coefficients between variables, highlight which independent variables have significant effects and which ones are not significant, and analyze the effects of main factors on collaborative learning performance. The regression results of influencing factors on individual collaborative learning interest are shown in Figure 6. It can be seen that there is an extremely significant causal relationship between "emotional state," "intention to flip" and individual collaborative learning interest. Students like to learn by video before class first, and then they can deepen and consolidate their knowledge points by solving problems in class. They recognize and accept the teaching form of flipped classroom, and naturally they will accept collaborative learning as a unique learning method in flipped classroom. Through group collaboration, it not only compares and learns other people's problem-solving ideas, but also promotes the relationship between classmates, realizes the effect of group collaboration on course learning, and further stimulates students' interest in collaborative learning.

As shown in Figure 7, with the individual learning attitude as the dependent variable, the influencing factors "emotional state," "online learning input," and "teacher-student interaction" enter the regression equation, and the regression results of the influencing factors on the individual learning attitude are obtained. The regression results show that there is a significant causal relationship between "emotional state," "online learning input," and "teacher-student interaction" and individual learning attitudes.

4.5. Data's Moderating Effect Test. Through the main effect test on the data, the main factors affecting the performance of collaborative learning and their relationship are found, and the path coefficient is obtained. Some research hypotheses have also been verified. Among them, the nonsubject factors "grouping strategy" and "collaborative learning activity design" have no significant influence in the results of this research. Part of the reason is that the test subjects, whether it is a trial test or a formal survey, the students in these three classes only tried the grouping strategy of random grouping and lacked the feeling and evaluation of other grouping methods. Moreover, it was learned in the interviews that most students approve of this random grouping method, so there is no difference in opinions on the issue of "grouping strategy." At the same time, the main effect test results did not indicate the significance level of the

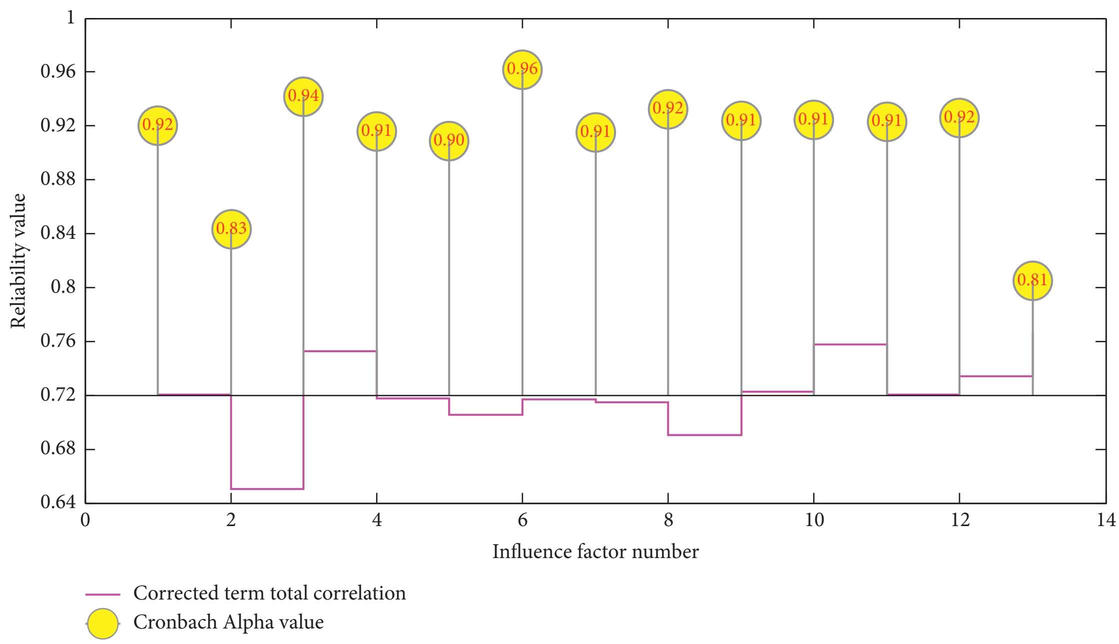

Figure 5: Reliability test of influencing factors.

Table 1: Descriptive statistical results of collaborative learning performance.

Project	Standard deviation	Mean	
	Statistics	Statistics	Standard error
Team task completion quality	0.90	3.50	0.02
Individual performance	0.91	3.42	0.01
Group knowledge sharing	0.92	3.31	0.10
Group conversation quality	0.85	4.11	0.11
Individual task management ability	0.88	3.80	0.12
Individual cooperation ability	0.85	3.78	0.14
Individual expression ability	0.92	3.91	0.15
Individual knowledge	1.10	3.62	0.17
Individual interest in collaborative learning	1.01	3.55	0.10
Group collaborative learning atmosphere	0.92	4.00	0.16
Individual learning attitude	0.89	4.03	0.17

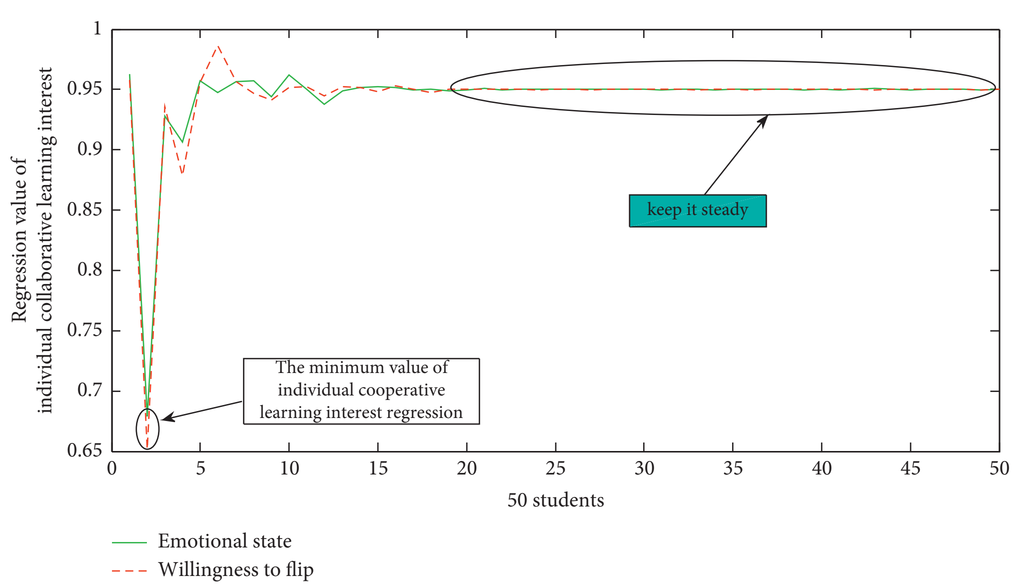

Figure 6: The regression of influencing factors on individual collaborative learning interest.

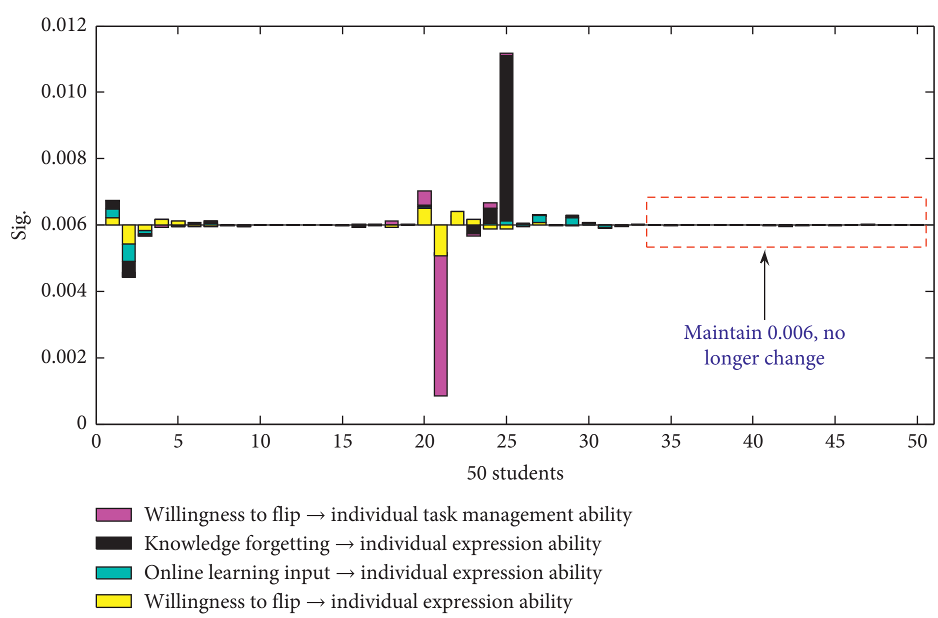

Figure 8: Test results of the moderating effect.

"collaborative learning activity design." It can only show that this factor does not directly affect the collaborative learning performance, but it may change the effect of other factors on the collaborative learning performance to a certain extent.

Moreover, different frontline flipped teachers have different considerations and ideas for the design of learning activities. Due to changes in the teaching objectives and content of each lesson, the design of collaborative learning activities in the classroom is also constantly being adjusted. Therefore, after the main effect analysis of the data, the adjustment effect is analyzed, and the influence of the "collaborative learning activity design" as the adjustment variable is tested, and the path model is improved.

The first step of the moderating effect test is to add the interaction term between the independent variable and the moderating variable as a new predictor variable and incorporate it into the subsequent moderating effect analysis. In order to accurately determine the interaction items, this research first analyzes the correlation between the factors. Here, we mainly examine the correlation between the "collaborative learning activity design" and the main factors. Using SPSS19.0 software to use Pearson's correlation analysis on the data, the relevant results of the respective influencing factors of the main factors and the "collaborative learning activity design" are shown in Figure 8. The significance levels of "collaborative learning activity design" and “flipping willingness,” “emotional state,” “leadership role,” “online learning input,” and “knowledge forgetting” are significantly correlated at the bilateral level. There is a significant positive correlation with turnover willingness, emotional state, leadership role, online learning input, and knowledge forgetting. The design of collaborative learning activities has an obvious moderating effect on collaborative learning performance.

The moderating effect shows that a suitable and high-quality collaborative learning activity design will “magnify” or “accelerate” the influence of the main factor on the performance of collaborative learning. Under the regulation of the collaborative learning activity design, the higher the learner’s willingness to flip, the stronger the individual task management ability and individual expression ability; and the higher the knowledge forgetting, the lower the memory retention, which will lead to lower individual expression ability. The group dynamics theory puts forward that the environment is one of the key group constituent elements, which refers to all the physical environment, social environment, and even individual psychological environment that may have an impact on the group. Therefore, in addition to the physical environment such as the flipped classroom, teachers should also help students construct problem situations through the design of collaborative learning activities, create a social environment that is conducive to learners’ collaboration and interaction, and promote effective learning of students. Therefore, the moderating effect of collaborative learning activity design is the influence of environment as an external factor on collaborative learning performance.

5. Conclusion

This article analyzes the characteristics of curriculum big data and finds that, as a common educational big data, it can better reflect the characteristics of education big data in the teaching work of students. And according to the characteristics of the big data of the course, the deficiencies of the current popular association rule algorithms are analyzed. Through the analysis, it is found that the current association rule mining algorithm has the problem of the target data set being too large and the accuracy of the mining results. Through the analysis, it is concluded that the data set can be clustered through the K-means algorithm to achieve the purpose of reducing the data set, and then the Ball-tree structure in the KNN algorithm is analyzed. After analysis, it is proposed that it can be used in the K-means algorithm Ball-tree structure to improve efficiency. Any high-quality classroom teaching will not lack teacher-student interaction, and as classroom teaching becomes more and more intelligent, teacher-student interaction is not only a simple human-to-human interaction, but also an interaction based on technical support. Regardless of its form, its purpose is to promote teaching and learning. Teachers’ questions in flipped classrooms are more complex and hierarchical. Students’ behaviors after asking questions last longer and the quality of learning is higher. Teacher-student interaction in flipped classrooms improves the quality of the classroom. At the same time, teachers’ speech and behavior feedback give students the feeling of being paid attention to. Appropriate participation of teachers in group collaboration promotes deeper discussions. The essence of teacher motivation is the concrete manifestation of teacher’s speech behavior in teacher-student interaction. Verbal motivation can positively strengthen learners’ learning motivation. At the same time, it can encourage and praise the quality of group results and students’ performance in answering questions, which is conducive to comparison and reflection between groups and students. Therefore, teacher-student interaction and timely and appropriate verbal stimulation are a powerful guarantee for good classroom collaborative learning performance. The starting point of evaluation is to test, and its purpose is to guide and motivate students through learning evaluation. The learning activities in the flipped classroom basically revolve around collaborative tasks, so the evaluation objects, methods, content, etc., are closely linked to each link of the learning activities. The group or individual score is a comprehensive result of objective score, teacher evaluation, and individual or group mutual evaluation of students. Therefore, members listen to the opinions of others and reflect on themselves, while also paying attention to the results of other groups and the performance of collaboration. If the teacher emphasizes the attitudes, methods, and skills of member collaboration in the evaluation content, it will be more conducive to improving the collaborative learning performance of the classroom.

To improve the performance for distributed blockchain system, a novel and effective consensus algorithm is designed in this paper. It firstly constructs a more random additive constant through the generation matrix of the error correction code and uses the value of the hash entropy to prove that the constructed hash function can meet the requirements of high throughput and fast consensus in performance. In addition, a distributed consensus coordination service system is used in the blockchain system to realize the synchronization of metadata and ensure the consistency of block data, configuration information, and transaction information. The experiment results show that our proposed strategy can reduce the waste of computing resources, increase the block generation speed, and ensure the fairness of nodes participating in the competition, which is an effective solution to ensure the stable operation of the blockchain system.

1. Introduction

Blockchain is a technique of distributed database which is developed with the applications of digital encrypted currency [1]. A blockchain system has the characteristics of decentralization, nontampering, distributed consensus, provenance, and eventual consistency, which makes it be applied to solve data management problems of the encrusted environments [2].

As a new distributed computing paradigm, it is the combination of point-to-point network, cryptography, distributed storage, and other technologies. It has attracted extensive attention from academia and industry and is mainly used in many fields such as finance, artificial intelligence, Internet of things, medical treatment, and so on [3].

Consensus mechanism is an important part of blockchain technology. It is the key to building trust among untrusted participants. How to make each node efficiently reach a consensus on the effectiveness and consistency of block data in a decentralized system has always been the focus of blockchain technology research [4–7]. Consensus mechanism plays an important role in maintaining the security and efficiency of blockchain [5]. In other words, the correct consensus mechanism can improve the system performance. So far, many different types of blockchain consensus mechanisms have been developed, where the more classic is the proof of work (PoW) mechanism. Its core idea is that each node solves the hash problem through hash-rate competition, to ensure the consistency and consensus security of network distributed ledger. However, PoW needs to consume a lot of computing power and resources. In addition, due to the difference of computing power, there is an imbalance in the probability of packaging accounting right between each node [6].

It is well-known that the consensus mechanism is closely related to the security, stability, and scalability of the blockchain system. The early Bitcoin system adopted the PoW mechanism, which took hash-rate computing power as a means of competition. At the same time, there were also problems such as excessive consumption of computing power, energy-power, and other resources [8, 9]. The proof of stake (PoS) consensus mechanism is an alternative solution to solve the security defects and resource waste of PoW consensus mechanism [10]. *Coinage* is introduced into the PoS mechanism as equity parameter, where the node with the highest equity (*Coinage*) rather than the highest computing power obtains the accounting right of the block. This greatly improves the consensus efficiency and throughput of the blockchain system to some extent but also intensifies the centralization trend for the blockchain system. The PoS mechanism essentially discloses the identity and wealth of stakeholders, so it seems to be incompatible with the cryptocurrency to protect privacy [11].

Consensus mechanism is the algorithm for achieving distributed consensus on transactions in the blockchain system. It is the key to ensuring the consistency of transaction data management by each accounting node [12]. The current public blockchain system generally adopts consensus algorithms on basis of the improved PoW and PoS. The improved PoW algorithm prevents *sybil* attacks [13] by calculating complex mathematical problems, but it causes a decrease in consensus efficiency and a waste of computing resources, resulting in lower throughput and scalability of the blockchain system. With the gradual concentration of computing power, the computing power of a few mining pools can exceed 51% of the entire network's computing power. It can be seen that PoW cannot guarantee against 51% attacks in the mode of computing power aggregation. Although the PoS consensus mechanism can solve the problem of 51% computing power attacks, there is a potential 51% equity monopoly problem, and there are still security issues when the block is forked. The DPoS consensus mechanism selects 101 nodes with equivalent accounting rights through equity voting, which solves the problem of the attacks on the computing power of PoW and the equity of PoS, but there are still 51% attacks on malicious nodes caused by the low participation voting.

It can be seen from the above analysis that the consensus mechanism is one of the factors limiting the development of the current blockchain [14]. For the public-chain system, the consensus mechanism converges the computing power to a small number of nodes, resulting in a significant increase in the probability of 51% attacks. The essential reason is that the computing resources are easier to be concentrated to solve the decomposable centralized problem through the distributed processing environment. In other words, it can be seen that distributed technology brings security problems to blockchain system. In alliance chain and private chain systems, distributed consistency algorithms such as *Pasox* can be used to improve transaction verification throughput and reduce resource consumption. In terms of security, the problems faced by *alliance chain* and *private chain* systems are mainly Byzantine fault tolerance [15], which requires that the number of malicious nodes in the network should be less than 1/3 of the total number of nodes. In addition, a large number of improved consensus algorithms have been proposed to solve the efficiency and security problems of transaction verification in the blockchain system, including the proof of space (PoSp) [16], the authorized Byzantine fault-tolerant algorithm [17], hash graph and hierarchical consensus algorithm [18], etc. The core idea of PoSp is to determine the probability of obtaining the accounting right by proving the amount of data stored by the node, so as to solve the waste of computing resources and improve the verification efficiency. However, there is a potential 51% attack on storage space. Therefore, Hashgraph and HashNet algorithms are mainly aimed at Directed Acyclic Graph (DAG) blockchain system [16]. Hashgraph uses Gossip communication protocol and Byzantine protocol of virtual voting to realize transaction consensus. Its biggest feature is to realize asynchronous consensus. However, its main problem is that multiple rounds of voting verification may reduce the efficiency of consensus.

Consistency is an important issue in distributed blockchain system. The center of the problem is to design appropriate protocols and algorithms so that nodes in the system can only use their own information and neighbors' information under circumstances such as limited information, unreliable information exchanges, communication delays or input delays, and dynamic variations of communication typologies. In order to ensure data consistency and high availability which are the core features of a blockchain system, this paper will use BPFT protocol as the theoretical basis and design high availability scheme, which includes data synchronization, fault recovery, and synchronization. Therefore, our proposed algorithm firstly constructs a more random additive constant through the generation matrix of the error correction code and uses the value of the hash entropy to prove that the constructed hash function can meet the requirements of high throughput and fast consensus in performance. In addition, a distributed consensus coordination service system is used in the blockchain system to realize the synchronization of metadata and ensure the consistency of block data, configuration information, and transaction information.

2. Related Works

2.1. Hash Entropy. The hash function is one of the important data encryption protocols in the blockchain. Since the hash function has irreversible characteristics, it is used to ensure the security and the authenticity of the data, so the data in the blockchain is generally encrypted by the hash function. The blockchain usually uses the *SHA256* function, and its encryption process of the hash function is mainly shown in Figure 1, where Key represents the key of the hash function. After weighting by the hash function, the corresponding hash value is obtained and is stored in the corresponding location in the hash table.

For the rapid positioning of block data, Satoshi Nakamoto [17] proposed a simple payment verification method based on Bloom filter to solve the problems of excessive storage demand and storage redundancy in the Bitcoin system, which allows users to store part of the information to verify the transaction. The Bloom filter is implemented through a hash function, the transaction is weighted by the hash function, and then the information obtained according to the hash function is placed in the location of the hash table corresponding to the Bloom filter. In addition, only the hash table needs to be verified for each transaction. Due to the existence of the hash function, the storage of the blockchain is easier.

Users in the blockchain and their account addresses are encrypted by digital signatures, but for some digital currency

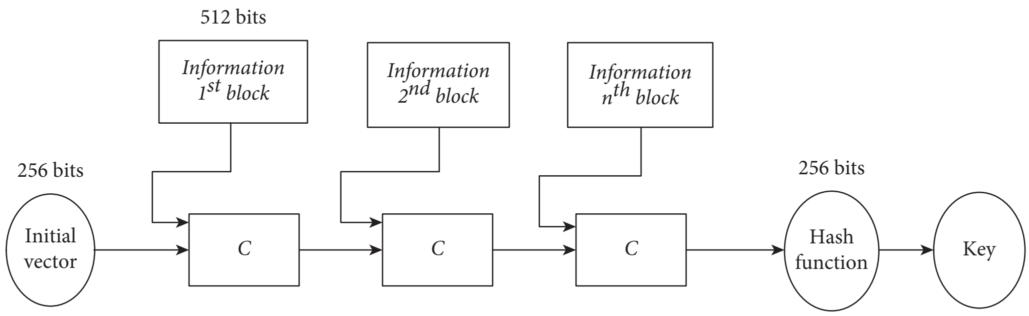

Figure 1: Diagram for SHA256 function.

platforms, users need to make real-name requirements. When real-name users want to cash out their own currency in the blockchain, the own information, the relationship network, and the identity will be exposed, where this behavior greatly affects the confidentiality and security of the blockchain system.

Hash entropy is an encryption algorithm in the blockchain. It is mainly used for miners who package and view transactions, which do not need to know the relevant data of both parties to the transaction and only need to verify the correctness of the transaction according to the hash value of the transaction [18, 19]. These traditional hash entropies require trusted initialization settings, which must be performed by a trusted third party. During the initialization process, some additional variables are often generated. Once these variables are leaked, the attacker can use them to generate false proofs that cannot be detected. It should be noted that the initialization setting is a one-time credible setting for a specific circuit. After the circuit is changed, the initialization setting needs to be performed again.

In order to solve the above problems, some scholars recently proposed several improved encryption mechanisms. For example, Akhtar designed an open and transparent initialization setting to generate a common reference string (CRS) without additional variables in [20]. However, it is still impractical for these new constructions to be applied to the blockchain because their proof size is larger than the traditional construction scheme. Based on hash entropy, an effective privacy protection proposal for account-model blockchain is hiding users' private data such as account balances, transaction amounts, and sender/recipient addresses. More specifically, a hash commitment is adopted to hide account balance and transfer amount, which is a statistically hiding noninteractive commitment scheme with hiding and binding properties.

2.2. Classical Distributed Consensus Algorithm. The distributed consensus mechanism refers to the state machine replication of a group of nodes in the authorized network. It is mainly for some distributed blockchain systems. For example, the Paxos algorithm is mainly designed for the collapsed nodes that may appear in the network; Practical Byzantine Fault Tolerance (PBFT) [16, 21] algorithm can tolerate a certain Byzantine Error node. The classic distributed consensus algorithm has a primary node and other replica nodes. As shown in Figure 2, the PBFT consensus mechanism mainly consists of two parts: The first part is the achievement of a distributed consensus, which is completed by the three steps of preparation, preparation, and commitment; the second part is view-change; when the master node has a problem and cannot process the data request in time, other replica nodes initiate the view after conversion; the new master node starts to work after the conversion is successful. The master node is alternately replaced in a round robin manner. The client uploads the request message m to the nodes in the network, including the master node and other replica nodes. The master node receives the request message m uploaded by the client, assigns the message sequence number s, and then calculates the pre-prepare message $(H(m), s, v)$, where $H(\cdot)$ is a one-way hash function, and v represents the view at this time. The view is generally used to record the replacement of the master node. When the master node is replaced, the view increases 1. The message sender node needs to use its own private key to digitally sign the message before sending the message. The master node sends the pre-preparation message to other replica nodes. The replica node receives the pre-preparation message from the master node and verifies the validity of $H(m)$. In other words, as for view v and sequence number s, the replica node has not received previously other messages. After the verification is passed, the replica node calculates the preparation message $(H(m), s, v)$ and broadcasts it on the entire network. Simultaneously, all nodes collect the preparation message. If the number of the collected legal preparation messages is greater than or equal to $2f+1$ (including its own preparation message), it will be composed of a prepared certificate. If the node collects enough preparation messages and generates a preparation certificate in the preparation phase, then the node will calculate and broadcast the committed message (s, v), where the message m is put into the local log. At the same time, the node collects the committed message in the network. If the number of the collected legal committed messages is greater than or equal to $2f+1$ (including its own promise messages), it will be combined into a committed certificate, which prove that the message m completes the final commitment. The replica node and the master node arbitrarily collect enough

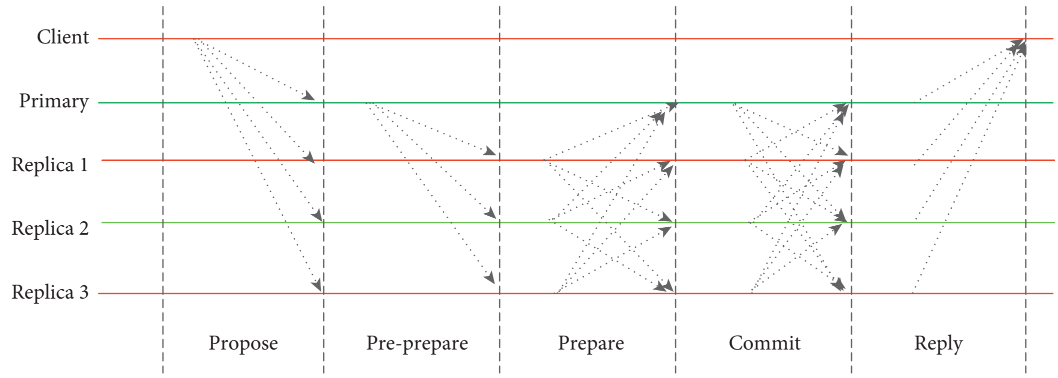

FIGURE 2: Flowchart of practical Byzantine fault tolerance.

committed messages and form the committed certificate, and it is sent to the client as a reply to message m, so the client confirms the final promise of message m.

3. Our Proposed Consensus Strategy

3.1. Problem Description. Given a collection $\{P_1, P_2, \ldots, P_n\}$ of data source suppliers and a collection $\{U_1, U_2, U_3\}$ of data source users, the data source suppliers server group can constitute the data blockchain (DBC) and transaction blockchain (TBC) [17–22]. For a piece of raw data, a certain server node may be the data source supplier, and another piece of raw data is the data user. In addition, a bilinear mapping (q, g, G_1, G_T, e) is used to initialize the system parameters. H: $\{0,1\} \longrightarrow \{0,1\}$ is a one-way, anticollision hash function in cryptography and is instantiated using SHA-256. Let g_1 be a generator different from g in G_1, so the public parameters $\text{Param} = (q, g, G_1, G_T, e, g_1, H)$ can be obtained.

The data source supplier divides the data D to be uploaded into n blocks $d_1, d_2, \ldots, d_n \in Z_p$, where p are a large prime number. In other words, the big data block $D = \{d_z\}(z \in [1, n])$ is the basic unit of data sharing and flow path detection. A data source provider p_i selects a random number x in z_p^* and generates a key pair (pk_i, sk_i), where $pk = g^x$ and the random number x is the private key sk_i.

3.2. Reencryption with Hash Entropy. The compression function of SHA256 mainly operates on 512-bit message block and 256-bit intermediate hash value. In essence, it is a 256-bit encryption algorithm that encrypts the intermediate hash value by using the message block as a key. The data source supplier p_i uses the public parameter *param*, public key pk and data plain-text d_z to obtain the cipher-text after the first encryption. The encryption process is described as follows: A random number r_i in z_p^* is selected, and the reencrypted cipher-text C_z can be calculated from the equation $C_z = (c_1, c_2, c_3)$, where $c_1 = g^{r_1}$, $c_2 = d_z \cdot e(g_1, pk_i)^{r_1}$, and $c_3 = H(H(c_1)\|H(c_1\|c_2))$. And then, cipher-text set $\{C_z\}(z \in [1, n])$ can be obtained, which can be stored into DBC through a consensus mechanism based on threshold cryptography. The decryption operation of data cipher-text first verifies whether the equation $C_z = (c_1, c_2, c_3)$ is true. Otherwise, the data plain-text is calculated by the following equation:

$$d_z = \frac{c_2}{e(c_1)}. \tag{1}$$

When the data source provider p_i wants to share the data D with a data user or a data user buys the data D, p_i needs to generate a reencryption key $rk_{i \longrightarrow j}$ according to the public key pk_i, private key sk_i, and public parameter *param*; p_i will use $rk_{i \longrightarrow j}$ to convert the cipher-text encrypted by pk_i; then $rk_{i \longrightarrow j}$ can be decrypted by private key of p_i. The reencryption key generation process is written as follows:

$$\begin{aligned} rk_{i \longrightarrow j} &= (rk_1, rk_2, rk_3), \\ rk_1 &= g^{r_j}, \\ rk_2 &= g^{-sk_i} pk_j^{r_j}, \\ rk_3 &= H\left(H(rk_1)\|H\left(rk_1\|rk_2\right)\right), \end{aligned} \tag{2}$$

where r_j is random number r_i in z_p^*.

When the data source supplier p_i broadcasts the reencryption key $rk_{i \longrightarrow j}$, the data sharing or delivery process is completed. The conversion of cipher-text can be completed after obtaining the reencryption key $rk_{i \longrightarrow j}$. The specific operations are as follows:

(1) Verify the following two equations. If the above equation does not hold, it indicates that there is a problem with the transmission and retransmission is requested. If the equation holds, continue step 2.

(2) Calculate the cipher-text set $\{W_j\}(j \in [1, n])$ encrypted by the public key pk_j of p_i and convert the cipher-text in $W_j = (\widehat{W}_1, \widehat{W}_2, \widehat{W}_3, \widehat{W}_4)$, where $\widehat{W}_1 = c_1$; $\widehat{W}_2 = c_2 \cdot e(c_1, rk_2)$; $\widehat{W}_3 = rk_1$; and $\widehat{W}_4 = H(H(\widehat{W}_1)\|H(\widehat{W}_1\|\widehat{W}_2)H(\widehat{W}_2\|\widehat{W}_3))$.

If p_i wants to further obtain the plain-text of the data, it only needs to decrypt it with own private key. Firstly, it is verified whether equation (3) is true. If not, return to the initial verification. Otherwise, the plain-text $d_z = \widehat{W}_2 / e(\widehat{W}_1, \widehat{W}_3)^{sk_1}$ of the data block is calculated and output in turn.

Similarly, the data $D = \{d_z\}(z \in [1, n])$ can be obtained to realize data sharing or transaction. After the data sharing or transaction is completed on the DBC, n data transaction record will be formed on the TBC (since the data is cut into n parts) and metadata records will be made. The nodes on the TBC query the authenticity of the transaction through the classic consensus mechanism based on threshold cryptography protocol. When it is true, the transaction will be placed in the transaction pool; otherwise, it will be discarded. Since the blockchain node will verify each transaction, the blockchain itself also has very good traceability, which will prevent the reselling of data and provide users with the function of data-flow path query.

When the data source provider p_i divides the raw data D to be uploaded into n data blocks $d_1, d_2, \ldots, d_n$, some of it could be embezzled. It is assumed that a data block d_k is embezzled data. When the data block is packaged as an *item* and propagates on the TBC network, the node receiving the *item* will check one by one against a standard verification process list. If the data block d_k is a shared data block, we can find the signature of p_s from the signature pool and metadata information, which is to say the operation can complete the flow path query from p_h to p_s. Similarly, it can continue to trace the source of the original data block according to the signature stored in the *item of* p_s. Therefore, log entries only flow from the leader to other servers, which simplifies the management of replicated logs. The reencryption key generation process uses a random timer for leader election, which only needs to add a small number of mechanisms to the heartbeats required by any consensus algorithm, while being able to resolve conflicts simply and quickly. In addition, our improved joint consensus method will allow the cluster to continue normal operation during configuration changes.

3.3. Improved Distributed Consistency. The matrix form of the standard weighted discrete consensus algorithm [18] model is

$$\begin{cases} x(k+1) = p_{\varepsilon w} x(k), \\ p_{\varepsilon w} = I_n - \varepsilon L_{\mathrm{nw}}, \\ L_{\mathrm{nw}} = W^{-1} L_n, \end{cases} \tag{3}$$

where $x \in R^n$ is a consensus variable; ε is the iteration step; $p_{\varepsilon w}$ is a nonnegative random matrix; W is a weighted matrix $W = \mathrm{diag}(w_1, w_2, \ldots, w_n)$, $w_i \geq 1$. When W is a unit matrix, it is the standard average discrete consensus algorithm; n is the number of vertices of the communication topology graph G; I_n is the n order unit matrix; L_n is the corresponding Laplacian matrix, where $L_n = D_n - A_n$. A_n is the adjacency matrix of the graph G and D_n is the dictionary matrix of the graph G.

It can be emphasized that the value range ε of the iteration step is often $0 < \varepsilon < 1/d_{\max}$ in most literature, where $d_{\max}$ is the maximum vertex degree of the graph. The calculation equation of the range is simple, but relatively conservative. When L_n is unknown, the step size can be defined by this range; and when L_n is known, the value range of the iteration step size is denoted as follows:

$$0 < \varepsilon < \frac{2}{\rho\left(W^{-1} L_n\right)}, \tag{4}$$

where $\rho(\cdot)$ is the spectral radius of the matrix.

It can be seen that the improved method takes the state difference between its own unit and the adjacent unit as the adjustment direction. It is a simple autonomous system. Through iterative calculation, the state variable x can be brought to the weighted average of the initial state $x(0)$.

After continuous dynamic adjustment of nodes, the nodes in the alliance chain can achieve high credibility and rapid consensus, which increases the throughput of the blockchain system [23]. Before the consensus preparation stage, the improved consensus mechanism based on threshold cryptography algorithm uses weights to determine the probability of each node participating in the consensus.

The ratio of the current weight to the initial weight is set as the probability distribution of the current node participating in the system consensus service [24], so as to reduce the number of nodes with more downtime and malicious behavior participating in the consensus as a whole, speed up the consensus efficiency and consensus communication process, and optimize the performance of blockchain system. The designed formula is written as follows:

$$P = \frac{w_i}{W}, \tag{5}$$

where P represents the node's participation probability, w_i represents the current weight of the node, and W represents the initial value of the node's weight.

4. Experiment and Result Analysis

4.1. Experiment Configuration. The improvement strategy designed in this paper is coded in *Python 3* on basis of Python *FlaskWeb* framework, and the efficiency of node communication and data interaction is realized through socket network programming and JSON data exchange format [22]. A test blockchain with 8 nodes is built according to the consensus mechanism. Through experiments the block generation time, hash value of the improved consensus algorithm, the influence of the number of node accounting rights, and the influence on the number of node accounting rights are verified. This experiment also compares the results of other consensus algorithms to verify the performance of the consensus algorithm. The configuration information is shown in Table 1.

In the experiment, the client node sends a request to the consensus nodes through the interface, the request contains the required JSON format data, the consensus completion result is stored in the database, and the client query directly queries the database through the interface. In practical applications, the packaged consensus module, storage module, access module, etc. can be directly used to modularize the distributed system, and the systems can call each other through the request interface. In order to verify the superiority of the improved consensus strategy, some comparison algorithms are tested through the blockchain system. In the system, the Random function is used to

Table 1: Configuration information.

Node name	Address	CPU	RAM	OS
Node_1	0fd78b963...	I5-10600	8	Win 10
Node_2	3ed8fr23a1...	I3-6200	8	Win 7

Node_8	4d6f9fh85...	I5-8700	8	Win 10

randomly determine whether a node has malicious or downtime behavior during the current consensus process.

4.2. Time-Delay Analysis. Time-delay is one of the important indicators to evaluate the performance of consensus algorithms. Time-delay mainly refers to the time it takes for a user to submit a request to reach a consensus. A lower delay can improve the commercial performance of the alliance chain system and complete more business processing.

Different block generation time in the blockchain system means that the size of the transaction information accumulated during this period is different. Different data sizes will directly affect the system's network communication time, so the block generation time has a strong impact on the consensus delay. This experiment uses a combination of multiple node numbers in the consensus network, a single test is performed 10 times, and the average value of the 10 times is used as the final experimental data of the current block generation time to test the impact of different block generation times on the consensus time-delay.

From the above results in Table 2, it can be found that the average delay of our proposed model is 17.59% lower than that of HPoW and 12.1% lower than that of HPoS.

With the increase of generation time, the consensus delay of the blockchain system also increases. When the system block generation time is greater than a certain value, the consensus delay increases exponentially. The increase of block generation time means that more transaction information will be generated in this time interval, resulting in the increase of consensus delay. Due to the multiple forwarding of transaction information in the consensus process, when the amount of data acceptable to the system node is exceeded, the system consensus will be blocked, and the consensus delay increases exponentially. Compared with HPoW and H PoS, our proposed model increases the node reward and punishment mechanism, optimizes the consensus process, and reduces the steps of consensus communication. In the experiment, we assume that the amount of transaction information is fixed, set the same block generation time, and conduct 20 consensus experiments. The simulation machine carries out the control experiment in the real environment. The experimental results of the three algorithms are shown in Figure 3.

Our proposed model reduces the time cost of calculating the random number by dynamically adjusting the difficulty value. The difficulty value is set to 6 and the first 6 bits of the calculated hash value are obtained. The average time of each block is about 1 min. Set up the operation experiment of the blockchain system and record the time spent for each block. In the first 100 blocks, every 10 blocks are interval, and calculate the average value of block time. The statistical results are shown in Figure 4. It can be seen from the experimental results that the fluctuation range of the obtained curve is small. Except that the blocking time of some blocks exceeds 1 min, most of the blocking time is about 1 min. At the same time, the concept of variance is introduced to calculate the variance of the blocking time of our proposed model. The average blocking time of the first 100 blocks is 58.1 s. After calculation, the variance is 45.89. This is because a small part of the data fluctuates greatly. Therefore, the variance is relatively large. However, the experimental results basically meet the requirements, improve the transaction efficiency of the blockchain system, and save a lot of time and computing resources.

4.3. Throughput Analysis. Data throughput is also an important indicator to measure the consensus algorithm. Throughput is a measure to process transactions, requests, and transactions per unit time. In the blockchain, it is expressed as the number of transactions packaged in a unit of time. Figure 5 shows the relationship between the time of different algorithms and the number of packaged transactions. The slope of its tangent line at a certain point indicates the data throughput of the time period. From the slope of the curve, it can be seen that as time increases, the average data throughput gap of the four algorithms gradually increases. The throughput of the proposed algorithm is relatively close to that of the HPoS algorithm, but slightly larger than the throughput of the HPoS algorithm, and is always much greater than the throughput of the HPoW algorithm. Compared with the HPoW algorithm, the throughput of the HPoW algorithm is not as good as the proposed algorithm, so the proposed algorithm has better throughput performance.

In the alliance chain system, the consensus requires multiple complicated communication between nodes. The proposed strategy optimizes the communication process. In the experiment, the improved model is used in a simulated environment, where variables such as block time, number of nodes, and transaction information are set to fixed values. The experimental results of the throughput of the three algorithms can be analyzed in Figure 5, where we also analyze the performance of the proposed strategy without hash entropy. Compared with these comparison algorithms, the consensus throughput of our proposed algorithm is significantly improved.

4.4. Security Analysis. The consensus algorithm mainly refers to the incidence of malicious behavior. In the current complex network environment, ensuring the safe and stable operation of the blockchain is the focus of current research. The security performance analysis of the proposed consensus blockchain system is as follows: Blockchain is a special distributed database system in which each node

Table 2: Average time-delay.

	4 nodes	8 nodes	12 nodes	16 nodes	Average	Result_1	Result_2
PoW	156	168	175	198	172.1	—	—
PoS	148	152	168	174	165.2	7.11%	—
Proposed	129	136	145	152	148.1	17.59%	12.11%

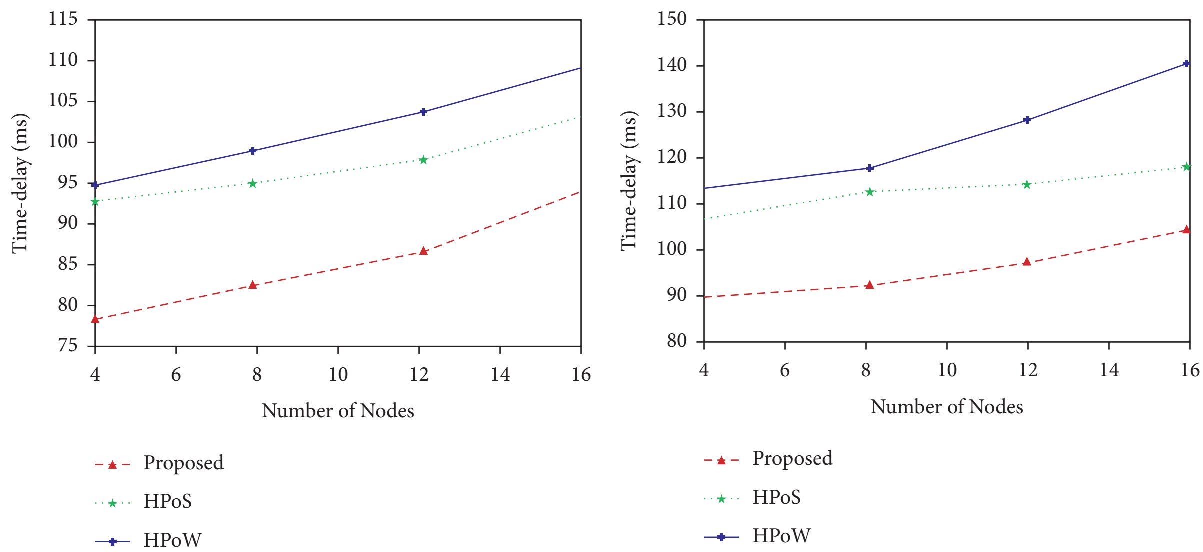

Figure 3: Time-delay for different algorithm. (a) 10 blocks, (b) 20 blocks.

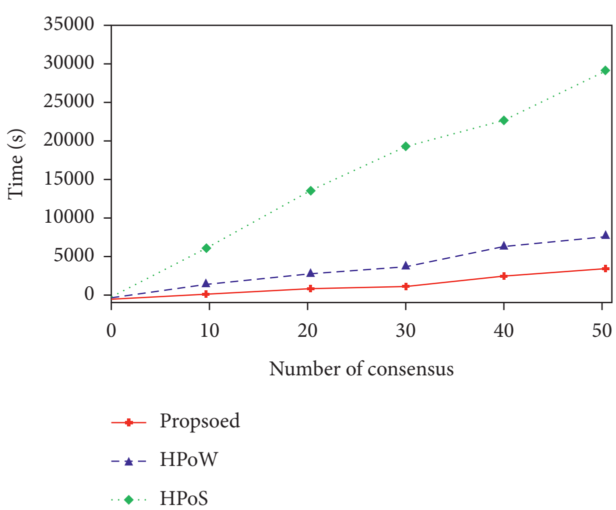

Figure 4: Comparison of consensus times for different algorithms.

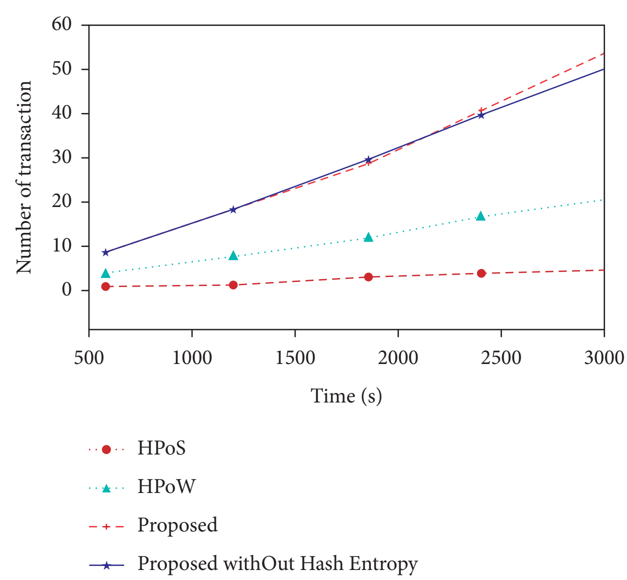

Figure 5: Comparison of the number of transactions for different algorithms.

stores a copy of transaction information. When a node in the blockchain is attacked, other nodes can verify the misinformation data spread by the malicious node so as to ensure the correctness of the entire blockchain system. Therefore, for a single attack on a node, the system has the capability of Denial-of-Service attack.

The proposed consensus algorithm can provide the corresponding consensus participation access mechanism for the nodes in the system. The system can decide whether to participate in the current consensus on the basis of the historical data of the nodes, thereby shielding possible malicious behaviors and reducing the overall number of occurrences of malicious behaviors. The proposed strategy

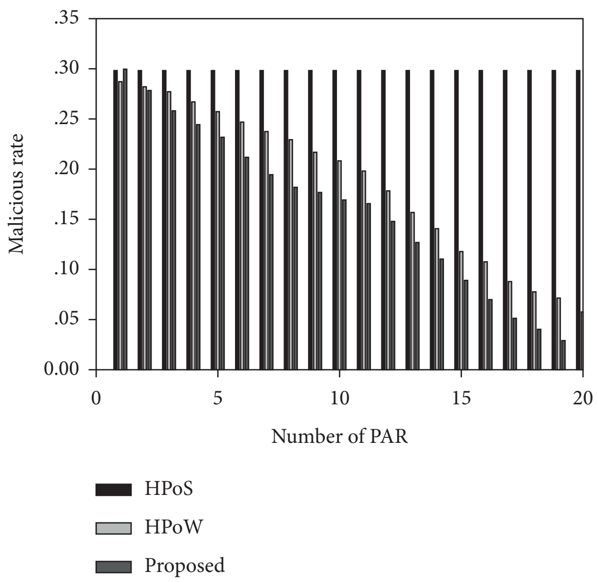

Figure 6: Average malicious behavior rates of comparison algorithms.

can help the blockchain system to improve its robustness, so that the system can operate more efficiently.

Under the improved mechanism, the hash value of the node that successfully obtains the package accounting right (PAR) will be reduced by about half, and it will take a long time to accumulate to reach the level of competition with a higher probability of the package accounting right. If there is a collusion attack, the node will transfer its own hash value to other benefiting nodes. Even if the benefiting node obtains the right to package accounting and obtains the benefits, it does not matter to the node that transfers the value or to the benefiting node.

As shown in Figure 6, the average malicious behavior rates of comparison algorithms are 30%, 18.72%, and 15.65%, respectively. The experimental results show that the improved strategy has obvious advantages in reducing the probability of malicious behavior in the blockchain system and effectively improves the security of the system.

5. Conclusion

The improved distributed consensus algorithm constructs a more random additive constant through the generation matrix of the error correction code and uses the value of the hash function information entropy to prove that the constructed hash function can meet the requirements of high throughput and fast consensus in performance. In addition, a distributed consensus coordination service system is used in the blockchain system to realize the synchronization of metadata and ensure the consistency of block data, configuration information, and transaction information. The experiment results show that the proposed strategy can reduce the waste of computing resources, increase the block generation speed, and ensure the fairness of nodes participating in the competition, which is an effective solution to ensure the smooth operation of the blockchain.

However, our proposed algorithm still needs to be actively explored and improved. The design of consensus algorithm with high-throughput and low-delay performance is the focus of blockchain technology development. The transaction processing capacity of our proposed algorithm needs to be improved. For example, the cross-chain consensus of multichain architecture (including isomorphic or heterogeneous blockchain) can greatly improve transaction performance, which will be one of our research directions in the future [25].

Academic Editor: Tongguang Ni

This paper provides an in-depth study and analysis of software defect prediction methods in a cloud environment and uses a deep learning approach to justify software prediction. A cost penalty term is added to the supervised part of the deep ladder network; that is, the misclassification cost of different classes is added to the model. A cost-sensitive deep ladder network-based software defect prediction model is proposed, which effectively mitigates the negative impact of the class imbalance problem on defect prediction. To address the problem of lack or insufficiency of historical data from the same project, a flow learning-based geodesic cross-project software defect prediction method is proposed. Drawing on data information from other projects, a migration learning approach was used to embed the source and target datasets into a Gaussian manifold. The kernel encapsulates the incremental changes between the differences and commonalities between the two domains. To this point, the subspace is the space of two distributional approximations formed by the source and target data transformations, with traditional in-project software defect classifiers used to predict labels. It is found that real-time defect prediction is more practical because it has a smaller amount of code to review; only individual changes need to be reviewed rather than entire files or packages while making it easier for developers to assign fixes to defects. More importantly, this paper combines deep belief network techniques with real-time defect prediction at a fine-grained level and TCA techniques to deal with data imbalance and proposes an improved deep belief network approach for real-time defect prediction, while trying to change the machine learning classifier underlying DBN for different experimental studies, and the results not only validate the effectiveness of using TCA techniques to solve the data imbalance problem but also show that the defect prediction model learned by the improved method in this paper has better prediction performance.

1. Introduction

With the rapid development of computer technology, software applications have expanded to all parts of people's daily lives, creating a situation in which the economy, production, and life are fully dependent on computer software. But software failure can bring about serious or even fatal consequences, especially for high-risk systems. System failure is more often caused by software defects, which are important factors affecting software quality and are potential root causes of errors and failures in the relevant systems. In the early stages of software development, due to the limited processing power of computer hardware, software popularity is not high, and the functions realized by the software are relatively simple, so software was mostly developed in an individualized manner [1]. Although the collected data is concentrated, most of the malicious samples are 64-bit programs, but there are still 417 32-bit programs. However, with the development of hardware technology and the popularity of computers, the scale and complexity of software became larger and larger, and the previous way of software development became increasingly difficult, and, to solve the resulting "software crisis," the way of software development was gradually systematized and engineered [2]. However, in the software development process, the existence of software defects is inevitable due to the limitations of resources and developers' experience. Therefore, the prevention of software defects and the timely correction of software defects have become the reason for the prediction of software defects. People started to collect and use data related to software defects (e.g., data describing the size, complexity, and process of software) and use the data combined with algorithms to construct software defect prediction models for predicting defect information of software.

At the internal level of software, defects are errors or faults in the software development or maintenance process; at the external level of software, defects are violations or failures of the functions that the software needs to perform. Defects in software affect software quality, and early detection of defects and their treatment are important for software quality assurance [3]. However, with the increasing complexity of software systems and the increasing cost of testing, traditional software testing and quality assurance techniques can hardly meet the current needs. If the software development and testing stage can be combined with machine learning technology to deep search, crawl, and analyze the software's historical defect data, to predict and count the distribution and number of defects in the software system in advance to a certain extent, it can better help the quality assurance team to understand the software quality status timely, accurately, and objectively and effectively allocate testing resources to improve software testing efficiency and save testing costs. This can improve software testing efficiency, save testing cost, and guarantee software quality. Through the study of memory analysis technology, a control flow transfer graph generation algorithm based on system calls is proposed. The algorithm is based on the traditional program control flow graph combined with the system call information to automate the generation of system call transfer graph, which can effectively detect and identify malware by using the existing graph neural network model [4]. When it is greater than 0.7, it shows an increasing trend, and the fine-tuned prediction model can show good prediction performance under different sparsity parameters, and the recall rate and F1-measure are better than the performance of the non-fine-tuned prediction model. By mining the software history repository, extracting program modules and metrics, marking whether they contain defects or the number of defects, building software defect prediction models using machine learning and other methods, and then predicting the propensity of defects, defect density, or number of defects for new program modules, software defect prediction technology can be developed [5]. Software defect prediction technology gives software development teams one more chance to retest software defective modules, and, by spending more effort on defect-prone program modules and less on non-defect-prone program modules, the resources of software projects will be better utilized, which can also greatly reduce the human and material resources consumed by testing work, save testing costs, and improve R&D efficiency.

For the core elements involved in software defect prediction techniques, namely, data and algorithms, artificial intelligence plays a great role. When humans first designed programmable computers, they were already thinking about whether computers could become intelligent. Now, artificial intelligence (AI) has many practical applications, is an active research topic, and is flourishing. We expect software to intelligently handle routine labor, understand speech or images, and support basic scientific research. In the early days of AI, problems that were very difficult for human intelligence but simpler for computers were rapidly solved, for example, those that could be described by a set of formal mathematical rules. The challenge for AI is to solve tasks that are easy for a human to perform but difficult to describe formally, such as recognizing what a person says or an image. For these problems, it is often easy for a human to solve them by intuition. Whereas abstract and formalized tasks are among the most difficult mental tasks for humans, they are among the easiest for computers. A key challenge for artificial intelligence is how to communicate nonformal knowledge to computers. Some AI projects seek to hard-code knowledge about the world informal language. Computers can automatically understand this formal language using logical inference rules.

2. Current Status of Research

Currently, the available software defect prediction techniques can be simply classified into dynamic defect prediction techniques and static defect prediction techniques according to the techniques used. Among them, the dynamic defect prediction technique is a study of the entire software system life cycle and predicts the distribution of software defects over time, based on the time when the software failure or system failure occurs, while the static defect prediction technique is based on the size of the software system, loop complexity, and other metric data that have relevance to software defects, as well as the propensity of software program modules to have defects, defect density, or a number of defects prediction [6]. Compared to other machine learning algorithms, the prediction accuracy of SVM is higher, but its algorithm complexity is higher and its operating speed is slower [7]. In addition, since there is no unified theoretical guidance for parameter selection in SVM, many researchers have combined parameter search algorithms with SVM and proposed various software defect prediction models that optimize SVM. Combining the parameter-seeking ability of ant colony optimization algorithm and the nonlinear operation ability of SVM improves the classification performance of SVM; the better global search ability of genetic algorithm is used for the selection of optimal features and the calculation of optimal parameters of SVM, which can avoid the premature sieving of beneficial information in feature selection and further improve the performance of prediction models [8]. It inputs software defect features and historical defect data into the artificial neural network model, compares the error between the output results and the actual results, and corrects the data using a back-propagation algorithm to adjust parameters such as the connection weights of ANNs by an iterative method to continuously optimize and obtain the optimal network parameters [9]. This method has the feature of high prediction accuracy, but the training speed is slow because of the need to iteratively optimize the network parameters. Based on the traditional ANN, the ANN improved first initializing the parameters of the ANN using a particle swarm optimization algorithm and then using a simulated annealing algorithm to modify the weights and thresholds of the network, which effectively improves the accuracy and precision of the software defect prediction model [10].

Different types of software metrics have been proposed, and many machine learning and data mining algorithms have been applied to solve the problems that arise in the process of software defect prediction based on machine learning algorithms [11]. The cost of classifying defective instances as nondefective instances is too high, thus affecting the usefulness of the prediction model; the high redundancy in the software metric and the high similarity between nondefective instances allow the data quality to be improved by methods such as feature selection [3]. The three methods, as researchers imaginatively call them, analyze software testing in terms of its length, volume, and structure, respectively [12]. Dynamic software defect prediction refers to the technique of predicting the distribution of system defects over time based on the time of defect generation or failure. Most of the researchers study static software defect prediction techniques and, in this paper, also the static software prediction techniques are mainly studied [4]. The study of static software defect prediction techniques is divided into three main aspects: first, how to evaluate software defect prediction models; second, for the problem of choosing software metrics, effectively choosing metrics applicable to software defect prediction; and third, which qualitative or quantitative or hybrid models can be applied to software defect prediction [2, 13]. Regarding evaluation metrics, precision, clarity, and sensitivity are frequently used evaluation metrics.

Precision refers to the proportion of correctly predicted modules to total modules, clarity refers to the proportion of defective modules predicted as defective, and sensitivity refers to the proportion of all modules without defects that are correctly classified. These three metrics do not achieve a comprehensive evaluation of a model, but they enhance the understandability of the model and facilitate further summarization of the model to improve it. Of course, in practical defect prediction, testers can identify some defective modules based on some testing rules. Programmers are also able to identify a set of defect-free modules based on their programming experience. Thus, the initially marked defective modules can be obtained through the efforts of testers and programmers. Using limited defect marking data to predict the propensity for defects in other modules, researchers typically use a limited number of defective modules and many unlabeled modules to be predicted to construct a predictive model using semisupervised learning. Semisupervised learning methods have the advantage of being able to use both labeled and unlabeled data to make use of as much valid data information as possible.

3. Analysis of Deep Learning Software Defect Prediction Methods for Cloud Environments

3.1. Deep Learning Prediction Methods for Cloud Environments. Researchers generally agree that there is a link between internal properties of the software (e.g., static code features) and its external performance (e.g., defects) and that developers collect historical data from the same project or from other projects in their own company and similar projects in other companies, from which they extract static properties of the code (usually expressed using software metrics) and thus have data on the relevant features of the software, and then research can be conducted based on statistical methods. Machine learning is devoted to the study of how experience can be used to improve the performance of the system itself utilizing computation [1]. Therefore, the performance of the prediction model is stable, but, from the running time comparison chart, the running time of the prediction model basically increases linearly with the number of trees in the forest. In computer systems, the experience usually exists in the form of data, and therefore the main part of machine learning research is about algorithms that generate models from data on a computer, that is, learning algorithms. Linear regression can be extended to the classification case by defining different probability distributions; and here the continuous random variables in logistic regression obey the coordination distribution, which means having the following distribution function and density function:

$$p\left(y.x^2;\theta\right) = N\left(y;\theta^2 x, 1\right),$$
$$F(x) = \frac{1}{1+\left(-b \pm \sqrt{b^2-3ac}/2a\right)}. \tag{1}$$

A feature is an abstract representation of some property extracted from an entity and can consist of data or text; in this paper, features refer to the software defect feature metric already detailed in the previous section. One very important phase that precedes the construction of machine learning models is feature engineering [14]. Feature engineering is the process by which software engineers apply their expertise and skills to analyze and process the dataset to make feature data more useful for machine learning modeling. Subset evaluation is required after the feature subset candidate table is constructed to evaluate the merits of the subset to select the optimal subset. The evaluation methods include the following: the distance measure in FFS, which analyzes the correlation between features and features or features and classes by commonly used measures such as Euclidean distance and squared distance; the information measure in FFS, which evaluates the strength of interdependencies between features and gives a reference for feature selection; the dependency measure in FFS, which gives the separability of features and classes; the consistency metric, which uses inconsistency rate to select the optimal subset; and the classification error rate metric in WFS, which has higher accuracy in evaluating the subset compared to the metric in FFS but takes more time, as shown in Figure 1.

The stopping criterion controls the generation of subsets, which is related to the subset evaluation criterion or search strategy [6]. The hidden neurons of the autoencoder need to be activated too much, which causes the autoencoder training to be overfitted, so the performance of the prediction model is reduced; but when the sparsity parameter is

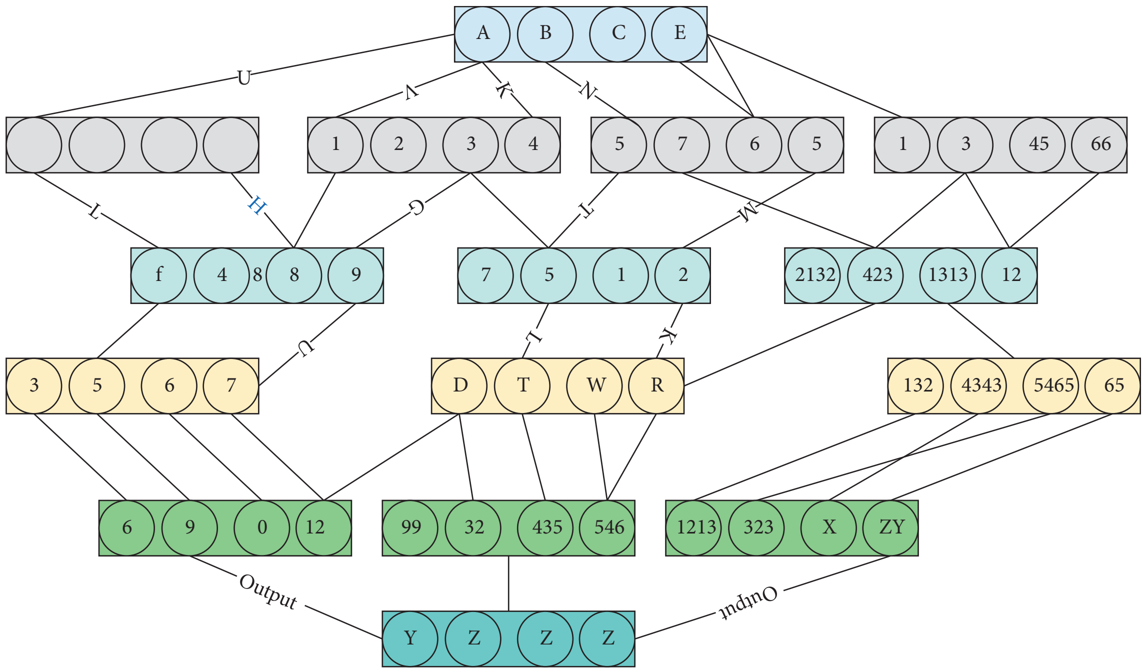

Figure 1: Deep stacking network structure.

greater than 0.7, it means that most neurons in the hidden layer need to be activated this unreasonable setting will destroy the normal optimization of network parameters. The stopping criterion generally includes execution time limit, iteration number limit, and threshold setting. When the global optimal search strategy deals with datasets with many features, its time complexity far exceeds that of other search strategies, and it will greatly affect the efficiency of subset generation, which in turn affects the construction of the whole model while performing a time limit can forcibly end the search, but performing a time limit will affect the optimal subset search performed by this strategy. The stochastic search strategy reduces its time complexity by limiting the number of iterations. The heuristic optimal search strategy prevents the algorithm from entering a dead loop by setting a reasonable threshold.

$$y^3 = f\left(ab_2^3 - \sqrt{a^2 + b^2}\right). \tag{2}$$

Feature extraction is a key step in software defect prediction, and the quality of feature extraction determines the performance of software defect prediction, but traditional feature extraction methods are difficult to uncover the deep-seated essential features in software defect data. Autoencoder models in deep learning theory can automatically learn features from the original data and obtain feature representations of the input data. In this paper, we apply autoencoder to feature extraction for software defect prediction and to improve the loss cost function and sparsity constraint method of autoencoder for its slow convergence of loss cost function and too many sparse regularization parameters, complicated tuning parameters, and so forth. Meanwhile, to reduce the influence of noise on the input data, we propose a software defect prediction based on stacked noise-reducing sparse autoencoder method, which can automatically learn features from the original defect data, extract the required features at each level from the software defect data directly and efficiently by setting different hidden layers, sparse regularization parameters, and noise addition ratios, and then combine with a logistic regression classifier to classify and predict the extracted features.

$$\begin{aligned} \theta^* &= \arg\max \sum_{j+2} nL\left(x_j^{(i)}, y_m^{(i)}\right), \\ J_{SE}(x, y) &= \frac{1}{n} \sum_{y-1}^{n} N\left(\frac{1}{2}\left(\|m\|^3 + \|m'\|_2^3\right)\right). \end{aligned} \tag{3}$$

The inclusion or not of system call execution is added as code block node information in the control flow graph. Some of these nodes do not execute system calls, and this paper is concerned with system call execution information that reflects the intent of the program behavior; such a node is redundant for the graph and needs to be fused with neighboring nodes that contain the system calls. The complexity of the graph is further reduced by generating a control flow transfer graph based on system calls. It propagates labels from labeled data to unlabeled data [15]. The basic idea is that, given a finite amount of labeled data, the labels of the labeled data are propagated through a dense region of unlabeled data, searching for more data with similar properties to the labeled data. A straightforward approach is to compute pairwise similarities between data points and then transform the problem into a harmonic energy minimization problem.

$$\begin{aligned} w_{ab} &= e\left(\left\|a_i - b_y\right\|^3\right)/ - (5\pi), \\ &\max\left\|Xm^2 - y\right\| + \pi m^3 \le 3. \end{aligned} \tag{4}$$

The basic assumption of graph-based semisupervised learning is the cluster assumption. It states that if there is a path that connects two points only through a high-density region, then the two points may have the same class label. In computing nonnegative sparse weights for all samples, a sparse matrix can be constructed. With traditional machine learning classification models, the model is often built based on a condition that the data classification is balanced; however, when the data class distribution is unbalanced, it can affect the classification effect. The Pd value increased by 0.07, 0.07, 0.06, and 0.07, respectively. SOM-ANN uses autoencoders to extract data features and trains neural network classifiers to predict defects in software modules. Classifiers that classify classes based on decision surfaces in the feature space can be affected by unbalanced data class distribution. To reduce the effect of noisy data as well as overfitting, the optimal decision surface considers both the accuracy of the classification and the complexity of the decision surface, also called the structural risk minimization principle. However, if the training sample dataset class distribution is unbalanced, in this case, the number of support vectors is also unbalanced. With the principle of structural risk minimization, the support vector will ignore the effect of rare classes on the structural risk and expand the bounds of the decision. Finally, it will lead to a large gap between the actual hyperplane of training and the optimal hyperplane, as shown in Figure 2.

Based on the actual defect prediction needs, defect prediction models are constructed based on the training set and selected machine learning methods (e.g., plain Bayes, support vector machines, linear regression, etc.); the constructed models can be used to perform defect prediction for non-training-set instances (e.g., unlabeled instances or new instances) in this project; the goal of prediction is to discover whether the instances have defects or the number of defects, and this paper studies the former; that is, the instances with or without defects are predicted. To address the problem that the sparsity parameters need to be set in advance and all neurons in the hidden layer have the same sparsity in the traditional sparse autoencoder, a sparse autoencoder with sparsity constraints based on L1 rules is proposed by penalizing the nonzero activation of hidden neurons in the autoencoder, inspired by the sparsity coding algorithm with L1 rules.

Since the different layers of the stacked noise-reducing sparse autoencoder are learned separately, they must be combined with the classifier to form a complete deep neural network model with fine-tuning of the network parameters. Fine-tuning is done by adjusting the parameters of all layers in the model simultaneously by gradient descent to improve its performance after the pretraining process is completed. Fine-tuning is done by removing the decoding layer of the stacked noise-reducing sparse autoencoder, inputting the features of the last layer directly to the classifier for classification, calculating the loss cost of the predicted class versus the actual class, and iteratively optimizing the network parameters by a back-propagation algorithm using gradient descent to obtain a deep model with optimal network parameters.

3.2. Software Defect Prediction Method Design. Increasing the number of trees will not increase the learning performance. Deep belief networks, an example of the deep learning methods, have the greatest advantage over logistic regression in that deep belief networks can generate more expressive sets of features from an initial set of features. If the input is these generated features rather than the initial set of basic features, the two weaknesses that logistic regression has above can be overcome. Based on migration component analysis to deal with imbalanced data, according to the Introduction, the principle of migration component analysis is that even if the distribution of features in the domain is different, when there are some common underlying factors between the source and target domains, the domains can be put into a potential space to explore the hidden common factors in this way to reduce the domain differences, while the original data characteristics can be retained. Therefore, this paper takes advantage of TCA to map the datasets of two different items to a potential space, and when this potential space is found, a few classes of data from the source item are selected and added to the target item as the training set of the target item, so that the two classes of data in the target item are equal in number, and the imbalance of the dataset is improved at this time, and the loss of information from the deleted data is avoided [16]. The imbalance of the dataset is improved, and the situation of losing information by deleting data is avoided. In contrast, when training the target project dataset (intraproject defect prediction), the dataset needs to be mapped to the potential space first, and then the training model is learned in the potential space. Specifically, for the practical application of defect prediction in this paper, the steps are as follows: suppose that the defect prediction model is to be learned in project when the dataset in project 1 is extremely unbalanced; that is, there is less data with defects and more data without defects, as shown in Figure 3.

Although Sigmoid + SVM has the best checking accuracy, its checking completeness rate is very low. This is especially true for the Mozilla, Eclipse JDT, and Eclipse Platform datasets, but the percentage of defective change instances for these three datasets is about 5%, 14%, and 14%, respectively, for which Sigmoid + SVM has only about 4%, 3%, and 3% find-all rates, while Deeper and the improved DBN method achieve a better find-all rate of over 65%. The results show that Sigmoid + SVM is not good enough for defect prediction, illustrating that imbalanced data preprocessing is necessary and important, and Figure 3 demonstrates that addressing the imbalance in the dataset is critical to the prediction performance of the model. When comparing the improved DBNs with the Deeper approach, it is found that the accuracy of almost all the improved DBNs is higher than the accuracy of Deeper. However, only on one dataset, PostgreSQL, the F-measure metric of the Deeper method is larger than that of the improved DBN, which is due to the relatively low accuracy of the improved DBN method in this paper on the PostgreSQL dataset. However, given the defect prediction setting, the check-all rate is relatively more important than the check-accuracy rate; that is, trying to find as many defective changes as possible

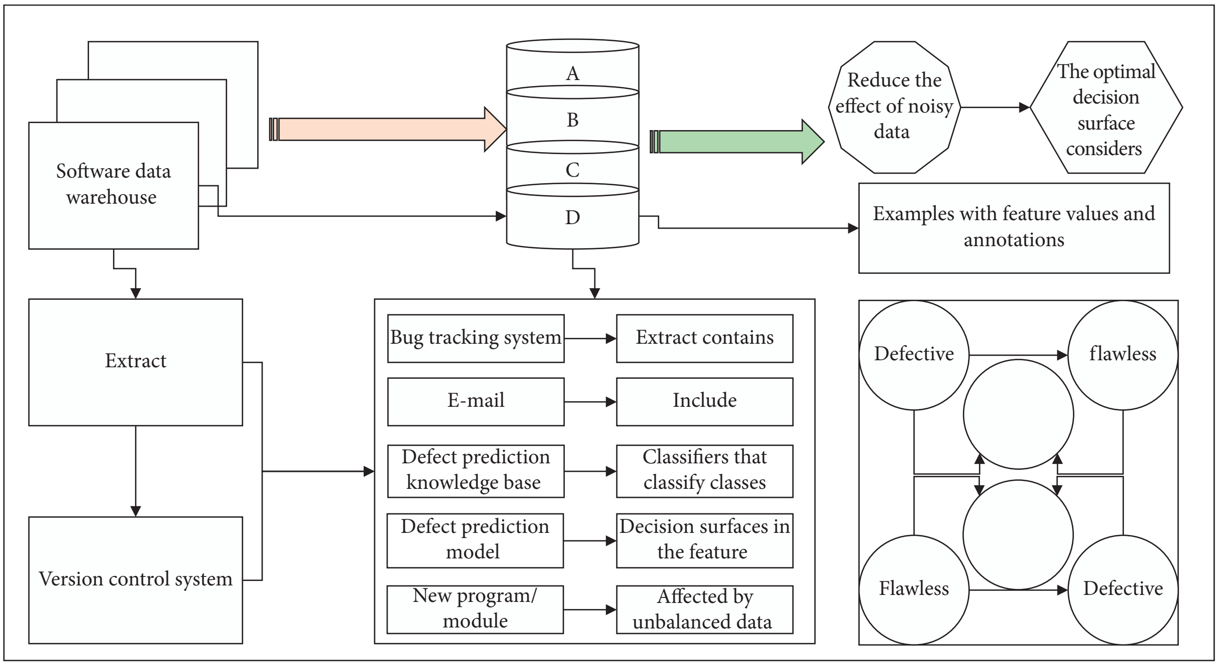

Figure 2: Steps in software defect prediction.

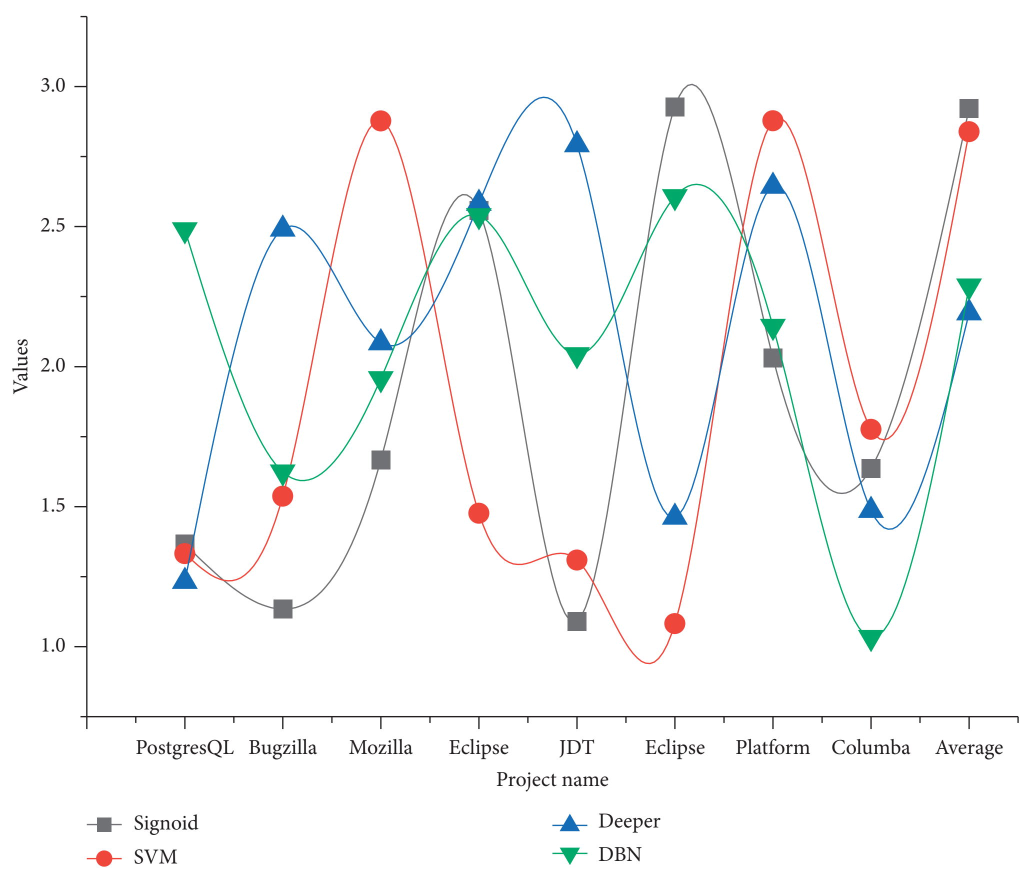

Figure 3: Chakra accuracy.

requires sacrificing some more checking costs to check nondefective instances. Therefore, the improved DBN in this paper is useful and, overall, more effective than the Deeper approach.

