Online reviews of e-commerce, such as consumer-initiated comments on the quality of goods and services, etc., play a role in the purchasing decisions of potential consumers and directly influence the user stickiness of e-commerce platforms. The process of mining these reviews for positive and negative attitudes in order to identify people's propensity to buy a product is known as sentiment analysis [2] (SA). The goal of sentiment analysis is to extract all the points of view from a document that contains information about the points of view, an analysis method that uses natural language processing and text mining techniques, a method that takes a large amount of data and analyses it to get an understanding

of something. In the early days, sentiment analysis was solved by constructing classifiers methods. Leeuw et al. [3] first proposed to solve the problem of sentiment classification using machine learning algorithms including parsimonious Bayes (NB), they used n-grams models and lexical properties to extract features of film reviews [4]. The main contribution of the fine-grained sentiment analysis method is to extract the corresponding features by syntactic analysis and to compare the experiments with the TF-IDF benchmark model, and their proposed model improves the accuracy (precision), recall (recall), and F1-score in positive or negative evaluations. Wei et al. [4, 5] extracted the features of Chinese hotel reviews by word embedding and put them into classifiers plain Bayesian (NB), support vector machine (SVM), and CNN for comparison, where SVM performed the best in classification. The word embedding approach can extract key information and hierarchical information of words from the comment text, but it cannot extract the information of emotions expressed in the words, so fusing the two features can express the information in the comment more comprehensively.

Now many scholars are very enthusiastic about applying deep learning models to sentiment analysis, applying ever-improving classical deep learning models to this domain, and even proposing new deep learning models in order to solve problems in this domain. TextCNN models were proposed earlier by Mosleh [6], using CNN algorithm to deal with the problem of sentence classification, and obtained better results than previous studies in four out of seven tasks. Liu et al. [7] used Glove to extract features and put them into a very deep CNN model for Twitter sentiment classification experiments, and the results showed that their model had higher accuracy and F1 values than the baseline model. In addition to CNNs, the long short term memory (LSTM) algorithm in deep learning, which is believed to be better at learning contextual information from text, has also been applied to the problem of sentiment classification, and Mansaray et al. [8] used LSTMs to replace the pooling layer in CNNs to perform binary and quintuple classification experiments with higher accuracy than the previously proposed models. In addition, many scholars have combined multiple features in text [9] to achieve better classification results. Nguyen et al. [10] fused word embedding features, sentiment information features, and linguistic knowledge features and overcame the disadvantages of word embedding based on relevant strategies, and their model has advantages over other classical methods. The feature fusion method used in this paper is implemented using the Syuzhet R language package. This is done by extracting the sentiment time series of a literary work to obtain the sentiment score of each sentence in the literary work and then using channel fusion and attention mechanisms to quantitatively analyze the sentiment of a variety of foreign literary works.

2. Model Principles

Since the word embedding model cannot contain the sentiment information of words well, this paper proposes the PWCNN model and PW2CNN model to apply the

combination of lexical features to make the information contained in the features richer. While a single CNN model cannot capture the temporal information of a sentence well, adds an attention mechanism, and proposes a parallel classification algorithm PW2CNN and BiLSTMatt model.

2.1. Word2vec + CNN Model. The classical model of TextCNN was [11] proposed by Phan, where each word is a one dimensional vector and a sentence forms a matrix. Convolutional operations are performed by different convolutional kernels, then dimensionality reduction is performed by pooling operations, and finally, binary classification is performed using a sigmoid function.

Earlier, the bag of words (BOW) model represented a vector of word frequencies for each sentence by making a bag of all the words in the document and constructing a corresponding dictionary so that the resulting vector corresponds to the dictionary and represents the frequency of the words. In longer sentence sets, this approach results in a very sparse matrix and the loss of information about the order of words. The word embedding model word2vec takes better account of word position relations [12–14] and solves the problem of oversparsity when vectorizing words with one-hot encoding.

The word embedding model is proposed to better learn word representations quickly and accurately on a large dataset, using the idea of embedding high-dimensional word vectors into a low-dimensional space so that words with adjacent meanings have closer spatial distances. By improving on the BOW model, the continuous bag-of-words model (CBOW) produces a matrix with a dimension of 256×128 , which is initially set in the article, with each matrix text represented by 128 dimensions so that the concatenation of words can form a feature vector matrix, which is filled with zeros in the case of a sentence with no more than 256 words.

The word2vec + CNN model is a modification of the classical TextCNN model, where the CNN structure is convolved on the feature matrix of each sentence by a number of different 4×4 convolution kernels. The input text matrix $X \in R^{N \times N}$ and filter $W \in R^{N \times V}$, and the two-dimensional convolution is given as follows:

$$c_{ij} = \sum_U^{u=0} \sum_V^{v=0} w_{uv} x_{i-u+1, j-v+1}. \quad (1)$$

Equation (1) represents the process of multiplying the elements of the text matrix $Xx_{i,j}$ and the elements w_{uv} of the convolution kernel matrix W to obtain the features c_{ij} using a filter W with a window size of $U \times Vx_{i,j}$ to, $x_{i-u+1, j-v+1}$, which results in multiple feature matrices.

The first layer in Figure 1 is the input layer, the last layer is the output layer, and the layers in between represent the structure [15] of the CNN. This model has two convolutional layers and one pooling layer. The first has 32 convolutional kernels, all of which are 4×4 matrices, and the activation function is a ReLu function. The second convolutional layer has 16 convolutional kernels, all of which are 4×4 in size,

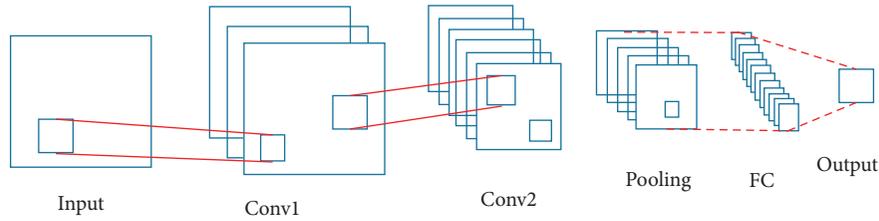

FIGURE 1: CNN model in 1word2vec + CNN model.

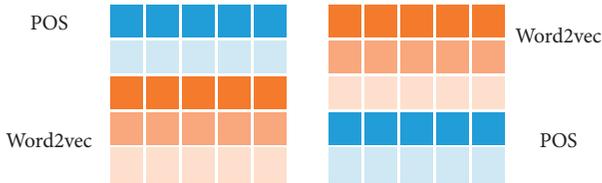

FIGURE 2: Word vector and lexical vector splicing diagram for word embedding model training.

and also uses the ReLu function. The reason for using the ReLu function is that it is less computationally intensive than the other activation functions and provides better protection against overfitting. The third layer is the maximum pooling layer, with a pooling kernel size of 2×2 .

2.2. PWCNN Model. In this experiment, the word2vec + CNN benchmark model is a single-channel CNN model with word2vec as input, and has the same structure as the CNN model in the two-channel PWCNN model, except for the input of the features [16, 17]. The two features are the word embedding word2vec model matrix ($256 \times 128 \times 1$ dimension) and the part-of-speech (POS) feature input matrix ($220 \times 56 \times 1$ dimension).

The lexical annotation determines the lexical annotation of each word in the sentence and uses lexical features to disambiguate on the basis of participles. These lexical words are better able to express the subjective feelings of the reviewer, so the model focuses more on adverbs, verbs, and adjectives. The more important lexical features that the model focuses on are adjectives, adverbs, and verbs, as these lexical features are better at conveying the subjective feelings of the commenter. In addition, punctuation is also important in a sentence and thus is not considered for removal of punctuation when performing subordination and giving the lexicality of the corresponding subword. The PWCNN model splices the word vectors trained by the word embedding word2vec model with the lexical vectors, including two splicing methods, as shown in Figure 2 and Equation (2) [18].

$$X = [X_W, X_P], \quad (2)$$

where X_W denotes the word embedding word2vec model matrix; X_P denotes the lexical annotation feature input matrix.

In addition, the POS features and word2vec features of each sentence are stitched together one by one so that the whole feature matrix is meaningful. The spliced feature

vectors are then trained in the same single-channel CNN model as the word2vec + CNN model, mainly to directly compare [19] the experimental results of the feature fusion single-channel model with the benchmark model. Given the difference in structure between the CNN model and the classical TextCNN model, this “top-down” rather than “left-right” splicing was chosen, but the “left-right” splicing is also worth trying. The stitching is also worth trying. At the same time, it was found that the two splicing methods have little effect on the experimental results and made no difference to the CNN. The word vector of fused features was put into the same structure of convolution as mentioned above for the experiments, and the activation function and parameters were set in the same way. The information in the feature vector is extracted through a two-layer convolutional layer, then further reduced and aggregated through a pooling layer, where full connectivity is performed through a random dropout, and to further prevent overfitting (reducing parameters), a dropout is added after this flatten layer, and finally, classification is performed. The experimental model is shown in Figure 3.

This experiment is compared with the word2vec + CNN model to clearly determine whether POS features can play a role in this classification experiment. The experiments prove that the input matrix with POS features does have better classification results. The next step is to further consider a two-channel CNN model based on this single-channel model and explore whether the same features are affected when they enter the same structural CNN model separately.

2.3. PW2CNN Model. It is well known that the two-channel model differs from the single-channel model in terms of the input method. In the single-channel model, the input is spliced with multiple features to obtain the fused features, while in the two-channel model, it is obtained by inputting different features separately [20, 21], and feature fusion can be achieved by matrix splicing. The two-channel CNN model has a matrix of POS features on one side and a matrix of word2vec features on the other side. The two feature matrices are processed separately by the CNN (two convolutional layers, a pooling layer), and the two processed features are “flattened” in the transition layer (the process of turning multidimensional data into one dimensional) and “left-right.” The purpose of this is also to preserve the information on both sides.

$$C = [C_1, C_2], \quad (3)$$

FIGURE 3: PWCNN model.

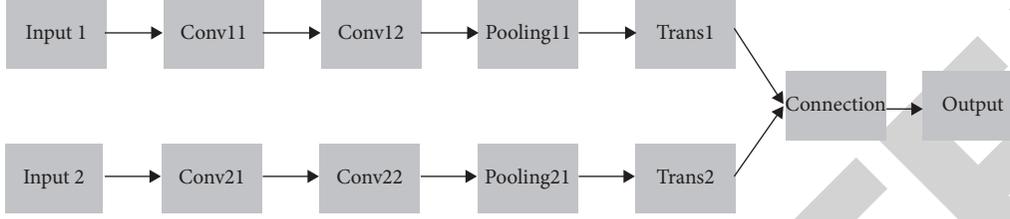

FIGURE 4: PW2CNN model.

where C_1 denotes the convolutional feature matrix with POS features as input; C_2 denotes the matrix convolutional feature matrix with word2vec model as input.

The overall structure of the model is shown in Figure 4.

In order to ensure comparability between the models, the structure of the CNNs for the dual and single channels was basically kept the same [22], and the comparison of the experimental results revealed that the improvement in the correctness and F1 values on their validation sets was not significant. However, when the CNN on the dual channel side of the model was replaced with a BiLSTM, the results changed significantly, indicating that it is not only the selection of features (the selection of information) but also the selection of the classifier that affects the overall results. When one side of the input is a POS feature, the CNN is able to extract the local features very well. When the other side of the input is a word2vec model, a BiLSTM model that takes into account the context is used, as the word embedding features themselves have information about the word itself. In summary, such a classifier has better experimental results and is the reason why this model is proposed in this paper.

2.4. PW2CNN and BiLSTMatt Models. The proposed PW2CNN and BiLSTMatt model uses the word2vec model [23] for word embedding, CNN, and BiLSTM models for classifier, and incorporates an attention mechanism. As the RNN (recurrent neural network) will lose its ability to learn long-term information, i.e., there is a long-term dependency problem, as the gradient will disappear or explode after multiple propagations with increasing input time series. For this reason, LSTM [24], is introduced into the model design. LSTM removes or adds information to the cell states through a gate structure.

A bidirectional long and short-term memory network (BiLSTM) usually consists of two LSTMs connected, including a positive and a negative one. The positive LSTM captures the past information in the sentence and the negative LSTM acquires the future information in the sentence. In this way, the model is able to extract contextual information, and therefore, the prediction results of the bidirectional LSTM will be more accurate. For the problem of sentiment classification of text, the model is very suitable,

as it contains all the forward and backward information in the sentence.

$$\begin{aligned} i_t &= \sigma(W_i[h_{t-1}, x_t] + b_i) & c_t &= f_t \odot c_{t-1} + i_t \odot \tilde{c}_t \\ f_t &= \sigma(W_f[h_{t-1}, x_t] + b_f) & o_t &= \sigma(W_o[h_{t-1}, x_t] + b_o) \\ \tilde{c}_t &= \tanh(W_c[h_{t-1}, x_t] + b_c) & h_t &= o_t \odot \tanh C_t \end{aligned} \quad (4)$$

The LSTM network introduces a new internal state (*internalstate*) $c_t \in R^D$ for information transfer and outputs information to the state $h_t \in R^D$ of the hidden layer b_i , where $f_t \in [0, 1]^D$, $i_t \in [0, 1]^D$, and $O_t \in [0, 1]^D$ are three gates to control the path of information transfer and \odot is the product of vector elements. c_{t-1} is the product of vector elements. $\tilde{c}_t \in R^D$ is the memory unit of the previous moment.

The attention mechanism (AM) [25, 26] is inspired by the human cognitive function of extracting and receiving small portions of important information from a large amount of information and ignoring the rest. Similarly, the essence of the AM is to focus on certain key parts of the input and give them a higher weight. The hidden state of an LSTM model based on the AM at any given moment depends not only on the state of the hidden layer at the current moment and the output at the previous moment but also on the contextual features, which are obtained by a weighted average. This is calculated as follows:

- (a) Calculate the attention distribution.

$$a_i = p(z = i | \mathbf{X}, \mathbf{q}) = \text{softmax}(s(x_i, q)) = \frac{\exp(s(x_i, q))}{\sum_{j=1}^N \exp(s(x_j, q))} \quad (5)$$

- (b) A weighted average of the input information is calculated based on the attention distribution.

$$\text{att}(\mathbf{X}, \mathbf{q}) = \sum_{i=1}^N \alpha_i x_i = E_{z \sim p(z|X, q)}[x]. \quad (6)$$

To calculate the attention distribution is to calculate the probability of selecting the first input vector given the query

TABLE 1: Information on crawled literature data.

vector a, q and the input X . Where: $z \in [1, N]$ is the attention variable. The first $z = ii$ input vector is selected; a_i is the AM; $s(x_i, q)$ is the attention scoring function.

The CNN and BiLSTM were chosen as parallel structures for the model classifier. The CNN model was able to extract a certain class of lexical features (e.g. adjectives, adverbs, nouns) that are more significant for the expression of emotions. The BiLSTM is more suitable for capturing temporal information features [27].

The current state in the bidirectional LSTM should also be related to the contextual features, and the output is influenced by the weighted average of the hidden states of all moments fed into the current state through the attention mechanism. The weights in the attention mechanism are adjusted according to the difference between the output and the real situation. In fact, it can be demonstrated through this

experiment that this parallel model gives the best classification results compared to the benchmark model, which not only makes full use of the different feature information but also takes advantage of the different neural network models [28, 29]. This model gives better classification results than the two-channel CNN model, suggesting that the BiLSTM model with the attention mechanism plays an important role.

3. Experimental Preparation

3.1. Data Sets. The datasets used for the experiment were sentiment data from five literary works: Don Giovanni, Boyhood, On Earth, War and Peace, and Red and Black. Table 1 gives information on the number of people, who received positive reviews before and after the five works, were adapted for film and television. The sentiment of each

film line was extracted using Syuzhet [30], and the sentiment indices of the novel and film lines were compared to correlate the Hurst indices of the film lines with the Rotten Tomatoes and IMDB ratings.

The results of the comparison of the number of literary works and film and television works that received positive reviews are shown in Figure 5.

3.2. Experimental Environment. In order to validate the performance metrics of the model, the comparison environment was set up as follows: Windows 64 operating system, 64 GB of memory, Intel(R) Xeon(R) CPU E5-2650v4 @ 2.20 GHz (2 processors), and the model used the Keras deep learning framework.

3.3. Loss Function. The loss function used in the experiments in this paper is a cross-entropy loss function (binary cross-entropy), with the following equation.

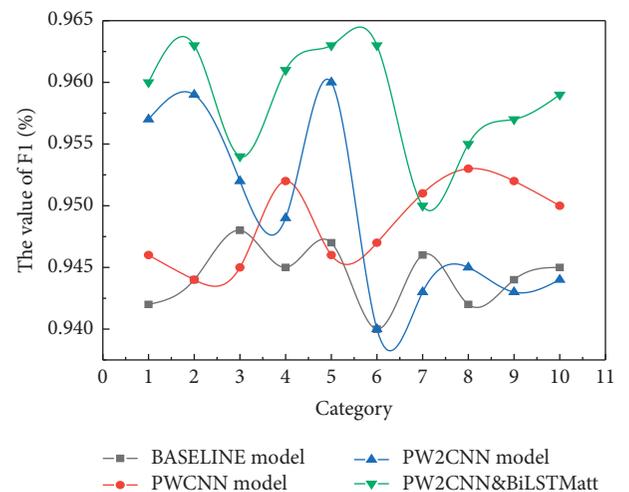

FIGURE 6: Comparison of the different F1 values for the four models.

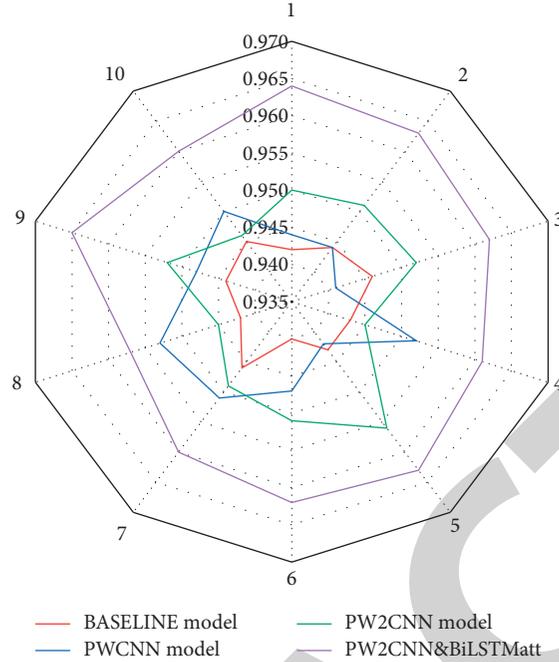

FIGURE 7: Comparison of the different accuracy rates of the four models.

TABLE 5: t-test among four models.

Models	BASELINE	PWCNN	PW2CNN	PW2CNN and BiLSTMatt
PWCNN	0.1339	0.3458	0.3141	0.4123
PW2CNN	0.2128	0.36937	0.2821	0.3896
PW2CNN and BiLSTMatt	0.28009	0.3596	0.2431	0.4012

$$\text{loss} = - \sum_n^{i=1} y_i \lg \hat{y}_i + (1 - y_i) \lg (1 - \hat{y}_i). \quad (7)$$

where: y_i is the true discrete category; \hat{y}_i is the conditional probability distribution of the predicted category labels.

3.4. Experimental Parameters. The hyperparameters on the CNN model in this paper are set as shown in Table 2.

The PW2CNN and BiLSTMatt model puts the long memory model into a parallel structure and adds the attention mechanism, the activation function (AF) of the attention layer in the parallel structure is the softmax function, and the AF of the middle output layer is the ReLU function, and the dropout value of the attention layer is 0.3. For the model with a nonparallel structure, the FC layer and the output layer are also followed by the FC layer and the sigmoid function, respectively, with the dropout value set to 0.5 for the FC layer. The output layer is also followed by the FC layer and the output layer with the same parameters as above, mainly to maintain consistency across multiple models. Four different comparison experiments showed that the best results were obtained with the cross-entropy function as the loss function. In this case, the batch size is set to 64, and the model converges when the epoch is 10, so the epoch is set to 10.

4. Experimental Results and Analysis

4.1. Multimodel Testing. The results of 10 experiments with the four models were compared by the method mentioned previously, and the F1 values and accurate information of the four models are given in Tables 3 and 4. The BASELINE benchmark model is a word2vec + CNN model, the PWCNN is a CNN model with feature fusion, the PW2CNN model is a two-channel CNN model, and the PW2CNN and BiLSTMatt model is a parallel CNN and BiLSTM model (with attention added).

A visual comparison of the F1 values of the four models is shown in Figure 6, and information on the accuracy data of the different experimental models is given in Table 4.

A visual comparison of the accuracy of four of these models is shown in Figure 7.

4.2. Significance Tests between Different Models. The t -test is a method of significance testing that uses a small probability counterfactual method of logical reasoning to determine whether the hypothesis is valid. This test can be used to test the degree of difference between two sample means. The reason for using the t -test here is to test whether there is a difference between the experimental results of the different models. Table 5 shows the t -test values between the four models.

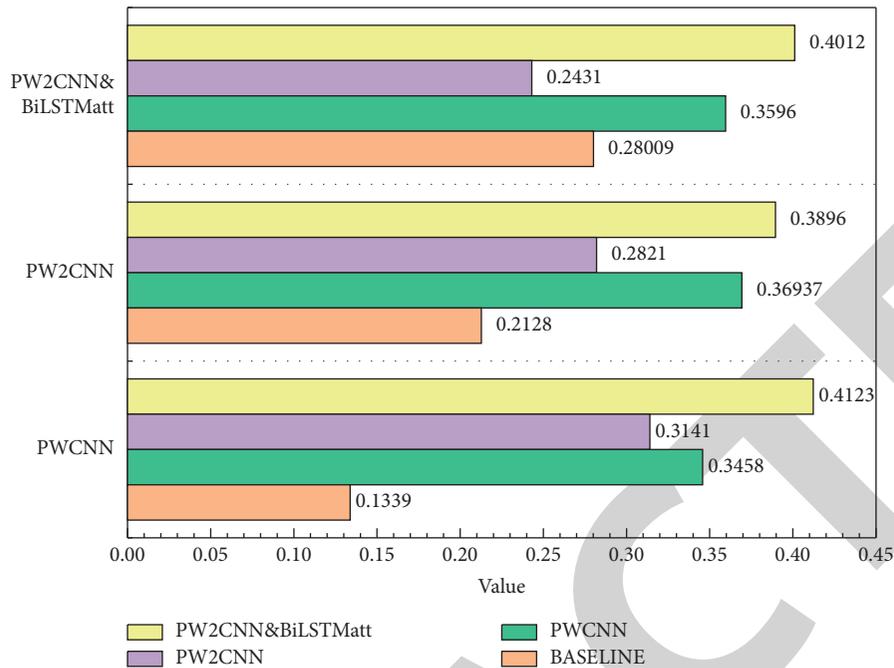

FIGURE 8: Comparison effect of t -test for the four models.

The comparative effect of the t -test for the four models is shown in Figure 8.

At a significance level of 0.001, the p value of the t -test of the PW2CNN&BiLSTMatt model against the BASELINE, PWCNN, and PW2CNN models was less than 0.001. Therefore, there was a difference between the PW2CNN&BiLSTMatt and the BASELINE, PWCNN, and PW2CNN models. Models were all significantly different from each other. In other words, at a significance level of 0.001, the PW2CNN&BiLSTMatt model significantly outperformed the BASELINE, PWCNN, and PW2CNN models. In addition, the p value of the t -test of the PWCNN model against the BASELINE model (0.003 39) was less than 0.05 at a level of 0.05. Therefore, there was a difference between the PWCNN model and the BASELINE. In other words, the PWCNN is significantly better than the BASELINE model at a significance level of 0.05.

5. Conclusion

A PW2CNN and BiLSTMatt model for sentiment evaluation is proposed for mining and analyzing the sentiment of foreign literary works, using both word vectors and POS feature vectors. These two features are two ways of extracting information from textual data, mainly taking into account the characteristics of words themselves and the characteristics of features containing sentiment information. The role of lexical features in the model is verified by comparing the BASELINE model with the PWCNN model. At the same time, two options are proposed for the fusion of these two features, one is the direct splicing of two vectors and the other is the “fusion” by means of a parallel structural neural network model. A comparison is made between a CNN and a bidirectional long and short-term memory network incorporating an attention mechanism, and experimental

results are presented to demonstrate which model is more suitable. The convolutional network is good at capturing local features, while the long and short-term model is more suitable for features containing “temporal” information. Since in the summary of the study of BASELINE and PWCNN models, no comparative experiments with multiple parameters were conducted, but only between models, the study of the effect of multiple parameters on experimental results will be a key direction, in future work.

With the development of information technology, music education in universities is also changing. Traditional music education can not effectively explore the feature of students, resulting in the quality of music education being restricted. The rapid development of Electroencephalogram (EEG) signals has brought a new educational model to music education. Through the extraction of students' psychological features of music by EEG, psychological features can be identified and different educational programs can be formulated according to the results. Multifeature extraction and combination method can improve the accuracy of EEG feature extraction. Using empirical mode decomposition and wavelet packet decomposition of the two kinds of methods to analyze EEG data, respectively, then the average energy, volatility index, sample entropy, and approximate entropy and multiscale features such as permutation entropy and Hurst index, select features in combination, to classify the feature set after the combination, so as to find out the feature of the performance of the optimal combination. The experimental results show that the feature combination of sample entropy and approximate entropy can better represent the main features of EEG psychological characteristic signals after wavelet packet decomposition, and the recognition accuracy is more than 90%.