The model parallel approach is executed by partitioning the model and putting different computational parts of the model on different machines for the same training samples. For example, the input layer to the first hidden layer of the neural network model is assigned to machine 1, the first hidden layer to the second hidden layer is assigned to machine 2, and the third hidden layer to the output layer is assigned to machine. The disadvantage of model parallelism is that if one of the assigned machines fails, the entire model will stop. The entire dataset consists of a total of 66,301 malware replay images, amounting to 1.3 terabytes of data. The entire dataset was briefly filtered and cleaned before formal analysis. While most malicious samples in the dataset were 64-bit programs, there were 417 32-bit programs in the collection. Although all malware samples run on 64-bit operating systems, all 32-bit images generated by these malicious programs were excluded for data consistency; secondly, the validity of this dataset was checked. By playing back all images and checking the instruction execution during the entire runtime of the malware, it was found that as many as 3462 (5.2%) of the samples did not execute any instruction during the entire runtime. This could be caused by an error during the loading of the malware into memory or by the absence of a necessary component of the target virtual machine operating system of the runtime environment, which prevents the malware from executing correctly. This part of the sample set was also excluded, as shown in Figure 4.

In terms of prediction accuracy, recall, and F1-measure, the prediction model without fine-tuning shows a monotonic increasing trend when the sparsity parameter is less than 0.4, a decreasing trend in the interval of 0.4–0.7, and an increasing trend when it is greater than 0.7. The fine-tuned prediction models show good prediction performance with different sparsity parameters, and the recall and F1-measure are better than the performance of the untrimmed prediction models. To analyze the reason, the number of hidden neuron activations of the autoencoder increases with the increase of the sparsity parameter when the sparsity parameter is less than 0.4, so that the autoencoder can learn the original data with more detailed feature representation and get more essential feature representation of the original data; therefore, the performance of the prediction model increases with the increase of the sparsity parameter. When the sparsity parameter is between 0.4 and 0.7, too many hidden neurons of the autoencoder need to be activated, resulting in overfitting of the autoencoder training, so the performance of the prediction model decreases; but when the sparsity parameter is greater than 0.7, it means that most of the neurons in the hidden layer need to be activated, and this unreasonable setting will destroy the normal optimization of the network parameters, although the prediction model can still achieve the prediction ability. Therefore, prevention of software defects and timely correction of software defects have become the cause of software defect prediction. People began to collect and use data related to software defects and use data combined with algorithms to construct software defect prediction models for predicting software defect information. Although the prediction model can still achieve the prediction ability, the parameters are not obtained through "learning," so the prediction model is an invalid prediction model, and the prediction result is not a valid prediction result. In contrast, the network parameters of the fine-tuned prediction model have been adjusted under the supervision of the classifier, so that the effect of the sparsity parameter setting of the autoencoder on the performance of the prediction model disappears; therefore, the fine-tuned prediction model can show good performance under different sparsity parameters.

4. Analysis of Results

4.1. Deep Learning Predictive Analytics for Cloud Environments. From Figure 5, the nonnegative sparse graph-based label propagation prediction (NSGLP) method has significantly improved the prediction results compared to SVM, CC4.5, and NB; however, compared to the method proposed in this paper, ILR-SDP method, the Pd values of this paper's method based on NSGLP are improved on CM1, MW1, PCL, PC3, and PC4 by 0.09 and 0.08. Because the NSGLP method uses the label propagation method to predict labels on unlabeled data, the predicted obtained labels are used in the trained prediction model, and predicting wrong labels will affect the accuracy of the model. In contrast to the NSGLP method, the ILR-SDP method in this paper uses both real and valid labeled and unlabeled data to train the trapezoidal network. The method in this paper improves the Pd values by 0.07, 0.07, 0.06, and 0.07, respectively, compared to the SOM-SDP method. SOM-ANN uses self-encoders to extract data features and train neural network classifiers for defect prediction of software modules. Compared to these methods, this method uses noise-reducing self-encoders and adds lateral jumps to them. In addition, a small amount of labeled data is used for training. The experimental results prove that the method in this paper does outperform the SOM-ANN method which only uses the traditional self-encoder.

It follows that, in most combinations, JDM can improve the performance of cross-project software defect prediction through a single iteration, and the pseudolabeling refinement mentioned in the method can further improve or consolidate the cross-project software defect prediction performance of the model; the number of convergences of JDM varies from combination to combination due to the differences in both the instance and labeling distributions across combinations; furthermore, not all combinations can be improved by the JDM. One possible reason for this is that the conditional probability distributions used in JDM are computed from pseudoannotations rather than real annotations, and thus the computation of conditional probability distributions may be biased, leading to some degree of degradation in prediction performance. In practical use cases, the efficiency of the detection method and the performance load introduced on the target VM also need to be

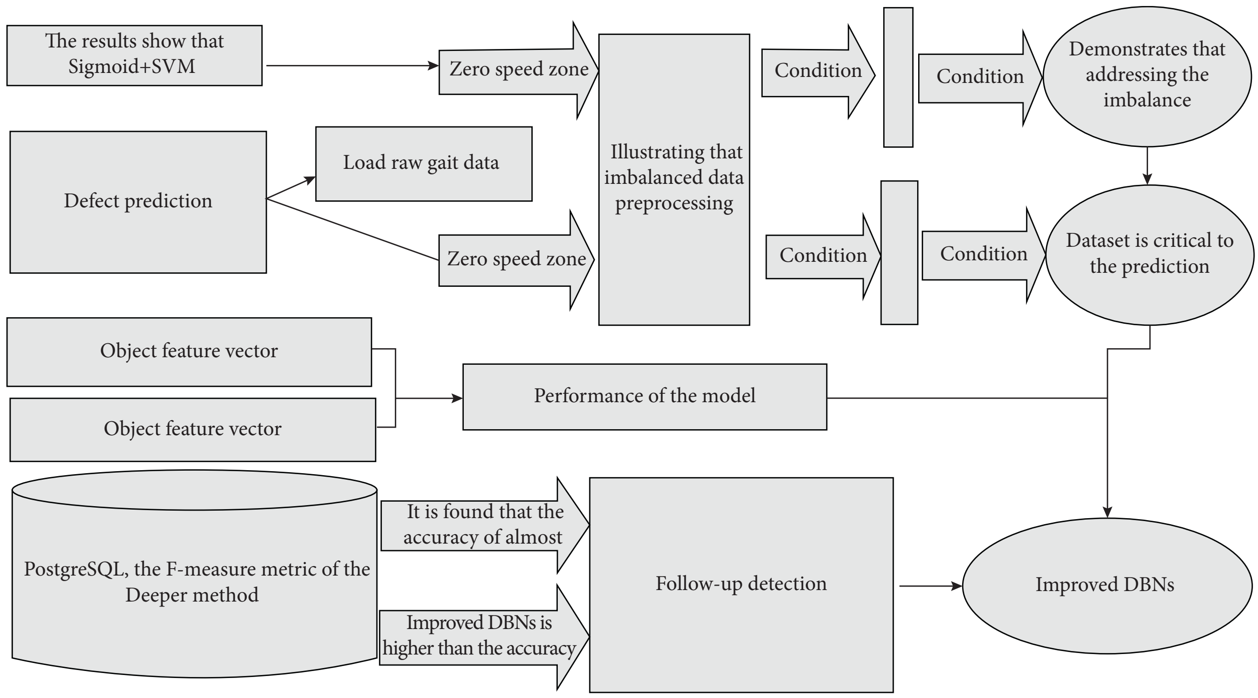

Figure 4: Model parallel framework.

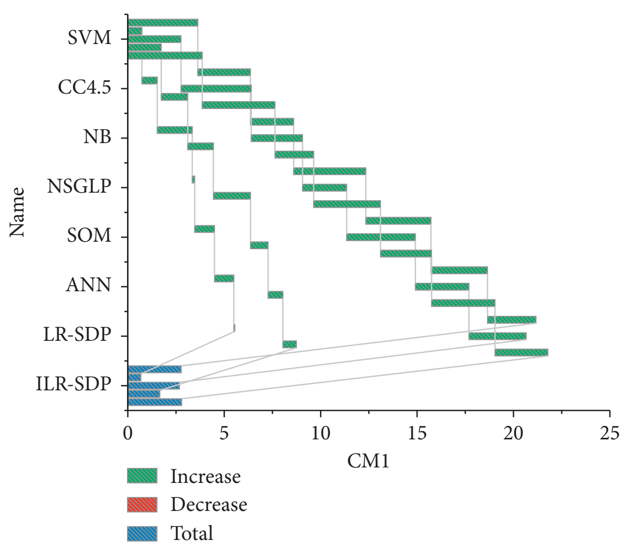

Figure 5: Experimental results of the ILR-SDP method in the NASA dataset.

measured. Improve software testing efficiency, reduce testing expenses, and ensure software quality by assisting the quality assurance team in understanding the software quality status in a fast, accurate, and objective manner and effectively allocating testing resources. If the additional load is high, it may even lead to the unavailability of the target VM. Finally, this paper tests the performance load of each method on the target VM. For the prediction model with the same masking rate, the more hidden layers it has, the higher the correct prediction rate is, and the better the prediction performance in terms of prediction accuracy, recall, and F1-measure is; meanwhile, for the prediction model with the same hidden layers, the prediction performance remains the same when the masking rate is less than 30%, and when the masking rate is greater than 30%, as the masking rate increases, the performance of the prediction model shows a decreasing trend, as shown in Figure 6. Analyzing the reason, for the same masking rate of the prediction model, the deeper the model can obtain the input data deeper feature information, the deeper the layer to obtain the feature information has a stronger feature expression ability, so the more hidden layers of the prediction model prediction performance are better. However, the number of hidden layers is not better but depends on the scale of the prediction model and the training data.

When the prediction model is too deep, it will cause the phenomenon of "gradient disappearance," so that the model training cannot be completed and the prediction results will not be obtained. Therefore, the number of hidden layers should not be increased blindly. For the prediction model with the same number of hidden layers, when the masking rate is less than 30%, the masking noise will remove the noisy data in the training data, which can make the learned prediction model have more robust generalization ability; when the masking rate is greater than 30%, the masking noise will remove the data in the training data that are relevant to software defects, that is, the information that is useful for defect prediction, so the larger the masking rate, the worse the performance of the prediction model. A software defect prediction model is built with the help of machine learning and other methods, and then the defect tendency, defect density, or number of defects of the new program module is predicted. Software defect prediction technology gives the software development team one more opportunity to redetect software defect modules.

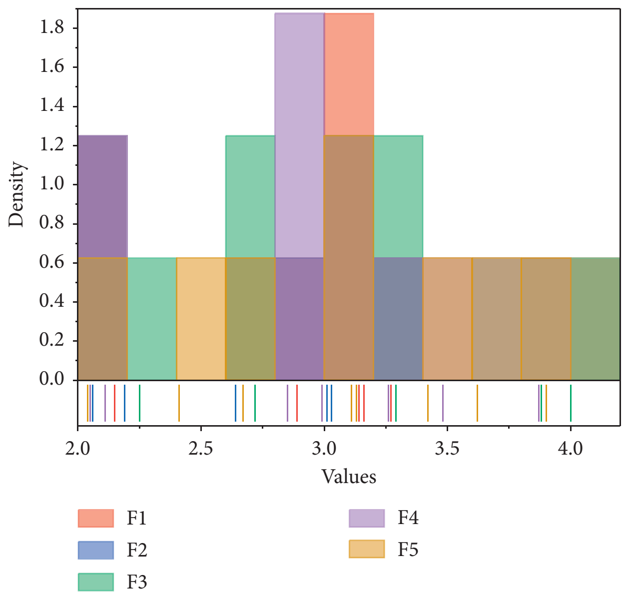

Figure 6: Algorithm performance.

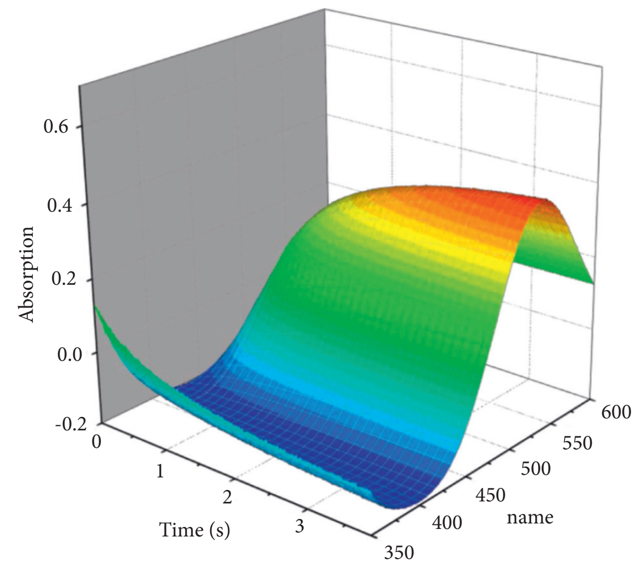

Figure 7: Comparison of F1-measure results for NASA dataset.

4.2. Software Defect Prediction Results. According to the summary of the experimental results, it can be obtained that the experimental metric F1-measure of TNB and the proposed algorithm GFK-SDP in this paper is higher than NN-filter. This is caused by the disadvantage of the NN-filter algorithm in the paper, in which the training dataset is selected during the construction of the algorithm, and this selection process may cause the loss of useful data information, so the final F1-measure value is lower than those in the other two methods. Besides, the GFK-SDP method is significantly better than the TNB method, thanks to the introduction of the geodesic kernel space transformation technique. In the new subspace representation, the distributions of the source and target data are approximated. This effectively reduces the error caused by the inaccurate model training effect due to different data distribution of different datasets and at the same time effectively maximizes the useful feature information in the source and target data. On this basis, the results were effectively improved using the traditional classical classification method, as shown in Figure 7.

Learning-based cross-project software defect prediction techniques have now become a technique of interest to researchers due to the superior performance of stream learning techniques on cross-project software defect prediction problems. For cross-project software defect prediction techniques, it is an important research topic to solve the problem of a different distribution of data features between source and target projects and to effectively mine the shared information between different projects.

People often find it easy to solve these problems by intuition. Abstract and formal tasks are one of the most difficult mental tasks for humans, but they are the easiest for computers. In this chapter, a cross-project software defect prediction method based on geodesic streamlines is proposed, which draws on the knowledge of incremental learning to effectively solve the problem of different data distribution between different projects. The software defect prediction model is based on the cross-project model, and the source dataset is used as training data to obtain the software defect prediction model, and, finally, the obtained training model is used to test the data to be predicted. The main problem is that the data distribution of the source data and the target data are different, as shown in Figure 8.

As can be seen from the figure, for a stacked forest of the same depth, when the number of trees in the forest is less than 200, the prediction correct rate, accuracy rate, and AUC value all show an increasing trend, and the prediction recall rate shows a decreasing trend, while the prediction F1-measure shows a stable performance. To analyze the reason, when the number of trees in the forest is less than 200, the learning ability of the random forest and completely random tree forest in the stacked forest increases with the increase of the number of trees, so that the stacked forest can learn more detailed data information, and, therefore, the performance of the prediction model increases with the increase of the number of trees in the forest. For these three datasets, the recall rates of Sigmoid + SVM are only about 4%, 3%, and 3%, while Deeper and the improved DBN method achieve a better recall rate of more than 65%. When the number of trees in the forest is greater than 200, the learning ability of the random forest and the completely random tree forest in the stacked forest has reached saturation, and increasing the number of trees again will not increase the learning performance, so the performance of the prediction model is smooth, but it can be seen from the running time comparison graph that the running time of the prediction model basically grows linearly with the number of trees in the forest, so the performance of the stacked forest is the best when the number of trees in the forest is 200. The loss cost function and sparsity constraint method of the autoencoder are improved. At the same time, to reduce the influence of noise on the input data, a software defect prediction method based on the stacked noise-reducing sparse autoencoder is proposed; and, for the same number of

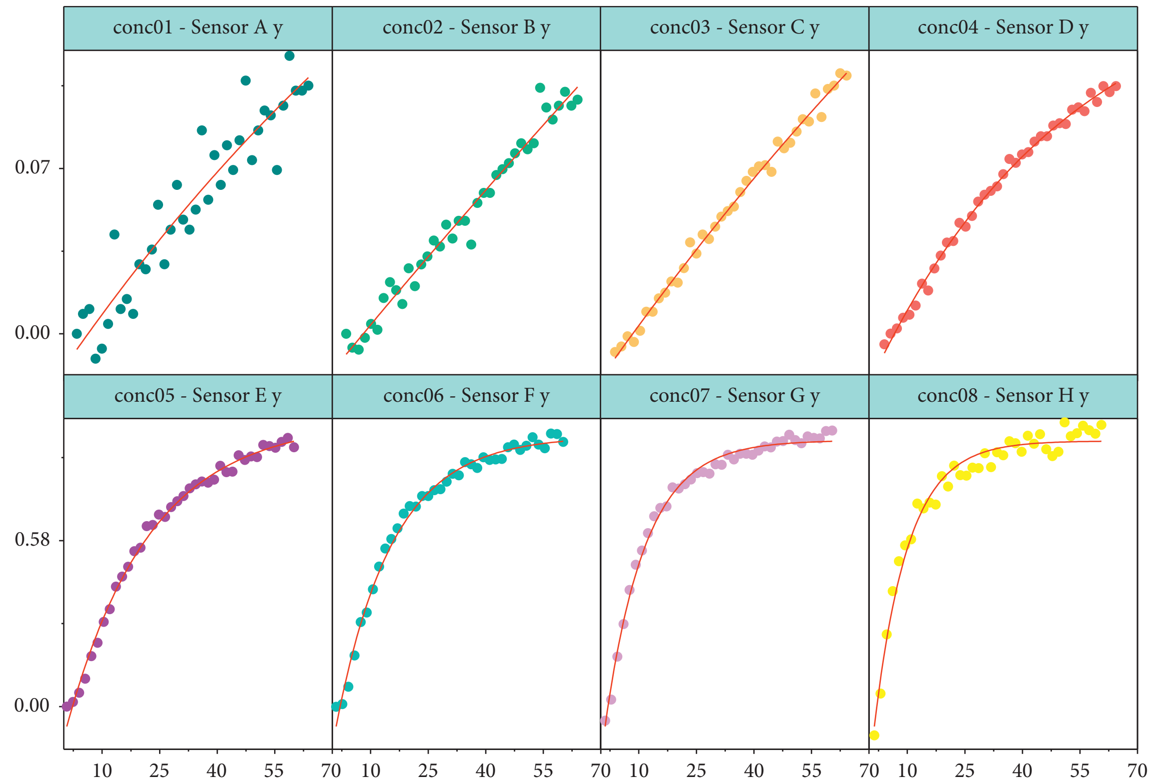

Figure 8: Effect of depth of stacked forest and number of trees on prediction model performance.

trees in the stacked forest, when the stacked forest is deeper, the correct prediction rate remains the same, and the prediction accuracy tends to decrease, but the prediction recall, F1-measure, and AUC values all show an increasing trend, and it can be seen from the comparison graph of prediction AUC values that the performance of the prediction model increases slowly and negligibly when the depth of the stacked forest is greater than three layers so that the stacked forest depth of three layers is the best choice.

5. Conclusion

Deep neural networks require large-scale training data during training, and the task for small-scale data will fail to achieve the desired effect due to training underfitting, and the hyperparameters of deep neural networks are too many, which makes tuning the parameters complicated. To address these problems, the deep forest is applied to software defect prediction, and its feature vector generation method, feature transformation method, and feature enhancement method are improved to address the shortcomings in software defect prediction performance, and the software defect prediction release method based on the deep stacked forest is proposed. The experimental results show that the prediction method based on the deep stacked forest has advantages over the prediction method based on deep forest in terms of prediction performance and operational efficiency. The method of three rounds of manual testing and software defect prediction is used; that is, some program modules are first randomly selected for manual testing, and then the tested program modules are used as training sets to construct software defect prediction models, predict the defect propensity of untested program modules, and then manually test the program modules with defect propensity, and so on. If the class distribution of the training sample dataset is unbalanced, the number of support vectors is also unbalanced. Based on the principle of minimizing structural risks, support vector opportunities ignore the impact of rare classes on structural risks and expand the boundaries of decision-making. After three rounds of manual testing and software defect prediction, the system contains the defect, and the number of defective program modules in the system is reduced to an acceptable level. The combination of manual testing and software defect prediction greatly reduces the number of manually tested program modules, reduces software testing time, and improves software development efficiency. It is practical to apply deep learning methods to malware detection. This paper combines the existing virtual machine introspection technology to migrate all security work outside the virtual machine, which is more secure and efficient; and the use of deep learning methods can also effectively solve the drawbacks of traditional detection methods to make effective detection and early warning of unknown malware variants; differing from single detection methods, this paper effectively combines dynamic/static detection methods.

Starting from the current problems facing Industry 4.0, this article analyzes the changes in the macro and industrial environment that Industry 4.0 faces and explains the problems, opportunities, and strategies for the manufacturing industry in the external environment. First, the reference system of the intelligent manufacturing system, the current status, and the existing problems of industrial production management are analyzed through the investigation of the status quo of industrial production and management. This puts forward the detailed requirements of the industrial intelligent manufacturing system in the data acquisition layer, data storage layer, and analysis and decision support layer and then designs the hierarchical structure of the industrial intelligent manufacturing system. Subsequently, it adopts design methods and lists product manufacturing costs, pointing out that Industry 4.0 requires industrial transformation, and finally proposes the strategic direction of smart manufacturing in combination with the Industry 4.0 network strategy. At the same time, in view of the problems of long parameter measurement time and untimely system feedback in the existing koji-making process, an online parameter measurement method based on network optimization is proposed. On the basis of the neural network, an industrial neural network with double hidden layers and self-feedback of the output layer is proposed. Through algorithm comparison experiments, the proposed parameter prediction model based on industrial neural network has better prediction results and higher accuracy. Finally, a comparison of cost, quality, delivery time, etc., before and after the implementation of Industry 4.0 intelligent manufacturing is carried out. An intelligent solution is proposed, the implementation goal is formulated, and the implementation is gradually implemented in stages, and finally an intelligent upgrade and transformation are realized. It is shown in many aspects that intelligent manufacturing provides a powerful means for enterprises to achieve agility, virtualization, lean, integration, and collaboration, and it can bring efficiency, reliability, and safety to the manufacturing process of enterprises.

1. Introduction

With the gradual rise of customized manufacturing, intelligent manufacturing systems have been widely used, and the resulting intelligent scheduling problems have become a hot research topic [1]. Industry 4.0 focuses on intelligent manufacturing and strives to ensure that the manufacturing industry can continue to develop at a high speed with green, environmental protection, intelligence, and efficiency. The three parts of smart factory, smart production, and smart logistics form the core of Industry 4.0 [2]. Regardless of whether it is smart production or smart logistics, it requires systematic and efficient manufacturing, intelligent allocation of manufacturing resources, and reasonable management of warehousing logistics. These are all multiobjective intelligent scheduling problems. Intelligent scheduling plays a role equivalent to the human brain in intelligent manufacturing, and system modeling and intelligent scheduling are the basis of intelligent manufacturing systems [3]. In particular, the introduction of Industry 4.0 makes intelligent scheduling play the role of the core brain in both smart factories and smart logistics in smart manufacturing, which is the basis of smart manufacturing [4]. Most of the intelligent scheduling problems are combinatorial optimization problems, and their computational theory has been proven to be NP-hard problems. The traditional method of studying combinatorial optimization cannot find the optimal solution of the scheduling problem in polynomial time, and then people began to study to find the near-optimal solution in polynomial time to meet the demand of production scheduling [5].

The purpose of intelligent scheduling is to complete the production tasks of production processing and machine assembly under the premise of satisfying various constraints of the manufacturing system. In the process of intelligent production, due to the frequent changes of production goals, such as the acceleration of product upgrades, the intelligent manufacturing system must also be adjusted according to the new production tasks to ensure that the machine can complete the production tasks with a higher utilization rate [6]. More importantly, in the process of intelligent manufacturing, production is fully automated and unmanned. Once an unreasonable processing arrangement occurs, the machine may collide and cause a safety accident, or two robots may compete for one processing equipment for conflict of loading materials [7]. Therefore, intelligent scheduling plays an extremely important role in the processing safety, equipment utilization, processing cost, and task completion of the intelligent manufacturing system. From the perspective of the manufacturing system, when the number of workpieces manufactured is small or the product is constantly changing, intelligent scheduling is irreplaceable in intelligent production. Intelligent manufacturing system has unique advantages in solving the above aspects [8–10]. And intelligent scheduling is the key to ensuring efficient, reliable, and safe production of intelligent manufacturing systems, so the research on intelligent scheduling has very important practical significance.

With regard to the modeling of intelligent manufacturing system, this paper studies how to use the industrial network to model and analyze the intelligent manufacturing system and proposes the modeling idea from the basic manufacturing unit to the entire manufacturing system. For the research on system model deadlock, we analyze the reachability graph of industrial network system to judge the deadlock situation during system operation and use the established model to study the scheduling method of single task and multitask. In the process of researching batch scheduling, this paper puts forward the idea of combining genetic algorithm and simulated annealing algorithm to form a hybrid algorithm applied to the field of intelligent scheduling. The inspection and evaluation stage mainly analyzes the current situation of K company's internal management and external competition environment and determines the research objectives, planning principles, implementation methods, evaluation index system, and technical methods. Research on the application of Internet of Things technology, industrial robot technology, cloud computing and big data technology in solid wood customization enterprises integrates ERP system, SCM system, CRM system, PLC system, MES system; realizes the interconnection of data and information; and cooperates with each other, promoting each other to form a complete intelligent manufacturing system.

2. Related Work

This article mainly focuses on the research of Industry 4.0 application systems. The research of Industry 4.0 for specific applications mainly focuses on transportation, medical treatment, smart grid, building, and environmental detection. We studied the design method of the transportation-oriented Industry 4.0 system and conducted in-depth research on several key system technologies, such as vehicle perception technology, wireless network protocol, multisensing node information fusion algorithm, and vehicle information feature extraction, and finally realized the transportation Industry 4.0-oriented Vehicle perception and recognition system [11].

Marques et al. [12] looked forward to the application of Industry 4.0 systems in smart medical care and proposed the general development trend of real-time sensing, adaptive response, and remote control medical services. They use sensors installed on the patient to sense vital signs, such as heartbeat and blood pressure. This information can be sent to medical caregivers on a regular basis so that they can provide real-time and effective care to patients. Annanth et al. [13] proposed the microgrid Industry 4.0 system architecture, introduced Industry 4.0 technology into the construction of the microgrid, and gave the microgrid Industry 4.0 architecture model. On this basis, the microgrid Industry 4.0 physical layer, adjustment layer, coordination layer, 6-layer system framework of connection layer, network layer, and application layer were proposed. Hu and Gao [14] researched and designed the building structure health monitoring Industry 4.0 system and studied how to build a reusable architecture so that physical testing and computer simulation testing can be precisely combined, which can effectively support mixed testing of building structures. Wang et al. [15] studied the use of wireless sensor networks (WSN) to construct distributed building structure health monitoring and defect location methods. The paper points out that the existing centralized sensor network structure health monitoring system has problems, such as data collection delay and large network energy overhead, and proposes a distributed processing method. Most of the research in the abovementioned literature is still at the stage of theoretical research on Industry 4.0 architecture, and there is little experience in combining theory with practice. This article will focus on the application of Industry 4.0 theoretical architecture to the design of specific intelligent manufacturing systems.

Tao et al. [16] proposed to combine cloud computing and next-generation Internet technology to study the semantic middleware of Industry 4.0. He Ming et al. [10] studied the Industry 4.0 architecture from the perspectives of system, function, and technology. It also gives the research direction of the Industry 4.0 system and the current challenges. At the same time, a three-tier architecture of Industry 4.0 physical layer, network layer, and application layer was constructed, and related concepts were described and analyzed in depth. Finally, the system architecture was applied to intelligent transportation, which proved the practicality of the architecture. Some scholars have proposed a service-oriented Industry 4.0 architecture, which is divided into a node layer, a network layer, a resource layer, and a service layer. In-depth discussion on the functional modules and technical foundations of each layer is also given, and the future research direction of the Industry 4.0 system is also given. At the same time, it is pointed out that intelligent manufacturing technology is a highly flexible and highly integrated way, through computer simulation of human brain analysis, judgment, and decision-making [17, 18]. Unlike the computer integrated manufacturing system that emphasizes the integration of enterprise material flow and information flow, the intelligent manufacturing system emphasizes the self-organization ability of the entire manufacturing process. It is believed that the intelligent manufacturing system is a combination of intelligence, integration, and automation, with super self-learning ability and self-organizing ability. Some scholars also believe that intelligent manufacturing systems should have self-discipline, self-organization, self-learning, and self-optimization capabilities. Second, from the perspective of industrial applications, we research the development of the intelligent part of the entire manufacturing environment and improve the intelligent manufacturing technology and manufacturing system [19–21].

3. Model Construction of Intelligent Manufacturing System Based on Industry 4.0 Model

3.1. Industry 4.0 Level Analysis. Industry 4.0 is the industrial development strategy of the fourth industrial revolution with intelligent manufacturing as the core. The strategy aims to transform manufacturing into intelligent manufacturing by making full use of information and communication technology and cyberspace virtual systems, a combination of information and physical systems. The main way to achieve this is to fully control the entire process from product demand to manufacturing by building a cyber-physical fusion system, thereby realizing efficient production process management. The Industry 4.0 system is mainly composed of a computing system, a communication system, and a control system, forming the 3C model of the Industry 4.0 system. Figure 1 shows the Industry 4.0 hierarchical topology.

Among them, a large number of sensor nodes and actuator nodes are distributed in the physical world, complete the real-time perception of the physical world, and send them to the computing system and control system through the communication network. The computing system completes various computing tasks required by Industry 4.0 and provides various information services including data mining, statistics, and forecasting.

$$Y(x) = \sum_{x=1,y=1}^{n} p(y \mid x) \times f(y \mid x). \tag{1}$$

The control system uses the data obtained from the analysis of the perception network and the computing system to perform scientific operations on the objects in the physical world, thereby realizing feedback control of the physical world. The communication network of the Industry 4.0 system can be seen as an extension of the sensor network, a combined communication network composed of sensor networks, computer networks, and next-generation communication technologies.

$$\begin{gathered} g(x) - \sum_{i,j=1}^{n} [s(1,i) + s(2,i) + \cdots + s(j,i)]/s(i,j) = 0, \\ \frac{p'(x) - p(x)}{p(x)} - \int \frac{\partial f(x)}{\partial x} \mathrm{d}x = 0. \end{gathered} \tag{2}$$

The activation function of the network has two main functions: first, it can provide a filtering function for the input of the unit node. It is generally hoped that when the correct input is given, the unit is in an active state, near +1. On the contrary, when the wrong input is given, the unit is in an inactive state, near 0; second, no excitation function is applied, and the transfer between neural network layers is just a linear transformation, which leads to insufficient expressive ability of the network model, and the excitation function is the fact that nonlinear factors can be introduced to increase the expressive ability of the model.

$$\begin{gathered} \{\sigma(x,x), \sigma(y,y), \sigma(z,z)\} \longrightarrow \{\varepsilon(x,y), \varepsilon(y,z), \varepsilon(z,x)\}, \\ U = 1/2 \times \int_{\Omega} \sigma(z,x)\sigma(x,y)\sigma(y,z)d\Omega. \end{gathered} \tag{3}$$

During the production process, changes in market demand and raw material supply can be changed and adjusted in time. More importantly, through the intelligent assistance system, employees are relieved. Their work is not on a step-by-step basis, but more energy is invested in innovation to make their work more valuable. This new model is conducive to employees to better integrate their own work, improve work efficiency, and increase work value.

3.2. Construction of Intelligent Manufacturing Platform. Intelligent manufacturing is the integration of manufacturing technology with intelligent technology, digital technology, and network technology in the entire life cycle of product design, manufacturing, operation management and after-sales service, intelligent reasoning, and intelligent decision-making and control to achieve timely response to consumer needs. It is the general term for product design, manufacturing, and supply chain logistics. It is divided into four types: intelligent production, intelligent design, intelligent manufacturing, and intelligent management. The characteristics of intelligent manufacturing are as follows: intelligently perceive and acquire production personnel, production equipment, raw and auxiliary materials, manufacturing environment, and related information in the manufacturing process, interconnection, collaboration, analysis and statistics, forecasting and early warning, decision support, control and execution. In smart manufacturing, the MES system based on smart production is the core component of smart manufacturing.

Figure 2 is the result of dispatching layer allocation of the intelligent manufacturing platform. In the planning phase, the planning and dispatching layer provides material

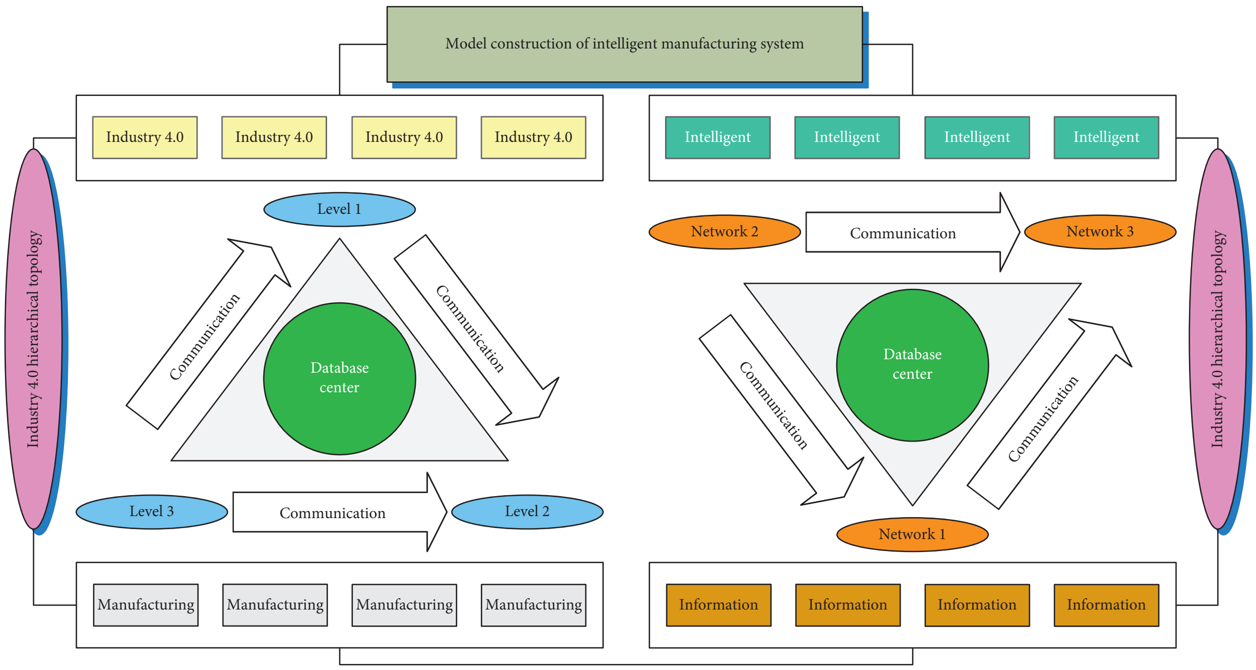

Figure 1: Industry 4.0 hierarchical topology.

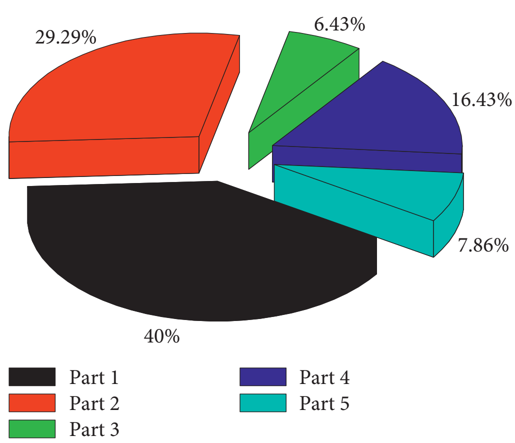

Figure 2: Distribution results of the scheduling layer of the intelligent manufacturing platform.

demand plans to the raw material depots and distribution centers; before production, the execution tracking layer sends out preparation instructions to the raw material depots and distribution centers; during production, the execution tracking layer sends the raw material depots and the control system of the distribution center issues an outbound instruction. The three-level coordination can ensure the timely and accurate supply of materials and ensure on-site production. In the production of refrigerators, the matching of cabinet doors is a difficult problem. Through three-level coordination, the matching of cabinet doors can be effectively achieved. When the planning and scheduling layer issues instructions, the execution tracking layer then issues corresponding process control parameters to the process control layer according to the instructions. At the same time, the process control layer feeds back information to the execution tracking layer, and the execution tracking layer updates the execution status of the work order and feeds it back to the planning and scheduling layer. Through the "three-level linkage," the correctness of the discharge of the library can be checked, and the error-proof interlocking of the execution of the work order can be performed. The basic requirements of automated intelligent manufacturing, data, intelligent equipment, and networks are all prepared to achieve this goal. The data in the entire production process is intelligently collected and dynamically produced to reflect the operation of the entire system in real time. According to the data in the knowledge base, the equipment is automatically maintained on a periodic basis, self-diagnosed, and automatically repaired to avoid the occurrence of failures. Not only the production equipment, but also the overall monitoring of the operation of the entire intelligent system, automatically adjust the production line, realize different production, analyze the results, and predict and prevent systemic failures. We realize interconnection and human-machine integration; integrate resources to quickly respond to market demand; realize intelligent, visual, and fully automated production: extract effective and provide a basis for top-level decision-making; reduce production costs, improve production efficiency, improve product quality, and shorten products cycle.

3.3. Model Weight Factor Update. At the system level, the intelligent manufacturing system is highly integrated with multiple subsystems. It is an organic whole, supplemented by each other, and interconnected with data to jointly achieve the goal of intelligence. At the control level, PLC controls intelligent equipment, system scheduling management, production execution system executes automated tasks, allocates orders, drives equipment, and collaborates to complete the production process. On the execution layer, the execution layer is the real-time perception object of the control layer and the actual terminal monitored by the system layer. Various on-site equipment, materials, areas, lines, etc., use RFlD technology to enable any entity in the system to have a unique identity. The sensing system collects equipment data in the production logistics process in real time and uses big data analysis technology to control the operation of the equipment in real-time parameter. The equipment layer is the entire intelligent equipment, various auxiliary units, which are indispensable for the production site.

Figure 3 is a ladder diagram of the weight of the manufacturing system data supply chain. The internal supply chain communicates with the external supply chain daily to ensure the smooth progress of product production. In addition, the supply chain is integrated to a certain extent through ERP, MES, and other information management systems and through the perception layer (RFID, barcode, GPS, etc.). The network layer (private network, Internet, wired and wireless communication network, etc.) and the application layer (PC, PAD, mobile phone, etc.) seamlessly connect the supply chain to achieve real-time monitoring of the customization process and problem solving appear to give intelligent judgments and make timely responses. Therefore, the corresponding supply chain is basically like a pull supply chain, which drives the production of the workshop by the customer's demand for enterprise products, but it is not a complete pull supply chain model because the design of customized products is not complete. This will involve the MES system and the EI punching system. As the manufacturing execution system, MES is in the middle part, as an intermediate connecting the upper-level planning system and the bottom-level control system. Its main task is the "real-time" production and scheduling of the workshop production process. For nonstandardized and nonmodular production, some parts are often fixed into standard modules for inventory storage through analysis and statistics. When a customer's order contains these modules, they can be used directly, thereby saving parts. The processing time has shortened the delivery time of the order to a certain extent, which not only improves the production efficiency, but also ensures the economic benefits of the enterprise.

3.4. Model Scheduler Design. Manufacturers use the "cyber-physical system" as the framework to build a global industrial network of factory equipment, warehouse management, and industrial products. In the manufacturing sector, Industry 4.0 means that all equipment of an enterprise can independently exchange information. Industry 4.0 is a small smart machine, a small storage system, and efficient product equipment that realize operation and mutual control. Through Industry 4.0, various industrial processes such as manufacturing, engineering, supply chain, and life cycle management are further linked together, and product production is carried out in a brand-new way. When the production instruction reaches the system composed of Industry 4.0, it can flow through the business processes of factories and companies, and the interconnection of equipment can create a derived equipment and product value system, forming a network of manufacturing systems through the Internet of Things. The idea of the Industry 4.0 system includes the whole process of how the physical world information is perceived by the information world in real time and how the information world calculates and makes decisions on the collected data. The ultimate goal of the Industry 4.0 system is to use the existing physical world infrastructure (including perception, computing, and communication hardware and software facilities) to realize intelligent monitoring from the physical world to the information world and from the information world to the physical world to the extent that the information world and the physical world are completely integrated.

The Industry 4.0 system architecture includes three systems: computing system, communication system, and control system. Figure 4 shows the design process of the model scheduler. Among them, the computing system is the central processor of the Industry 4.0 system, responsible for completing all the calculations and decision-making processes of the Industry 4.0 system. At the same time, it can bear the pressure of analysis and processing of massive data and perform fusion processing on multiple data; the communication system is the network transmission part of the Industry 4.0 system, which is responsible for completing the communication and data transmission between devices, from sensors, actuators to information. MES decomposes and refines the production plan information from ERP software to form specific operating instructions. The central network is interconnected; the control system is the central nerve of the Industry 4.0 system, which can perceive all the information in the physical world and respond to the information. Through the control system, the system can be operated according to predetermined rules, and the operation of the system can be maintained or changed. From the perspective of the system view, the Industry 4.0 system is relatively broad and has little guiding significance in practice.

4. Application and Analysis of Intelligent Manufacturing System Model Based on Industry 4.0 Model

4.1. Industry 4.0 Data Preprocessing. The data set mainly includes a training set and a test set. The training set is used to adjust the network connection weight and other internal structures, and the test set is used to verify the results of network training. The training set and test set of the experimental data are from the measured data of the product instrument during the process of making music. At present, 70 sets of data are randomly selected to construct the data set (product parameters are affected by factors such as seasons, and the data set is selected from the measured data in the past two months), of which 60 sets of data are used as the neural network training set, and 10

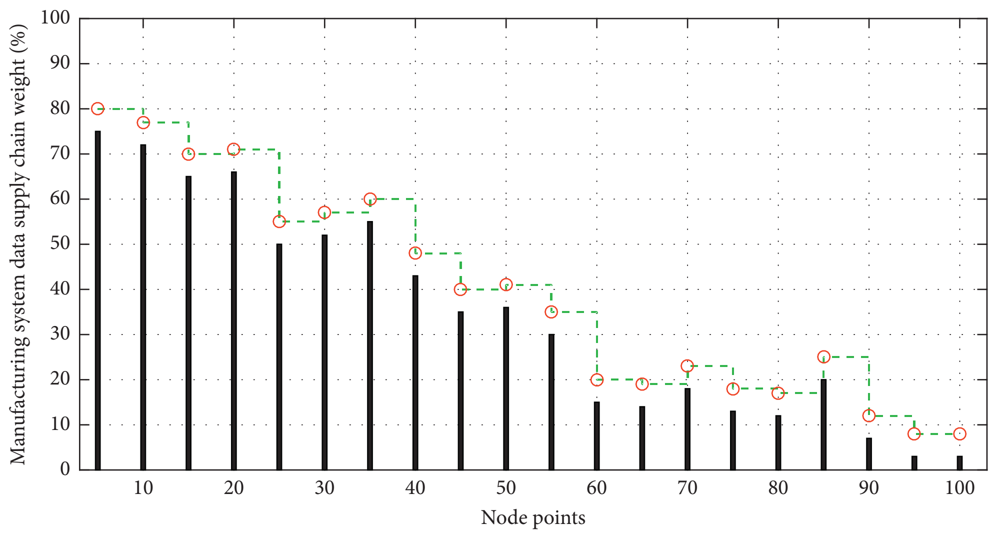

FIGURE 3: The ladder diagram of the weight of the manufacturing system data supply chain.

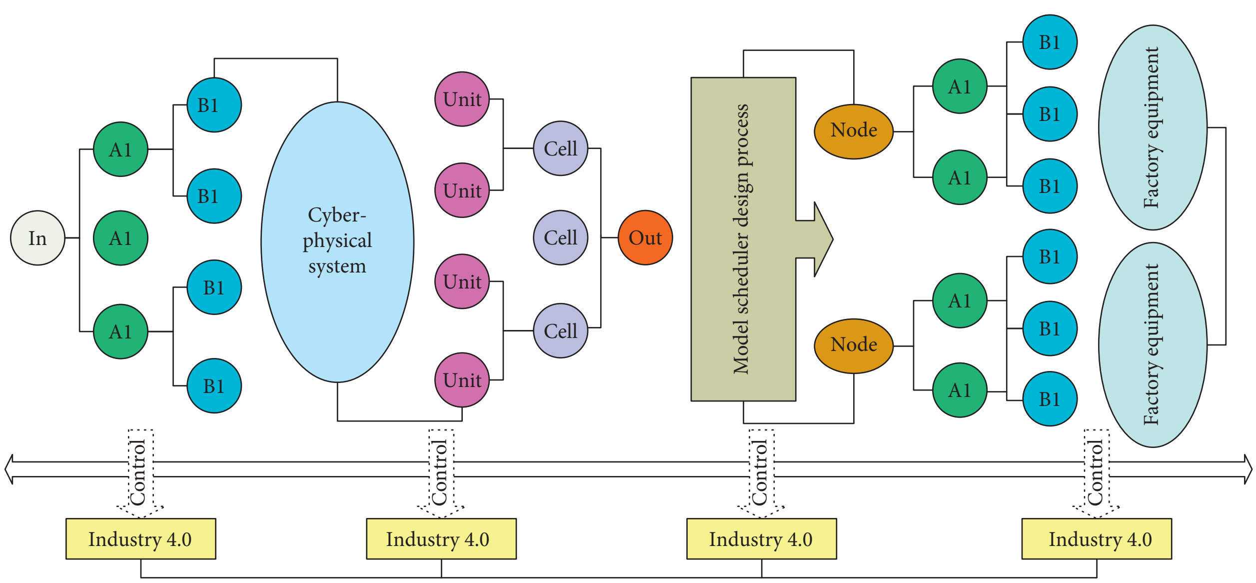

FIGURE 4: Model scheduler design process.

sets of data are used as the algorithm test set. For an example of a scheduling problem, the iterative curves of the optimal solutions of the three algorithms are given. GA-HS1 did not obtain a feasible solution to the problem in the initial iteration stage, so it is not drawn. It can be seen that the order preallocation strategy and the chromosome adjustment link can increase the probability of obtaining a feasible solution so that the algorithm can search in the entire feasible region, and a better solution can be searched in a limited time; that is, GA-HS has better convergence performance. Figure 5 is a histogram of the data convergence effect of the manufacturing system.

According to the basic method of fuzzy industrial network, the network elements of warehouses, tokens, and changes are defined, the topology structure of the network system, namely, the network relationship, is established, and the constraint conditions of the dynamic behavior of the system are given according to the actual production

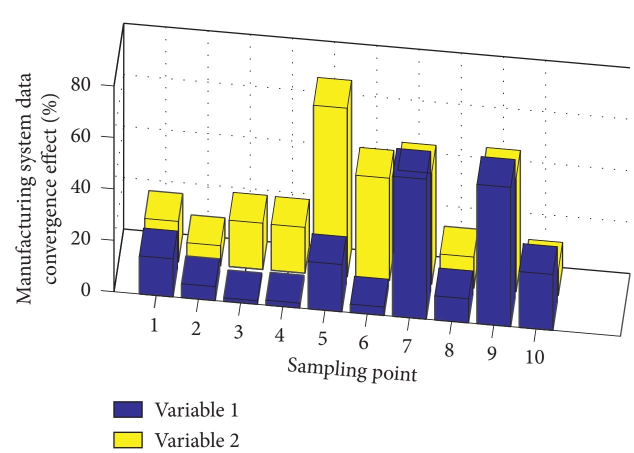

FIGURE 5: Histogram of data convergence effect of manufacturing system.

conditions and production requirements with a fuzzy industrial network energy consumption model suitable for aluminum alloy casting production process. The model describes the main production process and the energy conversion process, that is, the energy consumption process. The dynamic behavior of the system energy consumption is expressed as stimulating continuous changes, and the result of the behavior, the change of the system state, is described by the continuous stock token number, which is the label. The model simulates the relationship between the change in process status and energy consumption process caused by equipment actions derived from operating instructions. Taking into account the interdependence of multiobjectives and decision variables, the aluminum casting decision-making process is divided into two layers. The first layer uses a genetic algorithm based on a mixed code of real numbers and integers to select the corresponding furnace group or furnace group set for each order. The material data of the order provides timely feedback to the EI heart system, and the production plan is effectively connected with the ERP procurement plan and realizes the material analysis of the order, the analysis of the process route and the optimization of the production plan: make a refined production schedule plan for the production order, establish production instructions, and assign the production task list to the corresponding equipment; perform job scheduling, monitor the production progress of the workshop, collect process data, quality data, time data, and other big workshop data, accurately obtain the dynamic data of the workshop; realize order matching and warehouse management; generate various production analysis report; and feedback equipment related information.

4.2. Realization of Intelligent Manufacturing Simulation. Product instrument detection is a continuous measurement process, and data is uploaded every 5 seconds on average. A measurement process takes about 22 minutes, and approximately 260 data are generated. This article uses neural network to predict the product. The data node selects one point every minute and selects the measurement data of the first 5 minutes. At the same time, the quality of the test sample is used as an influencing factor. Then, there are 6 input nodes, and the output value is the measured value of the final wheat product. We select the measured value, sample quality, and final product 5 minutes before the measurement process for network training. Based on the overall structure of the model established above, using the working mechanism of each device in the product group and the actual structure and parameters of the system, the aluminum alloy melting and casting energy consumption model is solidly modeled, and the operating parameter settings under the actual working conditions of the production are used. We set value and operation behavior, equipment action, simulate the dynamic behavior of product group, and compare and verify the simulation result with the actual temperature recorded during the production.

Figure 6 is a line graph of the data training efficiency of the manufacturing system. It can be seen that the deviation

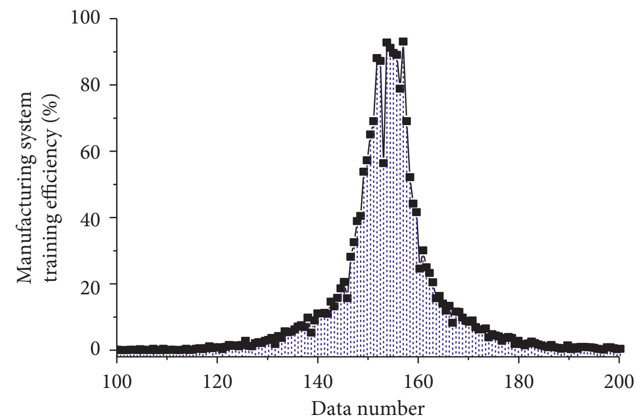

Figure 6: Line graph of data training efficiency of manufacturing system.

of the prediction results of the industrial neural network in 10 experiments is generally small, and the error is the smallest in 7 of the 10 experiments. It can be seen that the overall prediction accuracy of the algorithm is high. In the figure, it can be seen that the minimum cumulative error of the industrial algorithm for 10 experiments is 1.84%, and the average error is only 0.184%, which is far lower than the actual production 0.5% measurement accuracy requirement, which can meet the on-site measurement accuracy requirement. The fluctuation curve of the predicted value and the measured value can further illustrate that among the three algorithms, the industrial forecast result is the closest to the measured result, and the forecast error of the industrial algorithm is generally lower than that of the other two algorithms, and the forecast deviation is basically below 0.3%. A small number of prediction errors are large, but all are below 0.5%, which meets the actual production accuracy requirements. The fluctuation curve of the predicted value and the measured value can further illustrate that, among the three algorithms, the industrial forecast result is the closest to the measured result, and the forecast error of the industrial algorithm is generally lower than that of the other two algorithms, and the forecast deviation is basically below 0.3%. A small number of prediction errors are large, but all are below 0.5%, which meets the actual production accuracy requirements.

4.3. Case Application and Analysis. Deploy the temperature and humidity sensor in the yeast fermentation room; each room deploys 5 sensing nodes, including 3 temperature sensing nodes inside the yeast, which are deployed diagonally inside the room, 1 ambient temperature sensing node, and 1 ambient humidity The sensing node uploads the temperature and humidity data to the system server in real time through the real-time perception of the ambient temperature and humidity and the internal temperature of the curve, so as to achieve the purpose of remote monitoring and decision-making. The settings of the three network nodes are consistent, with 6 input nodes, 8 hidden layer nodes, and 1 output node. The layer proposes a harmony

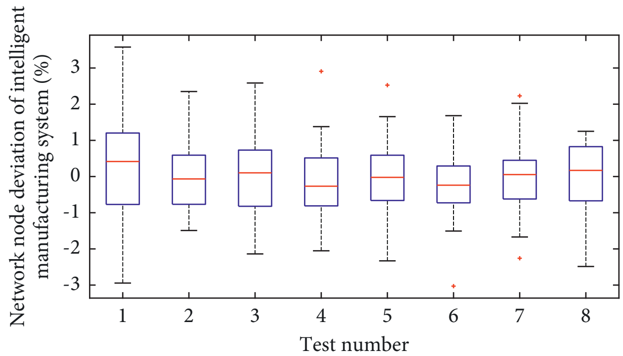

Figure 7: The distribution of network node deviation in intelligent manufacturing system.

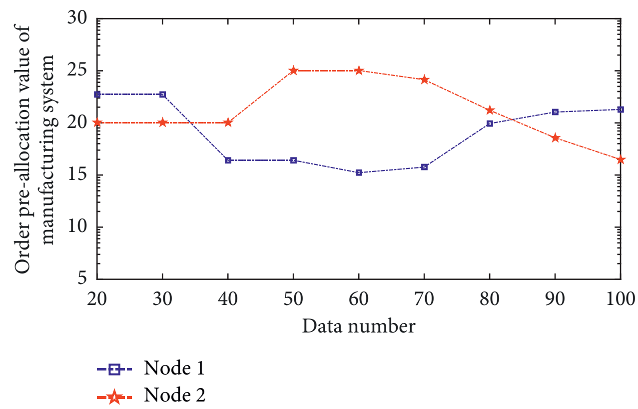

Figure 8: Value distribution of order preallocation in intelligent manufacturing system.

search algorithm based on chaotic sequences to make decisions on the processing order of each order on each furnace group. Each layer selects the same type of state transition function. The hidden layer activation function selects the sigmoid function to improve the nonlinear approximation ability of the model. The output layer selects the linear function to reduce the deviation between the predicted value and the measured value. The convergence condition set in the algorithm experiment is that one of the network training errors mse is less than 0.005 or the number of training iterations is greater than 5000 times. Figure 7 shows the distribution of deviations in the network nodes of the intelligent manufacturing system.

We build the WCC software factory product database, enter the R&D product modules, dock processing equipment, and complete the WCC software's order splitting function. After the dealer's order is verified and confirmed, the order is split through the WCC software, and the BOM list is exported through the E-fang auxiliary expansion interface, including the billing list, the bill of materials, the hardware list, the quotation list, the outsourcing list, and other reports. The implementation of share production management system lays a data foundation. The logo of the fuzzy place P18 represents the change trend of the molten aluminum temperature, which is represented by a solid line, the excitation of the discrete transition T6 represents the feeding action, which is represented by a dotted line, and the excitation of the discrete transition T7 represents the action of the valve, represented by a dashed line. The simulation results show that the change trend identified by the temperature library basically reflects the change trend of energy consumption during this production operation, and the excitation of each change in the model reflects the change of the working state of each device.

Figure 8 shows the distribution of preallocated values of orders in the intelligent manufacturing system. For examples of scheduling problems with scales of 10×5, 10×10, 30×5, and 30×10, the performance comparisons of each link in the proposed method are given respectively. Among them, the parts in bold are examples of the same problem, which are obtained by different methods. The best solution is GA-HS-1 no-order preallocation strategy and chromosome adjustment link and GA-HS-2 no-order preallocation strategy. It can be seen from this that for most scheduling problem instances, the methods proposed in this chapter can achieve better scheduling goals and have greater improvements. The chromosome adjustment link can increase the probability of obtaining a feasible solution, allowing the algorithm to search in the feasible area, and the order preallocation strategy can further improve the quality of the solution. For some small-scale scheduling problem examples, such as the 10×5 scheduling problem example, GA-HS-1 has a higher probability of obtaining the best solution. This is because the order preallocation strategy artificially reduces the search space for understanding; thus, in a smaller solution space, GA-HS-1 can search the entire solution space so that the probability of obtaining the optimal solution is greater. For large-scale scheduling problem examples, such as a scheduling problem with a scale of 30×10, the order preallocation strategy can increase the probability of obtaining the optimal solution within a limited search time.

5. Conclusion

This paper analyzes the intelligent manufacturing system based on Industry 4.0 and divides the task types into two types of problems: fixed delivery and fuzzy delivery according to the delivery situation so that the research of scheduling algorithm is more pertinent. Particularly for the fuzzy delivery problem, through its modeling and analysis, the algorithm becomes a scheduling algorithm that is judged by the processing cost, which is closer to the actual situation, and the application range is greatly expanded. At the same time, a music making intelligent manufacturing system architecture based on Industry 4.0 (a three-tier Industry 4.0 system architecture of perception layer, network layer, and application layer) is proposed to guide the specific design and implementation of the system. We carry out the hierarchical design of the system according to the proposed Industry 4.0 system architecture. The system perception layer design proposes four types of perception node design schemes to complete the comprehensive perception of music making parameters. The system network layer proposes a heterogeneous networking model for Industry 4.0 intelligent making and uses network model simulation to verify the feasibility of the networking model. The system application layer puts forward the software design process of the real-time perception system based on the B/S architecture and designs the key code of the industrial algorithm based on the Java language. The access layer realizes unified access to heterogeneous data sources and heterogeneous systems through data integration components and business integration components. Among them, the business integration component mainly realizes the integration of third-party business systems such as the upper-level ERP system, the bottom-level control system, and the supply chain system. Aiming at the shortcomings of the high coupling between traditional algorithm services and system business, the RPC algorithm service platform design is proposed, which separates the industrial neural network algorithm services and uses remote service calls to perform algorithm predictions, which can greatly improve the reliability of system software. Based on the analysis of the status quo of intelligent manufacturing in the industry, combined with the application of Internet of Things technology, industrial robots, and big data cloud computing technology in the industry, this paper formulates an implementation plan and implementation steps and verifies through examples to build an Industry-oriented 4.0 customized intelligent manufacturing theory system that has certain reference value and guiding significance for the development of intelligent manufacturing industry.

Academic Editor: Tongguang Ni

The existing clothing design model lacks the screening link of the human body part index, and the output clothing data are affected by the high correlation coefficient, resulting in large matching errors. Therefore, based on the analysis of human body shape, a management model of matching degree of human body shape and clothing design based on big data is constructed. After processing with big data methods, human body characteristic data used signals as the input layer of a neural network model and the matching degree management model of human body shape and fashion design. The simulation results show that the built-up model has a matching error of less than 5%, which can effectively improve the matching of human body shape and clothing design.

1. Introduction

In fashion design, all functions would be fully displayed on the human body. Based on this, the human body's posture and clothing style composition are complementary and integrated, and they cannot be designed separately [1–3]. Body posture is the theoretical basis of garment style composition, and garment style composition is the ultimate result of showing the smart charm of body posture. Based on the era of big data, the massive growth of data capacity and diversity prompted the use of data mining technology in all areas of mass data analysis. With the increasing demand of personalized clothing design, quickly matching fashion design with human body shape is a beneficial attempt of big data technology and neural network algorithm in the clothing industry. This intelligent fashion design solution can quickly meet the fashion needs of customers [4–6].

Neural network technology has gradually received widespread attention in the garment industry [7]. According to the research, Wang et al. [8] analyzed the apparel style composition under different timing of BP neural network integration and discussed the application of neural network technology in the apparel industry, including material usage calculation, size recommendation, comfort analysis, etc. Liu et al. [9] applied BP neural network technology to men's suit size range setting, researched and analyzed the factors that affect the proposed model, and obtained the optimal size range setting. But the above model only calculates the data of fashion design, not considering the problem of overfitting in the process of model calculation. So, the resulting error of the fashion design model is large.

Therefore, based on the study of human body shape, the human body index data are collected by the big data method, and the neural network integration method is used to construct the matching degree management model of human body shape and clothing design, so as to realize the automatic mapping matching between human body and clothing design and lay a technical foundation for the mass customization and tailoring of clothing.

2. Network Model of Fashion Design

2.1. Big Data Collection of Human Body Index. Based on the aesthetics of the human body, the images of the human body structure, bone, muscle, shape, and other aspects are collected by the big data method, and the morphological characteristic signals of the upper part of human body are extracted and decomposed into

$$a = \frac{\beta^2 \log_3 \lambda}{\eta} + \sqrt{\beta}, \tag{1}$$

where β represents the waist of the human body, λ represents the shoulder width of the human body, using centimeters as units, and η is the number of sampled signals.

Based on the collected human leg images, the morphological characteristic signals of the lower part of the human body are extracted, and the decomposition formula is as follows:

$$B = \frac{\mu^2 \log_3 \gamma}{\eta} - \gamma, \tag{2}$$

where μ refers to the length of human legs and γ refers to the data on human height. Combining the morphological characteristics of the upper half of the human body and the legs, the integral surface model is constructed as follows:

$$c = \frac{\mu^2 \log_3 a + \beta^2}{\eta} - \log_2 \tau, \tag{3}$$

where τ is the image error caused by the noise. Through this surface model, the data signal of each part of the human body is obtained, and the signal is input into BP neural network as the training sample.

2.2. Garment Data Calculation. The data signals of various parts of the human body were input into the neural network, and x_i was set as the basic sample. The physical meanings and dimensions of the data obtained are not uniform, and it is impossible to calculate them. Therefore, the samples need to be normalized [10] before the calculation, so that the data with different measurements can be uniformly processed and the final values of the data are between [0, 1] and [−1, 1]. The specific formula is as follows:

$$x_i' = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}}. \tag{4}$$

The body morphological characteristic signals after normalization are input into the hidden layer as the training signal, and the number of nodes in the hidden layer is calculated as follows:

$$j = \frac{\sqrt{n+m}}{\lambda^2} + x_i' - \log_2 \partial, \tag{5}$$

where n is the number of nodes in the input layer, m is the number of nodes in the output layer, and ∂ is the number of synapses of neurons. The output of the j node of the hidden layer is as follows:

$$G_j = \sum_{i=1} Q_{ij} x_i' + \frac{\theta_j + Q}{\log_2 \partial}. \tag{6}$$

The network weight between the input layer and the hidden layer shall be $Q = q_1, q_2, \ldots, q_m$. θ_j is the number of neurons in the hidden layer. The signal is transmitted from the hidden layer to the output layer. The number of neurons in the output layer is

$$Y_j = \sum_{j=1} G_j + \frac{\varepsilon \sqrt{n+m}}{\log_2 \partial}, \tag{7}$$

where ε is the training step. Through nonlinear dynamic calculation of the output layer signal, the activation function $f(x)$ can be expressed as follows:

$$f(x) = \frac{\varepsilon \sqrt{n+m}}{\log_2 \partial} - Y_j(\omega + \delta), \tag{8}$$

where ω is the parameter value of the upper half of the clothing design and δ is the parameter value of the lower half of the clothing design. Through weighted debugging of formula (8), the formula of network mapping force is as follows:

$$K = \frac{\varepsilon \sqrt{n+m}}{f(x) + W_1} - \sum_{r=1} W_r. \tag{9}$$

The network weight between the hidden layer and the node of the output layer shall be $W = w_1, w_2, \ldots, w_r$. In order to train the body parameter signal samples sufficiently, the dimension of the neural network samples is reduced, and the expressions are obtained as follows:

$$U = \sum_{r=1} W_r - \frac{(T+K)\log_2 \mu}{f(x) + W_1}, \tag{10}$$

where T is the error value in the process of dimensionality reduction. By constructing the data, the neural network model is as follows:

$$U = \sum_{j=1} W_j - \frac{U - \log_3 \ell}{f(x) + W_1}, \tag{11}$$

where ℓ is the training error. After many times of training, the value of the minimum node number is determined, and the number of nodes is determined to be 10. The experimental results are stable, so that the size of the network structure is established to be $12 \times 10 \times 14$. In the range of learning rate between 0.001 and 10, the optimal value of the final learning rate is determined by successive tests. Experiments show that the learning rate is set to 0.15, and the maximum number of training steps is 5000; when the sum of squares of errors is 0.001, the model achieves the best effect.

Based on the above calculation, the neural network topology of fashion design is constructed as shown in Figure 1.

In Figure 1, P_r refers to the output data. The output of the hidden layer is $Y = (y_1, y_2, \ldots, y_m)^T$.

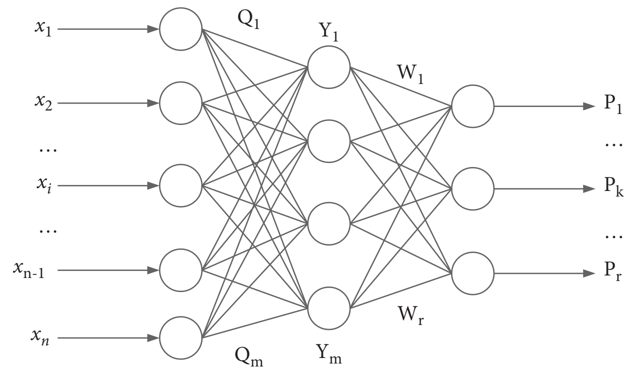

Figure 1: BP network topology diagram.

3. Management Model of Matching Degree between Human Body Shape and Fashion Design

When there is a simultaneous numerical transformation between the two variables [11–13], that is, when the correlation coefficient between the two variables is larger, then the performance stability of the obtained BP network model will decline, and the reliability of the model will be affected. In order to reduce the error of garment size data, the indexes were screened by the MIV method.

After training with sample p_i, the original indexes of BP network model increased/decreased by 12%, respectively, and the simulation test is carried out by using the obtained network structure. The result A_i is obtained, and the influence degree of each variable on the output result is calculated:

$$MIV_i = \frac{A_i - p_i}{i}. \tag{12}$$

The neural network calls the mean function in the running process of MATLAB software [14–17]. Select the appropriate variable values for constructing the neural network model. The filtering process is shown in Figure 2.

Screen waist and hip circumference and other variables, rank the results, and compose the MIV datasheet with the top 12 variables, as shown in Table 1.

From Table 1, it can be seen that the trouser length has the greatest influence on the garment pattern structure, while the hip circumference and waist circumference have the second and third place, respectively. Ankle circumference was the least influential variable, and waist length was the second. From the data in Table 1, it can be seen that ankle circumference on the garment pattern structure is negligible. Therefore, the factors of waist length and ankle girth should be removed in order to simplify the optimization procedure of the model.

The parameters are based on the selected body index data and the clothing design data from the neural network. Use the method of correlation analysis to construct the matching model:

$$V = (a_i b_i - \gamma)U + \sum_{j=1} W_j c, \tag{13}$$

where a_i refers to the morphological parameters of the upper part of the ith human body and b_i refers to the lower part of the ith human body. At this point, the matching degree model is constructed.

4. Model Simulation

The weak predictor is designed based on BP neural network model, using 5 control points as input layer and using AdaBoost algorithm to construct 10 strong predictors integrated by simple BP neural network.

The experiment selected 500 groups of human data, with 450 groups of human data randomly selected as training samples and the remaining human data selected as a test sample. The upper part of the input layer of BP neural network includes 15 parts related to it, including height, abdominal circumference, front length, back length, etc. The lower part of the input layer of BP neural network includes 10 parts related to it, including height, waist circumference, hip circumference, waist circumference, abdomen circumference, front crotch length, rear crotch length, thigh circumference, and knee height. The output layer of garment type adopts 160/84 form and chooses two values of height, chest circumference, or waist circumference according to the size style. The influence of different parts on height, chest circumference, or waist circumference was obtained accurately. Setting the output node to 1, the upper training curve is shown in Figures 3 and 4, and the lower training curve is shown in Figures 5 and 6.

It can be seen from Figure 3 that in 20 generations of training, the minimum mean square error of height prediction reaches 1×10^{-4}. As shown in Figure 4, in the 20th generation training, the minimum range of the predicted mean square error of waist circumference is $1 \times 10^{-2} \sim 1 \times 10^{-3}$. From Figure 5, the minimum value of the mean square error of height prediction after 4 generations of training is in the range of $1 \times 10^{-1} \sim 1 \times 10^{-4}$; from Figure 6, the minimum value of the mean square error of waist prediction after 6 generations of training is 1×10^{-1}.

Through the statistical analysis of the absolute value distribution of the errors of 50 test sets, it can be seen from Figure 7 that the error value of height prediction of the upper model is smaller than that of the ordinary test method, and the larger error fluctuation produced by the prediction

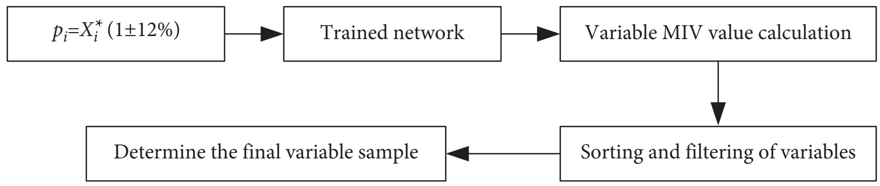

Figure 2: Diagram of MIV variable filtering process.

Table 1: MIV variable filter sort.

Number	Variable name	MIV values
1	Pant length	2.6011
2	Hips	1.9259
3	Waist circumference	0.9357
4	Inseam length	0.8534
5	Calf circumference	0.8216
6	Knee circumference	0.8122
7	Rise	0.6137
8	Waist height	0.2689
9	Thigh circumference	0.2018
10	Length of upper crotch	0.1856
11	Waist length	0.1754
12	Ankle circumference	0.0038

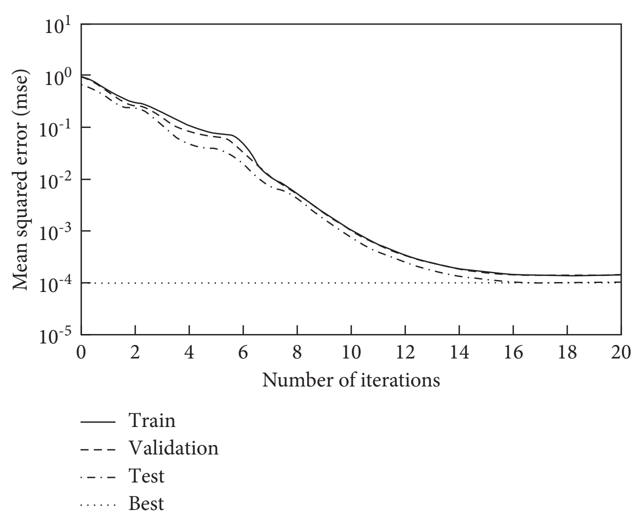

Figure 3: Training curve of height prediction model.

sample is in the acceptable range, and the overall absolute error fluctuation range of the quantitative model is less than 3%. As can be seen from Figure 8, the overall absolute error of the experimental model fluctuates slightly, less than 2%, much less than that of the ordinary model, and the range is small.

It can be seen from Figure 9 that the 50 test sets of absolute error distribution statistics in the proposed model are used for error statistics. The maximum absolute error of the ordinary model is close to 4%, while the maximum absolute error of the experimental model is only 1.6%. It proves that the experimental model is relatively stable; from Figure 10, it can be seen that the maximum absolute error of the ordinary model is slightly higher than 7%, while the maximum absolute error of the experimental model does not exceed 2%.

After the comparison of the above data, we can see that the absolute error rate of this experimental method is excellent in the coincidence degrees of predicting height with upper and lower, upper and bust, and lower and waist.

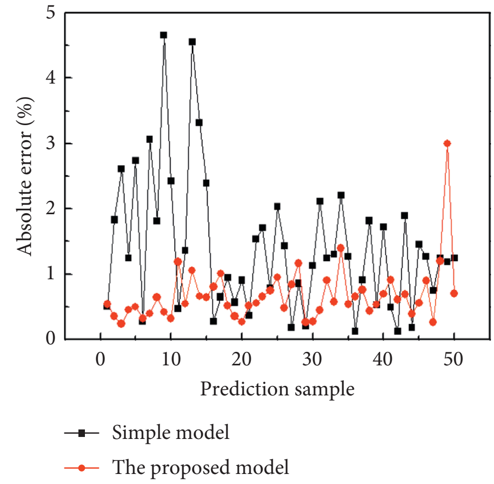

FIGURE 7: Absolute error of height prediction.

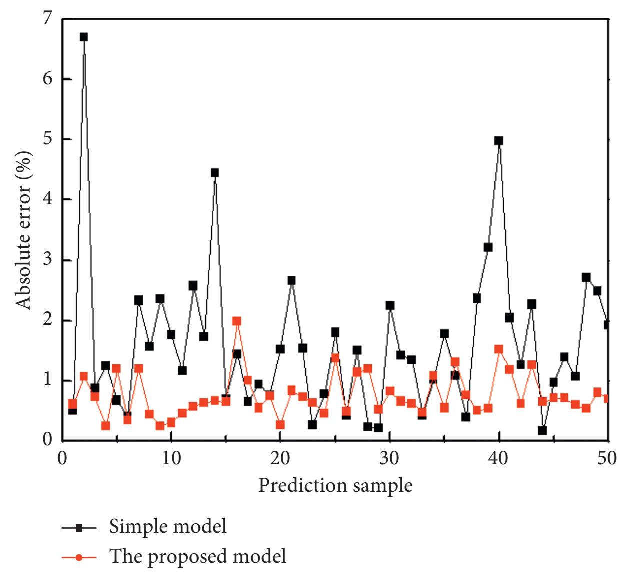

FIGURE 8: Absolute prediction error of bust size.

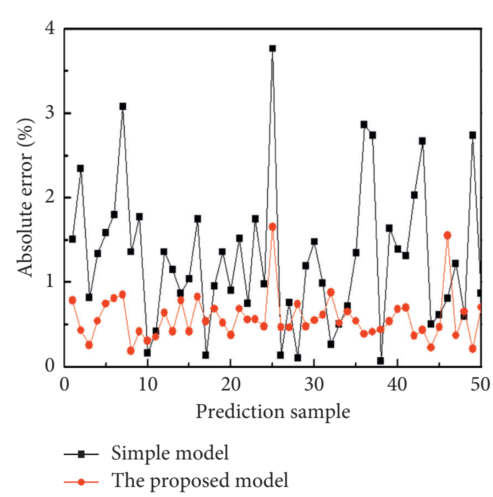

FIGURE 9: Error in height prediction.