1. Introduction

In the teaching of traditional music, most of the teachers have followed the same approach as in general subjects, from concept to illustration and back to the concept. This teaching method is dull and inflexible, and students can only passively accept knowledge. If the teacher can not design the teaching plan according to the characteristics of students, music teaching will become the 'stumbling block' of aesthetic education. The quality of music education can be effectively improved if the psychological characteristics of students learning music can be fed back at any time. [1, 2] Musical psychological feature refers to the psychological process including various human psychological factors generated during the interaction between people and music. [3] It includes the mood, preference, interest, and attitude related to music practice. It is a kind of special psychological fuzzy quantity, which includes both the psychological feature component caused by sound directly and the psychological component produced by the subject's thinking about the

content of social life. [4–7] It is a current synthesized from two sources. Musical psychological feature is a kind of realistic psychological features with special concretization and music images. Music psychological feature is a kind of artistic psychological feature, which is contained in music and reflected by music, and is also the artistic expression of realistic psychological features in music. [8] Its form and existence have their own feature. Compared with the real psychological feature, musical psychological feature is not only a means of communication between people, but also the connotation of art for people to appreciate. It is expected to arouse the sympathy of others. Therefore, it is more concentrated and generalized than the natural outpouring of psychological feature, and thus has a stronger susceptibility. [9, 10]

psychological feature recognition aims to establish a harmonious man-machine environment and make the computer have higher and more comprehensive intelligence by giving the computer the ability to recognize, understand and adapt to the psychological feature of college students.

psychological feature recognition is an interdisciplinary research field integrating cognitive science, psychology, computer science, and neuroscience. [11–15] It is a difficult and hot topic in the field of cognitive science. With the enhancement of the computing power of computer, the cost of machine learning algorithms is greatly reduced, which lays a solid foundation for the rapid development of machine learning algorithms. Building an appropriate machine learning algorithm model can effectively improve the accuracy of the psychological feature recognition system. [16, 17] At the same time, the development of noninvasive sensing technology and human-computer interaction technology, it also provides a new idea for the development of psychological feature recognition. psychological feature recognition has a broad application prospect, and it can be potentially applied to the field of education. [18].

The modes of musical psychological feature recognition can be divided into physiological signals and non-physiological signals according to the source of signals. In recent years, with the development of wearable and non-invasive physiological signal acquisition devices, the real-time performance and accuracy of physiological signal acquisition are greatly improved, which promotes the development of physiological signals in the field of music psychological feature recognition. Physiological signals such as EEG signals, eye-tracking, and Electrodermal activities (EDAs) are widely used in psychological feature recognition. [19, 20] The reason why EEG signals play an important role in psychological feature recognition based on physiological signals is that the amygdala located deep in the brain is closely related to feelings and psychological features. Multichannel EEG signals can record the measurement results of different parts of the brain including the amygdala, and this information can closely reflect the psychological featured state. With the rapid development of EEG signal acquisition technology, brain-computer interface technology, and artificial intelligence technology, the study of EEG signals has gotten great attention in many countries. [22–26] The US government launched the Human Brain Initiative in 2013 to explore brain mechanisms, advance neuroscience research and develop new treatments for brain diseases that currently have no cure. In the same year, the European Union and Japan also announced their respective “Brain Project”. The European Union’s Brain Project research focuses on brain-like computing, which uses supercomputers to simulate brain functions; Japan’s Brain program focuses on the medical field, studying brain diseases and developing new treatments. In 2016, China listed “brain science and brain-like research” as a major national scientific and technological innovation and engineering project in its planning outline. For the “China Brain Project”, experts jointly proposed the layout of “one body and two wings”: the “main body” of the research on the neural principles of brain cognition, and the “two wings” of the research on the treatment and diagnosis of major brain diseases and the new technology of brain intelligence. Brain planning has provided impetus for the development of cognitive science and neuroscience. Therefore, psychological feature recognition based on EEG signals has attracted the attention of many scholars. [27–30].

In this paper, we study a kind of effective EEG music psychological characteristic feature extraction algorithm, study how to extract a variety of electrical features and combinations, to seek the feature of the optimal combination, and to improve the accuracy of electrical psychological feature classification, based on EEG signals of music college students psychological feature extraction and recognition technology development to provide technical basis.

2. Brain Electricity

2.1. Acquisition Method of EEG Signal. Dry electrodes are used to collect EEG signals. The electrodes on the device that touches the scalp do not need to be coated or added with conductive materials and can be worn directly on the head to collect EEG signals. The method is easy to operate in the experiment and the equipment is easy to carry, which provides theoretical basis and technical support for the development of portable EEG psychological feature detection therapeutic instruments in the future. However, the cuticle of the scalp has a large impedance, so the extracted EEG signal is not strong.

The other is to obtain EEG signals from a wet electrode, which is attached to the scalp via a conductive paste to reduce the impedance of the cuticle. This collection method can collect more stable and effective EEG signals, but this collection method is not conducive to the application of real life in terms of convenience and comfort.

2.2. EEG Preprocessing. Early EEG research usually involved manual detection and discarding of parts of the signal that contained artifacts, or EEG acquisition experiments designed to avoid artifacts. However, in the actual EEG collection, artifact generation is inevitable. Three methods are commonly used for artifact removal:

- (1) Artifact subtraction. Assuming that the collected EEG signal is a linear combination of EEG signal and artifact signal and that the EEG signal is not correlated with the artifact signal, the artifact can be obtained by measurement. This method was used to remove electro-ophthalmic artifacts in the early stage. It is intuitive and has a clear physical meaning, but may lead to the loss of some useful EEG data.
- (2) Principal component analysis. The EEG signal is decomposed by the orthogonal principle and the artifacts are removed according to the energy proportion of each EEG component. This method is only related to the covariance matrix of the signal, and although it is better than the pseudo-trace subtraction method, there is still high-order residual information between the signal components because it does not involve the high-order statistical feature of the signal.
- (3) Independent Component Analysis (ICA). This blind source separation method has been widely used in EEG for artifact removal and feature extraction. Since this method does not have various noises of

physiological signals, and the sequence of separation signals cannot be determined, this method needs several iterations to obtain a separation matrix, and whether the independent components are artifacts needs manual judgment.

2.3. Feature Extraction Method. EEG feature extraction mainly involves noise reduction, reduction, and correlation removal. In the present research, the commonly used feature extraction methods are divided into time domain frequency domain analysis, space domain analysis, and nonlinear dynamics analysis.

2.3.1. Time Domain Frequency Domain Analysis. Frequency domain analysis of EEG signals mainly focuses on the statistical and geometric feature of EEG signal waveforms. Common analysis methods include probability density, time domain waveforms, autocorrelation, and cross-correlation. The analysis of EEG signals usually focuses on the amplitude, peak, waveform, histogram, mean, and variance of EEG signals. Although the time domain analysis of EEG has the advantage of intuition, it lacks objectivity. At present, the most common time-domain features in research are amplitude feature and amplitude energy feature (Band power, BP), while the most common filtering methods in time domain analysis are: band-pass filter, Laplace filter, full-lead average reference method, Kalman filter and moving average filter. Frequency domain analysis of EEG signals is usually to analyze the correlation and power spectrum of EEG signals. Frequency domain features usually use fast Fourier transform, Adaptive Autoregressive (AAR) model and wavelet transform to extract Power spectral density (PSD), AAR parameters or wavelet frequency band energy. Frequency domain analysis, known as power spectrum estimation, converts EEG signals based on the corresponding relationship between EEG power and frequency, making it easier to observe the distribution and variation of rhythm, as well as the energy distribution of each frequency. However, variance estimation is prone to fluctuation, so it will lead to the loss of higher-order information. Although autoregressive model is easy to estimate parameters, its parameters do not have specific physical meaning, so it cannot be extended in practice. The common time-frequency analysis of EG signal includes short-time Fourier transform, wavelet transform, wavelet packet decomposition, empirical mode decomposition, global empirical mode decomposition and local mean decomposition. What time-frequency analysis has in common is its powerful energy gathering ability. Even if it is impossible to know the relationship between signal changes over time, the corresponding time-frequency relationship can be obtained within a certain range of SNR. This method can easily describe the transient feature of EEG signals, but cannot describe the trend changes of EEG signals.

2.3.2. Airspace Analysis. Spatial domain analysis is to optimize the weighted combination of multilead EEG signals to obtain signal feature with higher signal-to-noise ratio.

Common spatial analysis algorithms include principal component analysis (PCA), independent component analysis (ICA), common space model (COSPIATIAL mode), Fisher's Criterion (FC), spatial adaptation of data and Canonical correlation analysis (CCA), etc.

2.3.3. Nonlinear Dynamics. In recent years, nonlinear dynamic analysis method has been widely used in EEG signal analysis because EEG signal is a collection of nonlinear coupling by a large number of nerve cells. In nonlinear analysis of EEG signals, one method is to analyze EEG signals through mixed pure theory. The common methods include Lorenz scatter diagram, maximum Lyapunov exponent, correlation dimension, and Hurst exponent. The other method is to analyze EEG signals by information theory. Common methods include permutation entropy, singular value decomposition entropy, LZC complexity, approximate entropy, and sample entropy.

3. Music Psychological Feature of EEG

3.1. Empirical Pattern Decomposition Algorithm of EEG. Empirical Mode Decomposition (EMD) algorithm does not need to set a basis function in advance, and it can decompose EEG signals according to the time-scale feature of EEG signals. Compared with Fourier decomposition which requires pre-setting of harmonic basis function and wavelet decomposition which requires pre-setting of wavelet basis function, the empirical mode decomposition algorithm does not need to set the feature of basis function, so its algorithm can be applied to any type of signal decomposition. EMD algorithm is suitable for the analysis of nonlinear and nonstationary signal sequences and has a high signal-to-noise ratio, so it has obvious advantages in processing nonstationary and nonlinear data. Since the EMD decomposition algorithm is based on local feature of EEG signal time scale, the EMD algorithm is adaptive. EMD algorithm can decompose THE EEG signal into several Intrinsic mode functions (IMF), and each IMF component covers local characteristic signals at different time scales of the original EEG signal. EMD can transform all the time domain signals of EEG signals into a linear steady state, and stabilize the nonstationary EEG data, so that more processing methods can be applied to EEG signals.

3.2. Eigenmode Functions. If the original EEG signal is decomposed by EMD, the original EEG signal can be reconstructed. The instantaneous frequency of a function is meaningful only when it is symmetric and its amplitude is 0 on average over local time periods, and when the point at which its amplitude is 0 is the same as the number of points at the minimax. The instantaneous frequency of each point in the eIGen mode function is meaningful, so the eigen mode function after EMD decomposition of EEG signal needs to satisfy 2 points. First of all, in the time period when the signal exists, the number of maximum and minimum points of the eigenmode function can differ at most by one in the local time period. Secondly, at any time point, the average value of

the envelope of the maximum and minimum values of the eigenmode function in the local time is 0.

The first point to be satisfied is similar to the narrowband requirement for stationary Gaussian signals. The second point that needs to be met is that the instantaneous frequency does not vary with the fluctuation of the asymmetric signal over a local time period. The second point can also be explained by the fact that the local mean of the data is zero, but for nonstationary EEG data, calculating the local mean involves local time scales, which are difficult to define. Therefore, the average value of the envelope formed by the local maximum and the envelope formed by the local minimum is zero, so that the waveform of the EEG signal is locally symmetric. IMF represents the intrinsic vibration mode of the EEG data, where each vibration period of IMF defined by zero crossing has only one vibration mode and does not contain other complex odd waves. IMF may be frequency and amplitude modulated or unsteady and not constrained to be a narrowband signal, while a signal modulated only by frequency or amplitude may also be called IMF.

3.3. Empirical Mode Decomposition Implementation Method.

EMD algorithm considers the oscillation in EEG signal as local oscillation. If the evaluation signal $x(t)$ is a variation between two adjacent minimum points at t^- and t^+ , a locally high-frequency component $d(t)$ corresponding to the oscillation is defined, where $t^- \leq t \leq t^+$ where the oscillation is between two minimum values and passes through the maximum. At the same time, it is still necessary to define a local low-frequency component $m(t)$, where $t^- \leq t \leq t^+$, then $x(t) = m(t) + d(t)$. This method can be used to decompose all the oscillating components of the EEG signal. It can also be applied to all the residual components of the local signal. Therefore, the components of the EEG signal can be decomposed by an iterative method, a process called EMD decomposition. EMD decomposition is performed for a given EEG signal, and the decomposition process is shown in Figure 1.

The EMD decomposition process of EEG signals is as follows:

- (1) Find all extreme values of $x(t)$.
- (2) The envelope of extreme points is formed by interpolation method. The minimum point forms the lower envelope, which is expressed as $E_{\min}(t)$. The maximum point forms an upper envelope and is expressed as $E_{\max}(t)$.
- (3) Calculate the mean value of upper and lower envelope $m(t) = (E_{\min}(t) + E_{\max}(t)) / 2$.
- (4) Extract details $d(t) = x(t) - m(t)$.
- (5) Repeat the above steps for residual $d(t)$ until the mean value of $d(t)$ is 0, and the iteration ends.

A screening process is needed during EMD decomposition, and the above EMD decomposition steps are redefined. In this screening process, steps 1–4 of EMD decomposition above are repeated for detail signal $d(t)$ at

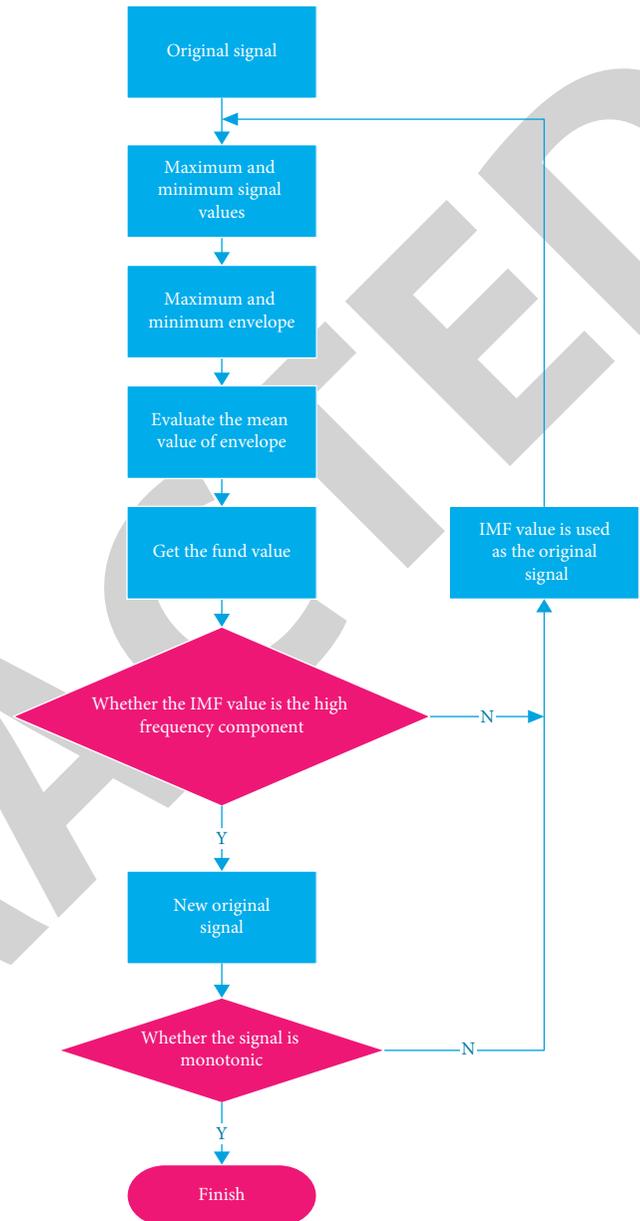

FIGURE 1: Empirical pattern decomposition process.

first, and iteration is not stopped until the mean value of detail signal $d(t)$ is 0 or meets the stop criteria. The detail signal $d(t)$ after iteration stop is called IMF, and the residual signal of detail signal $d(t)$ can be calculated through the fifth step of EMD decomposition above. After the above calculation process, with the generation of residual signals, the number of extreme points gradually decreases. After completing the EMD decomposition of the whole EEG signal, several IMF will be generated.

3.4. Feature Extraction Algorithm. The EEG signal will produce signal components after decomposition, and the EMD decomposition algorithm is used as an example to solve the average energy and fluctuation index of each component. Through the decomposition of the original EEG

signal by the EMD algorithm, the 1-order IMF components can be obtained, but the difference between the frequencies of the IMF components of each order is relatively large, so there is an energy difference between the IMF components of each order, and the average energy of the IMF components of each order can be used as a characteristic value of the EEG signal. The average energy per order IMF component is calculated as follows:

$$E_l = \frac{1}{n} \sum_{t=1}^n |S_l(t)|^2, \quad (1)$$

where S_l is the l th IMF component, n is the number of IMF component data points; E_l is the average energy characteristic of the l th IMF component.

According to the feature of each order IMF component after EMD decomposition, the representative first m -order IMF components are selected for feature extraction so that m average energy feature values can be extracted for each EEG data. Since the amplitude of brain waves varies with changes in musical psychological feature, the average of the sum of amplitude differences of adjacent IMF components is extracted as an eigenvalue, which characterizes the fluctuation intensity of the signal and is called the fluctuation index. Since the intensity of EEG signal changes varies across psychological feature states, the fluctuation index can be used as a measure of the intensity of EEG signal changes, which is defined as:

$$H_{i,j} = \frac{1}{n} \left(\sum_{t=1}^n |S_i(t) - S_j(t)| \right), \quad (2)$$

where $S_i(t)$ is the i -th IMF component after EMD decomposition; $S_j(t)$ is the j -th IMF component; n is the number of data points of the IMF component; H_{ij} is the average of the sum of the absolute values of the differences between the i -th and j -th IMF components, which is the fluctuation index.

The most representative top m -order IMF components are selected for feature extraction after EMD decomposition, so that $m-1$ IMF fluctuation index feature values can be obtained for each EEG data.

Approximate entropy (ApEn) is a nonlinear kinetic parameter that can be used to measure the pattern of EEG signal waveform changes and the unpredictability of EEG signal changes. ApEn characterizes the complexity of an EEG signal by a nonnegative number that is also used to indicate the probability of a change in the EEG signal, whose magnitude increases with the complexity of that EEG time series. Approximate entropy does not require a large number of data points for calculation in practical applications, and approximate entropy can suppress the mixed noise signals in EEG signals and has a strong resistance to interference signals. Since ApEn can analyze single or superimposed random signals, it is very suitable to be used for analyzing EEG signals. Denote a set of original EEG signals by $x(i)$, where $i = 1, 2, \dots, n$, and n is the number of data points. The detailed steps to extract ApEn from EEG signals are as follows.

- (1) This set of EEG signals $x(n)$ is converted into a set of vectors with dimension d according to the sequence of serial numbers.

$$Y(i) = X(i), X(i+1), \dots, X(i+d-1), \quad (3)$$

where d is the window length, i is satisfying $i = 1, 2, \dots, n-d+1$.

- (2) Calculate the distance between the i -th vector $Y(i)$ and the j -th vector $Y(j)$.

$$D\{Y(i), Y(j)\} = \max \{|Y(i+k) - Y(j+k)|\}, \quad (4)$$

where i is satisfied by $i = 1, 2, \dots, n-d+1$, j is satisfied by $j = 1, 2, \dots, n-d+1$, and k is satisfied by $k = 0, 1, \dots, d-1$.

- (3) When the threshold r is known and r is a nonnegative number, if the number of $D\{Y(i), Y(j)\} < r$ in a set of data points is denoted by $N^d(i)$, and the number of total vectors is denoted by $N-d+1$, and the ratio of these two is denoted by $C_i^d(r)$, the formula for calculating $C_i^d(r)$ for each EEG data series is shown below.

$$C_i^d(r) = \frac{N^d(i)}{(N-d+1)}, \quad (5)$$

where i is satisfied with $i = 1, 2, \dots, N-d+1$.

- (4) The natural logarithm is taken, and then the average of all the i 's is found for the requested logarithm.

$$\phi^d(r) = \frac{1}{N-d+1} \sum_{i=1}^{N-d+1} \ln C_i^d(r). \quad (6)$$

- (5) Then the data sequence $X(N)$ is further composed into a set of vectors of dimension $d+1$ according to the serial number, and $C_i^{d+1}(r)$ and $\phi^{d+1}(r)$ can be obtained after repeating the above steps.

$$\text{ApEn} = \phi^d(r) - \phi^{d+1}(r). \quad (7)$$

Since the length of the processed EEG data points is set, the value of the original data point length N is not discussed for the time being. The window length d is also called the embedding dimension, and if the value of d is set larger than 2, the calculated approximate entropy is not used to accurately characterize the EEG signal. If the EEG signal is reconstructed when the value of d is set to 2, the EEG information obtained after reconstruction is more detailed than that portrayed when the value of d is 1, so the value of d is set to 2. The value of the threshold r , also known as the similarity tolerance, is related to the ability of the requested approximate entropy to discriminate between EEG categories. the size of r is more relevant to the scenario of practical application, and $r = 0.2 * std$ is usually chosen, where std denotes the standard deviation of the original time series.

3.5. Holdings of Sample Entropy. Sample entropy (SampEn), which transforms some of the steps in approximate entropy calculation, is also used to measure the complexity of time series and is commonly used in the assessment of physiological time series complexity and in the diagnosis of case states.

Sample entropy algorithm is expressed as follows:

- (1) If the time series of an N -dimensional EEG signal is $u(1), u(2), \dots, u(N)$, the sequence is obtained by sampling at equal time intervals.
- (2) The parameters that determine the calculation results of the sample entropy algorithm are integer d and real number r , where d is the length of the comparison vector and r is the measure of similarity.
- (3) Reconstruct d vector $X(1), X(2), \dots, X(N-d+1)$, where $X(I) = [u(i), u(i+1), \dots, u(i+d-1)]$.
- (4) For $1 \leq i \leq N-d+1$, count the number of vectors that meet the following conditions:

$$B_i^d(r) = \frac{(X(j), D[X(i), X(j)] \leq r)}{(N-d)}, i \neq j. \quad (8)$$

Among them, the $D[X, X^*]$ is defined as $D[X, X^*] = \text{Max}|u(a) - u^*(a)|$, indicates $X \neq X^*$. $u(a)$ represents the element of vector X , and D represents the distance between vector $X(i)$ and vector $X(j)$, which is determined by the maximum difference of the corresponding element. The value range of j is $[1, N-d+1]$, but $j \neq i$.

- (5) Find the average value of $B_i^d(r)$ over all I values, denoted as $B^d(r)$.

$$B^d(r) = (N-d+1)^{-1} \sum_{i=1}^{N-d+1} B_i^d(r). \quad (9)$$

- (6) let $k = d+1$, repeat steps 3-4, get $A^k(r) = (N-k+1)^{-1} \sum_{i=1}^{N-k+1} A_i^k(r)$. Among them: $A_i^k(r) = (\text{number of } X(j) \text{ such that } d[X(i), X(j)] \leq r) / (N-k), i \neq j$.

- (7) Sample entropy (SampEn) is defined as:

$$\text{SampEn} = \lim_{N \rightarrow \infty} \left\{ -\ln \left[\frac{A^k(r)}{B^d(r)} \right] \right\}. \quad (10)$$

3.6. Multiscale Permutation Entropy. Permutation entropy (PE) is also a nonlinear parameter that can be used to characterize the complexity of an EEG signal. It has the advantages of simple calculation procedures and a strong ability to suppress the mixed noise in EEG signals. Multiscale permutation entropy is calculated on the basis of PE, and its calculation steps are as follows, as shown in Figure 2.

First, the EEG psychological feature time series were coarse-grained. If a group of EEG psychological feature time series is $\{x(i), i = 1, 2, \dots, n\}$, then the coarse-granulating method is as follows:

$$y_i = \frac{1}{s} \sum_{i=(j-1)s+1}^{js} x_i, 1 \leq j \leq \frac{N}{s}, \quad (11)$$

where s is a multiscale factor, and y_i is a multiscale time series.

When the scale factor s is 1, it means that the EEG psychological feature time series is the original EEG psychological feature time series, and the entropy calculated by the multiscale permutation entropy algorithm is the permutation entropy value.

Spatial reconstruction time series $\{y(i), i = 1, 2, \dots, N\}$, and you get the matrix Y . The length of the time series is N .

$$Y = \begin{bmatrix} y(1) & y(1+\tau) & \dots & y(1+(d-1)\tau) \\ y(2) & y(2+\tau) & \dots & y(2+(d-1)\tau) \\ y(j) & y(j+\tau) & \dots & y(j+(d-1)\tau) \\ \vdots & \vdots & \dots & \vdots \\ y(k) & y(k+\tau) & \dots & y(k+(d-1)\tau) \end{bmatrix}, \quad (12)$$

where d is the embedding dimension; τ is the delay factor; k is $k = N - (d-1)$; $y(j)$ is the j -th row component of the reconstruction matrix.

Consider $N - (d-1)\tau$ rows in the above formula as $N - (d-1)$ reconstruction components. The first j a, matrix component $\{y(j), y(j+\tau), \dots, y(j+(d-1)\tau)\}$, arranged in ascending order, is available:

Consider the $N - (d-1)\tau$ rows in the above equation as $N - (d-1)\tau$ reconstructed components. Then, the j -th component of the matrix $\{y(j), y(j+\tau), \dots, y(j+(d-1)\tau)\}$, rearranged in ascending order, gives the following equation.

$$\% y(i + (j_1 - 1)\tau) \leq y(i + (j_2 - 1)\tau) \leq \dots \leq y(i + (j_d - 1)\tau), \quad (13)$$

where j_1, j_2, \dots, j_d is the index value of the column where each element is located in the reconstructed component. If $y(i + (j_p - 1)\tau) = y(i + (j_q - 1)\tau)$ exists in the reconstructed component and $p \neq q$, then it is necessary to sort the values of j_p and j_q by their magnitude. If $j_p < j_q$, then there is $y(i + (j_p - 1)\tau) < y(i + (j_q - 1)\tau)$.

Each row of an arbitrary reconstruction matrix has a sequence of reconstruction symbols corresponding to it.

$$S(i) = (j_1, j_2, \dots, j_d), \quad (14)$$

where i is satisfied by $i = 1, 2, \dots, k$, where the value of k is less than d .

Since the dimension of the reconstructed EEG component is d , the arrangement can be obtained as d kind.

If p_1, p_2, \dots, p_k is used to denote the probability of occurrence of sequence $S(i)$, the permutation entropy of EEG sentiment time series $x(i)$ can be expressed as the following equation.

$$\text{MPE} = - \sum_{j=1}^k P_j \ln P_j. \quad (15)$$

The formula for calculating PE and the range of values of probability P_j shows that MPE is maximum when $P_j = 1/d$ and its value is $\ln(d)$.

$$0 \leq \text{MPE} \leq 1. \quad (16)$$

FIGURE 2: Multiscale permutation entropy calculation process.

The numerical size of the ranking entropy measures the complexity of the EEG signal $\{x(i), i = 1, 2, \dots, N\}$. a larger value of PE indicates a more complex and random EEG signal, and vice versa.

The three parameters, embedding dimension d and delay factor as well as scale factor, will have an impact on the accuracy of the multiscale alignment entropy calculation results. An EEG psychological feature signal containing high and low arousal is selected from the DEAP database, and the appropriate parameters d , τ , and s are found experimentally. When $d=3$ and $\tau=1$, the absolute value difference of the amplitude of the two types of signal alignment entropy with different scale factors s is shown in Figure 3 below. From the figure, it can be seen that the magnitude difference is the largest when s is 1, so $s=1$ is chosen. According to the previous research, it is known that when $2d \leq 5$ can make a good approximation to the asymptotic distribution by finite series.

Therefore, when $s=1$ and $\tau=1$, the absolute value difference of the amplitude of the two types of signal alignment entropy under different d is shown in Figure 4 below. From the figure, it can be seen that the amplitude difference is the largest when d is 5, so $d=5$ is chosen.

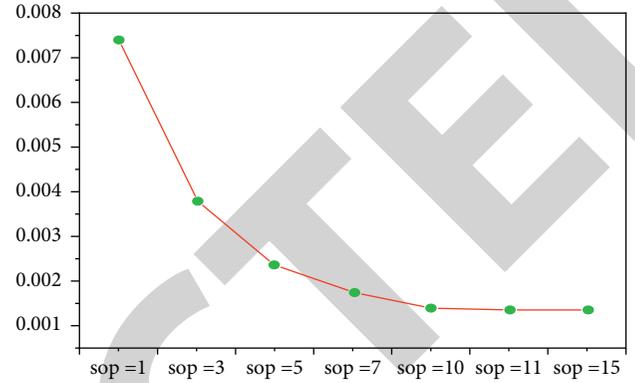

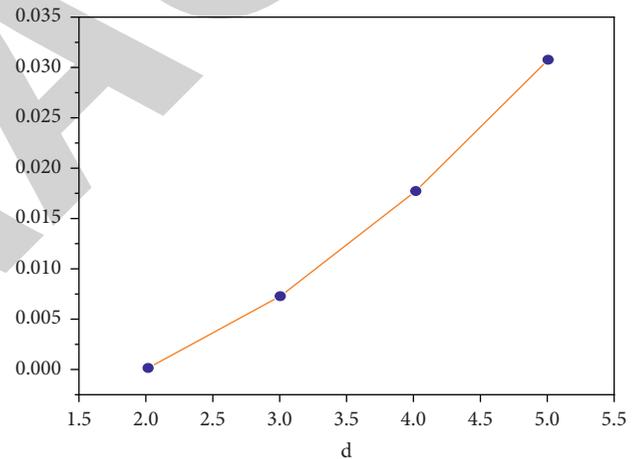

Therefore, when $s=1$, $d=5$, the absolute value difference of the amplitude of the two types of signal alignment entropy under different d is shown in Figure 5 below. From the figure, it can be seen that the amplitude difference is the largest when $s=1$, so it is chosen $\tau=1$.

3.7. Hurst Index. There are seven main methods for calculating the Hurst index: Aggregate variance method, R/S analysis method, Periodogram method, Absolute value method, Variance of residuals method, Abry-Veitch method, and Whittle method (Whittle estimator). R/S analysis is also called rescaled polar variance analysis, which is usually performed for only a few representative indices due to the complexity of the calculation method.

The Hurst index, calculated by R/S analysis, enables a quantitative description of the long-term dependence of time series information. The Hurst index is able to predict the trend of the EEG signal, but not the duration of new changes. In practical applications usually the system beyond a certain time scale shows a random behavior that is not correlated with the past. The quantity R for determining whether the EEG signal has acyclic cycles can be calculated by the following equation.

$$R_n = \frac{(R/S)_n}{\sqrt{n}}. \quad (17)$$

On the curve plotted by the relationship with $\ln n$, if the curve is a horizontal line, it means that the signal is random and the Hurst exponent is equal to 0.5; if the curve slopes

FIGURE 3: The difference of the average amplitude difference between the two categories at different s values.FIGURE 4: The difference of the average amplitude difference between the two categories at different d values.

downward, it means that the signal has inverse persistence and the Hurst exponent is less than 0.5; if the curve slopes upward, it means that the signal has persistence and the Hurst exponent is greater than 0.5.

4. Experimental Results Analysis of EEG Psychological Feature Extraction

The EMD decomposition algorithm was used to process the EEG signals to obtain the IMF components of each order, and the 11-order IMF components were obtained after the 1-second EEG psychological feature signals on channel Fp1 were decomposed. Fourier transform algorithm was used to transform the IMF components of each order into the frequency domain, and the spectrum graph of each order IMF was obtained. After EMD treatment, the frequency range of each order IMF component is different. The

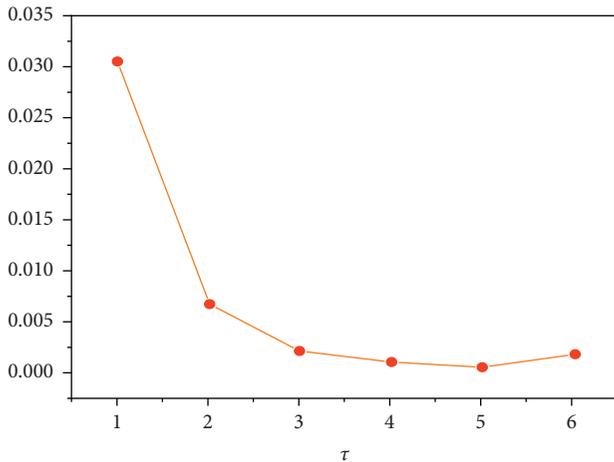

FIGURE 5: The difference of the average amplitude difference between the two categories at different τ values.

frequency of each IMF component decreases gradually with the increase of the order, and the higher the order IMF component, the lower the corresponding frequency. If the relevant features of each order IMF component are extracted, the obtained feature vector dimension will be very high, and these feature quantities will also contain many EEG features with little correlation with psychological features, thus reducing the accuracy of EEG psychological feature recognition. Since the frequency range of the EEG, rhythm wave is between 0.5 Hz and 45 Hz, and the IMF components obtained after EMD decomposition, in which the first 6th order IMF components occupy almost 90% of the energy of the EEG signal, the first 6th order IMF components are reconstructed with the original EEG signal on channel Fp1 for 1 second and the EEG signal on channel Fp1 for 1 second after reconstruction. The first 6 orders of IMF components can show the features of the original EEG signal on channel Fp1 for 1 second, so the first 6 orders of IMF components are selected for feature extraction respectively.

The data from the pre-processed DEAP dataset were analyzed in the time-frequency domain, and the EEG data of 32 subjects on 32 channels were decomposed into several eigen-simulation functions using the EMD algorithm. Based on the analysis of appropriate order IMF components, the first 6 order IMF components were selected for time-frequency analysis after EMD decomposition of EEG data from 32 subjects on 32 channels. The average energy features and fluctuation index features are first extracted for each order of IMF components selected as feature set 1 and feature set 2, respectively, and then the FFT transform is applied to the first 6 orders of IMF components after EMD decomposition, and the average energy features and fluctuation index features are extracted as feature set 3 and feature set 4, respectively. Finally, the sample entropy, approximate entropy, multiscale alignment entropy, and Hurst index of the first 6 order IMF components after EMD decomposition are extracted as feature set 5, feature set 6, feature set 7, and feature set 8, respectively. 80% of the extracted EEG

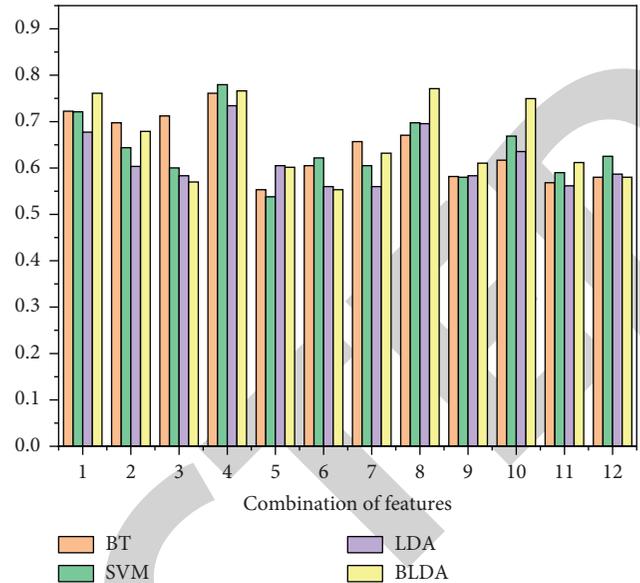

FIGURE 6: Average classification accuracy of feature combinations.

sentiment feature set is selected as the training set and 20% as the validation set, respectively. High/low arousal binary classification is performed by four classical classification methods, BT, SVM, LDA, and BLDA, one by one.

As can be seen from Figure 6, the classification accuracy of these features combined is not high, and the accuracy of EEG emotion classification after feature combination is lower than that before feature combination. The highest classification accuracy for the combination of all features is only 77.68%. It is 12.32% lower than the best result of 90% for classification by single features. The possible reasons for this phenomenon are: (1) the combined features produce redundant data, which affects the classification results; (2) when individual features are classified, the amount of feature data is relatively small compared to the combined features, and the classification results of the combined features may be oversaturated; (3) when each feature is classified individually, the feature values of the two categories have certain differences, but after combining them together, the differences between the two The difference between the feature values is reduced.

5. Conclusion

The psychological features of the music of college students are related to their preferences in learning music. It can effectively extract the psychological feature of music, identify and analyze the preferences of students, and develop different learning programs according to different students by combining their own features, so as to maximize the advantages of students. In this paper, multifeature extraction and combination methods are studied to improve the accuracy of mental feature extraction from EEG signals. The EEG emotion data after DEAP centralized preprocessing is processed by the Empirical Mode Decomposition algorithm. Through verification, it is found that the multifeature extraction method can effectively extract psychological feature

data, better reflect the psychological feature of students, and provide good data support for the development of music education programs [21].

People's requirements for material needs and living standards are gradually increasing, and consumers' demand for fresh, fruit, and vegetable cold chain foods is also increasing. This paper takes urban fresh agricultural products cold chain logistics as the research object, establishes a collaborative optimization model of urban fresh agricultural products cold chain logistics inventory and distribution based on distribution centers, proposes a partitioning solution strategy for the multidistribution center problem, and proposes a collaborative optimization in urban fresh agricultural products logistics inventory and distribution system. The application of collaborative optimization in urban fresh product logistics inventory and distribution system is proposed.

1. Introduction

In recent years, with the healthy and rapid development of China's national economy, people's requirements for material needs and living standards have gradually increased, and consumers' demand for fresh, fruit, and vegetable and other cold-chain foods has also increased day by day. With this, people's requirements for the safety and freshness of food are also getting higher and higher [1]. According to the analysis of relevant experts, it is because people pay more and more attention to food safety [2], so in recent years the public is more concerned about the safety and freshness of cold chain logistics products, and there are some products in the logistics system in the process of transportation and circulation need to be stored at low temperature and other technical means to maintain the maximum degree of freshness, nutrients, and so on; the cold chain logistics industry was born [3].

Since the establishment of the cold chain logistics system, some cold chain logistics products can be transported and sold over long distances; the seasonality of fresh fruits and vegetables in daily life has gradually become blurred; and the categories of food that people can buy in general are increasingly rich. The development of cold chain logistics benefits from the current high-speed economic situation and

people's increasing demand for daily consumption, and it is foreseeable that the development prospect of cold chain logistics will be very broad in the future. In recent years, the rapid development of logistics management, facility planning, safety monitoring, and other logistics-related disciplines has led to the gradual development of the cold chain logistics industry in China [4].

There are many shortcomings in China's cold chain logistics, such as higher costs, the extremely low delivery rate of cold chain logistics and product circulation rate, very backward infrastructure, serious losses of cold chain logistics products during inventory distribution, and so on. This is mainly due to the late start of China's cold chain logistics industry compared with developed countries, the lack of reasonable cold chain logistics system planning, and backward basic logistics facilities [5]. According to professional statistics, the current loss in the process of inventory distribution due to the spoilage of cold chain logistics products has caused a large amount of irretrievable losses in the cold chain logistics industry [6]. Under the guidance of the rapid development of the global economy, China's logistics industry is rising rapidly, and cold chain logistics is also gradually attached to the relevant national departments and the entire logistics industry. The depletion of cold chain logistics products is inevitable, so the research on it to

improve the cold chain logistics network can minimize the loss of cold chain products in the process of inventory distribution and then reduce the cost of cold chain logistics products, and it will also promote the economic and social development of China. Therefore, the cost of loss of goods in circulation considered in the study of the total cost of cold chain logistics network to improve the cold chain logistics network in China has now become an urgent problem [7].

Relying on the rapid development of the Internet [8], fresh product e-commerce has started to enter a golden age of development. Combined with the characteristics of perishability, easy deterioration, and high timeliness requirements of fresh products, high demands are placed on their timeliness of delivery and freshness at the time of delivery [9]. If the quality of the product is significantly degraded at the time of delivery, it will usually be rejected directly. This requires a perfect logistics system to support, through a reasonable logistics system planning to shorten the delivery time of the product, to protect the quality of the product, and at the same time can reduce the cost. With the continuous development of logistics systems and even pharmaceutical logistics systems, managers have gradually realized that there are two important decisions in logistics systems, which are inventory decisions at the tactical level and transportation path decisions at the technical operational level [10]. The two elements are interlinked and highly correlated, and inventory and distribution costs account for a large proportion of the total cost, so the backward phenomenon of benefits between the two is particularly prominent: if we hope that inventory costs are low, we need to reduce the amount of inventory, then the number of deliveries will increase, and distribution costs rise; if we hope that distribution costs are low, we need to make the number of deliveries decrease, and the amount of goods per delivery becomes larger, and then the pressure on warehouse storage becomes larger and Inventory cost increases. Therefore, in order to balance the contradiction between inventory and distribution and achieve the optimization of the logistics system, the inventory and distribution activities of this logistics network should be collaboratively optimized [11].

As the core link of cold chain logistics, inventory and distribution are mutually constrained, and changes in the decision of one link will directly affect the other link, so it is important for the long-term development of enterprises to consider the synergy of the two types of decisions [12]. Based on the existing research, this paper summarizes and refines the relevant concepts of cold chain logistics, constructs a collaborative platform for cold chain logistics supported by blockchain, ensures real-time sharing of inventory and distribution information upstream and downstream of the supply chain through the collaborative platform, focuses on the rational modeling and solution of inventory decision and collaborative arrangement of paths in the secondary network of cold chain logistics on this basis, and discusses the cold chain. It is of strong theoretical and practical significance to discuss the cooperative problem of inventory and distribution of cold chain logistics from the information technology level and business process operation level [13].

Fresh agricultural products are rich in elements and water required for life, and there are more microorganisms with life activities inside them than other products, so deterioration and corruption are the most important characteristics of fresh agricultural products [14]. The supply chain circulation is complicated and complex, mainly including raw materials, production, circulation and processing, sorting, storage, loading and unloading, distribution and sales, and so on. In the process of circulation, slight damage often causes irreversible effects on fresh agricultural products, which can lead to rapid deterioration and even corruption. Therefore, in the process of supply chain circulation, different temperatures need to be set according to the characteristics of different products such as the speed of freshness weakening to ensure product quality. Cold chain logistics of fresh products has the following characteristics compared with room temperature logistics. (1) Precise temperature control and high timeliness: cold chain logistics is more complicated compared with normal temperature logistics, mainly because the object of cold chain logistics is mainly fresh products, and the characteristics of different fresh products have big differences, and they are sensitive to the storage environment temperature, humidity, and light, so in each link of the supply chain, in order to ensure the quality of fresh products and slow down the decline of freshness, the optimal storage environment for fresh products varies greatly. In addition, fresh products have strict requirements on delivery time; cold chain logistics enterprises should deliver the products to the customer's designated location in a timely and accurate manner. Therefore, cold chain logistics enterprises need to plan the distribution path in advance to ensure timely and accurate delivery [15]. (2) More capital investment and frequent daily maintenance: fresh products have the characteristics of perishability and short life cycle and generally have extremely high requirements for temperature and humidity, so they must be equipped with professional refrigerated holding tanks and distribution vehicles in the circulation process. In the process of circulation from the upstream to the downstream of the supply chain, temperature changes are often caused by irregularities in handling and transportation operations. This can lead to the decline of product freshness, affect product quality, and cause damage to goods, which can bring huge capital losses. Therefore, it is necessary to regularly spend a lot of costs to maintain the facilities and equipment of cold chain logistics of fresh products to ensure normal temperature control of refrigeration equipment [16]. (3) Strong equipment expertise and high safety protection: in order to guarantee a constant temperature in the supply chain circulation, packaging materials with good anticollision ability and insulation capacity should be selected, and the selected facilities and equipment must also meet national standards and specifications. At the same time, to ensure product safety, safety protection is required for product information (including production date, expiration date, storage temperature, etc.), health status of distribution personnel, and cleanliness of shipping equipment [17].

Compared with ambient logistics, the main feature of the cold chain logistics operation process is the need for full temperature control of multiple products in the circulation process to delay the decay and deterioration of product freshness and ensure product quality [18]. The operation process of cold chain logistics mainly includes five links: production, storage, circulation and processing, transportation, distribution, and sales. After the raw materials of fresh products are simply processed into semifinished products at suppliers, they are packaged and sorted for transportation to distribution centers for secondary processing to become finished products, and then the products are distributed to retailers for sales, and finally, customers choose delivery or self-pickup according to their needs [19]. The basic operation process of cold chain logistics is shown in Figure 1.

Collaborative cooperation of logistics enterprises refers to logistics enterprises with autonomy, which adopt unified standards and standardized processes according to certain agreements to complete partial or comprehensive third-party logistics services and play the effect that the whole is greater than the sum of its parts, with the aim of integrating scattered logistics resources and realizing intensive operation [20]. There are three types of collaborative cooperation among logistics enterprises as follows.

The first one is horizontal synergistic logistics [21], that is, the complementary synergistic cooperation among logistics enterprises with different core competencies. On the basis of constructing their own core competitiveness, enterprises choose appropriate other logistics enterprises to reduce costs through collaborative planning and operation. For example, professional transportation enterprises can cooperate with distribution centers, and the transportation enterprises can complete long-distance and high-volume mainline cargo transportation, while the distribution centers can complete activities such as storage, sorting, packaging, and distribution of goods. For enterprises that can only provide logistics services within certain regions due to capacity constraints, they can also complete the whole process of logistics activities through different distribution centers in cooperation. This collaborative approach is flexible and can realize the complementary advantages among logistics enterprises, optimize resource allocation, and enable each enterprise to develop markets and expand business while developing, as shown in Figure 2.

The second type is vertical collaborative logistics. Its main form is the collaboration between suppliers, producers, wholesalers, and retailers. This type of synergy can reduce the cost of each logistics enterprise and is conducive to the operational effect of economies of scale. Each logistics enterprise invests and builds together, shares the benefits, and shares the risks and costs, forming a close community of interests, which helps form a stable synergistic relationship among the enterprises. However, there are many specific details involved in the implementation process. For example, the products of different industries have different characteristics and different requirements for logistics, and how to share the expenses and costs among the participating enterprises, which makes collaborative logistics difficult [22], as shown in Figure 3.

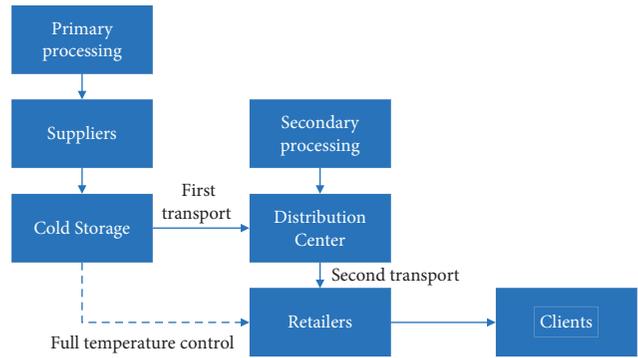

FIGURE 1: Basic operation process of cold chain logistics.

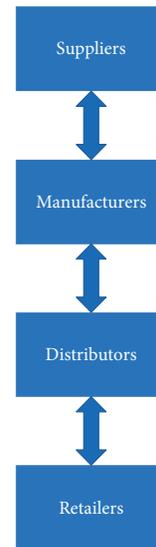

FIGURE 2: Horizontal collaborative logistics.

The third type is the collaborative logistics realized by the third-party logistics. Provision of necessary logistics services by relatively independent companies. This makes the logistics service system of each enterprise faster and safer. This type of logistics operation is particularly suitable for the replenishment mode of small-lot inventory. However, in the process of third-party logistics cooperation, there are barriers to information communication and exchange of sales data, business plans, development plans, market demand, and so on. Only on the basis of the collaborative exchange of these key information can immediate, accurate, and efficient logistics services be realized and a win-win strategic state be formed [23], as shown in Figure 4.

In the area of fresh product quality losses: Donis-González et al. developed a technique to detect the internal quality parameters of the fresh product without loss of the product. The aim of the study was to detect the internal quality of the fresh product earlier in the production and processing stages of the fresh product supply chain [24]. Prakash studied the effect of ionizing radiation on fresh products and concluded that ionizing radiation has the effect of slowing down the rate of decay of freshness, prolonging the period of spoilage, and destroying bacteria [25].

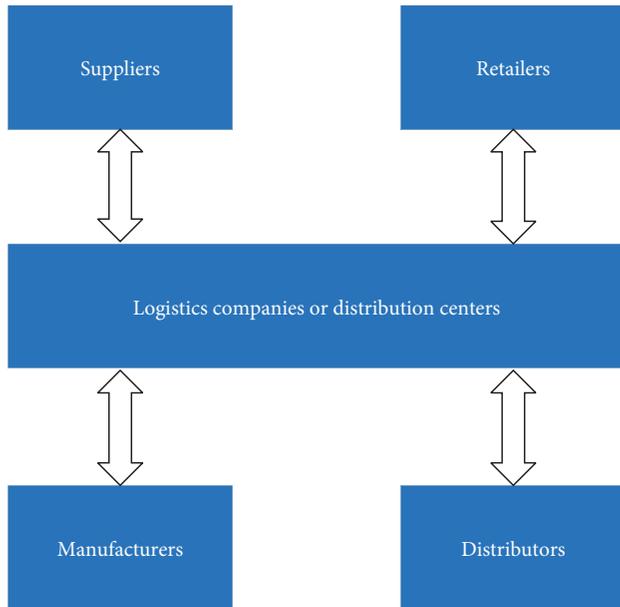

FIGURE 3: Vertical collaborative logistics.

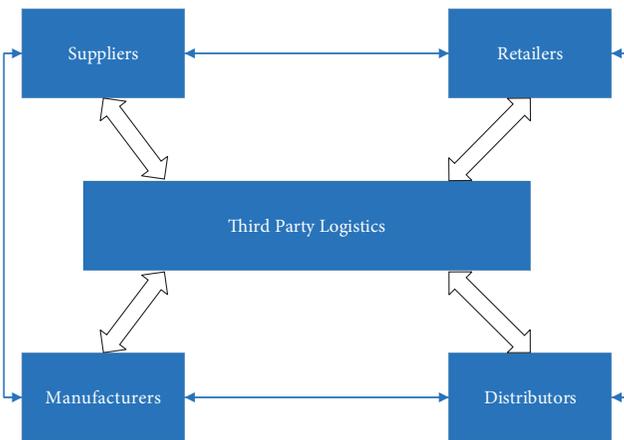

FIGURE 4: Collaborative logistics realized by the third-party logistics.