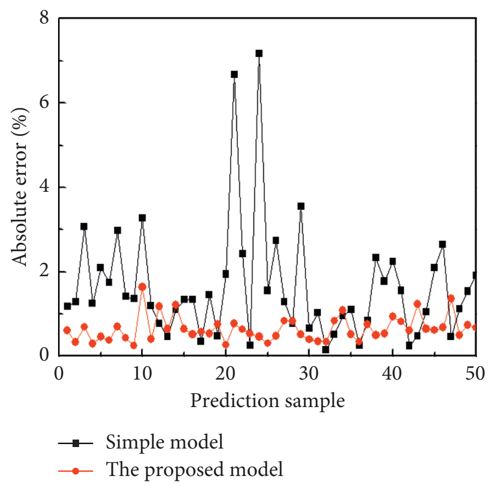

FIGURE 10: Prediction error of belts.

5. Conclusion

Based on the analysis of human body shape, this paper constructs the management model of matching degree between human body shape and fashion design. The mapping relationship between human body shape and fashion design is determined by the trial-run experiment, and the prediction model constructed by neural network is simplified by the method of selecting variables. The AdaBoost method is used to integrate 10 BP neural network classification models, and the matching degree management model of human body shape and clothing design based on neural network ensemble is constructed. The matching degree recognition precision of training set is over 95%. The modeling experience of this study shows that the shoulder width and waistline of the human body are vital in clothing design and should get more attention in follow-up studies.

Data Availability

The data used to support the findings of this study are included within the article.

Conflicts of Interest

We propose in this paper a new approach to solve the decision problem of robot-following. Different from the existing single policy model, we propose a multipolicy model, which can change the following policy in time according to the scene. The value of this paper is to obtain a multipolicy robot-following model by the self-learning method, which is used to improve the safety, efficiency, and stability of robot-following in the complex environments. Empirical investigation on a number of datasets reveals that overall, the proposed approach tends to have superior out-of-sample performance when compared to alternative robot-following decision methods. The performance of the model has been improved by about 2 times in situations where there are few obstacles and about 6 times in situations where there are lots of obstacles.

1. Introduction

Robot [1] is a topic of general interest in the automotive industry. It is a key problem that the agent attains a suitable decision of following. At present, there are two methods to solve this question, including the algorithm based on rule and the algorithm based on machine learning [2].

The algorithm based on rule, in general, makes a decision by establishing the appropriate kinematics model, so that the agent shows perfect performance in the predictable environment but may be not adjusted to the new environment. Gao et al. [3] proposed a kind of vehicle cruise system based on simulating driver method, which can safely follow the vehicle on most occasions but is hard to ensure safety and stability at the same time when it is used in complex scenes because it is governed by the driving experience of the designer. Li et al. [4] proposed a feedback control method, which has excellent following efficiency and safety performance. However, it lacks the consideration of stability in the situation of frequent speed changes.

One of the algorithms based on machine learning is based on deep learning [5] and the other is based on reinforcement learning [6]. Wang et al. [7] proposed a robot-following system based on deep neural network [8]. Compared with the traditional following model, it can adapt to complex situations better. This method, however, works by fitting the existing data, rather than generating an optimized strategy. So, it will be limited by the size of the training data set, and it sometimes fails to achieve the optimal decision in the new environment.

The algorithm based on reinforcement learning is that the agent explores continuously the environment and obtains the optimal decision by trial and error [9]. Gao et al. [10] proposed a following system based on Q-learning, which does not need a specific training set and has the ability of continuous learning. Howbeit, this method cannot respond immediately while the leading car changes its speed rapidly due to the discreteness of the algorithm. Deng et al. [11] proposed an improved DDPG algorithm. It transforms a multiobjective problem into a single objective problem by fixed weighting found by the experiment method. This method has better stability performance compared with the above methods and faster training speed compared with the traditional DDPG algorithm. However, this method finds out the real optimal weight only through a large number of simulation experiments, which is difficult to achieve in real scenes. Gao et al. gave a complete follow-up system [12] and proposed a method based on inverse reinforcement learning [13], which solves the problem that the reward function is difficult to set in the following process. Meanwhile, they conducted experiments on real scenes and verified the effectiveness of the system. Even so, he did not consider the diverse needs of robot-following decisions in different environments.

At present, the following problems still exist in the robot-following decision-making problem:

(1) It is difficult to obtain the optimal decision in different environments by the single decision-making method of robot-following
(2) It is difficult to properly weigh the relationship between various targets
(3) Most methods lack consideration of flexible targets such as robot-following stability

In order to solve the above problems, this paper proposes the multipolicy model based on reinforcement learning. This method solves the following problems such as setting reward function hardly, various users' needs, and unstable operation. It achieves the effect of surpassing the current many advanced methods in the simulation environment, basically achieves the target of safe, efficient, and stable following, and can quickly adjust the policy to deal with different environments. Empirical investigation on a number of datasets reveals that overall, compared to alternative robot-following decision methods, this method can reduce the safety risk by 66% and improve the stability performance by 6 times without affecting the robot-following efficiency when the speed of the target changes frequently. Meanwhile, the safety risk can be completely avoided, and the stability performance can be improved by 2 times when the target moves smoothly.

2. Model and Algorithm

2.1. Markova Model. Markova model is a model that the probability of the next action, which is usually used in reinforcement learning modeling, is only related to the current state, but not to the previous action and state. This model can be represented by a five-tuple (S, A, P, R, γ) [14]. S is the set of current state. A is the set of action at the next moment. P is the probability from S to A. R is the reward function. γ, ranging from 0 and 1, is the discount factor, which is used to calculate the cumulative reward value. Policy Π is the probability that the state in set S maps to every action in set $A{:}S \longrightarrow P(A)$. Provided that policy is $\pi_\theta(a, s)$, the cumulative reward value is $J(\theta) = E_{s\sim p^\pi, a\sim \pi_\theta}[\sum_{t=0}^{\infty} \gamma^t r^t]$. Reinforcement learning attains the optimal policy by maximizing.

Firstly, the robot-following process is discretized, and the sampling interval is τ. When time is recorded as t, the distance between the end-effector and the target is recorded as d_t, the relative velocity is recorded as $\triangle v_t$, the acceleration of the end-effector is recorded as a_t^2, and the state of t is recorded as s_t, $s_t(d_t, t, \triangle v_t, a_t^2) \in S$.

After getting the information of the state s_t, the end-effector outputs the action μ_t and attains the reward $R_t = f(\mu_t)$. Meanwhile, the state transforms s_t into s_{t+1}. μ_t is determined by policy Π.

2.2. Algorithm. The algorithm is a reinforcement algorithm based on the Actor-Critic structure [15]. The true Q function [16] is replaced by $Q^{\theta^Q}: S \times A \longrightarrow R$, and the target function is as [17]:

$$J(\theta^Q) = \max_{\theta^Q} E_\beta\left[\frac{1}{2}\left(r^t + \gamma Q^{\theta^Q}(s_{t+1}, a_{t+1}) - Q^{\theta^Q}(s_t, a_t)\right)^2\right], \quad (1)$$

$$J(\theta^\mu) = \max_{\theta^\mu} E_\beta\left[Q^{\theta^Q}(s_t, \mu(s_t))\right]. \quad (2)$$

The pseudocode of the algorithm is shown in Algorithm 1.

2.3. Pilot Experience Structure. Pilot experience structure is an important structure to reflect users' preferences and is also an important factor that affects the reward function.

The pilot experience structure consists of experience network and auxiliary network. Experience network is determined by the driving experience of the designer and auxiliary network is determined by users' preferences. The initial policy will be determined by the experience network and auxiliary network. The agent will generate multiple policies by adjusting the influence of the auxiliary network.

2.4. Reward Function. Reward function plays an important role in the reinforcement learning algorithm. A good reward function can accelerate the convergence of the algorithm and improve the performance of the policy. However, it may be hard to find out a good reward function when people face some problems, especially multiobjective optimization problem, in that how to balance the relationship between various targets is difficult to solve. This paper proposes a self-learning method of achieving reward function. The following will introduce the reward function of each single target and the structure of the self-learning method and multipolicy model.

2.4.1. Safety. Safety is the primary target. In general, keeping a reasonable safety distance can ensure safety performance, so the reward function of safety is defined as

$$R_1 = \begin{cases} 0, & d \geq D, \\ -1, & d \leq D, \end{cases} \quad (3)$$

Randomly initialize critic network $Q(s,a|\theta^Q)$ and actor $\mu(s|\theta^\mu)$ with weights θ^Q and θ^μ
Initialize target network Q' and μ' with weights $\theta^{Q'} \leftarrow \theta^Q$, $\theta^{\mu'} \leftarrow \theta^\mu$
Initialize replay buffer R
for episode = 1, M **do**
  Initialize a random process $\mathcal{N}$ for action exploration
  Receive initial observation state s_1
  for $t = 1$, T **do**
    Select action $a_t = \mu(s|\theta^\mu) + N_t$ according to the current policy and exploration noise
    Execute action a_t and observe reward r_t and observe new state s_{t+1}
    Store transition (s_t, a_t, r_t, s_{t+1}) in R
    Sample a random minibatch of N transitions (s_t, a_t, r_t, s_{t+1}) from R
    Set $y_i = r_i + \gamma Q'(s_{i+1}, \mu'(s_{i+1}|\theta^{\mu'})|\theta^{Q'})$
    Update critic by minimizing the loss: $L = (1/N)\sum_i (y_i - Q(s_i, a_i|\theta^Q)^2)$
    Update the actor policy using the sampled gradient:
    $\nabla_{\theta^\mu}\mu|s_i \approx (1/N)\sum_i \nabla_a Q(s,a|\theta^Q)_{|s=s_i,a=\mu(s_i)} \nabla_{\theta^\mu}\mu(s|\theta^\mu)|s_i$
    Update the target networks:
$\theta^{Q'} \leftarrow \tau\theta^Q + (1-\tau)\theta^{Q'}$
      $\theta^{\mu'} \leftarrow \tau\theta^\mu + (1-\tau)\theta^{\mu'}$
  end for
end for

Algorithm 1: The pseudocode of the algorithm.

where D is the safety distance.

2.4.2. Stability. Stability generally means that the robot should keep running smoothly at any time, and the speed should not change frequently. Therefore, the stability can be described by acceleration and acceleration change rate, so the reward function of stability is defined as

$$R_2 = \frac{1}{1+|a_t|} + \frac{1}{1+|\triangle a/\triangle t|}, \quad (4)$$

where a_t is the acceleration and $\triangle a_t/\Delta t$ is the acceleration change rate.

2.4.3. Efficiency. Efficiency mainly refers to the good co-operation between the robot and the target at any time. At the same time, if possible, the robot should maintain a high speed to ensure less time to complete the task.

Therefore, the reward function for efficiency can be defined as

$$R_3 = \begin{cases} \dfrac{v_t}{d(1+\triangle d)}, & d \geq D, \\ 0, & d < D, \end{cases} \quad (5)$$

where v_t is the current velocity, d is the relative distance, $\triangle d$ is the change of the relative distance, and D is the safety distance.

2.4.4. Self-Learning Method and Multipolicy Model. There is clearly a conflict between these targets. When the relative distance is small, the efficiency is high but there is a risk that the distance is less than the safety distance. When the speed changes small, the stability is high but the relative distance changes greatly, so the efficiency and safety are difficult to guarantee. How to determine the weight relationship between the targets is the key to integrating into a reward function. Thus, we propose the self-learning method and multipolicy model.

Firstly, several policies are given by the pilot experience structure. The agent will first use these policies for training, and at the same time, it will sample the state-action transition. After many times of training in the training environment, the user needs to give scores of every single target and a comprehensive score. The agent will convert the scores into the total reward of every training and then the reward function can be estimated according to the total reward and the distribution of state-action transition. The maximum likelihood estimation method can be used to estimate the parameter of the reward function. Likelihood function can be defined as

$$L(\mu) = \prod_{i=1}^{n} p(x_i: \mu). \quad (6)$$

Then, we can take logarithms on both sides of the likelihood function as

$$\begin{aligned} \ln L(\mu) &= \ln \prod_{i=1}^{n} p(x_i: \mu) \\ &= \sum_{i=1}^{n} \ln p(x_i: \mu). \end{aligned} \quad (7)$$

Then, we can derive the function $\ln L(\mu)$ with respect to the variable μ and make it equal to 0 as

$$\frac{d \ln L(\mu)}{d\mu} = 0. \quad (8)$$

Then, the estimated value of the parameter can be solved.

By the estimated value of the parameter μ, the probability distribution of the optimal action can be obtained. Then, the reward function can be derived from the optimal action sequence.

The agent will train a new policy from the new reward function. Similarly, the user needs to score the new policy again. If the comprehensive score is lower than before, the new policy will be added to the training data to estimate a better policy until the score of the new policy exceeds the scores of any policy before.

Since the policy function that meets the requirements is not unique, we can obtain several different value functions. In order to meet the various needs of different users for every target in the multiobjective problem, the agent will train several reward functions and policies which surpass the policies given by the pilot experience structure through the above method. Meanwhile, the agent will classify the policies according to the reward value of the subobjectives which can be calculated by the subevaluation function, which help itself choose the suitable policy in time. The subevaluation function can be attained by the subobjective reward function.

3. Experiment

To verify the validity of the model, two sets of trained policies (stability/efficiency) according to some users' needs are compared with other existing models in three different robot-following simulation scenarios.

In the following experiments, because the maximum measure distance of the distance sensor is 100 cm, we set $d_{\max}$ to 100 cm. Similarly, $v_{\max}$ is set to 55 cm/s, $a^1_{\max}$ is set to 5 cm/s^2, $a^1_{\min}$ is set to −5 cm/s^2, $a^2_{\max}$ is set to 5 cm/s^2, and $a^2_{\min}$ is set to −5 cm/s^2. Because we do not consider reversing in our experiment, $v_{\min}$ is set to 0 cm/s. In order to better observe the following state, we set τ to 0.1 ms. In order to ensure safety, we set D to 2 cm.

In general, when the distance between robot and target is less than the safe distance, we think that the state is in danger. Meanwhile, when the relative speed is equal to 0, the efficiency performance is thought of as well. Good stability performance requires that the acceleration of the robot following the target should be 0. Therefore, the average of $d - D$ and the frequency of $d < D$ can be used to evaluate the performance of safety and the StDev of $d - D$ can be used to evaluate the performance of efficiency. The average, StDev of $|\triangle v|$, and the frequency of $|\triangle v| \leq 0.1$ can also be used to evaluate the performance of efficiency. The average, StDev of $|a|$, and the frequency of $|a| = 0$ can be used to evaluate the performance of stability. Similarly, the average and StDev of $|\triangle a/\triangle t|$ can also be used to evaluate the performance of stability.

3.1. Training. The model needs to be trained first. The initial speed of the target is 0. During 0 to 30 seconds, it moves at constant acceleration which is 1 m/s^2. During 30 to 90 seconds, it moves at a constant speed. During 90 to 120 seconds, it moves at a changed speed that changes every 0.01 seconds and its value $\triangle v \sim U(-0.05, 0.05)$. After 210 seconds, the target slows down at constant acceleration, which is −0.5 m/s^2 until the velocity becomes 0. The initial relative distance is 0, and the robot starts to follow the target 3 seconds after the target starts. The change of the velocity of the target in the training scene is indicated by a solid line in Figure 1.

After training, the policy of the model is basically stable.

3.2. Testing. The method of this paper was compared with the simulation method from paper 2, Q-learning method from paper 5, and DDPG algorithm from paper 6. The performance of the models was first tested in the training scene, and the data analysis of distance, velocity, and acceleration is shown in Table 1.

In order to distinguish the various algorithms, the policy of algorithms proposed in paper 2 is called $P1$, and the policy of algorithms proposed in paper 5 is called $P2$. Similarly, the policy of algorithms proposed in paper 6 is called $P3$. $P4$ and $P5$ are the policy proposed by this paper. $P4$ tends to get higher efficiency but $P5$ prefers getting higher stability. $P4$ and $P5$ are trained by the self-learning method but do not apply the multipolicy model. $P6$ adopts the multipolicy model, and its policy set includes $P4$ and $P5$, which prefer ensuring safety and efficiency when the target changes velocity frequently and perform stability when the target moves at a constant speed.

We processed the original data to some extent and obtained the average value, standard deviation, and frequency of corresponding data. The calculation formula is as

$$\text{average: } \mu = \frac{\sum_i^n x_i}{n}, \tag{9}$$

$$\text{StDev: } \sigma = \sqrt{\frac{1}{n}\sum_i^n (x_i - \mu)^2}, \tag{10}$$

$$\text{frequency: } f(x < k)\% = \frac{\sum_n^i |k - x| + (k - x)}{2(k - x)\cdot n}. \tag{11}$$

From Table 1, compared with $P1$ to $P3$, $P4$ to $P6$ perform better according to safety. Meanwhile, $P4$ and $P6$ also ensure high efficiency. $P5$ and $P6$ have excellent stability performance.

To verify the performance of the model in different environments, the following will test the performance in two different test scenarios:

Scene 1. The initial speed of the target is 0. During 0 to 15 seconds, it moves with an acceleration of 1.5 m/s^2 + $\triangle a_{11}$, $\triangle a_1 \sim N(0, 0.5)$. During 15 to 60 seconds, it moves at a changed speed that changes every 0.01 seconds and its value $\triangle v \sim U(-0.1, 0.1)$. During 60 to 150 seconds, it moves at a changed speed that changes every 0.01 seconds and its value $\triangle v \sim U(-0.2, 0.2)$, and after 150 seconds, it moves with an acceleration of −0.5 m/s^2 until the speed is 0. The initial relative distance is 0, and the robot starts to follow the target 3 seconds after the target starts. The

change of the velocity of the target in scene 1 is indicated by a dashed line in Figure 1.

Scene 2. The initial speed of the target is 20 m/s. During 0 to 15 seconds, it moves at a constant speed. During 30 to 80 seconds, it moves with an acceleration of 0.1 m/s^2. During 80 to 180 seconds, it moves at a constant speed. During 180 to 230 seconds it moves with an acceleration of −0.2 m/s^2. When 230 to 250 seconds, it moves at a constant speed. The initial relative distance is 40, and the target and the robot begin to move at the same time. The speed variation of the target is indicated by a long-dashed line in Figure 1.

From Figure 1, we can find the difference between various methods. First, from the perspective of the change of the velocity of the target in the test scene, the moving speed of the target is changeable and irregular in scene 1 and the movement of the target is smooth and does not change greatly in scene 2. Obviously, the robot needs to ensure safety and improve efficiency as much as possible in scene 1. On the contrary, robots in scene 2 need not pay too much attention to the efficiency but need to improve the stability performance as much as possible.

From the results of the test scenarios on Tables 2 and 3, it is not difficult to find that *P*1 hardly keeps stable and sometimes does not leave enough distance with the target if its velocity changes fast. At the same time, *P*2 has bad stable performance and often cannot keep a safe distance with the target even if the target moves at a constant speed. *P*3 has excellent efficiency and not bad stable performance, but its poor security performance is worrying. *P*4 excessively pursues safety and efficiency without satisfactory stable performance. Similarly, *P*5 has excellent stable performance but poor efficiency. In terms of safety, efficiency, and stability, *P*6 mostly performed best in experiments.

From Figure 2, it is not difficult to find that these methods perform better in the training scene than in the testing scene, which proves that the new environment affects the performance of robot-following. Compared with other methods, the performance of *P*4, *P*5, and *P*6 is less affected. Therefore, the self-learning method has been proved to have better adaptability to the environment. At the same time, the efficiency performance of *P*6 is similar to that of *P*4, and the comfort performance of *P*6 is similar to that of *P*5, which shows that the multipolicy model can effectively improve the

comprehensive performance of robot-following and better complete the following task.

To sum up, the multipolicy model overcomes the shortcoming that the traditional single-strategy model cannot adapt to different environments. By using different policies according to different environments, the multipolicy model can perfectly meet people's different requirements for different environments. Therefore, it has high practicability and the value of the study.

4. Conclusion

In this paper, a Markov decision model for the robot-following process is first modeled, then a multiobjective reinforcement learning algorithm is proposed by improving the existing reinforcement learning algorithm, and the agent could obtain a multipolicy model.

This method improves the stability performance by 6 times without affecting the robot-following efficiency when the speed of the target changes frequently and the stability performance can be improved by 2 times when the target moves smoothly.

In summary, we adopt a multipolicy model, which can take different policy preferences for different environments, so as to ensure that the optimal decision can be made in most cases. Meanwhile, we adopt the self-learning method to avoid the problem of artificial weighting, so that the robot can determine the weight ratio by itself and realize the intelligence of the robot to a greater extent. In addition, we introduce more objective considerations into the algorithm, so that the final model is a multiobjective and multipolicy agent. The contributions of this paper mainly include the following:

(1) Self-learning mode is proposed to solve the problem that the reward function is difficult to determine in the robot-following problem.

(2) The adoption of pilot experience structure reduces a large number of unnecessary explorations in the early stage of intensive learning and training.

(3) The multipolicy model can effectively improve the adaptability of the algorithm to the environment so that the decision can meet the needs of more users.

However, because the algorithm is currently only tested in simulation and real experiment has not been done yet, there are still many unknown factors influencing the actual environment. Further experiments in real environment are needed.

This paper adopts a deep learning approach to analyze and study the mechanism of quantitative enhancement of college students' employment and entrepreneurial abilities in the context of the digital era. The deep learning connotation is predetermined as five abilities, which are metacognitive ability, active communication and cooperation ability, deep processing ability, creative practice ability, and learning empathy experience, and, based on this, the deep learning questionnaire is designed, and it is reclassified by exploratory factor analysis to reduce the dimensionality, and the specific indicators and scientific connotation dimensions of the deep learning questionnaire are determined; and, through the deep learning of each dimension, the problems of deep learning of college students are examined and in-depth analysis is conducted, and the inner relationship and correlation among the dimensions of deep learning of college students are derived through correlation analysis. The success of innovation and entrepreneurship depends on the innovation and entrepreneurial ability of college students, and the formation of the ability influenced various factors. Therefore, not only is studying the influencing factors of college students' innovation and entrepreneurship ability in line with the requirements of the times and social development, but also it can solve real problems. This thesis adopts a combination of two methods, qualitative research and quantitative research, to study the influencing factors of college students' innovation and entrepreneurship ability and tries to ensure the scientificity, accuracy, and comprehensiveness of the conclusion. In this paper, we analyzed the requirements of the employment prediction system for graduating secondary school students, carried out the software framework and database design of the employment analysis and prediction system for secondary school students, and designed the system modularly based on the analysis results. By applying the proposed deep feedforward neural network prediction model to the prediction system, a software system applicable to the employment prediction and guidance of secondary school students is implemented.

1. Introduction

In today's global economic system which is constantly developing and changing, whoever has the most innovative technology and the most innovative talents will have the first opportunity, and countries all over the world have launched the innovation-driven development strategy. Therefore, it is crucial to study the factors affecting the success of college students' entrepreneurship, and the ability of college students is the key that directly determines the success of their entrepreneurship, so it is crucial to study the ability of college students' entrepreneurship. As the future force of social development, the improvement of the entrepreneurial ability of college students is related to the implementation of China's innovative country construction plan and the speed of implementation [1]. Therefore, it is an effective way to solve the difficulties of entrepreneurship, the low success rate of entrepreneurship, and the pressure of social employment for college students by studying the factors influencing the entrepreneurial ability of college students and exploring the strategies to improve the it in three levels [2]. Therefore, the dataset needs to be segmented, and the model parameters are continuously adjusted through the verification set to allow the model to converge in a better direction. Not only can the improvement of college students' entrepreneurial ability improve their entrepreneurial success rate, but also the research on college students' ability can help to promote the cultivation of entrepreneurial talents and play a good role of promoting employment with entrepreneurship to drive social and economic development, enhance the country's economic strength, accelerate the construction of an innovative country, and improve the competitiveness for China in the international economic competition.

Using the method of qualitative research, through the integration, analysis, and refinement of a large amount of interview data, this paper constructs a model of the factors influencing college students' entrepreneurial ability and uses the model to discuss the factors influencing college students' entrepreneurial ability. To ensure the scientific and reasonable theoretical framework, based on the theoretical model of college students' entrepreneurial ability constructed, quantitative research on college students' entrepreneurial ability was conducted using statistical software [3]. In the research process, we make full use of the combination of qualitative and quantitative research methods, especially through in-depth interviews with college student entrepreneurs, to summarize and analyze the factors influencing the entrepreneurial ability of college student entrepreneurs and adopt questionnaire research to supplement the model of the previous qualitative research. Based on the survey data originating from the college student group, it truly reflects the influencing factors of college students' entrepreneurial ability, enriches the research theory of college students' entrepreneurial ability, and proposes entrepreneurial ability improvement strategies for the influencing factors, which provides a theoretical basis for the improvement of college students' entrepreneurial ability [4]. The employment situation of graduates from secondary colleges and universities is studied from various angles, and the problems and shortcomings of graduates in the employment process are summarized and analyzed through the analysis and tracking of the employment situation, to reflect on whether the current teaching methods and teaching priorities of secondary colleges and universities can provide students with good employment guidance and employment assistance and whether the current teaching model can cultivate excellent graduates who meet the needs of the country and society, to come up with conclusions that are conducive to adjusting the direction of career guidance and improving the quality of teaching in secondary institutions [5]. From this grid form, we can clearly see the result that these parameters can be combined. This is of far-reaching significance for the country, schools, and individuals.

The main feature of an innovative country is to realize the transformation of human resources into human capital, especially to make outstanding talents become the backbone to drive the efficient development of the economy and optimization and upgrading of industrial structure. The great demand for innovative talents in national social development has further promoted the development of innovation and entrepreneurship education in colleges and universities to cultivate and improve the innovation and entrepreneurship ability of college students, making it an important aspect of the construction of double-class universities. From the background of innovation and entrepreneurship, promoting innovation and entrepreneurship among college students is an important measure to respond to the development of new technologies and industries and to build an innovative country; from the background of the reform of entrepreneurship education in colleges and universities, cultivating entrepreneurial human capital among college students is an important path to deepen the reform of entrepreneurship education, implement the goal of quality education cultivation, realize comprehensive development of college students, and enhance social adaptability; from the background of improving national competitiveness, promoting innovation and entrepreneurship among college students is an important path to deepen the reform of entrepreneurship education, implement the goal of quality education cultivation, realize comprehensive development of college students, and enhance social adaptability. From the background of improving national competitiveness, promoting college students' innovation and entrepreneurship is an important means to give full play to the advantages of human resources and an important strategic plan to build a strong human resources country. In such a background, it is urgent to solve the problem of employment difficulties of graduates, and it has already aroused considerable concern in society. Through the analysis and refining of the initial sampling, sample selection and data mining are performed to carry out research work in a state of "theory saturation." If college students are unable to find suitable jobs after graduation and thus become unemployed, they will not be able to give full play to their strengths in various fields and add to the construction of socialist modernization. In this way, on the one hand, this will aggravate the conflicts in society, and, on the other hand, it will be a great waste of our human resources. According to incomplete statistics on the employment outlook of graduates, about 90% of school students are worried about their future employment prospects. A very important reason for this phenomenon is that college students do not receive good guidance during their school years, do not have a very clear career plan, and spend all day getting by, which eventually leads to employment failure. Therefore, early warning and guidance for school students are a proven solution to this phenomenon.

2. Current Status of Research

Neural network algorithms have made breakthroughs. A group of scientists have proposed the famous error backpropagation (BP) algorithm. The backpropagation algorithm is based on the traditional neural network algorithm, which continuously adjusts the weights and thresholds between neurons to correct the model error during the backpropagation process, significantly reducing the complexity of the model computation process [6]. The final output error of the model is reduced below an allowable threshold or terminated when the set number of training times is reached. The BP algorithm solves the nonlinear classification problem in neural network models, making a significant advance in the difficulty and scope of its use, and people once again start to focus on artificial neural networks [7]. In the research, firstly, through the unsupervised learning method, the model was trained in multiple levels, and, on this basis, the supervised backpropagation algorithm was used for parameter tuning and model correction, which successfully solved the "gradient disappearance" problem, which marked the formal introduction of the concept of "deep learning" [8]. Once deep learning was proposed, it caused a great sensation in the academic world, and world-renowned universities, represented by Stanford University, began to spend huge amounts of money and workforce on research in deep-learning-related fields. Deep learning methods have also been favored by industry, with a representative group using the deep learning model AlexNet to win the ImageNet image recognition competition. The model also took advantage of the GPU's strengths in floating-point computing, which greatly increased the speed of computing [9]. In the same year, renowned Stanford University machine learning professor Enda Wu developed a deep neural net model in conjunction with the world's leading computer experts [10]. The model extended the layers of traditional neural networks and achieved great success in the field of image recognition. Deep learning algorithms have once again attracted the attention of scholars and industry worldwide due to their superior performance.

The practice in student career guidance first began in Europe and the United States. In the United States, colleges and universities attach great importance to the employment of students, and almost all colleges and secondary schools in the United States have their career guidance organizations for all students [9]. In the UK, higher education institutions will start career guidance work for students from the moment they first enter the school and set up special career guidance files for all students in the school, so that they can carry out guidance work according to the individual students' needs so that students can be better employed [11]. According to the search results, we can see that the current career guidance in China's education is dominated by college students and higher education institutions, while information related to career guidance for students in secondary schools does not appear in the search buzzwords [12]. In addition, the search results counted subject distribution, and the distribution of the top ten subjects was obtained. From the results, higher education occupies the vast majority, followed by vocational education. This means that career guidance is also gradually gaining attention in vocational education in China, and the employment situation of students in secondary schools is getting the attention of society [13].

The purpose of this study is to predict the employment situation of secondary school graduates and provide referenceable solutions to the problems encountered by institutions in guiding students' employment. In recent years, some scholars in China have conducted relevant research on the prediction problem from different perspectives and using different algorithms. The research and application of the graduate employment prediction model using machine learning have been conducted, and, based on the research and analysis results, the hybrid feature selection algorithm with mutual information and weights (HMIGW) and XGBoost feature selection algorithm have been combined to provide an effective solution for student employment prediction, and the algorithm has been further optimized and improved based on the implementation feedback from relevant departments. The semisupervised self-training method was improved and applied to the applied research of student employment prediction in colleges and universities, combining the analysis of the prediction results of the data to be graduated students and the actual situation of students to propose guidance countermeasures, and its model has obvious advantages. The classical decision tree algorithm is used to construct a decision tree prediction model of the factors influencing students' employment, such as "whether to be employed" and "employment area," and the two models are applied to the students' employment guidance work. The natural nearest neighbor classification algorithm is used to predict the employability of college students. The model is based on the employment information input of graduates and is used to build a salary prediction model for employed college students.

3. Quantitative Analysis of Entrepreneurship Based on Deep Learning in the Context of Digital Era

3.1. Deep-Learning-Based Algorithm Design in the Context of the Digital Age. Artificial neural networks evolved from the original neuron model; inspired by biology, the learning system in the biological brain is a vast network of countless neurons, based on a topology that incorporates the basic principles of neural networks in biology, connecting many neurons to one another to process the input data [14]. In an artificial neural network, each neuron represents a specific activation function and every connection between two neurons represents a weight. In artificial neural networks, the weights and activation functions differ, and the output will be different. In order to respond to the requirements of national development for technological innovation, we need to cultivate students' corresponding innovation and entrepreneurship ability. For example, the classical algorithm in neural networks-backpropagation algorithm, based on the input layer, hidden layer, and output layer, constructs artificial neural networks, in the process of data transmission, constantly using gradient descent and adjusting the parameters, so that the error between the actual output and the desired output achieves minimum convergence and the best fit, greatly improving the robustness of data processing, and the neuron structure is shown in Figure 1.

Deep neural networks are predecessors of artificial neural networks, but, unlike artificial neural networks, they have more hidden layers. In deep neural networks, the model

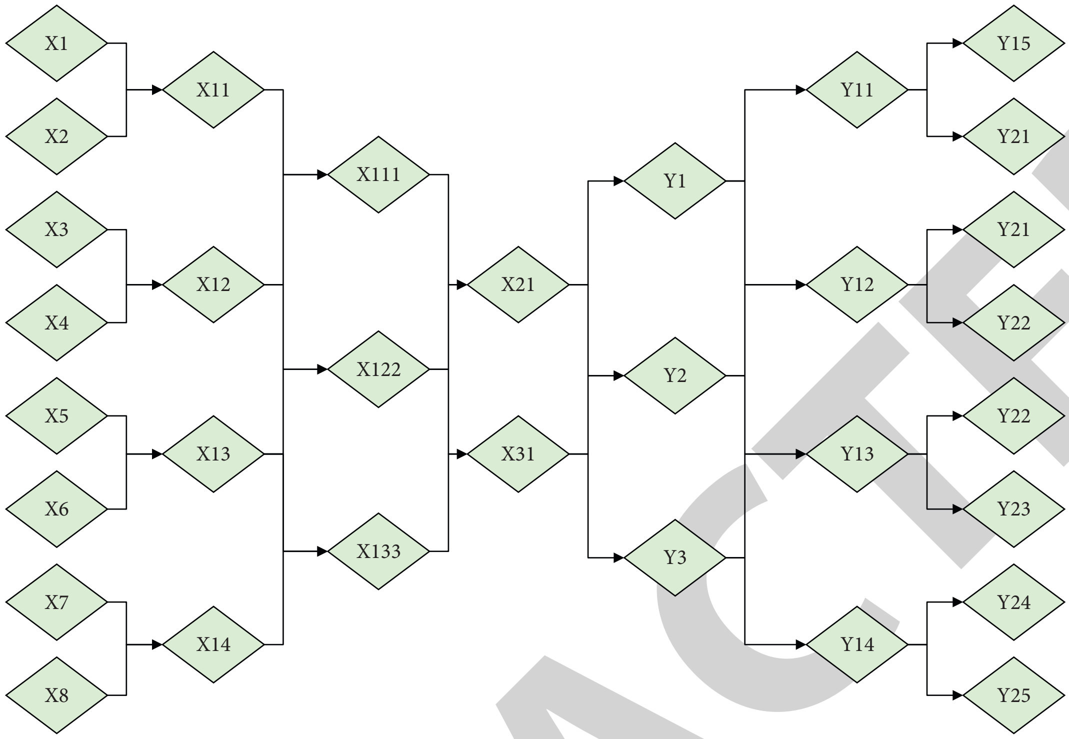

Figure 1: Deep neural network structure.

building has a strong structural feature. The interface of the network model is the input layer, which is also the entrance of the data into the model, and after the data passes through the input layer, it will enter the hidden layer, and the hidden layer is not only one layer after the data is transformed and calculated by multiple hidden layers; the result obtained is passed into the output layer and the final information is obtained. Deep feedforward neural network is a typical deep learning model whose goal is to fit some function to transform the input into some predicted output and learn the network parameters at the same time so that the model gets the optimal approximation of the function. Since there is no feedback connection to the model itself during the process from the input to the output, this model is called a feedforward model [15]. Deep feedforward networks are also composed of multiple functions compounded together, and the model is often associated with a directed acyclic graph, where the graph describes how the functions compounded and the full length of the chain is defined as the depth of the model. In practice, problems are often linearly indistinguishable and require nonlinear transformations to remap the distribution of the data, and the deep neural network itself goes through multiple levels of linear changes, with each change superimposing a nonlinear activation function, distinguishing it from a single layer of linear functions, where the multilayer network structure enables the construction of more accurate models, resulting in more powerful learning and fitting capabilities.

After building a deep feedforward neural network model, model evaluation is a key part, and the loss function defines the evaluation metric of the model when backpropagating in the network. As the name suggests, the loss function measures the difference between the predicted value of the output of the neural network and the actual value of a way to measure how good the network is, as well as by backpropagating the error to gradually improve the performance of the network on the prediction after data processing. The difficulty of optimizing the loss function varies with the parameters, the final model parameters obtained vary, and the appropriate loss parameters need to be selected for the specific problem. Common loss functions include least-squares loss function, cross-entropy loss function, and Smooth L1 loss function. In supervised learning, the loss functions we commonly use are mainly the least-squares loss function and the cross-entropy loss function.

$$L(y, f(x,\theta))\frac{1}{4}(y + f(x,\theta))^2. \tag{1}$$

The multiclassification cross-entropy loss function is an extension of the binary classification, with the following equation:

$$H\left(y^i, y^j\right) = \sum_{i,j=1}^{Q} y_i \ln\, y_j. \tag{2}$$

After determining the loss function, the model has all the functional structures to perform data processing and the next step is to determine the optimization algorithm for the model when performing backpropagation. The optimization algorithms for deep learning are stochastic gradient descent methods. In the gradient descent method, again, there are different forms of operations. The batch gradient descent method iterates through the entire sample of the network model to update the weights of the network, which greatly increases the number of operations on the network data and reduces the speed of backpropagation of network errors. The more professional and in-depth related abilities that need to be possessed in the later development period and maturity period are not the focus of training at this stage. The innovative and entrepreneurial abilities that should be possessed in the awakening stage should be generally oriented to all college students, with emphasis on innovation spirit, learning ability, entrepreneurial personality, and so forth; and the innovative and entrepreneurial abilities that should be possessed in the initial stage are mainly aimed at the transformation of scientific and technological achievements and practicality. In contrast, the stochastic gradient descent method will only iterate through one of the samples of the network model input samples to update the weights, which will increase the speed of the network to reduce the amount of computation, but because the iterations use too little data, this often leads to a decrease in the accuracy of the network model, which makes the result be a local optimal solution, but it cannot get the global optimal solution.

Dropout is a random strategy in the training process of a deep model, that is, dropping a neuron node in a neural network at random with a certain probability. Since the dropout method acts on a different small batch of training data each time, each time a random part of neurons is dropped can be seen as a retraining process of the neural network, resulting in a completely different network structure [16]. Dropout is compared to the Bagging method, which is traditionally used for large-scale deep neural network training methods due to its involvement of the overall model and data; when the size of the network is large, this integration method not only takes a lot of computational time but also consumes a lot of data storage space. Therefore, the Bagging method does not have a great advantage when training small batches of data. Dropout, as a lightweight alternative to Bagging, can achieve the good properties of the Bagging method on small batches of data, that is, to achieve exponential numbers of neural networks for training and evaluation.

$$Z_k = \frac{\exp\left(x_k\right)}{\sum_{i=1}^{k} \exp\left(x_k\right)}. \tag{3}$$

To apply deep neural networks for employment prediction, the computational process based on deep neural networks is given in Figure 2. The main processes are as follows: first, the dataset is preprocessed and all types of features are transformed into numerical features using one-hot coding; second, the dataset is divided into a training set and a test set in the ratio of 7 : 3, and the deep neural network is trained using the feature data from the training set and the training results are verified using the test set to find the best combination of parameters using a grid search method.

The definition of evaluation metrics is important for the evaluation of a network model and is an important factor in validating the quality of the network model; in this paper, accuracy, recall, and F1 value are selected as the evaluation metrics of the network model. For the categories, the formula is as follows:

$$\begin{aligned} p_c &= \frac{\mathrm{TP}}{\mathrm{TP\text{-}FP}}, \\ R_c &= \frac{\mathrm{TP}}{\mathrm{TP} + \mathrm{FN\text{-}1}}, \\ F_c &= \frac{1 - \beta^2 - p_c + R_c}{\beta^2 - R_c}. \end{aligned} \tag{4}$$

In deep learning, the data needs to be sliced and normalized for training and testing. The dataset is divided into the training set, validation set, and test set; the training set is used to train the model, the validation set is used to observe the model performance, and the test set is used to verify the model effectiveness. The model obtained from the training set alone does not prove that the prediction model is effective and may reduce the usefulness of the model due to overfitting, so the dataset needs to be sliced and the model parameters are continuously adjusted through the validation set so that the model converges towards a better direction. First, the dataset needs to be split into two parts: the training set and the test set. Nowadays, there are two popular methods of data partitioning: one is that 80% of the data is used for training and 20% of the data is used for testing, and the other is that 70% of the data is used for training and 30% of the data is used for testing. To better test the generalization ability of the model, the second method is chosen. 30% of the data is divided into the test set, which is not trained for model parameters and is only used as the final test evaluation of the model. Meanwhile, for the first 70% of the data, 10% is randomly selected as the validation set, which will act as a test evaluation within the training for each training of the model, while the remaining 60% or so of the data is the data that is trained for the parameters. They are 0.443 and 0.387, respectively. Among the three-level indicators, initiative spirit, reform willingness, and abiding by the contract have larger weights, indicating that they are more important to the spirit of innovation; in the evaluation of the various elements of innovation and entrepreneurship ability, the ability to transform results has the highest weight.

$$K\left(x_1, x_2\right) = \exp\left(\gamma\left(x_1 - x_2\right)\right)^2. \tag{5}$$

The method of lattice search belongs to the classical exhaustive search method from the mathematical essence. In this paper, all the possible values of the parameters of the network model are combined in a specific permutation, and after they are combined, the result of the permutation is presented in the form of a grid, from which we can see the results that can be combined into these parameters [17]. Then all the parameters in the formed grid can be combined in a way to feed the network model, and then the whole network model will be trained, the performance of the network model will be continuously evaluated, and the performance parameters after each evaluation will be compared so that the best combination of parameters can be continuously filtered.

3.2. Quantitative Design of University Students' Employability and Entrepreneurship. The theory and practice of statistics tell us that the connotation of everything comes from its essential properties, and the revelation of its essential properties comes from the data and information mining that portray its appearance [18]. Therefore, in the face of such a complex research topic as the qualitative study of the factors influencing college students' entrepreneurial ability, the key to achieving the purpose of the study is the way to collect data and to reprocess the data on this basis to obtain the most reliable information. Considering the limitations and timeliness of secondary data, according to the principle of "the best performance to price ratio" and focusing on the qualitative indicators that can best describe the factors influencing college students' entrepreneurial ability, we adopted a combination of theoretical sampling and interviewing and carried out sample selection and data mining through the analysis and refinement of the initial sample. The study was carried out in a state of "theoretical saturation" through sample selection and data mining. The optimal sample size is the smallest amount of data saturated with the highest level of content required to achieve the research objectives [14]. According to the requirements and operation procedures of in-depth interviews, to ensure the representativeness of the data, we first determined the sampling frame of regions, taking into account the concentration of college students' entrepreneurial bases and the number of entrepreneurs, through existing records and fieldwork, and then further determined the sampling frame of survey members, requiring that those who can be used as sample members must have at least one successful experience of entrepreneurship during their school years or within two years of graduation.

In this way, they can provide more convincing information, such as the initial intention of starting a business, the confusion of starting a business, what are the main factors affecting the business, what abilities are needed in the process of starting a business, and what kind of environment is more favorable for starting a business. According to the number of entrepreneurs and the current situation of entrepreneurship, stratified random sampling is adopted to draw a sample of 30 people from each area in the sampling area box, respectively; then interviews are conducted, the order of interviews is determined by drawing lots, the interviews start from number one, and if the interviewer can no longer provide new information they will be eliminated; to define the concept of the innovative entrepreneurial ability of college students, we cannot ignore the special characteristics of the college student group, so that its concept is different from the general concept of innovative entrepreneurial ability. The abovementioned method will be an effective way to solve the difficulties of college students in the aspects of starting a business, reducing success rate of starting a business and the pressure of social employment. To define the concept of innovation and entrepreneurship among university students, it is necessary to differentiate the concept from the general concept of innovation and entrepreneurship and to narrow down the scope and make it more specific and relevant. Unlike the entrepreneurs and start-ups studied in the past, the entrepreneurship of university students advocated by the state is not just as simple as "setting up a stall" or "doing a small business."

It should be an innovative and valuable venture. Therefore, based on the existing literature research and the characteristics of our society and college students, we define the concept of college students' innovative entrepreneurial ability as follows: the ability of college students to create and improve new things and transform them into economic, social, and cultural values that are beneficial to personal or social development by using their scientific and cultural knowledge and surrounding resources, which is mostly reflected in the innovative entrepreneurial primary stage, as shown in Figure 3.

At the critical period of accelerating the construction of an innovative country, great importance is attached to the cultivation of innovative talents and university students, as highly sophisticated talents who master scientific and cultural knowledge and advanced technology are the main force to achieve this grand strategic goal. Therefore, in the context of "mass entrepreneurship and innovation," the innovation and entrepreneurship ability of college students should actively respond to the theme of the times and reflect the characteristics of the new era. Therefore, the modernity of the innovation and entrepreneurship ability of college students refers to the fact that college students closely combine their ideal beliefs and life pursuits with national development and social progress, respond to the development requirements of national science and technology innovation, knowledge innovation, and system innovation, as well as strategic opportunities, focus on new technologies, new business modes, and new models, and take the initiative to accumulate and improve or cultivate the corresponding innovation and entrepreneurship ability with external support. This model is used to discuss the influencing factors of college students' entrepreneurial ability. To ensure that the theoretical framework is scientific and reasonable, based on constructing a theoretical model of college students' entrepreneurial ability, statistical software is used to conduct quantitative research on college students' entrepreneurial ability. The new round of business innovation and technological change is reshaping the global economic landscape, and countries all over the world are emphasizing the importance of innovation, but, due to the different social systems, different degrees of development, and different development processes in each country, the requirements for the innovation and entrepreneurship capabilities of college students also vary, and each country should develop corresponding specific strategies in line with national realities and development needs.

The innovation and entrepreneurship capabilities that need to be possessed or focused on by innovation and entrepreneurship subjects are different for each stage. Unlike other innovative entrepreneurial groups in society, such as entrepreneurs and migrant workers, the time frame for this particular group of university students is mainly limited to the period during which they attend university and within two years of graduation, and the corresponding entrepreneurial stage is the awakening of consciousness and the start-up phase, which focuses more on the innovative spirit, learning ability, and the knowledge and skills required for the start-up phase [19]. The more specialized and in-depth competencies required in the later development and maturity stages are not the focus of this stage. The innovation and entrepreneurial ability that should be possessed in the awakening stage should be generally oriented to all college students, focusing on the innovation spirit, learning ability, and entrepreneurial personality, while the innovation and entrepreneurial ability that should be possessed in the start-up stage mainly targets a small group of people who transform scientific and technological achievements and start a business, focusing on enterprise management ability and so forth, as shown in Figure 4.

The data obtained through survey research in quantitative research is the basis for scientific decision-making, and the selection of appropriate data analysis methods and data analysis software is an effective means to ensure scientific decision-making. According to the research needs and research questions, this paper will use descriptive statistical analysis, factor analysis, hierarchical analysis (AHP), principal component analysis (PCA), and full weight method to determine the weights of innovation and entrepreneurship education ecosystem composition indicators of research universities. Among them, the main methods used in the weight analysis were hierarchical analysis (AHP), principal component analysis (PCA), and the full weight method. In the specific data processing, statistical analysis software programs such as SPSS and AMOS were used as the main analytical tools for data analysis. The specific statistical analysis steps are as follows: Firstly, the research group distributed the questionnaire of "the composition index of innovation and entrepreneurship education ecosystem in research universities" to each university, the subjects were teachers and students, and the survey data were recorded into electronic files. Aiming at the influencing factors, a strategy to improve entrepreneurial ability was proposed, which provided a theoretical basis for the improvement of college students' entrepreneurial ability. Secondly, according to the questionnaire responses, incomplete responses, regular responses, short responses, and self-contradictory responses were eliminated, and valid questionnaires were obtained. Again, using SPSS statistical software, the obtained data were processed, and descriptive statistical analysis, exploratory factor analysis, and validation factor analysis were conducted on the questionnaire to determine that the questionnaire had good reliability. Finally, the combination of hierarchical analysis, principal component analysis, and full weight method was used to determine the weights of the composition indicators of the innovation and entrepreneurship education ecosystem of research universities to help managers better determine the focus of their work.

4. Analysis of Results

4.1. Deep Learning Algorithm-Based Results in the Context of the Digital Age. The method of lattice search belongs to the classical exhaustive search method from the mathematical essence. In this paper, all the possible values of the parameters of the network model are combined in a specific permutation, and after they are combined, the result of the permutation is presented in the form of a grid, from which we can see the results that can be combined into these parameters. Then all the parameters in the formed grid can be fed into the network model in the way of combination, and then the whole network model will be trained, the

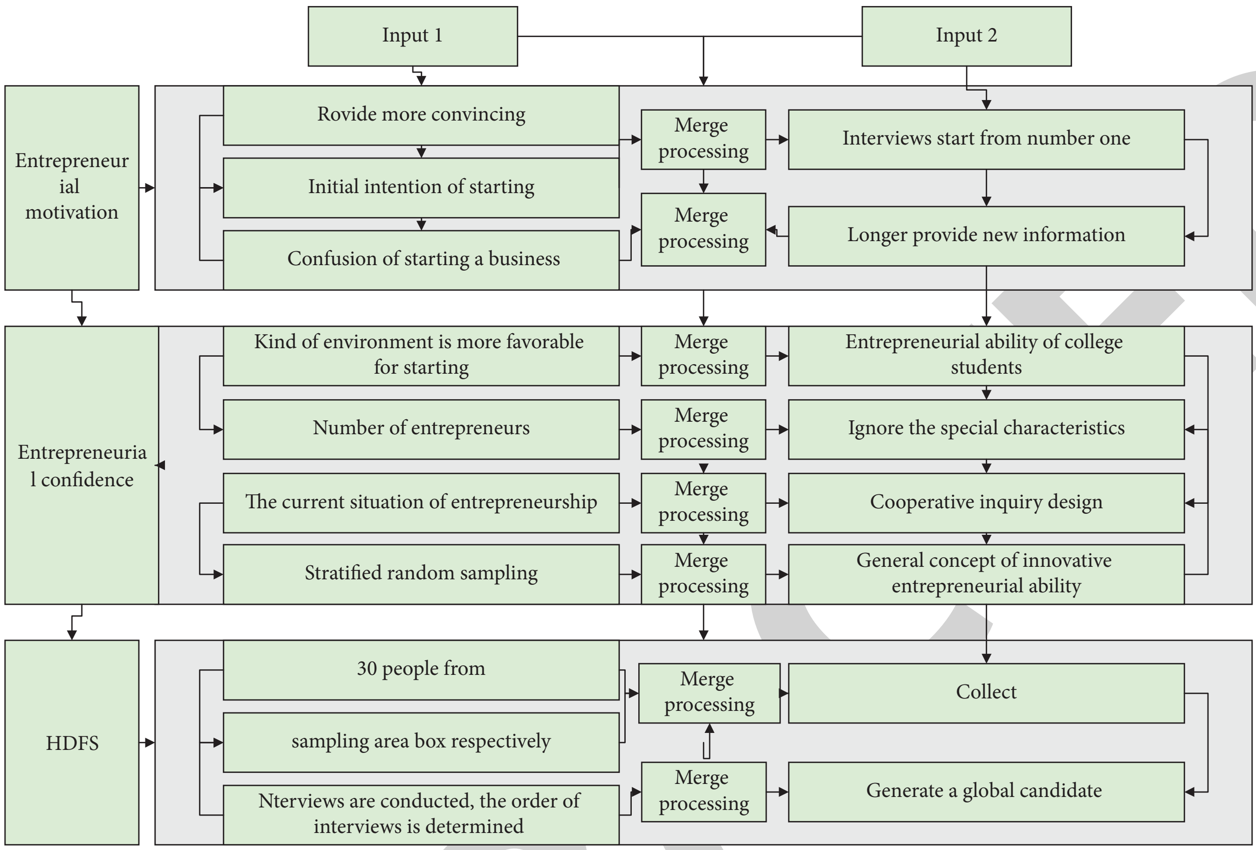

Figure 3: Hypothetical model diagram.

performance of the network model will be continuously evaluated, and the performance parameters after each evaluation will be compared so that the best combination of parameters can be continuously filtered. In the model proposed in this paper, the most important parameters are the number of training sessions, the number of batches, the number of hidden layer neurons, and the step size. Based on practical experience, the benchmark parameters in grid search are determined: the number of training times is 400, the number of batch processes is 20, the number of neurons in the first hidden layer is 16, the number of neurons in the second hidden layer is 8, and the step length is 0.001. Applying deep feedforward neural network for employment classification of secondary school graduates, Figure 5 gives the classification accuracy, loss function with iteration for the training and testing process of student employment dataset, and change curve with the number of iterations. From Figure 5, the accuracy of the training set of the student employment dataset rises rapidly in the oscillation until 20 iterations, and then the oscillation of the training set decreases until it stabilizes after 250 iterations; the test set rises rapidly until 15 iterations and then rises slowly and stabilizes. As can be seen from Figure 5, the training set loss decreases rapidly in oscillation until 250 iterations and then gradually stabilizes; the test set loss decreases rapidly until 300 iterations and then slowly decreases and stabilizes.

Recently, the gradient boosting decision tree model has been performing very well in commercial applications and is a good example of the concept of learning from mistakes. Gradient boosting decision tree is an iterative decision tree algorithm that consists of multiple decision trees and the conclusions of all the trees are accumulated to make the final answer. The obtained results can be used as an important measure to guide the construction of an innovative country; from the background of college entrepreneurship education reform, cultivating college students' entrepreneurial human capital is an important path to deepen entrepreneurship education reform, implement quality education training goals, achieve comprehensive development of college students, and enhance social adaptability. It was a more generalizable algorithm along with SVM when it was first proposed. The basic idea is to train the newly added weak classifiers based on the negative gradient information of the current model loss function and then combine the trained weak classifiers into the existing model in an accumulative form, and, in each iteration of the computation, the negative gradient is calculated with the current model sample as the goal to train the weak classifiers for merging. The final computed weights are used for the model update. In the experiments, the gradient boosting decision tree model is trained in the training set using XGBClassifier in XGBoost and then a grid search is performed in Scikit-Learn using Research on the estimates of the specified parameters, and all hyperparameters are tested to find the best combination to produce the best results as shown in Figure 6.

In machine learning, support vector machines (SVMs and support vector networks) are supervised learning

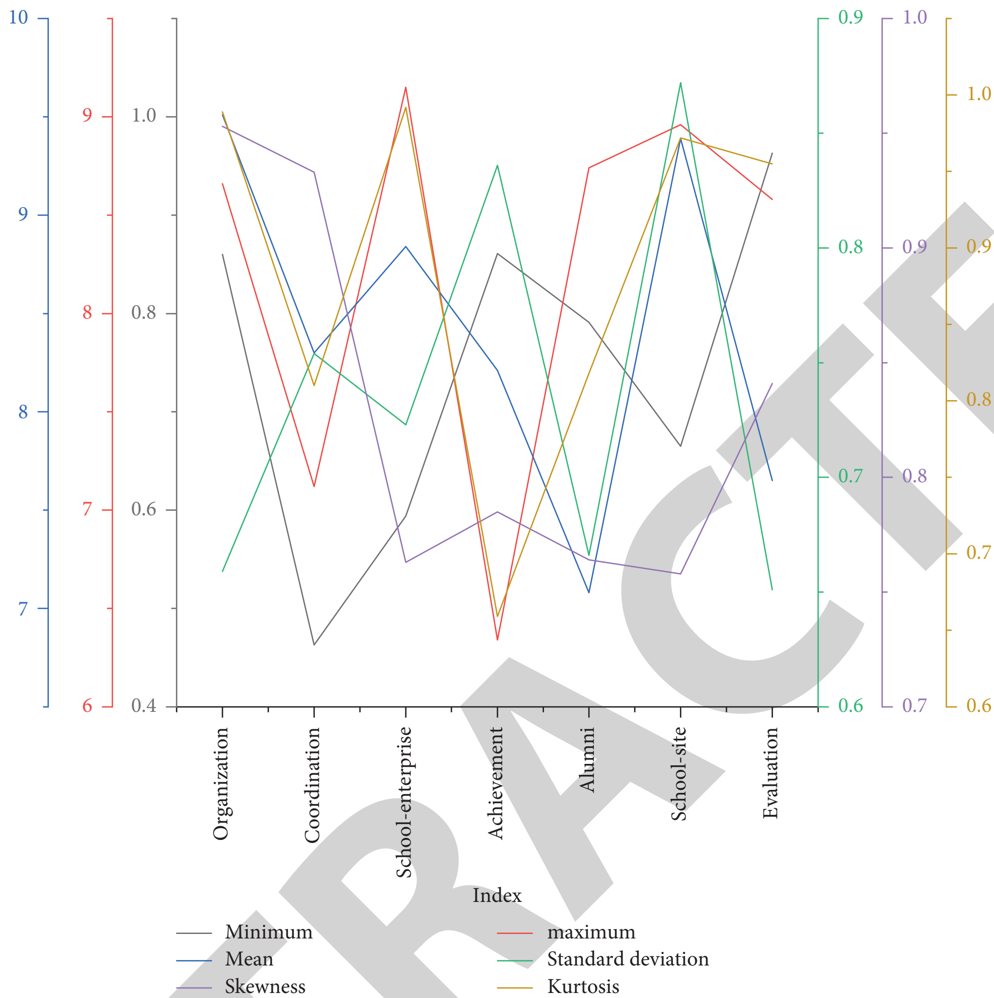

Figure 4: Descriptive statistics of organizational mechanisms.

models associated with relevant learning algorithms that analyze data and identify patterns for classification and regression analysis. Support vector machines are used to distinguish between various types by finding a hyperplane in a multidimensional space. This hyperplane is determined by the support vector. In the experiments, the support vector machine model is trained in the training set using SVM. Then a grid search is performed in Scikit-Learn using research on the estimates of the specified parameters and all hyperparameters are tested to find the best combination to produce the best results. In this paper, the classical cross-validation method is used to calculate the prediction accuracy of four different models. By comparison, it demonstrated that the deep feedforward neural network model used in this paper has better accuracy than the traditional algorithm. The results prove that the employment prediction algorithm for secondary school graduates based on deep neural networks outperforms other employment prediction algorithms in terms of accuracy, recall, F1 value, and training speed, proving that algorithms based on the current state-of-the-art deep learning have better prediction results compared to traditional machine learning algorithms and finally evaluating the algorithms used in this paper.

4.2. Quantitative Results of University Students' Employability and Entrepreneurship. The results of the evaluation of the degree of importance of the elements of entrepreneurial human capital indicators of university students show that in the structure of entrepreneurial human capital indicators of university students the weight of entrepreneurial consciousness is 0.312, the weight of innovative spirit is 0.198, and the weight of innovative entrepreneurial ability is 0.49. The innovative entrepreneurial ability has the highest weight and is the most important, and the weight and importance of entrepreneurial consciousness and innovative spirit are second to innovative entrepreneurial ability. This is highly consistent with the objective requirement of entrepreneurial activities for practical skills. The weight and importance of entrepreneurial consciousness are second only to innovation and entrepreneurial ability, which indicates the high importance of entrepreneurial consciousness to the cultivation of entrepreneurial human capital among college students. Gradient descent is continuously used to adjust parameters, so that the error between the actual output and the expected output reaches the minimum convergence, and the degree of fit is the best, which greatly improves the robustness of data processing. The weight and importance of innovation spirit

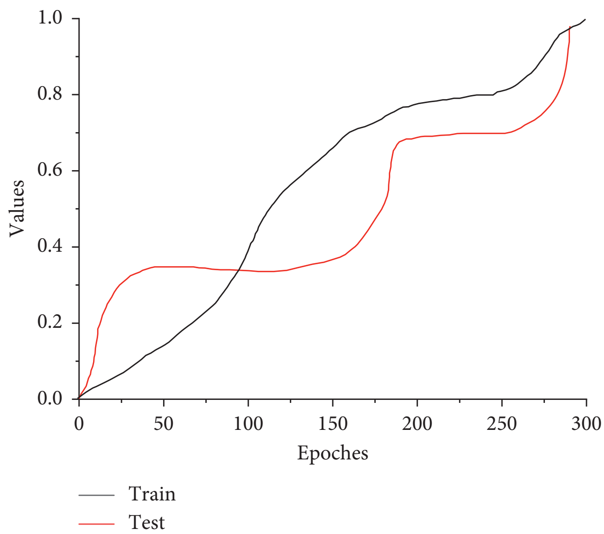

Figure 5: Training set and test set accuracy.

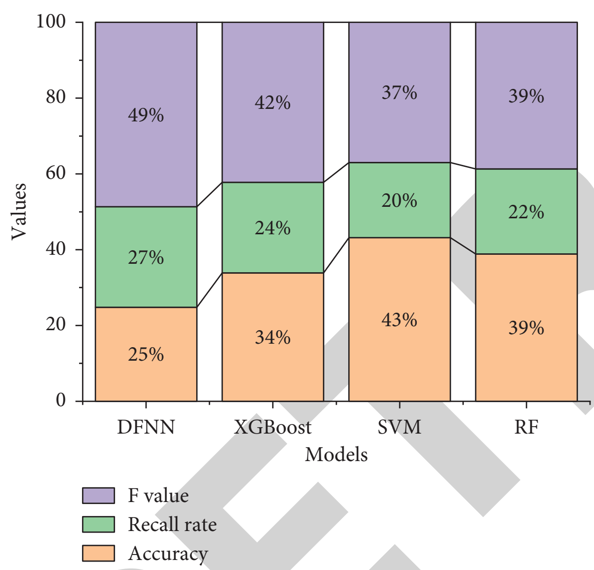

Figure 6: Comparison of prediction results of deep feedforward neural network model with other models.

are lower than innovation and entrepreneurial ability and entrepreneurial consciousness, which may be because innovation spirit is a more implicit and potential characteristic among human capital characteristics and is less visible compared with innovation and entrepreneurial ability and entrepreneurial consciousness, resulting in the relatively low perception of its importance among survey respondents, as shown in Figure 7.

In the evaluation of the elements of entrepreneurial consciousness, the weights of entrepreneurial motivation and entrepreneurial confidence are both 0.5, and the weight of each three-level indicator is the same, which indicates that entrepreneurial motivation and entrepreneurial confidence are equally important to entrepreneurial consciousness. In the evaluation of the elements of innovation and entrepreneurship, the weight of the ability to transform results is the highest, and the weights of innovative thinking, knowledge production ability, and technology transformation ability in the three-level indicators are higher and more important. In addition, the weight of innovation ability is second only to the result transformation ability, while the weight of business management ability is relatively low. The analysis may be due to the lack of experience in entrepreneurship and insufficient enterprise management ability among entrepreneurial college students in research universities in China, which causes the survey respondents to pay insufficient attention to business management ability.

The fuzzy comprehensive evaluation method is a comprehensive evaluation method based on fuzzy mathematics. This comprehensive evaluation method converts qualitative evaluation into quantitative evaluation according to the affiliation theory of fuzzy mathematics; that is, it uses fuzzy mathematics to make an overall evaluation of things or objects that are subject to multiple factors. It has the characteristics of clear and systematic results, can better solve the fuzzy and difficult to quantify problems, and is suitable for various nondeterministic problems. The empirical evaluation of the level of the entrepreneurial human capital of college students is mainly based on the sample data obtained from the questionnaire survey, and the fuzzy comprehensive evaluation method is used to evaluate the current situation of the level of the entrepreneurial human capital of college students in research universities. The overall level of the entrepreneurial human capital of college students in research universities is measured by the results of the scores of three first-level indicators of entrepreneurial consciousness, innovation spirit, and innovation and entrepreneurial ability, as shown in Figure 8.

From the overall score of the evaluation index of the entrepreneurial human capital of college students, the overall level of the evaluation index of the entrepreneurial human capital of college students is good (75.68 points). Among them, innovation and entrepreneurial ability and innovation spirit are at a good level, and entrepreneurial consciousness is relatively low and at a passing level. According to the weight distribution of the evaluation, innovation and entrepreneurial ability have the highest weight and the most prominent importance, followed by entrepreneurial consciousness. The speed of back propagation of network errors is reduced. When the stochastic gradient descent method is iterating, only one sample of the network model input samples will be iterated to update the weight, although this will increase the running speed of the network and reduce the amount of calculation. The results of the comprehensive evaluation of the model show that the innovation and entrepreneurship ability, which has a higher weight, has the highest score (79.82 points), which is close to the excellent level. This indicates that the special group of college students in research-oriented universities has a higher quality of innovation and entrepreneurship ability; the requirements and training objectives of research-oriented universities for students' innovation and entrepreneurship ability are more systematic and professional than other forms of education, and they also put forward more

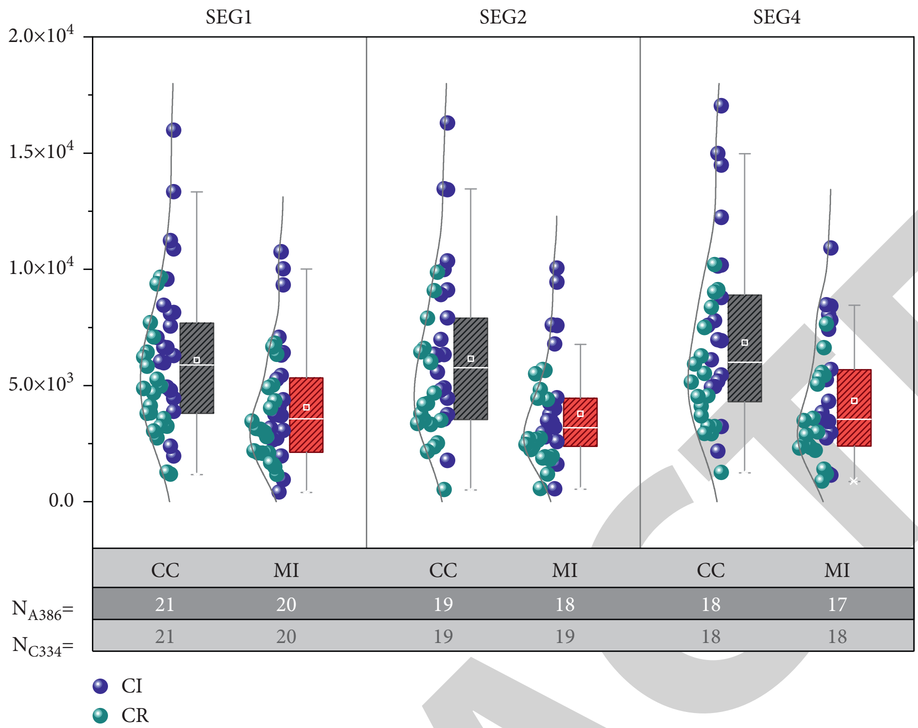

FIGURE 7: Comparison of secondary indicators to which innovation and entrepreneurship belong.

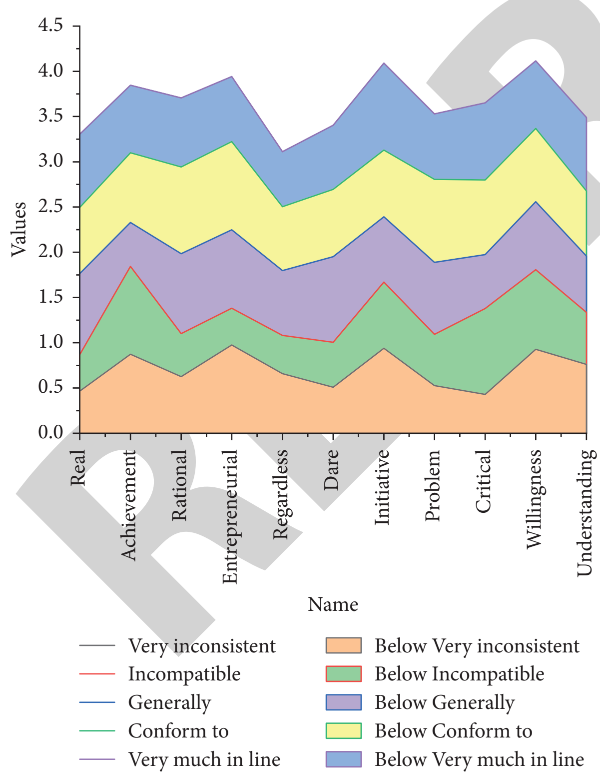

FIGURE 8: Quantitative indicator judgments.

strict requirements on the three core elements of innovation and entrepreneurship knowledge, innovation and entrepreneurship ability, and innovation and entrepreneurship quality. Through the combination of the three elements, the requirements for students' entrepreneurial ability and entrepreneurial quality are formed, and then entrepreneurial standards are formed. For research universities, it is to cultivate research-oriented entrepreneurial talents with innovative consciousness and creativity. Creativity is expressed in the creative thinking, creative knowledge, and creative ability of research university students in the entrepreneurial process, and innovation is expressed in the innovative spirit, entrepreneurial consciousness, and creative personality in the entrepreneurial process.

5. Conclusion

Based on the constructed evaluation indexes of the entrepreneurial human capital of college students in research universities, the overall level of the entrepreneurial human capital of college students in research universities was measured empirically through a fuzzy comprehensive evaluation. To theoretically explore the inner mechanism of entrepreneurial ability generation among college students, the research hypothesis that there is a positive correlation effect between professional ability and entrepreneurial human capital among college students in research universities is proposed and verified by structural equation modeling. The results of the model showed a significant positive correlation between professional competence and entrepreneurial human capital among college students in research universities. In response to the characteristics of data features exhibiting high dimensionality, the sparse connection between features and features, no centralized distribution, and complex and diverse feature attributes, among which discrete features are predominant and continuous features

Academic Editor: Tongguang Ni

This paper conducts in-depth research and analysis on the construction of an English digital resource library for higher education through the cloud platform. The cloud platform allows the English resource library to achieve integration, efficiency, scalability, and interactivity and then solves the problems of how to realize the co-construction and sharing of resources among multiple platforms in vocational institutions and improve the utilization rate of resources. The construction of the English resource library in higher vocational institutions cannot be separated from the collaboration between institutions and enterprises, and institutions must face up to the problems existing in the construction of the current resource library. Firstly, the requirements of various aspects of the higher vocational English digital resource library system are given from three aspects, functional requirements, performance requirements, and operational requirements, in strict accordance with the requirement analysis steps; secondly, the overall technical architecture and network topology architecture of the education cloud platform where the higher vocational English digital resource library system is located are analyzed and given in general to ensure the security, scalability, and ease of operation of this platform and then the resource collection and resource storage. The application of cloud computing technology can solve the problems of difficulty in obtaining teaching resources, insufficient storage space, limited communication, and slow circulation; it can realize the integration and integrated management of various resources through technologies such as networking, virtualization, and distributed storage. Finally, based on the optimization strategies proposed in this paper, the core modules of the higher vocational English digital resource library system are designed and implemented, and some important and representative interfaces and source codes are demonstrated. To ensure the operation performance, the situation of multiple users operating the higher-level English digital resource library system at the same time is simulated, and the overall performance of the higher-level English digital resource library system is evaluated for the common operations such as uploading resource files, downloading resource files, and querying resource files, which confirms the rationality of the design strategy in this paper and greatly improves the user experience and increases the utilization rate of teaching resources.

1. Introduction

With the development of modern science and technology, "informatization" is strongly advocated in all occupations, and the education industry is no exception, and the rapid development of information technology has provided great convenience to the education industry. In recent years, the emergence of various information-based teaching methods such as flipped classrooms, catechism, mobile classrooms, virtual learning communities, and collaborative laboratories have injected new vitality into modern vocational education and provided various channels for students to learn independently. The traditional classroom is no longer the main source of knowledge acquisition for students [1]. The teaching mode of self-learning before class, internalizing during class, and improving after class has become one of the most advocated teaching modes for English teaching in higher education institutions. However, due to the lack of sufficient teaching resources, it is often extremely difficult to implement this teaching model in practice, and its effect is not satisfactory. The use of cloud computing technology can solve the problems of difficult access to teaching resources, insufficient storage space, limited dissemination, and slow circulation; it can realize the integration and integrated management of various resources through networking, virtualization, distributed storage, and other technologies [2]. Using the cloud platform (i.e., cloud computing platform), we can easily realize the integration and utilization of resources, improve the efficiency of resource acquisition, and reduce the cost of resource storage management. Therefore, the establishment of a cloud-based higher vocational English teaching resource library is the most crucial step to solve the current bottleneck problem of higher vocational English teaching [3]. Teachers need to push learning resources to students before, during, and after class, while traditional higher vocational English digital resources have the characteristics of complex, scattered, disorderly, and incomplete content, and they also lack fragmentation suitable for mobile learning. Along with the forward movement of students' learning, the construction of ubiquitous and fragmented digital resources for mobile learning is increasing on the agenda. Traditional high-quality course resources do not have the characteristics of openness and sharing and are not suitable for mobile learning because of their complicated contents [4]. There are more studies on the construction of university English resources, but fewer studies on the construction of higher vocational English resources, and higher vocational students have their own practical and vocational characteristics. The traditional research on the content of higher vocational English resource construction based on cloud platforms is not comprehensive enough, such as the construction of students' independent learning resource library and the construction of a resource library for listening and speaking ability development which involve less content.

Using cloud computing to create an information platform for educational resources, a multitenant model is implemented with the help of SOA, SaaS, and network storage computing, which can be used by various educational institutions or other organizations for training and other purposes. With the distributed and parallel computing technology of cloud computing, the corresponding speed of servers is greatly increased [5]. The platform implements unified management of data, security, and applications in the "cloud" so that users only need to focus on their own business and do not need to spend more time on management. This mode greatly saves the investment of education information technology, changes the way the government invests in education, and will get more economical and better practical results and improve economic efficiency. It changes the obsolete way of learning for students, allowing them to choose their preferred personalized page form and style, select applications and resources on-demand, and integrate their learning, work, and life on this education cloud platform, greatly improving learning efficiency [6]. With the help of the education cloud platform, students can be provided with customized services to meet their different learning needs and learning styles and provide personalized learning support services such as learning tools so that students can develop lifelong learning using the education cloud platform, thus improving the overall education level for the establishment of a lifelong education system. Higher education students are not highly self-aware and do not develop the habit of searching English learning resources from the internet for a long time, much less spending a lot of energy to find learning materials. It is not only in line with the students' existing learning style but also can reduce the difficulty of searching for learning resources and strengthen their interest in English learning. Users only need to focus on their own business without spending more time on management. This mode greatly saves the investment in education informatization, changes the way the government invests in education, and will achieve more economical and better practical results. From the point of view of the development of teaching informatization, with the strong support and advocacy of the education department, the informatization infrastructure of vocational colleges has become more perfect, which has largely promoted the teaching reform, and the introduction of the blended learning model has brought vitality to the informatization process of higher vocational English. However, the lack of teaching resources has become a barrier to this process, and the lack of resources to support the implementation of the new teaching model has affected the final presentation effect Thus, the use of cloud technology to build English teaching resources in higher education is a part of the informatization process that cannot be ignored.