Ahumada et al. constructed a planning model on the stochastic allocation of fresh products based on uncertain climate and customer demand, which enables maneuvering selection risk [26]. Piramuthu and Zhao used an exponential function to represent the decaying changes in the quality of fresh product from the perspective of supermarkets and developed a model for fresh product inventory allocation by type and shelf space where demand is influenced by both product shelf display and freshness [27].

For fresh product inventory optimization research: Banerjee and Agrawal analyzed the influence of product selling price and freshness on customer demand and constructed an inventory segmentation control optimization model based on uncertain customer demand, which is only influenced by selling price before selling and determined by product freshness after starting selling [28]. Chan et al. analyzed the effect of supplier productivity on the total cost

of the supply chain system and, based on this, proposed an integrated model for constructing an exponential deterioration function of a single supplier corresponding to a single retailer under uninterrupted production conditions, considering the deterioration of the product at the time of delivery and using the production quantity as one of the independent variables affecting the objective function [29]. Hsieh and Dye proposed a customer demand function based on shipment loss neutrality, shipment loss avoidance, and shipment loss finding by analyzing the theory related to reference price effectiveness and integrating reference price effectiveness with inventory control problem and constructed a dynamic pricing model based on this to pursue long-term profit maximization [30]. Nemptajela and Mbohwa reviewed the relationship between FMCG inventory control problems and uncertain customer demand by analyzing the impact of uncertain customer demand on inventory control [31]. Mirzaei and Seifi developed an inventory path optimization model based on freight cost, inventory cost, and cost of goods lost on sale and designed a meta-heuristic algorithm by combining simulated annealing and taboo search [32]. Li et al. studied a demand-dependent and dynamic pricing inventory level model [33].

In the study of inventory and distribution synergy optimization, Anily Federgruen studied a secondary logistics system consisting of distribution centers and multiple retailers and constructed an optimization model to minimize the total cost of the inventory/distribution secondary system by analyzing the inventory and distribution cost of distribution centers and the inventory of each retailer. The solution process is mainly: firstly, the actual demand of each retailer is determined and summed, then the group distribution is carried out according to the design demand of each retailer, and finally the optimal inventory control strategy of the distribution center and the optimal replenishment strategy of retailers are determined [34]. In another paper, she studied a secondary system consisting of a single distribution center and multiple retailers; considered a retailer cost minimization model including inventory holding, fixed order, and transportation costs with a determined sales rate of goods, a limited load of distribution center vehicles, and no time window; and finally verified the feasibility of the model by a heuristic algorithm [35]. Monthatipkul and Yenradee developed an optimization model based on integer programming for a single distribution center and many retailers to determine the optimal inventory control strategy and distribution strategy for the distribution center. Through comparison and analysis, this algorithm was proved to be superior [36].

In terms of multidistribution center vehicle path optimization research, Laporte established a multidistribution center path shortest model based on the shortest distribution center single vehicle type and finally verified the feasibility of the model by genetic algorithm calculation example [37]. Nagy and Salhi established a multidistribution center multivehicle model based on multiple vehicle models and solved it with a genetic algorithm based on the shortest transport distance model [38].

Lack of fresh product spoilage preservation inputs and quality change related studies: in the theoretical studies related to fresh product spoilage, there is more literature on the study of the relationship between time and freshness, but it ignores the effect of the input of preservation cost on the freshness function, which is a binary continuous function about time and preservation cost. At the same time, most of the existing literature have fragmented the relationship between freshness function and quality change function. Most of the literature treat quality change rate as a fixed parameter value; quality change does not happen overnight; it increases with the decay of freshness; quality change is a continuous process; and when the quality change rate reaches a specific value, it causes product spoilage and deterioration. Low degree of synergistic optimization of inventory and distribution: in the study of synergistic optimization of inventory and distribution, the research on each link of the supply chain is more extensive and comprehensive, among which there are relatively more studies on inventory management control and vehicle path planning, but most of the theories only focus on one of the links of the research, so independent research on each link can only achieve local optimization, which is not conducive to maximizing the overall benefits of the system. Although some scholars have proposed the relationship between the quality change function and the product freshness function based on the deterioration rate obeying the three-parameter Weibull distribution, the research is on the integrated inventory model of the three-level system of the supply chain, and the research on the path planning of the distribution vehicles and the multidistribution center problem is missing [39]. Multidistribution center problem: the current research about the supply chain secondary system is limited to the inventory and distribution from a single distribution center and a single commodity, and there is less research about the scheduling problem of multiple distribution centers, multiple yards, and multiple models.

In the operation of the cold chain logistics system, the secondary cold chain logistics network consisting of distribution centers and retailers is the object of study. In a certain period of time, considering the freshness of fresh agricultural products, the distribution center will deliver the products to the retailers according to the optimal distribution path with the optimal quantity and number of times and pursue the process of minimizing the total cost of inventory and distribution. The process of minimizing inventory and total cost of distribution: specifically, within the ordering cycle of the distribution center, the best replenishment quantity and number of replenishment times of each retailer are determined, and the best distribution path from the distribution center to each retailer is determined on this basis so that the total cost of inventory and distribution cost of the distribution center and the total cost of inventory of the retailer are finally realized. In the secondary system center of urban fresh year agricultural products cold chain logistics, if the minimization of distribution center inventory cost is pursued, it will lead to the reduction of the volume of distribution and the increase of the number of deliveries, which indirectly increases the distribution cost of the

distribution center. Similarly, the minimization of the most sought-after distribution costs will lead to an increase in the volume of distribution and a decrease in the number of deliveries. The increase in the volume of distribution leads to an increase in the inventory of retailers within a certain period of time, and the inventory holding costs and freshness costs also increase, while the order quantity of the distribution center increases to meet the scale effect pursued by the volume of distribution, leading to an increase in the inventory costs of the distribution center. In short, the relationship between inventory cost and distribution cost is mutually influential and restrictive. By analyzing the relationship between inventory cost and distribution cost in the secondary system of urban fresh agricultural products cold chain logistics under the consideration of freshness cost input, it is determined that the main objects of the synergistic optimization of fresh agricultural products cold chain logistics inventory and distribution are the order quantity of distribution center, the number of delivery times and delivery quantity of each retailer, and the distribution path.

2. Collaborative Optimization Model

Urban cold chain logistics II system is a logistics network based on business flow, logistics, and capital flow with full temperature control. In addition to the functions of sorting and distribution of conventional logistics distribution centers, fresh agricultural products distribution centers also have the functions of fresh products circulation and processing, refrigeration and freshness preservation, fresh packaging, and so on. Therefore, cold chain logistics distribution centers on how to improve refrigeration technology and freshness preservation level, expand radiation radius, and realize cross-regional distribution and other issues have become the focus of research. Therefore, this paper takes the secondary system of urban fresh agricultural products cold chain logistics composed of N distribution centers and M retailers as the research object and firstly determines that the paper constructs a collaborative optimization model of inventory and distribution based on a single distribution center. Secondly, based on the single distribution center inventory and distribution co-optimization model, the thesis proposes a solution strategy for the multidistribution center problem, which is mainly based on partition processing to realize the conversion of multidistribution centers into single distribution centers for a solution.

Freshness, as an important characteristic of fresh agricultural products, is an irreplaceable factor that influences consumers to purchase fresh products, so the demand for fresh agricultural products of retailers must consider the influence of product freshness. As the freshness of fresh products decreases over time, the market demand decreases in line with the actual situation, that is, the fresher the fresh product is, the higher the demand is, so the market demand is positively related to the freshness of the product. In addition to the influence of product freshness on demand, the selling price also has an influence on demand, and the selling price has an inverse relationship with demand. Referring to

the defined equation of the function in the literature on the relationship between product freshness, product selling price, price elasticity, and market demand, the demand function in this paper is derived as follows:

$$D_{ij}(t) = (A_{ij} - c_j P_j) \cdot \varphi_{ij}(t), \quad (1)$$

where $D_{ij}(t)$ is the demand for product j by retailer i at time t ; A_{ij} is the potential market share, which is the maximum rate of demand for product j by retailer i ; P_j denotes the product the selling price of product j ; c_j is the price elasticity of demand ($c_j > 1$); and $\varphi_{ij}(t)$ is the product freshness function. When product freshness φ_{ij} tends to 0, regardless of how the product sales price is adjusted, the market demand D_{ij} also tends to 0. When the product freshness and price elasticity is certain, the market demand D_{ij} decrease with the increase in sales price P_j .

Based on the freshness model and the inventory level equation, the retailer's inventory level as a function of time is calculated by integration, as follows:

$$I_{ij}(t) = \frac{c_j P_j - A_{ij}}{(\alpha_j - \lambda_{bj}) \cdot \ln \theta_{bj}} \cdot \left[e^{\theta_{bj}^{(\alpha_j - \lambda_{bj})t} - \theta_{bj}} \frac{(\alpha_j - \lambda_{bj}) \omega_{ij} \cdot T}{n_{ij}} - 1 \right], \quad (2)$$

where $I_{ij}(t)$ is the inventory level of retailer i of product j , α_j is the freshness decay coefficient under normal condition of product j , λ_{bj} is the seller's investment factor for product j preservation, θ_{bj} is the initial freshness of the j product at the vendor, ω_{ij} is the replenishment cycle, and n_{ij} is the number of times the distribution center delivers product j to retailer i in an ordering interval.

During the replenishment interval, for the freshness cost of product j at retailer i , which is mainly expressed as the freshness cost, FC_1 , invested in the product by the retailer to ensure the freshness of fresh agricultural products, the freshness cost is can be calculated as follows:

$$FC_1 = b_{bj} \cdot Q_{bij}, \quad (3)$$

where b_{bj} is retailer's cost of freshness per unit of product j and Q_{bij} is the number of j products per retailer i purchase. For the cost of goods loss, DC_1 , it is mainly due to the cost of spoilage caused by the deterioration of fresh products as the freshness of the product decreases and the rate of spoilage increases over time after arrival at the retailer, as shown in the following equation:

$$DC_1 = (Q_{bij} - D_{ij}^{\omega_{ij}}) q_j, \quad (4)$$

where $D_{ij}^{\omega_{ij}}$ is the effective demand for product j by retailer in the w -th replenishment cycle and q_j is the cost of goods loss per unit of fresh product j . Retailers' inventory holding costs, HC_1 , are mainly the costs incurred by retailers in storing and maintaining fresh agricultural products for a certain period of time, according to the following equation:

$$HC_1 = C_{bj} \cdot I_{bij}, \quad (5)$$

where C_{bj} is the retailer's inventory holding cost for unit j product and I_{bij} is the weighted inventory for retailer i and product j . In a replenishment interval, the total cost, TC_{ij} , incurred for the product at retailer i , including the cost of freshness, the cost of damage to goods, and the cost of holding inventory, can be calculated as follows:

$$TC_{ij} = FC_1 + DC_1 + HC_1. \quad (6)$$

Assuming that retailer i replenishes fresh product j to the distribution center, the change of inventory level in the distribution center is only affected by the loss of product spoilage in the interval between replenishment periods, so the expression of the change of inventory level in the distribution center at time t is shown in the following equation:

$$I_{dij}^{\omega_{ij}}(t) = (Q_{bij} + Q_{dij}^{\omega_{ij}+1}) \cdot e^{\theta_{dj}^{(\alpha_j - \lambda_{dij})t} - \theta_{dj}} \frac{(\alpha_j - \lambda_{dij}) \omega_{ij} \cdot T}{n_{ij}}, \quad (7)$$

where $I_{dij}^{\omega_{ij}}(t)$ is the inventory level of the distribution center for retailer i of product j at replenishment interval; ω_{ij} , Q_{dij} and Q_{bij} are distribution center, retailer i for each purchase of product j in volume; λ_{dij} is the distribution center's investment factor for product j preservation; and θ_{dj} is the initial freshness of the j product at the distribution center.

In the ordering cycle T of the distribution center, for the procurement cost of product j distributed by the distribution center for retailer i , it is mainly expressed as the sum of the fixed order cost and purchase cost paid by the distribution center to the fresh product supplier, and the procurement cost, BC , is shown in the following equation:

$$BC = h_0 + h_j \cdot Q_{dij}^1, \quad (8)$$

where h_0 is fixed order cost per order for all products and h_j is unit cost per order for product j .

In the distribution center ordering cycle T , for the distribution center to deliver product j at retailer i , the inventory holding cost is mainly expressed as the cost of storage and storage of fresh agricultural products at the retailer in the distribution center, that is, the storage and storage cost, HC_2 , of product-weighted inventory in the ordering cycle can be calculated as follows:

$$HC_2 = C_{dj} \cdot \sum_{\omega_{ij}=1}^{n_{ij}} I_{dij}^{\omega_{ij}}. \quad (9)$$

The freshness cost, FC_2 , incurred by the distribution center when the distribution center delivers product j to retailer i during the distribution center's ordering cycle T can be calculated as follows:

$$FC_2 = b_{dj} \cdot Q_{dij}^1. \quad (10)$$

In the ordering cycle T , other than $n_{ij} \cdot Q_{bij}$ which is the fresh product that supplied by distribution center j to retailer i , the remaining fresh product will be spoilage depletion, so the cost of spoilage goods loss, DC_2 , for the distribution center can be calculated as follows:

$$DC_2 = (Q_{dij}^l - n_{ij} \cdot Q_{bij}) \cdot q_j. \quad (11)$$

In addition to the completion of storage, the products in the distribution center also involve a number of other businesses. The relatively fixed costs arising from these business links are additional costs, which mainly include the costs arising from loading and unloading, distribution processing, packaging, sorting, and other business links. The

amount of additional costs is mainly affected by the amount of products purchased by the distribution center. In the ordering cycle, the additional costs are mainly caused by the first replenishment period and the initial inventory of the distribution center, that is, the order quantity of the distribution center, so the total additional costs, AC_2 , can be calculated as follows:

$$AC_2 = \sum_{i=1}^N \sum_{j=1}^N C_0 Q_{dij}^l \cdot x_{ij}, \quad (12)$$

$$x_{ij} = \begin{cases} 1 & \text{Distribution center replenishes product } j \quad j = 1, 2, \dots \\ 0 & \text{Do not need replenishment product } j \quad j = 1, 2, \dots \end{cases}, \quad (13)$$

where C_0 is the additional cost per unit of product, that is, the total cost of packaging, sorting, distribution processing, handling, and transportation per unit of product.

In this paper, one distribution path planning is modeled as an example within one ordering interval T of a distribution center. In the retailer's one replenishment interval, the distribution cost is mainly generated by the transportation link, and the transportation cost will vary depending on the transportation distance and the number of transports. For the convenience of modeling, the transportation cost in this paper includes transportation variable cost and fixed cost, and vehicle driver cost. The fixed cost, FC_3 , generated by the distribution center vehicle for one delivery to the retailer can be calculated as follows:

$$FC_3 = S \sum_{y=1}^Z \sum_{i=1}^N X_{di}^y, \quad (14)$$

$$X_{di}^y = \begin{cases} 1 & \text{vehicle } y \text{ provides delivery service } i = 1, 2, \dots \\ 0 & \text{Do not provide delivery service } i = 1, 2, \dots \end{cases}. \quad (15)$$

For the variable cost of transportation, which is mainly affected by the distance from the fresh product distribution center to individual retailers, the variable cost, VC_3 , of transportation during the planning period can be calculated as follows:

$$VC_3 = S_1 \sum_{y=1}^Z \sum_{i=1}^N \sum_{k=1}^N d_{ik} Y_i^y X_{ik}^y, \quad (16)$$

$$Y_i^y = \begin{cases} 1 & \text{Provides delivery service for retailer } i = 1, 2, \dots \\ 0 & \text{Do not provide delivery service for retailer } i = 1, 2, \dots \end{cases}, \quad (17)$$

$$X_{ik}^y = \begin{cases} 1 & y \text{ vehicle move from } i \text{ to } k \quad i, k = 1, 2, \dots \\ 0 & \text{vehicle does not move } i, k = 1, 2, \dots \end{cases}. \quad (18)$$

The vehicle driver cost, DC_3 , represents the sum of the costs incurred by the driver driving the vehicle to complete the delivery of all retailers on a route and return it to the distribution center during the order cycle, as shown in

$$DC_3 = S_2 \sum_{y=1}^Z \sum_{i=1}^N X_{di}^y, \quad (19)$$

where d_{ik} is the distance from node i to point k in the distribution network, S is the fixed start-up costs per vehicle per delivery, S_1 is the unit transportation cost, and S_2 is the driver's labor cost per drive to deliver. In summary, the total cost incurred in the distribution chain during an ordering

period in the distribution center, that is, the distribution cost objective function, can be calculated as follows:

$$\min TC_3 = \sum_{y=1}^Z \sum_{i=1}^N X_{di}^y + S_1 \sum_{y=1}^Z \sum_{i=1}^N \sum_{k=1}^N d_{ik} Y_i^y X_{ik}^y + S_2 \sum_{y=1}^Z \sum_{i=1}^N X_{di}^y. \quad (20)$$

In the urban fresh agricultural products cold chain logistics system, it is often difficult for a single distribution center to supply the demand for fresh products from supermarkets in the region, and the multidistribution center supply mode appears to meet the demand for fresh products from supermarkets radiating throughout the region. To this

end, this section will propose a multidistribution center solution based on the single-distribution center inventory and distribution cooperative optimization model constructed above. At present, the solution methods for the multidistribution center problem include the partition processing method and the combinatorial optimization method, in which the partition processing method is to partition the retailers according to the distance between the distribution center and the retailers, and different regions are served by different distribution centers to realize the transformation of the multidistribution center distribution problem into a single-distribution center distribution problem for solving. The combinatorial optimization method converts the multidistribution center problem into a complex combinatorial optimization problem and realizes the multidistribution centers to provide services for retailers.

The multidistribution center combination optimization problem is computationally tedious and has harsh adaptation conditions, which are not suitable for the solution strategy of this paper. Therefore, this paper chooses the solution strategy of partitioning the retailers so as to transform the multidistribution center problem into a single-distribution center problem. At this stage, there are many kinds of partitioned distribution methods, mainly the mid-pipeline partitioning method, the scanning partitioning method, center of gravity partitioning method, and so on. The mid-pipeline partitioning method is to partition the retailers through the heavy vertical line of each distribution center connection, which is only applicable to two distribution centers distributed on the same line; scanning partitioning method is to use a kind of successive approximation method for partitioning, which is exponentially increasing and not easy to choose. The center of gravity partitioning method uses the center of gravity of all distribution centers and the line connecting the midpoints of two neighboring distribution centers to partition.

According to the constructed cooperative optimization model of urban fresh agricultural products cold chain logistics inventory and distribution, it is known that the cooperative optimization model consists of the inventory minimization model of the cold chain logistics secondary system and the distribution minimization model, which are interrelated and mutually synergistic, so the model solution algorithm is determined as a two-step cooperative process. Firstly, under the objective function of minimizing the total inventory cost of the cold chain logistics secondary system, the optimal order quantity, distribution quantity, and distribution times are determined in the distribution center. Then, based on the optimal replenishment strategy, the optimal distribution route is solved under the condition that the system distribution cost is minimized, so this paper involves the problem of inventory management control (IMC) and path optimization (PO).

In this paper, a genetic algorithm is used to solve the system inventory cost model. The genetic algorithm is mainly used for optimization problems or discrete problems where the objective function cannot be derived and has strong robustness. The objective function of the secondary system inventory in this paper is designed with numerous

constraints, which is difficult to derive, and the approximate optimal solution of the objective function may have certain dispersion, so the genetic algorithm is used to solve this paper.

For PO problems with small computational effort, they can be solved by using Dijkstra's algorithm, branch delimitation, and dynamic programming. The fresh product cold chain logistics distribution optimization model in this paper involves multiple retailers and multiple vehicles, and the model computation will explode exponentially with the increase of relevant parameters. Therefore, the solution methods for such problems mainly include ant colony algorithm, particle swarm algorithm, and simulated annealing method. In this paper, we mainly solve the path optimization problem based on the strong search ability of the ant colony algorithm. Therefore, the collaborative optimization solution flow is shown in Figure 5.

Based on the collaborative optimization model of fresh product cold chain logistics inventory and distribution, this paper adopts a genetic algorithm and an ant colony algorithm to solve the collaborative optimization model. Firstly, we use a genetic algorithm to solve the objective function of minimizing the total cost of secondary system inventory and calculate the optimal number of replenishment, replenishment quantity, and the total cost of minimum inventory for retailers.

The genetic algorithm first generates a random set of the initial population, then calculates the fitness value of individuals in the population using the fitness function transformed by the objective function, and then evaluates the merits of all individuals in the population according to the calculated fitness value, in which the unqualified individuals are selected, crossed, and mutated to produce new individuals, and the new individuals form a new population and continue to iterate repeatedly.

Combining the genetic algorithm solution process and the collaborative optimization model of urban fresh product cold chain logistics inventory and distribution constructed in this paper, the genetic algorithm is designed to meet the cold chain logistics secondary system inventory optimization model, which mainly includes the design of the following links: coding, population initialization, fitness function determination, selection operator, crossover operator, variation operator, and algorithm end rule.

The ant colony algorithm is a bionic algorithm based on the ability of ants to secrete pheromones on the paths they pass through during foraging to achieve mutual communication with other individuals. From the starting point to the end point, other ants are attracted to move to that path by secreting pheromones. As the ants increase, the amount of hormones on the short path becomes more and more, leaving less hormones on the long path. Therefore, the more ants after that choose the path with a greater concentration of pheromones the greater the probability, and vice versa, the smaller the probability.

In the ant colony algorithm of this paper, let there be m ants and n cities, and the state transfer probability of the k -th ant moving from city i to city j at moment t is P_{ij}^k ; the specific algorithm is

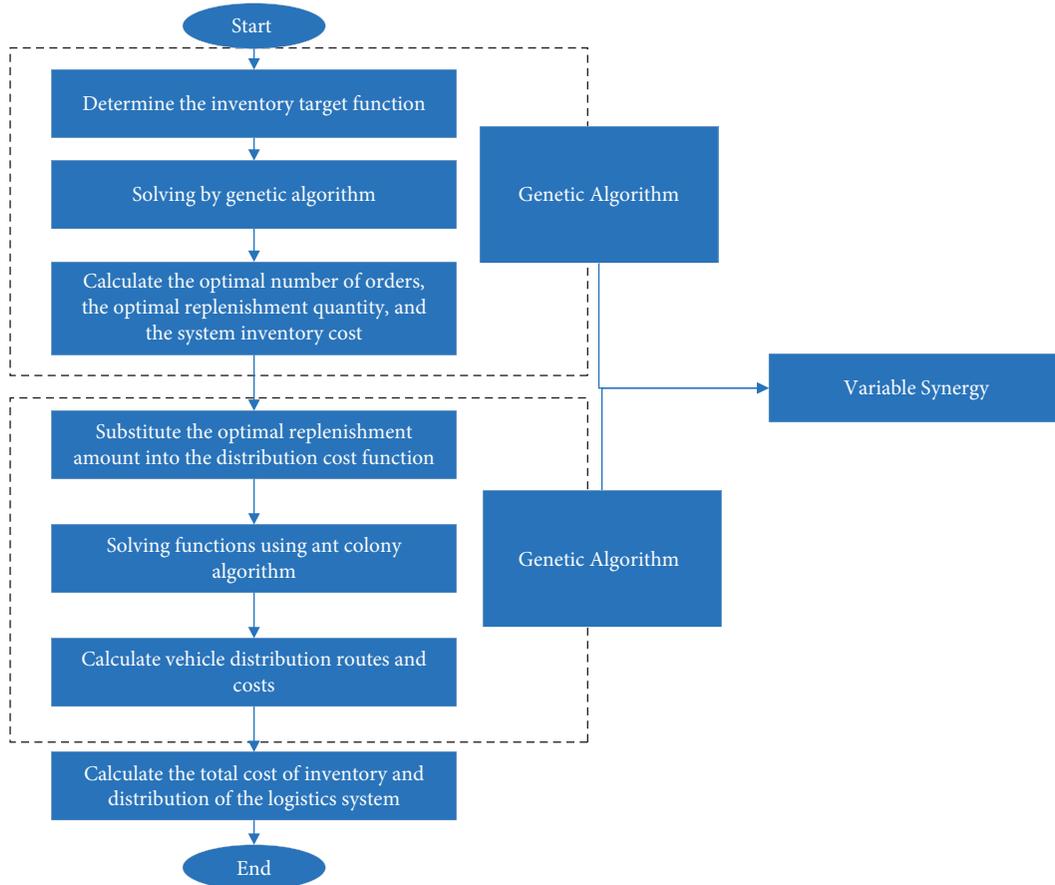

FIGURE 5: Collaborative optimization solution process.

$$P_{ij}^k(t) = \begin{cases} \frac{\tau_{ij}^\alpha(t)\eta_{ij}^\beta(t)}{\sum_{s \in j_k(i)} \tau_{is}^\alpha(t)\eta_{is}^\beta(t)}, & j \in j_k(i) \\ 0, & \text{else,} \end{cases} \quad (21)$$

where $\tau_{ij}(t)$ is the amount of pheromone secreted on path (i, j) when the ant moves from city i to city j at time t ; η_{ij} is the heuristic function (visibility), which refers to the expected value of ants moving from city i to city j ; α is the pheromone inspiration factor; β is the visibility importance expectation heuristic factor; and $j_k(i)$ is the set of cities that ant k untraversed, where $j_k(i) = \{1, 2, \dots, n\}$.