The necessity of establishing a resource bank for higher vocational English can be analyzed from both internal and external aspects: "internal" mainly refers to the change of students' learning style, and "external" mainly refers to the promotion of the information technology education process The internal and external changes and developments have put forward new requirements for learning resources and teaching resources, which make it urgent to establish a resource base for higher vocational English teaching. First, from the perspective of students' learning mode transformation, in the background of network development, students can search learning resources from the internet, and they are used to get the corresponding English learning materials from the internet platform. Cloud computing for higher education is an internet-based cluster service group, which is an easily scalable, user-targeted, and virtualized resource. The construction of a teaching library based on a cloud platform can improve the overall digital management level, deepen teaching reform, improve teaching quality, reduce the cost of software and hardware equipment, improve the utilization rate of resources, achieve maximum resource sharing, and solve the problem of uneven and insufficient resources. Under the teaching system, the analysis of resource data, timely replenishment of various types of tense and scarce resources, and understanding the user learning process propose the most suitable user learning methods and content to achieve push and trigger learning. The teaching resource base based on the cloud platform incorporates teaching resources from all over the world, which is rich in resources and easy to expand, and the platform automatically analyzes the data of the resource base at this stage so that the data of the resource base can be expanded in time according to it to better meet the needs of users. And the platform also recommends excellent learning materials and learning methods according to each user's situation to realize push and trigger learning.

2. Current Status of Research

Modeling user profiles and their integration with the retrieval process is an effective way to develop personalized information retrieval within educational digital repositories [7]. Therefore, it gradually raises the question about the dynamic development of this profile for the resource retrievers to set up queries. Slimani et al. also focused on this issue, and eventually, they proposed two models for personalized search based on digital educational resources. The first approach is to build an index of repository resources, and the second approach is to build user profiles and facilitate their development after each query is submitted by the user based on a classical Bayesian network (a probabilistic graphical model) representing the search activity. This model is used to meet the user's personalized information retrieval needs [8]. Bedenlier et al. focused on the ARIADNE project, supported by the European Commission; the project's goal is to facilitate the sharing and reuse of digital educational resources [9]. To achieve this, a Europe-wide repository of educational resources, called the Knowledge Pool System (KPS), has been created. They found that a key feature of the KPS is the underlying metadata specification, which has been used in a wide range of experiments [10]. This, in turn, is the basis for the emerging metadata standard for learning objects developed by the IEEE Learning Technologies Standards Committee. In their article, they, therefore, focus on the analysis of the metadata model of the ARIADNE project and discuss the ARIADNE tools developed to support metadata authoring, database querying, and course development activities. On the contrary, reliable adaptive systems, which require adaptation strategies and key characteristics of students, will help to automatically change the educational environment. Thus, they introduced an adaptive platform whose constituent parts are personal data, psychological characteristics, and special educational needs. And it can customize the delivery of digital educational resources provided through a database using the specific characteristics of the student. In addition to this, the platform has some adaptations in the user interface to meet the needs in special education.

However, there is a lack of understanding of students' attitudes and competencies regarding the use of digital educational resources in professional learning in the relevant studies [11]. Therefore, Xu analyzed the competencies that students should have in using digital educational resources which include understanding the requirements of using digital educational resources in professional learning and understanding the methods of using digital educational resources in professional learning. Then, he used the experimental method to establish a model of students' ability to use digital educational resources in professional learning and made an experimental demonstration of the validity of the model [12]. With this, he hopes that the process of professional training suitable for students can be optimized, and the use of digital educational resources can be increased. A collection of tags created individually by different users is called a mass taxonomy, and the motivation of such users to tag may have an impact on the data description of the resource [13].

In his study, the focus is on how user motivation to tag resources can affect educational resource creators in terms of resource design. Then, based on the study, methods are proposed to identify the motivations of different types of users as well as to reduce the impact of such user motivations on the metadata of digital educational resources. Finally, it is concluded that a universal resource model is designed to match user motivations, thus more closely matching the individual needs of users. It is reflected in learning through the digital education resource library to make changes in user motivation to explore the resource development model that is more suitable for user needs. The content should be practical, concise, and convenient for mobile learning. Teachers should fully consider the students' English foundation and the actual needs of mobile learning when building an online resource library for higher vocational English. The complex knowledge is miniaturized to facilitate students' mobile learning so that learning can happen anytime and anywhere, thus meeting learners' needs for practicality.

3. Analysis of the Digital Resource Library Construction of English for Higher Education on the Cloud Platform

3.1. Analysis of Digital Repositories on Cloud Platforms. With the development of internet technology, the storage and analysis of big data are imminent, and the resources of colleges and universities have also increased dramatically with the popularity of teaching; the traditional teaching resource platform data cannot meet the requirements of big data storage of various resources due to excessive maintenance costs [14]. It is urgent to migrate the resource data of traditional storage methods to the big data platform and unify the storage and management to provide a rich, user-centered, cloud-based teaching resource library for every teacher and student in colleges and universities [15]. The overall level of education is improved for the establishment of a lifelong education system. Higher vocational students have low self-consciousness, have not developed the habit of searching for English learning resources from the internet for a long time, and will not spend a lot of energy looking for learning materials. Figuratively speaking, the resource library is a bridge built between various available resource servers at the bottom and the application and analysis of resources, thus realizing the migration of teaching resources on-demand, storage management, common construction and sharing, access on-demand, resource analysis, and resource recommendation, comprehensively improving the utilization of resources and increasing the mutual collaboration between teachers and students.

Given the maturity of the internet and the Hadoop distributed storage technology, the server side of this university teaching resource library adopts the Hadoop-based distributed big data storage architecture, and the client side adopts the B/S architecture [16]. The repository provides functions such as accessing various teaching resources from the internet by different users according to their needs, online learning by teachers and students, recommendation of various resources of interest by the system according to the characteristics of the users, resource data migration from traditional resource data platforms, analysis of resource data, management, and monitoring of resource data. The number of file IO accesses should be minimized, which can greatly ease the pressure on the user's synchronous access server and improve the performance of the Hadoop file server. Considered comprehensively, Linux operating system should be used. When storing massive file data, the metadata of the file will generally reach hundreds of *G*, or even reach the TB level, so that it is difficult to load into memory at one time, and on comprehensive consideration, the system uses the HBase distributed database to store the metadata of the file and the absolute address of the file and to create a unique index from it.

When multiple users access concurrently, the client often has relatively low access efficiency, which can be detrimental to the client experience if the access time is too long. This repository should meet the access time efficiency of the client when concurrently accessing large files, but after all, Hadoop is a distributed storage and computing platform developed based on Java, which often has great limitations on the storage and access of a large amount of small data. The system needs to be designed based on the existing small file merging scheme to facilitate both the read operation of small files and the write operation of small files so that the read files and write files can cooperate and do their best to meet the storage, access, and analysis of all kinds of resource data by most teachers and students.

This system provides cloud storage services in the B/S mode, in the server cluster, the web server runs the HUFFS API application, while the database server consists of MySQL and HUFFS cluster server. The client users are connected to the router and switch through the internet so that they can access the Hadoop cluster and get the resources and data in the corresponding cluster as shown in Figure 1.

Various teaching resources contain rich and practical educational information. The teaching resources in this resource library refer to various media materials, online courses, common examination questions, high-quality courseware, and classic cases that have digital form and can provide substantial help to various users in learning, teaching, and research and optimize education-related business processes through various resources. This resource library is required to be built with the participation of people from all occupations to establish its resource-rich, resource-worthy, and substantially helpful resource library [17]. Various users collect various teaching resources through various daily methods, then submit requests for storage resources via HTTP through the terminal client, and finally transmit them to the Hadoop cluster using the TCP connection after forwarding by the web server and then transmit and store teaching resources. To a large extent, it has promoted the teaching reform and the introduction of the mixed learning model, which has brought vitality to the process of higher vocational English informatization. With the participation of many users, this repository will become increasingly rich. However, with the construction of this repository, the number of daily users will increase, and concurrent uploads and storage of various resources will occur from time to time. The response to the request sent to the web server will become very slow due to the load pressure on the web server and will cause the web service to crash, which will seriously affect the user experience. To this end, a message queue-based web server clustering strategy is proposed to optimize the teaching resource request process.

While building this repository, the resources in the old repository are collected after a long time of maintenance and management, and if they are discarded when building this repository, it will cause a great waste of resources. In this paper, we examine the migration of teaching resource data and design and implement a migration of the old repository's resource data to this repository's Hadoop cluster while minimizing the impact on the repository's normal operation, in order to lower the repository's construction costs and increase resource utilization, as shown in Figure 2.

One of the reasons for the construction of this resource library is that the construction of the old teaching resource system is not standardized, the classification of resources is unclear, there is a lack of unified standards, the content is redundant and messy, which is extremely inconvenient for teachers to access various teaching resources and for students to conduct independent learning according to their situation, and brings a lot of inconvenience to the management personnel for the management of various resources; secondly, various teaching resources are reconstructed, resulting in the poor utilization of a large number of storage devices. The cost of maintenance gradually increases in the later period, which brings a certain economic burden to the schools. For the consideration of repository construction cost, avoiding duplicate construction, and improving the utilization rate of existing resources, it is necessary to migrate various teaching resources to this Hadoop repository data platform by using data transfer, data copy, or data migration technology through the business function of this repository to reduce the input cost and improve the utilization rate of resources. Three factors need to be considered in the design of this repository for the migration of teaching resources. Migrating resources intend to reduce costs and avoid duplication of construction, and if the cost of migrating resources is higher than the expected cost, then there is no point in migrating resources. Resource data migration must ensure that the business can be used normally, so it is necessary to choose the least online users late at night. When the data are migrated, the integrity of the data needs to be ensured, and the loss of all kinds of important data cannot be caused by sudden power failure or human intervention. The client adopts the B/S system architecture. The resource library provides different users with

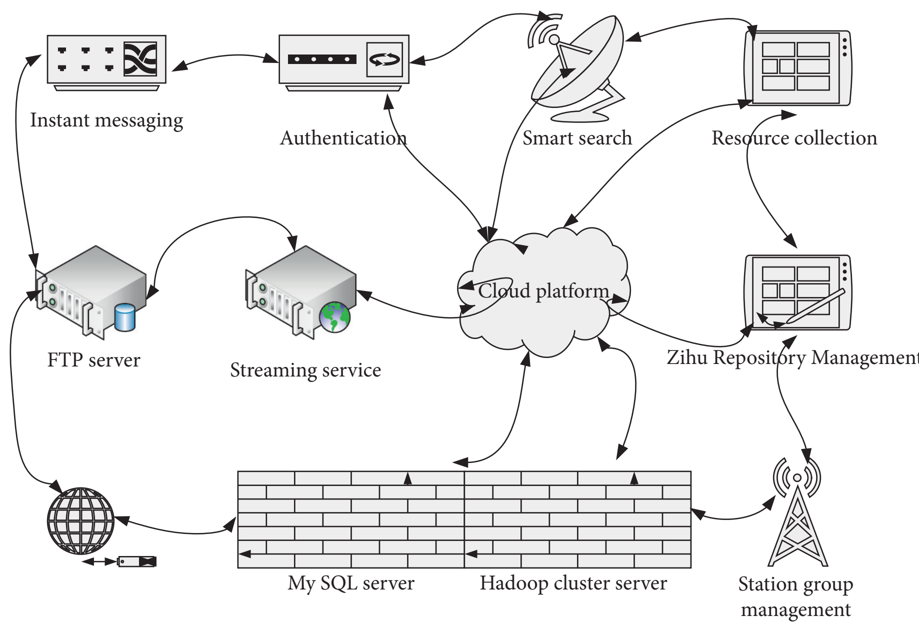

FIGURE 1: Overall technical architecture of the cloud service platform.

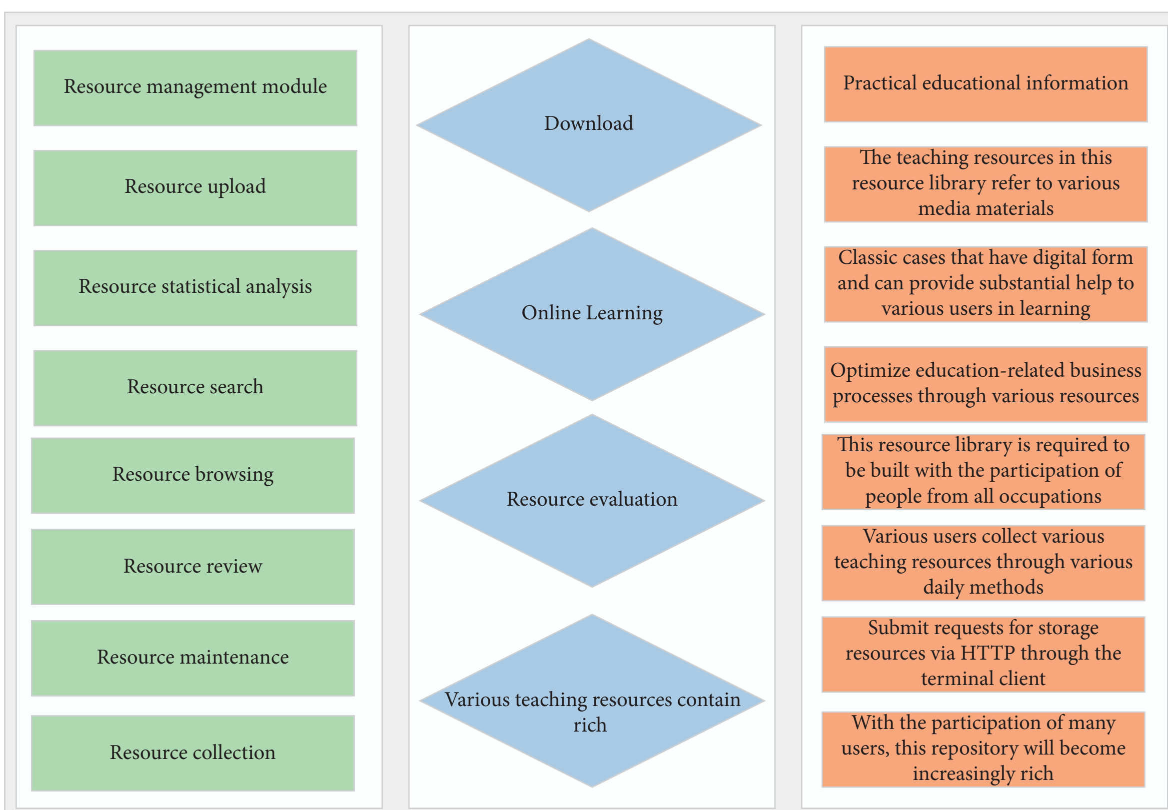

FIGURE 2: Functional diagram of the resource management module.

various teaching resources from the internet according to their needs and online learning for teachers and students, and the system recommends various resources of interest according to the characteristics of users and a traditional resource data platform.

There are numerous methods of data migration techniques, which have been summarized as structured data migration and unstructured data migration. Structured data migration refers to the migration of structured data from relational databases into nonrelational databases through various suitable methods. Unstructured data migration generally refers to copying or moving resource files to a Hadoop cluster in some way. The main methods for unstructured data migration are direct replication copy, data mirroring migration, database built-in tools, etc. The following is a detailed design of structured data migration and unstructured data migration.

3.2. Performance Analysis of the English Digital Resource Library for Higher Education. The module should have the complete management right of the whole system function, with the authority to manage the basic data of the system and manage other users. The system administrator has the highest authority and is responsible for the maintenance and management of the whole system functions and has the authority to access the database directly and is responsible for the parameter setting of the whole system, which includes user management, permission management, file storage path management, announcement management, and database management. The system administrator is not involved in the maintenance of the repository, so he only has the authority to browse the resource information [18]. The resource manager is mainly responsible for the maintenance of the resource library, which includes uploading resources, downloading resources, browsing resources, retrieving resources, approving resources, and other functions. The resource manager can modify or delete the resources when reviewing them, so the position it holds is very important and can be said to be the core part of the whole system. Teachers are the most beneficial group in the resource management system, not only can they browse and download all the resources in the system but also can upload resources to share with other teachers. Teachers have the functions of personal information modification, resource browsing, resource retrieval, resource uploading, resource downloading, resource evaluation, etc. After logging into the system, teachers can browse the resources in the system and download the resources they are interested in to help organize their teaching; at the same time, teachers can also upload their resources to the teachers' private resource library, and if they want to share the resources, they need to apply to the resource manager as public resources and wait for approval before other users can use them. Students are the most used group in the teaching resource library and have the functions of resource browsing, resource searching, resource downloading, and resource evaluation. Students can log in to the system, browse all the resources in the system, and download the resources they are interested in, which provides convenience for learning after school. Students can also retrieve the information in the resource library and search for the information they want to browse. Students can also evaluate the resources and interact with other users while browsing them, as shown in Figure 3.

The statistical analysis function provides school leaders and network administrators with statistics about the resource library for decision-making reference use [19]. There are often great restrictions on the storage and access of a large amount of small data. The system needs to design a set of convenient small file reading operations based on the existing small file merging scheme. The items of statistical analysis include resource uploads, usage, resource access ranking, resource depletion, and statistics on the classification of the resource library and the total number of resources. In resource uploads, we can know the total number of resources uploaded, the number of resources to be reviewed, the number of resources deleted, and the number of users involved in uploads, and we can also see the statistical analysis data of each user's resource uploads. In the resource usage statistics, we can see how many registered users the resource library has, the total number of clicks on the resources, and the total number of favorites created by the users.

This function realizes the user and resource as the center and provides personalized resource recommendation service according to user behavior data. The service object of this function is the user, and the recommendation object is the resource, which solves the problem that it is difficult for the user to choose the resource. This function first classifies the uploaded resources according to the content of the resources to get the resource topic relationship and then forms the resource topic model; then, the system establishes the user personalized interest relationship based on the interest preference information registered during user registration and the daily collected user operation behavior data and then establishes the user personalized interest model Finally, based on the previously generated resource topic model and the user personalized interest model, the relationship between the user and the resource is generated, and a user recommendation model is established to recommend several resources to the user that the user has not acted recently.

The design and implementation of the user personalized interest model for this feature relies on user behavior data, and a wide variety of user behavior data is generated in this feature. Table 1 shows the user behavior data required for this feature. From the data in the table, some behaviors were generated by student and teacher operations, while some behaviors can be generated by all users (including visitors). In terms of data size, the data size of resource online browsing, resource access time, and search resources is the largest, while the data of resource welcome, favorite resources, unfavorite resources, resource comments, and other behaviors can only be generated by registered users (e.g., students and teachers), and these behaviors are of medium size; for downloading resources, resource exposure behaviors can only be generated by a small percentage of registered users authorized by the administrator These behaviors are of moderate size. From the point of view of real-time access, behavioral data such as resource access time, resource welcome, favorite resources, unfavorite resources, resource comments, and download resources need to be accessed in real time. Some behaviors, such as clicking on a resource to view it and searching for it, do not require real-time access.

This feature is mainly to associate users and resources and then make recommendations for resources. And there are 3 main methods to associate between them: user and resource, user and user, and user and resource feature. User-resource means the user is directly associated with a

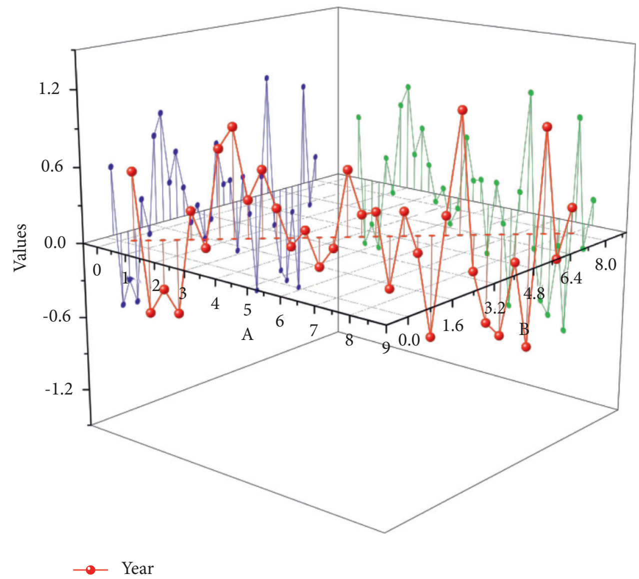

Figure 3: Average number of daily user visits to the platform.

Table 1: Structure of resource relationship data table.

Description	Type	Value	Field name
ID primary key	Int	13	ID
Relational data table number	Int	12324	Table ID
Resource number	Int	4324	Resource code
Resource name	Int	131432	Resource name
Resource relation data ID number	Int	54545	Resource ID
Description	Int	85654	Description

resource; user-user means the user is associated with other users who have similar interests; user-resource feature means the user is associated with certain resource hobby features of the user [20]. It is inconvenient for students to learn independently according to their own conditions, which brings a lot of inconvenience to the management of various resources. The reconstruction of various teaching resources results in low utilization of many storage equipment, and subsequent maintenance costs gradually increase. It also brings a certain economic burden. To facilitate management and design, a user's certain hobbies and other users with similar hobbies can also be treated as resource topics, and then users can be associated through resource topics, as shown in Figure 4. According to the above analysis, when an authorized user logs in to the system, the module will first generate resource topic information for the current user from three aspects, the resource itself, the user's hobby, and the resource characteristics, and then it will search for suitable resource information according to each resource topic, and after a series of filtering and ranking, it will generate a recommendation list for the current user. The core task of this module has two steps: one is to generate resource themes, and the other is to search for suitable resources according to the themes.

This design can be more flexible to recommend the required teaching resources according to the user's expectation; by configuring a combination of different recommendation engines, it can produce different information of the recommended list of resources to meet the user's expectation. If we study carefully, we can find that the recommendation engine is a recommendation strategy algorithm. Different users may require different recommended resources due to various reasons, some research users may like novel teaching resources, while other users may only focus on the type of resources they registered when they registered, so to meet the requirements of each type of user to the greatest extent, various recommendation strategies can be combined through the configuration of their behavioral data. The recommendation of teaching resources can be done by combining various recommendation strategies through the configuration, using the behavioral data of the user, and the hobbies registered at registration. After various recommendation strategies, the original list of recommended resources is generated, and then these resource lists are filtered, sorted, and merged to finally generate my recommended resource list, which is presented to the current user's interface in various visualized ways for the user's browsing and downloading.

4. Analysis of Results

4.1. Performance Results of the English Digital Resource Library for Higher Education on the Cloud Platform. The purpose of system testing is to check whether the software

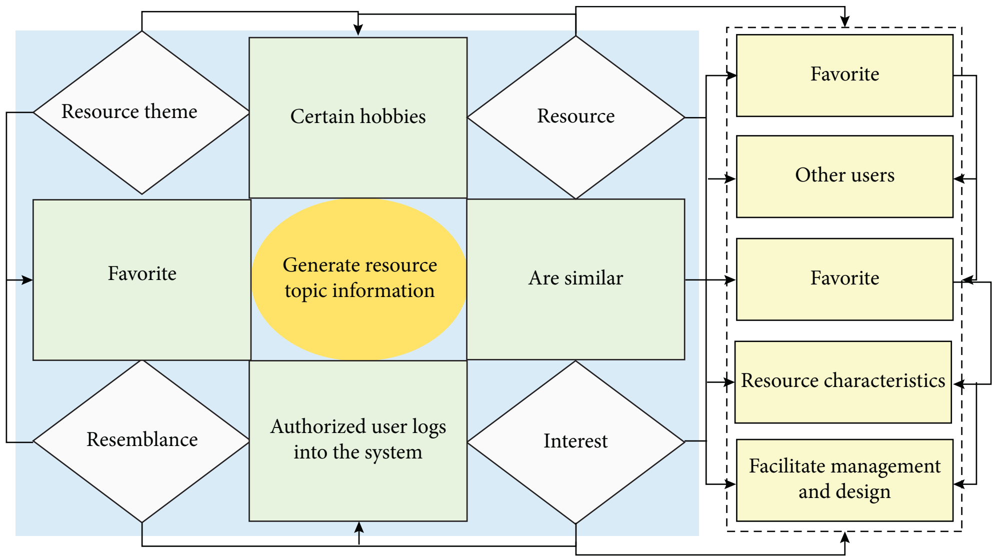

Figure 4: Map of ways to reach out to users and resources.

system meets the requirements; through testing, we can immediately find out the possible logical or physical errors in the software system and then better improve and optimize the system. This repository system is mainly used by many teachers and students, and the testing of this repository system is completed by functional testing and performance testing to ensure the normal operation of the system. To build the test environment, this repository uses the Eucalyptus cloud computing platform to build a private cloud environment and deploys Hadoop cluster, HBase, and MySQL database on it to store and manage various resources. This repository private cloud platform requires 10 physical servers, and the specific configuration and installation components are shown in Table 2.

Functional testing (also known as black-box testing) is a type of testing that only needs to confirm whether the module is functionally complete and correct, without focusing on the specific logic code. Finally, the test cases of the system are written according to the actual situation of the test results, and then the bugs in the system function can be modified immediately to ensure that the system works properly. All the test cases in this use case table cover all the core functional points, and all of them have passed the tests, responsible for the parameter settings of the entire system, including user management, authority management, file storage path management, announcement management, and database management. To ensure that the repository can better serve many students and teachers, it is necessary to test the resource storage performance, system swallowing metrics, IO response speed, and system response time of this repository. To ensure the integrity and correctness of the repository resources, three copies of each resource file are stored on the Hadoop resource cluster. Since the target users of this repository system are teachers and students of the school, although the school users may be over 10,000, the possibility of operating this repository system at the same time is very low, and it is known from experience that the amount of simultaneous online users will not exceed 1000, and the size of relevant resources in the repository is within 100 M. In summary, this test establishes 1000 users, and each user uploads 100 resource files of size 100 M once, the total size of the resource files is 10 TB, and each resource file has 3 copies, so it takes up a total of 30 TB space. To facilitate resource management, a user folder is created for each user in the cluster resource folder. Since a large amount of test data is used for this test, a shell script is executed to simulate the upload of the resource files, as shown in Figure 5.

In today's era, with the increasing amount of information, large data storage has become possible. According to the survey, the size of resource files generally does not exceed 5 G. To test the upload performance of large resource files, we prepare a large file of about 5 G and upload it synchronously through this repository system, which takes a total of 12430.4 seconds, and when downloading the large file, it takes a total of 11895.2 seconds, which meets the user's expectation. To simulate the concurrent load of certain users, monitor the performance of this repository system in real time, conduct a comprehensive test of the architecture of this repository, minimize the test time, and optimize the performance of this system to confirm and find problems early, the following LoadRunner test tool is used to conduct a load test of this repository system. It solves the problem that it is difficult for users to select resources. This function first classifies the uploaded resources according to the content of the resource, obtains the resource theme relationship, and then forms the resource theme model. This time, we recorded a series of operations such as user login, resource browsing, resource uploading, resource downloading, and logging out and then created a script to define load test scenarios, run scenario management, and monitor load tests to understand the performance of this repository and potential bottlenecks in real time.

After functional testing, the integrity of this repository system, the independence of resource data, and the high cohesion and low coupling of system modules are ensured; after performance testing, the high efficiency of system

Table 2: Physical equipment of the infrastructure platform.

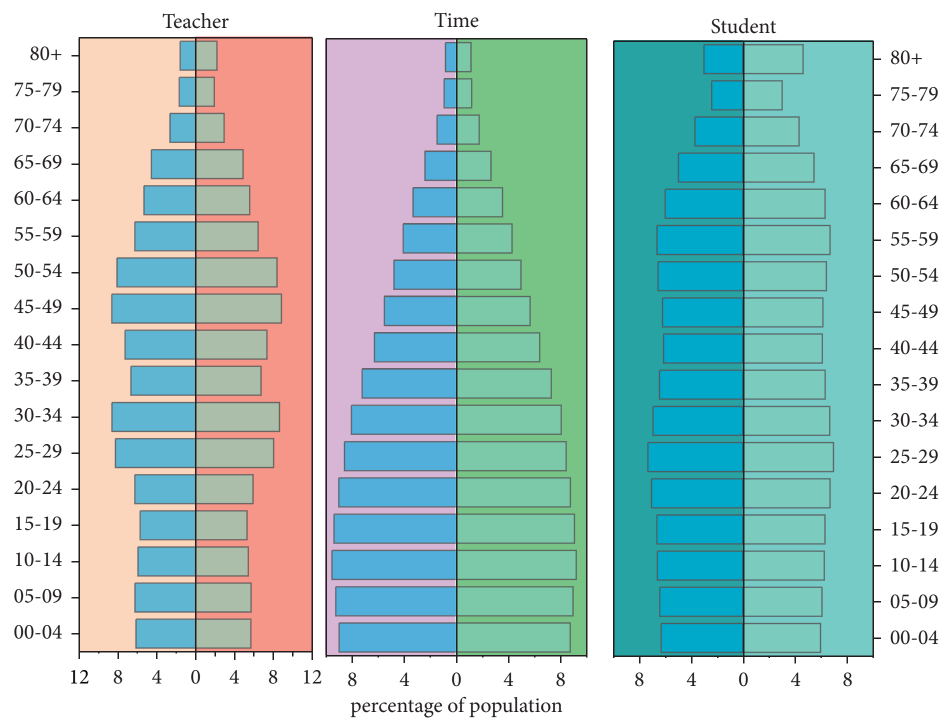

Figure 5: Analysis results.

access, the fault tolerance of resource data, the high scalability of resource servers, and the load balancing of data nodes of the repository are ensured. In summary, the number of interactions per second processed by this repository is relatively smooth, the load balancing capability is qualified, and the system response time is within the acceptable range of users, which is in line with the advantages of cloud computing for large-scale applications. Firstly, the test environment and the steps to build and publish to the private cloud platform are given, then the functional tests of the business functions of this repository are conducted, and some core test cases are given; secondly, the system performance tests of the business functions of this repository are conducted using the LoadRunner software tool, and after analysis and synthesis, the conclusion that this repository meets the initial requirements of users is given.

4.2. Analysis of Experimental Results. After testing, the system was able to accurately verify the normal login of legitimate users, accurately identify different permissions of different users, and smoothly access different management interfaces according to the user's click operation requirements. Logging into the system as different users, they visited the front page of the system and clicked on any resource to test whether they could browse resources, retrieve resources, download resources, collect resources, and evaluate resources; users other than visitors visited the back page of the system to test whether they could upload resources, review resources, modify resources, and delete resources. After the test, the results are as follows: all users can browse resources and retrieve resources; users other than visitors can download resources, collect resources, and evaluate resources; teacher users and resource administrators are allowed to upload resources; load test is a test method to test whether the system can work properly within a certain load level. Generally, you can test by increasing the number of accesses at the same time. For example, the first 50 people access the system at the same time to observe the system condition; if the system is normal, then increase the amount of access until the system cannot afford to crash.

In terms of the pedagogical effectiveness of the resources, teachers generally have a high level of agreement that the EngageNY platform digital education resources provide greater progress for students. Also, from RAND Corporation, a survey of teachers in CSSS-adopting states about the instructional effectiveness of EngageNY and other resources for themselves or their students showed that, across all dimensions, significantly more teachers felt positive about the instructional effectiveness of the EngageNY platform resources than about the instructional effectiveness of other resources. Then, the appropriate resource information will be searched according to each resource topic, and after a series of filtering and ranking, a recommendation list of the current user can be generated. This is because mathematics teachers generally believe that EngageNY is more likely to provide students with opportunities to explain learning and demonstrate teacher work, with more emphasis on conceptual understanding, procedural skills, and practice for the same amount of instructional time and intensity. English teachers who used EngageNY felt that the platform provided students with opportunities to read nonfiction texts of sufficient complexity to greatly enrich their vocabulary and practice skills, as shown in Figure 6.

The planning and construction of the resource bank must be scientific and reasonable to maximize its effectiveness and to make its utilization rate sustainable. At the same time, the content and modules of the resource library should be determined by combining the teaching objectives of higher vocational English and the learning characteristics of higher vocational students. The construction of the resource library should be student-centered, and the resources should be summarized and integrated according to the students' interests and employment-oriented so that students can find the contents they are interested in and can apply them to their studies in the resource library. In addition, all the contents in the resource library must be divided into different categories and clear. First of all, two modules can be set up according to the classification of courses, basic English module and professional English module, among which professional English should be divided into logistics English, mechanical English, automotive English, secretarial English, and other submodules; then, set up subcategories under the major course modules: teaching courseware, microlesson videos, exercises, test questions, skills' training, vocational examinations, and other contents so that teachers and students can quickly find the materials they need.

The construction of the English resource library is not a one-step, ultimate process, but a process that needs to constantly develop and improve with the development of education, so the resource library should make full use of the advantages of the cloud platform to implement dynamic management after the initial completion and adjust at any time according to the needs of teachers and students and development changes. In the process of putting it into use, a person should be assigned to be responsible for the management, timely handling, and repair of problems and regularly collect feedback and suggestions from users to effectively optimize the management and content of the repository. At the same time, the content of the repository should be constantly adjusted and updated according to the changes of relevant professions and social needs after the

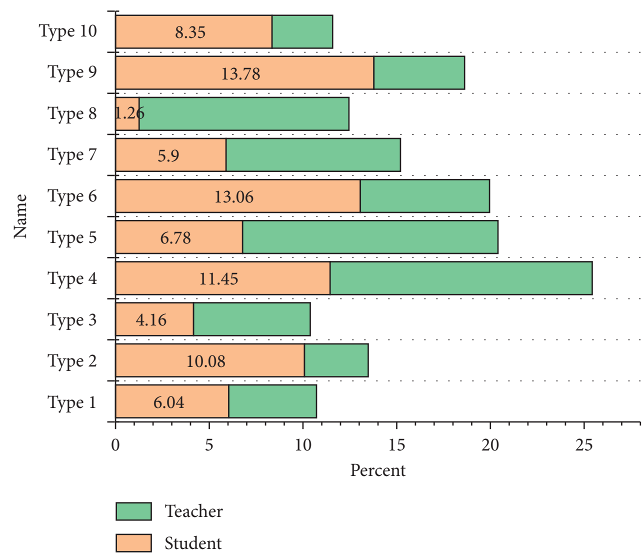

Figure 6: Teaching effectiveness.

repository has been built. Through some incentive mechanisms, users of the repository can be encouraged to upload some useful materials that are not available in the current repository, and then the administrator will include them in the repository after the screening so that the users of the repository can become builders at the same time so that the construction team of the repository can grow and improve the repository, as shown in Figure 7.

Overall, in the second round of teaching practice, there was no significant difference between the scores of the two groups on the accompanying test, which verifies that the application of digital teaching resources from the initial adaptation to the emergence of teaching effectiveness is not achieved in one or two class periods. The existence of significant differences on the topic in the teaching practice is related to the application of digital teaching resources, with the help of which the author carried out rich teaching activities and strengthened the practice of sentence variation in a subtle way, in which the application of digital teaching resources was first seen to be effective.

Overall, as shown in Figure 7 of the ratio of classroom teaching behavior category analysis in group A, the ratios of teacher-student behavior in the experimental class were 53.86% and 46.14%, respectively, and the ratios of teacher-student behavior in the control class were 60.43% and 39.57%, respectively. In the second round of teaching practice, the teacher-student behavior ratios in the experimental class tended to be balanced, and the status of teachers and students in the classroom teaching supported by digital teaching resources tended to be equal, and the problems in the first round of teaching practice were avoided in the second round of teaching practice.

Analyzed from the perspective of the actor, the ratio of teacher's behavior in the control class of group A was higher than the ratio of students' behavior; analyzed from the perspective of behavior type, the teacher's verbal behavior was much higher than the students' verbal behavior, the teacher's speaking component was more, the ratio of

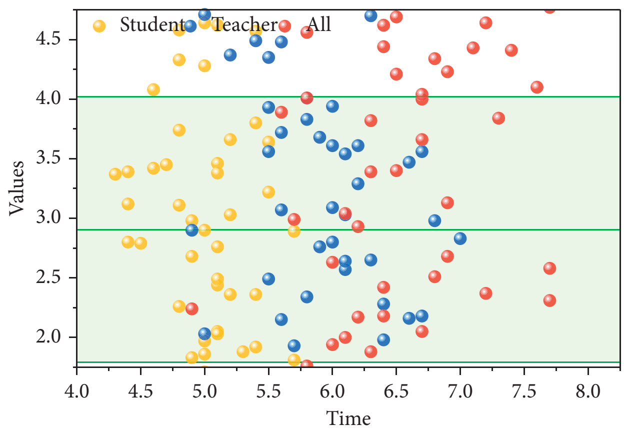

Figure 7: Results of the hands-on follow-on test.

students' activity behavior was higher than the teacher, the ratio of students doing exercises was higher, and the teacher-student interaction was less.

5. Conclusion

The construction of the resource base of any discipline cannot be achieved overnight but requires long-term persistence, constant updating, and dynamic management. This is especially true for the construction of the English resource base in higher education, which should not only be developed and improved with the development of education but also expand the content of the resource base in time with the social trend. Therefore, in the process of construction, the resource library can be dynamically managed by using the dynamic advantages of cloud computing technology in the data processing. Firstly, based on the changing needs of teachers and students, we will adjust, collect feedback from users, and optimize the content of the resource library management. To build a test environment, this resource library uses Eucalyptus cloud computing platform to build a private cloud environment and deploys Hadoop clusters, HBase, and MySQL databases on it. Secondly, according to the relevant professions and social needs, the resource library should be updated with English news, e-commerce information, and international expositions to help students understand the cultural background knowledge of business English, cultivate cross-cultural awareness, and enhance business English application skills. To sum up, the cloud era under scientific development has brought challenges and opportunities for higher vocational English and promoted the process of education informatization reform. To better play the function of cloud platform in the education field, relevant teaching researchers in higher vocational institutions should make full use of cloud computing technology to build the English resource library, combine the advantages of the cloud platform, make the resource library develop in the direction of efficiency, scalability, interactivity, and integration, realize resource sharing, improve resource utilization, provide perfect resource support for teachers' teaching and students' learning, and come out of a suitable path for the creation and application of higher vocational English resources. The aim is to develop a development path that is suitable for the creation and application of English resources in higher education.

The competition among enterprises is becoming increasingly fierce. The research on the financial management evaluation model is helpful for enterprises to find possible risks as soon as possible. This paper constructs the financial management evaluation model based on the deep belief network and applies the analytic hierarchy process to determine the weight of financial management evaluation indicators, which is compared with other classical deep learning evaluation methods, such as KNN, SVM-RBF, and SVM linear. It has achieved an accuracy of more than 81%, showing a satisfactory prediction effect, which is of great significance to formulate corresponding countermeasures, strengthen financial management, improve the capital market system, and promote high-quality economic development. In addition, aiming at the problem of abnormal financial data, this paper uses the new sample dataset obtained by principal component analysis for convolution neural network model learning, which enhances the prediction accuracy of the model and fully shows that deep learning is feasible in the research of financial management prediction, and there is still a lot of space to explore.

1. Introduction

With the development of society, financial intelligence increasingly affects our life and has a great impact on the traditional financial work, which is a topic of concern to enterprises all over the world. By importing data into the database or taking the existing data in the database as the analysis object [1], financial intelligence processes the data according to the financial management model and uses the high-speed and accurate computing power of the computer to quickly obtain the enterprise operation diagnosis report, so as to form a fast and reliable basis for business decision-making [2]. As a popular direction in the computer field, deep learning technology has been closely combined and applied with the financial field. Using reasonable deep learning technology can solve the problem of efficient automatic data analysis in the financial industry, provide valuable prediction information for managers, and provide reliable early warning for healthy institutional operation [3].

Throughout the research trends of financial management evaluation at home and abroad, it mainly focuses on financial evaluation indicators and evaluation models. In the selection of financial management evaluation indicators, existing studies mainly focus on which indicators can accurately predict enterprise crisis [4]. It has experienced the common application stage of multidimensional indicators from single financial ratio indicators and multivariable financial ratio indicators to the combination of financial indicators and nonfinancial indicators [5]. The above studies have achieved certain prediction results, but the selection of multidimensional early warning indicators usually uses statistical methods to test the normality and significance of sample index data and then combined with manual discrimination based on professional ability to select indicators. The selection method is more complex, and there is no unified conclusion on which indicators to select. In the selection of early warning models, early scholars often used univariate model, logistic model, discriminant analysis model, and so on [6]. With the development of information technology, a large number of open real data information can be obtained in the process of enterprise operation. These data can often reflect the past risk status of the enterprise and even some characteristics of the risk of the whole capital market [7]. Therefore, scholars began to apply neural network, support vector machine and other models based on artificial intelligence methods to financial crisis early warning. Generally speaking, the early warning model based on artificial intelligence method has made great progress in the mechanism and systematicness of early warning. It not only overcomes the limitations of the early warning model based on statistical method, such as requiring data to obey normal distribution and complex calculation and analysis, but also has strong fault tolerance and learning ability [8]. At present, artificial neural network has developed to the stage of deep learning network, which is characterized by self-learning and high dynamic adaptability. Therefore, deep learning is also applied to the field of financial management evaluation.

Deep learning can complete a lot of regular, simple, and repetitive work. The application of financial intelligence technology in the financial field has played an important role in improving business efficiency, reducing work errors, and preventing and controlling enterprise risks. This paper studies the financial risk by establishing the financial management evaluation model, which is a quantitative method. It is different from the qualitative analysis. The work is difficult, and the accuracy is low. The model research has higher reliability and uses the analytic hierarchy process to determine the enterprise evaluation index system. This model interprets the historical data, links the characteristics of the data with the financial situation of the enterprise, and then uses the existing data to analyze and predict the future, so as to ensure the accuracy of the prediction.

2. Related Work

Ng et al. proposed a new fuzzy CMAC (cerebellar model articulation controller) model based on reasoning component rules as a new method for bank fault classification and early warning system [9]. Artificial neural network is introduced into financial management evaluation for the first time. Artificial neural networks not only deal with the lack of data errors, but also allow for timely adjustment of internal control parameters. Erhan et al. have proved through practice that the unsupervised training method can better describe the complex functional relationship, which provides a good reference for financial risk early warning. Through the establishment of Yahoo information bulletin board, Jones studied the impact of network information on financial management by using the method of deep learning [10, 11]. Through the establishment of online information bulletin board, Jones reduced the fluctuation of stock price and found that investors' differences of opinion may reduce risk and increase turnover. Through the analysis of stock related blog information in support vector machine, Choudhury found that the fluctuation of stock price will be affected by blog content [12]. Tetlock conducted a 24-year analysis of 500 listed companies [13] and counted the negative words in various reports in this period through the method of deep learning. On the basis of the relationship between corporate income and stock income, this paper points out that the negative words in the news reports of listed companies can predict the decline of listed companies' profits and reevaluate the listed companies. Under the pressure of trading, news content may capture some information that is difficult to quantify, which has a certain early warning function in media reports. Najafabadi et al. abstracted the deep learning algorithm into data representation through the hierarchical learning process [14]. This method has attracted great attention from data science. It is widely used to solve problems, such as network security, medical information, national intelligence, and marketing. Jason Kuen and chin poo Lee applied deep learning to the representation of visual tracking invariance [15] and achieved good results through strong spatiotemporal constraints and stacking slow convolution tracking. Yudistira and Kurita [16] proposed that deep learning processor has become the most potential solution to accelerate deep learning algorithm and pointed out the disadvantage of low efficiency of assembly instructions written by deep learning, which puts forward higher requirements for the research of deep learning.

To sum up, although there are many researches on deep learning at home and abroad, covering a wide range of fields, they mainly focus on theory, speech recognition, and image recognition, which are the feature judgment of known information and lack of relevant empirical research. Many literature studies show that deep learning can well describe complex functions, and financial management evaluation can also be used as a complex function judgment, but so far, deep learning has not been used in the research of financial management evaluation. Based on the previous research, combined with the characteristics of financial management, this paper applies deep learning to the evaluation model of financial management.

3. Evaluation Modelling Based on Deep Belief Network

3.1. Deep Belief Network Model. Deep learning is a category of machine learning that focuses on neural networks. Machine learning can be applied to image, speech, pattern recognition, weather prediction, stock price prediction, gene expression, and content recommendation. This is very similar to the recognition of images by the cerebral cortex. The deep learning model first extracts the low-level features from the original signal, then obtains the higher-level features from the low-level features, and then obtains the higher-level expression. In the face recognition system, the original signal is the pixel, the low-level feature is the edge of the object, the high-level feature is the contour composed of edges, and the high-level expression is the face. Through training with characteristic data, the error is transmitted from top to bottom to fine tune the network. Based on the parameters of each layer obtained in the first step, the parameters of the whole multilayer model are further optimized. Finally, it classifies according to the high-level characteristics and outputs the prediction results of the model. Deep belief network is one of the mainstream deep learning algorithms [17]. According to the Boltzmann machine model of stochastic neural network, the principle architecture of restricted Boltzmann machine [18] is shown in Figure 1.

$a = (a_1, a_2, \ldots, a_{n_v})^T$ represents the offset vector of the visible layer, $b = (b_1, b_2, \ldots, b_{n_h})^T$ represents the offset vector of the hidden layer, and $W = (w_{i,j}) \in R^{n_h * n_v}$ is the weight matrix. The energy function in a deep confidence network generated by multiple constrained Boltzmann machines for any set of neurons with state vector (v, h) is expressed as follows:

$$E(v, h \mid \theta) = -\left[\sum_{i=1}^{n_v} a_i v_i + \sum_{j=1}^{n_h} b_j h_j\right] - \sum_{i=1}^{n_v} \sum_{j=1}^{n_h} a_i b_j h_j v_i, \quad (1)$$

where n_v is the number of all neurons, v is the state vector, h is the state vector in hidden layer, and n_h is the number of all neurons in the hidden layer, and $\theta = \{a_i, b_j, w_{i,j}\}$ denotes the adjustment factors that limit the Boltzmann machine architecture. Through the energy function defined in formula (1), we get the joint probability distribution of state (v, h), as shown in

$$P(v, h \mid \theta) = Z(\theta)^{-1} \exp[-E(v, h|\theta)], \quad (2)$$

where the expression of $Z(\theta)$ is shown in

$$Z(\theta) = \sum \exp[-E(v, h|\theta)], \quad (3)$$

where $Z(\theta)$ is the normalization parameter. It can be seen that in order to obtain $p(v|\theta)$ and $p(h|\theta)$, the key step is to calculate the normalized parameter $Z(\theta)$. The connection of a DBN is guided and determined by generating weights from top to bottom. RBMs is like a building block. Compared with the traditional and deeply layered sigmoid belief network, it can easily learn the connection weights. The probability of activation of a neural unit in the hidden layer can be calculated by the following formula [19]:

$$P\left(h_j = 1|v, \theta\right) = \sigma\left(b_j^2 + \sum_i \sqrt{2}\, v_i w_{i,j}\right), \quad (4)$$

where $\sigma(\bullet)$ indicates sigmoid activation function. The stochastic gradient algorithm is usually used to find the maximum value of $\sum_{i=1}^{t} \log P(v_i|\theta)$. The momentum coefficient is generally taken as (0, 1). Intuitively, it is understood that if the current gradient direction is the same as the gradient direction of the previous step, the weight update of this step will be increased, and if it is different, the update will be reduced. The depth belief network model adopted is shown in Figure 2.

3.2. Determination of Financial Management Evaluation Index by Analytic Hierarchy Process. The evaluation of financial management objectives of logistics enterprises is a complex systematic project, which requires the establishment

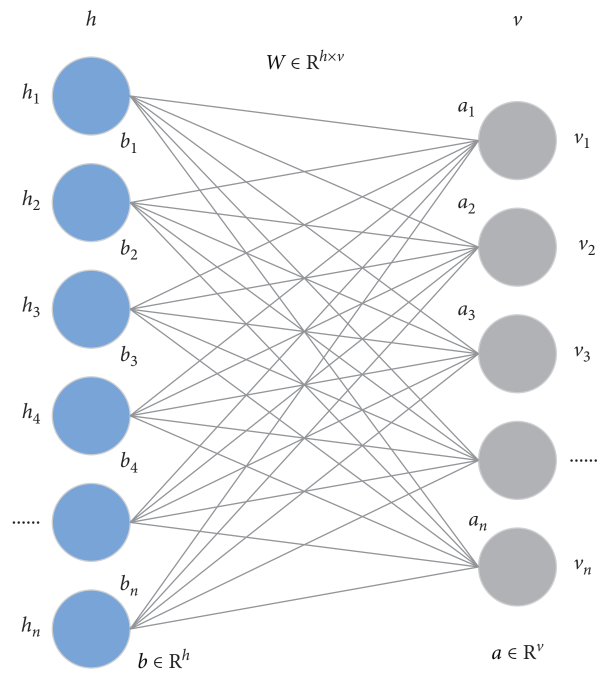

Figure 1: Restricted Boltzmann machine model.

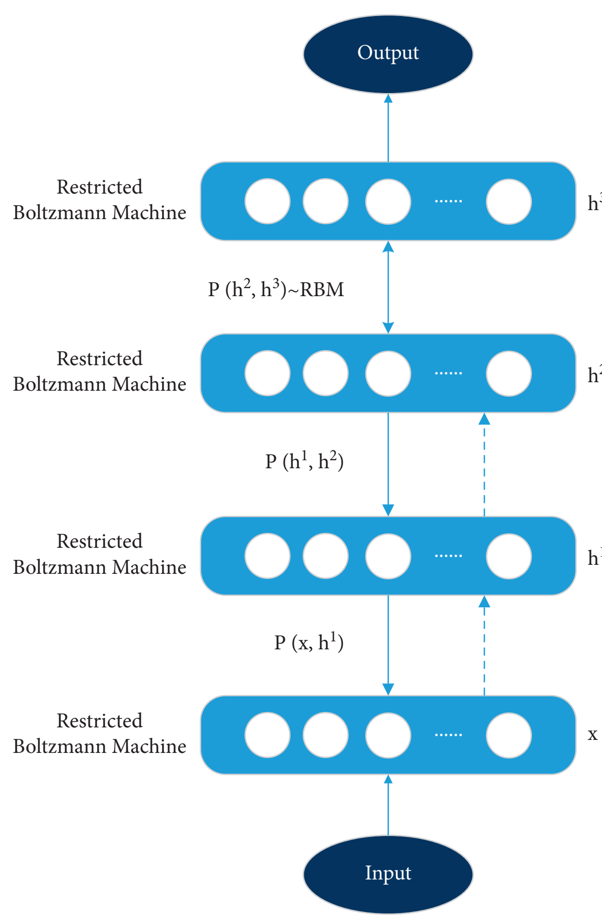

Figure 2: Deep generative model.

of a financial management evaluation system [20]. ST means "special treatment." The policy is aimed at those with abnormal financial or other conditions. The addition of * ST before the stock means that the listed company has suffered losses for three consecutive years, and the exchange makes a delisting warning. The weight of financial management evaluation indicators is determined by analytic hierarchy process. Analytic hierarchy process decomposes the problem into different constituent factors and gathers and combines the factors according to different levels according to the correlation, influence and subordinate relationship between the factors to form a multilevel analysis structure model. It is a model and method for making decisions on complex systems that are difficult to be fully quantitative. The steps are as follows. First, establish a financial management evaluation index system. In order to make a correct evaluation of financial management, we should start from the corporate governance structure; establish the financial management evaluation system from the perspectives of management decision-making and external environment. The corporate governance structure, management decision-making and external environment evaluation are composed of some related elements. See Figure 3 for details.

Then, the judgment matrix A is constructed to obtain the weights of $U1$, $U2$, and $U3$ of the evaluation index system. As an example, the calculation process is illustrated. For the above evaluation index system, the expert group believes that in the evaluation of financial management, corporate governance structure ($U1$) is more important than management decision ($U2$) and external environment ($U3$), and the management decision is more important than the external environment; then $A = \begin{bmatrix} 1 & 2 & 3 \\ 1/2 & 1 & 2 \\ 1/3 & 1/2 & 1 \end{bmatrix}$.

Calculate the product Mi of each row element of the judgment matrix, and then calculate the nth root of Mi. Finally, normalize the vector $[W_1, W_2, W_3]^T$ and calculate the index weight W_i:

$W_1 = \overline{W}_1 (\sum_{l=1}^{n} \overline{W}_1)^{-1} = 0.540$, $W_2 = \overline{W}_2 \ (\sum_{l=1}^{n} \overline{W}_2)^{-1} = 0.297$, $W_3 = \overline{W}_3 (\sum_{l=1}^{n} \overline{W}_3)^{-1} = 0.163$.

Calculate the maximum eigenvalue of judgment matrix A, $|\lambda_{\max}|$:

$$A \cdot W = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix} \begin{bmatrix} W_1 \\ W_2 \\ \cdots \\ W_n \end{bmatrix}. \tag{5}$$

$(A \bullet W)_1 = 1 \times 0.5396 + 2 \times 0.2970 + 3 \times 0.1634 = 1.624$. Similarly, $(A \bullet W)_2 = 0.894$, $(A \bullet W)_3 = 0.4922$. The last step is consistency testing. When $n = 3$, $R_1 = 0.58$, the judgment matrix has satisfactory consistency. Therefore, the weight of $U1$, $U2$, and $U3$ is [0.5396 0.2970 0.1634]. Other index weights can be calculated according to the above method, and the calculation results are shown in Table 1.

When $C_n = 0.0048$, $R_n = 0.90$, and $C_{R1} = 0.0054$, the judgment matrix has satisfactory consistency. When $C_{I2} = 0.0192$, $R_{I2} = 0.58$, and $C_{R2} = 0.0562$, the judgment matrix has satisfactory consistency. When $C_{I3} = 0.0268$, $R_{I3} = 0.58$, and $C_{R3} = 0.0562$, the judgment matrix has satisfactory consistency. The weight distribution data of indicators at each level are summarized in Table 2.

3.3. Intelligent Detection Model of Financial Data. Time series data is a data column recorded by the same unified indicator in chronological order. All data in the same data column must be of the same caliber and must be comparable. As IOT brings a large amount of time series data, we need to time slice the time series data. The traditional time-series data processing methods include median, extreme value, deviation, variance, year-on-year, month-on-month, and periodic methods. These methods can only roughly summarize the data and form a preliminary understanding. The overlapping slicing method of sliding window is used in this paper. This method sorts and counts the target data according to the time sequence, delimits the length and size of each window, summarizes and calculates the characteristics of each time period window, analyses different data with the same dimension in continuous time periods, and obtains the change trend of the target data. In this paper, it will be solved by convolution neural network, as shown in Figure 4.

Firstly, after the training data is processed by zero mean, principal component analysis is carried out to reduce the input parameters of convolutional neural network model and reduce the correlation between input factors. Then, the new sample dataset obtained by principal component analysis is used for convolutional neural network model learning, and the parameters in convolutional neural network are continuously adjusted by gradient descent. Finally, the test sample data are applied to the model to verify the prediction accuracy of the model.

Since this study only considers the impact of historical data on future enterprise finance, a one-dimensional convolutional neural network is adopted. The model includes two convolutional subnet works, as shown in Figure 5. The input layer is m k-dimensional index data output from formula (4), and the output layer is two classifiers. The convolution layer is used to extract different features of the input layer, the linear rectification layer is used to activate neurons in the network according to the linear function, the pooling layer is used to reduce the data dimension, and the full connection layer is used to combine all local features and calculate the final classification result.

In this study, the input data for one-dimensional convolutional neural network is the k-dimensional orthogonal feature Y'_{ij} of M companies. Then, three convolutional subnetworks are used to deeply learn the orthogonal feature data of enterprises. The first convolutional network selects 128 convolutional cores with the size of $1 * 3$, and the second convolutional network selects 128 convolutional cores with the size of $1 * 4$. The third subconvolution network selects 128 convolution cores with size of $1 * 5$. The calculation formula is as follows:

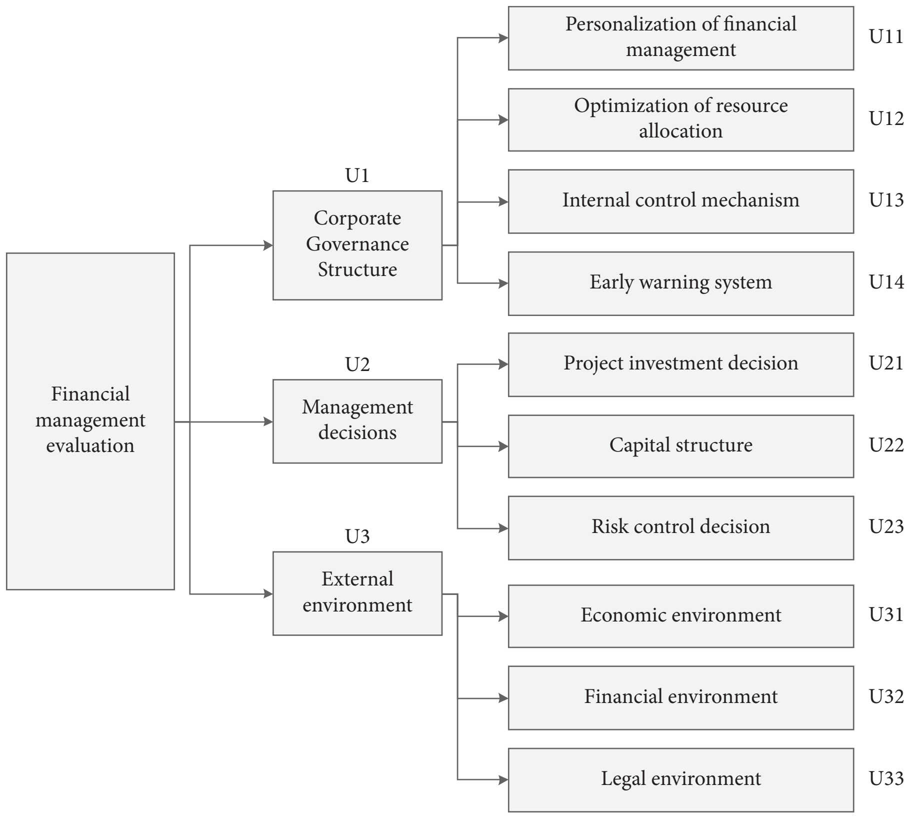

Figure 3: Comprehensive financial management evaluation system.

Table 1: Index weight.

	$U11$	$U12$	$U13$	$U14$	Weight
$U11$	1	2	3	4	0.6532
$U12$	1/2	1	2	3	0.3841
$U13$	1/3	1/2	1	3	0.2890
$U14$	1/4	1/3	1/2	1	0.1206

Table 2: Weight distribution data.

Index	$U1$	$U2$	$U3$	$U11$	$U12$	$U13$	$U14$
Weight	0.5396	0.2970	0.1634	0.4832	0.2717	0.1569	0.0882
Index	$U21$	$U22$	$U23$	$U31$	$U32$	$U33$	
Weight	0.6369	0.2583	0.1048	0.5278	0.3325	0.1397	

$$X^{(l)} = f\left(W^{(l)} \cdot X^{(l-1)} + b^{(l)}\right), \quad (6)$$

where $X^{(l)}$ and $X^{(l-1)}$ are the neuron output values of layer l and layer $l-1$, W^{l} is convolution kernel, and b is offset. The activation function adopts a modified linear unit. For the input x, the weight vector is ω, and the output with offset b is max $(0, \omega x + b)$. The linear activation function simply sets the threshold to zero, which greatly reduces the computational overhead. Moreover, compared with the expensive operations (exponents, etc.) of sigmoid and tanh neurons, relu can be activated through a simple zero threshold matrix and is not affected by saturation. Meanwhile, $L2$ norm is used to normalize the fitting cost, as shown in

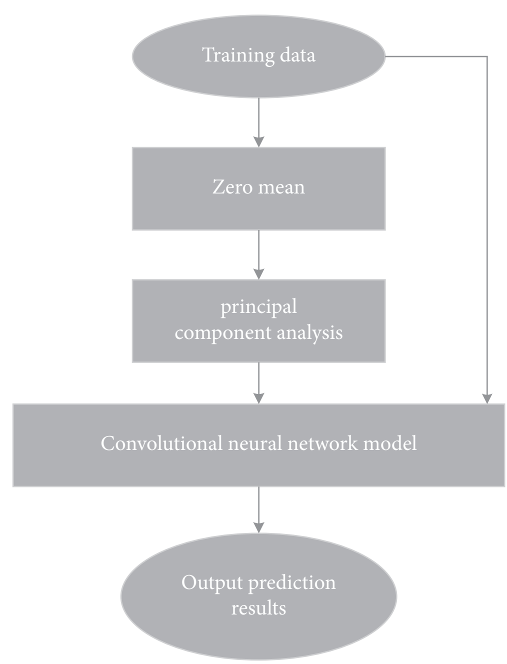

Figure 4: Financial management model framework based on convolutional neural network.

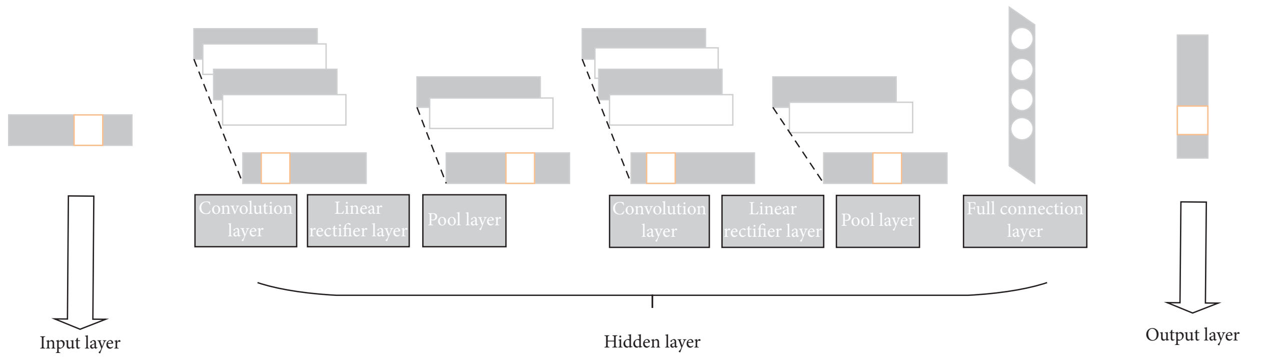

Figure 5: Framework of one-dimensional convolutional neural network model.

$$C = -n\sum_{1}^{x_j}\left[y_i \ln a_j^l + (1-y_i)\ln(1-y_i)\right] + n\sum \lambda\omega^2, \quad (7)$$

where the first term represents the cross entropy cost, the second term is the sum of squares of all weights added, and then the factor used $\lambda/2n$ to make quantitative adjustment, and $\lambda > 0$ is called the normalization parameter. The third convolution subnetwork outputs to the full connection layer and then outputs the final binary result; that is, whether the enterprise is ST in this study, the output result of ST enterprise is 0 and that of non-ST enterprise is 1 [21]. At the same time, this study uses the maximum pooling method to pool local feelings and selects the flexible maximum method to solve the problem of slow learning.

4. Results and Safety Analysis

4.1. Data and Empirical Design. In the future, A-share may form a two-way benign expansion of supply and demand, and the regulatory authorities' policies on its stock market are also more effective and in place, which is conducive to the dynamic balance of supply and demand. There are ST system and * ST system in stock market. From the perspective of data availability and effectiveness, it is a reasonable method to use enterprise stock ST or * ST as the symbol of enterprise financial crisis.

This paper first selects the companies that are ST and * ST (hereinafter referred to as ST companies) and then finds out the corresponding companies of each ST or * ST company (hereinafter referred to as non-ST companies) in the companies with normal financial conditions according to the industry and average total assets. Use the financial index data of ST companies and non-ST companies in the previous years of 2016 to predict whether there will be a financial crisis in 2016 (by ST or * ST), compare with the actual situation, count the accuracy of the prediction, and conduct empirical analysis. This paper selects a total of 3513 companies. The reason for data normalization is that the measurement units of each data are different, and the processed data will be between 0 and 1. If the data is not normalized, the gradient descent is carried out in one unit, so its descent step in each direction is the same. Non-standardized data will cause the gradient to follow a zigzag route in the direction perpendicular to the contour line when the gradient decreases, which will make the iteration very slow. In general, normalization can make the order of magnitude of each stock index correspond to the length of gradient decline [21].

This paper has conducted four empirical analyses, and the selection of data quantity is shown in Table 3. This paper has conducted four empirical analyses, and the selection of data volume is shown in Table 3. Taking the data of the first few years of 2016 as the training set and the data of the next few years of 2016 as the prediction set, the output result of no financial crisis is 0 and the output result of financial crisis is 1. The judgment result is recorded as x, the actual situation of the company is recorded as y, x and y are 0 or 1, the number of companies in the prediction set is n, and the calculation formula of accuracy P_a is

$$P_a = \left(1 - N^{-1}|X - Y|\right) \times 100\%. \quad (8)$$

4.2. Outcome Evaluation Criteria. Because each simulation will randomly take an initial value, the results of each simulation may be different. The experiments were conducted in four groups based on the size of the years of data selected. In general, the nodes in the hidden layers have an impact on the prediction results. If the number of hidden layer nodes is too small, the network cannot have the necessary learning ability and information processing ability. If too much, it will not only increase the complexity of the network structure and make the network more likely to fall into local minima in the learning process but also make the learning speed of the network very slow. The neural network structure has two hidden layers, and the number of them can be determined by the following formula:

$$\begin{aligned} L &= \alpha^2 + (m+n)^{1/2} \\ &= \log_2 m, \end{aligned} \quad (9)$$

where m and n represent the nodes of the output layer and the input layer, respectively, α can be any value between 1 and 10. These methods can only obtain feasible initial values for the nodes of the hidden layer, and this number usually needs to be corrected during training and learning. Generally, two methods of gradually increasing and gradually decreasing are used to correct the number of nodes in the

Table 3: Empirical quantity statistics.

		ST		Non-ST		Total	
		Number of companies	Amount of data	Number of companies	Amount of data	Number of companies	Amount of data
2 years	Total of training set and test set	55	2805	55	2805	110	5610

		17	3842	17	3842	34	7684
		34	7684	34	7684	68	15368

hidden layer to achieve the expected value and reduce the error to a reasonable range. This study uses formula (9) to calculate the hidden layer nodes and finally obtains the nodes of each network, as shown in Table 4.

From the results shown in Figure 6, the accuracy of the model in predicting whether an enterprise will have crisis can be maintained at more than 81%, which shows that the model based on deep learning has a general prediction effect for A-share listed companies, the more the years of data used for prediction, the higher the accuracy of prediction.

In order to test the effect of model training, this study inputs the test data into the model after the above training and observes the accuracy of the test data. From Figure 7, it can be seen that after training, the accuracy of the model on the training set is 79.1%, and the accuracy on the test set is 91.34%. The results show that the accuracy of the test set is slightly higher than that of the training set, which proves that the model has better generalization ability.

4.3. Intelligent Analysis of Financial Data Based on Deep Learning. In the pretraining stage, each layer of RBM network is trained separately and unsupervised to ensure that the feature vectors are mapped to different feature spaces and retain the feature information as much as possible. It is pretrained by an unsupervised greedy layer-by-layer method to obtain the weight. In this process, the data is input to the visible layer to generate a vector V, which is transmitted to the hidden layer through the weight W to obtain H. In the last layer of DBN, a BP network is set up to receive the output eigenvector of RBM as its input eigenvector and train the entity relationship classifier supervised. Moreover, each layer of RBM network can only ensure that the weight in its own layer is optimal for the eigenvector mapping of that layer, not for the eigenvector mapping of the whole DBN. Therefore, the backpropagation network also propagates the error information from top to bottom to each RBM layer and fine-tune the whole DBN network. The process of RBM network training model can be regarded as the initialization of the weight parameters of a deep BP network. The naive Bayesian classifier in this paper is realized by MATLAB programming. In this section, the financial data of traditional indicators are

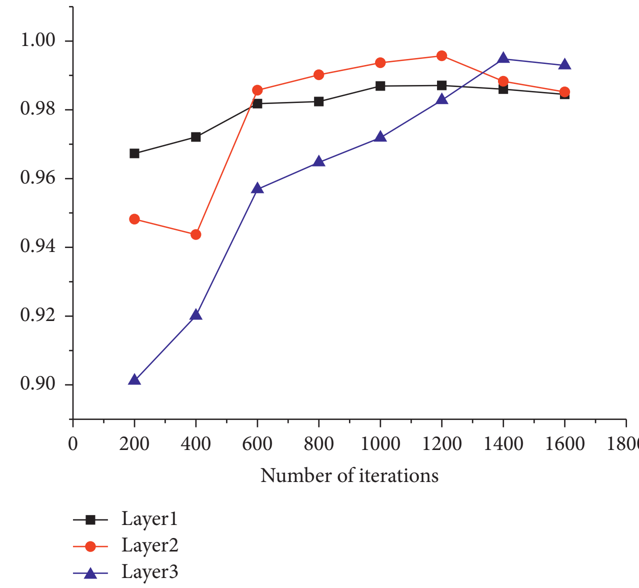

Figure 9: DCNN classification accuracy of different hidden layers.

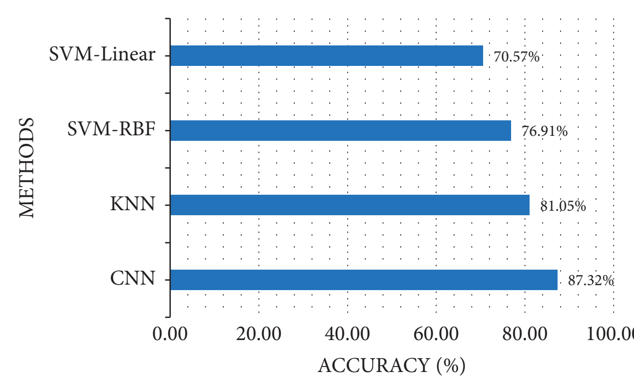

Figure 10: Comparison of prediction accuracy of different methods.

processed by the time-series construction method proposed above and then input into the classifier. After running, the classification effects of traditional models and various forms of models can be obtained. The operation results of each model are shown in Figure 8.

In Figure 8, the recall rate of the time series index model in the ratio form and the first relative value form is the highest. In terms of precision, the time series index model in the form of difference is the best. It can also be seen that the recall rate and precision rate show the law of one change and the other. The comparison of classification accuracy of DCNN under different hidden layer structures is shown in Figure 9.

According to Figure 10, hidden levels 1, 2, and 3 show good classification accuracy, all reaching more than 91%. After 600 iterations, the classification accuracy of the second level reaches 98.57%, which is the maximum of the classification accuracy. Therefore, the convolutional neural network model with 3-layer hidden layer structure has good classification accuracy.

In order to further prove the effectiveness and superiority of convolutional neural network model, this work compares it with traditional classical machine learning early warning methods. The methods used for comparison include *k*-nearest neighbor (KNN), support vector machine Gaussian kernel (SVM-RBF), support vector machine linear kernel (SVM linear). The basic parameter setting of the test is the same as the above. The number of neighbors in KNN is set to 6 and the kernel function parameter of support vector machine is set to 10. Making the weight smaller and smaller, then its corresponding loss function will be smaller and smaller, finally achieving our goal. The smaller the value of the loss function, the more accurate the prediction is. The prediction accuracy of the model established in this study can reach 81.65% showing a good financial prediction effect. This is because convolutional neural network can better learn the correlation between various indexes and extract the most effective abstract features, so as to ensure the accuracy of prediction results.

5. Conclusion

In order to improve the accuracy of corporate financial management evaluation, this paper constructs a financial management evaluation model based on deep learning and uses the data of A-share listed companies from 2007 to 2020 to explore whether deep learning can build a generally applicable financial management model for listed companies. By using the data of different years, it is also concluded that the more the data years the model constructed in this paper uses, the higher the prediction accuracy. The test results show that the intelligent analysis of financial abnormal data based on deep learning is also effective and accurate. Finally, the effectiveness and practicability of the intelligent analysis method are proved by an example.

Data Availability

The data used to support the findings of this study are included within the article.

With the improvement of people's cultural level, more and more museums are being built or renovated. The design of lighting products for museums is a specialized field that requires designers to take into account a variety of factors, such as safety, presentation, and maintainability. As museum lighting systems meet the needs of conservation, visitor experience, and maintenance, the traditional design process is limited by the experience of the designer and the actual situation of the museum, and the actual light conservation effect of the exhibits is difficult to quantify. We have designed a digital-twin-based intelligent lighting system for museums, which can facilitate museum managers to quantify and manage the light life of exhibits while providing a more immersive viewing experience and recognition effect for visitors.

1. Introduction

Lighting design is an important part of museum exhibition design [1–3]. Without the existence of light, the audience will not be able to appreciate the form, material, and color of the exhibits [4, 5]. Without the change of light, the exhibition space will lose its vitality and artistic conception [6]. Because the light is directly related to vision, the construction of light environment is also what designers need to pay attention to when planning the exhibition space and the modeling performance of exhibits. Excellent museum lighting should first have the function of cultural relics' protection [7, 8], and the lighting should filter out harmful infrared and ultraviolet rays. At the same time, due to the damage of visible light to some exhibits, it is necessary to consider the quantity of the exhibits. In addition, the design also needs to choose the light source with appropriate color temperature and color rendering so that the exhibits can be clearly viewed by the audience, and the colors of the exhibits can be restored to the maximum. For the lighting of the whole exhibition area, we should control the glare, contrast, uniformity, and other parameters to create a soft and comfortable light environment so that the audience can immerse themselves in it and enjoy it.

Lighting serves the function of museums [9–11]. Museums [12] have three basic functions: "collection and preservation of cultural relics," "protection and research of exhibits," and "education and appreciation." In order to reduce the damage of optical radiation to exhibits, most countries have formulated standards to provide reference values of illumination and limit annual exposure of different exhibits. However, in order to create a good visual environment for the audience, we need to improve the illumination of the exhibits. Due to the reduction of environmental light [13], the ability of recognition will decline, so will the human visual ability, people will not be able to identify the information that the exhibits need to transmit [13]. To solve this contradiction and realize the balance between exhibits' protection and viewing experience are the key points of museum lighting design. In order to make the museum, lighting environment not only provides a good visual experience for the audience but also minimizes the exposure of exhibits in the exhibition cycle; the lighting design must comply with the principles of safety, reliability, economy, advanced technology, energy saving, and convenient maintenance. In addition, many artificial intelligent technologies [14–17] have been used in some display applications [18–20] and also used in the smart city's applications [21–24].