This paper mainly designs the algorithm of the collaborative optimization model of inventory and distribution of urban fresh agricultural products cold chain logistics. Firstly, according to the characteristics of the constructed inventory optimization model and distribution optimization model, the design idea of the algorithm of this collaborative optimization model is determined, and the solution is finally determined by using a genetic algorithm and ant colony algorithm together, and the relevant theoretical analysis of genetic algorithm and ant colony algorithm is conducted.

3. Results

The object of this case study is a large fresh product retail supermarket in Beijing, which is the first batch of fresh product supermarkets in China, and after years of development, the company operates a chain of fresh product supermarkets covering 24 provinces and cities in China. Up to now, the company has developed more than 900 supermarket chains in the country, with an operating area of more than 6 million square meters, and has been ranked among the top 100 Chinese chains and the top 100 FMCG chains many times. The company has built its own distribution center in the sales region, which is responsible for the storage, processing, and distribution of regional supermarket products.

In recent years, due to the popularity of green concepts, the development of fresh product supermarkets has reached a climax, and many retail supermarkets have begun to transform into fresh product supermarkets, which has led to the expansion of the fresh product market and increased competitiveness. In such a context, the company began to focus on the costs incurred by logistics, seeking ways to “reduce costs and increase efficiency” in the fresh product inventory and distribution chain, seeking to reduce fresh

food cold chain logistics costs and improve cold chain logistics operational efficiency through advanced operational management methods and inventory management control strategies. Therefore, the thesis selects a secondary cold chain logistics network consisting of 18 fresh food supermarket chains and 3 fresh food distribution centers in Beijing to test the synergistic optimization of inventory and distribution according to the needs of the enterprise.

The case designed in this paper is 18 fresh food supermarkets with 3 distribution centers, which belong to the multidistribution center's inventory and distribution cooperative optimization problem. In the process of solving the example, this paper firstly applies the center of gravity method according to the above section to transform the multidistribution center problem into the inventory and distribution of three independent distribution centers and then selects one of the distribution center problems as an example and applies the central solution strategy, distribution optimization problem, single distribution center inventory, and distribution cooperative optimization model and genetic algorithm in the above section to solve the problem.

In order to verify the validity of the synergistic optimization model of cold chain logistics inventory and distribution of fresh agricultural products, this paper analyzes the synergistic optimization of cold chain logistics inventory and distribution of three products in an order cycle $T=3$ days in the distribution center of this large chain fresh supermarket. The freshness decay coefficients of the three products were $\alpha_1 = 2.2$, $\alpha_2 = 2$, and $\alpha_3 = 2.1$ under the case of freshness preservation measures.

In the secondary cold chain logistics system, the distribution center is responsible for the inventory and distribution of all supermarkets' fresh products, and the instantaneous replenishment and real-time information sharing between the distribution center and supermarkets can be realized. Based on the above coordinates of each fresh food supermarket and distribution center, a plane coordinate system is established on the map.

In order to facilitate the subsequent calculation, each supermarket in the distribution center is numbered; the distribution center is numbered as 0; and supermarket 1, supermarket 2, supermarket 3, supermarket 6, supermarket 8, supermarket 13, supermarket 15, supermarket 16, supermarket 17, and supermarket 18 are numbered as 1 to 10, respectively. Meanwhile, according to the inventory and distribution cooperative optimization model for distribution path planning, the distance between fresh produce supermarkets and the distance to the distribution center are measured.

In this example, the relevant parameters of the distribution center for each product are shown in Table 1.

The relevant parameters of the supermarkets for each product are shown in Table 2.

The maximum market share of 10 supermarkets for the three products, which is the maximum market demand, A_{ij} , is shown in Table 3.

The distribution-related parameters are shown in Table 4.

Among them, this paper is a collaborative optimization model established in the case that the replenishment intervals of various products in supermarkets are different, and the replenishment intervals of the same product in each supermarket are also different. The replenishment intervals of each product are different, Resulting in a distribution path based on the solution of one product that is not suitable for the distribution path of another product, and path planning is a dynamic process. Therefore, in order to facilitate the subsequent solution of path planning, this section specifies that each supermarket replenishes only one product as an example for system inventory optimization and distribution path optimization.

In this paper, the original genetic algorithm is used to obtain the local optimal solution after 50 iterations, that is, the optimal number of replenishment and replenishment quantity for each retailer when the total inventory cost of the distribution center and retailer of the fresh supermarket cold chain logistics secondary system is minimal. The optimal solution is the lowest point of the iterations.

According to the design of the genetic algorithm and the ant colony algorithm, the distribution strategy and distribution path of the distribution center are calculated. (1) The calculation results of the genetic algorithm are based on the inventory and distribution optimization model of fresh agricultural products cold chain logistics, and the inventory optimization solution of the calculation case is carried out using the genetic algorithm to derive the minimum inventory cost of the secondary logistics system of this fresh supermarket chain within one order cycle of the distribution center, including the optimal number of deliveries and the optimal distribution quantity. In the process of designing the genetic algorithm, the relevant parameters are set. The specific values are as follows: pop size of 100, cross possibility of 0.85, mutation possibility of 0.015, and max generation of 50 times.

The objective function of minimizing the inventory cost of distribution centers and retailers is solved by MATLAB genetic algorithm, and the local optimal solution is generated after 100 iterations of operation, and the total inventory cost of distribution centers and retailers in the example tends to be an optimal solution. The optimal replenishment strategy for each retailer within 3 days of an order cycle of the distribution center is shown in Table 5.

The costs associated with the distribution centers of the fresh product supermarket chain and the 10 supermarkets during the ordering interval of the distribution centers include inventory holding costs, freshness costs, damage costs, purchasing costs, and additional costs. Based on the actual research data, the total costs associated with the distribution centers were 127,343.2 RMB, and the total costs associated with the supermarkets were 8945.39 RMB.

Based on the above genetic algorithm solution, the distribution center delivers to 10 fresh food supermarkets within 3 days of the ordering cycle, and the replenishment cycle is calculated based on the number of deliveries to each supermarket. It can be concluded that the replenishment cycle of each supermarket has decimal places, which is not conducive to calculation, so the time is converted into hours

17	2	6	171.30	168.09	3.21
18	2	4	248.71	241.94	6.77

for calculation, the time unit of the distribution service is hours, and the total time of replenishment is 72 hours.

Based on the optimal number of replenishments and the optimal replenishment quantity of each fresh food supermarket calculated by the genetic algorithm and the operating time of each replenishment of the supermarket, the optimal distribution path of the distribution center was solved by using the ant colony algorithm. According to the results of the algorithm, the distribution center makes 17 deliveries for each supermarket within 3 days of an order cycle; and the total vehicle travels 767.2 km; and the total cost of delivery is 4,695.1 RMB. In this paper, we firstly use a genetic algorithm to solve the minimum total inventory cost of distribution centers and fresh food supermarkets and calculate the optimal replenishment quantity and replenishment times for each fresh food supermarket, based on which we use an ant colony algorithm to solve the distribution path with the minimum distribution cost. Therefore, the total cost of the

cold chain secondary logistics system of the fresh supermarket chain within one order cycle 3 of the distribution center is 140,983.69 RMB.

In order to further elaborate on the rationality and feasibility of the urban fresh product cold chain logistics inventory and distribution synergy optimization model, this section introduces the data related to inventory and distribution in the actual operation of the fresh product supermarket chain for comparison, which mainly includes the order quantity of the distribution center, the replenishment quantity and the replenishment times of each supermarket.

The distribution center inventory costs, supermarket inventory costs, distribution costs, and total system costs for the actual operation of this fresh product supermarket with separate decisions are compared to the costs associated with the inventory and distribution synergy strategy derived in this paper, as shown in Figure 6.

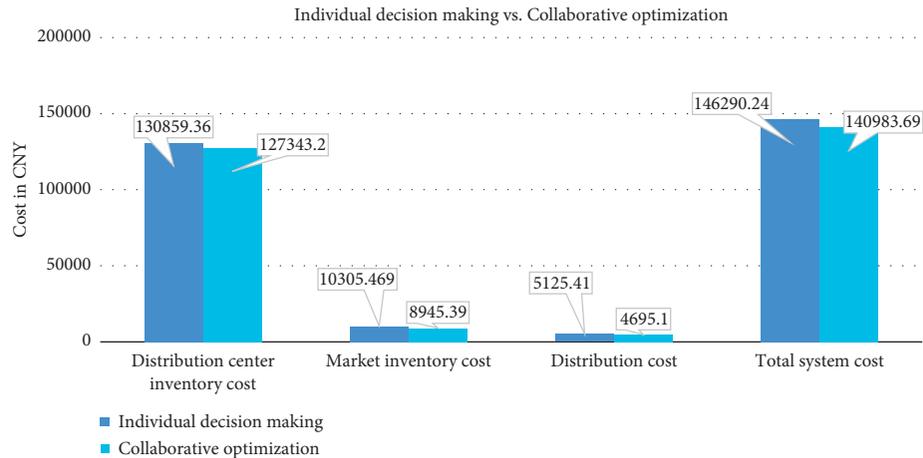

FIGURE 6: Cost comparison of stand-alone decision-making and collaborative optimization.

Compared with the separate decision, the total cost of the system solution of inventory and distribution co-optimization in this paper is reduced by 5,306.55 RMB. This is because the synergistic optimization model is based on the freshness function and the deterioration rate function of fresh agricultural products, which largely ensures the freshness of fresh products and reduces the deterioration loss of products, thus reducing the cost of goods loss in the distribution center. In addition, the distribution cost is reduced by 430.31 RMB, which is mainly due to the fact that the distribution model is solved in the delivery path with the lowest delivery cost, which reduces the cost of distribution to a certain extent. After solving the collaborative optimization model, the supermarket inventory cost is reduced by 1,360.079. This is due to the fact that the collaborative optimization model in this paper is based on the fact that customer demand is determined by the freshness of fresh products and the sales price. The model ensures that the sales volume of the supermarket increases per unit replenishment cycle and the time that the products occupy the inventory is reduced by minimizing the decay rate of freshness, thus reducing fresh product supermarkets' inventory costs.

4. Conclusion and Discussion

This paper takes urban fresh agricultural products cold chain logistics as the research object; analyzes the relationship among freshness cost input, freshness, and deterioration rate; establishes a collaborative optimization model of urban fresh agricultural products cold chain logistics inventory and distribution based on a single distribution center under the condition that the customer market demand is influenced by both freshness and sales price of fresh agricultural products; and proposes a partitioned solution strategy for the multidistribution center problem. Among them, the main work of the thesis is as follows. (1) The thesis takes the secondary system composed of urban fresh agricultural products cold chain logistics distribution center and retailer as the research object; analyzes the relationship between fresh agricultural products freshness function, deterioration rate function, freshness cost input, and so on; also analyzes the relationship

between customer demand and product freshness and sales price; and establishes the urban fresh agricultural products cold chain logistics inventory and distribution collaborative optimization based on single distribution center. The model of optimization is established. (2) The thesis analyzes the structure of the cold chain logistics secondary network with multiple distribution centers for fresh agricultural products, proposes a strategy of partitioning solution, uses the center of gravity partitioning method to partition each retailer, converts the multiple distribution center problem into a single distribution center problem, and finally solves it through the single distribution center inventory and distribution cooperative optimization model. (3) The thesis realizes the combination of a genetic algorithm and ant colony algorithm to solve the problem. Firstly, the genetic algorithm is used to solve the optimal distribution volume and number of deliveries for each retailer by distribution center under the condition that the total sum of inventory cost of fresh product distribution center and retailer inventory cost is minimized. (4) The thesis verifies the feasibility of the collaborative optimization model of inventory and distribution of urban fresh agricultural products cold chain logistics by designing practical arithmetic cases, using MATLAB genetic algorithm and ant colony algorithm, and at the end, the minimum cost, optimal order quantity, optimal distribution quantity, and distribution route are derived. (5) In the modeling process, the relationship between freshness input cost and freshness and deterioration rate is considered more comprehensively, and the effective customer demand is combined with freshness and sales price to design the actual customer demand function. At the same time, the paper comprehensively considers the actual influencing factors, such as the limitation of each retailer on the delivery time and the maximum load capacity of the vehicle.

Based on the above analysis, the following conclusions can be drawn: (1) The cooperative optimization model of inventory and distribution of urban fresh agricultural products cold chain logistics based on the freshness and customer demand influenced by both freshness and sales price is practical and feasible, and the model solution can realize the cooperative

optimization of inventory and distribution of urban fresh agricultural products cold chain logistics secondary system. (2) The algorithm designed in this paper is feasible, and the genetic algorithm and ant colony algorithm of the collaborative optimization model designed in this paper can solve the optimal solution of the secondary system of urban fresh product cold chain logistics through the calculation example. (3) The strategy of the center of gravity partitioning designed in this paper can realize the solution of the problem of multiple distribution centers corresponding to multiple retailers and convert the complex multidistribution center problem into a single distribution center problem to be carried out; therefore, the solution strategy has certain practicality.

The problem of collaborative optimization of inventory and distribution of urban fresh agricultural products cold chain logistics involves complex and uncertain constraints and influencing factors in practice, which needs continuous improvement in practice. Based on the previous theories, this paper further investigates such problems and establishes an inventory-distribution collaborative optimization model for urban fresh product cold chain logistics, considering freshness cost input, freshness, deterioration rate, and customer demand, and designs an algorithm that conforms to the model, but many practical influencing factors are ignored in the modeling and solving process, so there are more problems that need further research, such as: (1) this paper does not study the freshness of fresh agricultural products in the inventory and distribution of loading and unloading, handling, and other aspects of the irreversible damage to product quality caused by irregularities in the operation, but in the actual distribution process, the damage caused by a handling of the product exists, so this factor needs to be taken into account in the subsequent research. (2) The paper only considers the case that the distribution center delivers only one product for each retailer in the solution of the calculation, but in practice, there are multiple products replenished by each retailer, and the replenishment cycle of each product is different for each retailer, so this situation needs to be improved in the subsequent research. (3) The model in this paper is a system optimization model constructed based on the fact that customer demand is influenced by both product sales price and freshness, but in the actual operation of fresh product supermarkets, customer demand is stochastic, so the theory related to stochastic demand should be improved in future research on inventory and distribution optimization.

Due to the rapid development of hardware devices, the analytical processing and algorithmic capabilities of computers are also being enhanced, which makes machine learning play an increasingly important role in the field of quantitative investment. For this reason, the possibility of replacing traditional human traders with automated investment algorithms that have been trained several times has become a hot topic in recent years. The majority of machine algorithms used in today's stock trading market are supervised learning algorithms, which are still unable to objectively analyse the market and find the optimal solution for market trading on their own. To solve the two major challenges of environment awareness and automated decision-making, this study uses three core algorithms, PPO, A2C, and SAC, to build a set of ensemble automated trading strategies in a deep reinforcement learning-based framework. The *ensemble* trading strategy combines the advantages of each of the three algorithms to make the original reinforcement learning algorithm more adaptive, and to avoid consuming a large amount of memory when training the network, the study uses the PCA method to compress the dimension of the stock feature vector. We test our algorithm on 40 A-share stocks with sufficient liquidity and compare it with different trading strategies. The results show that the ensemble strategy proposed in this study outperforms three independent algorithms and two selected baselines, achieving an accumulated return of around 70%.

1. Introduction

Increasing computer processing power has led to the gradual digitization of financial market transactions, and it has become a reality to use computers to access large amounts of financial market data and complete high-frequency transactions within milliseconds [1]. The massive amount of data in the financial markets is often highly dimensional and noisy, and traditional econometrics cannot accurately quantify this multidimensional market data, so forecasting financial market data has always been a challenging problem in finance [2]. Most of the quantitative trading algorithms in the market today use supervised learning methods, which rely on manual design to select features and construct labels [3]. Quantitative trading systems under this approach require external managers with a certain level of financial knowledge to be able to change labels and parameters in a timely manner in response to market conditions, and therefore, the objectivity and independence of the algorithm cannot be guaranteed [4]. In contrast to supervised learning

methods, reinforcement learning methods have the ability to learn control strategies from high-dimensional data [5]. Reinforcement learning methods do not require supervision by external managers and can continuously optimize paths to achieve the best cumulative returns through rewards and penalties during the interaction of market transactions [6].

Although reinforcement learning offers a new way of thinking about the analysis and prediction of financial data, there is still room for improvement. The first is that derivative algorithms on reinforcement learning often ignore the dominance of irrational investor sentiment in financial markets in the pursuit of decision objectivity, and researchers often combine sentiment mining with supervised algorithms, but few apply this to reinforcement learning methods [7]. This study addresses this issue by expressing market sentiment as a sentiment indicator and effectively improving the adaptability of algorithms to irrational markets. Secondly, it has been shown that reinforcement learning relies on a large amount of external environment as input data, but existing trading algorithms tend to select

fewer technical indicators as the spatial state of the underlying investment to alleviate memory pressure [8], making the benefits of reinforcement learning methods less impressive than supervised learning methods. This study uses the PCA algorithm to compress the spatial vector dimension, incorporating more technical indicators to extend the spatial state of the underlying under the same memory pressure. In addition, the researcher found that different agents are suitable for different conditions of the stock market, which means that the model constructed by a single agent does not have the effectiveness and generalization ability in the face of different stock assets and different market environments [9]. So, this study constructs an ensemble strategy of three algorithms: PPO, A2C, and SAC. The ensemble strategy can choose the appropriate agent to maximize the accumulated return for different market environments and situations, so the ensemble strategy is more stable and reliable than a single strategy.

In the design of the ensemble model, we firstly constructed a deep reinforcement learning framework, setting up the environment, state space, and action space. Secondly, we designed a reward and punishment function for the agent to ensure that it can effectively optimize its own decisions. Thirdly, we connect the three different agents effectively through the Sharpe ratio. Finally, we demonstrate the effectiveness of the ensemble algorithm through ablation experiments and two baselines.

The study is structured as follows: Section 2 presents the relevant literature in the same research area, Section 3 describes the theoretical approach used in this study, Section 4 describes the detailed construction process of the ensemble model, Section 5 presents the data processing and empirical results, and finally we place the summary in Section 6.

2. Literature Review

Reinforcement learning has now evolved from its initial stand-alone application to a multiplicity of applications in combination with deep learning. It has been extensively investigated by many researchers in the field of finance due to its ability to effectively deal with continuous decision-making.

In terms of practical applications of reinforcement learning, Moody and Saffell proposed to construct portfolios and trade stocks with recurrent reinforcement learning and eventually proved that the returns of the reinforcement learning strategy were higher than those of the buy-and-hold strategy [10]. Tan et al. added an adaptive network fuzzy inference system as a supplement to the reinforcement learning framework to design a high-frequency trading strategy [11]. Sun and Bi selected convolutional neural networks and LSTM neural networks to build up and down classification models, respectively, based on which a high-frequency trading strategy was proposed and backtested with the main asphalt futures contract and demonstrated that the high-frequency trading strategy based on convolutional neural networks and long- and short-term memory neural networks had better profitability [12]. Dai and Zhang demonstrated that the reinforcement learning

model outperformed the buy-and-hold strategy and MACD strategy in stock selection [13]. Lu and Salem applied the long- and short-term memory model (LSTM) to reinforcement learning and backtested it through forex trading, and the results demonstrated that the improved reinforcement learning model could effectively control the number of trades and maintain stable profitability [14]. Hu et al. constructed a cointegrated pair trading model based on the reinforcement learning SARSA algorithm and conducted simulation trading experiments on the Chinese bond market and demonstrated that the model outperformed the traditional model in all aspects and could significantly improve the profitability of the trading system [15].

In terms of algorithm design for reinforcement learning, Zhang and Wang and other scholars (2015) constructed a stock prediction model based on neural networks, which can solve the problem of high dimensionality of input data through genetic algorithms, and the results showed that genetic algorithms can improve model training efficiency [16]. Yung added news headlines for market opinion mining on the basis of stock time-series price data and in this way effectively improved the correct rate of model decisions [17]. Zhou et al. improved the traditional quantitative trading algorithm using the sentiment indicator ARBR, enabling the improved reinforcement learning algorithm to have richer returns in irrational markets [18]. Li et al. proposed a new trading model for deep reinforcement learning, which used two different reinforcement learning methods, stacked denoising self-coding (SDAEs) and long- and short-term memory (LSTM), and can effectively extract features from the raw data to build a robust trading agent, and experimental results show that the model achieves stable risk-adjusted returns in both the stock and future markets [19]. Gabrielsson and Johansson introduced seven new features based on Japanese candlesticks into the reinforcement learning input, and their HFT system outperformed the S&P 500 index and significantly outperformed the basic RRL algorithm in the test [20].

It is therefore easy to see that trading models built on reinforcement learning are well established and widely used in the financial field, achieving good returns in both the equity and foreign exchange markets. In terms of improvements to reinforcement learning algorithms, researchers have focused on improving different neural network structures and expanding the spatial state of the model.

3. Methodology

3.1. Reinforcement Learning Theory. Reinforcement learning is an important machine learning approach in current quantitative trading research [21]. Unlike common machine learning algorithms, the core of reinforcement learning is to allow an agent in an interactive environment to calculate the reward value for different actions using the current action state at the moment and to continuously optimize the agent's internal policy along the direction of the best reward value until the best policy is found [22]. In summary, the reinforcement learning framework consists

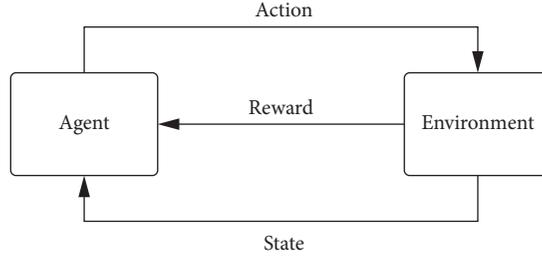

FIGURE 1: Structure of the reinforcement learning algorithm.

of the interactable state of the agent in the current environment, the different actions resulting from the decision, the policy for the decision made in the current state, the reward function used to calculate the reward value at the end of the action, the value function for the different actions and states, and the environment used to implement the agent interaction process.

The flow of the whole reinforcement learning algorithm is shown in Figure 1. At time t , the agent obtains the current state of the environment S_t and uses the policy function to process S_t to output the action a_t in the current state. After the action is completed, the action a_t will be applied to the environment, causing the environment state to change from S_t to S_{t+1} , and then, the function uses the action transfer state to calculate the reward value τ_t for the action a_t . The agent can use τ_t to continuously optimize future action strategies and ultimately maximize the cumulative reward value. The optimal strategy can be shown in (1), where π is the chosen strategy, γ is the discount rate, T is the total moment of interaction, and a is the state space.

$$\pi^* = \operatorname{argmax}_{\pi} E_{\pi} \left\{ \sum_{T=0}^{\infty} \gamma^T r_{t+T} | S_t = S \right\}, \forall S \in S, \forall t \geq 0. \quad (1)$$

3.2. Markov Decision Process. The Markov decision process is the classical algorithm for reinforcement learning modelling, and its main idea is to perform dynamic planning with finding the maximum cumulative payoff on the MDP [23]. If the current state, which contains all relevant historical information, can be used to determine the future cumulative payoff, then we can consider the state to have Markovianity, and this property can be described as follows:

$$P(s_{t+1}|s_t) = P(s_{t+1}|s_t, \dots, s_2, s_1). \quad (2)$$

We can describe the MDP using a set, as in (3), where S is the state space, which stores all states in the environment, A is the action space, which represents all actions that the agent can interact with, and P is the transfer probability, which represents the probability that an action taken by the agent in a state will result in a state transfer, which we usually identify as needing to satisfy $0 \leq p(s|s_t, a_t) \leq 1$. R is the reward generated by the action.

$$M = \{S, A, P, R, \gamma\}. \quad (3)$$

3.3. A2C. The actor-critic approach is one of the mainstream approaches in reinforcement learning, combining the advantages of both value-based and policy-based classical algorithms [24]. The core idea is to use the value of the state actions predicted by the critic model to optimize the decision-making behaviour of the actor model, and by alternating training, the generated actions can be made to better match the current environment and state. The structure of the model is shown in Figure 2.

Since the original AC model was slow to converge, the A2C algorithm was proposed to reduce the variance of the strategy gradient by adding a baseline to the strategy gradient while keeping the expectation of the strategy gradient random variable constant, allowing for faster convergence.

The gradient formula of the AC algorithm in its original state can be expressed as follows:

$$\nabla_{\theta} J(\theta) = E_{\pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(s, a) (Q_{\pi}(s, a) - B)]. \quad (4)$$

Since the baseline function B is only related to the state S and not to the action A , the above equation can be derived as follows:

$$\nabla_{\theta} J(\theta) = E_{\pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta} Q_{\pi}(s, a)]. \quad (5)$$

Since the baseline function B is a function independent of the action A , we can further optimize the formula using the state value function $V(s)$ as the baseline $B(s)$ and let the dominance function be $A(s, a) = Q(s, a) - V(s)$. Eventually, we can obtain the optimized gradient as follows:

$$\nabla_{\theta} J(\theta) = E_{\pi_{\theta}} [\nabla_{\theta} \log \pi_{\theta}(s, a) A(s, a)]. \quad (6)$$

In this study, the MLP neural network is chosen to build the A2C algorithm. The algorithm is updated step by step during training, and its training process is seen in Table 1.