2. Lighting Design of the Museum

2.1. Museum Lighting Design Requirements. In order to solve the contradiction between the aforementioned viewing experience and the protection of exhibits, some museums use infrared induction technology; the lights are on when people come, and the lights are off when people go. In this way, the exposure time is reduced, and the illumination of exhibits can be appropriately improved. Some studies have shown that the exposure time can be controlled when the illumination is properly increased, and no additional damage will be caused to the exhibits. At the same time, lighting design not only pays attention to the experience of the audience but also needs to consider the experience of managers. With the development of Internet of Things technology and mobile devices, some designers provide mobile terminal management software of lighting equipment for museum managers, realizing intelligent management. Traditionally, owners need to operate lighting equipment switch and maintenance on-site. Now, it can be processed through the mobile terminal.

However, the single induction control, fixed illumination adjustment logic, and simple management software cannot meet the growing needs of museum lighting design. Therefore, it is of great practical significance to design multisensor integrated interactive control lighting products and intelligent management software. We designed a museum intelligent lighting system based on digital twin, which realized the interaction between the audience and the museum lighting equipment through a variety of sensor devices and procedures such as target detection, position detection, and illumination detection, dynamically adjusted the best lighting brightness for the audience, exhibition area, and exhibits, and provided quantitative management of exhibits' health for museum managers.

2.2. Problems in the Lighting Design of Existing Museums. At the beginning of the design, we chose a large comprehensive museum for field investigation, evaluated the existing display design of two exhibition halls, and summarized the existing problems in lighting in order to design a lighting system that can take into account the exposure and display effect of the exhibits; see Figure 1.

We sum up the following four problems:

① The glare of the basic lighting is serious, and the point light source used for the basic lighting in the exhibition hall produces a lot of light spots and glare on the glass cover of the exhibits.

When analyzing this aspect, the first thing is to interpret the angle of natural light. When the light is sufficient, the exhibits will have the optimal visual effects.

② The guiding effect of key lighting is insufficient (see Figure 2), and the brightness of some wall washing lighting is too high, and the range is too large, which affects the local lighting (see Figure 3).

For artificial lighting, we can use the halogen lamps at 45° angle, and the exhibits can meet the general viewing requirements of the audience.

③ The local illumination brightness is insufficient, and the focus range is uneven, which leads to poor display effect and unreal appearance.

In addition, the smallpox part of the display space and the light irradiation of the wall facade are coordinated, and the design of the color sense of the ground is more dark. For the precious exhibits displayed in textiles, clothing, paper painting and calligraphy, and other vertical forms, the angle of light must be more rigorous.

④ During the opening period of the exhibition, all the lighting brightness is constant, and there is still a certain amount of exposure when there is no audience to watch the exhibits in part of the time.

When light angles vertically to 30° of the exhibit, viewing the surface of the vertical artifacts does not produce any glare for the best viewing experience, but the light source is best extended to make the edge of the shade softer (see Figure 4).

In view of the above problems, our research objectives include the following: the lighting design system can adjust the exposure level of exhibits according to whether the exhibits are being watched; that is, when the exhibits are being watched, it can provide the best illumination for the exhibits; when there is no audience around the exhibits, it can enhance the guiding effect of key lighting and, at the same time, reduce the basic lighting and local lighting to the minimum safety limit.

2.3. Related Work at Home and Abroad. The balance between exhibits' protection and viewing experience is the core of museum lighting design. The problem of light damage in museum lighting is not a new topic in the field of museum lighting at home and abroad, but the research on museum lighting design is still in the exploratory stage. At present, there are still many problems and deficiencies in this field. The theoretical research and practice of museum lighting without light damage are still at a low level, and a complete design system has not yet been formed. Although some museums began to use infrared induction control lighting and mobile terminal software control lighting schemes, these schemes are still too simple. With the development and improvement of light source equipment, interactive control mode, and digital twin theory in recent years, some new technologies worthy of designers' adoption have emerged. Through theoretical exploration and practical verification, we have applied some research results to our design scheme, mainly involving the following three aspects.

The space light environment of the museum can be divided into basic lighting, key lighting, local lighting, and atmosphere lighting. This paper summarizes the following common space elements and lighting methods: display cabinet space is used to display small precious cultural relics, suitable for local lighting; large-scale cultural relics and art exhibition space, suitable for the key lighting mode; wall

Figure 1: Spot and glare.

Figure 2: Improper setting of key lighting.

Figure 3: Improper setting of local lighting.

washing space is used for paintings, murals, thangka, and other exhibitions, suitable for key lighting methods.

According to the research results of many museums at home and abroad, all sensitive exhibits adopt artificial lighting, which combines general lighting with key lighting, rather than uncontrollable natural lighting. Traditional light sources mainly include halogen lamp, fluorescent lamp, and metal halide lamp, which have their own advantages and disadvantages. However, the survey also found that the LED light source, as a rising star, has the

Figure 4: Continuous exposure of exhibits when no one is watching.

characteristics of energy saving and environmental protection, long service life, adjustable, convenient maintenance, and so on, which make it widely used in the lighting market. In recent years, after the white LED light source came out, it developed rapidly, which provides conditions for the LED light source to be used in indoor lighting. And the relevant research data show that a large number of museums represented by the Palace Museum have generally realized the application of the LED light source in lighting design, and the proportion of museums and art museums considering using the LED light source instead of the traditional light source is as high as 75%.

We finally decided to use the LED light source in this design for the following reasons: small size of LED lamps, easy installation, and debugging; no thermal and chemical damage to the exhibits; the color temperature and brightness of the LED can be easily controlled; high reliability and low maintenance cost. Because the LED basically does not contain infrared light and ultraviolet light, this design selects the LED light source with high color rendering index and only considers the illumination and exposure time to control the exposure of the exhibits in the low color temperature lighting mode.

2.4. Multisensor Fusion and Interactive Control. The intelligent Internet of Things control system connects all kinds of household appliances through the network to realize the functions of data collection, centralized monitoring, and management. The powerful network communication function is an indispensable part of the intelligent Internet of Things system. At present, the mainstream communication technologies used in the control system of intelligent Internet of Things are as follows: fieldbus technology, whose wiring adopts the bus structure, which is mainly composed of three basic parts: power supply, twisted pair, and function module; the power line carrier technology is to transmit analog or digital signals at high speed using carrier mode; wireless technology is a networking mode with WLAN technology as the main connection mode. Wireless technology is usually classified according to the wireless communication protocol, such as wireless Ethernet, Bluetooth, ZigBee, and LoRa. At the same time, the wireless Internet of Things control system also needs to meet the requirements of low power consumption, stability, easy expansion, and grid connection.

In this design, the main hardware devices are LED light source, temperature sensor, humidity sensor, PM fine particle sensor, camera, gateway, and industrial computer. Due to the scene limitation of museum exhibition area, in this design, LED light source, temperature sensor, humidity sensor, PM fine particle sensor, and camera of each exhibition area are connected to the gateway equipment of each exhibition area through the WiFi communication protocol, and the gateway equipment of each exhibition area is summarized to the local area network of the industrial control computer through wired Ethernet.

In order to reduce the exposure of exhibits (see Figure 4), some museums use the infrared sensor to control the light source switch. However, the sensing range of the infrared sensor is limited, and it cannot accurately perceive the real-time position and moving track of the audience in the exhibition area, so its control logic is too simple. Therefore, in this design, the camera is used to capture the overall picture of the exhibition area, and the target detection algorithm is used to detect the audience position algorithm and predict its viewing path, so as to achieve the effective control of lighting and smooth transition. Target detection is one of the key technologies of intelligent video image recognition and individual target behavior recognition. At present, with the development of deep learning technology, target detection algorithm has entered the research track of rapid development. In recent years, a number of excellent deep learning target detection algorithms such as R-CNN, Fast R-CNN, SSD, and YOLO have emerged. These algorithms have excellent detection effect and performance in some open-source target detection video image datasets. Among these algorithms, YOLO algorithm is a rising star. It is a target detection algorithm based on deep learning, which was published by Joseph et al. in a paper published in 2016. Compared with other algorithms, the biggest advantage of YOLO algorithm is its fast detection speed, which is a necessary condition for target detection engineering. Since 2016, the latest version of YOLO algorithm is YOLOv4 algorithm released in 2020. For the original YOLOv1 algorithm, in addition to maintaining the advantages of fast detection speed, great progress has been made in accuracy. Because of the excellent accuracy and speed of YOLO algorithm, it is very suitable for this system to detect the position and trajectory of the museum audience, so we use the most widely used YOLOv3 algorithm to develop the light source interactive control program of this system.

2.5. Twin Digital Platform. The concept of the digital twin platform has been born for decades. When it first appeared, it was defined as product production and real-time virtual presentation. However, due to the shackles of the technical level at that time, this new concept did not get enough attention. With the development of intelligent devices in recent years, sensor technology, hardware and software technology, and computer computing performance have been greatly improved. The concept of the digital twin platform has also been further developed, especially in the real-time monitoring of products and devices in industrial scenes. In 2019, by building the digital twin platform of the exhibition hall and cooperating with the UWB sensor to obtain the real-world indoor positioning data of the audience, some researchers have realized the functions of real-time positioning, hot spot analysis, and pedestrian trajectory tracking in the exhibition hall scene (ref. [5]). In our system, we use the computer vision scheme to get the audience's position in the exhibition hall through the target detection algorithm, which saves the cost of preparing a large number of positioning tags for the audience.

3. Design Details of the Museum Interactive Lighting System Based on the Twin Digital Platform

3.1. Lighting Control and Illumination Detection Hardware. Our design is suitable for a variety of museum exhibition space. In order to better reflect the application effect of this design, we decided to find a real exhibition area of a museum, design the lighting scheme after remodeling, and apply our intelligent lighting system to explore the improvement effect of the existing museum after reconstruction.

The lighting control equipment is mainly composed of the controller, communication module, and LED drive circuit. The controller is STM32F103C8T6 MCU, and the communication module is an ESP8266 wireless network chip. After the equipment is connected to the power supply circuit of LED lamps in the exhibition hall, it can realize the switch and brightness adjustment and receive the light adjustment instructions from the server through the wireless local area network.

The hardware part of illumination detection equipment is mainly divided into the controller, communication module, sensor module, and power supply module. The controller is STM32F103C8T6, the communication module is an ESP8266 wireless network chip, the illumination detection sensor is MAX44009 light intensity sensor, and the power supply module is low-voltage DC power supply. All the environmental data detection devices are sent to the server through the wireless LAN network and stored in the digital twin platform database (see Figure 5).

3.2. Pedestrian Detection and Twin Digital Platform. In this design, we need to install a webcam at the top of the exhibition area which can capture the largest panoramic image and transmit the video stream to the server through Ethernet. The main configuration of the server used in this system is 8-core 16-thread CPU, RTX2080Ti GPU, and 32 GB memory, Gigabit Ethernet card.

The system in this paper uses the method based on deep learning to detect pedestrian targets. In the field of pedestrian target detection, YOLOv3 is widely praised as a good choice. With its excellent characteristics, YOLOv3 can

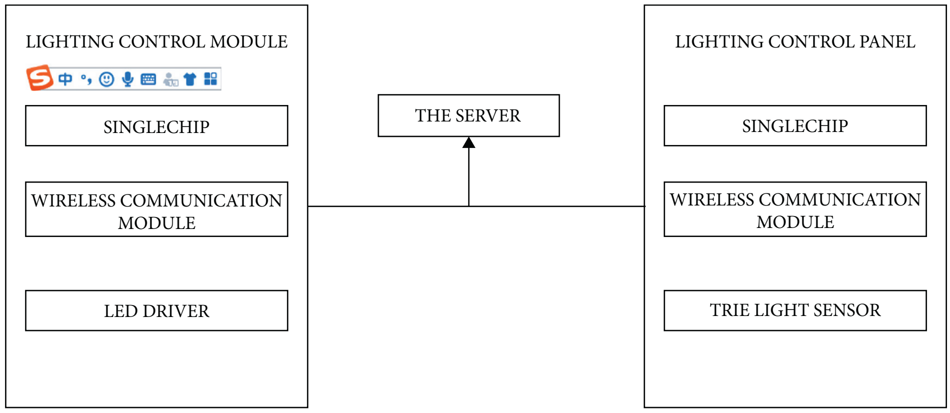

Figure 5: Hardware architecture.

effectively solve the scaling, background clutter, and morphological diversity of pedestrian targets (see Figure 6).

The pedestrian target detection dataset used in this system is divided into two parts, one is the open-source data pedestrian dataset, and the other is the video segmentation dataset, including pedestrian targets captured in the exhibition area of Nanjing Museum and nearby roads. After finishing the dataset, we get 902 images containing pedestrian targets and their corresponding XML annotation files. Another dataset is the video taken by ourselves in the exhibition area of Nanjing Museum and nearby roads. We use labelling annotation software to annotate the captured images and finally sort out 1000 images containing pedestrian targets and their corresponding XML annotation files. Through the synthesis of the above two datasets, a dataset containing more than 2000 pedestrian images is obtained. Following the basic principles of deep learning training and testing, the dataset needs to be divided into two parts: training set and test set. The pictures of the training set and test set cannot be repeated. In the experiment designed in this paper, the author randomly divided the comprehensive pedestrian dataset into the training set and test set according to the ratio of 8 : 2 and then trained and tested the neural network. Finally, the weight obtained from the training can be used to collect the video in the exhibition area to detect the audience.

After detecting the audience in each frame of the video stream (see Figure 7), the program developed by the open computer vision library can calculate the geometric center point of the audience in the picture. Through the conversion between the camera shooting angle and the plane coordinates of the exhibition area, the position of the audience in the exhibition area can be calculated, and the nearest light source can be adjusted to the preset optimal viewing illumination. The illuminance of the distant light source decreases according to the preset value, and only the minimum safe illuminance of the distant exhibition area is maintained.

The above programs are written by using Python programming language, and the audience position information and light source illumination control information are stored in the database for the digital twin platform to read.

3.3. Exhibition Health Twin Digital Platform. The digital twin platform of this system uses Blender software to model the scene and exhibits, and the model is imported into Unity 3D software to develop the whole system (see Figure 8). The digital twin platform is developed with C# programming language, and the client can develop the web version/PC version/APP version according to the requirements. The illumination data can be saved locally or hosted in the cloud, such as Baidu's time series database, which is determined according to the needs of remote management and the networking environment of the site.

For the users of this system, that is, the owner of the museum, we can use this platform to intuitively monitor the exposure of each exhibit in the exhibition cycle, which can not only grasp the health status of the exhibits but also flexibly adjust the exhibition time accordingly. Compared with the traditional fixed exhibition period in which the manager has no knowledge of the exposure of the exhibits, after the introduction of this system, the manager can quantitatively analyze the exposure of the exhibits and then make a more reasonable decision on the exhibition period.

4. Human-Computer Interaction Design Based on Motion Capture Technology

The previous pedestrian detection algorithm focuses on the detection of pedestrian distribution in a large area and then adjusts the illumination of basic lighting and key lighting. For the local lighting near the exhibits, it needs to identify and adjust the viewing state of the audience near the exhibits.

The recognition of the audience's viewing state can be summarized into the category of action interaction in human-computer interaction. In this paper, the most typical action of "leaning to watch" is selected as an example to study, and a set of human-computer interaction schemes based on motion capture technology is designed.

Because this research is in the stage of conceptual design, Kinect DK hardware of Microsoft company and its supporting body tracking SDK are used in the technical prototype. Several Kinect DKs need to be installed near the exhibition stand to ensure that the pedestrians around the exhibits are within the camera's field of vision. Kinect DK

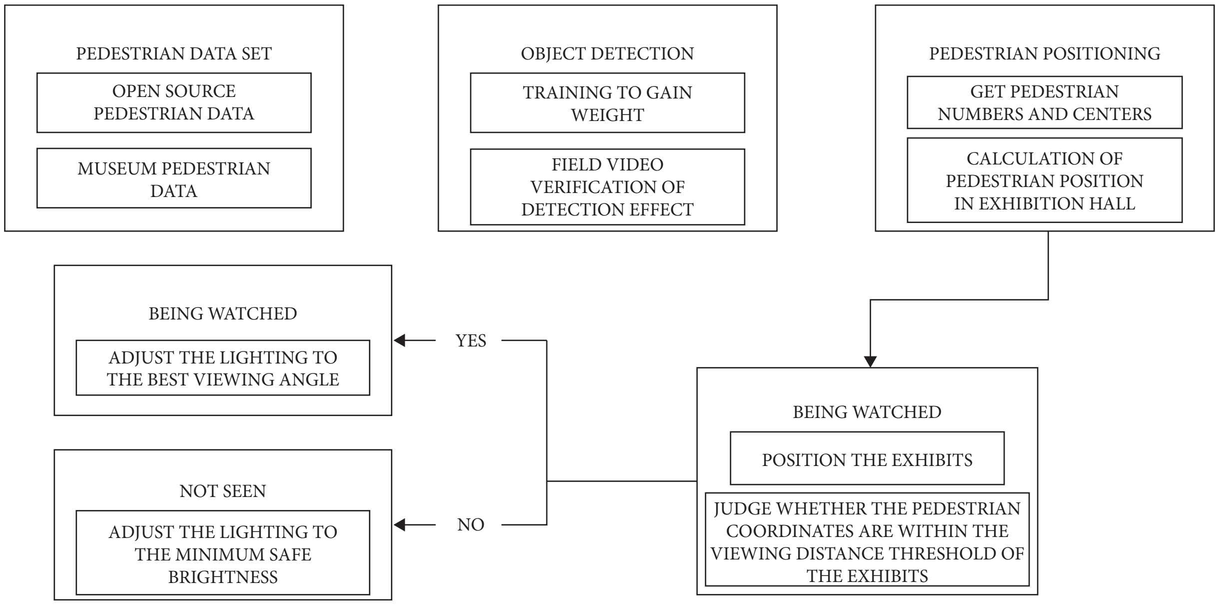

Figure 6: Lighting control system based on behavior detection.

Figure 7: Museum pedestrian dataset production.

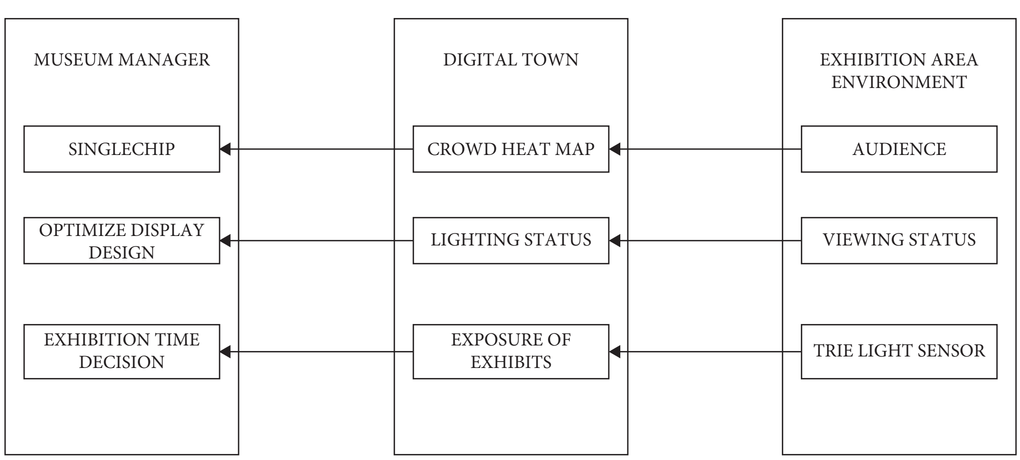

Figure 8: Twin digital platform.

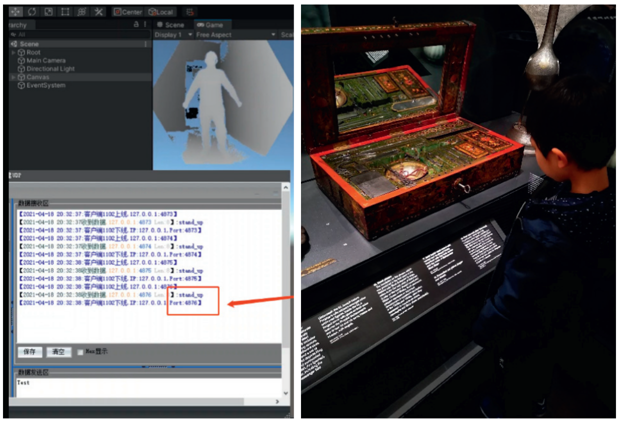

Figure 9: Recognition of the standing posture.

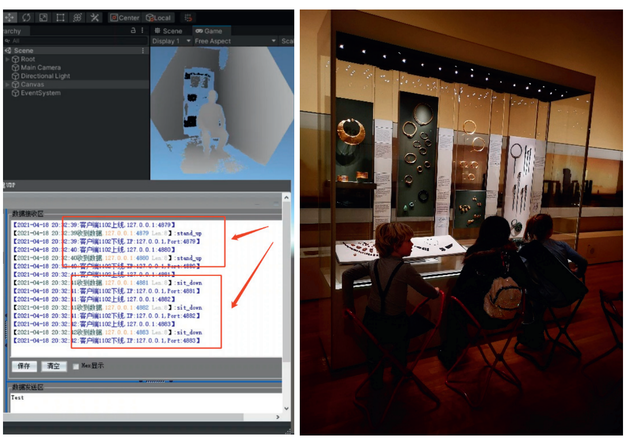

Figure 10: Recognition of the sitting posture.

transmits RGB and depth data to the aforementioned server in the venue through the optical fiber.

Kinect DK device based on Microsoft can track multiple human bodies at the same time. Through the development of body tracking SDK, the data of each human body in the field of vision can be obtained, including the time-dependent sequence between each picture and the moving bones and the number of human bodies detected in each picture. Based on this, we can determine whether there is an audience near the booth.

After confirming the audience is close to the exhibits, it is necessary to judge whether they are in the viewing position. The most important part of each human body data is the joint data. Joint position and orientation are estimated based on the depth learning framework of the global depth sensor. The unit of position is mm, and the direction is expressed by Euler angle. The position and direction of each joint constitute its own joint coordinate system, and all joint coordinate systems are absolute coordinates relative to the 3D coordinate system of deep camera data.

If the light source is too close to the object, the surface of the object will reflect high-reflection light. If the angle of the light is too vertical, the projected shadow will become longer and the edges will become sharper. When the smallpox part uses a translucent light source, the place where it produces the strongest reflected light is most likely the overhead part of the visitor. If the visitor looks directly at the showcase, the reflected light will enter the viewer's view (see Figure 9).

After realizing the accurate recognition of the posture of "looking down," we can determine whether an exhibit is in the state of being watched. When the exhibits are being viewed, the background adjusts the local lighting of the exhibits to the best viewing illumination; when the exhibit is not viewed, the background adjusts the local lighting of the exhibit to the lowest detectable illumination (see Figure 10).

5. Conclusion

Based on the field investigation of museum lighting design, this paper finds some problems and shows how target detection technology, digital twin technology, and human-computer interaction based on motion capture technology are applied to museum lighting design from the perspective of exhibition exposure protection. The intelligent lighting system designed in this paper can ensure the exhibition experience and reduce the unnecessary exposure of museum exhibits. At present, there are still limitations in our research work and design scheme. For example, we have not studied a more detailed light radiation control scheme for specific exhibits and only protect them at the actual exposure quantization level, which is also a research vacancy in the world. In addition, as the workload of the project team is focused on the theoretical research and design of the intelligent lighting system, no equipment test is installed on the spot, and there are bound to be many detailed problems in the application process of large exhibition space, complex structure, and crowded exhibition scenes, which will be discussed in the follow-up research process. The human-computer interaction scheme based on motion capture technology studied in this paper can be further studied in the future in order to become a set of low-cost and portable motion capture schemes. Motion capture has great potential in game animation, film and television animation, virtual image, and other fields. However, in the current commonly used motion capture schemes, the cost of equipment is very high, and the implementation site is limited. The author will continue to study on the basis of the existing achievements in this paper in order to form a more mature human-computer interaction scheme and motion capture scheme [25].

Due to the lack of domain and interface knowledge, it is difficult for users to create suitable service processes according to their needs. Thus, the paper puts forward a new service composition recommendation method. The method is composed of two steps: the first step is service component recommendation based on recurrent neural network (RNN). When a user selects a service component, the RNN algorithm is exploited to recommend other matched services to the user, aiding the completion of a service composition. The second step is service composition recommendation based on Naive Bayes. When the user completes a service composition, considering the diversity of user interests, the Bayesian classifier is used to model their interests, and other service compositions that satisfy the user interests are recommended to the user. Experiments show that the proposed method can accurately recommend relevant service components and service compositions to users.

1. Introduction

With the rapid development of Web 2.0, users gradually participate in the creation of web content. However, it is becoming more and more difficult to meet users' complex needs with the single service. Thus, users begin to combine different services for the generation of their own service composition [1–3]. Service compositions refer to several services in a certain logical order to form an integrated application. For example, IFTTT (If This Then That) was used to customize smog SMS. IFTTT has started a new trend, shifting users from creating content to creating service composition. The traditional service system, however, is too complicated and has poor scalability. It is difficult for users to combine services. Therefore, the lightweight WEB-API has become the future direction of service composition, owing to its easy access, extensibility, and easy development.

The user-oriented lightweight service composition allows users to drag and drop service components on a lightweight service composition platform to generate a new service sequence. It can thus fulfill users' individual needs. Generally speaking, the platform tools of lightweight service composition can support graphical components encapsulated by third parties, such as RSS/Atom feeds, web services, and various programming APIs (Google Maps, Flickr). Users can create service compositions through a visual operation interface without programming skills. Both the industry and the academia have shown great interest in this user-oriented lightweight service composition method.

Although the service composition tools are recognized by users, they still need strategic guidelines when combining lightweight services [4]. These guidelines include initial user guidance and user interest extraction. For the initial user guidance, at the beginning phase of the service selection, when a user selects a service component, other service components that effectively associate with the selected service should also be added in the recommendation list and be recommended to the user because of their potential unknown interests. For user interest extraction, owing to the diversity of user interests, the current user interest scenario should be modelled according to the user's selection. Other service compositions similar to the user interests should be recommended to the user.

In view of the above reasons, the paper puts forward a service composition recommendation method based on recurrent neural network and Naive Bayes. The method is divided into two stages: (1) When a user's initial interests are unknown, according to the user's selection, the method firstly recommends n service components with the highest correlation to the user by the RNN algorithm. (2) When the user completes a service composition, considering the diversity of their interests, the Bayesian classifier is used to model these interests, and other service compositions suitable for the user interests are recommended to the user. In the current research, the RNN algorithm recommends related services to users, which is likely to alleviate the problem of service mismatch. The Naive Bayes algorithm provides users with other service compositions that can satisfy their interests. It not only can meet the diversity of user interests but also can create excellent service compositions in the template with reused library. Experiments show that the proposed method is able to accurately recommend service components and service compositions to users.

2. Related Works

Previous researchers mainly utilized the topic model to obtain the latent topics for the improvement of the recommendation accuracy, for instance, the Latent Dirichlet Allocation (LDA) [5]. However the training of topic model was time-consuming. Subsequently, the matrix factorization was widely applied in service recommendations [6]. As the matrix factorization was not suitable for general prediction tasks, a general predictor method named Factorization Machines (FM) [7] was proposed. By exploiting Factorization Machines, Cao et al. [8] proposed the Self-Organization Map-Based functionality clustering algorithm and the Deep Factorization Machine-Based quality prediction algorithm to recommend API services. In addition, to solve the sparsity problem of historical interactions, Cao et al. [9] used topic models to extract the relationships between mashups and to model the latent topics. Although the above methods had generated several satisfactory results, traditional service recommendation approaches usually overlooked the dynamic nature of usage pattern. Therefore, it is suggested by Bai et al. [10] to incorporate both the textual content and the historical usage to build latent vector models for service recommendation. Meanwhile, to address the cold-start problem, Ma et al. [11] proposed learning the interaction information between candidate services and mashups based on the content and the history. Then, according to interaction vectors, a multiple layer perceptron was used to predict the rank of candidate services. Through the user's historical service access records, Gao et al. [12] utilized a PLSA-based semantic analysis model to capture the user's interests and to recommend the services that meet the user's preference.

In recent years, a few researchers have begun to pay attention to service recommendation from the perspective of Quality of Service (QoS) [9,13–19]. By focusing on the network resource consumption, Zhou et al. [13] used an integer nonlinear programming to solve microservice mashup problems, and an approximation algorithm was designed to solve the NP-hard problem. Xia et al. [14] offered to determine each service's virtual cost according to the service's attributes and the user's preference. As a result, the service composition with the least total virtual cost was recommended to users. In addition, in terms of service function, by weighing the relationship between maximizing service cousage, maximizing functional diversity, and maximizing functional matching, Almarimi et al. [20] provided the nondominated sorting genetic algorithm to extract an optimal set to create a mashup. Shin et al. [21] proposed a service composition method based on functional semantics, and Shi et al. [22] employed a Long Short-Term Memory- (LSTM-) based method with a functional attention mechanism and a contextual attention mechanism to recommend services. In terms of semantic relevance, Ge et al.[23] suggested to effectively use the existing service composition and semantic association to expand the scope of service recommendation. In the research of Duan et al. [24], the integration of the probabilistic matrix factorization (PMF) model and the probabilistic latent semantic index (PLSI) model were adopted to recommend services to users. In the present study, the PLSI model was used to train user access records. By mining historical execution trajectories, He et al. [25] discovered potential behavior patterns based on the context and user characteristics. And context-related and preference-related user activity selection probability models were established. This potentially supported the construction and the recommendation of optimized personalized mashup.

In summary, when a user clicks on the service "Flickr," combining the user has clicked the service "Facebook" before, it can thus recommend other services linked to the sequence Facebook- > Flickr. After the user finishes a service process, because of the diversity of user interests, it is necessary to recommend other service processes that are of potential interests. However, most schemes in previous studies only focus on one point, weakening the user's experience. In addition, the service component recommendation based on association rules ignores the relevance between word orders; thereby, it has a relatively low recommendation accuracy. The service composition recommendation based on QoS mainly focuses on the nonfunctional needs of users. In the Mobile Internet and the 5G era, users, however, pay more attention to their functional requirements. Therefore, this paper proposes a service composition recommendation method based on the RNN and Naive Bayes. The RNN is used to ensure the relevance between word orders. Naive Bayes is adopted to identify users' potential interests according to the component function and provides users with excellent service processes in the template library.

3. Algorithm Description

3.1. Service Component Recommendation Based on Recurrent Neural Network. In this section, service compositions are first sent to RNN for training. The training is divided into two phases: forward propagation and back propagation. Then the error losses of the output layers at different times are obtained through forward propagation. Subsequently, according to the cross entropy of error losses, weight increments $\nabla U, \nabla V, \nabla W$ are calculated through back propagation. Finally, the weights U, V, W are updated by a gradient descent method.

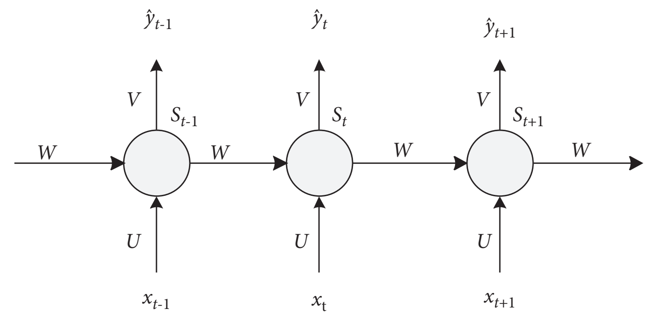

Figure 1: The forward propagation process of RNN.

3.1.1. Preprocessing of Service Process Call Records. To train a suitable RNN, it is needed to preprocess the service process call records as the input data and the predefined output data. Here, for each service composition in the training set, the last service component is deleted, and other service components are inserted into the list x_data as a list element. For each service composition, the first service component is deleted, and other service components as the corresponding list element are inserted into the list y_data. For example, if two service compositions are Facebook- > Flickr- > GoogleMaps and Time- > Weather- > Text, where - > represents the linked sequence between service components, then $x\_data =$ [["Facebook", "Flickr"], ["Time", "Weather"]], $y\_data =$ [["Flickr", "GoogleMasp"], and ["Weather", "Text"]]. Here x_data_j will be used as the input data of forward propagation, and y_data_j will be used as the predefined output data of back propagation. x_data_j and y_data_j need to be converted to a one-hot vector before training. In other words, there are L words in the dictionary; if the position of a service in the dictionary is j, then the service can be represented as an L-dimensional vector, where the j^{th} dimension is set to 1, and the remaining dimensions are all set to 0.

3.1.2. Forward Propagation. The forward propagation process of RNN is shown in Figure 1. Here U represents the weight between the input layer and the hidden layer. V represents the weight between the hidden layer and the output layer. W represents the weight of the adjacent hidden layers.

At time t, x_t is the input value, and s_t is the state in the hidden layer, which is related to the input value x_t and the state s_{t-1} of the previous hidden layer. The mathematical expression is $s_t = f(Ux_t + Ws_{t-1})$. f represents an activation function in the hidden layer. In the paper, $f = \tanh$.

$\hat{y}_t$ is the output value at time t. The mathematical expression is $\hat{y}_t = g(Vs_t)$. In the output layer, g represents an activation function. In the paper, $g() =$ softmax().

3.1.3. Back Propagation. RNN uses the back propagation to add up the error losses of the output layers at different times to obtain the total error loss E and then calculates the gradient of each weight U, V, W to obtain weight increments $\nabla U, \nabla V, \nabla W$ and finally employs a gradient descent method to update each weight U, V, W.

(1) Error Loss Function. For each time t, there will be an error loss e_t between the output value $\hat{y}_t$ of RNN and the predefined output value y_t. Assuming that the cross entropy is used as the error loss function, there is a total error loss $E = \sum_{t=1}^{N} e_t$, and $e_t = -\sum_{i=1}^{L} y_t(i) \ln \hat{y}_t(i)$, where N represents the length of x_data_j or y_data_j, L represents the length of the one-hot vector, and $x_t \in x\_data_j$, $y_t \in y\_data_j$.

(2) Gradient Calculation. For ∇V, V does not depend on the previous states; thus, it is relatively easy to obtain. However, for $\nabla W, \nabla U$, the chain derivation rule is needed to obtain them. The calculation process is as follows:

$$\begin{cases} \nabla U = \dfrac{\partial e_t}{\partial U} = \dfrac{\partial e_t}{\partial \hat{y}_t} \cdot \dfrac{\partial \hat{y}_t}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial U} + \dfrac{\partial e_{t+1}}{\partial \hat{y}_{t+1}} \cdot \dfrac{\partial \hat{y}_{t+1}}{\partial s_{t+1}} \cdot \dfrac{\partial s_{t+1}}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial U} \\ = \left(\dfrac{\partial e_t}{\partial \hat{y}_t} \cdot \dfrac{\partial \hat{y}_t}{\partial s_t} + \dfrac{\partial e_{t+1}}{\partial \hat{y}_{t+1}} \cdot \dfrac{\partial \hat{y}_{t+1}}{\partial s_{t+1}} \cdot \dfrac{\partial s_{t+1}}{\partial s_t} \right) \cdot \dfrac{\partial s_t}{\partial U}, \\ \nabla V = \dfrac{\partial e_t}{\partial V} = \dfrac{\partial e_t}{\partial \hat{y}_t} \cdot \dfrac{\partial \hat{y}_t}{\partial V}, \\ \nabla W = \dfrac{\partial e_t}{\partial W} = \dfrac{\partial e_t}{\partial \hat{y}_t} \cdot \dfrac{\partial \hat{y}_t}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial W} + \dfrac{\partial e_{t+1}}{\partial \hat{y}_{t+1}} \cdot \dfrac{\partial \hat{y}_{t+1}}{\partial s_{t+1}} \cdot \dfrac{\partial s_{t+1}}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial W} \\ = \left(\dfrac{\partial e_t}{\partial \hat{y}_t} \cdot \dfrac{\partial \hat{y}_t}{\partial s_t} + \dfrac{\partial e_{t+1}}{\partial \hat{y}_{t+1}} \cdot \dfrac{\partial \hat{y}_{t+1}}{\partial s_{t+1}} \cdot \dfrac{\partial s_{t+1}}{\partial s_t} \right) \cdot \dfrac{\partial s_t}{\partial W}. \end{cases} \tag{1}$$

Assuming the error variation of the hidden layer $\delta_t^h = \partial e_t / \partial \hat{y}_t \cdot \partial \hat{y}_t / \partial s_t + \partial e_{t+1} / \partial \hat{y}_{t+1} \cdot \partial \hat{y}_{t+1} / \partial s_{t+1} \cdot \partial s_{t+1} / \partial s_t$ and the error variation of the output layer $\delta_t^o = \partial e_t / \partial \hat{y}_t$, $\nabla U, \nabla V, \nabla W$ can be expressed as follows:

$$\begin{cases} \nabla U = \dfrac{\partial e_t}{\partial U} = \dfrac{\partial e_t}{\partial \hat{y}_t} \cdot \dfrac{\partial \hat{y}_t}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial U} + \dfrac{\partial e_{t+1}}{\partial \hat{y}_{t+1}} \cdot \dfrac{\partial \hat{y}_{t+1}}{\partial s_{t+1}} \cdot \dfrac{\partial s_{t+1}}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial U} \\ = \delta_t^h \cdot \dfrac{\partial s_t}{\partial U}, \\ \nabla V = \dfrac{\partial e_t}{\partial V} \\ = \delta_t^o \cdot \dfrac{\partial \hat{y}_t}{\partial V}, \\ \nabla W = \dfrac{\partial e_t}{\partial W} = \dfrac{\partial e_t}{\partial \hat{y}_t} \cdot \dfrac{\partial \hat{y}_t}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial W} + \dfrac{\partial e_{t+1}}{\partial \hat{y}_{t+1}} \cdot \dfrac{\partial \hat{y}_{t+1}}{\partial s_{t+1}} \cdot \dfrac{\partial s_{t+1}}{\partial s_t} \cdot \dfrac{\partial s_t}{\partial W} \\ = \delta_t^h \cdot \dfrac{\partial s_t}{\partial W}. \end{cases} \tag{2}$$

In RNN, the calculation of back propagation is from the back to the front. At each moment, weight increments $\nabla U, \nabla V, \nabla W$ are updated as follows:

$$\begin{cases} \Delta U = \Delta U + \delta_t^h \cdot \dfrac{\partial s_t}{\partial U}, \\ \Delta V = \Delta V + \delta_t^o \cdot \dfrac{\partial \hat{y}_t}{\partial V}, \\ \Delta W = \Delta W + \delta_t^h \cdot \dfrac{\partial s_t}{\partial W}. \end{cases} \tag{3}$$

(3) Weight Update. When the training of a service composition is completed, the RNN uses a gradient descent method to update U, V, W along the negative gradient direction. The updated process is as follows:

$$\begin{cases} U = U - lr * \Delta U, \\ V = V - lr * \Delta V, \\ W = W - lr * \Delta W. \end{cases} \tag{4}$$

Here the initial U, V, W are randomly generated. lr is the step length of the gradient descent method.

After the update of U, V, W is completed, the loop is repeated until the error loss E reaches the threshold. At this time, the weights U, V, W are used to predict the output results according to the input data.

3.1.4. Service Components Recommendation. When users select a service component, the service component is sent to the RNN. It uses the weights U, V, W obtained in Section 3.1.3 to compute the following prediction services and then sends the top n prediction services to the recommendation list and posts them to users.

3.2. Service Composition Recommendation Based on Naive Bayes. It is noted that service components selected by users need to be further reduced through the information gain, and then the Naive Bayes classifier is exploited to extract user interests based on the reduced service component set. Finally, similar service compositions are recommended to the user according to their interests. Bayesian can quickly and efficiently identify the user's interest according to several service components clicked by the user; and those with similar interest in the user template library can directly match the common components clicked by the user.

3.2.1. Information Gain. After users finish a service composition, we need to determine user interests based on this service composition. To decrease the interference of noncritical service components, the information gain algorithm is used to reduce the service component set. The gain value *IG(s)* of each service component in the service composition can be calculated. The service components are sorted by the gain value *IG(s)*, and the first n service components are regarded as the reduced service component set.

The process is as follows:

(1) The entropy of each service component SC_j in the service composition SC is calculated, which is $H(SC_j|SC)$.
(2) The entropy without this service component SC_j in the service composition SC is calculated, which is $H(SC_j|\overline{SC})$.
(3) The difference between the entropy $H(SC_j|SC)$ and the entropy $H(SC_j|\overline{SC})$ is the classification gain value of this service component, which is $IG(SC_j)$, as shown in the following formula:

$$\begin{aligned} IG(SC_j) &= H(SC_j|SC) - H(SC_j|\overline{SC}) \\ &= -\sum_{i=1}^{n} P(c_i).\ \log_2 P(c_i) + \sum_{i=1}^{n} P(c_i|SC_j)\log_2 P(c_i|SC_j) + \sum_{i=1}^{n} P(c_i|\overline{SC_j})\log_2 P(c_i|\overline{SC_j}), \\ P(c_i|SC_j) &= \frac{n(SC_j|c_i)}{n(c_i)}, \\ P(c_i|\overline{SC_j}) &= \frac{n(\overline{SC_j}|c_i)}{n(c_i)}. \end{aligned} \tag{5}$$

Here $P(c_i|SC_j)$ represents the probability of the service component SC_j belonging to interest c_i. $P(c_i|\overline{SC_j})$ denotes the probability of the service component SC_j not belonging to interest c_i. $n(SC_j|c_i)$ means the number of service compositions including SC_j in interest c_i. $n(\overline{SC_j}|c_i)$ means the number of service compositions excluding SC_j in interest c_i. $n(c_i)$ is the number of service compositions in interest c_i. $P(c_i)$ represents the proportion of services compositions belonging to interest c_i in all services compositions.

(4) The service components are sorted according to the classification gain value, and the first n service components form a reduced service component set.

3.2.2. User Interest Modeling. According to the reduced service component set, the Naive Bayes classifier is exploited to determine the user interests.

The process is specified as follows:

(1) As discussed in Section 3.2.1, the probability of the reduced service component set belonging to each interest category is calculated by the Naive Bayes classifier, which is $P(c_i|SC)$. According to the Bayesian formula, $P(c_i|SC) = P(c_i|SC_1, SC_2, \ldots, SC_n) \propto P(SC_1, SC_2, \ldots, SC_n|c_i)P(c_i)$. Assuming that $SC_1, SC_2, \ldots, SC_n$ are independent, $P(SC_1, SC_2, \ldots, SC_n|c_i) = \prod_{j=1}^{n} P(SC_j|c_i)$. As shown in formula (6), SC represents the sequence of the reduced service components ($SC_1, SC_2, \ldots, SC_n$).

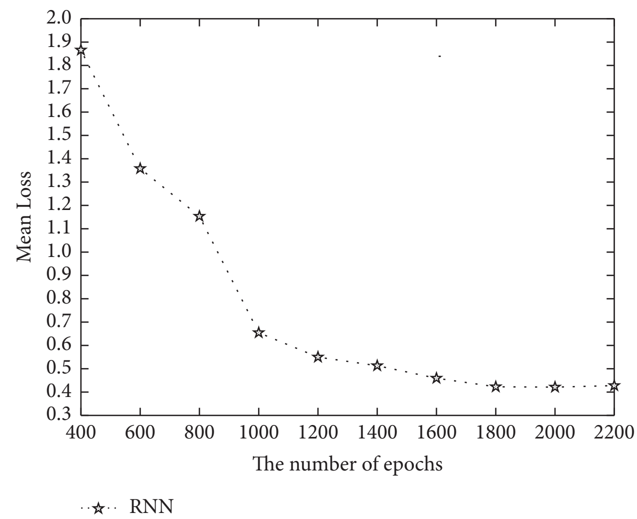

Figure 2: The number of RNN's iterations.

$$P(c_i|SC) = P(c_i|SC_1, SC_2, \ldots, SC_n) \propto P(SC_1, SC_2, \ldots, SC_n|c_i)P(c_i),$$
$$P(SC_1, SC_2, \ldots, SC_n|c_i) = \prod_{j=1}^{n} P(SC_j|c_i). \quad (6)$$

(2) According to formula (6), $P(c_i|SC) \propto P(c_i)\prod_{j=1}^{n} P(SC_j|c_i)$. This paper selects the interest category with the highest probability as the user interest; therefore, formula (7) is feasible.

$$\arg\max P(c_i|SC) \propto \arg\max\left[P(c_i)\prod_{j=1}^{n} P(SC_j|c_i)\right]. \quad (7)$$

3.2.3. Service Compositions Recommendation. According to the reduced service component set, the Naive Bayes classifier is exploited to determine the user interests.

The N-gram distance is used to compute the distance between different service compositions, and the service compositions are recommended to the user based on the similarities from high to low.

The process is specified as follows:

(1) In the service composition data set, service compositions consistent with the user interests are selected.

(2) The N-gram distance is used to compute the distance between the selected service compositions and the reduced service component set. Depending on the distance, service compositions that are most similar to the reduced service component set are recommended, as shown in the following formula:

$$\text{distance}(SC^p, SC^q) = GN(SC^p) + GN(SC^q) - 2 \times |GN(SC^p) \cap GN(SC^q)|. \quad (8)$$

(3) Here, $GN(SC^p)$ denotes the number of service components in service composition SC^p. $GN(SC^q)$ denotes the number of service components in service composition SC^q. $GN(SC_l) \cap GN(SC_p)$ is the number of the same service components in two service compositions. The similarity between two service compositions increases with the decrease in their distance.

4. Experiments

Experiments in this paper attempt to verify the effectiveness of RNN and Naive Bayes. Section 4.1 describes the data set used in Sections 3.1 and 3.2. Section 4.2 depicts the linked prediction performance of RNN, including the number of RNN's iterations, the precision, and the time comparison with the traditional algorithms (Apriori and N-gram).

Section 4.3 reports the classification performance of Naive Bayes. Section 4.4 explores the recommendation performance of N-gram distance.

4.1. Dataset. This paper uses service process call records and the service composition data set from the ProgrammableWeb website to conduct experiments. Service process call records include 20035 users' records. To improve the precision of experiments, the paper eliminates records of inactive users. In particular, users who call service processes less than 3 are regarded as inactive users; thus, there are 11730 service process call records used for our experiments. The service composition data set includes 13,082 service processes, and there are 24 types of the classification labels of service processes.

4.2. The Linked Prediction Performance of RNN

4.2.1. The Number of Iterations. The mean loss is given as follows:

$$\text{mean loss} = \frac{\sum E}{\text{the number of iterations}}. \quad (9)$$

This paper adopts the free-running mode for training. The training results are shown in Figure 2 and the mean loss is shown in formula (9). Here E represents the loss of each round iteration. It can be seen that as the number of iterations increases, the mean loss of each epoch gradually decreases. When the number of iterations reaches 2000, the convergence of the RNN algorithm is achieved.

4.2.2. Algorithm Comparison. This section compares the RNN algorithm with the traditional Apriori algorithm and the N-gram algorithm. The Apriori algorithm is a common association rule algorithm in data mining, mainly used in recommendation systems. The N-gram algorithm is also used in recommendation systems, but it can effectively reduce the recommendation space through learning the context. The comparison results demonstrate the feasibility of the RNN algorithm.

(1) Comparison of the Recommendation Precision between RNN(1), Apriori(1), and N-Gram(1). RNN(1) represents the recommendation algorithm RNN after the user calls a service component. Apriori(1) represents the recommendation algorithm Apriori after the user calls a service component. N-gram(1) represents the recommendation algorithm N-gram after the user calls a service component.

$$\text{precision} = \frac{L\left(\text{Rec}\left(sc_1 \ldots sc_i\right) \cap sc_{i+1}\right)}{L\left(\text{Rec}\left(sc_1 \ldots sc_i\right)\right)}. \quad (10)$$

As shown in Figure 3, the ordinate represents the recommendation precision of service components, as shown in formula (10). Here, $L(\text{Rec}(sc_1 \ldots sc_i))$ represents the number of recommended service components for the called service component sequence $sc_1 \ldots sc_i$. sc_{i+1} represents the actually linked service component for the called service component sequence $sc_1 \ldots sc_i$. $\cap$ represents the intersection. $L(\text{Rec}(sc_1 \ldots sc_i) \cap sc_{i+1})$ equals 0 or 1. The abscissa Top-P represents the number of service components required to be recommended. In practice, due to the control of the predefined threshold T, $L(\text{Rec}(sc_1 \ldots sc_i)) \leq \text{Top} - P$, where $T = 0.42$. As can be seen, the precision of RNN(1) is superior to those of Apriori(1) and N-gram(1). When the Top-P is 5, RNN(1) presents the best performance. At this time, the precision of RNN(1) is 0.41, higher than 0.17 of Apriori(1) and 0.24 of N-gram(1). This is because the RNN and the N-gram can learn the linked relationships between service components through training, while Apriori can only learn the correlations between service components and cannot capture the linked order between service components. Meanwhile, due to the limitation of the Markov model, the RNN has shown superior context learning effects than the N-gram.

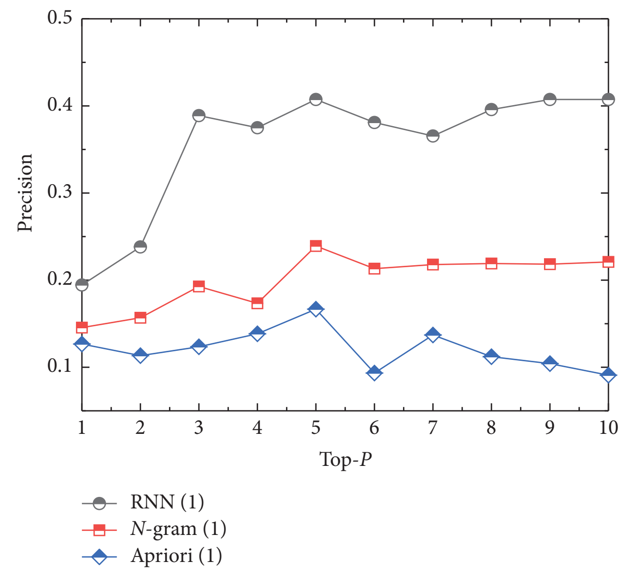

Figure 3: Comparison of the recommendation precision between RNN(1), Apriori(1), and (N)-gram(1).

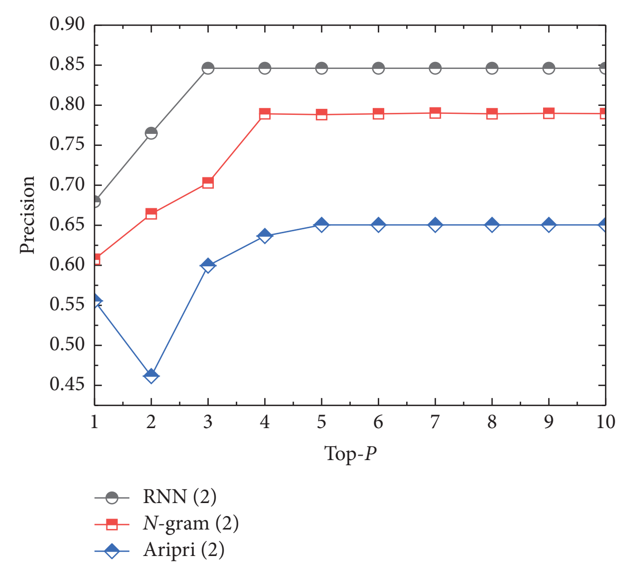

Figure 4: Comparison of the recommendation precision between RNN(2), Apriori(2), and (N)-gram(2).

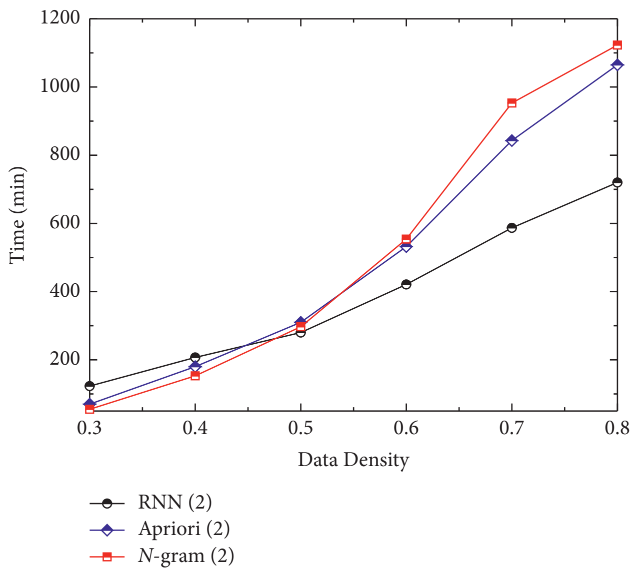

Figure 5: Comparison of the training time between RNN(2), Apriori(2), and (*N*)-gram(2).

(2) Comparison of the Recommendation Precision between RNN(2), Apriori(2), and (N)-Gram(2). As shown in Figure 4, RNN(2) represents the recommendation algorithm RNN after the user calls two components. Apriori(2) represents the recommendation algorithm Apriori after the user calls two components. *N*-gram(2) represents the recommendation algorithm *N*-gram after the user calls two components. When the user's initial selection of service components is greater than 1, the precision of RNN(2) is still superior to those of Apriori(2) and *N*-gram(2). When the Top-*P* is 5, the recommendation precision of RNN(2) is 0.85. The recommendation precision of Apriori(2) is 0.65. The recommendation precision of *N*-gram(2) is 0.79. At this time, the recommendation precisions of RNN(2), Apriori(2), and *N*-gram(2) are higher than those of RNN(1), Apriori(1), and *N*-gram(1). This is mainly because when the user selects more initial component sequences, there are fewer subsequently related service components, and the recommendation precision becomes higher.

(3) Comparison of Training Time. As shown in Figure 5, when the training data is small, the training times of the Apriori(2) algorithm and the *N*-gram(2) algorithm are lesser than that of the RNN(2) algorithm. But as the training data increases, the amount of data processed by the Apriori(2) algorithm and the *N*-gram(2) algorithm will increase exponentially. The training time of RNN(2) is lesser than those of Apriori(2) and *N*-gram(2). When the data density is 80%, it costs RNN(2) 720 minutes to train, while Apriori(2) takes 1065 minutes and *N*-gram(2) takes 1123 minutes.

4.3. The Classification Performance of Naive Bayes. As shown in Figure 6, precision% (classfication) refers to the precision of classification prediction through the service composition data set. The predicted label is compared with the real label, and finally the classification precision of the algorithm is obtained. As can be seen, with the increase in the training data, the

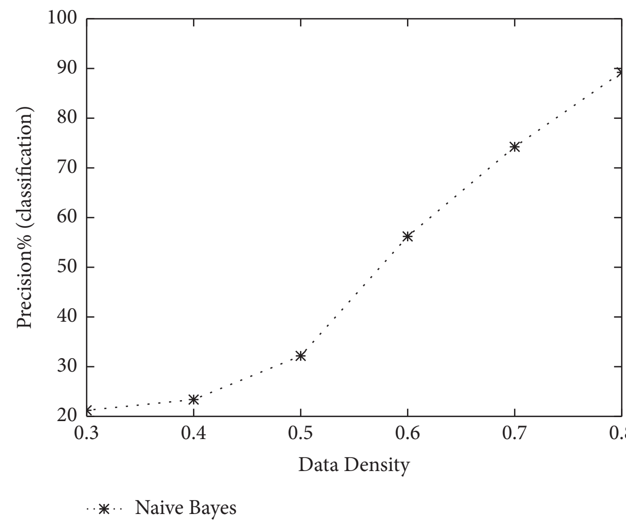

Figure 6: The classification performance of Naive Bayes.

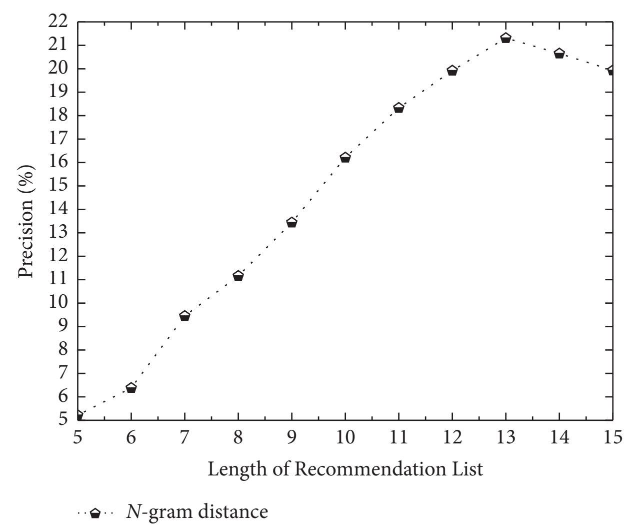

Figure 7: The recommendation performance of (*N*)-gram distance.

recommendation precision becomes higher. When the density of training data is 80% and that of the test data is 20%, the classification precision of Naive Bayes reaches 89.1%.

4.4. The Recommendation Performance of N-Gram Distance. Figure 7 analyzes the recommendation performance of *N*-gram distance. As the length of the recommendation list increases, the recommendation precision first increases and then decreases. When the length is 13, the recommendation performance is the optimal. At this time, the recommendation precision is 21.3%.

5. Conclusions

In order to optimize the assistance to users in their decision-making, this paper proposes a service composition recommendation method based on the RNN and Naive Bayes. This method has the following contributions:

(1) Different from traditional algorithms, this paper uses the context learning to reduce the recommendation space and provides users with more accurate service-linked components.

(2) To fulfill the diversity of user interests, this paper adopts the interest modeling to recommend other service processes that meet users' current interests. This can effectively promote the reuse of the template library.

It is yet worth noting that the interest modeling of Naive Bayes does not take the semantic similarity into consideration. As a result, future research would consider using the semantic analysis to model user interests.

In recent years, urban buildings have become taller, occupying more and more areas, frequent fires, and increasingly difficult fire rescue tasks. Predicting fire risks in advance will help fire rescue work. Therefore, this paper proposes a fire risk prediction based on the ARIMA model. By analyzing the fire rescue data of a certain place from 2016 to 2020 and based on the data from January 1, 2016, to December 31, 2019, an ARIMA model for predicting the number of fire rescue polices was established. The data from January 1, 2020, to December 31, 2020, are used as the validation data set of the model to evaluate the accuracy and stability of the model. The results show that the ARIMA model can be better applied to fire rescue prediction and provides a scientific prediction method for the research of smart fire rescue work.

1. Introduction

With the rapid development of our country's economy, the environmental complexity has risen sharply, various accidents and disasters have occurred frequently, and safety risks have continued to increase. The challenges of fire prevention, control, firefighting, and rescue problems such as physical, underground engineering, and large chemical companies will be even more severe. Smart fire rescue is an important part of the construction of smart cities. It is necessary to actively apply new technologies such as artificial intelligence [1, 2], big data [3, 4], cloud computing, Internet of Things [5, 6], and geographic information to establish a smart fire rescue system [7,8] to realize the identification and early warning of disaster occurrence patterns and risks, real-time monitoring of disaster information, intelligent remote monitoring of firefighting facilities, intelligent deployment of rescuers, and so on to build an unbreakable line of fire safety defense for the construction of smart cities. At the same time, with the rapid expansion of the city, the number and density of urban buildings are growing at a high rate. The complex function and structure of modern urban buildings bring a great difficulty to fire control. Efficient and safe building fire emergency rescue is a problem that needs to be solved urgently. Although in the past many experts and scholars have paid attention to how to improve the city's fire emergency rescue capabilities, it is a pity that the iteration speed of fire emergency rescue methods is still far behind the development speed of urban buildings. At present, the fire department's assessment of unit fire risk still depends on the experience of firefighters, which has great subjective uncertainty. Therefore, it is necessary to adopt a more general scientific method to assess the risk of fire. At the same time, local fire departments have stored a large amount of relevant data in fire protection practice, including fire rescue data, fire inspection data, basic information data of related units, and urban building data. To deeply analyze the historical data of fire protection and obtain the information hidden behind the data through technical means, so as to support the accuracy of the desired target, it is necessary to use reasonable methods and tools to process the data. Machine learning technology is an efficient method to obtain effective information through data cleaning, reasonable feature construction, learning, and training from databases, texts, data warehouses, and other information bases.

The ARIMA model was proposed by American statistician Jenkins and British statistician box in the 1970s. The ARIMA model is mainly used in the short-term prediction of time series variables. The single time series value is unpredictable, but the overall time series value has a certain law. The ARIMA model expresses this rule in mathematical form to realize the short-term prediction of time series value.

To predict the fire risk more accurately, this paper proposes a fire risk prediction and analysis method based on the ARIMA model. The time series analysis method is used to observe the changing trend of the number of fire rescue in a certain interval, mine the rule from the data, and predict the number of fire rescue alarms in the future. The significance of our work is as follows. (1) This paper proposes a fire risk prediction and analysis method based on the ARIMA model. By analyzing the fire and rescue data of a certain place, an ARIMA model is established to predict the number of times of fire and rescue police. (2) The ARIMA model has a simple structure and few parameters, and only endogenous variables are needed to build a predictive model. The model predicts the number of times of fire and rescue police iteratively, which is conducive to better mining the factors that affect the number of fire rescue police and the evolution trajectory. (3) The results show that the ARIMA model can be better applied to fire rescue prediction and provides a scientific prediction method for the research of smart fire rescue work.

2. Introduction to Fire Risk Prediction and Analysis Methods

The ability to predict fire risk [9, 10] is an important aspect of smart fire rescue. Time series forecasting, neural network, and polynomial fitting are some of the most commonly used methods for predicting and analyzing fire risks. However, assessing such multivariate environmental disasters has always been difficult because modeling can be skewed by a variety of factors, including the quality and quantity of input parameters, the training process, and hyperparameter default settings.

2.1. Time Series Analysis. A time series is a collection of observations derived from the progression of time, which is essentially the dependence of adjacent observations. Analyzing time series data allows researchers to determine the system's internal evolution law, as well as observe and predict the system's future development trend [11]. For example, Qiu Jie et al. [12] used Landsat time series data and machine learning methods to conduct quantitative research on forest fires and postdisaster vegetation restoration in the Daxinganling area, drawing a forest distribution map 1987–2016 disturbances in the Daxinganling area using the vegetation change tracking (VCT) algorithm. The VCT Block separates the burning points from the disturbance patches using the vector machine (SVM) classifier and historical fire records. The results show that VCT's forest interference events have high spatial precision. Most years have between 70% and 86 percent spatial accuracy. The proposed VCT-SVM algorithm extracts annual fire patches with an overall accuracy rate of 92%. The RF algorithm's prediction accuracy is better than that of SVM and SMLR according to the verification results. Gao Natekar et al. [13] investigated the use of long- and short-term memory neural networks to predict the spread of forest fires. In the northern beaches of Sydney, Naderpour Mohsen et al. [14] proposed a spatial framework for quantifying the risk of forest fires. In order to maximize the impact of multilayer perceptrons on forests, 36 key indicators from various backgrounds, such as terrain, form, climate, man-made, social, and physical, were selected and used as input to the model. The model can be tailored to different parts of Australia and has fewer requirements for weighting procedure localization, enhancing adaptability and decision-making ability.

2.2. ARIMA Model. The modeling of the ARIMA model can be divided into the following four steps. First, the stationarity test is performed on the original sequence. If the test result is not stable, it is necessary to make the sequence meet the stationarity conditions through differential changes or other changes. Second, the model is determined by calculating the statistics describing the characteristics of the sequence, and the order of the model is determined by combining certain criterion. Third, the parameters of the model are estimated, such as by the least square method, and the rationality test is carried out. Finally, the diagnostic analysis is carried out, the data are predicted through the generated model, and the actual data are compared with it for the prediction accuracy determination test. If the parameters are not determined accurately, a new model is established again.

2.3. Polynomial Fitting. Polynomial fitting is to use a polynomial expansion to fit all observation points in an analysis area containing several analysis grid points to obtain the objective analysis field of the observation data, and the expansion coefficient is determined by least square fitting [15]. Mei Peng et al. [16] proposed a rapid loss assessment network analysis method (ANP) for high casualties fires, established a context index (SI) and outcome index (CI) network, and compared ANP and multiple logistic regression. The correct classification rate of the accident level is directly related to the multilayer perceptron network and the radial basis function network. The findings show that ANP excels at high and extreme levels, as well as when accident levels are taken into account. Weighted least squares polynomial fitting is used to generate meaningful extreme possibility results for decision-making reference, and it can be used to obtain the relationship between the context index (SI) and the outcome index (CI) of high-level and extreme HCFs. To investigate the impact of temperature on the frequency of fires in Changsha, Liu Dingli et al. [17] collected and processed 20,622 fire data as well as historical weather data in Changsha. Data mining reveals that the average daily fire frequency is lowest in the temperature range of 20 °C and 25 °C, which is likely due to the low power utilization rate. The lowest daily temperature predicts better performance than the highest daily temperature, according to polynomial fitting.

3. Fire Rescue Prediction Based on ARIMA Model

3.1. Data Sources. This paper uses the situation of fire rescue police in a certain place from 2016 to 2020 as the data source. The calculation process is based on the data of that place from January 1, 2016, to December 31, 2019, and the number of fire rescue police is established by month. Predictive model uses the data from January 1, 2020, to December 31, 2020, as the model's verification data set, evaluates the accuracy and stability of the model, and predicts the number of fire rescue alarms in each month of 2021. The situation of fire and rescue police from 2016 to 2020 is shown in Table 1.

3.2. The Proposed Modeling for Fire Rescue Prediction

3.2.1. The Procedure of ARIMA Model. In our study, we use the ARIMA model for fire rescue prediction. The prerequisite for the establishment of the ARIMA model is that the time series are required to have stationarity. It can be judged intuitively by making the original sequence diagram, and the stationarity of the sequence can also be verified by the inspection method. If the sequence is not stable, one can use data transformation or difference to make the data stable. Combined with the data stabilization processing, the autocorrelation (ACF) diagram and partial correlation (PACF) diagram are drawn for the sequences that meet the stability requirements after preprocessing, and the model is preliminarily identified and ranked according to the tail-cutting or tailing of the ACF diagram and PACF diagram. If the ACF graph is tailing and the PACF graph is tail-cutting, the AR(p) model is applicable, and the value of PACF tail-cutting is the p value. Otherwise, the MA(q) model is selected, and the tail-cutting value of the ACF graph is the q value. If both ACF and PACF graphs are tailed, one can consider the ARIMA(p, d, q) model. Generally, a method of gradually trying from low order to high order is adopted. The next step is the fitting of the ARIMA function. The optimal model is tested to see whether there is a correlation between residuals. Then, the optimal model is used to predict the historical data. Finally, the optimal model is used for prediction.

From the historical data in Table 1, it can be seen that in order to predict the number of fire rescue polices in 2021, a fitting relationship between the numbers of polices and time should be established.

At present, the classic time series forecasting models include the ARIMA model, regression model, time convolutional network, and gray model. We use the ARIMA algorithm in this study. The ARIMA algorithm is one of the main tools for linear time series forecasting [18]. It takes the time data sequence of the prediction object as a random sequence for difference and smoothing and then uses a mathematical model to approximate the sequence to predict the future value of the time sequence.

The ARIMA model is a time series combination model that combines the autoregressive process (AR) and the moving average process (MA), written as ARIMA (p, d, q). P is the lag order of the autoregressive process, d is the lag order of the time series, and q is the lag order of the moving average process. The linear equation is as follows:

$$x_i = c + \sum_{i=0}^{p} \phi_i x_{i-1} + \varepsilon_i + \sum_{i=0}^{q} \theta_i \varepsilon_{i-1}, \tag{1}$$

where x_i is a stationary variable, c is a constant, $\phi_i (\phi_i \neq 0)$ is the coefficient of the coefficient $x_{i-1}, x_{i-2}, \ldots, x_{i-p}$of the autoregressive lag term, and ε_i is the residual. It is assumed that the residual sequence is a Gaussian white noise sequence. θ_i $(\theta_i \neq 0)$ is the coefficient of the moving average lag term $\varepsilon_{i-1}, \varepsilon_{i-2}, \ldots, \varepsilon_{i-q}$.

3.2.2. Data Stability Analysis and Processing. Let $\{X_t\}$ be the time series data of the number of alarms. From the time series diagram (Figure 1), it can be seen that the values of each series fluctuate up and down along a straight line, but the fluctuation range is very irregular, so it is a nonstationary time series. First, $\{X_t\}$ is smoothed to obtain the stationary time series $\{Z_t\}$, the statistical characteristics of the sequence $\{Z_t\}$ are judged, and the stationary time series model required for the modeling sequence $\{Z_t\}$ is determined. By calculating the ACF and PACF of the time series $\{Z_t\}$, the time series model required for the modeling sequence $\{Z_t\}$ is determined. The ACF and PACF diagrams of the sequence $\{Z_t\}$ are shown in Figures 2 and 3.

It can be seen from Figure 3 that the ACF of the sequence $\{Z_t\}$ always fluctuates around zero, rather than tending to zero. The ACF of the sequence $\{Z_t\}$ does not have tail-cutting properties and has tailing properties. In Figure 3, the PACF value of the sequence $\{Z_t\}$ always fluctuates around the zero value; instead of tending to zero at a certain moment, it also has a tailing property. Both of these functions have tailing properties, which are consistent with the characteristics of the ARIMA model [19].

3.2.3. Significance Test of Model Order and Parameters. After completing the stationary sequence, since the nonstationary sequence becomes a stationary sequence after k-th difference is completed, it obeys the ARMA(p, q) model, so the order is determined. Commonly used methods of order determination include F-test order determination method, residual variance graph order determination method, and function criterion order determination method [20]. The function criterion order determination method is to determine the order of the model by defining a criterion function. At present, there are Akaike information criterion (AIC) guidelines and BIC guidelines in the mainstream. For the ARMA (n, m) model, the calculation equation of the AIC quasi-measurement function is as follows:

Table 1: The situation of fire rescue police from 2016 to 2020 (unit: times).

	Jan.	Feb.	Mar.	Apr.	May	Jun.	Jul.	Aug.	Sep.	Oct.	Nov.	Dec.
2016	79	95	98	51	275	67	63	40	50	31	38	43
2017	58	28	44	14	148	87	23	42	49	33	65	68
2018	54	129	68	71	107	119	59	50	46	44	40	63
2019	67	76	73	44	138	146	72	30	41	26	25	36
2020	28	23	28	46	62	55	25	29	36	25	51	62

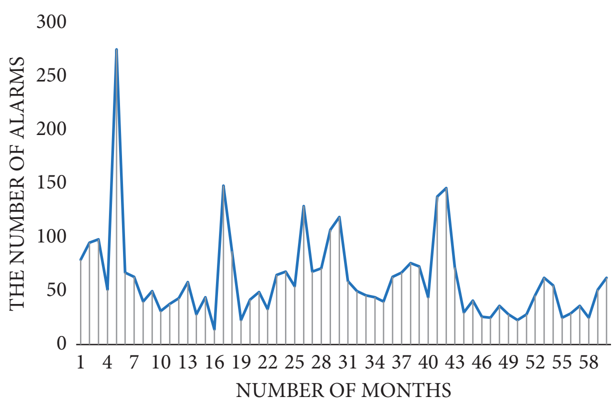

Figure 1: Time series chart distributed by month.

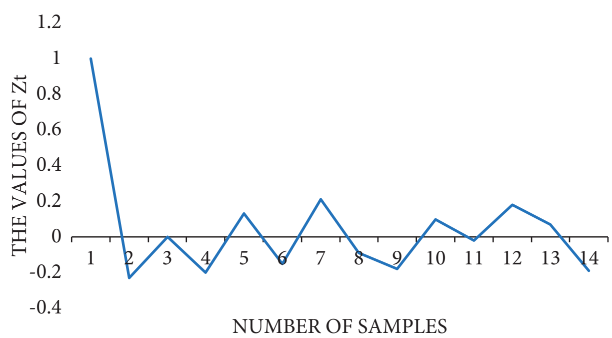

Figure 2: Autocorrelation function of sequence $\{Z_t\}$.

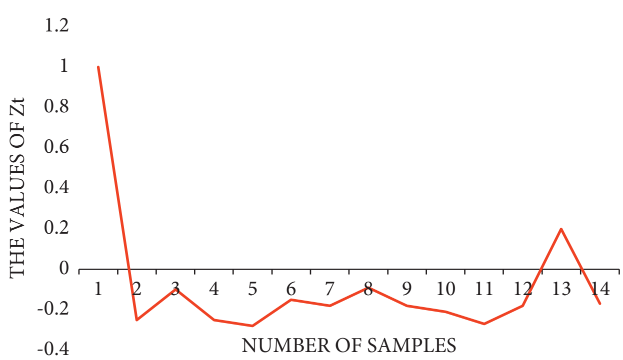

Figure 3: Partial autocorrelation function of sequence $\{Z_t\}$.

$$\mathrm{AIC}\,(n,m) = In\left(\sigma^2\right) + \frac{2\,(n+m)}{N}, \tag{2}$$

where n and m, respectively, model the autoregressive and moving average partial orders of ARMA, N is the number of sequence values, and σ^2 is the estimated value of noise variance in the model. The sequence $\{X_t\}$ is smoothed to get the sequence $\{Z_t\}$, and the order is determined by the AIC criterion. For a stationary time series $\{Z_t\}$, the order of ARMA (n,m) describing the sequence $\{Z_t\}$ is determined by comparing the AIC values of different models; that is, the autoregressive order n and the moving average order m in the model are determined. For a sequence $\{Z_t\}$ with 48 data, the corresponding model AIC value is calculated by the above formula. For the model ARMA (n,m), the upper and lower limits of n and m are determined, that is, the range of values for n and m. Generally, the lower limit is 1, and the upper limit is 1/10 of the number N of values in the sequence. Therefore, the lower limit of n and m is 1, and the upper limit is 5. It can be obtained that n and m have a total of $5{\times}5 = 25$ combinations of values, so there are a total of 25 AIC values. See Table 2 for details.

Through Matlab calculation, it is found that the minimum AIC value is AICmin = 6.7066. At this time, the corresponding orders n and m of the ARMA model are both 5. Therefore, the final selection model is ARMA (5, 5). According to the calculation, the number of differences $k = 1$.

3.3. ARIMA Model Analysis and Forecast. The application uses ARIMA (5,1,5) to model the sequence $\{Z_t\}$, and the fitting is shown in Figure 4.

In Figure 4, the trends of peaks and valleys fit more closely, so a rough forecast can be given. When evaluating the accuracy of the model using 12 data in 2020, an error analysis chart (Figure 5) and the error analysis table (Table 3) are listed.

Because there are many causes of accidents and disasters, the randomness is extremely large, so there is no complete law to follow. Therefore, the data given are very volatile, and the regularity is very weak. It is difficult to establish the prediction model itself. Therefore, when the ARIMA model gives data, the forecast in a certain few months may be very inaccurate (as in July 2020 in the above table). However, in general, the error has been small, the model is still more successful, and the accuracy is high.