3.4. PPO. The principle of the PPO algorithm is to represent the policy parametrically as $\pi_{\theta}(a|s)$, using a parametrized linear function or neural network to represent the policy [25].

The PPO algorithm strategy gradient is implemented by calculating an estimator combined with a stochastic gradient ascent algorithm, and the updated formula can be seen as follows:

$$\theta_r = \theta_b + \alpha \nabla_{\theta} J, \quad (7)$$

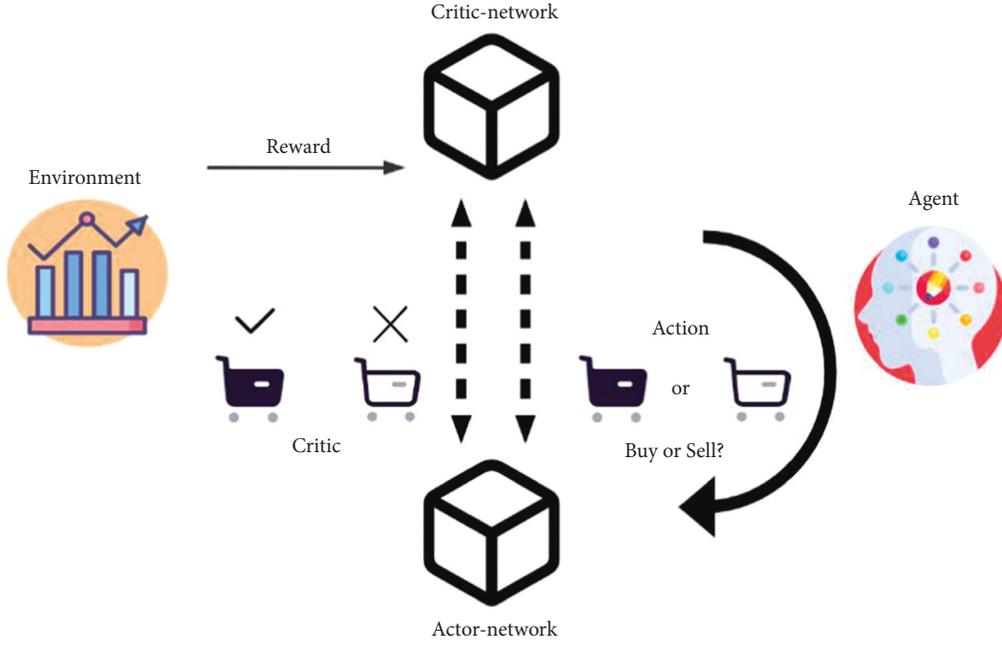

FIGURE 2: Structure of the actor-critic model.

For episodes = 0, 1, 2, . . . , N do :
Get state S and calculate $\pi(AS; \theta)$ to get action A
IF the episode does not end there:
Get S' with reward τ
Using critic networks to obtain return values to estimate Q
Calculating the gradient using Q values and updating the actor network
Updating the critic network to reduce the difference
Update status S
End
End
To convergence

where θ_b is the policy parameter before the update, θ_r is the updated policy parameter, α is the learning rate, and ∇_{θ} is the importance weight. J is the optimization objective, which is the expected value of the future reward in state S .

3.5. SAC. SAC is a heteroskedastic AC algorithm developed for maximum entropy reinforcement learning [26]. Unlike other methodological theories, the SAC algorithm changes the goal of reinforcement learning by the introduction of the concept of entropy, which actually improves the exploratory and robustness of the algorithm [27].

The entropy [28–35] of the distribution x can be expressed as follows:

$$H(p) = E_{X \sim p}[-\ln p(x)]. \quad (8)$$

In order not to miss any valid actions and trajectories and to promote strategy randomization for greater

robustness and exploration, the maximum entropy reinforcement learning algorithm requires the strategy function to output the action expressed as follows:

$$\pi^* = \operatorname{argmax}_{\pi} E_{S_t, a_t \sim \rho_{\pi}} \left[\sum_t r_t + \alpha H(\pi(\cdot | S_t)) \right]. \quad (9)$$

4. Ensemble Model Development

The ensemble model can be divided into two parts: the first part is to select a suitable algorithm from A2C, PPO, and SAC as agent, and the second part is to build the state space of the stock through stock price, technical indicators, and sentiment indicators to describe the stock trading market environment [36–39]. When these two parts are completed, the action space and reward function will link the agent with the environment so that the agent

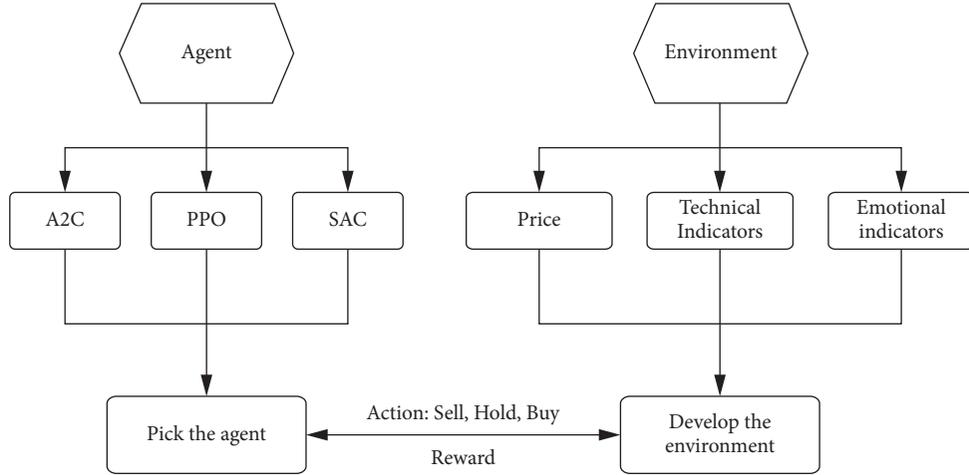

FIGURE 3: Structure of the ensemble strategy.

can make continuous decisions to maximize the cumulative return. The structure of the ensemble model is shown in Figure 3.

4.1. Select the Agent. In this study, we use a several months' long window to train all three agents simultaneously, and every three months, we retrain our three agents. At the same time, we use the latter three months of the training window to validate the performance of the three different agents and select the agent with the highest Sharpe ratio as the agent of the ensemble strategy for the underlying investment. The following equation shows how the Sharpe ratio is calculated:

$$\text{Sharpe ratio} = \frac{\bar{r}_p - r_f}{\sigma_p}. \quad (10)$$

4.2. Setting Up the Environment. We incorporate the daily opening and closing prices of the stock: the technical indicators of the stock and the sentiment indicator ARBR, which describes market sentiment, as the spatial state of the stock.

It is worth mentioning that to incorporate more indicators as the spatial state of the stock while relieving the memory pressure on the algorithm, we used the PCA algorithm to compress the original 24-dimensional feature vector to 20 dimensions. Figure 4 shows the correlation hotspots of the technical indicators selected by the ensemble model. It is easy to see that there is a large positive correlation between vol10 and vol20 and a large negative correlation between the deviation rate BIAS and MA, so the PCA algorithm can be used to reduce the dimensionality.

4.3. Transaction Cost. Since every transaction in the stock market incurs transaction costs and the rules for transaction costs in the stock exchange vary from country to country, we have set a uniform transaction cost of 0.1% of the value of each transaction.

4.4. Reward Function. We define the reward value as the maximum profit that each group of stocks can take in a given period of time, expressed as follows:

$$r_t = p_t - p_{t-1}, \quad (11)$$

where r_t is the value of the reward currently received, p_t is the price of the stock at time t , and p_{t-1} is the price of the stock at the previous time. The reward value is therefore the difference between the two momentary prices. When the current price is greater than the past price, a positive reward value is obtained; when the current price is lower than the past price, a negative reward value is obtained. The final cumulative return is as follows:

$$R_t = \sum_{t=1}^T r_t. \quad (12)$$

4.5. Action Space. To make it easier to calculate the profitability of the ensemble model in the stock market, we do not consider shorting trades in the stock and simply use buy, sell, hold, and wait and see as the action states of the stock. This can be expressed as follows:

$$a = \begin{cases} 1, & \text{Buy,} \\ 0, & \text{Wait and see,} \\ -1, & \text{Sell.} \end{cases} \quad (13)$$

5. Empirical Results

5.1. Data Preprocessing. We select the constituent stocks of the CSI 100 index as the pool of stocks to be traded in the pooled strategy. We use historical daily data from 1 January 2010 to 12 February 2021 for the evaluation of model returns. The stock data used in this study are downloaded via the wind terminal. As mentioned above, we split the historical stock data into two parts: one for the training of the three agents, PPO, A2C, and SAC, and the other for the validation of the three agents, including the adjustment of the learning

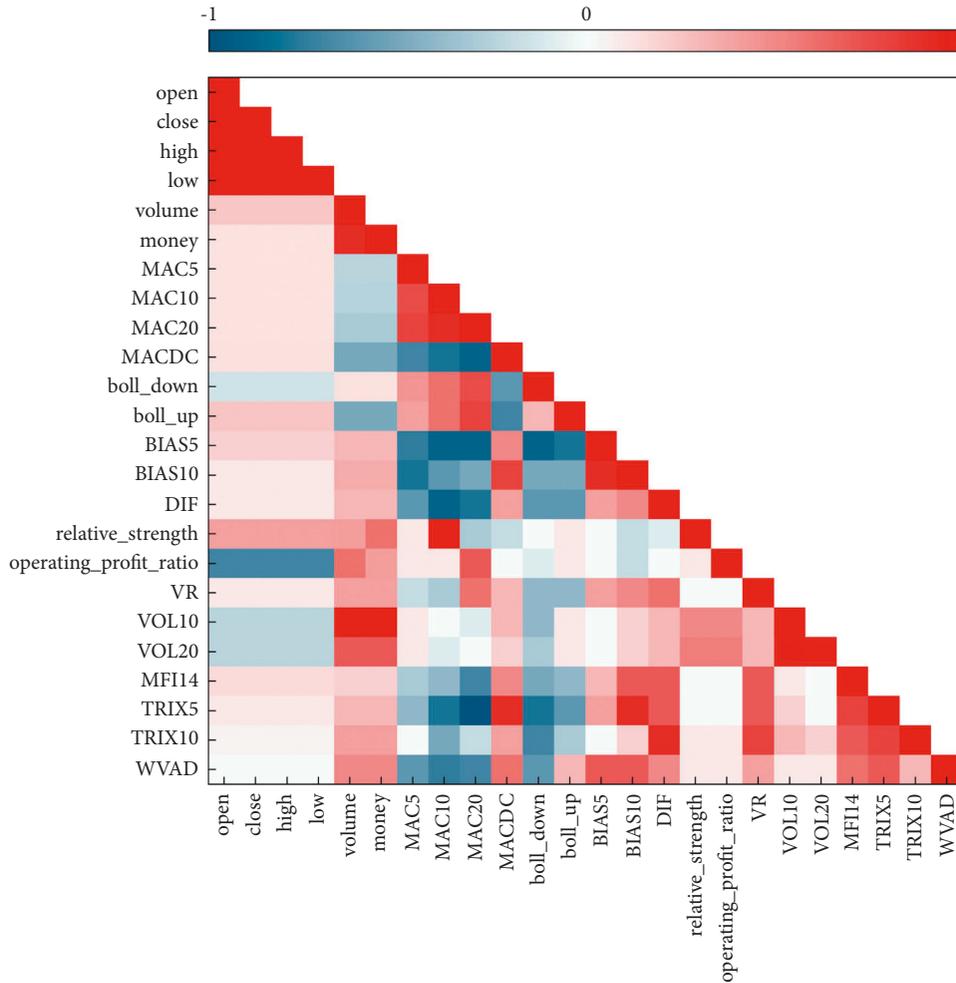

FIGURE 4: Relevance of selected technical indicators.

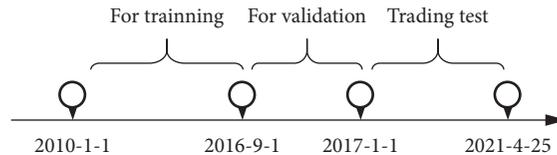

FIGURE 5: Classification of empirical data.

rate and key parameters. After selecting a suitable agent by comparing the Sharpe ratio, we start the real trading test and compare the results. The three agent’s algorithms are MACD, and Min-Variance two baselines. A breakdown of the training data used is seen in Figure 5.

5.2. Test Result. The backtest results of the ensemble model and the comparison model are shown in Figure 6. It is easy to see that the ensemble model achieved a cumulative return of 71.92% and an annual return of 17.98%, which is higher than the remaining two individual agent models with the baseline in terms of return results. More detailed backtesting data are shown in Table 2. The ensemble model

has the lowest annual volatility, which proves that the model is more stable and reliable than the other models, while the min-variance model has the highest annual volatility. In terms of the Sharpe ratio, the ensemble model achieved the highest Sharpe ratio, while it had the lowest maximum capital withdrawal rate. Overall, the A2C, PPO, and SAC models all achieved above-baseline returns, demonstrating that all three models have some portfolio management capability. In contrast, the ensemble model achieved a cumulative return of 70%, while its stability, Sharpe ratio, and maximum return were better than the other models, demonstrating the effectiveness of the model in the equity market.

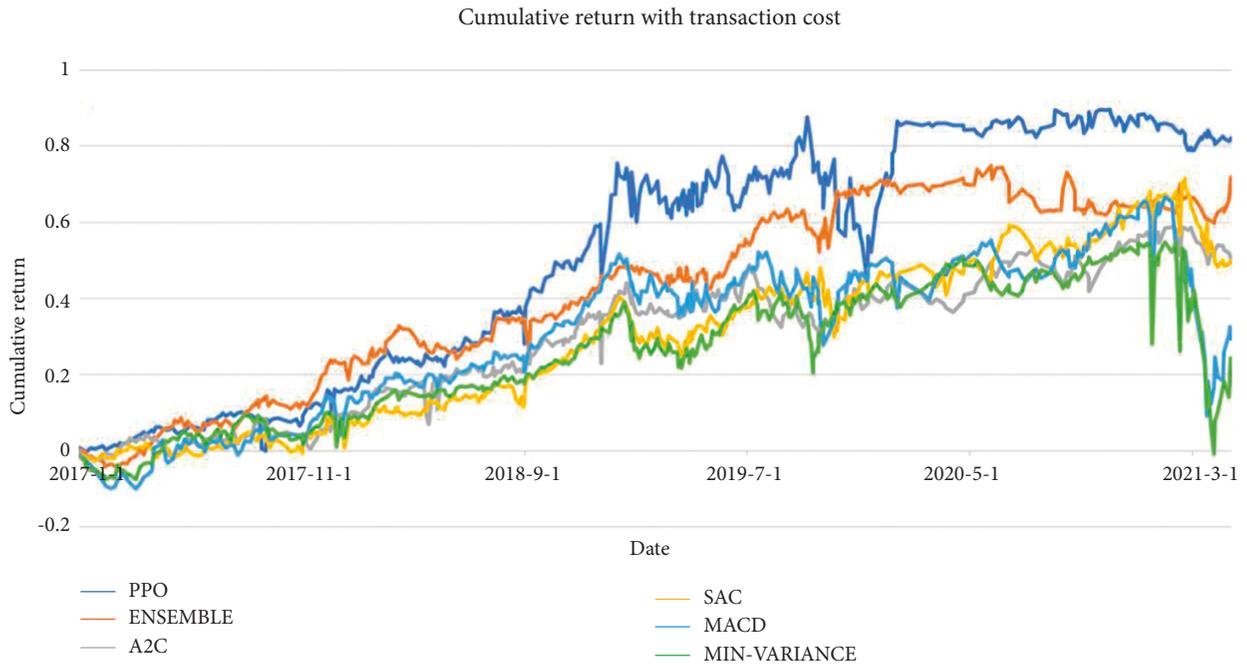

FIGURE 6: Cumulative return with transaction cost.

TABLE 2: Backtest results under different strategies.

2017/01/01–2021/04/25	Ensemble	PPO	A2C	SAC	MACD	Min-variance
Cumulative return	71.92%	81.99%	50.73%	49.23%	29.32%	24.27%
Annual return	17.98%	20.5%	12.68%	12.31%	7.33%	6.07%
Annual volatility	9.7%	14.8%	11.3%	14.9%	18.3%	20.1%
Sharpe ratio	1.41	1.12	1.15	0.78	0.42	0.45
Max drawdown	−9.5%	−25.3%	−18.4%	−14.8%	−38.8%	−34.6%

6. Conclusion

In this study, we propose an ensemble trading strategy in a reinforcement learning framework, which selects the appropriate strategy as agent from three strategies, PPO, A2C, and SAC, through the Sharpe ratio, and incorporates more stock indicators and data as the state space of the stock using the PCA method. Through backtesting on the CSI 100, the results show that the proposed model outperforms the two agent models A2C and SAC in terms of return and outperforms all three independent agent models and the two baselines in terms of Sharpe ratio, annual volatility, and maximum retracement, so the ensemble model is innovative and superior and has research and application value.

There are some problems in feature extraction and representation of Chinese mental verbs, such as low accuracy and low efficiency. In order to further improve the computational efficiency and accuracy of Chinese mental verb text, based on deep learning theory, activation function and damage function were used to optimize the original model. Considering the calculation method of model gradient, the optimization model describing the characteristics of Chinese mental verbs is finally obtained. The model can be used to analyze the variation of the characteristic parameters of Chinese verbs and the method of representation. Finally, the model error is analyzed by the method of comparative verification. Relevant studies show that the number of outputs and output results corresponding to softmax function will influence the test results of the model. By comparing the curves, it can be seen that the curve corresponding to the output number has an obvious increasing trend, while the corresponding output result curve has an opposite changing trend. The linear and nonlinear characteristics of the two curves are obvious. The real value of the mean square error function shows a change of linear increase, while the corresponding output value shows a change trend of gradual decline, which indicates that the two kinds of data have different influences on the model under related algorithms. It can be seen from the error data that the gradual increase of independent variables will improve the accuracy of the test results. Five different Chinese mental verb parameters have different manifestations in the deep learning model: among them, declarative verbs fluctuate in a small range and have little corresponding influence. However, the fluctuation of nondeclarative verbs and positive and negative declarative verbs is relatively small, and the curve is relatively stable. Negative verbs have a positive influence on the test output. Double negative verbs have negative effects. Finally, the accuracy of the model is verified by calculating the difference between experimental data and model data. This research can provide theoretical support and model verification method for the application of deep learning model in other fields of Chinese language.

1. Introduction

Deep learning models have been widely applied in artificial intelligence and other fields and also have obvious application prospects in face recognition [1], information security [2], molecular microscopy [3], retinopathy monitoring [4], and other fields. In view of the low calculation accuracy and slow calculation efficiency of partial differential equation in the calculation process, based on deep learning theory, fuzzy analysis method was adopted to extract the features of calculus calculation process, so as to obtain the periodic characteristic parameters. Through damage estimation of

characteristic parameters, an optimized deep learning model was obtained [5]. This model can provide new research thinking for the solution of calculus equation and can further improve the solution accuracy of the model and further compress the solution time of the model. Finally, the accuracy of the model was verified by comparing experimental data with model data. Through verification and analysis, it can be seen that relevant theories based on deep learning model can provide reference for solving calculus equation. The analysis and prediction of cancer have always been a difficult medical problem. There were some problems in the process of cancer analysis, such as backward analysis

methods and complicated cancer lesions. In order to further improve and optimize the tissue framework in the process of cancer treatment, artificial intelligence technology was used to analyze the original model based on deep learning model, so as to obtain a new optimization model [6]. This model mainly uses different types of activation functions to analyze the framework of treatment, so as to extract the required data and characteristic indicators. The model algorithm was used to analyze these indexes and find out the changing rules of different indexes. Finally, the deficiencies of existing data can be further optimized according to these calculation and research rules, so as to obtain the final optimization model. Through experimental calculation, different frames and types of the model can be analyzed, and finally, the accuracy of the model can be verified by experimental data.

The above studies mainly started from the fields of industry and medical treatment and failed to provide better solutions to the problems existing in the analysis of characteristic parameters of Chinese mental verbs. Based on deep learning theory, this paper uses activation function and damage equation to analyze and study the text features of Chinese mental verbs. Model gradient analysis was used to further characterize the text features of Chinese verbs so as to find the corresponding representation methods. Finally, the analysis model of Chinese mental verbs based on deep learning theory was obtained. This model can provide research ideas for the analysis of the text characteristics of Chinese mental verbs and use the method of index calculation to analyze the different indicators of Chinese. Finally, the error analysis method was used to verify the model, and the results show that the model has good advantages and application prospects. This study can provide research ideas for the textual analysis of Chinese mental verbs.

2. Theoretical Basis of Deep Learning

Based on the relevant theories of deep learning model, this paper mainly uses activation function and damage function to extract the text features of Chinese mental verbs, so as to get the change rules of Chinese mental verbs under different indicators [7, 8]. In order to introduce the change rules of different indicators into the original deep learning model, model gradient algorithm is adopted to classify and analyze the change rules of different indicators [9, 10]. The common points of indicators were found and introduced into the original model combined with algorithm rules. The optimized deep learning model was obtained by revising the original model. The calculation of model can calculate the text features of Chinese mental verbs, and the calculation results can well reflect the actual change rules of verbs. The ultimate goal is for machines to be able to learn analytically, like humans, and to recognize data such as text, images, and sound. Deep learning is a complex machine learning algorithm that has achieved far more results in speech and image recognition than previous related technologies.

Deep learning model has been widely used in feature extraction of Chinese mental verbs [11, 12]. In order to further illustrate the application process of this model in the field of Chinese mental verbs, the training process of the

corresponding deep learning model is obtained through summary analysis, as shown in Figure 1. The coordinates of the corresponding text features of Chinese mental verbs should be extracted first, and then the multipath errors are analyzed as training samples. By importing the model samples into the sample database, and then setting the relevant parameters, the corresponding analysis model of Chinese mental verb text features based on deep learning theory is obtained, and the model is further built. In order to further illustrate the accuracy of the model, the training accuracy of the model should be identified first. If the model does not meet the requirements, the corresponding sample should be imported into the sample input for circulation. If it meets the requirements, the grid of the model should be saved and then analyzed in the output grid under the action of coordinate sequence, so as to finally get the corresponding error mining.

2.1. Activation Function. Each layer of neural network contains several neurons. Through repeated training and learning, the weight value of neuron connection is adjusted, so as to obtain data processing ability [13, 14]. Neuron is the basic element of neural network. Neuron structure consists of input signal, sum, threshold judgment, activation function, and output. Input values of neurons are transmitted by input signals of other neurons through their respective connection weights, and finally, output is generated through activation function processing. x_i is the input signal transmitted by other neurons, w_i is the corresponding connection weight of other neurons, θ is the threshold, and y is the output, which is output by the following formula:

$$y = f\left(\sum_{i=1}^m w_i x_i - \theta\right), \quad (1)$$

where $f(x)$ is the activation function of the neuron.

In the activation function, different parameters have different effects on the output value [15, 16]. The variation rules of output value and activation function under the action of different neurons were further explained, and the calculation indexes of different neurons were obtained as shown in Figure 2. When the number of neurons exceeds 17, the curve increases rapidly, showing the characteristics of nonlinear change, and the increase range of the curve is relatively large. It can be seen from the corresponding activation function that it shows a downward change with the increase of neurons, and then shows a change trend of approximately linear increase with the increase of neurons. The curve then rapidly increased to the maximum value and remained stable, and then decreased rapidly under the action of higher neurons, with a relatively large fluctuation range. Through the curve changes of the two, it can be seen that the overall change is relatively obvious, with opposite change characteristics, which can reflect the actual rule of parameter change.

The activation function in neurons is usually nonlinear. Since the input and output of neurons are linearly correlated, the neuron has more powerful performance and can process

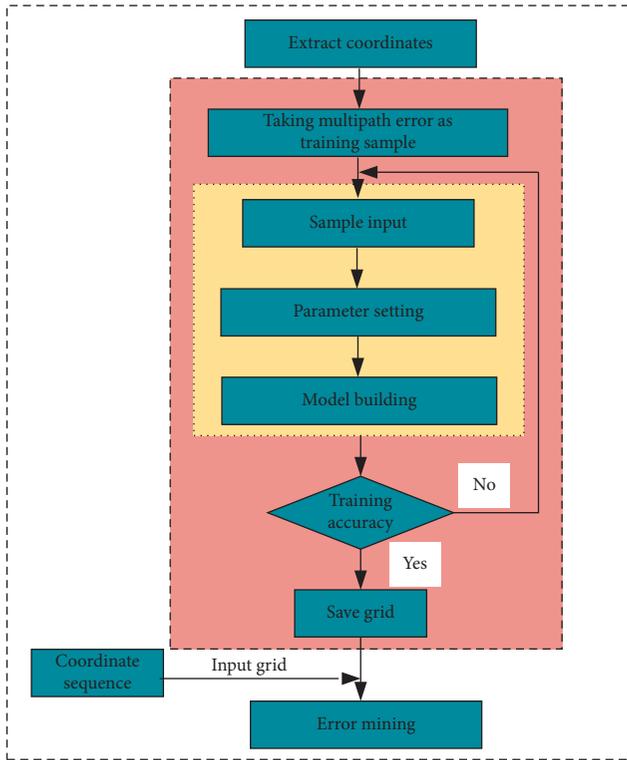

FIGURE 1: Flow chart of deep learning training.

complex feature information through the nonlinear operation of activation function. The choice of activation function changes with the further research. Common activation functions include the following:

- (1) Sigmoid function, its formula is as follows:

$$\sigma(x) = \frac{1}{1 + \exp(-x)}. \quad (2)$$

The characteristic of this function is that its output value varies between (0, 1) and can be used for dichotomies. In information science, Sigmoid function is often used as threshold function of neural network due to its properties of singleton and inverse singleton. The main disadvantages of the Sigmoid function include the following: when the input value is large, the function is not sensitive to its change perception, which easily leads to the situation that the gradient is 0 in the back propagation, resulting in slow update of weight in network training.

- (2) Tan h function, its formula is as follows:

$$\tan hx = \frac{\exp(x) - \exp(-x)}{\exp(x) + \exp(-x)}. \quad (3)$$

This function can be regarded as magnifying and translating the Sigmoid function, and its output value varies between $[-1, 1]$, and the output mean value is around 0. Compared with Sigmoid function, Tan h function performs better, has the effect of data center, and can accelerate network training, but it

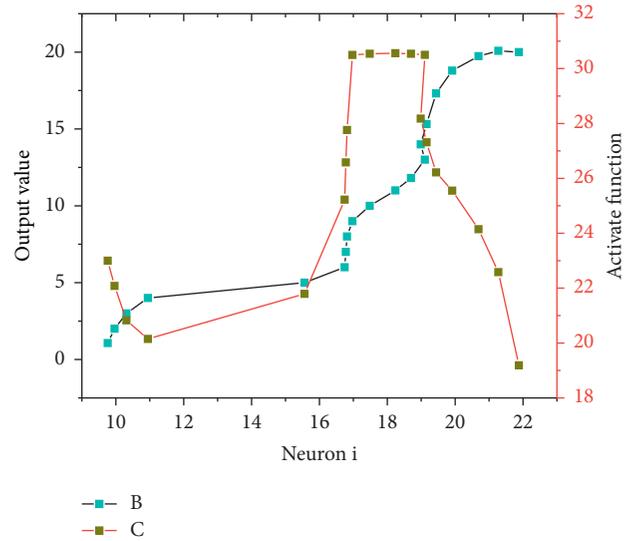

FIGURE 2: Different neuron computation index.

also has the same gradient disappearance. Moreover, the calculated data corresponding to Tan h function have more extensive output results, which makes the research scope of Tan h function more extensive.

- (3) ReLU function, whose formula is expressed as follows:

$$f(x) = \max(0, x). \quad (4)$$

This function is the most commonly used activation function in neural networks and can accelerate the convergence of network models. Compared with Sigmoid function and Tan h function, ReLU function has the advantage that when the input value is greater than 0, it will not tend to saturation with its change. However, there are also obvious disadvantages: the constant gradient of some neurons is 0, so that the corresponding parameters can never be adjusted, namely, the phenomenon of neuron necrosis.

- (4) Leaky ReLU function, whose formula can be expressed as follows:

$$f(x) = \max(ax, x). \quad (5)$$

By introducing constant a , this function solves the neuron failure phenomenon of ReLU function in the region whose input value is less than 0 and effectively reduces the disappearance of gradient.

Leaky ReLU function is an optimization of ReLU function in a linear interval. To further illustrate the accuracy of the optimization, the Leaky ReLU function and ReLU function as well as the calculation results between the parameters have been obtained through calculation and analysis, as shown in Figure 3. The test data show a two-stage variation trend with the increase of independent variables: in the first stage, the curve gradually drops to the lowest

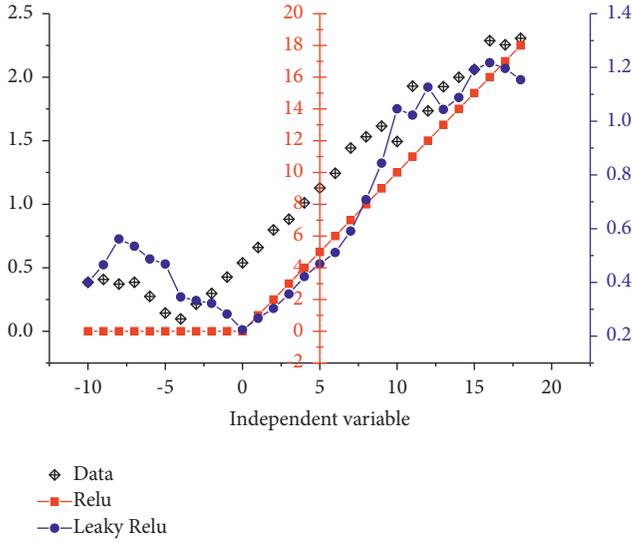

FIGURE 3: ReLU function optimization results.

point. Then in the second stage, the curve gradually increases to the maximum value, and the increment is basically the same, indicating that the linear characteristics are relatively obvious. The corresponding traditional ReLU function tends to zero in the first stage, which cannot better describe the decline and change of the test data in the first stage. In the second stage, ReLU function showed a trend of linear increase, but it could not reflect the test data well in terms of specific values and could only be consistent with the test data in the trend. Leaky ReLU function can not only explain the change of its linear decline in the first stage but also describe the change trend and specific data in the second stage relatively well. Therefore, the optimized Leaky ReLU function can better reflect the change rule of experimental data.

(5) Softmax function, its formula is as follows:

$$\text{Softmax}(x) = \frac{\exp(x)}{\sum_{i=1}^I \exp(x)}, \quad (6)$$

where x is the output of the i th neuron and I is the total number of output neurons of this layer. This function can realize feature mapping and is often used in multiclassification problems.

In softmax function, the number of neuron input and output result will affect the output value. In order to further explain the variation rule of output number and output result under different output time, the time variation curve of softmax function under different output time was calculated as shown in Figure 4. It can be seen from the changes in the figure that the number of output and the change of output result have an opposite trend. Firstly, it can be seen from the number of output that it shows a trend of slow increase with the increase of output time, and then in a higher output time, the curve shows a gradual increase.

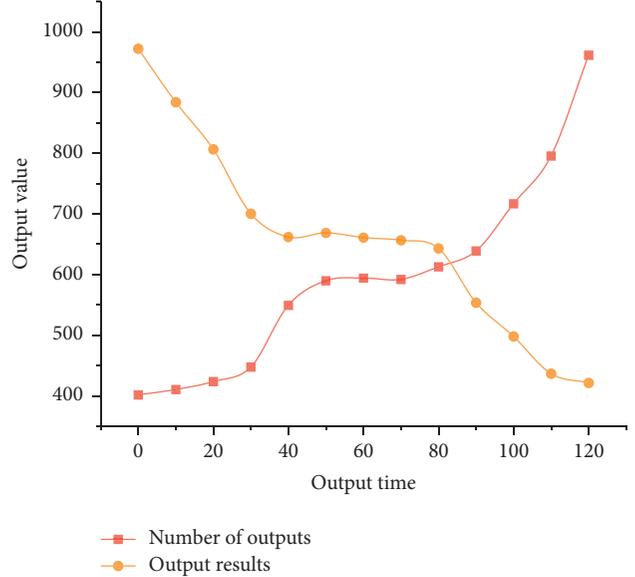

FIGURE 4: Change value of softmax function at different output time.

When the curve increases to the local maximum value, the curve gradually tends to be stable. At a higher output time, the corresponding output value of the output number curve increases rapidly to the maximum value, and the range of the curve is relatively large. The output results show a linear decreasing trend under the action of lower output time, and then the curve gradually tends to be stable. Under the action of higher output time, the corresponding output results tend to be stable. This shows that the number of outputs increases linearly while the output results decrease linearly.

2.2. *Loss Function.* Loss function is used to calculate the error between the output value and the real value during model training, which can reflect the training effect of the model in real time and provide direction for model training optimization [17, 18]. The smaller the loss function, the better the robustness of the model. Common regression loss functions include mean square error loss and mean absolute error loss. Common classification loss functions include piecewise loss, binary loss, and exponential loss [19, 20].

(1) Mean square error loss function: this function is the most commonly used loss function in regression tasks, and its formula is expressed as follows:

$$\text{MSE} = \frac{1}{N} \sum_{i=1}^N (y_i - \bar{y}_i)^2, \quad (7)$$

where N is the number of true values, y_i is the output value of the model, and \bar{y}_i is the true value. The loss function does not consider the direction of the error, but only the average value of the error, which can better reflect the error degree between the output value and the real value. Because the variation relationship between the real value and the output value is considered, the loss function is easy to

calculate the gradient. However, since the loss function assumes that the error between the output value and the real value of the model meets the Gaussian distribution, the error of outliers will be too large, resulting in poor robustness.

It can be seen that the real value and the output value have different influences on the specific data of the model by calculating the mean-square error loss function in the loss function. In order to further explain the change rule between the real value and the output value and the corresponding change of the error, the curve of the error value of the mean-square error loss function was obtained through calculation as shown in Figure 5. The true value shows a gradually increasing trend with the increase of the independent variable, and the change amount of the true value decreases is relatively consistent, indicating that its linear characteristics are obvious. With the increase of independent variables, the corresponding output results show a trend of gradual decline, and the slope of decline is constant, which indicates that the real value and the corresponding output value have obvious linear characteristics. The corresponding error is obtained through calculation, and the corresponding error curve is basically maintained at a higher level under a lower independent variable. When the independent variable increases gradually, the curve drops rapidly to the lowest point and tends to be stable gradually under the action of higher independent variable. This indicates that the independent variable will have a certain influence on the test results and also indicates that there is a certain error between the real value and the output value.

- (2) Average absolute error loss function, which is given by the absolute error value between the output value and the true value, and its formula is expressed as follows:

$$MAE = \frac{1}{N} \sum_{i=1}^N |y_i - \bar{y}_i|, \quad (8)$$

where $(y_j - \bar{y}_j)$ is the learning error. In the process of gradient descent, the loss value of the loss function will be positive or negative 1, which is not conducive to the training of the model. Although the loss function assumes that the error between the output value of the model and the real value satisfies the Laplace distribution, the Laplace distribution is more robust to the processing of outliers.

- (3) The piecewise loss function means that the loss is 0 when the output value is equal to the true value and 1 when the output value is unequal. The formula is expressed as follows:

$$F(y, f(x)) = \begin{cases} 0, & y = f(x), \\ 1, & y \neq f(x). \end{cases} \quad (9)$$

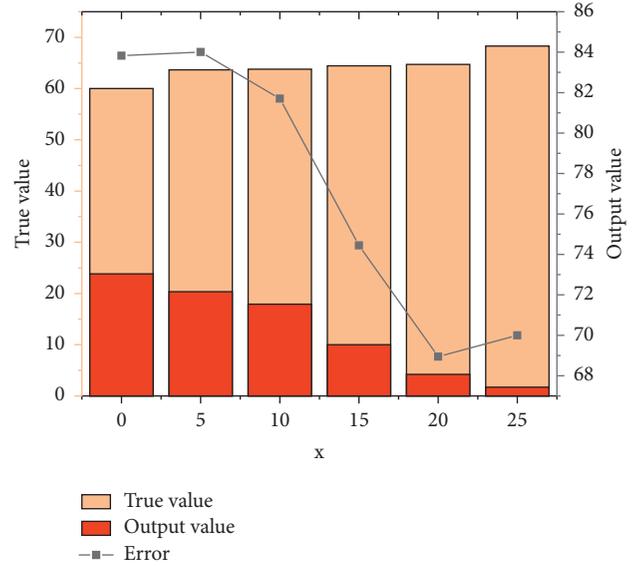

FIGURE 5: Curve of error of mean square error loss function.

The loss function directly reflects the number of classification errors.

- (4) Binary loss function is the most commonly used loss function in model classification loss calculation. It is often used in binary classification problems and can effectively reflect the degree of deviation from the true value of the output value. Its formula is expressed as follows:

$$E(y_i, \bar{y}_i) = - \sum_{i=1}^N p(y_i) \log p(y_i) - (1 - p(\bar{y}_i)) \log (1 - p(y_i)), \quad (10)$$

where N is the number of true values, $P(y_i)$ is the output probability distribution value of the model, and $P(\bar{y}_i)$ is the true probability distribution value. In the process of gradient descent, the binary loss function has a good learning characteristic of fast update with large error weight and slow update with small error weight. Considering the probability distribution of model parameters, the calculation results of binary loss function are more consistent with the characteristics of data distribution.

- (5) Exponential loss function is often used in model algorithms and is very sensitive to noise and outliers. Its formula is expressed as follows:

$$Z = \exp[-yf(x)]. \quad (11)$$

It can be seen from the above analysis that the classified loss function includes three different functions: piecewise function, binary function, and exponential function. There are differences in the calculation formulas of the three different functions, indicating that there are some differences in the corresponding calculation results. In order to further

explain the change rules of different specific functions in the classification loss function, the change curves of the classification loss function are obtained through calculation, as shown in Figure 6. First of all, it can be seen from the test data that the curve first decreases to the lowest point and then gradually tends to be stable. However, when the independent variable gradually increases, the test data show a linear increase in the change law, and its change range is relatively large. As can be seen from the piecewise loss function, when the independent variable is less than 20, the corresponding output value is zero, while when the independent variable is more than 20, the corresponding curve increases. Then, the corresponding output value shows a fluctuation trend and finally gradually tends to decline. The overall variation range of the curve is relatively small. Through the binary loss function, it can be seen that the curve drops first, then fluctuates, and finally gradually rises in three stages. The corresponding range of variation is relatively small, overall between 0.2 and 0.5. It can be seen from the exponential damage function that it has typical exponential function change characteristics. Under the action of small independent variables, the curve shows a rapid downward trend, and then the curve gradually tends to be stable. Under the action of higher independent variable, the curve decreases gradually. This shows that three different loss functions have different typical characteristics, and it is necessary to comprehensively consider two or three functions to accurately describe and analyze the test data.

2.3. Model Gradient Descent. The training process of neural network includes forward propagation and back propagation [21, 22]. Backpropagation is the core part of network training to realize the dynamic adjustment of network training parameters. Forward propagation propagates data from the shallow layer to the deep layer of the neural network until the output layer is cut off [23, 24]. During the calculation of gradient descent, the neural network can obtain the error between the output value and the real value through the loss function. Back propagation is to obtain the updated weight value of neurons calculated by gradient descent method through the errors generated by forward propagation, and then use the chain derivative formula to carry out the back propagation calculation. In gradient descent, the method of partial derivative is usually used to calculate the gradient value of the current parameter. Then a learning rate η is introduced to control the change speed of updating weight value, and the weight updating formula is as follows:

$$W = w - \eta \frac{\partial J(w)}{\partial w}. \quad (12)$$

However, in order to update the parameter values of other layers in the neural network, it is necessary to make further use of back propagation. In this process, the back propagation uses the chain rule to calculate the gradient:

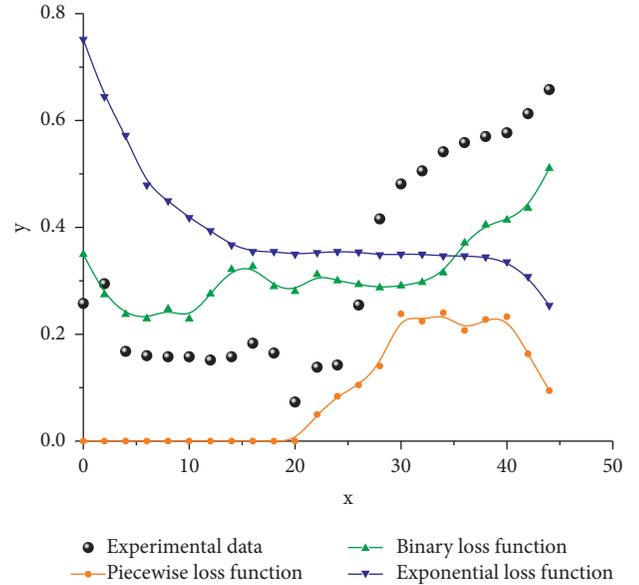

FIGURE 6: Classification loss function curve.

$$\frac{\partial J(w)}{\partial w} = \frac{\partial J^*(x)}{\partial y} \times \frac{\partial y}{\partial w}, \quad (13)$$

where w is the parameter value of the network and y is the output value of the network activation function.

Therefore, back propagation can pass the updated parameter value to the corresponding position layer by layer through the chain rule using the error function. Thus, the parameter value update formula of layer L network is as follows:

$$W = w - \eta \frac{\partial J(w)}{\partial w} = w - \eta \left[\delta \times (x^{L-1})^T \right], \quad (14)$$

where x is the input value.

The accuracy of the model can be further illustrated by analyzing the formula of the model gradient descent and the corresponding calculation results. It can be seen that different learning rates and corresponding parameter values will have different influences on the output results of the model. In order to further illustrate the influence of learning efficiency and parameter values on test data, the model gradient curve was obtained through calculation, as shown in Figure 7. It can be seen from the curve that the learning rate curve and the parameter value curve have different change rules. Firstly, it can be seen from the test data that, with the increase of input value, the corresponding test data first increases and then decreases, and the overall fluctuation range is relatively small. When the input value of the curve gradually increases, the corresponding output results show a trend of gradual increase; when it reaches the maximum value, the corresponding test data gradually decreases with great volatility. This shows that the nonlinear characteristics of the test data are obvious. As can be seen from the learning rate curve, with the increase of input value, the corresponding curve fluctuates in a larger range first, and then gradually increases to the maximum value. As the value

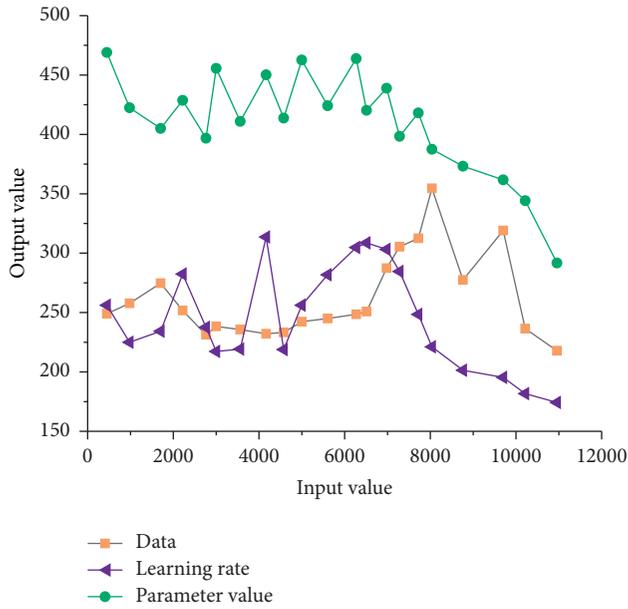

FIGURE 7: Model gradient curve.

increases, the curve drops rapidly and then flattens out. It can be seen from the variation curve of parameter values that the parameter curve fluctuates rapidly under the action of small input values, and the fluctuation range is relatively small. Then, as the input value gradually increases, the corresponding output result gradually decreases to the lowest value.

3. Analysis of the Characteristics of Chinese Mental Verbs Based on Deep Learning

3.1. Text Feature Extraction of Chinese Mental Verbs. There are many problems in the analysis of the textual features of Chinese mental verbs, mainly including the unclear description and analysis of Chinese features. In order to further analyze the characteristics of Chinese mental verb text, five different feature parameters are obtained through analysis: declarative verbs, nondeclarative verbs, positive and negative verbs, negative verbs, and double negative verbs. In order to further explain the proportion of these five verbs in actual Chinese mental verbs, the pie chart of Chinese mental verbs is obtained through statistics as shown in Figure 8. The proportion of declarative verbs is about 10%, while that of nondeclarative verbs is about 15%. The proportion of positive and negative declarative verbs is the smallest, only 7%. Negative verbs make up the most, about 43 percent, while double negatives make up about 25 percent. It can be seen from the above analysis that the proportion of negative verbs is the highest, while the proportion of positive and negative verbs is the lowest.

3.2. Analysis of Text Features of Chinese Mental Verbs Based on Deep Learning. Based on the deep learning model, the activation function and loss function are used to analyze the original model, so as to obtain the optimization value of the

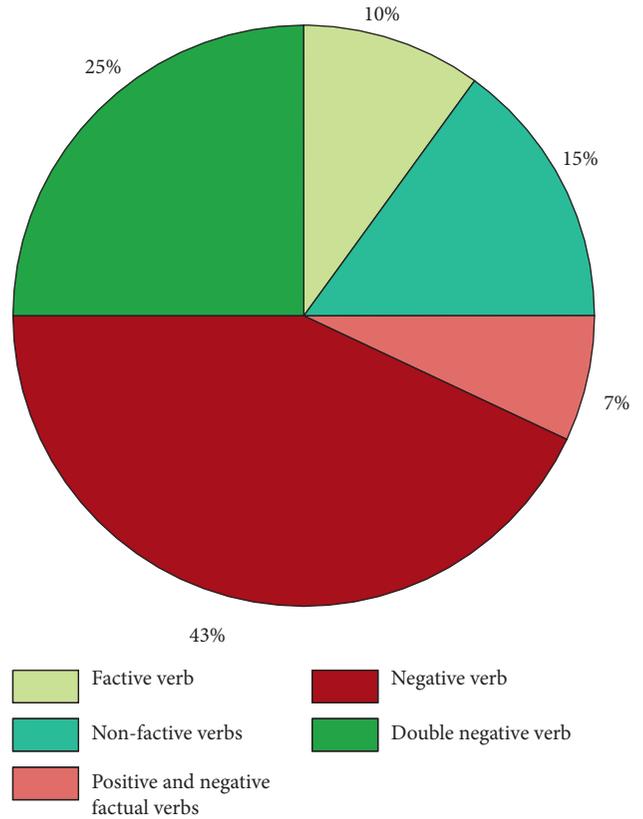

FIGURE 8: Pie chart of Chinese mental verbs.

deep learning model. The model gradient descent is introduced into the model to obtain the optimized deep learning model, which can be used for the analysis of Chinese mental verbs [25]. In order to further illustrate the application of the deep learning model in Chinese mental verbs, the flow chart of the application of the deep learning model in Chinese mental verbs is obtained through the above analysis, as shown in Figure 9. As can be seen from the computational flow chart of text feature extraction of Chinese mental verbs, the data of Chinese mental verbs are first imported into the model and then divided into different sections according to different feature parameters. Then, the critical value of the model can be obtained according to the verb feature of the calculated value. Based on the critical value, the verb feature can be further clipped and analyzed. The results of clipping and analysis are introduced into the activation function to analyze the change between the activation function and the damage function. Furthermore, the linear difference and gradient descent results are obtained to obtain the reconstruction scheme and model of Chinese mental verbs. Finally, the model calculation results and optimization results are output.

Based on the deep learning model, the activation function and damage function are used to optimize the original model, so as to obtain the optimization model for describing Chinese mental verbs. This optimization model can calculate the characteristic parameters of Chinese mental verbs, and thus obtain the histogram of the calculation results of characteristic parameters of Chinese mental

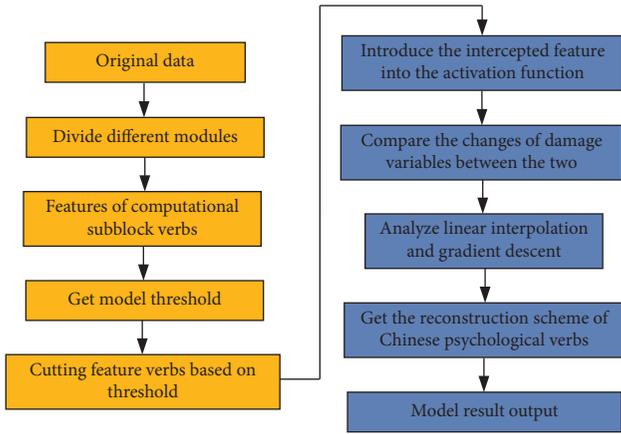

FIGURE 9: Flow chart of deep learning algorithm.

verbs, as shown in Figure 10. It can be seen from the figure that different characteristic parameters show different variation trends with different sample parameters. First of all, it can be seen from the calculation results of declarative verbs that the calculation results are relatively small and the overall range of change is relatively small. A trend in volatility in which a curve increases gradually, then drops to a low point, and then increases gradually. While the corresponding nonpredicate verbs show a linear increase trend with the gradual increase of samples. When the curve reaches the local maximum value, the curve gradually decreases to the local minimum value with the increase of samples. As can be seen from the positive and negative narrative verbs, the change of positive and negative narrative verbs gradually decreases with the increase of samples, and the change of positive and negative narrative verbs gradually tends to be stable with the further increase of samples. It shows that with a higher sample size, positive and negative verbs tend to be constant. However, it can be seen from the negative verb that its change increases linearly with the increase of samples, and the overall change range of the curve is relatively large. As can be seen from the change of double negative verbs, the curve has a high output result under the action of small specimens, while the corresponding output result drops to the lowest value rapidly with the increase of samples, and the overall change range is relatively large.