In the stability check, several larger parameters were modified, and the excessively large parameters were reduced to a large extent. After changing the data, it is found that within the scope of 2020, the change in the fitted image is not

Table 2: AIC value.

No.	AIC	No.	AIC
1	7.4735	14	7.7080

Table 4: Forecast of the number of fire and rescue police in each month of 2021.

Month	Jan.	Feb.	Mar.	Apr.	May	Jun.	Jul.	Aug.	Sep.	Oct.	Nov.	Dec.
Forecast value/time	32	48	59	45	61	31	35	24	16	31	28	40

very large (see Figure 6). Therefore, this algorithm can guarantee certain stability in practical applications. When the parameters change within a certain range, the ARIMA algorithm can ensure that the sensitivity is not too high. The result will not change much. Table 4 shows the forecast results of the number of fire rescue police in each month of 2021.

4. Conclusion

This paper analyzes the fire rescue data from 2016 to 2020, uses the ARIMA algorithm to establish a predictive model of the number of fire rescue polices, uses the 2020 data for proofreading and analysis, and finally predicts the monthly number of police fires in 2021. This method only needs endogenous variables and not other exogenous variables and has strong operability and high accuracy. Through verification, the ARIMA model can better predict the number of fire rescue alarms. However, our ARIMA model also has several shortcomings. First, in our model, the future value of the sequence variable is assumed to satisfy the linear function relationship between the past observation value of the variable and the random error value. Since most time series contain nonlinearity, there are great limitations in the application of the ARIMA method in practical economic field. Second, the training of the ARIMA model requires enough historical data. These are the directions of our research work in the next stage.

Academic Editor: Tongguang Ni

For most current sentiment analysis models, it is difficult to capture the complex semantic and grammatical information in the text, and they are not fully applicable to the analysis of student sentiments. A novel student text sentiment analysis model using the convolutional neural network with the bidirectional gated recurrent unit and an attention mechanism, called CNN-BiGRU-AT model, is proposed. Firstly, the text is divided into multiple sentences, and the convolutional neural network (CNN) is used to extract n-gram information of different granularities from each sentence to construct a sentence-level feature representation. Then, the sentences are sequentially integrated through the bidirectional gated recurrent unit (BiGRU) to extract the contextual semantic information features of the text. Finally, an attention mechanism is added to the CNN-BiGRU model, and different learning weights are applied to the model by calculating the attention score. The top-down text features of "word-sentence-text" are input into the softmax classifier to realize sentiment classification. Based on the weibo_senti_100 k dataset, the proposed model is experimentally demonstrated. The results show that the accuracy rate and recall rate of its classification mostly exceed 0.9, and the $F1$ value is not lower than 0.8, which are better than the results of other models. The proposed model can provide a certain reference for the related students' text sentiment analysis research.

1. Introduction

In recent years, Internet social networking, especially mobile Internet social networking platforms, has rapidly emerged around the world, and online social platforms such as Facebook and Weibo have emerged. People tend to express their own opinions on events at online social media. The student group especially occupies a large proportion of the Internet social platform users [1]. People's evaluation often contains emotional tendencies. If you can collect these comment texts and analyze the emotional tendencies of the student groups, you can understand their emotional state for certain events and provide strong support for subsequent decision-making [2, 3]. With the continuous expansion of social network user groups, tens of thousands of data are generated per second on social platforms. However, it is extremely unrealistic to collect, query, analyze, and count this massive data information manually. Therefore, exploring an efficient and reliable way of student sentiment analysis has become a research focus [4].

With the development of statistics and computers, it has become possible for computer automation to quickly obtain text data generated by social platforms in real time. At the same time, the text can be counted, sorted, and analyzed [5]. At present, researchers have constructed many corpora for different text analysis tasks. Text segmentation is performed by the possibility of searching for words in the corpus [6]. After the computer performs basic word segmentation on these texts, its powerful computing power can be used to mine the emotions contained in the text. The existing methods for sentiment analysis research mainly include dictionary-based methods, traditional machine learning-based methods, and deep learning-based methods. The method based on the sentiment dictionary needs to construct the sentiment dictionary manually, which is not only time consuming but also laborious. Furthermore, the sentiment dictionary for a certain dataset may not be suitable for sentiment analysis tasks of other datasets [7, 8]. The traditional machine learning models usually need to manually or automatically select features, and then we can apply these machine learning models to classify the test data using these selected features [9, 10]. Not only does this method require a large amount of data as a basis, but also the characteristics of a certain dataset may not be adapted to other datasets. Deep learning technology can obtain the deep semantic and grammatical features of the text through the nonlinear learning of the neural network and achieve the purpose of automatically extracting features by the machine [11].

However, sentiment analysis has developed from the initial two categories of emotions to multiple categories of emotions. Most existing deep learning technologies cannot meet the requirements of high accuracy, and there is little research on student text sentiment analysis. To this end, a student text sentiment analysis model using the convolutional neural network-bidirectional gated recurrent unit-attention mechanism (CNN-BiGRU-AT) model is proposed. Compared with the traditional text sentiment analysis model, its innovations are summarized as follows:

(1) Existing research often uses hand-designed feature extraction methods to extract text features, which cannot capture the complex language phenomena in the text. The proposed model uses a combination of CNN and BiGRU to automatically learn the deep semantic information of the text from a large amount of data, which further ensures the accuracy of sentiment classification.

(2) Aiming at the problem that the feature matrix dimension of CNN-BiGRU model is too large and easy to overfit, the proposed model introduces an attention mechanism. Through a perception function, the target matrix and the weight matrix in the deep learning model are connected to strengthen the generalization ability of the model.

(3) The proposed CNN-BiGRU-AT model has solved the problem of accuracy degradation caused by sample randomness.

2. Related Research

Several major problems in text sentiment polarity analysis include the following: the establishment of word vectors, the establishment of associations between words, and the tendency classification of multiple sentiment dimensions in sentiment classification prediction [12]. Text sentiment analysis refers to the use of computers to automatically calculate and process human natural language texts, involving comprehensive problems in mathematics, statistics, and computational science. Its goal is to solve the problem of computer and text sentiment analysis in order to maximize the extraction of valuable information and achieve better human-computer interaction [13].

Text sentiment analysis is essentially symbolic, so people initially tried to use symbolic methods to express language, using logic-based, rule-based, and ontology-based methods [14]. According to whether a label set is required for training, text sentiment analysis algorithms can be divided into supervised learning and unsupervised learning. Supervised learning is a hot research topic, and a large number of high-quality models have emerged. Some models have also been put into practical application in the industry and have achieved good application results. Reference [15] created emotion label training data based on an emotion expression dictionary and used fastText for supervised learning to achieve accurate sentiment analysis and evaluation results. However, it did not consider the influence of different contexts on the emotional tendency of words. Reference [16] proposed a soft classification method to measure the probability of assigning information to each emotion category for factors such as blurred emotion boundaries, expression, and perceptual changes in automatic emotion detection. A supervised learning system is established to automatically classify emotions in text stream messages. However, the continuous field annotation of sentiment labels in the dataset configuration requires a high cost, which seriously affects the efficiency of analysis. Reference [17] proposed a multimodal emotion recognition system based on speech and facial images. The supervised learning methods k-nearest neighbor network and artificial neural network are used for emotion analysis, which can accurately extract facial expression features to complete emotion analysis. However, the cost of sentiment analysis is relatively high, and the analysis effect for students with strong arbitrariness is poor.

Unsupervised learning and semisupervised learning based on the two have always been the focus and difficulty of research. Recent research has increasingly focused on unsupervised and semisupervised learning algorithms. Core algorithms such as MLP, Support Vector Machine (SVM), and Logistic Regression are all trained on high-dimensional sparse feature vectors [18]. Reference [19] proposed a method of emotion recognition based on deep learning combined with semisupervised learning of long- and short-term memory. By using an appropriate amount of unlabeled datasets in parallel, the use of labeled datasets that require high training costs is minimized, and the analysis accuracy is guaranteed while the analysis efficiency is improved. However, the classification and recognition effect of some neutral words or irony words in the text data is poor. Reference [20] proposed a sentiment analysis model using sentiment dictionary and multichannel convolutional neural network. The input matrix of the emotion dictionary is constructed according to the emotion information, so that the model can learn the emotion information of the input sentence from the various feature representations in the training process. Then, the loss function is reconstructed to realize the semisupervised learning of the network, but the classification effect for colloquial and nonstandard expressions is not good. Reference [21] studied a mechanism in which the emotions in each pair of sentences conflict with each other. By observing the emotional orientation of each pair of sentences, we can identify the true value of the proposed conflict hypothesis and use the conflict matrix to identify the conflict emotion in the text and measure its characteristics. However, the use of unlabeled data is not enough, and the performance of unbalanced processing is poor. Reference [22] proposed a new attention-based label consistency (ALC) model. It makes good use of the relationship between different samples and smoothes the classes of unlabeled data by establishing a label imbalance ALC model. The model realizes more accurate text sentiment analysis. However, there is a certain degree of randomness in the text data submitted by students, and the accuracy of sentiment analysis needs to be improved.

Therefore, for the sentiment analysis of student texts, an analysis model based on CNN-BiGRU-AT is proposed. Under the premise of adapting to the randomness and nonstandardization of students' texts, it effectively takes into account the efficiency and accuracy of analysis.

3. Sentiment Classification Model Based on the CNN-BiGRU-AT Model

3.1. Model Building. In order to implement a deep learning model for predicting the emotional distribution of students' texts, a model that combines the attention mechanism and the convolutional gated recurrent unit is proposed, that is, the CNN-BiGRU-AT model. Its structure is shown in Figure 1.

The model first uses the word2vec tool to map the words in the text into a low-dimensional real number vector representation and build a matrix that represents the initial features of the text. Then, it is used as the input of the CNN-BiGRU-AT model. Finally, the backpropagation algorithm is used for end-to-end training to generate the final model. The model can classify students' text emotions based on the text represented by low-dimensional real number vectors.

3.2. CNN Text Sentiment Analysis Feature Extraction. Unlike the usual way of processing the entire text as a long sentence, the proposed model divides the text into multiple sentences. Among them, the sentence-level feature representation is extracted through the convolutional layer and downsampling layer of CNN [23].

The first layer is the input layer. The maximum sentence length L in the dataset is defined as the fixed length of the sentence. Each sentence is represented as a two-dimensional data matrix $x \in R^{d\times L}$ formed by longitudinal splicing of L d-dimensional word vectors. If the sentence length is less than L, the missing vector is randomly initialized from the uniform Gaussian distribution U (−0.25, 0.25). The two-dimensional data matrix is represented as follows:

$$x = w_1 \oplus w_2 \oplus \cdots \oplus w_n, \tag{1}$$

where $\oplus$ is the concatenation operator. $w_i \in R^d$ is the word vector corresponding to the i-th word in the sentence. The three sentences $s_i = \{w_1^{s_i}, w_2^{s_i}, \cdots, w_L^{s_i}\}$, $s_j = \{w_1^{s_j}, w_2^{s_j}, \cdots, w_L^{s_j}\}$, and $s_k = \{w_1^{s_k}, w_2^{s_k}, \cdots, w_L^{s_k}\}$ constitute the sentence input matrices x^{s_i}, x^{s_j}, and x^{s_k}, respectively.

The second layer is a sentence feature extraction layer composed of a convolutional layer and a downsampling layer. Using the CNN model structure, multiple sets of local feature maps are extracted by multiple convolution filters in the convolution layer. Subsequently, the most representative features in each feature map are extracted in the downsampling layer, and a sentence-level feature representation is obtained.

Given a sentence input matrix $x \in R^{d\times L}$, use a filter with a window size of κ to perform convolution operations on all consecutive word windows; namely,

$$y_i = f\left(\omega_c \cdot x_{i:\, i+\kappa-1} + b_c\right), \tag{2}$$

where y_i represents the i-th element in the feature map. $\omega_c \in R^{\kappa\times d}$ is the coefficient matrix. $b_c \in R$ is the bias vector. $f(\cdot)$ represents the convolution kernel function. $x_{i:\, i+\kappa-1} \in R^{\kappa\times h}$ represents a partial word window composed of κ words. When the word window gradually slides from $x_{1:\,\kappa}$ to $x_{L-\kappa+1:\, L}$, a feature map is obtained:

$$c = \left\{y_1, y_2, \cdots, y_{L+\kappa-1}\right\}. \tag{3}$$

In the downsampling layer, the max-over-time pooling method is used to sample the feature map, and the obtained feature value is

$$\widehat{c} = \max\{c\}. \tag{4}$$

A filter with a window size in the convolutional layer can extract a local n-gram feature, and C filter structures are used by changing the window size. Each filter extracts m feature maps to fully consider the contextual information between words as much as possible. The feature maps extracted by all types of filters are subjected to the maximum pooling operation of the downsampling layer to obtain a sentence feature vector F of length $C \times m$:

$$F = \left\{\widehat{c}_{1,\kappa_1}, \cdots, \widehat{c}_{m,\kappa_1}, \cdots, \widehat{c}_{1,\kappa_j}, \cdots, \widehat{c}_{l,\kappa_j}, \cdots\right\}, \tag{5}$$

where $\widehat{c}_{l,\kappa_j}$ represents the $(1 \le l \le m)$ eigenvalue produced by the j $(1 \le j \le C)$ type filter. For a text composed of L sentence sequences, the sentence feature vector $S_1, S_2, \cdots, S_L$ is obtained after the convolutional layer and the downsampling layer are sequentially pooled.

3.3. BiGRU Text Sentiment Analysis Feature Extraction. The basic unit of the gated recurrent neural network (GRNN) is the gated recurrent unit (GRU), which is a variant of the current popular long- and short-term memory network. At each time point, GRNN accepts a sentence input vector S_t and combines the output vector h_{t-1} at the previous time point to update its hidden layer node state h_t. The iteration formula is as follows:

$$\begin{cases} z_t = \sigma\left(\omega_z S_t + \lambda_z h_{t-1} + b_z\right) \\ r_t = \sigma\left(\omega_r S_t + \lambda_r h_{t-1} + b_r\right) \\ \widetilde{h}_t = \tanh\left(\omega_h S_t + r_t \otimes \left(\lambda_h h_{t-1}\right) + b_h\right) \\ h_t = \left(1 - z_t\right) \otimes h_{t-1} + z_t \otimes \widetilde{h}_t \end{cases}, \tag{6}$$

where $\otimes$ is a cross product operation. Reset threshold r_t and update threshold z_t control the information update of each hidden layer. ω_* and λ_* represent coefficient matrices. b_*

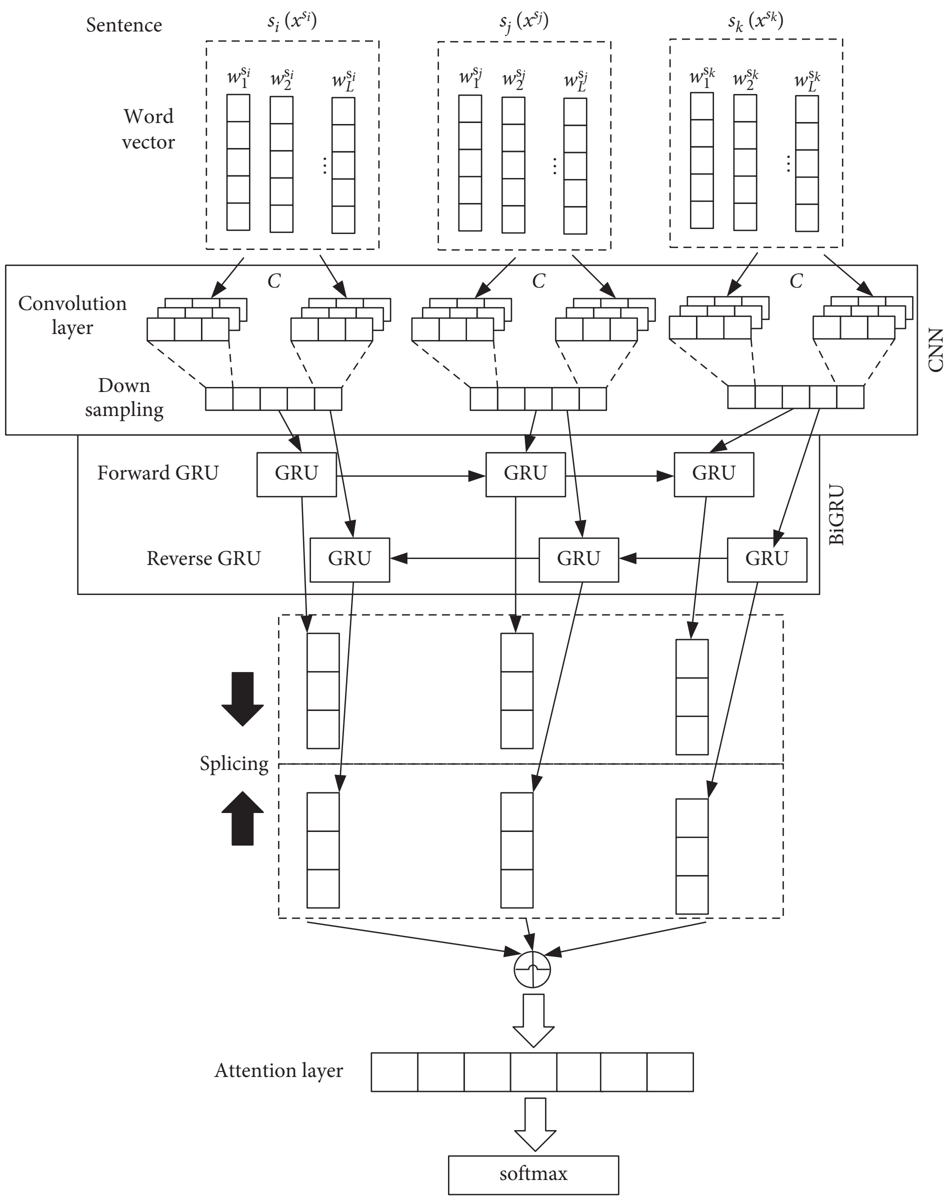

Figure 1: Structure of the CNN-BiGRU-AT model.

represents a bias vector, which is used to adaptively select and discard historical information that constructs the current semantics.

In this paper, BiGRU is used to extract the contextual semantic information features of the text. The direction of one GRU is the positive sequence direction of the input sequence, and the other is the reverse sequence direction of the input sequence. When feature extraction is performed on the input sequence, the GRUs in the two directions do not share the state. The state transition rules of GRU follow the transition occurrence between the same states. However, at the same moment, the output results of the GRUs in the two directions are spliced as the output of the entire BiGRU layer. This not only considers the above semantic information, but also considers the following semantic information.

3.4. Attention Mechanism. In the CNN-BiGRU model, CNN is responsible for extracting text features, and BiGRU is responsible for processing context and extracting sentence representations. BiGRU solves the problem of long-term dependence by adding forget gates, input gates, and output gates. The contextual semantic information processed by BiGRU is stored in a vector, but the length of the vector is fixed. When the input length of the initial sequence is extremely large, it is usually impossible to store all the semantic information in the vector. The contextual semantic information is limited, and it also prevents the model's understanding ability from reaching the ideal level [24]. Therefore, consider adding a metric that can characterize the similarity to the BiGRU model. To achieve that, the more the current input is similar to the target output, the more the weight of the current input is increased, so that the current output is more dependent on the current input. By adding adaptive weights, the model can learn more features, strengthen the generalization ability, and reduce the occurrence of overfitting [25, 26].

The essence of the attention mechanism is to calculate dynamic adaptive weights based on probability distribution. It was originally proposed by the Google Mind team and was mainly used for image classification at the time. Later, Bahdanau et al. used attention in machine translation, which also achieved good results. Nevertheless, no one has applied attention in sentiment analysis tasks. Therefore, adding the attention mechanism to the proposed model is of innovative significance. The calculation process of attention is shown in Figure 2.

The weight score is an important part of the dynamic adaptive weight in the attention mechanism, and its calculation method is as follows:

$$e_i = \chi_a^T \tanh\left(\omega_a h_i + b\right), \tag{7}$$

where h_i is the hidden layer output, ω_a is the random initialization weight matrix, χ_a is the random initialization vector, and b is the offset vector. Next, calculate the weight score ϑ as follows:

$$\vartheta = \frac{\exp\left(e_i\right)}{\sum_{k=1}^{L} \exp\left(e_i k\right)}. \tag{8}$$

According to (8), the output vector c_i weighted by the dynamic adaptive weight is

$$c_i = \sum_{j=1}^{L} \vartheta \cdot h_j. \tag{9}$$

It can be seen that the attention model connects the target matrix with the weight matrix in the neural network through a perception function. Then, use the softmax function to normalize it to get the probability distribution.

3.5. Classification Output. The classification output layer of the proposed model chooses the softmax classifier to achieve the final emotion classification. After the attention layer assigns weights to the features output by the BiGRU layer, the results are input into the softmax classifier. The classifier outputs the final result of the integration in the form of an array. Since the research object is multiemotion classification, the content in the array represents the probability of multiple emotions in the text [27, 28]. The softmax classifier calculates the probability that a sample belongs to a certain category as follows:

$$\text{softmax}\left(p_q\right) = \frac{\exp\left(w_q(x)\right)}{\sum_j \exp\left(w_j(x)\right)}, \tag{10}$$

where x represents the sample to be classified. q represents one of the j categories. p_q represents the probability that the sample x belongs to the q-th category.

At the same time, the loss function of (11) is used, and the backpropagation algorithm is used to train and update

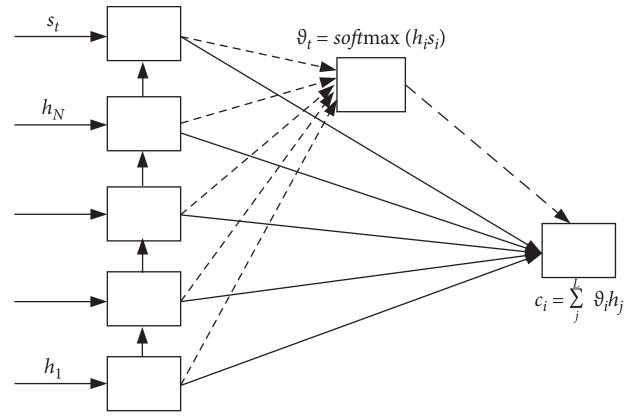

Figure 2: Calculation process of attention.

the parameter set $\theta = \{\theta_{\text{CNN}}, \theta_{\text{BiGRU}}, \theta_{\text{Other}}\}$ in the model to obtain the optimal parameters:

$$\theta = \theta - \varepsilon_1 \frac{\partial J(\theta)}{\partial J(\theta)}, \tag{11}$$

where θ_{CNN} is the parameter set of the CNN network. θ_{BiGRU} is the parameter set of the BiGRU network. θ_{others} is the parameter set of the attention layer and the softmax layer, and ε_1 is the learning rate.

4. Experiment and Analysis

In the experiment, the weibo_senti_100 k dataset (dataset address: https://github.com/SophonPlus/ChineseNlpCorpus/blob/master/datasets/weibo_senti_100k/intro.ipynb) is used to demonstrate the proposed model. The dataset contains more than 100,000 Weibo posts, all with sentiment annotations. Furthermore, the Skip-gram model in Google's open source word2vec is used in advance to perform unsupervised word vector learning on the 1.2 G Chinese Wikipedia corpus. The word vector dimension is set to 250, the learning rate is 0.01, and a distributed word vector representation model containing 520,000 words is generated. The learned word vector is stored in the vocabulary. ICTCLAS word segmentation tool is used to segment the experimental text. Used as the basic unit of sentence, the words are expressed in the form of corresponding word vectors. For unregistered words that do not appear in the vocabulary, a Gaussian distribution U (−0.25, 0.25) is used to randomly generate word vectors.

The filter window size of CNN is set to 3, 4, and 5, respectively. Each filter extracts 120 feature maps. The convolution kernel function selects the Rectified Linear Unit (ReLU) function. Both the hidden layer vector of the GRU and the context vector in the attention layer have a dimension of 120. The context vector is initialized in a randomly generated manner. During training, set the minibatch size to 64. Texts of similar length (the number of sentences in the text) are organized in a batch, and random gradient descent is performed on small batches of samples in disorder. The specific parameter settings of a single GRU are shown in Table 1.

Table 1: Parameter setting of the GRU model.

Parameter	Parameter setting
Dimension of the output of a single GRU unit	120
Iteration	100
Dropout	0.3

4.1. Classification Result Statistics. In the experiment, the number of correctly classified texts and the number of incorrectly classified texts after the classification of each emotion category in the test set are counted. The analysis results of the eight emotions are shown in Figure 3.

It can be seen from Figure 3 that the number of misclassifications of "fear," "surprised," and "happy" is relatively small, accounting for less than 10% of the total test set. Compared with other types of data, the texts of these three categories usually have explicit emotional expression words, such as "terrible," "unexpected," "shocked," and "support." Therefore, in classification, the proposed model can better capture these explicit emotional expressions. However, for emotions that lack explicit expression, such as "sadness" and "no-emotion," the proposed model has a large number of misclassifications, accounting for more than half of the total test set. Still, on the whole, the performance of the student text sentiment analysis of the proposed model is relatively ideal.

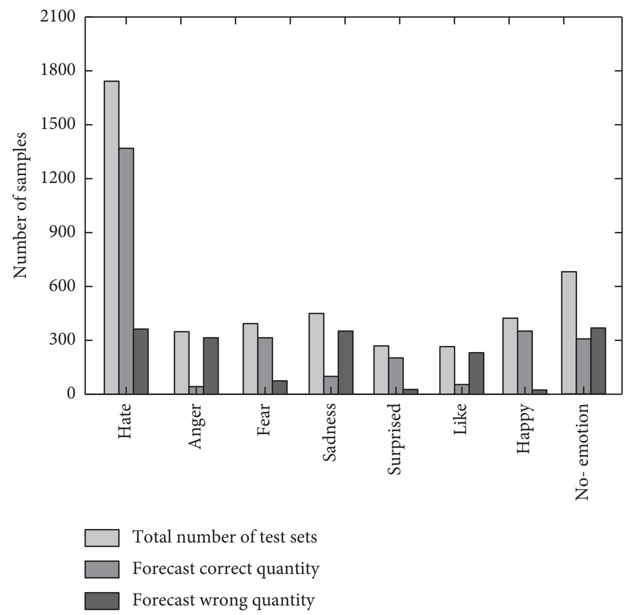

Figure 3: Text emotion classification results.

4.2. Reader Sentiment Distribution Prediction. We evaluate the ability of the proposed model to analyze students' text emotions on the experimental dataset. That is, the performance evaluation is performed by calculating the Kullback–Leibler (KL) Divergence distance between the predicted emotion distribution and the real emotion distribution. The smaller the KL distance, the better the effect of the model in analyzing sentiment distribution. The KL distance is calculated as follows:

$$KL(\widehat{p}\|p) = \sum_i \ln(\widehat{p}_i/p_i), \tag{12}$$

where $\widehat{p}$ represents the true probability value of the student's emotional label. p represents the predicted probability value of the student's emotional label.

In order to demonstrate the student text sentiment analysis ability of the proposed model, it is compared with the models in [15, 19] and [20]. The result is shown in Figure 4.

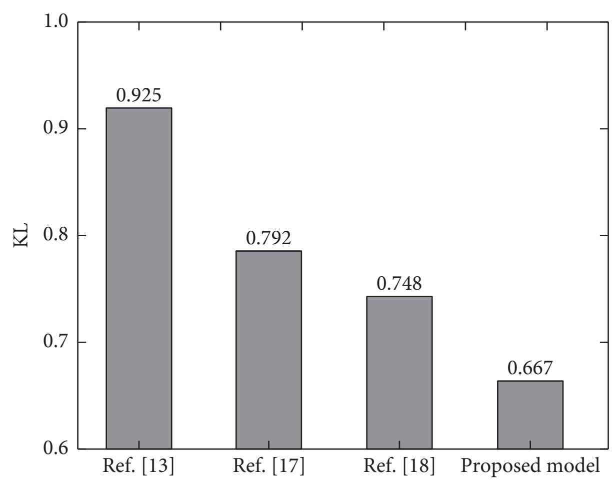

Figure 4: Comparison of experimental results of predicting students' emotional distribution.

It can be seen from Figure 4 that, compared with other models, the CNN-BiGRU-AT model can significantly improve the prediction effect, and the KL distance is only 0.667. It uses CNN to extract text features and BiGRU to process context and extract sentence representations. At the same time, using AT to link the target matrix with the weight matrix of the neural network, the model can learn more features and strengthen the generalization ability. Reference [15] uses fastText to learn emotion tags based on emotion expression dictionaries. However, with the lack of contextual considerations, the prediction effect is not good, and the KL distance is as high as 0.925. Reference [19] proposed a semisupervised learning model based on deep learning combined with long- and short-term memory to predict emotion types. The combination of models improves the accuracy of sentiment classification prediction, with a KL distance of 0.792. Nonetheless, for some emotions that are not easy to recognize, the prediction performance is poor. Similarly, [20] uses sentiment dictionary and multichannel CNN model for sentiment analysis, and the KL distance value is similar to that of [19]. However, the prediction effect of colloquial and nonstandard expression classification needs to be improved. Through comparison, it is found that the proposed CNN-BiGRU-AT model is effective in extracting the semantic features of the text with the bottom-up hierarchical structure of "word-sentence-text." Not only the semantic

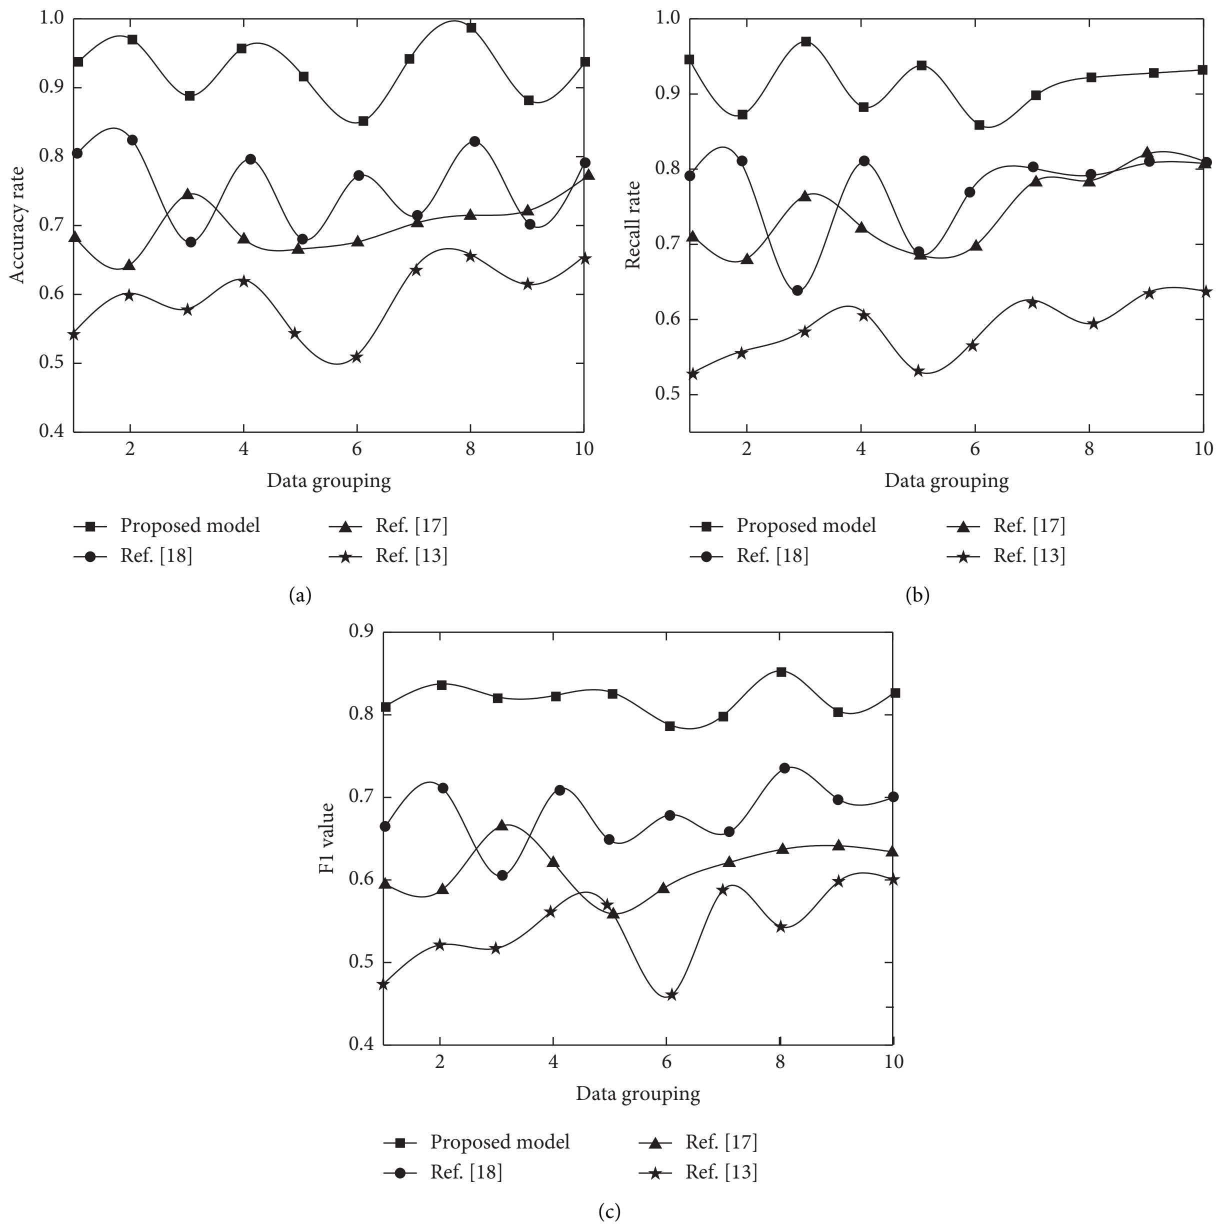

Figure 5: Performance comparison of different classification models: (a) accuracy rate; (b) recall rate; (c) $F1$ value.

information within the sentence but also the dependency relationship between the sentences is considered. In addition, the fusion of the AT mechanism can further improve the predictive ability of the model, and the obtained predictive distribution is closest to the true emotional distribution. That is, the attention mechanism can perceive contextual information and find key text features that can more affect readers' emotions, thereby improving the accuracy of emotion prediction.

4.3. Classification Performance Comparison. In order to demonstrate the effectiveness of the proposed CNN-BiGRU-AT model compared to [15, 19] and [20], a significance test experiment was designed. On the weibo_senti_100 k dataset, using word frequency as a feature, the four models are subjected to 10-fold cross-validation. The accuracy rate, recall rate, and $F1$ value of the classification results are shown in Figure 5.

It can be seen from Figure 5 that [15] uses a single fastText learning model, and the values of its three evaluation indicators are mostly distributed in the range of 0.5 to 0.6. Because the model is single and the classification of emotion types is small, the overall performance is relatively low. Reference [19] combines deep learning and long- and short-term memory network models, and [20] uses sentiment dictionary and multichannel CNN model to achieve sentiment classification, both of which use fusion models. Therefore, the performance is similar, and the values of the three indicators are mostly distributed in the range of 0.6 to 0.8. However, there is a lack of consideration of the connection between words and sentences. Therefore, the classification effect for recessive expressions is poor. The proposed model integrates CNN, BiGRU, and attention mechanism and extracts the semantic features of the text from bottom to top through "word-sentence-text." Not only the semantic information within the sentence but also the dependency relationship between the sentences is considered. Therefore, the overall performance is the best, the accuracy rate and recall rate are mostly more than 0.9, and the *F*1 value is not less than 0.8. Additionally, the results of the ten sets of data have little fluctuation, and the classification of the proposed model is more stable.

5. Conclusion

With the large-scale commercial use of 5G technology and the rapid development of the mobile Internet, social media platforms generate massive amounts of user social information every day. Obtaining people's views and emotional tendencies with high precision has become an urgent problem to be solved. To this end, a student text sentiment analysis model using the CNN-BiGRU-AT model is proposed. Among them, CNN, BiGRU, and AT are used to obtain the features of words, sentences, and texts, respectively. Through the top-down analysis of the connections between words and sentences, more features are sent to the softmax classifier to complete the classification of students' emotions. The experiment analyzes the proposed model based on the weibo_senti_100 k dataset. The results show that the KL distance is only 0.667, and the emotion prediction performance is better. In addition, the accuracy rate and recall rate of sentiment classification mostly exceed 0.9, and the *F*1 value is not less than 0.8, which are better than the results of other models. The proposed model effectively improves the accuracy of student text sentiment analysis.

At present, the CNN-BiGRU-AT model is not ideal for implicit expression analysis. However, the implicit expression analysis exists in a large number of emotional texts, so we have to face this problem in the next work. To further solve this problem, the processing of emerging network languages and nonexplicit text expressions will be strengthened to further improve students' text analysis capabilities.

This study combs through relevant literature, adopts a combination of typical sampling and random sampling, collects three big data technology-driven interactive marketing e-commerce companies in a specific period of Sina Weibo sample data for research, obtains historical information and data, and constructs a model. Through relevant analysis to eliminate invalid variables, we creatively selected three variables of Internet hot words, activities, and microtopics as independent variables and used marketing effects as dependent variables to carry out empirical analysis and study the marketing innovation of three representative companies based on big data technology. We discussed the use of self-media in interactive marketing e-commerce and the situation of marketing innovation based on self-media, focusing on the interactive relationship between marketing innovation and Internet word-of-mouth (brand image). Through research, we have derived the three-force model, which is the biggest result of this research, and provided a reference model for interactive marketing e-commerce companies to carry out follow-up marketing innovation based on the media. Limited to the level of research and ability, there are some deficiencies in the research, such as barrage marketing, big data marketing, and emotional computing, that have not been analyzed in depth. This article fully considers the dependence of small and medium e-commerce companies on e-commerce platforms in the era of big data and conducted detailed market research on their precision marketing strategies in the era of big data. This will be a new field that does not come from media marketing. This article intends to summarize a series of experiences and laws from special to general, from individuality to generality, so as to give full play to the role of personalized marketing in increasing website traffic and order conversion, in order to personalize the use of data by other e-commerce companies with marketing provides some valuable experiences and methods for reference.

1. Introduction

With the rapid development of information technology, the arrival of big data has brought new development opportunities for scientific research, business, and technological progress. Big data has become one of the important tools in the field of e-commerce [1]. In recent years, the country's e-commerce has ushered in a period of rapid development, and the transaction volume and scale of e-commerce have expanded rapidly [2]. On the other hand, the huge user and product base of e-commerce requires e-commerce companies to build precision marketing systems based on user needs and potential needs. The rapid development of information technology and the continuous progress of network technology have promoted the vigorous development of e-commerce. The development of e-commerce is profoundly changing people's consumption and living habits [3]. The total online retail sales have accounted for one-sixth of the total retail sales of consumer goods. E-commerce has become a powerful driving force that drives national consumption and promotes national economic growth. After nearly two decades of development, the country's e-commerce market has basically matured, and a domestic retail system represented by online retail giants, such as Taobao, JD.com, and Amazon, has formed, and the industrial competition pattern has basically taken shape [4–6].

Modern society is a society with rapid development of science and technology, and the ability to process information is continuously enhanced. Information is generated by human activities and fed back to people through data analysis techniques. Big data are the product born under this background [7]. The term big data has begun to be widely used by various media. Big data analysis methods are widely used in computer, cloud computing, Internet, and and other fields [8, 9]. Scholars from all walks of life have carried out a lot of research on the methods of collecting, processing, analyzing, and using big data and achieved fruitful results [10]. Big data analysis methods take cloud computing technology as the main thrust and gradually penetrate into the analysis and research of various disciplines and industries. In addition, big data technology has been deeply integrated with enterprise management. At present, big data are not only used to promote enterprise management and market information collection but also combined with e-commerce has brought new development opportunities for all types of enterprises. The Internet and related industries have become the first source and demand side of big data [11]. E-commerce companies can use big data technology to analyze consumer needs through massive data mining, integrated analysis, and application, and they can provide consumers with personalized services and push notifications. With the continuous fermentation of big data technology, marketing strategies based on big data have also begun to be used by small- and medium-sized e-commerce companies, bringing many opportunities and challenges to e-commerce companies [12–14].

The purpose of this research is to integrate the relevant theories of the four disciplines of tourism, economics, marketing, and communication from a microperspective and examine the marketing innovation activities of interactive marketing e-commerce companies based on self-media. Therefore, the development of e-commerce big data research must be deeply integrated with relevant marketing strategies, which supported the basic strategies of precision marketing, combined with big data analysis technology, and explored the survival method of small- and medium-sized enterprises in the era of big data. Based on the gaps in academic research and the actual development needs of e-commerce companies, this article uses E-Commerce Co., Ltd. to study how e-commerce companies, especially small- and medium-sized e-commerce companies that rely on major e-commerce platforms, should adapt to the background of the era of big data. In the era of big data, we use big data technology to track changes in customer needs, better discover customer needs, cater to changes in customer needs, and carry out research on the development of enterprises. Through relevant research on the company's products, pricing, promotion, and business strategies, it discusses how small- and medium-sized e-commerce companies can do precision marketing from the perspective of the development and trend of small- and medium-sized e-commerce platforms. Through the introduction of statistical analysis, content analysis, and other techniques to establish a complete quantitative indicator system, we extract representative interactive marketing e-commerce companies, conduct comprehensive analysis and evaluation of interactive marketing e-commerce based on self-media marketing and marketing innovation, and analyze the actual situation. We stage interactive marketing e-commerce companies publish content and effects in operating Weibo accounts, sum up experience, and give suggestions for improving the marketing strategies of interactive marketing e-commerce companies.

2. Related Work

The research scope of foreign scholars is relatively wide. The first is the organization and operation of the tourism destination marketing system, marketing alliances, and their performance evaluation. The solution usually adopted abroad is to establish marketing alliances and conduct research on their development and operations. Secondly, the research also focuses on the characteristics, advantages, development issues, evaluation system, and operation of online marketing. In terms of operational research on tourism destination marketing systems, more emphasis is placed on the research on actual operational effects [15].

Malhotra and Rishi [16] referred to the tourism destination marketing system as a tourist information system. They believed that the basic theme and commonly used dominant function of DMS is to publish and process information and processing of all tourism activities-related organizations and attractions in a particular tourist area for reservation business and several core database-based application systems used in tourism information management, public information services, industry exchanges, and tourism online marketing. The e-commerce expansion model of the destination marketing system established by Hu [17] realized the three functions of commercial activities: online promotion, service provision, and transaction execution. From this perspective, the three functions of the destination marketing system are proposed with information and service provision functions, marketing functions, and transaction execution functions. Wright et al. [18] believed that the destination marketing system is an integrated marketing tool that gathers resources and services from a marketing perspective and is also a one-stop shopping center for tourists to choose and purchase products and services from the perspective of tourists. Elia et al. [19] research focused on how destination tourism information is delivered to tourists and how software and hardware equipment can meet tourists' needs. They gave particular attention to how national-level tourism agencies use this system to publicize and promote tourism destinations in the country. This concept is more appropriate to explain the functions of the national-level tourist agency information system, but its core focuses more on reflecting the function of information data processing, ignoring the other important functions of the system, namely, the interactive communication function and the needs of tourists for the function of the service. Liu et al. [20] pointed out that the destination marketing system should consider functions from two levels: management and information technology. At the management level, the system should achieve three major functions: information provision, marketing, and market research; at the technical level, three tasks must be completed: web design, website promotion, and website evaluation.

Other scholars believe that the tourism destination marketing system organically combines efficient Internet-based tourism promotion and marketing with local tourism consulting services to provide tourists with full service, which can greatly enhance the image of the tourist destination and the overall service level. The tourism destination marketing system is not only a destination information system but also a regional organization system. They pointed out that the tourism destination marketing system has competitive advantages in terms of network sales market agglomeration, the establishment of regional unified cognition, and the sharing of information resources [21]. Some scholars have introduced integrated marketing theories into the research of DMS, introduced the forms of integrating information resources, products, and services in the system, as well as introduced specific integrated methods for unified external publicity, promotion, and communication with customers. Scholars discussed it from multiple angles. Some experts also pointed out that marketing innovation is a new product, new process, or new system that has the potential to create a new market or change the existing market. They believe that marketing innovation is a general practice in a different industry, which is a jump in the rules of the game. In this way, the marketing process or the results of the marketing process are not the same as the conventional ones. Marketing innovation is a part of strategic innovation. It is a kind of corporate ability that can create value for customers, weaken competitors, and create wealth for stakeholders. The essence of innovation lies in the formation of a "communication element" and marketing activities that play its role so that users can have a sense of trust in their products and motivate them to buy. The communication element is expressed as an idea or concept, expressed as images, words, sounds, and symbols, which can give consumers a deep impression and redistribute. Researchers believe that there are two types of marketing innovation: incremental innovation and transformative innovation. Incremental marketing innovation is mainly product innovation, whereas transformative marketing innovation is technology oriented and market oriented [22, 23].

3. Construction of an Interactive Marketing E-Commerce Recommendation System Driven by Big Data Technology

3.1. Spatial Composition of Big Data Technology. Big data mean that it does not rely on sampling surveys but integrates all the data on a certain issue for analysis and processing. It is completely different from the method of sampling samples in terms of data sources and analysis methods. Big data contain the most complete reflection of the information of an event. Figure 1 shows a big data technology space architecture. Therefore, the information contained in big data is often far more than general data. The most complete information that can be reflected on the above. Compared with general data, big data contain a larger amount of information, which means more data.

The information contained in big data has gone beyond a single text form. The information of big data can be reflected in various forms, such as pictures, videos, audios, and geographic information, and it can also reflect a certain behavior from different dimensions. Therefore, the multi-dimensional nature of big data determines that an event can be reflected from more dimensions, and it also contains more useful information, but it also increases the difficulty of information processing.

$$p(x(1), x(2), \ldots, x(n)) = \prod_{i=1}^{n} p\{x(n) \mid x(n-i+1)\}. \quad (1)$$

At present, there are many ways to apply big data at the technical and decision-making levels, and there is no fixed research method. Big data analysis technology is still in the integration stage.

$$\begin{aligned} C &= 2 \times \frac{(p(x) \times p(n))^{1/2}}{(p(x) + p(n))}, \\ f(x) &= x(i) + \frac{x(i) \times x(j)}{x(i) + x(j)}. \end{aligned} \quad (2)$$

More importantly, big data are how t_o effectively collect market data, and at the same time, on the basis of further processing and researching market data, it can obtain information that is beneficial to the organization or enterprise, obtain market dynamics, understand customer needs, and adjust it. The business strategy of an enterprise, obtaining greater profits, and the scope of market operations are all important content that big data can achieve for enterprise development.

$$T^2 - \frac{1}{n} \times \sum_{i=1}^{n} (p(i) - p(x))^2 = 0. \quad (3)$$

Because big data contain a large amount of information and reflect a large number of dimensions, and the factors that play a decisive role in a certain matter often only account for a small part, so in the processing of large-capacity but low-density information, data analysis technology seems particularly important.

$$\begin{aligned} U(x) &= (I - C)^{-1} \times C^T - \sum_{i=1}^{n} p(x) \times C(i) \sum_{i=1}^{n} p(x) \times Z(i), \\ V(x) &= \frac{\sum_{i=1}^{n} \sum_{j=1}^{n} w(i,j) \times (x(i) - x) \times (x(j) - x)}{\sum_{i=1}^{n} \sum_{j=1}^{n} w(i,j) \times x(i,j)}. \end{aligned} \quad (4)$$

Big data have the characteristics of variability, authenticity, and high value. Variability refers to the fact that data are prone to change during the recording process of big data, which increases the difficulty of information processing, and

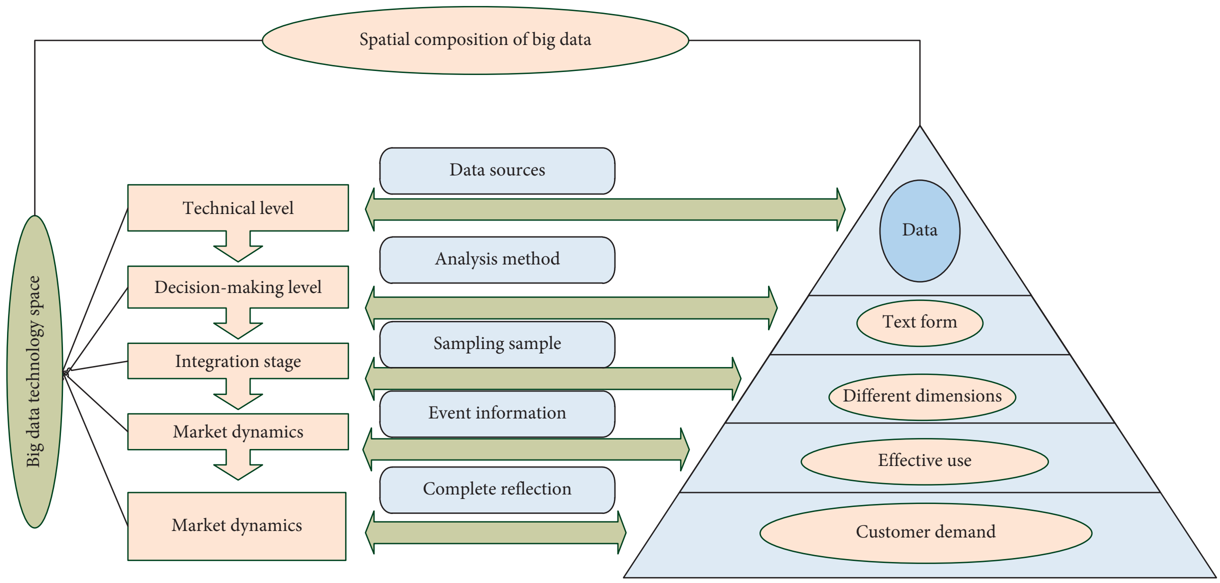

Figure 1: Big data technology space architecture.

complexity is an extension of low density. High value is the most fundamental feature of big data. Its main connotation is that if big data are used reasonably, it can derive greater value. However, the value of big data are directly proportional to the overall amount of big data collected.

3.2. Interactive Marketing Content Elements. Interactive marketing technology is a deeper method in big data analysis methods, which mainly refers to the effective analysis of data by appropriate methods from massive amounts of data. Interactive marketing technology provides technical support for precision marketing, and many scholars have made outstanding contributions in this regard. The core of interactive marketing is to analyze the characteristics of consumer behavior and to manage and research consumer groups with common characteristics based on the characteristics of consumer behavior obtained by interactive marketing. The first process of big data analysis is collection. Big data collection refers to the use of big data collection information collection platforms to collect users or other data collection tools. In the process of big data collection, the main problem is that the amount of data information is huge, the amount of data collected is high, and there are many data collection points. In the same period, a large amount of data needs to be collected at the same time. Figure 2 shows the statistical distribution of the deviation of interactive marketing data collection. Therefore, in the process of big data collection, it is necessary to establish a fairly large database, and how to further design the reasonable use and distribution of the database.

The second step is import and preprocessing, which mainly refers to the elimination of invalid information, redundant information, and low-value information after the first collection of information. Therefore, it is necessary to effectively filter and analyze the data before processing. Then, we import the obtained preliminary screening information into another large database. This step is mainly to preprocess the big data. The third step is to conduct statistics and analysis. This process is a process of further refined processing of big data. The effective data are analyzed and filtered, and statistical processing is performed, and finally, effective information is obtained. Different from the above process, big data information mining does not have a definite path or statistical analysis method. The division of labor for small- and medium-sized e-commerce companies has been further refined, and the industrialization of commodities, art, operations, inventory management, and delivery has been formally formed, which has also led to the development of models, express delivery, and other industries. It mainly uses a large amount of data collected in a database and uses various algorithms to perform calculations, which results in complex data. As far as possible to get the effect of prediction or to be able to draw other effective conclusions, the statistical analysis and mining process of big data are considered to be the key process of whether data can be transformed into value space and source of value in the process of big data information processing.

3.3. E-Commerce Platform Construction. E-commerce usually refers to the use of Internet technology, based on the browser/server application method, where buyers and sellers conduct various trade activities on the Internet platform in a face-to-face manner to realize consumers' online shopping, online payment, and various business activities and transaction activities and other new business operating models. Figure 3 shows the distribution of e-commerce platform models. The rise of e-commerce has a close relationship with the development of computer network technology, and the development history of e-commerce has a close relationship with the progress of computer network technology. E-commerce includes many models, typically, B2B (Business to Business), B2C (Business to Consumer), C2C (Consumer

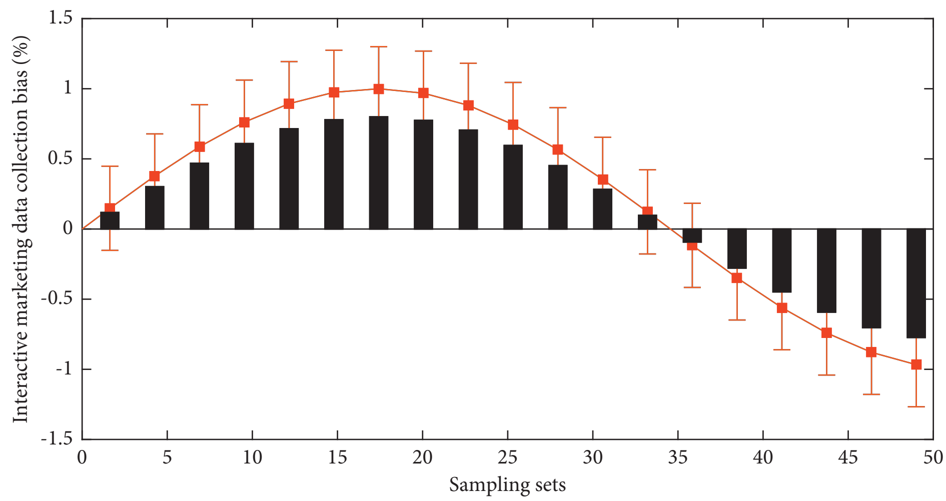

Figure 2: Statistical distribution of the deviation of interactive marketing data collection.

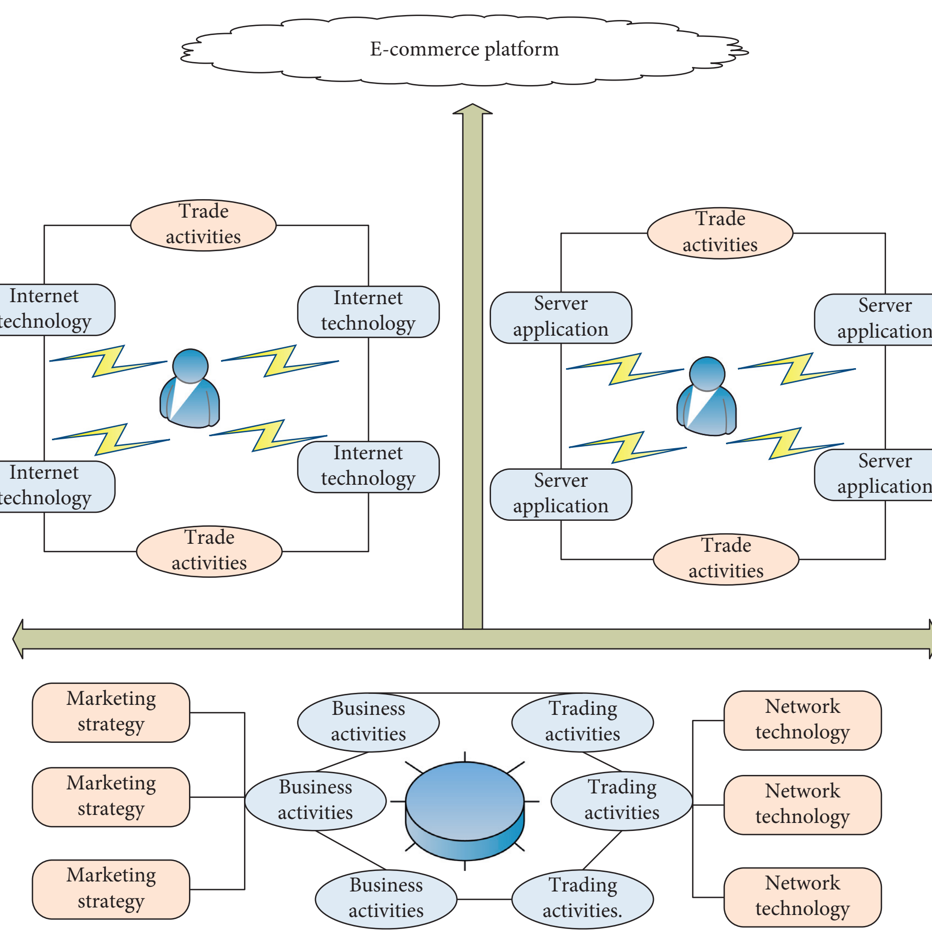

Figure 3: Distribution of e-commerce platform models.

to Consumer), and the recent emergence of P2P (Peer to Peer), and O2O (Online to Offline). Small- and medium-sized e-commerce enterprises refer to small- and medium-sized enterprises that are engaged in e-commerce business (mainly B2C, C2C, O2O) and conduct e-commerce business on large-scale e-commerce platforms. These enterprises are generally small in scale, with traffic entrances and payment methods. Goods transportation is mainly controlled by large-scale e-commerce platforms and express operators.

E-commerce platform companies provide a good development platform for small- and medium-sized e-commerce companies. Customs clearance is directly attached to large-scale e-commerce platforms, saving small- and medium-sized e-commerce companies the trouble of building their own traffic portals. Users can complete what they need on an e-commerce platform. For most of the transactions, the integrated platform operation also helps small- and medium-sized e-commerce companies develop better. However, with the increasingly fierce competition in the industry, the emergence of big data, and the transformation of small- and medium-sized e-commerce companies themselves, market competition has turned to competition characterized by the discovery and satisfaction of user needs, precision marketing strategies, and differentiated competition strategies; the combination of big data strategies is an important path for the continued development of small- and medium-sized e-commerce companies in the future. Precision marketing is a company that pays more attention to marketing actions and results when formulating marketing communication plans. This requires marketing communication and the implementation of marketing activities to be more precise, measurable, and able to achieve higher returns. Small- and medium-sized e-commerce companies have large and small data, simple and relatively complex data, and generally use Access databases or SQL-server databases. Considering that the data types and specific characteristics of user profile data may be more cumbersome, the use of NoSQL databases may be more reasonable and common. NoSQL databases are integrated with the data analysis package, which can efficiently process, organize, and manage data, which has very important advantages. The use of the database is very wide, so it is also widely used by e-commerce companies, with lower usage and maintenance costs.

3.4. System Hierarchical Weight Distribution. After having the database, the next step is to analyze the data. The analysis of the data mainly starts from the two steps of statistical data and exploratory analysis. The statistical data are mainly to analyze the existing data, from which some conclusions can be drawn, such as the popularity of the product, the consumer's preference for buying the product, the relationship between the consumer's demographic characteristics, and the purchase of a certain product or service to compare product sales with similar products or products of different categories in other stores. Table 1 shows the cluster analysis of consumer purchasing preferences. Exploratory analysis is a further level of data analysis. It is mainly to dig out some of the content and conclusions of the existing data that are not represented by the appearance, such as clustering and classification. These require unique analysis techniques, and how big the information can be extent to which the value is played also differs in this process.

The goal of precision marketing is to achieve a low-cost sales strategy through precise customer communication channel selection and sales channel selection, so that both customers and manufacturers can benefit. The core of the word "precision" in precision marketing is to focus on the needs of consumers, which means that the precision marketing system can distinguish a consumer from other consumers, and recommend the best for consumers according to their needs. It is possible that a certain product or service, instead of the previous emphasis on marketing coverage, should be broad and comprehensive. With the development of information technology, after effective integration, analysis and processing of big data generated by consumers, target consumers can be found among consumer groups, so as to achieve accurate information transmission.

Table 1: Cluster analysis of consumer purchasing preferences.

Cluster index	Popularity	Fusion rate/ %	Economic efficiency ratio
1	0.71	82.5	1.01
2	0.84	81.7	1.17
3	0.69	79.6	1.14
4	0.82	77.1	1.07

Figure 4 shows the histogram of the economic efficiency of marketing activities. We screen out the information used for identification on the website, such as baby ID; through comprehensive comparison, screen out cross-cutting and interfering data, such as "sales" in the number of sales and successful transactions; do not consider those that do not affect the decision-making factors such as store name, store reputation, and product rating. Specifically, precision marketing means that companies pay more attention to marketing actions and results when formulating marketing communication plans. This requires marketing communications and marketing activities to be implemented more accurately, measurably, and with high returns. In addition, more and more investment in direct sales. In the end, factors that have an impact on the selection of products are left: product specifications, transaction prices, and other customer-related factors; store-related factors such as the number of successful transactions and service commitments; and factors related to platform and regional sales, such as shelves. Precision marketing greatly reduces the cost of investing in unrealistic consumers by discovering potential consumers in consumer groups, improves the economic efficiency of marketing activities, and greatly reduces the cost of marketing activities themselves, but the cost reduction will not weaken the marketing activities themselves, it will increase the accuracy of the activities.

4. Application and Analysis of Interactive Marketing E-Commerce Recommendation System Driven by Big Data Technology

4.1. Big Data Feature Extraction. The dependent variable in this study is marketing effect, which can be defined as feedback from media content. This definition mainly measures the short-term effects of self-media marketing. The marketing effect index is expressed by the sum of the number of likes and the number of comments. Typical sampling is used for the selection of self-media platforms. Figure 5 shows the pie chart of the percentage of marketing effect indicators. Sina is selected as the representative from the relevant Weibo platforms, so the data come from Sina Weibo. Its

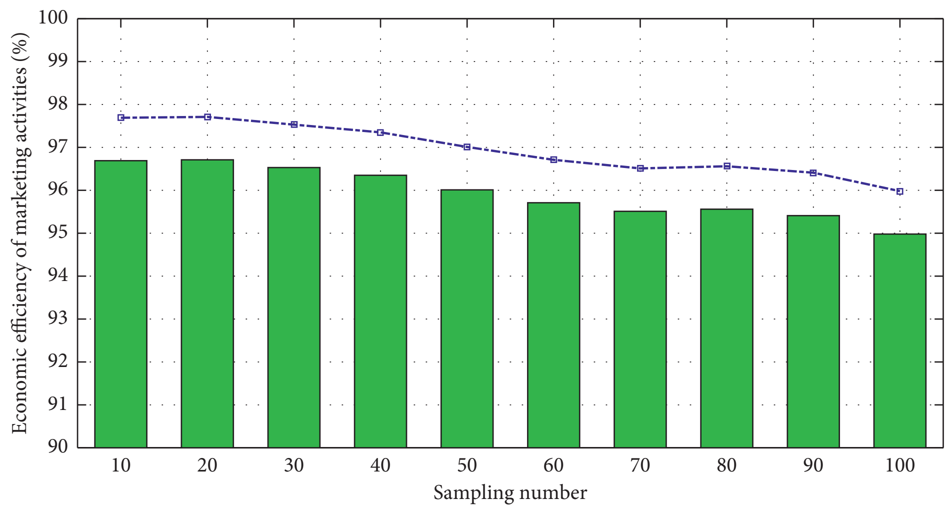

FIGURE 4: Histogram of economic efficiency of marketing activities.

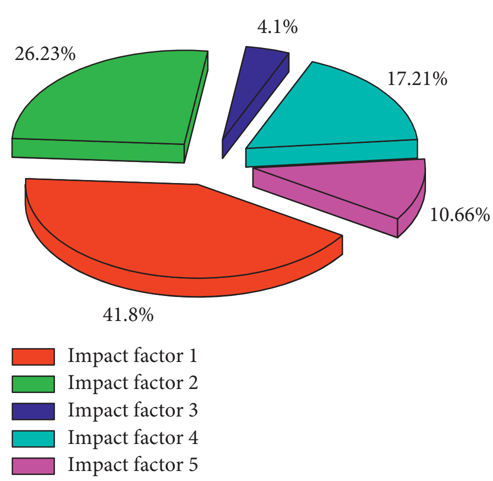

FIGURE 5: Fan chart of the proportion of marketing effect indicators.

representative significance is that Sina Weibo is the largest self-media platform, covering a large consumer group. At the same time, all major interactive marketing e-commerce companies have opened Weibo accounts on Sina Weibo, which is an important platform for interactive marketing e-commerce online marketing, which facilitates horizontal comparison between manufacturers. At the same time, Sina Weibo has the characteristics of open access, can obtain historical information and data, and can provide a sufficient number of samples. Therefore, this article chooses to collect Sina Weibo sample data from a specific period for research.

Using the network data collector, we will analyze the collected 927,174 sets of 268.88 million data. Because these data have the characteristics of large data volume, various types, and low-value density, we will do the data before analysis. After a certain amount of preprocessing, the results of this preprocessing are used to position the target market in terms of channels and regions, and in terms of product attributes and brands, to position consumer demand preferences. We take the seller's ten service promises as the product attribute influencing factors that influence customers to choose between different brands, set it as a dummy variable to introduce the model, and use the MNL model to predict the probability of customers choosing between different brands, which is then the company's selection of promotion channels during the product launch process that provides a basis for decision-making. From the perspective of consumer preferences, we analyze different platform structures through data, and make a certain analysis of which category and which brand of products sell well and the positioning of average prices. Specific to the price range, we discover the potential purchasing power and consumption range of the target customer group; through the analysis of product attributes, we can find out which features of the product will be particularly favored by consumers. Finally, it provides a basis for company A's precise marketing decision on the product.

4.2. E-Commerce System Evaluation. Because the total number of microblogs in the three sample companies exceeded 2,000 within a year, the existing research methods are not sufficient to analyze all of them. Therefore, this article adopts the method of random sampling by computer. We establish a personnel service feedback and evaluation system and establish a personnel efficiency database based on big data. Based on consumer feedback to various service personnel, company internal evaluation system information, and basic information data, the performance of employees can be analyzed and compared, various personnel arrangements can be made, and avoidable accidents can be predicted. The specific steps are to use the random sampling function of the *R* language, and each manufacturer will sample three months. Secondly, we extract the page numbers of each manufacturer in each month. According to power analysis, this number of microblogs can represent the total sample during the study at a significance level of 0.95. After we have a detailed understanding of the requirements, we need to sort out the data collected on this page. In the end, I chose the store name, product name, price, and number of successful transactions as the collection object. Figure 6

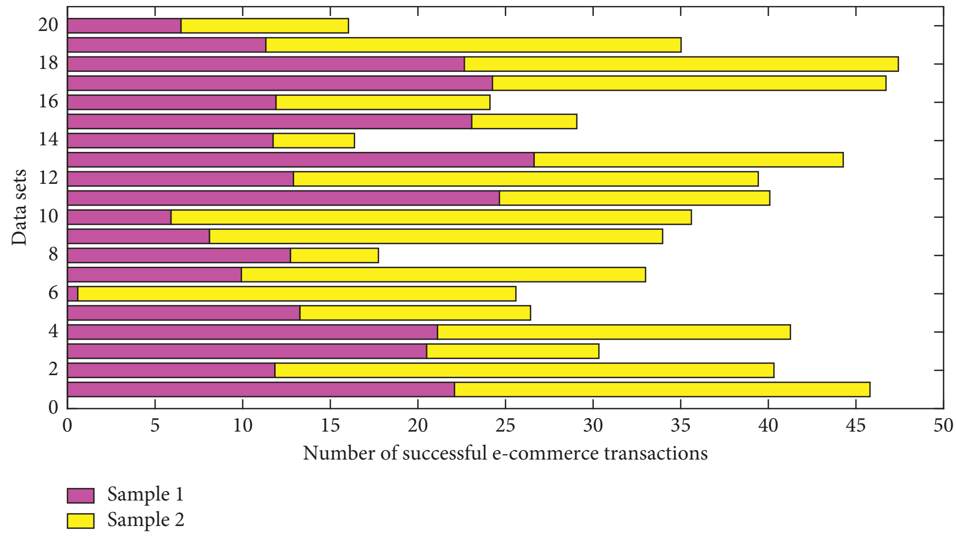

Figure 6: Histogram of the number of successful e-commerce transactions.

shows the histogram of the number of successful e-commerce transactions. After completing the data collection, the second step is to classify and filter the data: which are the information used by the website for identification and do not have the value of data exploration and mining; which data are almost duplicated and can be eliminated in half; and which data need to simultaneously consider and get useful data.

The information included in the transaction data that I finally sorted out includes product type, platform, store name, store reputation, product rating, store location, title, baby ID, brand, product specifications, whether it is free shipping, title, price, transaction price, sales volume, number of successful transactions, number of comments, number of favorites, and payment methods. After screening, there are 174 groups of valid and complete data information. Although the target of collaborative filtering technology is specific users, it cleverly uses the information of all users. Recommendations are mainly based on the preferences of other users who are most similar to the user. There are many ways to calculate similarity, such as cosine similarity (the denominator is the square root of the product of the number of products purchased by two users). After we calculate the similarity, we can sort the preferences of other users on the products according to the similarity weighted summation method and then recommend them to specific target users. This collaborative filtering recommendation technology can not only accurately infer the potential needs of users, but more importantly, it can increase cross-sales, that is, when users purchase a certain category of products, they recommend other categories of products to users, thereby increasing the diversity of high user purchases.

4.3. Example Application and Analysis. Content-based recommendation technology is one of the important contents of personalized marketing in the era of big data. This technology originated from information retrieval and information filtering, and its root lies in the acquisition and quantitative analysis of content. Because the research in text information acquisition and filtering is relatively mature, most of the current content-based recommendation systems are mostly the text of the product information operation after analyzing. Coding is to place the analysis unit in the category system. For the first time, we have arranged a week to train coders and improve the coding plan based on the training situation to make the understanding between coders similar to achieve the predetermined reliability. Second, we conduct preresearch to check the reliability of coders and ensure that they master coding skills and methods. Third, in the formal study, standardized tables are used, and computer-aided coding and statistical work are used. Based on similar research, we use a category system to classify each Weibo. The classification is carried out from the three levels of Weibo's basic information, content category, and form, and 21 subcategories are determined to try to exhaust the possibilities of interactive marketing e-commerce microblogs and produce meaningful results.

Figure 7 shows a stick chart of the significance test of e-commerce product categories. To analyze the data of the target product, it is first necessary to separate the data that meet the requirements from the 100 sets of data that have been preliminarily sorted out. After preliminary screening, 100 sets of target product data were obtained, and then, service commitment attributes were selected among them as the data basis for modeling. Next, we need to analyze and process this part of the data. We will use 70% (the first 50 groups) of samples as training samples for modeling and analysis. In addition to taking security measures to protect consumers' personal information, the industry has also developed a star-rated label on the web page to allow consumers to identify the company's logo for safeguarding consumer data. We will substitute variables into the MNL model and use SAS to test them for empirical analysis, and based on the results of this analysis, we make the choice of promotion channels for the products on the shelves. After

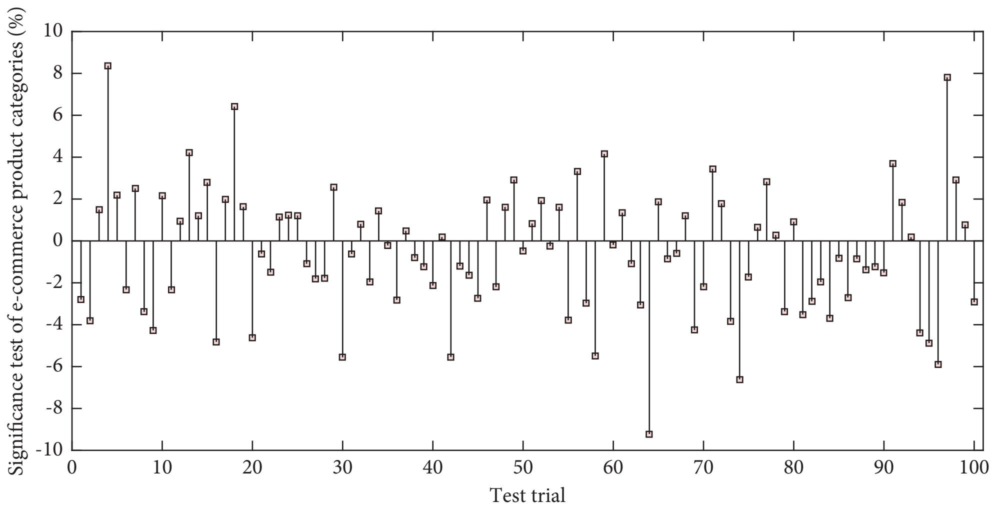

FIGURE 7: Matchsticks for the significance test of e-commerce product categories.

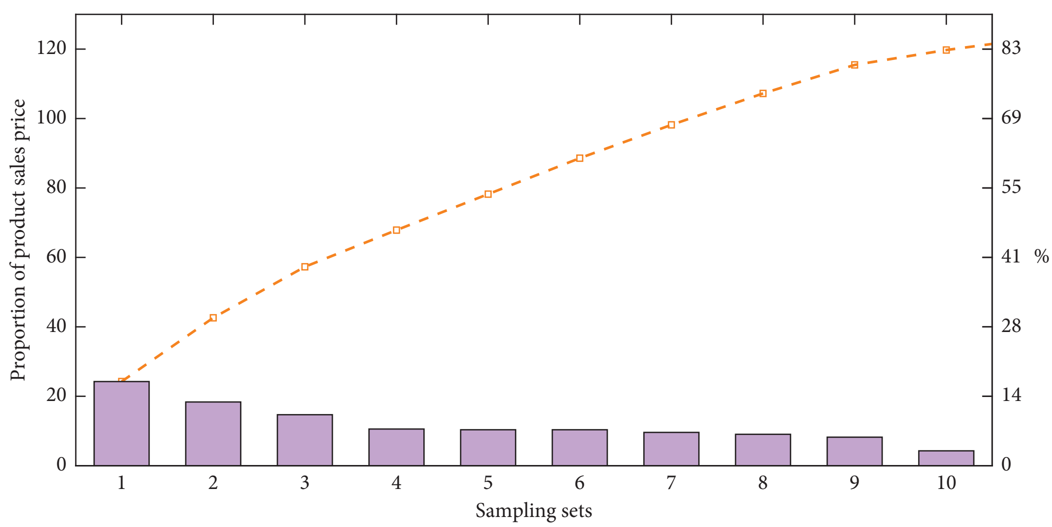

FIGURE 8: Line chart of product sales price percentage.

the model is obtained, the model is used to predict the remaining 30% (15 groups) of the test samples, and finally, the prediction results are tested. Using 70% (the first 50 groups) of samples as training samples, the following results are obtained through repeated screening of variables. Obtaining the data summary, the significance test of the respective variables' influence on the overall model, and the estimated value and significance test of the respective variables are given. It can be seen that the variables VAR18, VAR19, and VAR25 all passed the significance test. The last line is the likelihood ratio test of the goodness of fit of the model. The likelihood ratio statistic is 6.93, and the statistical result is not significant ($p = 0.0743$), which shows that the fitted model is acceptable. The last column gives the results of the significance test of each independent variable for each MNL model, in which the coefficient estimates of the remaining independent variables are not significant except for the estimated value of the second coefficient of VAR18 and the estimated value of the third coefficient of VAR19. All passed the significance test.

Figure 8 shows a line chart of the percentage of product sales prices. It can be seen that in terms of product prices, from the perspective of Taobao's entire network, the product industry's most shipped price range is between 11 yuan and 22 yuan, of which shipments accounted for 27.9%, and the high sales price range is between 22 yuan and 33 yuan, of which sales accounted for 14.3%. In addition, there is a significant increase in the range of 333–432 yuan, indicating that most consumers still choose relatively low-end cosmetics and do not pursue branded products; the other part tends to buy branded products, focusing on products purchased in several well-known brands, although the products at the midprice range are seldom bought. Judging from the basic information of the research subjects, they have the ability to read and understand the questionnaire of this research and can accurately express their opinions.

Therefore, the data of this questionnaire are valid. The sales of normal specifications accounted for the highest proportion, accounting for nearly 90% of the market share, whereas the choice of suits was less, indicating that consumers' demand is only to choose a certain type or a certain fragrance of the product according to their preferences, rather than buying a certain brand. For a full set of products, some consumers tend to prefer to purchase the corresponding light-backed products, and such consumers may prefer to use them for their own use.

5. Conclusion

This article mainly studies the precision marketing system based on big data, sorts out the history of e-commerce development, discusses the possibility of combining big data and precision marketing systems, and analyzes the major e-commerce platforms and enterprise application of big data technology in the era of big data. At the same time, the study is carried out with it as a typical case, focusing on small and medium e-commerce companies, especially small e-commerce companies that rely on e-commerce platforms, such as Amazon, JD.com, and Taobao, to carry out the real possibility and necessity of precision marketing based on big data. Based on practical factors, this article designs a general system platform based on general big data precision marketing strategies and uses clustering algorithms as an example to illustrate the use of the system. At the same time, from the aspects of improving enterprises' understanding of big data strategy and precision marketing, applying big data to adjust corporate marketing strategies, precision marketing channels, deepening consumer demand analysis, applying big data analysis results to optimize business operations, and the like, it proposes to optimize the precision marketing of system countermeasures and suggestions. In most cases, the measurement of validity is the measurement of construction validity, and the measurement of construction validity is carried out through confirmatory factor analysis. Specifically, it is judged by the standardized factor loading of the item, if the fit is good, then it can be further tested for validity through standardized factor loading coefficients. This study avoids the complicated model construction and high-specialization design and selects the MNL model (Multinominal Logit Model), which is simple in model construction and widely used in data analysis, to quantitatively construct the predictive model and obtain the customer's purchase probability, and it achieved a high accuracy rate, rather than a general qualitative analysis, so that small and micro e-commerce merchants can more targeted product selection and sales, which can provide a basis for e-commerce precision marketing but also have a high actual operation. We hope that through the analysis of typical cases in this article, we can develop precision marketing strategies for small- and medium-sized e-commerce companies in the future and provide a good reference and experience.

Academic Editor: Tongguang Ni

The application of existing datasets to construct a probabilistic network has always been the primary research focus for mobile Bayesian networks, particularly when the dataset size is large. In this study, we improve the K2 algorithm. First, we relax the K2 algorithm requirements for node order and generate the node order randomly to obtain the best result in multiple random node order. Second, a genetic incremental K2 learning method is used to learn the Bayesian network structure. The training dataset is divided into two groups, and the standard K2 algorithm is used to find the optimal value for the first set of training data; simultaneously, three similar suboptimal values are recorded. To avoid falling into the local optimum, these four optimal values are mutated into a new genetic optimal value. When the second set of training data is used, only the best Bayesian network structure within the five abovementioned optimal values is identified. The experimental results indicate that the genetic incremental K2 algorithm based on random attribute order achieves higher computational efficiency and accuracy than the standard algorithm. The new algorithm is especially suitable for building Bayesian network structures in cases where the dataset and number of nodes are large.

1. Introduction

The effective expression of uncertain knowledge is an important content of knowledge intelligent learning. In this research field, Bayesian network has always been the focus of attention. Bayesian network is a probability graph model. It represents the dependency relationship between a group of random variables through a directed acyclic graph. The conditional probability table (CPT) formed by each variable represents the probability relationship between variables [1]. It has strong uncertainty reasoning ability, which can realize top-down prediction analysis and bottom-up diagnostic inference [2]. Machine learning technologies have become more and more important in many applications, such as medicine [3], e-commerce [4, 5], transportation [6], and image denoising [7]. As one of the machine learning technologies, Bayesian network is widely used in many fields, such as machine vision, biomedicine, classification, fault diagnosis, prediction, natural language processing, and data mining [8].

The Bayesian network is primarily based on Bayesian network learning, which is divided into two steps: structural learning and parameter learning. Structure learning is to obtain a directed acyclic graph that can represent attribute dependencies based on training data and a priori knowledge. Parameter learning is to obtain the conditional probability of each node based on the directed acyclic graph. It is usually called conditional probability table. In these two learning, structural learning is more difficult, and it is also a research hotspot. It mainly focuses on how to avoid falling into local optimization and find the best structure when there are many attributes and few sample data [9, 10].The Bayesian network structure learning algorithm can be divided into a method based on scoring and searching, the conditional independence test, and a hybrid of the two methods.

(1) Method based on scoring and searching: it uses the scoring function to measure the matching degree between the Bayesian network structure and the training sample set. After defining the scoring function, apply the search strategy to find the network structure with the highest score. K2 algorithm is the common one [11]. Due to the constraint of node order, K2 algorithm can effectively avoid the problem of likelihood equivalence and is better than most classical algorithms in running speed and accuracy. However, in most cases, the node order is unknown and usually needs to be determined according to expert knowledge. The difference of expert knowledge is large, which cannot ensure objectivity and accuracy, and it is difficult to achieve when there are a large number of nodes. Therefore, researchers have put forward many solutions. It is proposed that conditional frequency is used to determine the node ranking of K2 algorithm. The algorithm does not need complex search strategy and effectively reduces the time complexity. However, it has high requirements for the quality of data set and is not easy to obtain the accurate model [10]. Combining the maximum spanning tree and ant colony algorithm, the MUST-ACO-K2 (MAK) algorithm is proposed to search the node order, but the algorithm needs to substitute the obtained node order into K2 algorithm to get the network structure before scoring, resulting that its running time is too long [10].

(2) Method based on conditional independence test: this method abstracts the learning process of the Bayesian network structure as the process of discovering a set of variables hidden in the network structure that satisfy the independence condition test. Spirtes proposed the SGS algorithm in 1989 [12], which uses conditional independence to test the existence and direction of edges and eliminates the prior constraint of the K2 algorithm that requires a given order of nodes, but the cost of the test calculation is exponential. In the second year, he proposed a PC algorithm [13], which improved upon the search strategy of the SGS algorithm. It requires less computational load when learning a sparse network structure, and it was used by Tsagris [14]. Cheng combined the idea of information theory with an independent testing method [15], and the proposed learning method exhibited good performance in structural learning.

(3) Hybrid algorithm: because the method based on score search and the method based on constraint have their own advantages and disadvantages, the hybrid optimization algorithm combining the two has gradually become the mainstream of research. The improved whale optimization algorithm is used to optimize the structure of Bayesian network. The optimization efficiency and accuracy of this method are good, but the complexity is very high [16]. The improved particle swarm optimization (PSO) is proposed to learn the Bayesian network structure. After the initial network is constrained by mutual information, the improved PSO algorithm is used to search the optimal Bayesian network, which improves the optimization efficiency. However, due to the instability of the algorithm, the accuracy of the structure cannot be guaranteed [17]. The bird swarm algorithm is used as the search strategy to improve the search strategy, which makes the search ability stronger and the convergence further improved [18].

For the K2 algorithm, as stated by Cooper, the K2 algorithm can reconstruct a moderately complex belief network rapidly, but it is sensitive to the ordering of the nodes [11]. Further information can be found in [19, 20].

This paper presents a new Bayesian network structure learning method based on random node order and genetic incremental search for an optimal path and compares this method with the K2 algorithm. Experiments demonstrate that the method of random node order can yield a better Bayesian network structure without expert knowledge, and the genetic incremental structure learning method can greatly improve the computational efficiency when tested on big datasets, especially when the number of samples and nodes are large. It always exhibits a runtime that is shorter than that of the K2 algorithm.

2. K2 Algorithm

The K2 algorithm [21] effectively integrates prior information in the search process and exhibits good time performance. It is a classic structure learning algorithm based on scoring search.

2.1. Scoring Function. The node sequence is given in advance, and each node greedily searches its parent node set from its predecessor node according to the Bayesian scoring function and finally obtains the network structure with the best score.

The learning of the network structure can be attributed to the given dataset D and finds a network structure B_s with the largest a posteriori probability, that is, B_s is set to maximise $P(B_s|D)$. Additionally, $P(B_s|D) = P(B_s|D)/P(D)$, the denominator $P(D)$is unrelated to B_s, so the ultimate objective is to find the maximum B_s of $P(B_s|D)$. Through a series of derivations (for the specific derivation process, see [6]), we obtain

$$P(B_s|D) = P(B_s)\prod_{i=1}^{n}\prod_{j=1}^{q_i}\frac{(r_i-1)!}{\left(N_{ij}+r_i-1\right)!}\prod_{k=1}^{r_i}N_{ijk}!, \qquad (1)$$

where $P(B_s)$is the priori probability of B_s. This is the probability set for each structure without providing data. N_{ijk} denotes the jth unique instantiation of π_i relative to D.

Suppose there are q_i such unique instantiations of π_i. Define N_{ijk} to be the number of cases in D in which variable x_i has the value v_{ik} and π_i is instantiated as w_{ij}; the value of N_{ij} can be obtained using

$$N_{ij} = \sum_{k=1}^{r_i} N_{ijk}. \tag{2}$$

For equation (1), the first multiplicative symbol traverses each random variable x_i by i, and n denotes the number of random variables.

The second multiplicative symbol traverses all parent variables of x_i by j, and q_i indicates the number of types of x_i parent variable instances.

The last multiplicative symbol traverses all possible values of the current variable x_i, where r_i denotes the number of possible values.

It can be assumed that the probability of each structure obeys a uniform distribution, that is, the probability $P(B_s)$ is the same constant as c. Using constant c to replace $P(B_s)$, equation (1) changes to

$$P(B_s|D) = c\prod_{i=1}^{n}\prod_{j=1}^{q_i}\frac{(r_i-1)!}{\left(N_{ij}+r_i-1\right)!}\prod_{k=1}^{r_i}N_{ijk}!. \tag{3}$$

The objective is to obtain B_s that can maximise the posterior probability, as follows:

$$\max_{B_s}\left[P(B_s, D)\right] = c\prod_{i=1}^{n}\max_{\pi_i}\left[\prod_{j=1}^{q_i}\frac{(r_i-1)!}{\left(N_{ij}+r_i-1\right)!}\prod_{k=1}^{r_i}N_{ijk}!\right]. \tag{4}$$

As can be seen from the above equation, as long as the local maximum for each variable is provided, the overall maximum can be obtained. The component of each variable is presented as a new scoring function, as follows:

$$g(i, \pi_i) = \prod_{j=1}^{q_i}\frac{(r_i-1)!}{\left(N_{ij}+r_i-1\right)!}\prod_{k=1}^{r_i}N_{ijk}!. \tag{5}$$

2.2. Search Strategy. The core of Bayesian network structure optimization is to narrow the search scope through search strategy after determining the scoring function. Greedy search algorithm is the most commonly used method. But it is easy to fall into local optimization. In 2017, the authors of [1] proposed adding disturbance factor to local greedy search, and using the idea of genetic algorithm, the metaheuristic method was used to improve the performance of local greedy search. In 2020, the authors of [22] introduced microbial genetic algorithm into Bayesian network structure learning. The undirected graph with most correct edges is calculated by the maximum information coefficient, and it is used as the initial population, and then the excellent individuals in the initial population are retained by using the operator of microbial genetic algorithm. Through the combination of the two, the purpose of learning close to the real network structure from a small amount of data can be achieved. Search strategy assumes the nodes are ordered. If x_i precedes x_j, there can be no edges from x_j to x_i. Simultaneously, it assumes that the maximum number of parent variables per variable is u. Each time the largest parent variable of the scoring function is selected and inserted into the set, the loop is terminated, and the scoring function cannot be increased further.

3. Incremental K2 Algorithm Based on Random Attribute Order

3.1. Random Generate Nodes Order. The K2 algorithm must initialise the order of nodes such that only the node in front of node i can be the parent of node i. This is defined as

$$\mathrm{Pred}(x_i) = x_j\,(j = 1, 2, \ldots, i-1). \tag{6}$$

The disadvantages are as follows. First, the order of nodes is not easy to obtain in most actual network structures, and the expression of this a priori knowledge is not conducive to the understanding of expert knowledge. Second, the fault tolerance for the order of nodes is poor. If the order of nodes that is input into the K2 algorithm is dissimilar to that in the real structure, the accuracy of the K2 algorithm will be greatly reduced; this is owing to its algorithmic theory. In this study, our first objective is to reduce the dependence on the order of nodes. For nodes, each iteration randomly generates an array of nodes, and the generation procedure (see Algorithm 1) is as follows.

3.2. Genetic Incremental K2 Algorithm. The basic idea is to divide the training data into two groups and use the first set of training data to learn a basic Bayesian network structure using the K2 algorithm. In the process of learning, not only the current optimal value, i.e., the decision-making of the algorithm each time, but also several suboptimal values are saved [23], a GA is applied, and the current four optimal values are mutated to a new optimal value. The number of suboptimal values can be adjusted, for example, three or four. This study selects three suboptimal values. When using the second set of incremental data, it will not research; instead, it will take the four optimal values and the new genetic value as the next search space. The algorithm skilfully eliminates the low-level model, reduces the search space, and improves the efficiency of the algorithm.

In addition, the optimal score function value is preserved in each iteration. After the iteration, the node order of the Bayesian network with the optimal score function value is considered to be the best node order.

The algorithm is divided into two parts. The first part (see Algorithm 2)is to generate one optimal value and three suboptimal values, mutate a new optimal value from the first set of data, and store all values in the candidate matrix. The following pseudocode expresses the first part.

The second part (see Algorithm 3) of the algorithm uses the second set of data to optimize the suboptimal value. The core content is as follows.

```
Procedure randomarray(len, start, end) (
  {Input n, n is nodes number.}
  {Output: an array that has n values between 1 and n.}
    Define the array[1,n]: order
      for1 1-n {
        Random generation of a number between 1 and n
        If (the number is the first number) {insert the number into the array; }
          Else{
          for2 1-length(array){
        If(the number exits){ regenerate a random number, loop for2}
      else{insert the number into the array; loop for1}
      End for2}
    End else }
  End for1}
End randomarray }
```

Algorithm 1: Random array algorithm.

```
Procedure GCDK2{
{Input: K2 algorithm need parameter initialisation, mutation rate pm = 0.5}
{Output: a bayesian network and a matrix contain optimal value and location }
  For i = 1-n{
  P_old = g(i, π_i)
  While OK To Proceed and Length is OK
    pps = mysetdiff (order (1: i − 1), ps){Potential parents}
    nps = length (pps)
      For pi = 1-nps{
    pscore (pi) = g(i, π_i ∪ {z})
  End for}
[P_first, best_p_first] = max (pscore);{best_p_first is a location, P_first is the max first score}
    Get second_pscore and second_p
Get third_pscore and third_p
      Get fourth_pscore and fourth_p
      Mutate optimal values get a new genetic value GA_pscore
      If (P_first > P_old) {P_old = P_first;ps = [ ps  best_p_first ]
      Input P_first best_p_first second_pscoresecond_p,third_pscore ,
    third_pfourth_pscore,fourth_p and GA_pscoreinto candidate matrix
    End if}
  End while}
End for}
End GCDK2}
```

Algorithm 2: GCDK2 algorithm.

4. Experimental Results

To test the algorithm, the general ALARM, Asia, and CANCER networks were selected in the experiment. Under different sample numbers, the running time and structural hamming distance [24] were used to evaluate different algorithms.

The experiment adopted the Bayesian network toolbox in the MATLAB platform. The operating environment was Windows 7, Intel (*R*) Core(TM) i3-4170, 3.70 GHz CPU, 8.00 GB RAM. The results of the experiment are listed in Tables 1 and 2.

This algorithm relaxes the strict requirement of the K2 algorithm on node order and improves the efficiency of learning the Bayesian network structure.

(1) In the ALARM network (comprising 37 nodes), the experiment began with a sample size of 4000, the running time of K2 was 7.928, GAK2 was 5.675, and GIMK2 was 0.861; when the size varied to 50000, the times were 29.877, 18.429, and 3.128; when the size was 100000, the times were 55.659, 37.839, and 5.987. SHD is large at first; however, it eventually reduces to zero.

```
Procedure GIMK2(part){
  For i = 1-length (candidate)
  child = candidate (i, 1)
  For j = k to k+4 {from k to k+4 because the candidate stored 5 values}
    ppar = candidae (i, j)
    u = find (clamped (child, : ) == 0)
    Get P_new from child and u
  End for
  best_action = candidate (i, best_p)
  End for
  . . .
End GIMK2}
```

Algorithm 3: GIMK2 algorithm.

Table 1: Result of learning ALARM by learn_struct_K2 and GIK2.

Sample size	K2		GAK2		GIK2	
	Time (s)	SHD	Time (s)	SHD	Time (s)	SHD
4000	7.928	2	5.675	2	0.861	2
5000	8.348	2	6.253	2	0.831	2
10000	11.047	2	8.754	2	1.110	2
15000	12.740	2	10.546	2	1.348	2
20000	15.456	1	11.328	1	1.547	1
50000	29.877	1	18.429	1	3.128	0
100000	55.659	0	37.839	0	5.987	0

Table 2: Result of learning Asia by learn_struct_K2 and GIMK2.

Sample size	K2		GAK2		GIK2	
	Time (s)	SHD	Time (s)	SHD	Time (s)	SHD
200	0.234	3	0.205	2	0.058	2
500	0.240	1	0.218	1	0.073	1
1000	0.255	1	0.220	1	0.057	1
3000	0.225	1	0.231	1	0.062	1
5000	0.232	1	0.236	1	0.078	1
10000	0.264	1	0.238	1	0.089	1
15000	0.291	0	0.247	0	0.141	0
20000	0.376	0	0.275	0	0.137	0
50000	0.593	0	0.279	0	0.235	0
100000	1.084	0	0.884	0	0.423	0

(2) In the Asia network (comprising 8 nodes), the experiment began with a sample size of 200; however, when the size varied to 5000, the running time of K2 was 0.232, GAK2 was 0.236, and GIMK2 was 0.078; when the size varied to 50000, the times were 0.593, 0.279, and 0.235; when the size was 100000, the times were 1.084, 0.884, and 0.423.

(3) In the CANCER network (comprising 5 nodes), the experiment began with a sample size of 200; however, when the size was 5000, the running time of K2 was 0.158, GAK2 was 0.139 and GIMK2 was 0.053; when the size varied to 50000, the times were 0.248, 0.218, and 0.188; when the size was 100000, the times were 0.353, 0.245, and 0.191.

The results of the program operation indicate that the genetic incremental K2 algorithm has a shorter running time than K2 and GAK2 for the same sample size. When the mobile Bayesian networks with different number of nodes, particularly when the dataset size increases with the number of nodes, the running time of K2 and GAK2 becomes extremely long.

5. Conclusion

As data analysis is now being conducted on big data, if we need to analyse big data with uncertain knowledge, especially in the case of numerous attributes, the genetic incremental K2 algorithm can reduce the search space and considerably improve the efficiency of the algorithm. The improved algorithm in this paper is effective; however, it has disadvantages such as the fact that the search space of each algorithm depends on the current optimal path; thus, it is easy to fall into local optimum. The algorithm should thus combine particle swarm optimization, ant colony, or another optimization algorithm to avoid falling into local optimum.

Blockchain, the underlying technology of Bitcoin, has been deeply studied in various fields after its development in recent years. As a typical decentralized distributed data storage system, consensus reached among all participants in a blockchain system requires a consensus mechanism to be realized. In order to make blockchain applicable to different application scenarios, different consensus mechanisms have been proposed. With the further development of blockchain applications, more and more studies have been conducted on the consensus mechanism. However, some existing consensus mechanisms still have some problems in various aspects. Therefore, this paper proposes a trade deal algorithm based on the blockchain mechanism of consensus. First of all, according to PBFT, the lack of a dynamic problem in the VPBFT voting mechanism was introduced. The node system is divided into four types with different responsibilities and gives the number of relations between nodes. When the number of nodes is changed, it can be calculated according to the quantity relation, ensuring dynamic. Second, a data anonymous transaction and authentication protocol is designed. In the protocol, when the seller sells data, the mapping relationship between the real identity and the false identity of the data owner is blinded and sent to the buyer. When the buyer wants to verify their identity, the seller's identity can only be verified with the authentication of the blockchain. The proposed algorithm is superior to the current consensus in terms of time and energy consumption, throughput, and fault tolerance methods, which is proven through experimental tests and simulation analysis.

1. Introduction

Blockchain [1] is a decentralized distributed database characterized by decentralization [2], immutability [3], anonymity [4], autonomy [5], consensus, and other characteristics. It is a new technology that has the potential to change social interaction and trading methods. This technology's main benefit is its ability to exchange transactions without relying on trusted third-party entities in any way. Data integrity, built-in authenticity, and user transparency are all features it can provide. Blockchain is a decentralized distributed computing paradigm, not a technological innovation. The data structure it adopts is a series of data blocks formed in a chain in time sequence. It involves various technologies of cryptography and integrates technologies such as smart contracts [6], P2P networks [7], and consensus mechanisms. Cryptography is used to ensure that data blocks in the chain of ownership and right of privacy, due to the data block in the chain is electronic data. It is not easy to prove to belong to source and transparent data. As a result, we will need to include some information in the data signature to indicate the data and sources as well as some cryptography technology to ensure privacy and prevent data leaking. Smart contracts, which are programs or scripts that can be automatically triggered and executed, ensure that bookkeeping participants conduct transactions and bookkeeping in accordance with certain rules [8]. They use algorithmic scripts to implement some commercial logic rules and regulations, ensuring that blockchain can be used in more systems. To ensure the consistency of the generated data across the entire distributed system, a consensus mechanism is used. Because blockchain is a distributed and open network, there is no or little trust between the transaction's two parties. In order to reach a consensus on a specific topic, the consensus mechanism is critical.

Consensus [9] has always been a hot topic in the field of distributed systems research. As people's cognition has deepened and blockchain research has advanced, relevant research on the consensus mechanism to solve the consensus problem has become a hot research topic in recent years. In a distributed system, the so-called consensus problem occurs when all participants have the same status. The distributed system is maintained, checked, and maintained by each participant in the same way. As a result, a consensus mechanism ensures that all participants in a distributed system can trust one another and reach an accurate consensus on a proposal that needs to be confirmed. This paper further studies the PBFT consensus mechanism and its existing improved consensus mechanism and then proposes a new, improved PBFT mechanism: "Byzantine fault-tolerant consensus mechanism based on machine learning." A logical regression algorithm is used to predict whether the request is passed or not [10]. Data blocks are produced in advance and cached when the prediction is passed to wait for validation and reduce the delay. Then, the nodes in the system are dynamically classified by K-means clustering algorithm to ensure the regular operation of the anonymous trade transaction system.

The main contributions of this paper are as follows:

(1) In this paper, a data transaction and authentication protocol for anonymous data are being developed. The mapping relationship between the real identity and the false identity of the data owner is blinded and sent to the buyer when the seller sells the data. When a buyer wants to verify the seller's identity, the only way to do so is through blockchain authentication.

(2) In this paper, a machine learning-based Byzantine fault-tolerant consensus mechanism is proposed. All nodes in the system are initially classified into different types using K-means clustering and then reclassified as the number of nodes changes to ensure dynamic performance. A logistics regression algorithm is also used to predict validation results ahead of time, make full use of node idle waiting time, and reduce delay and resource waste.

The remainder of the paper is organized in the following manner. The background work is examined first in Section 2, followed by methodology in Section 3. The results and discussion are then presented in detail in Section 4. Finally, Section 5 concludes the paper.

2. Background

This section discusses the related work in the context of blockchain technology and anonymous storage transaction technology.

2.1. Blockchain Technology. Blockchain technology is proposed to solve the long-standing Byzantine general problem and the problem of double cost. In recent years, it has developed rapidly, and various kinds of digital currencies have emerged in an endless stream. For example, inspired by Bitcoin, a programmer at Google launched an improved version of the digital currency, Litecoin. The technical principle is the same as Bitcoin, but Litecoin is produced and traded on a different principle. In addition, Miers et al. [11] proposed the concept of Zerocoin based on the zero-knowledge proof cryptography principle. So far, there have been dozens of digital cryptocurrencies. In the future, not only in the field of digital cryptography but also in other fields blockchain will be fully developed.

So far, blockchain has proven to be successful not only in theory but also in practice. Vitalik proposed Ethereum, a single blockchain that allows for reprogramming to achieve arbitrarily complex computing functions, in 2013. Simply put, Ethereum is a smart contract-enabled public blockchain platform. More than 30 companies announced the Hyperledger Consortium Project in 2015, led by the world's largest open-source organization, the Linux Foundation. The goal of the project is to advance the development of blockchain and distributed ledger protocols. SuperLedger is a collaborative project that consists of subprojects for various purposes and scenarios, with a modular design, code readability, and long-term evolution path in mind. The SuperLedger community now includes over 140 businesses and organizations.

2.2. Anonymous Storage Transaction Technology. With the continued growth of the Internet, the number of terminal devices, servers, and users on the network is increasing. The amount of data produced is also on the rise. The question of how to protect these data and the data owner has become a focus of data security research. Furthermore, blockchain technology has cryptographic properties that allow one's identity to be protected without being revealed. As a result, current research is focusing on the combination of blockchain with anonymous storage and anonymous transactions. In terms of anonymous storage, Do and Ng [12] proposed a secure distributed data storage system with a keyword search service based on blockchain technology [13–15]. RSA [16] and the discrete logarithm hypothesis allow clients to upload data to cloud nodes in ciphertext form [17, 18]. While ensuring the availability of data, it also provides the data owner with the ability to grant others the right to search their data. Lu et al. [19] proposed a blockchain-based anonymous reputation system (BARS) to break the linkability between real identity and public key to protect privacy. Finally, Shafagh et al. [20] proposed a blockchain-based distributed access control and data management system for the Internet of Things, customized for IoT data traffic, and can achieve secure data sharing. Using blockchain as the storage layer, secure and flexible access control management is realized.

In terms of anonymous transactions, Heilman et al. proposed a solution to anonymity for transactions on and off the blockchain of Bitcoin. They have used an untrusted third party to issue anonymous credentials, which users can exchange into Bitcoin. The simultaneous use of blind signatures [21] and smart contracts ensures anonymity and fairness during the exchange of Bitcoin certificates [22]. Aitzhan and Svetinovic [23] do not rely on certificates but trusted third parties in distributed smart grid energy trading transaction security problems. They use blockchain technology, multiple signatures, and anonymous to encrypt the message flow to realize the concept of decentralized energy trading system validation. It allows peers to negotiate anonymous energy prices and trade safely. Wang et al. [24] introduced a blockchain-based mutual authentication and key agreement protocol for edge computing-based smart grid systems. Using blockchain, the protocol can support effective conditional anonymity and key management without the need for other complex cryptographic primitives.

3. Methodology

In this section, the following subsections attention-based graph convolution, third-order hourglass networks, and residual dense module are discussed in detail.

3.1. Data Anonymous Transaction and Authentication Protocol. After the edge device encrypts the data and stores the address on the blockchain, it makes a transaction request when a user demands the stored data. At this time, the edge device serves as the seller, and the user serves as the buyer. The protocol uses the elliptic curve public-key encryption system to ensure the anonymity of the transaction. The corresponding relationship between the real identity and the false identity mapping is blinded by the improved blind signature and sent to the buyer. Under normal circumstances, the buyer cannot know the corresponding real identity and can only obtain its real identity by blind-decoding it during arbitration, as shown in Figure 1.

There are four actors in this agreement: buyer, seller, blockchain, and bank. Each has different responsibilities and functions.

(1) Buyer: a buyer is a user who is interested in specific data and has the need to purchase data. When the buyer wants to purchase a certain type of data, the buyer will issue a transaction on the blockchain network. The labeled type of data that the buyer wants to purchase is declared. The amount used to purchase data is valid. In addition, the buyer's public key, PK_Buyer, and the parameter, eq_b, are used to prove his identity.

(2) Seller: in this agreement, the edge device as the seller transacts data with the buyer. Before the transaction, the seller will check the transaction request issued by the buyer in the blockchain network. Suppose the seller is willing to transact with one of the buyers. In that case, it will publish a transaction in the blockchain, claiming that it is willing to transact with the buyer. The seller can show the data type LABEL of the data he owns.

(3) Blockchain: as a trading platform for buyers and sellers, blockchain releases transactions on the blockchain to realize direct transactions between the two parties without the intervention of a third party. Meanwhile, all transaction records are searchable on the blockchain and cannot be tampered.

(4) Bank: when the seller and the buyer make a formal transaction, the buyer will issue a cheque. After receiving the cheque, the seller will send it to the bank. The bank will complete the transfer through the corresponding accounts of the seller and the buyer on the cheque.

The agreement is divided into the following stages:

(1) Peripheral device registration stage: peripheral device, as the seller, needs to register with the blockchain before selling data to obtain the right to trade with the buyer.

(2) Check generation stage: this stage mainly includes the buyer sending a transaction request to the blockchain. The seller agrees to trade with the buyer and obtains the check.

(3) Data transaction stage: after the seller gets the cheque signed by the buyer, he/she initiates a transfer request to the bank. The bank verifies his/her identity and transfers the corresponding amount of the buyer's account to the seller's account. After successful transfer, the bank informs the seller, and the seller sends the corresponding data to the buyer.

(4) Certification stage: the buyer thinks that the seller's selling data is wrong and requests the arbitrator for arbitration. Under the supervision of the arbitrator, authentication is carried out.

3.2. Consensus Mechanism Based on Machine Learning. This paper proposes a practical Byzantine fault tolerance based on machine learning [25–29] (MLPBFT). To begin, the mechanism divides the nodes in the system into three nodes with different responsibilities: customer node, master node, and supervision node, using the K-means clustering algorithm [30]. The client node is also the data block producer and request initiator in MLPBFT. The transit node, or master node, preprocesses and forwards the request initiated by the client node to the supervising node. The monitor node primarily verifies and confirms the messages it receives and then replies to confirm the message once the verification is complete. Finally, after the client node sends the request, the waiting time will be used to predict the probability of the request passing through the logistic regression algorithm [31]. Then, based on the prediction result, decide whether to produce the block ahead of time. In addition, the consensus process will be suspended when the number of nodes in the system changes, to ensure the system's dynamism. The data pairs of multiple groups of different classification types caused by a change in the total number of nodes will be calculated using the K-means clustering algorithm, and the appropriate classification will be chosen.

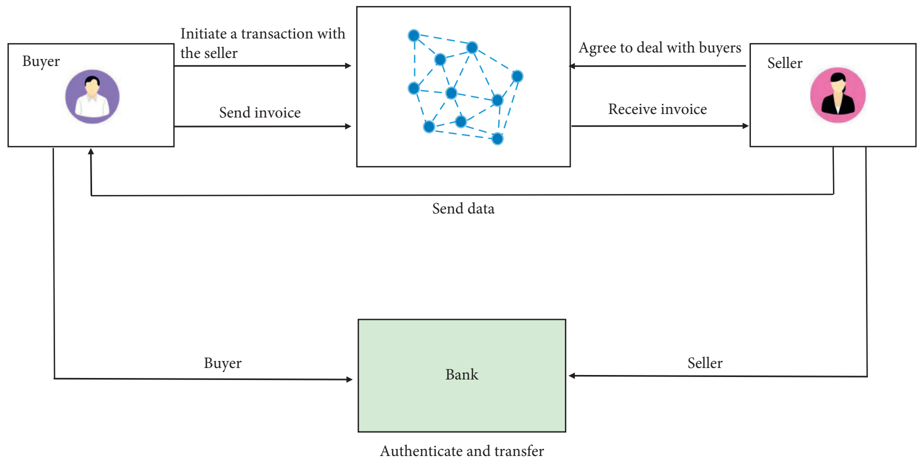

Figure 1: Model of the proposed protocol.

3.2.1. K-Means Algorithm. K-means is usually used to solve clustering problems and is a form of unsupervised learning [32, 33]. It is a clustering algorithm based on the distance between data. The distance between two data points is used as a criterion to judge whether the data is similar. The closer the distance is, the more similar the two data points are. The implementation steps are as follows:

(1) Suppose $D = \{d_1, d_2, \ldots, d_n\}$ is the training sample data, where $d_i = \{X_i, Y_i\}, 1 \leq i \leq n$. Select K data from D as the initial K cluster centers, $K < n$. Set the selected K initial cluster centers as $\{(X_1, Y_1), (X_2, Y_2), \ldots, (X_K, Y_K)\}$. Then, the remaining data is recorded as $\{(X_{K+1}, Y_{K+1}), (X_{K+2}, Y_{K+2}), \ldots, (X_n, Y_n)\}$.

(2) Use the Euclidean distance method to calculate the distance $\{r_1, r_2, \cdots, r_K\}$ from each data in the dataset to each cluster center and record it. The calculation equation is as follows:

$$r_i = \sqrt{(X - X_i)^2 + (Y - Y_i)^2}, \quad 1 \leq i \leq K. \tag{1}$$

(3) According to the recorded and calculated distance, select the smallest distance, namely, $\min\{r_1, r_2, \cdots, r_K\}$, and classify the data and the corresponding initial cluster center into the same category.

(4) When all the data are divided, there are K clusters of the data set. All the data in each category are recalculated to calculate the new clustering center. The calculation method is generally to select the arithmetic mean of each dimension of all the data in this cluster.

(5) Go to step 2 and continue to calculate and iterate until the iteration ends when the relationship between the initial cluster center and the new cluster center meets the preset threshold.

3.2.2. Consensus Mechanism. A PBFT improvement scheme using a logistic regression algorithm is proposed in this paper. The K-means clustering algorithm can easily manage with a faster convergence speed before the data changes are easier to update the model characteristics. The differences between clusters produce a better result, and all that is required is to adjust the number of clusters in the K MLPBFT scheme. The MLPBFT consensus mechanism divides the network's nodes into three categories: client node, master node, and supervision node, using a K-means clustering algorithm. Nodes fall into various categories, each with its own set of responsibilities. The consensus process is completed through two stages: the preparation stage and the verification stage. On this basis, MLPBFT will use the logistic regression algorithm to predict the verification result of the request made by the customer node, while the customer node is waiting for the reply message, and complete the production of the data block in advance, when the predicted result is passed. Moreover, the K-means clustering algorithm will be started again when the nodes change. The nodes in the system will be reclassified to ensure the system's dynamic. In addition to the characteristics of dynamic and security, MLPBFT also has certain advantages compared with the consensus in terms of time and energy consumption, throughput, fault tolerance, and communication times.

3.2.3. Consensus Process. The MLPBFT is similar to the VPBFT consensus process. Instead of the PBFT's "three-phase" model, the MLPBFT adopts a "two-phase" model, consisting of a preparation phase and a validation phase, as shown in Figure 2.

The customer node initiates the request for the production data block. The *request* message is Request: <Bcontent, Tc, Sc>, where Bcontent is the data block to be produced, Tc is the timestamp of the *request* message sent by the customer node, and Sc is the signature of the customer node. The data block is divided into two parts, the block and the data. The block contains the relevant information of the previous data block. If the block is a creative block, the information of the block only identifies the block as a creative block.

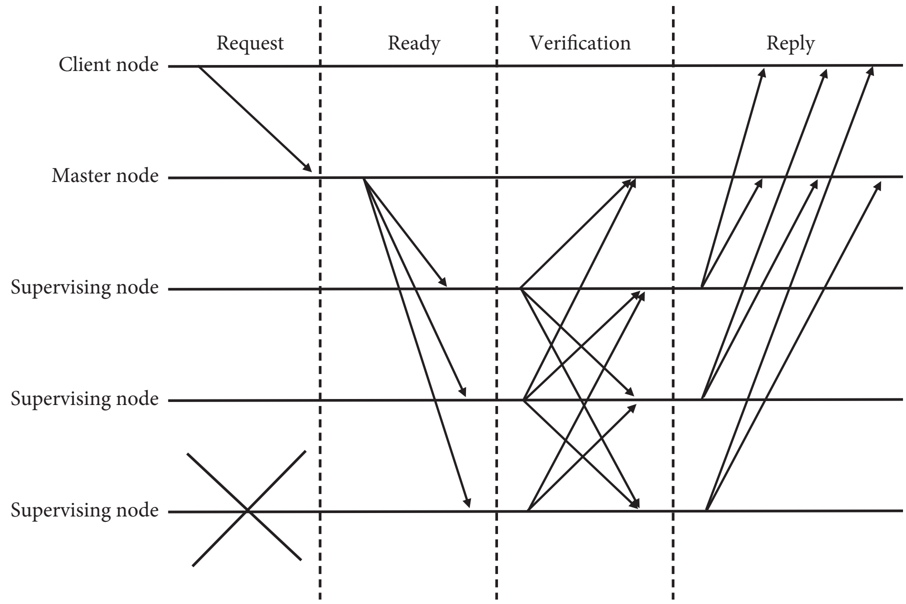

Figure 2: The consensus process of MLPBFT.

After the master node receives the *request* message, it first numbers the message and then extracts the message's important information. A summarized message is appended to the *request* message, then adds the timestamp and signature to form a *query* message, and then broadcasts the *query* message to all the supervising nodes. The *query* message is Query: <D, Tm, Sm>, where Num is the number, D is the abstract, Tm is the primary node's timestamp, and Sm is the primary node's signature. This stage is the preparation stage.

Monitoring nodes after receiving the master node to send over the query message, first verification, validation message contained within the request's specific content, and information are consistent. The master node is correct. Add validation results to Y; otherwise, add validation results to N. The valid form contains information of verification results. Supervisor nodes will broadcast *valid* messages to other monitoring nodes for mutual confirmation and verification. Valid:< ID, Num, Bcontent, Tc, Sc, D, Tm, Sm, Y/N>, where ID is the number of the monitor node itself. This phase is the validation phase.

When the supervisory node receives at least $1 + Ns/2$ (Ns is the number of supervisory nodes). A valid message with Y will reply to a confirmation message to the client node. The confirmation message is Commit: <ID, Num, Bcontent, Tc, Sc, D, Tm, Sm, Y/N, Ts, Ss>, where Ts is the timestamp added by the supervisory node and Ss is the signature of the supervisory node.

If the client node receives at least $1 + Ns/2$ Commit messages containing Y, it will be considered that the request was passed. The client node will directly chain the data block produced in advance according to the predicted result or produce the corresponding data block and chain it. Otherwise, the request was not approved. Discard the request and restart the request.

3.2.4. Dynamic Classification Based on K-Means. To conduct the initial type division of nodes in the system, the K-means clustering algorithm was started before the consensus process. The K-means clustering algorithm is triggered again when the total number of nodes in the system changes, automatically classifying all nodes in the system. They ensure that the system can continue to function without restarting after the number of nodes changes. The K-means clustering algorithm was chosen for two reasons. To begin, nodes in the MLPBFT consensus mechanism must be divided into three types, each with different responsibilities. The number of nodes of different types must be redivided when nodes join or leave. Second, the K-means clustering method is a more widely used clustering method, mainly used to complete data aggregation and classification. The algorithm is easy to understand and implement.

4. Experiments and Results

This section discusses experimental setup, data sets, evaluation methods, and experimental results discussed in detail.

4.1. Consensus Time-Consuming Analysis. Among the consensus mechanisms such as PBFT, VPBFT, K-PBFT, and MLPBFT, the consensus process is the most important. This experiment will simulate the consensus process of each consensus mechanism using a Python program in a network environment with fixed network bandwidth in order to compare the time consumed in the consensus process of these several consensus mechanisms. The consensus process, which is used in the experimentation process, starts with a consensus process and progresses over time. This time, all messages sent are serial transmissions, with the same data transmission resources and message size. At the same time, all consensus mechanisms are the same, with the same node number, data processing speed, and processing time. Figure 3 depicts the results of 10 experiments that were

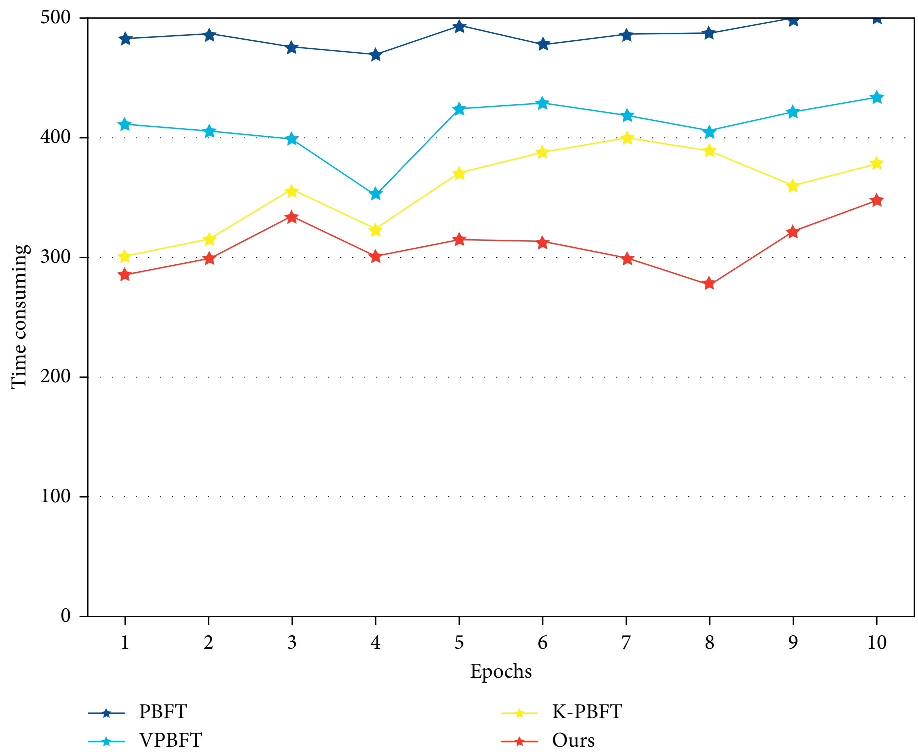

FIGURE 3: Time-consuming comparison results of the consensus process.

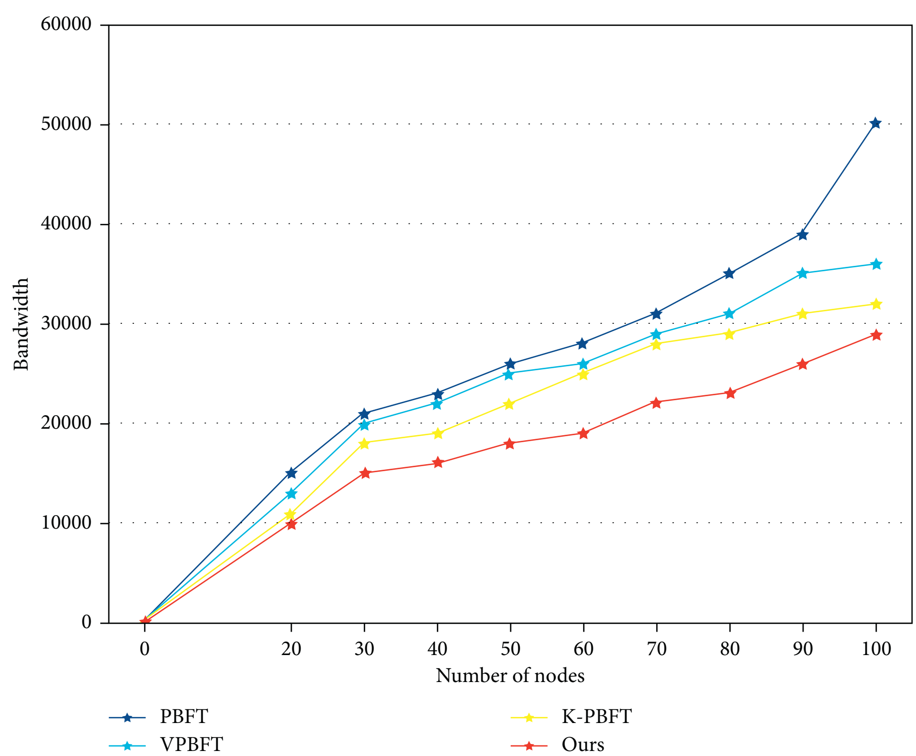

FIGURE 4: Comparison results of the bandwidth consumed by the consensus process.

conducted after simulating a consensus process of a consensus mechanism using Python and the program of the node itself.

As can be seen from Figure 3, under the same network environment and the same nodes, the time consumed by a consensus process of 1VB and PBFT is less than that of

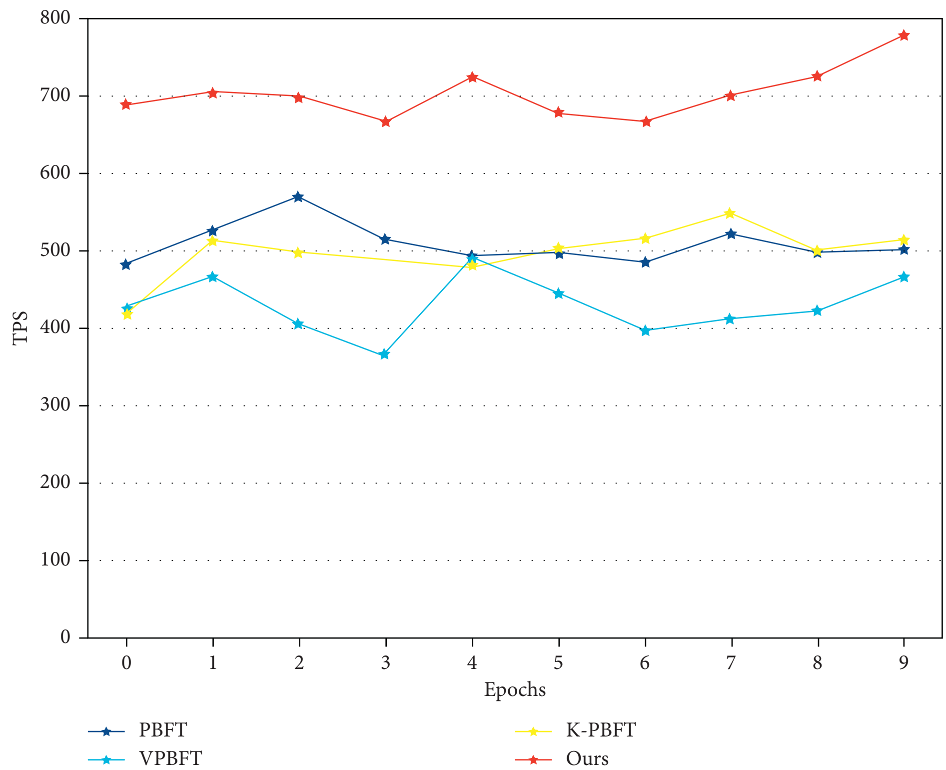

Figure 5: Comparative experiment results of throughput.

PBFT, VPBFT, and K-PBFT. For example, after calculating the average time of 10 experiments of each consensus mechanism, the average time of one consensus for MLPBFT was about 308.5 ms. In contrast, the average time of one consensus for PBFT, VPBFT, and K-PBFT was 484.8 ms, 409.4 ms, and 357.2 ms, respectively.

4.2. Bandwidth Usage Analysis. In the improvement scheme MLPBFT proposed in this paper, the consensus process is divided into a preparation phase and a verification phase. In the preparation phase, the master node needs to broadcast the entire network to send the query message to the supervisory node. The supervisory node needs to broadcast the valid message to other supervisory nodes for mutual confirmation and verification in the verification phase. Thus, it can be seen that the total network bandwidth required for the entire consensus process is twice the bandwidth.

It can be seen from Figure 4 that the network bandwidth consumed by the MLPBFT in the consensus process is lower than that of PBFT, K-PBFT, and VPBFT, which proves the superiority of this algorithm.

4.3. Throughput Analysis. One of the most important indicators for evaluating the benefits and drawbacks of the consensus mechanism is throughput. It is measured in transactions per second (TPS) and has the following calculation equation:

$$\mathrm{TPS} = \frac{\mathrm{SUM}\,(\text{transactions})}{T}, \quad (2)$$

where T is the time interval from when a transaction is issued to when a consensus is reached to generate a block, and SUM (transactions) is the total number of transactions included in the block generated in this time interval.

Figure 5 shows that the average throughput of MLPBFT is around 702.1 per second for the same number of nodes. It has a throughput of 194.12 per second, 175.64 per second, and 253.11 per second, respectively, which is higher than PBFT, VPBFT, and K-PBFT.

5. Conclusion

For some existing consensus mechanisms, there are still some problems in various aspects. This paper proposes a trade transaction protocol algorithm based on the blockchain consensus mechanism. First, in response to the lack of dynamics of PBFT, we proposed to introduce a voting mechanism in VPBFT. This mechanism divides the nodes into four types with different responsibilities and gives the number relationship between the nodes. When the number of nodes changes, it can be calculated according to the number relationship to ensure dynamicity. Second, a data anonymous transaction and authentication protocol is designed. In the agreement, when the seller sells the data, the mapping relationship between the real identity and the pseudoidentity of the data owner is blinded and sent to the buyer. When the buyer wants to verify the identity, the seller's identity can only be verified under the authentication of the blockchain. After experimental testing and simulation analysis, the algorithm in this paper is superior to existing methods in terms of consensus time-consuming, energy consumption, throughput, and fault tolerance.

As a new generation of search engine, automatic question answering system (QAS) is becoming more and more important and has become one of the hotspots of computer application research and natural language processing (NLP). However, as an indispensable part of the QAS, the role of question classification is an understood thing in the system. In view of this, to further make the performance of question classification much better, both the feature extraction and the classification model were explored. On the study of existing CNN research, an improved CNN model based on Bagging integrated classification ("W2V + B-CNN" for short) is proposed and applied to question classification. Firstly, we combine the characteristics of short texts, use the Word2Vec tool to map the features of the words to a certain dimension, and organize the question sentences into the form of a two-dimensional matrix similar to the image. Then, the trained word vectors are used as the input of the CNN for feature extraction. Finally, the Bagging integrated classification algorithm is used to replace the Softmax classification of the traditional CNN for classification. In other words, the good of W2V + B-CNN model is that it can make use of the advantages of CNN and Bagging integrated classification at the same time. Overall, the new model can not only use the powerful feature extraction capabilities of CNN to extract the potential features of natural language questions but also use the good data classification capabilities of the integrated classification algorithm for feature classification at the same time, which can help improve the accuracy of the W2V + B-CNN in the application of question classification. The comparative experiment results prove that the effect of the W2V + B-CNN is significantly better than that of the CNN and other classification algorithms in question classification.

1. Introduction

In the Internet age, information has exploded. In the face of massive fragmented information, people's desire to quickly obtain accurate and concise information has become more and more urgent, and the QAS has emerged at the historic moment. Unlike traditional search engines, QAS is a high-level form of information retrieval, which has become a hot focus in the field of current natural language. It allows users to describe the problems in natural language and can find or infer the answers to the users' questions from massive heterogeneous data and then submit them to the users. For example, for the question "What color is the skin of Chinese people," the system will give the answer directly as "yellow." It greatly improves the users' query efficiency and better meets the users' needs. The QAS generally includes three main parts: question analysis, information retrieval, and answer extraction [1], and each part cooperates with each other to efficiently obtain the target information required by the user. If question analysis is the cornerstone of QAS, then question classification is not only one of the key parts of question analysis but also an indispensable module of the QAS. It not only helps to optimize the performance of the system, such as reducing the search space of candidate answers and the time to locate the correct position of answers, but also helps to formulate answer extraction strategies. It can be seen that the result of question classification can provide useful guidance information for other modules of the system, and its accuracy will have a direct influence on the quality of the whole QAS. Therefore, it can be said that the research on question classification has important practical significance and has a positive influence on improving the quality and performance of QAS.

Question classification is to determine the type of question associated with the characteristics of the answer or the semantic information of the question under a certain classification standard. Currently, with the persistent maturity and improvement of its research, it has also attracted much attention in the field of NLP. The essence of question classification is short text classification. The current research on it is generally based on the idea of text classification and combined with the characteristics of question classification itself. But different from ordinary text classification, question classification contains unique word feature information. How to fully mine this information is the key to question classification. There are two types of traditional question classification methods: rule-based methods and statistical machine learning methods. Early rule-based methods mainly used artificial analysis of the syntactic structure to extract rules and then judge the question type [2, 3]. This kind of method has many advantages. For example, it is relatively easy to implement and does not need a lot of training data, so the classification speed is fast. But the disadvantage is that these methods rely more on experts and are subjective. Moreover, the classification decision of experts is very easy to be affected by the classification system, which makes it less flexible. Subsequently, the methods based on statistical learning showed a good classification effect, which have the advantages of strong versatility, easy transplantation, and expansion [4, 5]. The machine learning models based on statistical methods commonly used in question classification are Bayes [6], SVM [7, 8], KNN [9, 10], ME [11], and so on. However, the disadvantage of the statistical learning method is that its classification accuracy is still easily affected by the accuracy of syntactic analysis.

Recently, with the wide application of deep learning technology in the field of NLP, its characteristics of not relying on complex feature engineering and fully mining the feature information of natural language have attracted the interest of a large number of scholars. They began to use deep learning methods to classify questions. Therefore, question classification methods based on deep learning technology came into being. Different from the previous classification methods, the DNN model has significant advantages in question representation and feature extraction. The multilayer network structure can abstract the original question sentence into a high-level vector representation so that the dimension of the feature vector becomes higher and the classification accuracy is greatly improved. Meanwhile, with the wide study of word vector technology and deep neural network technology, people have more new ideas in NLP tasks. Among the deep neural networks applied to NLP tasks, the most commonly used ones are RNN and CNN. Among them, CNN is a typical spatial deep neural network. It has significant advantages in feature extraction and is good at feature self-extraction, which can reduce the difficulty of feature extraction to a certain extent in question classification and improve the accuracy of classification. Based on this, it has inspired researchers to use CNN as one of the commonly used architectures in the application of deep learning in question classification. Many methods based on CNN have been proposed and a large number of research results have emerged [12, 13]. Therefore, there is still a lot of research space for question classification with deep learning, which is worthy of further research.

2. Related Work

2.1. Question Classification. The purpose of question classification is to classify questions into corresponding semantic classes according to the type of answer. As a key link of the question answering system, it has an important guiding role for subsequent answer extraction modules, and it also has a very important significance for the QAS [14]. The so-called question classification means that, under a certain classification system, for questions that are not marked with a class, the system automatically classifies the relevant class of the question according to the content of the question. This correspondence can be abstracted as a mapping process in a mathematical sense, which can be represented by the following mapping function [15]:

$$R: X \longrightarrow \{C_1, C_2, \ldots, C_N\}, \tag{1}$$

where X represents a set of question samples and $\{C_1, C_2, \ldots, C_N\}$ represents a set of question classes. R is responsible for mapping the question $x \in X$ of the unknown class to a class C_i according to a certain rule or a certain classification algorithm.

However, the current methods based on question classification research usually draw on ideas of text classification. The difference between them is that common words such as "what" and "is" are often overlooked in text classification, but these words that may be used as stop words are often very important in question classification. This is also one of the characteristics of question classification. What the two have in common is that they both analyze the information contained in the text and combine the characteristics of question classification to classify the questions into their categories. Based on the ideas of text classification, the question classification process can be described as shown in Figure 1, which specifically includes the division of training set and test set, preprocessing, feature extraction, classifier training, classification prediction, and others [16]. For Chinese text, data preprocessing includes Chinese word segmentation, part-of-speech tagging, and stop word removal. The advantage of feature extraction is that it helps to reduce the complexity and improve the accuracy of question classification by extracting better feature information from the original samples. Common methods include TF-IDF calculation, n-gram, Word2Vec, and LDA. Since question classification is generally a multiclass model, machine learning generally uses methods like Bayes, KNN, and SVM for classification. The flowchart of the question classification process is shown in Figure 1.

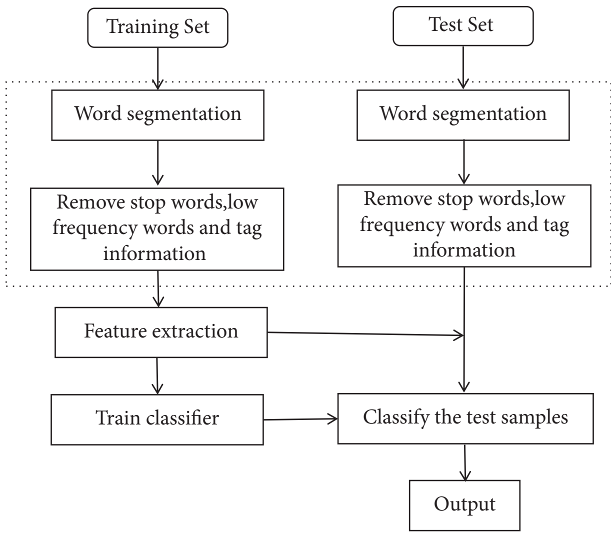

Figure 1: The flowchart of the question classification process.

2.2. Question Classification Based on Deep Learning. The concept of deep learning was first proposed by Hinton and Salakhutdinov [17] and others in 2006. It stimulates the mechanism of the human brain and can extract features layer by layer from the original data. To a large extent, it is helpful for solving the problems of time-consuming, laborious, and poor effectiveness that often occur in traditional machine learning methods which need to customize feature extraction rules by themselves. In recent years, with continuous development of deep learning technology, its application value in the fields of image processing [18], pattern recognition [19], and NLP is self-evident. For question classification tasks, deep learning can be used to actively analyze and learn the syntactic and semantic features implicit in the questions. This helps us to analyze the semantic feature structure of the question at a deeper level and perform feature extraction, so as to make the question classification more accurate. Unlike traditional machine learning methods, deep learning does not require manual extraction of the characteristics of question sentences, which greatly reduces labor and time costs. It can automatically obtain basic features, then combine these basic features into complex features, and finally train the model to judge the semantic relationship between question features and question classes. Therefore, the method based on deep learning has faster data processing capabilities and strong adaptive deep learning capabilities. Meanwhile, its fault tolerance and noise resistance are relatively high, which is very suitable for question classification.

Currently, the most representative models in deep learning for question classification are CNN model, long short-term memory network (LSTM) model, and Bi-LSTM model. What is more, a large number of relevant research results have also emerged. Kim et al. introduced a sentence classification method with a convolutional neural network based on word vectors in 2014. They used CNN to classify English questions by turning question sentences into word vectors [20]. After that, Zhang et al. further improved Kim's model and proposed a novel low-complexity model termed CNN-BiGRU [21]. They introduced the bidirectional gated recurrent unit (BiGRU) into the traditional CNN model to naturally learn the question sentence and achieve classification. It improves the classification accuracy of the CNN model on a variety of English classification data sets. Kalchbrenner et al. [12] constructed a Dynamic Convolutional Neural Network (DCNN). In the network, they used a global k-max pooling operation to solve the problem of inconsistent question length, used the DCNN network to simulate the semantic information of the question, and achieved a better question classification effect. Le and Zuidema studied the problems of incorrect modification of syntactic components and incorrect conversion of syntactic tree in the question classification of Recurrent Neural Network (RNN). They used the syntactic forest as the input of the CNN network, proposed the Forest Convolutional Network (FCN), and achieved good results in the question classification task [22]. Nan et al. constructed a neural network model based on LSTM to complete the joint modeling of the description subject and the description text and achieved a good classification effect [23].

Inspired by the above research, we started research from two aspects of feature extraction and classification model. On the basis of CNN, we further integrated the advantages of the Bagging classification algorithm, proposed an integrated convolutional neural network model, and applied it to the problem classification. The specific research content is as follows:

(1) Firstly, we use Word2Vec and CNN to complete the feature representation and feature extraction of question sentences. Since the question contains fewer words, the traditional vector space model may cause problems, such as the feature latitude that is too high and or feature vector data that is sparse. Moreover, since the correlation between words and the position information of the words in the document is not considered, these factors will affect the accuracy of question classification. Therefore, we combine the characteristics of short texts, use the Word2Vec tool to map the features of the words to a certain dimension, organize the question sentences into the form of a two-dimensional matrix similar to the image, and then set the matrix as the input of the CNN. Then, we design the CNN model and complete the feature extraction of the input data through operations such as convolution and pooling.

(2) Based on the study of the CNN model, the Bagging algorithm is used to construct the classification layer. Aiming at the problem of weak generalization ability caused by the Softmax classifier used by most convolutional neural networks at present, we propose a B-CNN integrated model combined with the Bagging algorithm to improve the accuracy and generalization of question classification.

(3) Finally, to verify the effectiveness and feasibility of the new model in question classification, several

experiments were conducted in the Chinese question set provided by the Information Retrieval Laboratory of Harbin Institute of Technology. The results prove that the effect of the W2V + B-CNN model on question classification is significantly better than that of the CNN and other classification algorithms.

3. Question Classification Model of CNN Based on Bagging Integrated Classification

To optimize the accuracy of the CNN model in processing multiclassification of questions, the paper further combines the advantages of the Bagging algorithm on the basis of the CNN and proposes an integrated convolutional neural network model referred to as W2V + B-CNN. Meanwhile, we apply it to question classification. The basic principle of W2V + B-CNN is to express the question as a word sequence with words as the unit and map it to a multidimensional vector to construct a set of word vectors. Furthermore, the characteristic information in the question is extracted through the integrated neural network, so as to realize the question classification. The structure diagram of the W2V + B-CNN model used in question classification in this paper is shown in Figure 2.

In Figure 2, we can see that the model is mainly composed of three layers, namely, the word vector matrix input layer, the convolutional feature extraction layer (including convolution layer and maximum pooling layer), and the integrated classification layer (including Dropout and Bagging integrated classification output). The word vector matrix input layer uses the Word2Vec tool to train the input sentence, converts the words into word vectors, and then splices them into a text word vector matrix. The convolution layer uses the convolution kernel to perform convolution operation on the input feature vector to extract features. The pooling layer performs sampling processing on the features extracted by the upper layer and retains important features in the form of filtering. In the integrated classification layer, the pooled and spliced feature vectors should be dropout processed during model training. Finally, the Bagging integrated classifier is used to complete the mapping of the feature vector to the category, so as to obtain the final classification result.

3.1. Word Vector Matrix Input Layer. Word vector can also be called word embedding technology, which can map words containing rich semantic information to abstract high-dimensional vector space. It is a method of continuous digital vectorization of words using a shallow neural network [24, 25]. The advantage of word vector technology is that it is helpful in solving the problem of data sparsity in traditional question classification methods. In the research of a large number of word vector learning methods, Mikolov and others from Google open-sourced a tool for generating word vectors called Word2Vecor in 2013, which includes two models of CBOW and Skip-gram [26, 27]. The structure of the two models is shown in Figure 3. The modeling idea of CBOW is to use the words in the window to predict the central word, while the modeling idea of Skip-gram is to use the central word to predict the surrounding words. In our study, the Skip-gram model will be chosen to train word vectors.

Assume that, after training, each question S can be represented by a word vector matrix, that is, $S = \{s_1, s_2, \ldots, s_n\}$, where s_i is the ith word of question S and n represents the number of words contained in S. Each word s_i can be represented by a word vector, that is, $\{w_1, w_2, \ldots, w_k\}$, where w_i is the weight of the ith dimension in the word vector and k represents the dimension of the word vector. Two models of CBOW and Skip-gram are shown in Figure 3.

3.2. Convolutional Layer. The convolutional layer is the core component of the CNN, and the core point is to capture the local correlation. Specifically for question classification tasks, the convolution kernel can extract key information similar to N-grams in the sentence. The convolution operation in the text is somewhat different from the convolution operation in the image. Because a word vector is a whole in the text, it makes sense to perform a convolution operation on the whole word vector. Therefore, assuming that the dimension of the word vector is k, then the width of the convolution kernel should also be k. When convolution operation is performed on the sentence $S = \{s_1, s_2, \ldots, s_n\}$, the convolution kernel W can be expressed as $W \in R^{hk}$, and h is the height of the convolution kernel. Then, every time you slide a word vector matrix with length h and width n, you will get an eigenvalue. The calculation formula of the eigenvalue is

$$d_i = f\left(S_{i:\, i+h-1} \cdot W + b\right), \quad (2)$$

where b is a bias term, $S_{i:\, i+h-1}$ is a word sequence of length h, namely, $(s_i, s_{i+1}, \ldots, s_{i+h-1})$, and f is an activation function. Commonly used activation functions include tanh, ReLU, and sigmoid. Increasing the activation function can make the model introduce nonlinear factors, so as to better fit the data. And the ReLU activation function will be applied in our study. After the entire question sentence is subjected to convolution operation, several feature vectors representing the sentence can be obtained:

$$D = \left(d_1, d_2, \ldots, d_{n-h+1}\right). \quad (3)$$

Because convolution kernels of different sizes can extract the features of questions from different angles, the feature information extracted by the convolution layer is affected by the size of the convolution kernel.

3.3. Pooling Layer. The pooling layer can reduce the dimensionality of features by downsampling the output vector of the convolutional layer. On the one hand, it can speed up the calculation, and on the other hand, it can effectively prevent the problem of simulation overfitting. In this paper, the maximum pooling method is used to process the feature vector D obtained by the convolutional layer, so as to select the most representative feature. The formula is

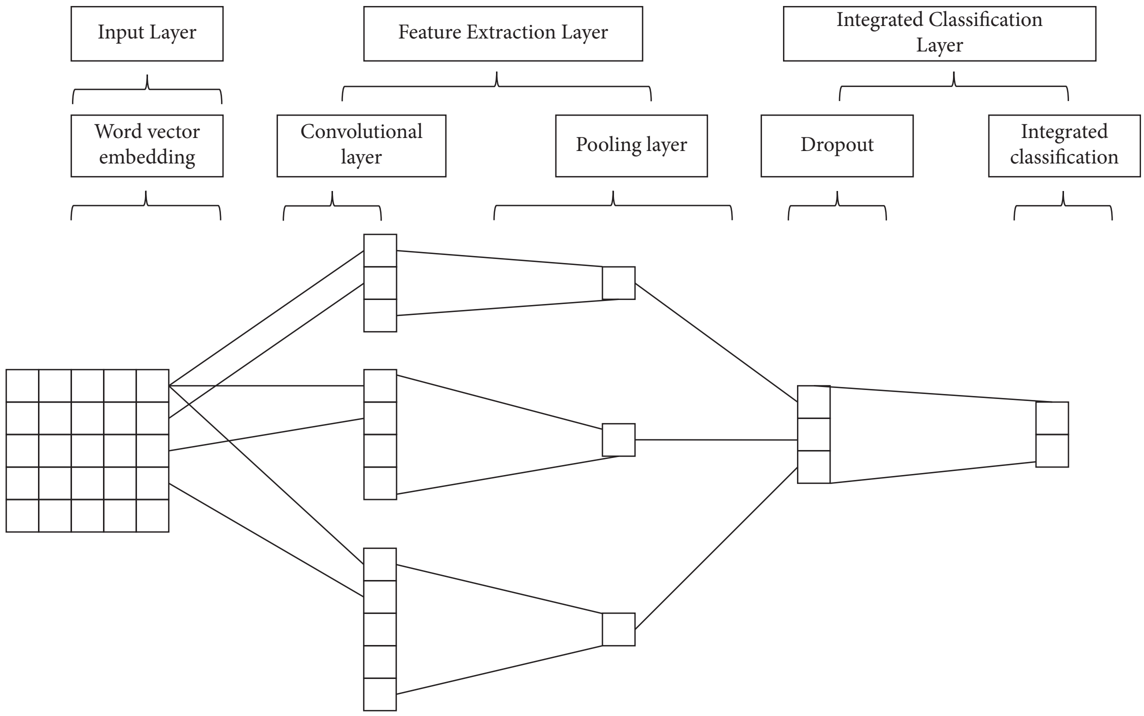

FIGURE 2: The structure diagram of the W2V + B-CNN model.

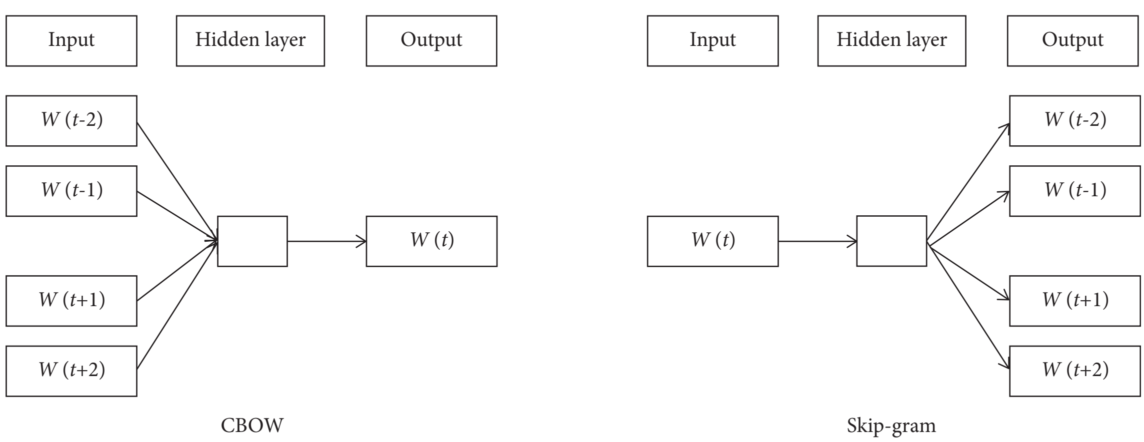

FIGURE 3: Two models of CBOW and Skip-gram.

$$D_{\max} = \max(D). \tag{4}$$

3.4. Integrated Classification Layer

3.4.1. Dropout. To avoid the problem of overfitting in the process of training, the Dropout operation is usually used to prohibit some hidden nodes from participating in forward propagation. These neurons will not participate in the update process so that the update of the weight will not rely on the role of the fixed nodes.

3.4.2. Bagging Integrated Algorithm. To further optimize the classification ability of the CNN, the Bagging integrated algorithm with better classification performance will be utilized to replace the Softmax classification function in the CNN. In the integrated classification layer, we will first apply the trained features of the convolutional layer and pooling layer as a new feature set, then input them into the Bagging integrated learning classifier for training, and finally output the classification results according to the voting method. In this way, CNN can be used to extract the potential features of the data set, and the integrated learning can be used for feature classification, which can help improve the accuracy of multiclassification tasks.

Suppose that, after the Dropout operation, the data set input to the integrated classifier is $D = \{(x_1, y_1), (x_2, y_2), \ldots, (x_m, y_m)\}$. Define $Y = \{-1, +1\}$ as the set of classification labels, T represents the number of base classifiers, and L represents the base classifiers. The hypothetical function after integration with the Bagging method is

$$H(x) = \arg\max_{y\in Y} \sum_{l=1}^{T} sign\left(\sum_{i=1}^{T} h_i(x) = y\right), \tag{5}$$

where $h_i\,(i = 1, 2, \ldots, T)$ represents the bootstrap distribution and its formula is

$$h_i = \frac{L(D, D_{bs})}{D_{bs}}. \tag{6}$$

4. Experimental Results and Analysis

4.1. Experimental Data. To verify the performance of the W2V B-CNN model, we designed several experiments on the Chinese question set provided by the Information Retrieval Laboratory of Harbin Institute of Technology. It is a relatively classic Chinese question classification data set with good universality and can better prove the performance of the algorithms. The classification system of the question set is divided into 7 classes, including description (DES), human (HUM), location (LOC), number (NUM), object (OBJ), time (TIME), and unknown (UNKNOWN). Each class contains some unique subclasses, so the data set has a total of 84 subclasses. Since there are no instances of UNKNOW type in the question set, we do not consider this class. The question set contains 6260 questions. During the experiment, we took 4960 of them as training samples and 1300 as test samples. The distribution of samples is shown in Table 1.

4.2. Data Processing. After the training sample set and test sample set are determined, these data need to be preprocessed. First of all, the preprocessing of the data includes format conversion, filtering punctuation marks, and special characters. Secondly, for the Chinese question data set, word segmentation is required. In the experiments, we can convert each Chinese question sentence into a sequence of words separated by spaces with the JIEBA word segmentation tool. Then, for Chinese question sentence, stop word removal processing is also needed. Stop words refer to words that often appear in the text without an actual meaning. The stop word list provided by the Harbin Institute of Technology is applied for follow-up experiments. The stop word list includes numeric characters, special characters, and commonly used nonsense words. Finally, the word vector training is carried out on each question sentence.

4.3. Evaluation Standard. In the experiment, we applied the classification accuracy (Acc) to judge the performance of the model, and its formula is defined as follows:

$$\mathrm{Acc} = \frac{\mathrm{AccNum}}{\mathrm{TNum}}, \tag{7}$$

where AccNum represents the number of questions in the test set that are classified correctly and TNum represents the total number of questions in the test set.

Table 1: The number of samples in training set and test set.

Class	DES	HUM	LOC	NUM	OBJ	TIME
Training set	797	328	882	1089	1274	590
Test set	159	177	370	241	198	155

4.4. Experimental Design and Result Analysis

4.4.1. Set Experiment Parameters. We know that traditional CNN training uses a gradient descent method. Generally speaking, although the batch gradient descent method can find the optimal solution, all the total samples are required to participate in the operation when the weight is updated, which will cause a large number of calculations and a slow convergence speed. As for the random gradient descent method, its advantage is that it only needs one sample to participate in the operation each time, and the convergence speed is fast. The disadvantage is that it falls into the local optimal solution easily. So we use the minibatch method for training in the experiments. In this way, the network can speed up the training speed while finding the optimal solution as much as possible to reduce the training loss. We set the minibatch size to 50. When training the word vector, each Chinese question is taken as a line to learn the word vector. And the Skip-gram model of the Word2Vec tool was applied during the process. The dimension parameter d of the word vector was set to 300. In addition, we also set other basic parameters in the experiment, the size of the convolution kernel sliding window is set to 5, and the dropout rate is set to 0.5.

4.4.2. Experimental Results and Analysis.

Experiment 1. Verify that the feature extraction method based on Word2Vec is better than traditional methods in Chinese question classification.

To verify the effect of different feature processing methods on classification, we carried out comparative experiments among the Word2Vec method, the bag of words method, the mutual information, and the IF-IDF method. In the experiment, 2480 pieces of data in the training set were randomly selected as training data, and 650 pieces of data in the test set were used as test data. The classification results are shown in Table 2.

The results in Table 2 prove that, compared with the traditional feature extraction methods, the method based on the Word2Vec has a higher accuracy rate. The main reason is that the feature vectors obtained by training and learning with word vectors can overcome the problem of data feature sparseness in traditional feature training methods. It helps alleviate the dimensionality disaster and high computational complexity. In addition, it can also help improve the accuracy of question classification and reduce the computational complexity of the model.

Experiment 2. Verify that the CNN based on Bagging integrated classification is better than traditional machine learning methods and CNN in Chinese question classification.

Table 2: Classification results based on different feature training methods.

Method	DES	HUM	LOC	NUM	OBJ	TIME	Total
Bag of words	72.87	56.74	64.31	75.16	64.25	60.48	65.67
Mutual information	70.43	54.84	60.66	72.57	62.40	58.16	63.26
IF-IDF	73.95	59.57	64.41	76.35	66.53	62.36	67.82
Word2Vec	79.32	65.95	73.64	84.53	73.06	69.57	74.71

Table 3: Comparative experimental results of different models.

Models	DES	HUM	LOC	NUM	OBJ	TIME	Total
Bayes	85.41	69.28	75.63	87.82	77.58	73.14	78.20
SVM	86.20	68.74	76.48	88.24	77.82	74.15	78.73
CNN	84.65	71.38	78.82	87.64	78.43	74.48	80.81
W2V + CNN	86.46	78.54	79.23	89.17	79.35	77.79	82.62
W2V + B-CNN	88.57	80.24	84.72	92.47	83.18	82.74	85.67

To verify the performance of the W2V + B-CNN model in the application of question classification, comparative experiments were conducted with traditional machine learning methods such as Bayes and SVM, as well as deep network models such as CNN and W2V + CNN. The comparative results are illustrated in Table 3.

From Table 3, the following conclusions can be drawn:

Conclusion 1. The results of Table 3 illustrate that the W2V + B-CNN model proposed in the paper has the best classification effect. Compared with traditional machine methods and CNN models, the W2V + B-CNN model has significantly improved classification accuracy both in the major class and in each subclass. Finally, the experimental results prove the effectiveness and feasibility of the W2V + B-CNN model in question classification.

Conclusion 2. In Table 3, we can also see that the question classification methods based on the CNN model are better than the machine learning method on the task of question classification. It shows that, for the distributed feature representation of word vectors in the task of Chinese question classification, using machine learning methods to construct and match features is not as advantageous as using CNN. The main reason is that the CNN can reduce the parameters of the model through local perception and weight sharing, thereby effectively reducing the complexity of the model. Meanwhile, the classification accuracy of the CNN models is higher than other machine learning models, which shows that CNN performs very well in the classification of Chinese questions.

Conclusion 3. We can also draw the conclusions from Table 3 that, compared with the CNN model, the classification accuracy of W2V + CNN model and W2V + B-CNN in each class has been improved. What is more, the classification accuracy of the W2V + B-CNN model has improved significantly. The reason is that, because the question contains fewer words, the problems of too high feature latitude and sparse feature vector data will occur when the traditional vector space model is used. Moreover, since the correlation between words and the position information of the words in the sentence are not considered, these factors will affect the accuracy of question classification, and the classification effect of CNN is not very satisfactory. Therefore, compared with SVM and Bayes learning methods, the accuracy of the CNN model has a relatively small improvement. Combining the characteristics of short texts, we took the Word2Vec tool to map the features of the words to a certain dimension, then organize the question sentences into the form of a two-dimensional matrix similar to the image, and use it as the input of the CNN model. The advantage is that it solves the data sparsity problem in traditional question classification methods and greatly improves the classification accuracy.

Conclusion 4. Comparing the W2V + CNN model with the W2V + B-CNN model, it can be found that the W2V + B-CNN model can further combine the advantages of the Bagging algorithm and has a greater degree of improvement in classification accuracy than the W2V + CNN model.

In summary, the W2V + B-CNN model proposed in this paper combines the idea of integrated classification with CNN. In this way, the CNN can be used to extract the potential features of the natural question, and the Bagging algorithm can also be utilized to optimize the classifier in the new model. It not only strengthens the positive influence of more complete data on classification but also weakens the negative influence of noisy data, thereby greatly improving the classification performance of the algorithm.

5. Conclusion

Question classification is a key link in the QAS, and its classification performance has an important impact on subsequent document retrieval and answer extraction. It can be said that, as an important submodule of the QAS, the importance of question classification is self-evident. Therefore, to optimize the performance of question classification, we conducted a certain research on the application of CNN and proposed a new model based on the Bagging integrated classification called W2V + B-CNN. Firstly, the model uses Word2Vec for word vector training and then uses the convolutional layer and pooling layer of the CNN for feature extraction and feature selection. Finally, in the integrated classification layer, the Bagging algorithm with better classification performance was used to replace the Softmax classifier for feature classification. On one hand, the new model can apply the CNN to extract the potential features of natural questions. On the other hand, it can also take advantage of integrated learning for feature classification. In the end, to fully verify the feasibility and effectiveness of the W2V + B-CNN model applied to question classification, we conduct comparative experiments with traditional machine learning algorithms and CNN. The results prove that, compared with other algorithms, the improved W2V + B-CNN model has higher classification accuracy and better question classification performance.

In order to help badminton players make reasonable training plans and realize a comprehensive grasp of the training process, this paper mainly recognizes and perceives the posture of badminton athletes based on the method of moving edge calculation. Firstly, from the perspective of moving edge motion analysis, considering the vector field formed by moving edge vector as movable spatial distribution information, the spatial distribution model of moving edge field is realized. Secondly, while athletes interact with the computer through limb movement, the overall posture of athletes is divided into several parts, and each part is perceived separately. Finally, in the human posture evaluation module, an algorithm for human posture evaluation in the image pixel plane is proposed. Through comparative experiments, the motion recognition algorithm can effectively recognize the three typical swing movements of badminton players in the video and improve the overall performance of the existing recognition algorithms.

1. Introduction

Collecting data in sports and analyzing the data to complete posture perception is a hot spot in the intellectualization of the sports industry in recent years. In badminton competitions, athletes' attitude perception information can become an important semantic clue to understand the competition process, discover technical details, and extract highlights [1, 2]. In terms of the fineness of visual content analysis, the movement trajectory information of badminton players can be regarded as a coarse-grained description, which is the macroperformance of the whole game. The attitude perception of badminton players can be regarded as a fine-grained description, which can embody the details of the game [3, 4]. In order to analyze and understand sports video content in more detail, it is necessary to identify athletes' actions and collect the training information and posture information of athletes, so as to reasonably formulate the training arrangement [5]. On the basis of a large number of data analyses, we can realize a comprehensive grasp of the sports training process.

There are two main research directions of attitude perception. One is attitude perception based on inertial sensors. For example, in literature [6], three-axis acceleration sensors are used to collect user action data, and gesture recognition is realized for time-series modeling based on the Hidden Markov model. Literature [7] uses principal component analysis to perceive human posture based on the data collected by the three-axis acceleration sensor. The other is to use video surveillance and image processing for gesture perception. For example, in [8], for the complex environment, depth image technology is used for gesture recognition, and the average recognition rate of gesture can reach 98.4%. In racket motion recognition based on image and video data acquisition, [9] established an event hiding Markov model with binary classification according to the position of players on the court. Literature [10] proposed a badminton game data mining method based on two-dimensional sequence images. Literature [11] classifies the badminton shot of the compressed video and identifies the type of attack ball by detecting the badminton trajectory. Among the research topics based on badminton, most of them focus on the relationship between racket speed and ball speed, the prediction of ball speed, and the monitoring of players' state characteristics. There are few studies on the detection, analysis, and training of controlled steps for the classification, recognition, and training of hitting movements. The hitting action and controlled step are two important parts of badminton technology. By analyzing different hitting actions and comparing the hitting action characteristics of athletes with different technical levels, it is an important way to improve badminton skills.

This paper will take badminton game video as the research object to track and recognize the badminton players' swing in time-series images. Based on the idea of local motion vision analysis and grid classification, this paper proposes a motion descriptor based on moving edge calculation and constructs an athlete's attitude perception and evaluation algorithm to classify and recognize three typical swing movements of badminton players [12]. The first part is the introduction, which mainly introduces the research significance and research status at home and abroad. The second part is the swing motion perception based on moving edge calculation, which mainly focuses on the perception, segmentation, and recognition of badminton players' swing motion. The third part is the posture evaluation of badminton players, which mainly evaluates the perception of human posture, which helps athletes improve the standard of movement. The fourth part is the experimental results and analysis, and the fifth part is the summary and prospect of the full text.

2. Swing Motion Perception Based on Moving Edge Computing

Athletes' three-dimensional posture perception technology is the basis of realizing sports training auxiliary systems. In order to carry out a three-dimensional simulation of athletes' movement posture, so as to adjust the training mode and improve the training level, this paper studies the application of the unmarked three-dimensional posture perception method in a training assistant system [13, 14]. While the athletes interact with the computer through limb movement, they adopt the method of partial estimation, that is, the athletes' overall posture is divided into multiple partial postures, and each part is perceived separately. Then, the overall posture is generated from part of the posture, so as to realize the estimation of athletes' sports posture. The algorithm block diagram is shown in Figure 1. It includes an action segmentation module and pattern recognition module. The purpose of the action segmentation module is to segment the action interval of the original data, so as to extract the data of a single action of athletes, including signal selection, smoothing processing, and segmentation point acquisition.

2.1. Mobile Edge Computing. Based on the machine learning [15–17] methods, a descriptor describing different types of motion is proposed after calculating the moving edge features of the player tracking image time series. The key to using moving edge computing is that the features obtained from a large number of noisy videos are extremely inaccurate. In the process of visual analysis using moving edge calculation, moving edge is considered as the timing displacement information of each pixel in the video frame, which puts forward higher requirements for the accuracy of moving edge calculation [18]. In order to make effective use of the moving edge features of a large number of noisy moving videos, we start with the analysis of the moving edge field and consider the vector field formed by the moving edge vector as movable spatial distribution information. Then, with the help of the motion descriptor of compact expression, the robustness of these features is enhanced. The movement of these images is the result of the relative displacement of the athlete's limbs and trunk. These relative motions are represented in different regions of the tracking image [19]. These local features can not be effectively expressed by global features. At present, we can use the local analysis technology based on grid classification to divide the moving edge field of the adjusted image into nonoverlapping subdomains. Each subfield is called a grid. Through the histogram statistics of each grid, the spatial distribution model of the moving edge field can be realized.

The moving edge feature based on the tracking image can only reflect the motion information of athletes in the image foreground, and the background in the tracking image will affect the moving edge calculation. Therefore, it is necessary to clear the background. Considering the uniform characteristics of the background color of the sports field, it is necessary to adopt the modeling method based on the Gaussian mixture model and use the region growth algorithm for postprocessing to obtain the athletes with global foreground [20].

The light field can be estimated by adjusting the image sequence according to the player with clear background. However, considering the following points, it is necessary to use the difference between adjacent tracking images to calculate the light field. Firstly, the brightness of the athlete's tracking image will be different due to the changes of camera flash and light intensity in the stadium. This difference will lead to incorrect moving edge calculation [21]. Therefore, it is necessary to use image difference calculation to eliminate the influence of brightness change. Secondly, the academic findings of the biological vision system show that human visual cells are more sensitive to the direction and speed of object edge movement. Therefore, the moving edge calculation based on image difference can better reflect the mechanism of the human visual system's response to object motion. Based on the differential image, the horn Schunck algorithm is used to estimate the moving edge field of the player tracking image. The whole calculation process can be formalized as

$$\begin{aligned} \mathrm{EI}_k &= \mathrm{ID}_k - \mathrm{ID}_{k-1}, \\ \mathrm{Mov}_k &= G\left(\mathrm{EI}_k\right) + \delta. \end{aligned} \tag{1}$$

In the equation, EI_k is the tracking image ID_k and ID_{k-1} differential image. Mov_k is the calculated mobile edge field. K is the number of image sequence alignments.

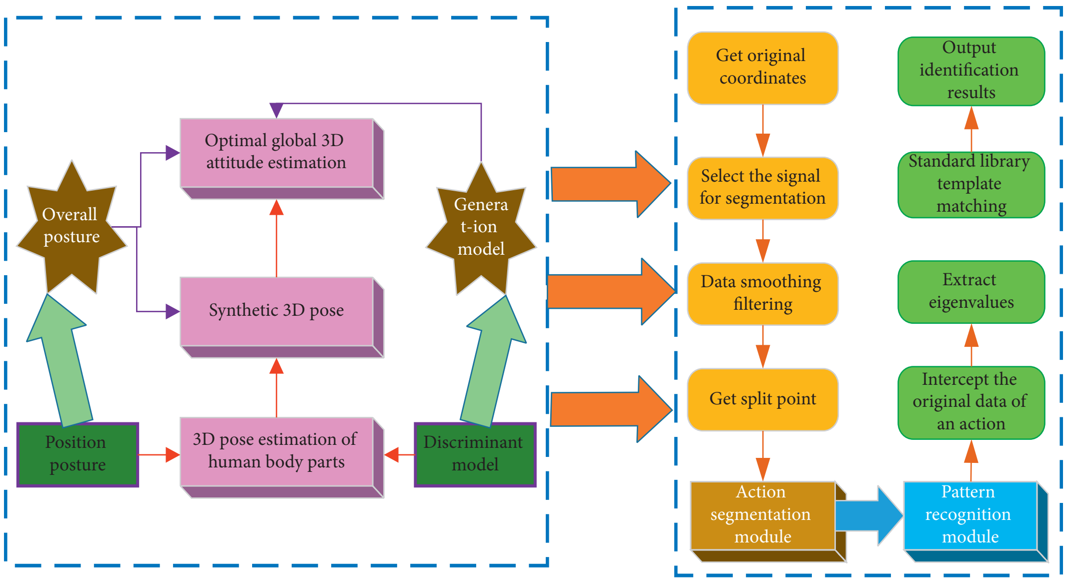

Figure 1: Estimation process of motion attitude.

2.2. *Swing Motion Segmentation*

2.2.1. Action Segmentation Algorithm. The action segmentation algorithm is used to separate the athletes' actions in a period of time and get the starting point and endpoint of each action. The accuracy of the motion segmentation algorithm will directly affect the accuracy of motion recognition and motion counting. The action segmentation algorithm used in this paper can segment continuous complex actions, which is helpful to improve the accuracy of action recognition and counting.

The motion segmentation algorithm needs to select a signal with relatively large signal amplitude and relatively few local peaks and troughs from the nine signals of x-, y-, and z-axis acceleration, angular velocity, and attitude angle. This is conducive to removing local peaks and troughs in later smoothing filtering and improving the accuracy of action segmentation. Since the three-axis attitude angle signal range is -180° to 180°, when the attitude angle exceeds 180°, the signal will suddenly change to -180°, which is easy to misjudge the peak and trough, so only the waveforms of three-axis acceleration. Figure 2 reflects the six signal waveforms of acceleration and angular velocity when athletes continuously perform table tennis forehand action. It can be found that the number of local peaks of the z-axis in an action cycle is relatively small and the amplitude is large, which is more suitable for limited smoothing processing. The arrow in the figure indicates the acceleration signal direction of each axis of the MEMS sensor, and the angular velocity direction of each axis conforms to the spiral law of the right hand of the human body. When the human body performs swing, walking, and running, the arm tends to rotate around the z-axis. After that, the signals of various axes of badminton forehand, walking, running, and other movements are compared. The z-axis angular velocity signal can still reflect good separability. Therefore, this algorithm uses this signal as the segmentation signal.

The diamond represents the peak and trough, and the circle represents the zero point. The smoothed waveform makes it easier to find the signal peak, trough, and zero point by using the program, and the left and right adjacent zeros as the starting point or endpoint are trough and peak, respectively. In order to further reduce the local peaks and troughs caused by action details, this paper adds the minimum threshold Tmin of action interval on the time axis. It is generally considered that the fastest completion time of action of the human body is 0.2 s. All zeros occurring in this time period will be removed; otherwise, the recognition error rate and counting error times will be increased. Therefore, Tmin is selected as 0.2 s. By using the human body detector to detect the position of the player in the badminton swing video segment, the position of the player in the video frame is detected and marked with a rectangular box. Then, only the feature points in the inner region of the rectangular box are detected, and the feature points detected in the region are tracked. In this way, the position information of the trajectory in the video frame not only can be obtained, which reduces the amount of computation of the algorithm, but also excludes the motion trajectory in the other unwanted background, which effectively increases the robustness of the algorithm.

2.2.2. Eigenvalue Extraction. The average resultant acceleration a is the average value of the resultant triaxial acceleration signal of action. The formula is as follows:

$$\overline{\mathrm{Acc}} = \frac{\sum_{i=1}^{N} \mathrm{Acc}_i}{N}. \tag{2}$$

N is the number of sampling points of action. Composite acceleration variance σ_{Acc}^2 is as follows:

$$\sigma_{\mathrm{Acc}}^2 = \frac{\sum_{i=1}^{N} \left(\mathrm{Acc}_i - \overline{\mathrm{Acc}}\right)^2}{N}. \tag{3}$$

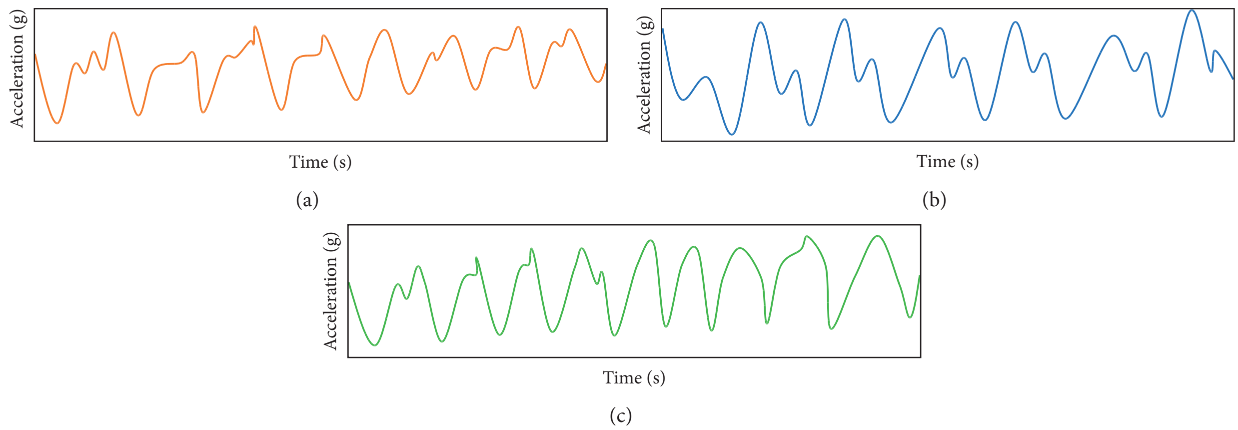

Figure 2: Comparison of acceleration signal waveforms of each axis.

The peak and valley value of synthetic acceleration Acc_{pv} is as follows:

$$\mathrm{Acc}_{pv} = \mathrm{Max}(\mathrm{Acc}) - \mathrm{Min}(\mathrm{Acc}). \tag{4}$$

The average synthetic angular velocity is ω. The average value of the synthesized three-axis angular velocity signal of an action is calculated as follows:

$$\overline{Av} = \frac{\sum_{i=1}^{k} Av}{K}. \tag{5}$$

Composite acceleration variance σ_{Av}^2 is as follows:

$$\sigma_{Av}^2 = \frac{\sum_{i=1}^{N} \left(Av_i - \overline{Av}\right)^2}{N},$$
$$Av_{pv} = \mathrm{Max}(Av) - \mathrm{Min}(Av). \tag{6}$$

The formula is as follows:

$$\mathrm{Cov}(\mathrm{Acc}, Av) = \frac{\sum_{i=1}^{k} \left(\mathrm{Acc}_i - \overline{\mathrm{Acc}}\right)\left(Av_i - \overline{Av}\right)}{(k-1)}. \tag{7}$$

The attitude angle changes ϕ_x, ϕ_y, and ϕ_z of x, y, and z axes are expressed by the following equations, respectively.

$$\phi_x = \sum_{i=2}^{k} \left|\omega_{x,i} - \omega_{x,i-1}\right|,$$
$$\phi_y = \sum_{i=2}^{k} \left|\omega_{y,i} - \omega_{y,i-1}\right|, \tag{8}$$
$$\phi_z = \sum_{i=2}^{k} \left|\omega_{z,i} - \omega_{z,i-1}\right|.$$

2.3. Recognition of Swing Movement. As described above, the movement of the athlete in the adjustment image is caused by the relative displacement in his body, and these movements exist in the corresponding image area. For different gestures, the spatial distribution of the moving edge field is different. The whole process of swing recognition includes data acquisition, window interception, feature extraction and selection, and recognition algorithm research. In Figure 3, the moving edge vector of the image of the up swing racket is densely distributed in the upper part of the image. In the normal image of the left swing of the racket, the moving edge field on the left is more concentrated than that on the right. In contrast, in the image of the right swing racket, the right side is denser than the left side. The usual action recognition methods only use the distribution characteristics and characterize them based on the idea of local analysis. In this paper, an effective region division method is proposed, which is called mesh division.

The moving edge field after smoothing and denoising is divided into nonintersecting grid regions in the vertical and horizontal directions of the adjusted image. Theoretically, meshing can be constructed in any spatial form. Specifically, the number of vertical and horizontal grids is random. However, considering the adjustment of the player's body structure and computational complexity in the image, we use $3 * 3$ grid segmentation. Too simple partition model cannot give a complete description of the spatial distribution of moving edges. However, too complex partitions such as $5 * 5$ and $7 * 7$ will reduce the grid area, so it is estimated that the histogram of moving edges will become sparse. A dense trajectory algorithm can be selected as the basic algorithm for badminton swing recognition, and then, optimization measures are proposed on the basis of this algorithm, so that the algorithm can recognize badminton swing more effectively.

Its main principle is to identify the pixels with an obvious color change or brightness change in the digital image. The significant change of these pixels often represents the important change of this part of the attributes of the image, including discontinuity in depth, discontinuity in direction, and discontinuity in brightness. Based on the kernel density estimation of color layout and the grid histogram of direction gradient, a moving edge histogram based on grid division is developed as the motion descriptor of player swing. For an optical vector with coordinate P in a given moving edge field, its horizontal and vertical components are $H_x(r)$ and $H_y(r)$, respectively. Then, use equation (2) to define the amplitude $N(r)$ and the direction angle $\delta(r)$:

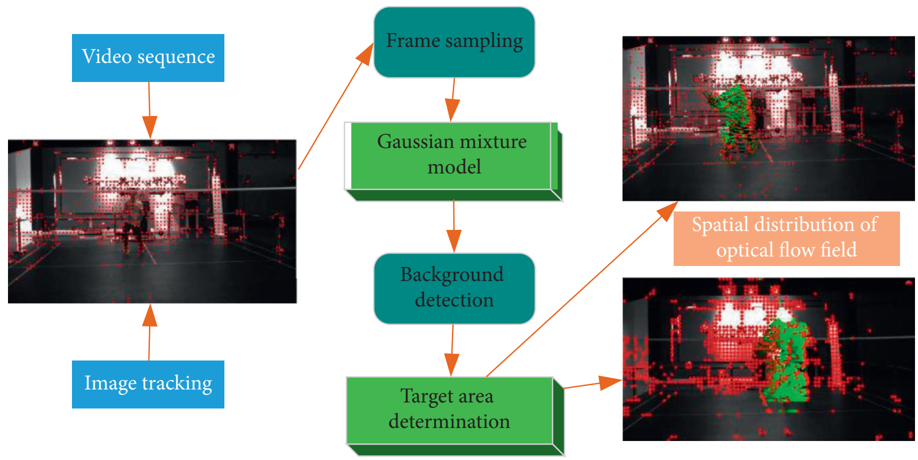

Figure 3: Distribution of movement edge field of athletes.

$$N(r) = \sqrt{H_x^2(r) + H_y^2(r)},$$
$$\delta(r) = \arctan\left[\frac{H_x(r)}{H_y(r)}\right]. \tag{9}$$

The main idea of grid division based on moving edge histogram is that for each grid region, the moving edge vector of any coordinate r is the angle after $N(r)$ weighted quantization $\delta(r)$ of the magnitude. The quantization weighting strategy not only considers its own amplitude $N(r)$ but also uses the kernel density estimation method to consider the distribution information of adjacent moving edge vectors.

Using the existing sports posture database C, the sports posture sample set D can be obtained through classification. For the new athlete posture image, the athlete's posture can be determined only by looking for the sample with the maximum probability of $p(y|z)$. X represents the posture state variable of a specific part, and Z represents the posture state variable of the athlete's posture image.

First, we take $p(y|z)$ as the edge distribution of motion attitude sample set D; then,

$$p(y|z) = \sum_i p(y|z, D)p(D), \tag{10}$$

where $p(y|z, D)$ is used to represent the position posture state variable x; that is, it conforms to the athlete's observed posture state variable Z. At the same time, it belongs to the probability of motion attitude sample library D.

Assuming that the position attitude state variable x and the motion attitude sample library D are independent of each other, there are

$$p(z|y, D) = \frac{p(z|y)p(z|D)}{p(z)}. \tag{11}$$

Then, the equation can be changed to

$$p(y|z) = p(z|y)\sum_i p(z|\mathrm{D})p(y, D)p(D). \tag{12}$$

It is assumed that all attitude samples in the attitude sample library are evenly distributed, and the probability of p (D) is uniform. Then, the posterior probability can be simplified as

$$p(y|z) = p(z|y)\sum_i p(z|\mathrm{D})p(y, D). \tag{13}$$

After classification, the set of samples in category D can be reasonably regarded as Gaussian distribution; that is, it meets the following requirements:

$$y|D \sim N(\mu, Z). \tag{14}$$

μ and Z are the probability mean and covariance of the sample in the motion attitude sample set D. Then, the probability of occurrence of posture state variables on the athlete's posture image is

$$p(z|D) = \int p(z|y)p(y|D). \tag{15}$$

For the Monte Carlo approximate calculation of equation (5), firstly, the probability p $(x|c)$ needs to be sampled and calculated. Then, the confidence $p(z|y)$ of each sampling point is calculated. Finally, the weighted sum of the confidence of all sampling points is obtained.

Then, according to the above equation (4), under the condition of giving the athlete's posture state variable z, the posterior probability $p(y|z)$ can be calculated for each sports posture example y in the sports posture database D. Through this value, we can judge the similarity between the athlete's current posture and the sample posture in the database, so as to estimate the athlete's posture. In order to put forward the shortcomings of the action to be analyzed in the execution process, we need to get the difference between it and the standard action.

3. Posture Evaluation of Badminton Players

In the process of badminton players' movement, there are high requirements for the standard degree of their own actions, but in training, they always rely on the coach's correction of badminton players' posture, and there is no more accurate evaluation system. After analysis, the human posture evaluation system designs an algorithm: take a group of bone point coordinates of badminton players in the camera coordinate system in a single frame image as input, compare it with the badminton players' standard posture library from the same perspective, and then calculate the matching standard posture and cumulative error. The cumulative error reflects the similarity with the matched standard attitude. The lower the cumulative error, the higher the similarity.

3.1. Human Posture Evaluation Algorithm

3.1.1. Algorithm Flow. The overall flow of the human posture evaluation algorithm is shown in Figure 4.

The specific process is as follows:

(1) Coordinate conversion is performed on the coordinates of human bone points conforming to the 13 point human posture model, the image pixel coordinate system is converted to the rectangular coordinate system with point 0 as the origin, and the vectors from the coordinates of each human bone point to point 0 and the included angle between the vectors and the bone points formed in the positive direction of the x-axis of the rectangular coordinate system are calculated, respectively.

(2) Set the priority of each bone point, take one bone point in sequence according to the priority, calculate the cumulative difference with the corresponding bone points of all pose models in the candidate pose set, and output the cumulative difference. After all bone points of the pose model to be measured are calculated, enter step (3). Wherein, the cumulative difference is the absolute value of the difference of the included angle of the bone points in step (1), and the candidate posture set is initially a preset human posture standard library.

(3) Calculate the cumulative error, find the attitude model with the smallest cumulative error in the candidate attitude set, and output the serial number of the attitude model and the cumulative error. The cumulative error is the sum of the cumulative differences of each bone point in the attitude model of the attitude model to be measured in a candidate attitude set.

3.1.2. Algorithm Analysis. At present, the mainstream human posture evaluation algorithms are human posture evaluation in the world coordinate system. The conversion from camera coordinate system (image pixel coordinate system) to world coordinate system requires a depth camera. At the same time, there is an origin (0,0,0) in the conversion process. By comparing the vector set of human postures in the world coordinate system, we can achieve real-time tracking and evaluation of human posture.

This algorithm is different from most current human pose evaluation algorithms. Although it is more comprehensive to evaluate human pose in three-dimensional space, the cost of methods such as depth camera and binocular vision to supplement the missing information in the conversion process is too high. Therefore, this algorithm matches the human posture with the standard posture library under the image pixel coordinate system, so as to obtain the evaluation results, and makes the standard human posture library (forehand, backhand, and jump ball) in badminton for testing.

The evaluation part of the human pose evaluation algorithm has three steps: (1) coordinate transformation of the input bone point coordinates, (2) matching with the standard attitude library, and (3) matching result processing.

In the image pixel coordinate system, the change of human posture coordinate set is not only affected by the position of badminton players on the badminton court (such as front and rear half-court, left and right half-court) but also affected by the camera model, so it can not be directly matched with the standard posture. If we want to match the human posture coordinate set, the above two problems must be solved. The idea of this algorithm is to transform the input coordinates. The transformation steps are mainly divided into two steps, as shown in Figure 5.

The transformation step (a) is carried out because the athletes' different positions on the badminton court will lead to problems in matching with the standard posture. Even if a certain posture appears in different positions on the badminton court, it will show different coordinates in the camera perspective. Therefore, this algorithm puts forward an idea: convert the input coordinate system to the coordinate system composed of the athlete's own human body, so that the positions of the other 12 bone points are determined relative to the neck point. Regardless of the standard posture or the input athlete posture, the neck point is the origin, which can eliminate the problems caused by different positions.

The reason for performing the transformation step (b) is that there are differences between individual body shapes, which will lead to uncertain matching results even if each individual makes the same posture. Therefore, based on the "cosine similarity," the (b) transformation step is proposed: transform the image pixel coordinate system into a rectangular coordinate system with the neck point as the origin, and solve the included angle between the vector formed by the other points and the origin and the positive direction of the x-axis, in order to eliminate the uncertainty caused by this individual difference.

3.2. Matching Human Posture with Standard Library. In the human posture evaluation system, the human standard posture database is also an important index. If the human body standard posture itself is not standardized, the accuracy of human body posture evaluation cannot be guaranteed. Due to the complexity of modeling and the continuous improvement of the effect of deep learning, human posture estimation has gradually focused on deep

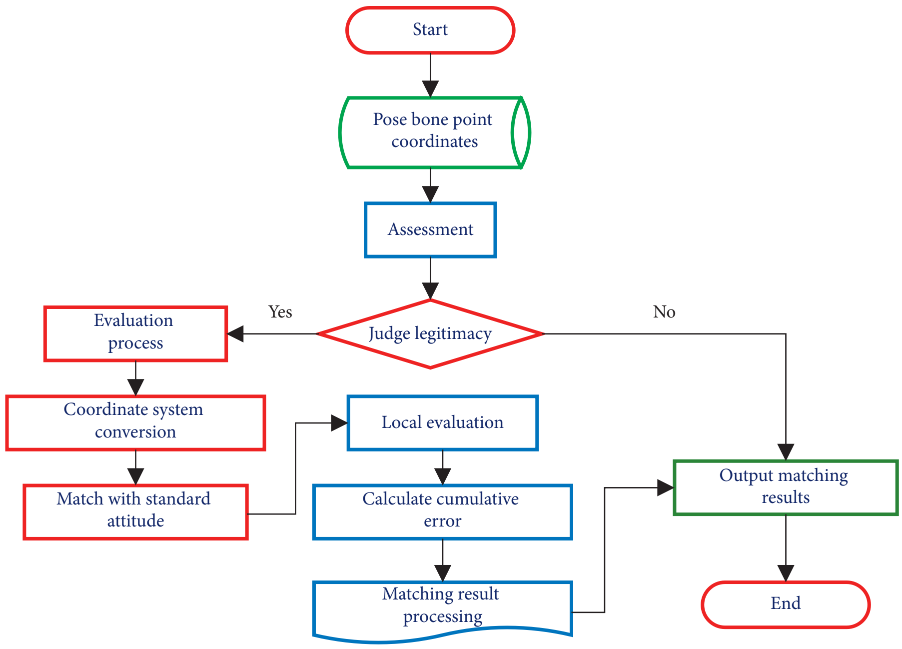

Figure 4: Human posture evaluation algorithm flow.

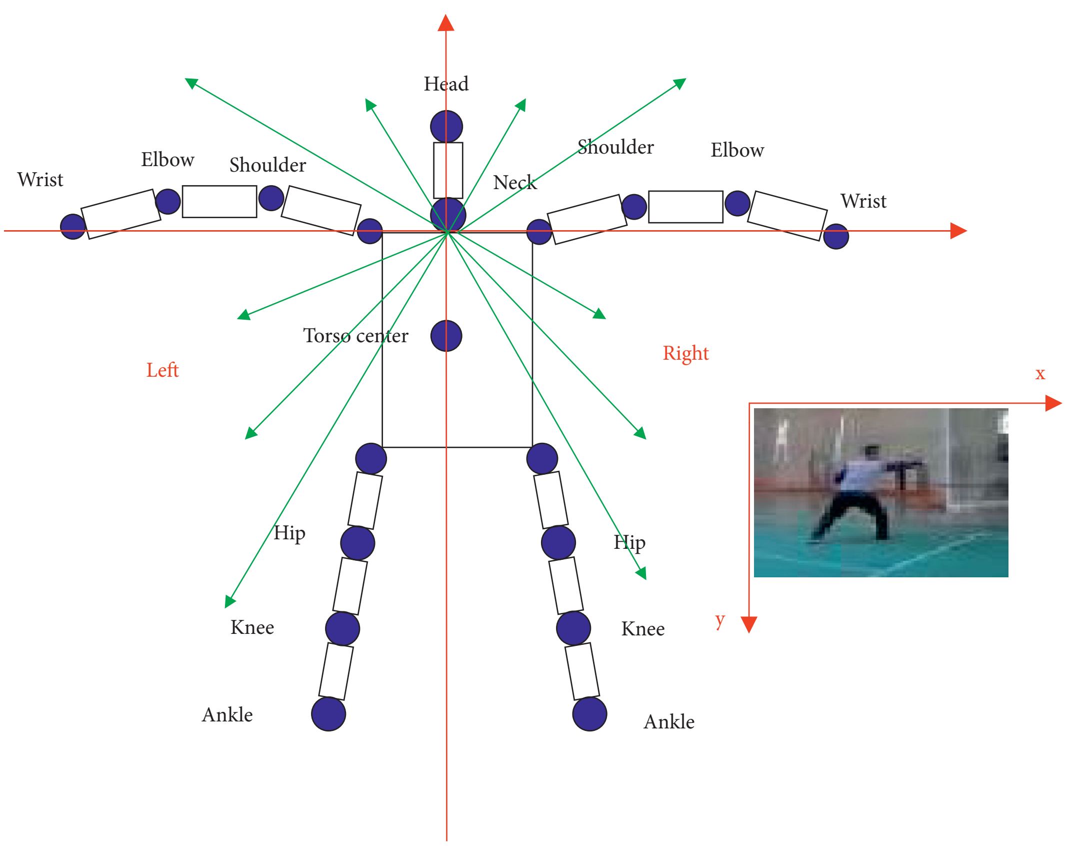

Figure 5: Bone point coordinate system.

learning, but estimation speed and ReLU optimization are still a new challenge. Therefore, in order to show the effect, this algorithm selects three actions: forehand pick, backhand draw, and jump ball, so that an athlete can make a standard posture first and then calculate the parameters of the standard posture of the human body through the process shown in Figure 6. Calculate the similarity between the action and the standard action of this kind of action, and

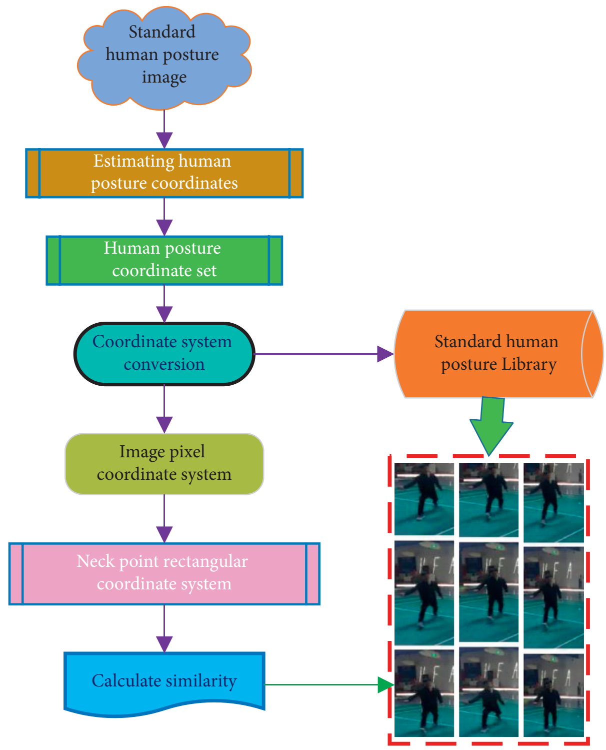

FIGURE 6: Production process of standard human posture library.

then use the scoring formula to calculate the score of the action through the similarity.

After the coordinate transformation of the rest points in the human posture model, the serial number is readjusted. The right upper limb area contains three bone points: right shoulder, right elbow, and right wrist. The adjusted coordinate numbers are 0, 1, and 2. The left region of the upper limb contains three bone points: left shoulder, left elbow, and left wrist. The adjusted coordinate numbers are 3, 4, and 5. The right area of the lower limb includes three bone points: right hip, right knee, and right ankle. The adjusted coordinate numbers are 6, 7, and 8; The left area of the lower limb contains three bone points: left hip, left knee, and left ankle. The adjusted coordinate numbers are 9, 10, and 11.

The overall matching process is divided into 9 small stages, matching 0, 1, 2, 6, 7, 8, 9, 10, and 11 areas, respectively. The of each small area is to take the corresponding angle between the attitude to be evaluated and the candidate standard pose in the previous stage and calculate the absolute value of the difference between them, which is later called cumulative error. If the cumulative error is less than or equal to the allowable error of this stage, the standard pose of the human body conforms to the evaluation of this stage, and the standard pose is put into the candidate standard pose set of this stage.

There are two possible evaluation results in this process: (1) if the angle of the pose to be evaluated in this stage is the loss angle due to the absence of the bone point in the input), the candidate standard pose set in this stage is the candidate standard pose set in the previous stage, that is, skip this stage. (2) After all matching is completed, if there is no candidate standard pose set in this stage, the comparison output result is directly ended. The output results include all the standard poses matched, the stage at the end of matching, and the loss caused by the accumulation of accumulated errors in the matching process.

After the human posture evaluation algorithm, there are two output results: one is the most appropriate standard human posture sequence number, and the other is the similarity with the matched standard human posture, expressed by loss. The matching results obtained in the human posture evaluation algorithm also need to be processed.

If "−1," "0", and "1" appear, this indicates that the comparison of the left area of the upper limb is not completed, and "matching failed" is output. Because the key point of a badminton player's posture matching is the left area of the upper limb, it represents the badminton player's racket holding posture, which is the key area to judge whether the badminton action is standard or not. If "matching failure" occurs, it indicates that the posture of the athlete in the frame image does not conform to any posture in the standard library.

If other information appears, the matching result has appeared. The higher the sequence number, the better the matching result. The loss reflects the similarity between the standard posture meeting the matching conditions and the human posture to be matched at the same stage. The lower the loss, the higher the similarity. How to introduce this feedback into the process of human posture evaluation is still the focus of follow-up work, and it is also a breakthrough for human posture evaluation algorithms to improve the accuracy of evaluation.

How to introduce this feedback into the process of human posture evaluation is still the focus of follow-up work, and it is also a breakthrough for human posture evaluation algorithms to improve the accuracy of evaluation. In the follow-up research, we not only need to get the similarity between the action to be analyzed and the standard action but also give the differences between them, so as to provide the basis for the subsequent correction opinions of the action to be analyzed.

4. Experimental Results and Analysis

We used badminton competitions from radio and television programs and the London Olympic Games. Video is stored in MPEG-2 compressed format, and the size of the video frame is $352 * 288$. The types of different swings in these competitions are marked in manual mode. The real value is created in the ground truth, as listed in Table 1 and Figure 7, including the game name, player, video time length, and the number of three swings.

In order to quantitatively evaluate the algorithm, three evaluation indexes are defined in this paper. Firstly, recall rate (R) and accuracy rate (P) are defined to determine the recognition ability of each swing.

4.1. Action Recognition Results. For the badminton video data shown in Table 1, a classifier is trained to judge the players' actions. All data use the three times cross-validation strategy to form the training set and test set, that is, 2/3 of the data are used as training samples, and the rest are test samples. After three iterative tests, the average of the three evaluation data is considered as the final result. Table 2 shows the experimental results of the algorithm. The experimental comparison results of action recognition are shown in Figure 8.

It can be seen from Table 2 that, for badminton competition, the methods proposed in this paper have good recognition accuracy, which can reach 87.6%. In the test video, the moving image has 30~40 pixels. Due to factors such as low-quality video and camera movement, the swing action is not obvious in every detail. The above research results confirm that the proposed motion descriptor and recognition strategy are very effective. In the experiment, the recognition error of swing movement occurs because high-level athletes will use some unconventional swing techniques to hit a difficult return ball in the game. The optical flow field distribution of these abnormal swing movements is different from the normal situation, so the moving edge histogram based on grid division cannot accurately describe these movements.

4.2. Attitude Perception Analysis. While evaluating the motion recognition method based on motion analysis, the effectiveness of the method based on motion pose feature analysis and the recognition method in this paper is compared. The method based on motion posture feature analysis is to track the athlete's action trajectory to obtain the target area. The contour of athletes' action posture is obtained by processing the background, and the action contour information is mapped into a feature space by Karttunen Loeve (KL) transform. Then, the eigenvalues are arranged in descending order, and the eigenvector of the first m maximum constitutes the apparent descriptor of action and gesture. Finally, the nearest neighbor classifier is used to recognize the action sequence according to these descriptors. As in the above experiments, three cross-validation strategies are applied to separate all data into the training set and test set. In the experiment, the structure of the action descriptor is simplified by modifying and selecting the percentage of the sorted apparent vector. The data set used here achieves the best accuracy when the first 80% of the view vectors are selected. The evaluation results based on the action attitude feature analysis method are shown in Table 3. The effect comparison is shown in Figure 9.

It can be seen from Table 3 that the method proposed in this paper is better than the feature analysis method. This is because this method cannot effectively distinguish the changes of camera angle or athlete's working direction in sports video, so the descriptor based on action posture contour reconstruction does not have excellent classification

Table 1: Experimental data of motion recognition.

Game video clip	Up swing times	Left swing times	Right swing times
Olympic games	52	102	147
Masters	251	398	289

Video 6	51	45	0.8823

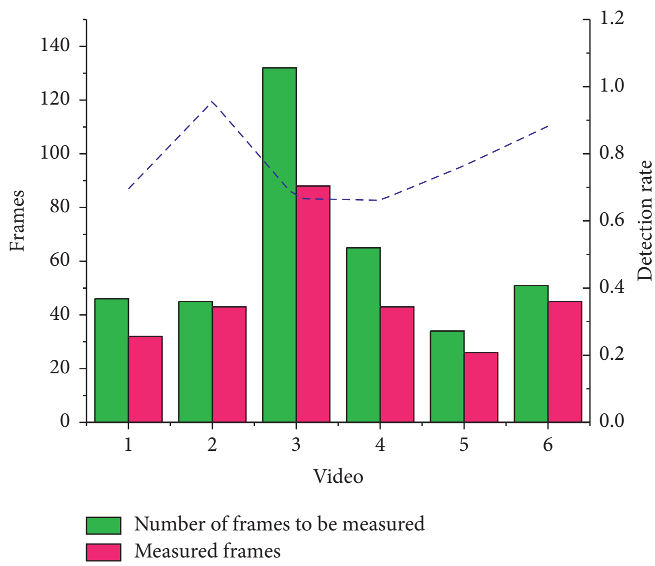

Figure 10: Comparison between the number of frames to be measured and the number of frames actually measured in the video.

robustness. Through comparison, it can be concluded that the motion descriptor in this paper is much better than other motion descriptors in robustness.

Six videos are used for the human posture evaluation module to count the number of frames of posture that should be detected in each video, which is called “frames to be measured.” Counting the number of frames of attitude actually detected in each video is called “measured frames.” The data comparison is shown in Table 4 and the effect comparison is shown in Figure 10.

5. Conclusion

In badminton competitions, athletes’ attitude perception information can become an important semantic clue to understand the competition process, discover technical details, and extract highlights. Therefore, this paper studies badminton athletes’ attitude perception based on moving edge computing. Taking the badminton game video as the research object, the badminton player’s swing action in the time-series image is tracked and recognized. The segmented three-dimensional pose estimation method is adopted to realize the three-dimensional perception of the badminton player’s pose. The action segmentation algorithm is used to determine the starting point and endpoint of each action, and the counting function of various actions is realized. A motion descriptor based on edge calculation is proposed, and the audio keyword strategy is used to find the player’s swing image. Finally, a group of bone point coordinates of badminton players in the camera coordinate system in a single frame image are used as input. Compared with the standard posture library of badminton players from the same perspective, the matching standard posture and cumulative error are calculated. In the future, we can use the current popular big data and cloud computing-related technologies to build a cloud platform for big data analysis, conduct data mining and data analysis on a large number of players’ competition and training data, and analyze the technical advantages and weaknesses of various athletes, so as to improve the technical level of athletes faster.

A remote sensing image semantic segmentation algorithm based on improved ENet network is proposed to improve the accuracy of segmentation. First, dilated convolution and decomposition convolution are introduced in the coding stage. They are used in conjunction with ordinary convolution to increase the receptive field of the model. Each convolution output contains a larger range of image information. Second, in the decoding stage, the image information of different scales is obtained through the upsampling operation and then through the compression, excitation, and reweighting operations of the Squeeze and Excitation (SE) module. The weight of each feature channel is recalibrated to improve the accuracy of the network. Finally, the Softmax activation function and the Argmax function are used to obtain the final segmentation result. Experiments show that our algorithm can significantly improve the accuracy of remote sensing image semantic segmentation.

1. Introduction

Image segmentation technology divides the image into different types of uniform areas according to the internal characteristics of the image. It is required that the dividing edge between regions must be accurately delineated; and the internal features of the segmented objects have consistency or similarity. Each area belongs to the same category, and different areas belong to different categories [1]. Its purpose is not only to simplify the information of the image but also to make the image easier to understand and analyze [2–4]. Remote sensing image segmentation technology aims to classify remote sensing images at the pixel level based on actual semantic information. It is divided into a series of areas with landmarks such as roads, farmland, villages, and industrial areas [5]. In recent years, with the advancement of high-resolution earth observation technology, image segmentation has been carried out through data obtained from remote sensing satellites. It is the processing basis for the application research of urban planning, disaster monitoring, target recognition, and so forth [6, 7]. However, the rapid increase in the amount of remote sensing data also brings about many challenges to the segmentation of optical remote sensing images. For example, an increase in spatial resolution brings about higher complexity of ground objects (more shadows and backgrounds). The phenomena of the same substance with different spectrum and foreign substance with the same spectrum are brought about by the drastic change of spectral information. There are huge amounts of data to be processed and features with variable scales to be extracted [8–10].

Deep convolutional neural networks have become the mainstream method to solve image semantic segmentation. The best fitting model is obtained by training the network with a large amount of ground truth (GT) [11]. Existing methods build complex networks by stacking a large number of convolutional layers. Although the recognition accuracy is improved, the amount of calculation is too large [12, 13]. The SE module can increase the influence of useful features in the network. The proportion of useless features is weakened to improve network performance. Through the combination with the ENet network, the accuracy of the remote sensing image semantic segmentation network can be further improved. Therefore, in order to improve the accuracy and speed at the same time, this paper has made improvements based on the ENet network. The specific research content is as follows:

(1) In the encoder, dilated convolution, decomposition convolution, and ordinary convolution are used in an interleaved manner, ensuring the size of the feature map while increasing the receptive field. This makes each convolution output more image information.

(2) In the decoder, the weight of the characteristic channel is adjusted through the SE module. The accuracy of the remote sensing image semantic segmentation network is improved.

(3) The original image size is restored by linear interpolation. Softmax activation function and Argmax function are used to get the final semantic segmentation result of remote sensing image.

2. Related Works

With the development of deep learning, researchers have found that deep neural networks can extract deep features useful for image segmentation [14–16]. At present, the common technical methods of image semantic segmentation can be summarized into two categories. The first category is the traditional image semantic segmentation method. Image segmentation is mainly performed by extracting artificial features as visual information. Some examples are image semantic segmentation method based on threshold, image semantic segmentation method based on edge detection, image semantic segmentation method based on region, image semantic segmentation method based on graph theory, and so forth [17–19]. The features extracted by traditional methods are rough, and the segmentation results lack semantic information. The complexity of the algorithm is low, and the performance of the algorithm is poor in complex scenarios. The second type of method is the image semantic segmentation algorithm based on deep convolutional neural network [20]. In the absence of human operations, the image features are extracted by training a convolutional neural network on the target dataset. Convolutional neural networks (CNN) consist of multiple convolutional layers to form a deep network model. The network obtains the final feature representation through layer-by-layer abstraction of the original input data, so as to realize the deep feature extraction of the original data. At present, most of the segmentation methods based on deep features are extended and developed on the basis of CNN. CNN trains the neural network classifier through layer-by-layer feature learning of optical remote sensing images. Classification is performed at the image pixel level to achieve image segmentation. It is generally composed of convolutional layer, pooling layer, and fully connected layer. Through the combination of these multilayer structures, image features are automatically learned and mapped to a new feature space for representation. As a typical data-driven network, CNN needs a lot of training data to get a good segmentation model. Then the model is used to segment the test image.

Reference [21] proposed an attentional SegNet network semantic segmentation algorithm combining SegNet and attention mechanism. The network can segment vegetation, buildings, water bodies, and roads in remote sensing images. Reference [22] proposed a semisupervised semantic segmentation method for high-resolution remote sensing images based on generative adversarial networks. It only needs a small number of labeled samples to obtain a better segmentation effect. Reference [23] proposed a semantic segmentation method that combines dense connections and the idea of a fully convolutional network (DFCN). In order to automatically provide fine-grained semantic segmentation maps, multiscale filters are used to improve DFCN, which increases the diversity of extracted information. Reference [24] adopts the DeepLabV3 architecture with high computational efficiency, adding spatial pyramid pooling and fully connected fusion path layer. Without reducing the resolution of the feature map, the receptive field of feature points is expanded. The improved algorithm enhances the segmentation effect of high-resolution remote sensing images. Reference [25] used the full convolutional network (FCN) semantic segmentation model to achieve pixel-level image semantic segmentation. It replaces the fully connected layer used for classification mapping in the CNN structure with a convolutional layer. Through the deconvolution operation, the obtained feature heat map is upsampled to the original input image size. At the same time, the intermediate pooling layer information is combined to generate the image prediction segmentation map. Reference [26] combined the spectral recognition index of blue-board houses and bare soil. The index of the remote sensing image is blurred to improve the accuracy and recall rate of segmentation. Reference [27] used Conditional Random Field (CRF), which can obtain global context information, as an optimization method, and it is also a common improvement method. First FCN is used to achieve coarse segmentation, and then CRF is used to refine the segmentation results based on the target's multiscale information. Reference [28] proposed a deep convolutional encoder-decoder structure SegNet to identify and segment objects in cities such as streets and vehicles. The idea of block-by-block upsampling is used to restore the image to the original input size. The memory space is saved by retaining only the pooling index value of the encoder structure, and the detailed information of the image is retained, thereby effectively improving the segmentation accuracy. In [29], using the spectral and spatial feature information of remote sensing images, SegNet is used to extract the building coverage areas of rural areas in remote sensing images. The above methods can accurately extract network features of remote sensing images. However, due to the influence of network depth, the accuracy of feature extraction is not high. In addition, the remote sensing image network features obtained by deep learning are not smooth, and further improvement is needed. This paper proposes a remote sensing image semantic segmentation algorithm based on SE module and ENet model. In the encoding stage, different convolution methods are introduced to increase the receptive field of the model. Each convolution output contains a larger range of image information. In the decoding stage, the compression, excitation, and reweighting operations of the SE module are performed. The weight of each feature channel is recalibrated, and the network accuracy is improved.

3. Remote Sensing Image Semantic Segmentation Algorithm Based on Improved ENet Network

ENet network is a lightweight image semantic segmentation network, which can achieve target pixel-level semantic segmentation. This method has the characteristics of few parameters and fast calculation speed. It meets the real-time and accuracy requirements of remote sensing image segmentation [30]. Based on this, this paper proposes a remote sensing image semantic segmentation algorithm based on improved ENet network.

3.1. ENet Network Structure. The ENet network changes the previous encoder-decoder symmetry structure. The convolution operation is reduced in the decoder, which greatly speeds up the processing speed. The ENet network has an initialization operation for the input image, as shown in Figure 1. Its main purpose is to generate feature maps and to fuse the feature maps generated by pooling and convolution operations. The convolution operation has a total of 13 3×3 filters with a sliding step of 2, and a total of 13 feature maps are obtained. Max Pooling is a noncovered 2×2 sliding window, and finally feature fusion is performed.

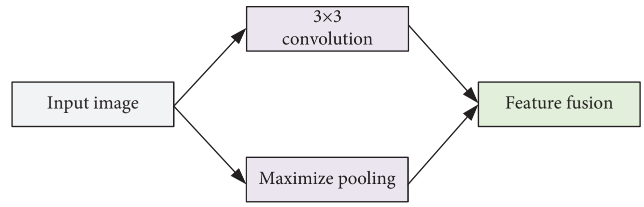

Figure 1: Initialization operation.

In addition, a Bottleneck convolution structure is also used in the ENet network. It is mainly used in the encoder-decoder structure, and the specific structure is shown in Figure 2. Each Bottleneck convolution module contains 3 convolutional layers. From top to bottom in Figure 2 are a 1×1 projection map for reducing dimensionality, a main convolutional layer, and a 1×1 ascending dimension. Normalization and PReLU activation are performed between the convolution layers. The Bottleneck module is not set in stone and will be changed according to specific operations. If it is a downsampled Bottleneck module, the 1×1 projection mapping is replaced by the Max Pooling layer with a kernel size of 2×2 and a step size of 2, and it is filled with 0 to match the size of the feature map. Conv is a 3×3 conventional convolution, expansion convolution, or full convolution, and sometimes 1×5 and 5×1 asymmetric convolutions are used instead. Regularization is used to solve the problem of model overfitting.

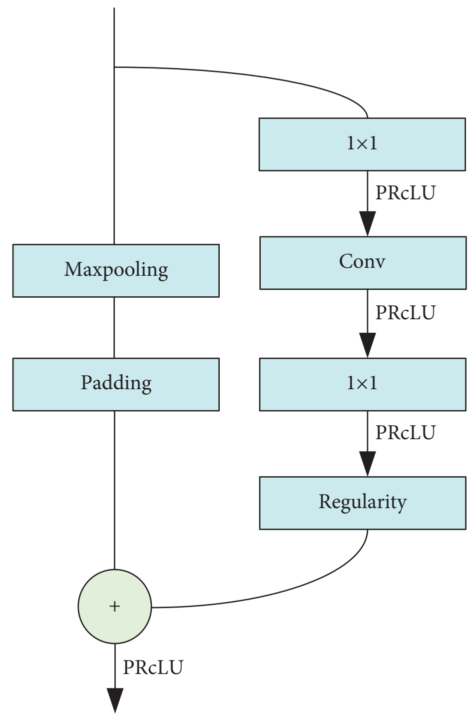

Figure 2: Bottleneck convolution structure.

The overall architecture of the ENet network is shown in Table 1. Between the initialization and the final full convolution, there are also 5 parts. In the first part, there is a downsampled Bottleneck module, followed by four ordinary convolutional Bottleneck modules. In the second part, the first is the Maximum Pooling Bottleneck module, followed by eight different Bottleneck modules in turn: ordinary Bottleneck module, an expanded Bottleneck module with a main convolution expansion rate of 2, an asymmetric Bottleneck module, a Bottleneck module with a main convolution expansion rate of 4, and four Bottleneck modules that are repeated in turn except for the maximum pooling operation. The expansion rate is doubled sequentially; that is, the expansion rate is 2, 4, 8, and 16 in sequence. In the third part, all operations in the second part except the maximum pooling Bottleneck operation are repeated. In the fourth part, there is an upsampled Bottleneck, followed by 2 regular Bottlenecks. The previous operation has extracted enough feature information. Here we need to restore the image resolution to its original size and then output it. Therefore, the fifth part is an upsampled Bottleneck followed by a regular Bottleneck module. The fourth and fifth parts did not use the expanded convolution module. This is because the coding modules of the first three parts have already segmented the image completely. Therefore, there is no need to expand the field of view to extract feature information. The main function of the decoding structure is to restore the resolution of the image. At the same time, the efficiency of network model operation is improved.

3.2. SE Module. The core of the SE module is Squeeze and Excitation. After the convolution operation has obtained features with multiple channels, the SE module can be used

Table 1: Framework of ENet network.

Name	Type	Output size
Initial		$16\times256\times256$
Bottleneck	Downsampling	$64\times128\times128$
$4\times$ Bottleneck 1.x		$64\times128\times128$

to recalibrate the weight of each feature channel. The SE module is divided into 3 steps, namely, Squeeze, Excitation, and Reweight. The schematic diagram is shown in Figure 3.

The Squeeze operation uses Global Average Pooling to compress each characteristic channel into a real number. This expands the receptive field to the global scope. The real number is obtained by the following formula:

$$z_k = \frac{1}{W\times S}\sum_{i=1}^{W}\sum_{j=1}^{S}u_k(i,j), \quad k = 1,2,\ldots,N, \tag{1}$$

where u is the feature map obtained after convolution, N is the number of channels of u, and $W\times S$ is the spatial dimension of u.

Next, the Excitation operation captures the compressed real number sequence information. Two fully connected (FC) layers are used to increase the nonlinearity of the module. First, the dimension is reduced through the first full connection layer and then activated through ReLU and then through the second fully connected layer to upgrade, and, finally, through the sigmoid activation function. The whole process is as follows:

$$s = \sigma\left[W_2\delta\left(W_1 z\right)\right], \tag{2}$$

where σ is the sigmoid function, δ is the nonlinear activation function ReLU, and W_1 and W_2 are the parameters of the two FC layers, respectively.

In reweighting, the channel importance coefficient is obtained by multiplying the original feature channel by channel by the excitation operation. The recalibrated features are obtained.

$$\tilde{x}_k = s_k\cdot u_k \quad k = 1,2,\ldots,N. \tag{3}$$

3.3. ENet Network Architecture Integrated with SE Module. The remote sensing image segmentation and extraction process includes three stages: data preprocessing stage, training stage, and testing stage. In the preprocessing stage of remote sensing data, LabelMe is used to manually label and separate remote sensing image features. Training data and test data are generated by cutting the research area. The training data includes the training set and the validation set. K-fold cross-validation is used to realize the automatic division of the training set and the validation set. In the training phase, the preprocessed training samples are input to the improved ENet network with SE structure. The network model architecture is shown in Figure 4. Small batch gradient descent algorithm is used for iterative optimization. When the loss no longer decreases, the iteration task ends. In the test stage, the trained optimal model is applied to the test image for remote sensing image segmentation and extraction.

Figure 4 shows the improved ENet model structure with SE structure proposed in this paper. The model uses an encoder-decoder structure; and the encoder uses conventional convolution and a residual structure with dilated convolution to extract high-level semantic features. After that each layer of convolution is followed by BN and ReLU activation functions. In the decoding stage, image information of different scales is obtained through upsampling operation. Then the weight of each feature channel is recalibrated through the SE module to improve the accuracy of the network. Then the feature map is restored to the original image size through linear interpolation. Finally, the Softmax activation function and the Argmax function are used to obtain the final prediction result, so as to realize the end-to-end remote sensing image segmentation task.

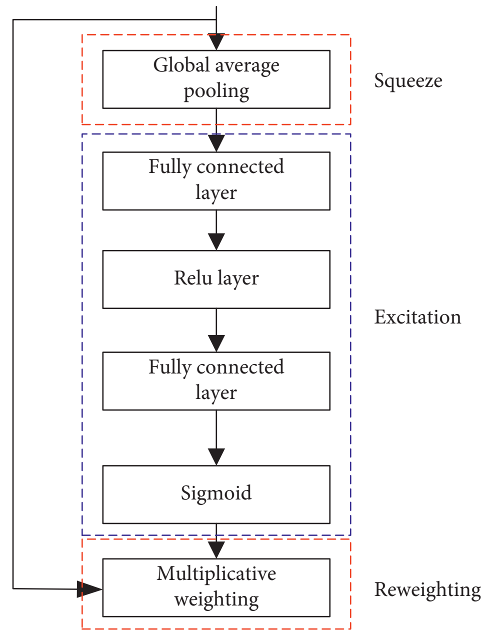

Figure 3: Schematic diagram of SE module.

4. Experiment

4.1. Experimental Environment and Network Parameters. The computer used in this paper is configured with 16 G memory, i7-8700K CPU, and GTX 1080ti graphics card. The experiment was carried out on TensorFlow. TensorFlow can run on one or more CPU/GPU.

When training the network, in order to enhance the generalization ability of the network, the input image undergoes local response normalization before the first layer of convolution; $\alpha = 0.0001$ and $\beta = 0.75$. The learning rate is set to 0.001 and iterated until the loss function converges. In the training process, the training dataset is randomly shuffled, and then every 5 images are treated as a batch. The objective function of the network uses the cross-entropy loss function; and L2 regularization is added to the last layer of the network to prevent overfitting.

4.2. Evaluation Index. *F*1 score is a measure of classification problems. It is the harmonic mean of precision and recall. The formula is as follows:

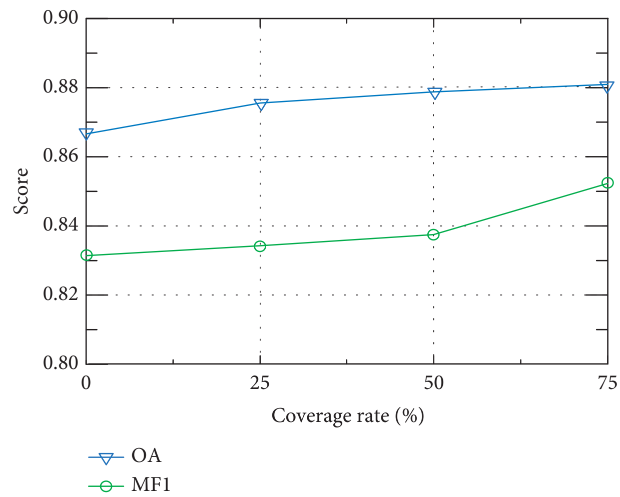

Figure 5: OA and MF1 under different coverage rate.

$$F1 = \frac{2\text{precision} \times \text{recall}}{\text{precision} + \text{recall}},$$

$$\text{precision} = \frac{\text{tp}}{\text{tp} + \text{fp}}, \tag{4}$$

$$\text{recall} = \frac{\text{tp}}{\text{tp} + \text{fn}},$$

where tp is true positive, tn is true negative, fp is false positive, and fn is false negative.

MF1 score (mean $F1$ score) is the average of $F1$ scores, used to evaluate the global standard:

$$\text{MF1} = \frac{\sum_1^n F1_n}{n}, \tag{5}$$

where n is the number of feature types.

Overall accuracy (OA) is the ratio between the correct prediction of the model on all test sets and the total number. It is used to evaluate the global standard:

$$\text{OA} = \frac{\text{tp} + \text{tn}}{\text{tp} + \text{fp} + \text{tn} + \text{fn}}. \tag{6}$$

4.3. Vaihingen Dataset. The Vaihingen dataset was taken in Vaihingen, Germany. The dataset contains 33 remote sensing images of different sizes. Each image is extracted from a larger top-level orthophoto image. It contains 3 channels of IRRG (Infrared, Red, and Green) images, DSM (Digital Surface Model) images, and NDSM (Normalized Digital Surface Model) images. The average size of the images is 2494×2064. The experiment only used IRRG images, not DSM images or NDSM images.

In order to study the effect of the time coverage of the dicing and the crop size on the accuracy of the segmentation, in this paper, experiments with different dicing strategies are carried out on the Vaihingen dataset. Firstly, the crop size is fixed to 512×512. Experiments were performed according to the interblock coverage rates of 0%, 25%, 50%, and 75% (step sizes: 512, 384, 256, and 128, respectively). The experimental results are shown in Figure 5. It can be seen that OA and MF1 score the highest when the coverage rate is 75%.

Table 2 shows the comparison between the proposed algorithm and Semi-GAN [22], DFCNN [23], and DeepLabV3+ [24] on the Vaihingen dataset. Judging from the final score, the algorithm proposed in this article is 2.0% higher than the DNCC algorithm on MF1 and 2.3% higher on OA. From the perspective of different classifications, according to the $F1$ scoring standard, the algorithm in this paper has achieved the first place in the classification of roads, buildings, vegetation, trees, and vehicles. Figure 6 shows the qualitative comparison between this algorithm and the Semi-GAN, DFCNN, and DeepLabV3+ on the Vaihingen dataset. From the challenging high-density car scene in the second row, we can see that the algorithm in this paper divides each car very finely. Other networks even divide the gray cars in the shadows into buildings. From the scenes with more trees and vegetation in the first and third rows, it can be seen that the classification error of the algorithm in this paper is less. Other algorithms often confuse similar features when classifying.

4.4. Potsdam Dataset. The Potsdam dataset was taken in Potsdam, Germany, and it contains IRRG images, IRGB images, DSM images, and NDSM images. The image size is 6000×6000, and the total number of images is 38, of which 14 are used as the test set. In this experiment, 17 images are used as the training set, 5 images are used as the verification set, and 14 images are used as the test set. In the experiment, only IRRG images were used, and two incorrectly labeled images in the training set were deleted.

Table 3 shows the comparison between the proposed algorithm and the Semi-GAN, DFCNN, and DeepLabV3+ on the Potsdam dataset. From the final score, the algorithm proposed in this paper is 1.5% higher than the second DFCNN algorithm on MF1 and 1.1% on OA. From the perspective of different categories, according to the $F1$ scoring standard, the algorithm proposed in this article has

Table 2: Comparison of $F1$, OA, and MF1 in different algorithms of Vaihingen dataset.

Method	F1 (%)					OA (%)	MF1 (%)
	Road	Architecture	Vegetation	Tree	Vehicle		
Semi-GAN	87.8	90.1	75.9	86.5	74.2	84.5	82.9
DFCNN	89.1	90.5	75.2	85.6	75.8	86.1	83.2

Method	F1 (%)					OA (%)	MF1 (%)
	Road	Architecture	Vegetation	Tree	Vehicle		
Semi-GAN	86.7	90.3	76.1	82.5	75.8	83.5	82.3
DFCNN	87.5	90.8	76.5	84.6	76.1	86.2	83.1
DeepLabV3+	84.6	87.4	75.7	83.9	65.5	91.3	79.4
SE-ENet	88.8	91.4	78.4	84.9	79.7	87.3	84.6

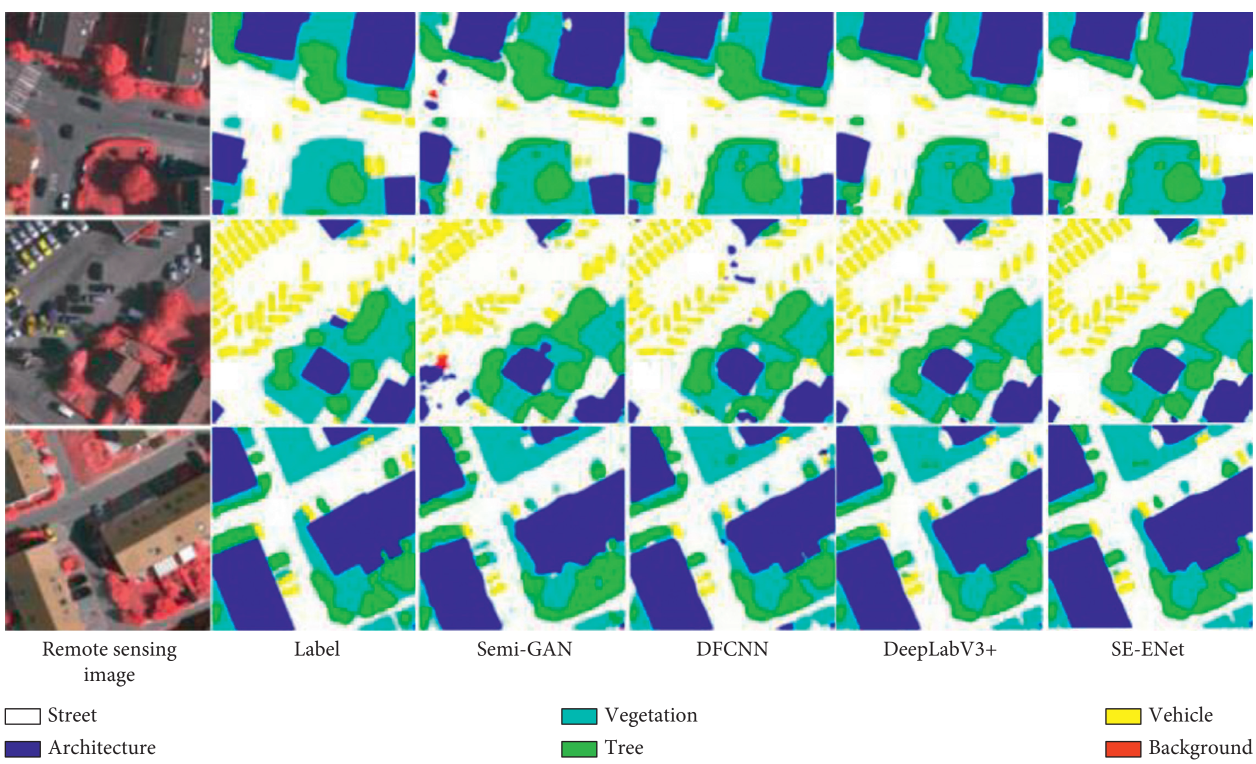

Figure 6: Comparison of different algorithms on Vaihingen dataset.

achieved the first place in all categories. Figure 7 shows the qualitative comparison between the proposed algorithm and other general networks on the Potsdam dataset. From the scene where there are many cars in the second line and a single tree, it can be seen that the division of trees and cars is fine. However, other networks have serious misclassification. It can be seen from the third row that the forest area segmentation is more accurate, and there is less confusion between vegetation and trees. Other networks often misclassify similar features.

4.5. Massachusetts Buildings Dataset. In order to verify the generality of the model, experiments are carried out on the Massachusetts building dataset. The Massachusetts buildings dataset is a large dataset used for building segmentation. The dataset consists of 151 groups of aerial images and corresponding single-channel label images. The size of the images in the data set is 1500 pixels × 1500 pixels. Among them, there are 137 training images, 10 test images, and 4 verification images. The annotated image only contains buildings. Random cropping and data enhancement are used to

DFCNN	88.3
DeepLabV3+	88.5
SE-ENet	89.7

generate experimental images with a size of 256 pixels × 256 pixels. The red pixels represent the building area, and the black pixels are the background. The details of the building segmentation experiment are similar to the remote sensing satellite image segmentation experiment. During the training process of segmentation experiment, the number of training images in batch size is 4. The number of training epochs is 10 rounds, and 10,000 batches are trained in each round. There are 3000 test images with a size of 256 pixels × 256 pixels.

The experiment chooses Semi-GAN, DFCNN, and DeepLabV3+ for comparison. Each network is trained 10 times, and the best model is selected for testing. The segmentation result of the network is shown in Figure 8. It can be found from Figure 8 that there is little difference between the networks for the segmentation of small buildings (villas). For the recognition of large buildings (factories, shopping malls), the segmentation results of this algorithm are more complete and refined. In this paper, a segmentation experiment is carried out on 3000 experimental datasets of 256 pixels × 256 pixels. The experimental results are shown in Table 4. It can be seen from Table 4 that SE-ENet achieved an $F1$ value of 89.7%, which is the highest among the comparison algorithms.

5. Conclusion

Through experiments on the TensorFlow platform, this paper proves that the ENet network integrated with the SE module has higher accuracy. It can be better applied to remote sensing image segmentation. Compared with other semantic segmentation algorithms, the image features generated by the proposed method are more complete. Through the introduction of dilated convolution and decomposition convolution and the cross-use of ordinary convolution, the receptive field of the model is increased. Each convolution output contains a larger range of image information. The SE module recalibrates the weight of each characteristic channel to improve the accuracy of the network. Experimental results prove that the proposed algorithm has higher segmentation accuracy. In the following research, we will focus on the segmentation of small and medium targets in remote sensing images to further improve the accuracy and segmentation speed of the model.