4. Discussion

The optimization model based on deep learning theory can carry out targeted data analysis by considering activation function and loss function. In order to further illustrate the superiority of the calculated results, the test curve, model curve, and corresponding error curve were obtained by summarizing, as shown in Figure 11. As can be seen from the model verification curve, the test curve first presents a V-shaped change with the increase of iteration steps, and then rapidly drops to the lowest point and then carries on a small fluctuation. With the further improvement of iteration steps, the test data gradually increased to the maximum value, and the overall change range was approximately U-

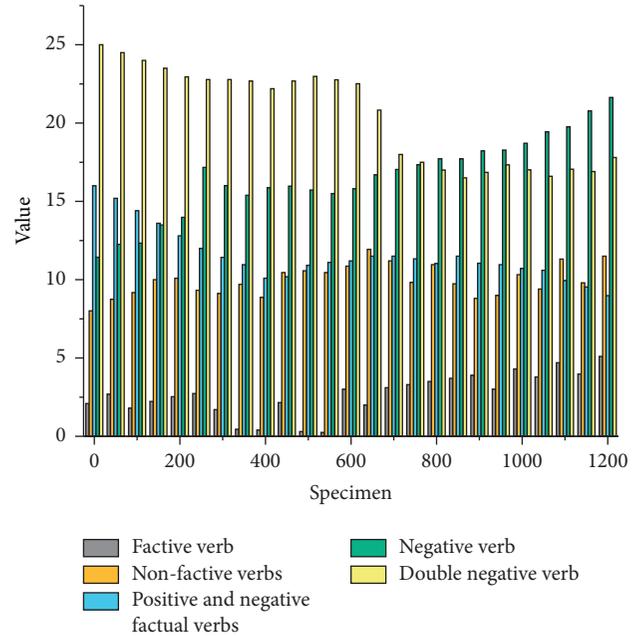

FIGURE 10: Histogram of calculation of characteristic parameters of Chinese mental verbs.

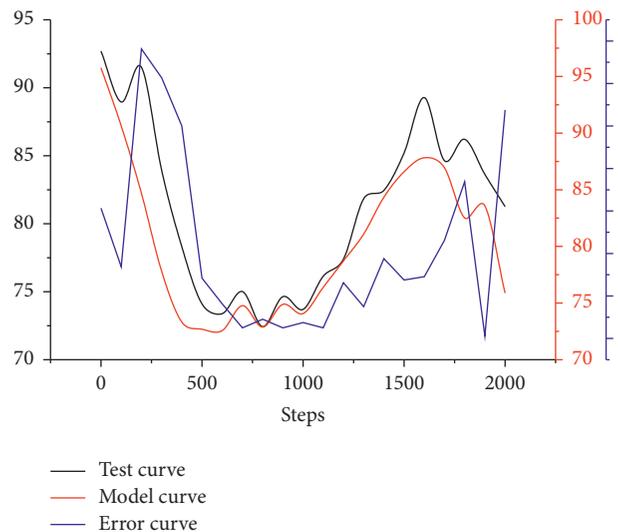

FIGURE 11: Model validation curve.

shaped. The corresponding model curve can better reflect the overall change trend of the test data, and then get the error curve through the comparison between the two. It can be seen from the error curve that the overall error range is within 7%, while with the increase of the number of test steps, the corresponding error range gradually decreases. As the sample increases, the curve is driven by increasing variation. This shows that the error is also U-shaped in a certain range. The curve has different error ranges under different iteration steps. Therefore, in practical application, it is necessary to determine the number of iterations according to the specific test data, so as to obtain the optimal calculation results.

5. Conclusion

- (1) It can be seen that the output value and the activation function have the same variation range through the change curves of the calculated indexes of different neurons. When the neuron is low, the output value and the corresponding activation function have the same change trend. When the neuron is high, the output value shows a rapid decline, while the corresponding activation function shows a rapid increase.
- (2) The comparison curve between Leaky ReLU function and ReLU function shows that the original model can only provide a good description of the second stage of the test data. The optimized activation function can not only explain the change rule of the first stage but also better analyze the experimental data in the key points of the second stage.
- (3) Model gradient changes mainly include learning rate and parameter values of the model. By comparing the experimental data, it can be seen that the curve shows obvious fluctuation in the first stage, among which the fluctuation of learning rate is relatively large. The corresponding parameter values change in a small range, and the curves all decline significantly in the second stage.

Panax ginseng enjoys a wide range of medicinal applications and good economic value, the market demand is large, but *Panax ginseng* seed's after-ripening characteristic seriously restricts development of *Panax ginseng* industry. In this experiment, starting from the main action hormone ABA and GA of *Panax ginseng*, primers of GA and ABA related to *Panax ginseng* seed after-ripening were screened and designed, and the possible relationship between transcription factor WRKY gene and *Panax ginseng* seed after-ripening was probed. Semiquantitative and quantitative real-time PCR of these genes were performed. ABA and GA-related metabolizing enzymes play an important role in the process of *Panax ginseng* seed after-ripening, and WRKY transcription factor regulates gene expression. In this study, we cloned the PgGA2ox gene, which is the key metabolic enzyme of GA, and analyzed the genes by the bioinformatics software, which laid a foundation for studying the molecular mechanism of *Panax ginseng* seed after-ripening.

1. Introduction

Panax ginseng, a valuable medicinal plant, is widely used in human medical treatment and healthcare, and the market demand is on the rise [1]. *Panax ginseng* is a plant of seed propagation, and *Panax ginseng* seeds have not fully developed embryo after natural maturity [2–4]. With the characteristic of postripening, it must be treated by a long period of stratification to break dormancy and germinate. In the main producing areas of *Panax ginseng*, seeds are planted in early August every year and seeded immediately after harvest. Most of the seeds will germinate in the spring of the third year (after 21–22 months) under natural conditions. Many growers cannot promote seed after-ripening, leading to plant failure and seriously affecting economic benefits. The long production cycle restricts large-scale popularization of *Panax ginseng* cultivation to a certain extent, and cultivation process is vulnerable to climate, cultivation conditions, pests, and diseases, resulting in low production of *Panax ginseng* and low economic efficiency. Therefore, it is necessary to find an effective way to improve *Panax*

ginseng yield and quality, thereby improving production efficiency [5].

Phytohormone is a minor molecule signal substance, with very small concentration or even close to 0, but plays a very important role in the plant's life cycle. During seed dormancy and germination, hormones regulate the metabolism of proteins and enzymes through signal transduction, regulating seed dormancy and germination [6].

ABA is a positive regulatory factor of dormancy and is involved in induction and maintenance of dormancy, which negatively regulates germination [7–9]. ABA will resynthesize during imbibition of dormant seeds, which is a requirement for seed to remain dormant. ABA produced by the embryo is necessary for dormancy [10]. The decrease of ABA content before germination is due to inhibition of newly synthesized ABA and activation of ABA catabolism.

NCED is the key rate-limiting enzyme in ABA synthesis. There are five types present in *Arabidopsis thaliana*, including AtNCED1, AtNCED3, AtNCED5, AtNCED6, and AtNCED9. AtNCED6 and AtNCED9 are essential ABA biosynthetic enzymes [11, 12]. The expression level of

NCEDs is directly related to ABA content [13]. AtNCED5 and AtNCED6 are highly expressed in the mid to late stages of *Arabidopsis thaliana* embryogenesis [11]. The CYP707A family encodes the ABA 8'-hydroxylase, which is involved in ABA catabolism. CYP707A1 enhances expression at the early stage of seed maturation, while CYP707A2 enhances expression at the late stage of maturation [14]. After seed imbibition, ABA content decreased, CYP707A2 activity increased, and lack of this enzyme will increase ABA content and strengthen dormancy [14, 15].

GA, a positive regulatory factor of germination, can antagonize inhibition of ABA [16]. In the early stage of seed germination, GA can promote embryonic development and material decomposition. According to Kucera, GA exerts two positive effects on seed: enhancing seed vigor and promoting germination; breaking the seed coat bound and weakening the radicle surrounding tissue [17]. Low-temperature stratification can promote GA synthesis, enable ABA/GA changes, and promote dormancy release and seed germination [18].

GA can regulate GA metabolism by controlling the expression of many key enzymes in the GA synthesis pathway through feedforward or feedback regulation. GA synthesis regulation occurs mainly in late course of transduction. GA2-oxidase (GA20ox) can be catalyzed into active GA1, which is a key regulatory enzyme of GA biosynthesis. GA2-oxidase (GA2ox) can catalyze active GA1 to inactive GA34, catalyzing degradation of GA (Henderson et al. [19–21]).

WRKY transcription factor regulates seed germination and growth after seed germination. In 2004, ScWRKY1 transcription factor was isolated from wild potato ovule. ScWRKY1 transcription factor was transiently highly expressed in the embryo of torpedo stage. Its expression level was low in the fruit, root, and stem, suggesting that ScWRKY1 might participate in the embryogenesis process. *Arabidopsis thaliana* AtWRKY10 was expressed in pollen and globular embryos and also expressed in binucleate stage of endosperm development to cell stage. New plant with the gene deleted cannot form seed of normal size. The result showed that WRKY transcription factor played an important role in the embryo growth and in reducing early cellularization of endosperm [22].

In this study, beginning from the key hormones ABA and GA directly related to after-ripening characteristic of *Panax ginseng* seed by removing seed dormancy, the related primers were designed. Semiquantitative PCR and real-time quantitative PCR of these genes were performed. As WRKY transcription factor could regulate seed embryo growth to determine its expression level and understand its relationship with other genes can lay a foundation for the study of molecular mechanism of *Panax ginseng* seed postripening. Table 1.

2. Materials and Methods

- (1) *Panax ginseng* seeds were purchased from the Tonghua Changlong Forest Farm in Jilin Province. The seed was harvested for lamination treatment,

washed with 75% ethanol 3 times, rinsed with distilled water 3 times, and wiped with filter paper, to be placed in sterilized sand with carbendazim treatment, with seed: sand=1:3 at lamination. The stratified seeds were sampled at 45-day intervals, 30 seeds at a time, for a total of 5 samples. The samples were washed and frozen with liquid nitrogen and then stored in a refrigerator at -80°C until use.

- (2) Total RNA extraction and cDNA synthesis: Total RNA was extracted in accordance with instructions of RNA extraction kit; and then, reverse transcription synthesis of cDNA was performed in accordance with instructions of reverse transcription kit. The kit was purchased from the Dalian Takara Bio Company.
- (3) Quantitative real-time PCR primer design: Primers were designed using the Primer Premier 5.0 software. Semiquantitative and quantitative real-time PCR were performed according to the primer sequence in Table 1, and all primers were synthesized by the Beijing Genewiz Company.
- (4) Semiquantitative PCR system and procedures: Reaction system: cDNA $1\mu\text{l}$, upstream and downstream primers $1\mu\text{l}$, Ex Taq enzyme $0.2\mu\text{l}$, dNTP $1\mu\text{l}$, $20\times$ Ex Taq enzyme buffer $2.5\mu\text{l}$, ddH₂O $18.3\mu\text{l}$, final volume of $25\mu\text{l}$; Reaction procedure: pre-denaturation at 94°C for 5 min; denaturation at 94°C for 30 s, 50°C – 60°C (according to different primer changes in T_m value) annealing 30 s, 72°C extension for 30 s, 35 cycles; 72°C extension for 5 min; and storage at 4°C .
- (5) Quantitative real-time PCR system and procedures: Reaction system: $2\times$ SYBR Green Mix $10\mu\text{l}$, upstream and downstream primers $1\mu\text{l}$, cDNA $1\mu\text{l}$, ddH₂O $7\mu\text{l}$, final volume of $20\mu\text{l}$; Reaction procedure: 95°C 5 min; 95°C 15 s, 56°C 15 s, and 72°C 30 s single lighting, 40 cycles; 95°C , 1 min; 65°C , 1 min; solubility curve: target temperature 95°C , initial temperature 65°C , constant temperature time 20 s, and step $0.5^{\circ}\text{C}/\text{s}$; 30°C , 1 min; and end 4°C .

(6) Cloning the full-length cDNA of PgGA2ox gene: The cDNA of *Panax ginseng* seed was used as template, and PgGA2ox gene was amplified by the following system: 1 μ l of cDNA, 1 μ l of upstream and downstream primers, 0.2 μ l of Ex Taq enzyme, 1 μ l of dNTP, 20 \times Ex Taq enzyme buffer 2.5 μ l, 18.3 μ l of ddH₂O, and final volume of 25 μ l. PCR reaction annealing temperature was 55°C; the reaction primers were F-ATGGTAGTCTTGCCCAAGC-CAACAA and R-TCATGAGGCTGCAATTTTCTCAAAG. PCR products were detected by 1% agarose gel electrophoresis, and extraction of DNA from agarose gel of target amplified fragments was performed according to operation instructions of the DNA purification recovery kit. The recycling products were ligated into pMD18-T vector and transferred into *E.coli* to be cultured on LB medium containing ampicillin. After 12 hours, the colonies were observed. The positive clones were placed in LB medium containing ampicillin for 12 hours' culture before colony PCR amplification. After electrophoresis detection, it was sent to Genewiz for sequencing.

3. Results

3.1. *Panax ginseng* Embryos in Different Stages of After-Ripening. Dormancy of *Panax ginseng* seed needs to pass through the two stages of morphological after-ripening and physiological after-ripening. Samples were taken 5 times at 45-day intervals and defined as SE1–SE5 stages: SE1, initial phase of morphological after-ripening; SE2, mid-term of morphological after-ripening; SE3, late morphological after-ripening, seed fissure; SE4, initial phase of physiological after-ripening; and SE5, mi-term of physiological after-ripening.

3.2. Semiquantitative PCR Results. The cDNA of seeds of the five stages of *Panax ginseng* embryo after-ripening was used as template, and 5S rRNA was used as internal reference. The seven primers were amplified after the annealing temperature was set based on primer T_m value. Detection was performed with 1% agarose gel electrophoresis, and loading quantity of sample was 5 μ l. Picture was taken in the ultraviolet light irradiation after electrophoresis, and gene expression is shown in Figure 1.

From the figure, we can see that most of the genes were in low expression or no expression in the morphological after-ripening stage, GA2ox gene expression in morphological after-ripening stage is higher than that in physiological after-ripening, and CYP707A gene and GA2ox gene expression level tends to be consistent. WRKY transcription factor family showed a completely different expression. WRKY6 expression level in the physiological after-ripening period was higher than that in the morphological after-ripening stage, suggesting that it was associated with seed dormancy. WRKY3 and WRKY27 in morphological and physiological after-ripening stage were in low expression.

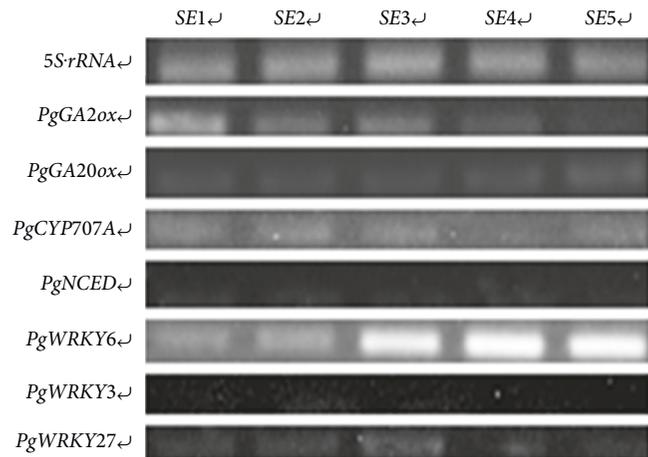

FIGURE 1: Gel electrophoresis photograph of semiquantitative PCR.

3.3. qRT-PCR Results. With 5S rRNA as internal reference, expression of GA, ABA, and WRKY transcription factor and embryo after-ripening related genes was detected in different period of *Panax ginseng* seed. The experimental data were analyzed by a software that came with quantitative real-time PCR instrument, as shown in Figures 2–4.

GA is a key factor in embryo dormancy and germination, GA2ox is a key gene in GA anabolism and catabolism. The study on action law of these two genes is helpful for the analysis of GA action mechanism in *Panax ginseng* seed after-ripening. The expression of GA20ox gene in physiological after-ripening stage was higher than that in morphological after-ripening stage, and GA20ox gene expression increased gradually in the two periods, which indicated that GA20ox gene played a more important role in physiological after-ripening. The expression level of GA20ox gene decreased in physiological after-ripening stage, quite low in physiological after-ripening stage, but increased slightly at the end of physiological after-ripening stage. It was inferred that the increase of expression level was related to release of seed dormancy.

ABA can induce and maintain dormancy, a positive regulatory factor of dormancy, a negative regulatory factor of germination, which acts antagonistically with GA. NCED is the key rate-limiting enzyme in ABA synthesis. The expression of NCED gene is directly related to ABA content. CYP707A gene is involved in ABA catabolism. The expression level of NCED gene decreased gradually at morphological and physiological after-ripening stages, with the former higher than the latter, indicating that the content of ABA was decreased and the dormancy was gradually broken. The expression level of CYP707A gene declined continuously in morphological after-ripening stage and increased at SE5 stage.

WRKY transcription factor has a special zinc finger structure, which plays an important regulatory role in the process of plant response to biological and abiotic stress, plant development (such as seed germination, dormancy, and leaf senescence). The three WRKY genes showed different expression trends in after-ripening stage of *Panax ginseng* seed. Expression levels of WRKY3 and WRKY27

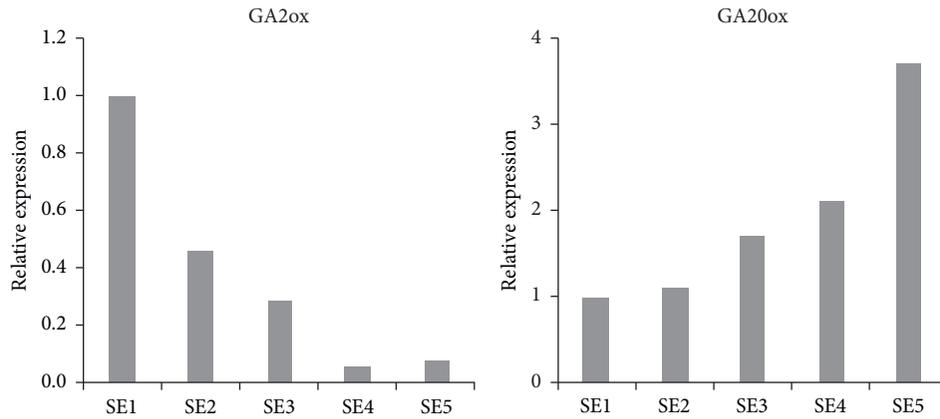

FIGURE 2: Expression of genes related to GA metabolism in after-ripening stage of *Panax ginseng* seeds.

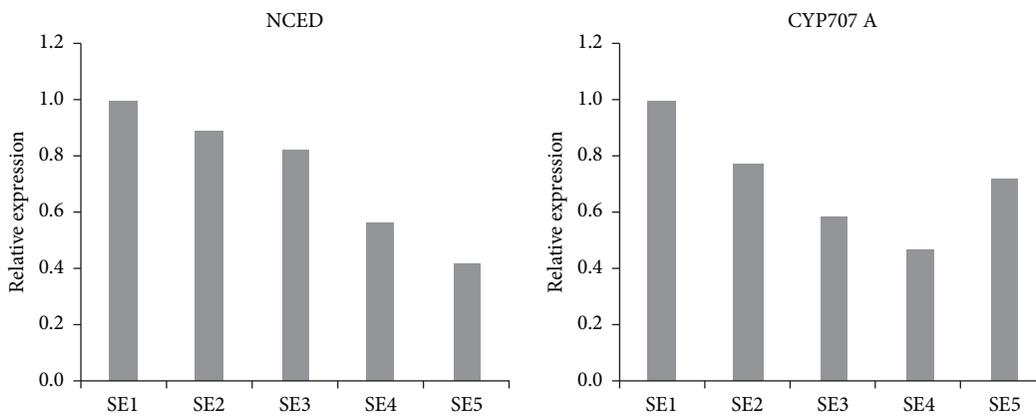

FIGURE 3: Expression of ABA-related genes in after-ripening stage of *Panax ginseng* seeds.

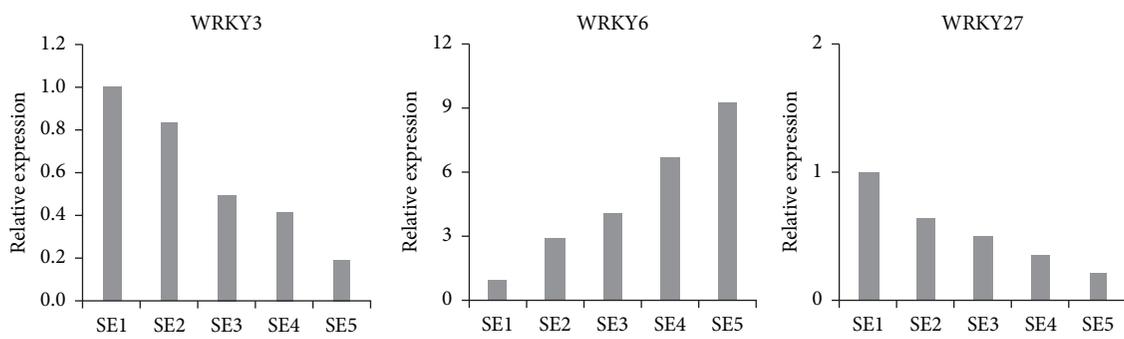

FIGURE 4: Expression of WRKY transcription factor in after-ripening stage of *Panax ginseng* seeds.

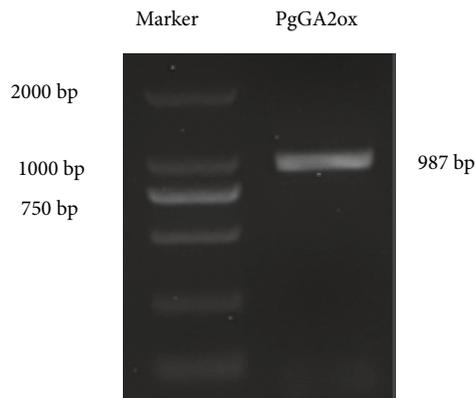

FIGURE 5: Gel electrophoresis photograph of cloned PgGA2ox gene.

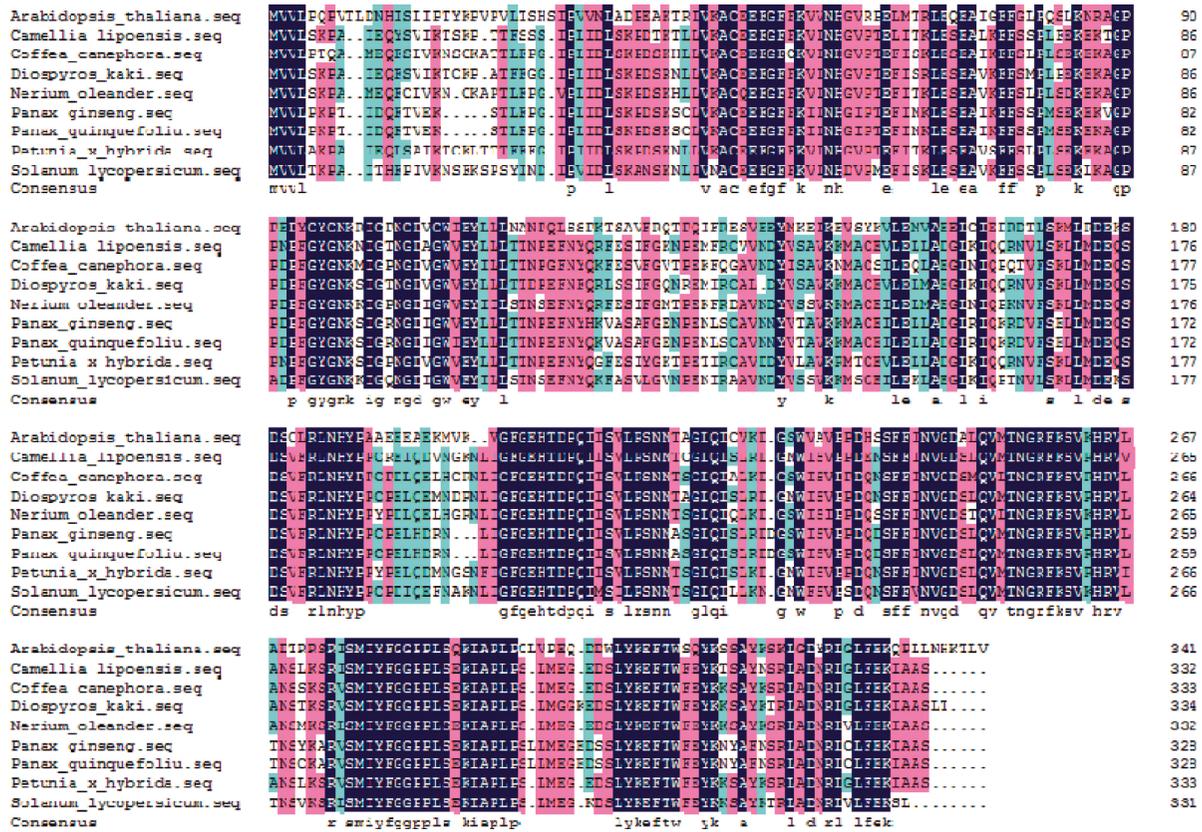

FIGURE 6: Comparison of amino acid sequence similarity between PgGA2ox and other species.

were low, which decreased in morphological and physiological after-ripening stages. But expression level of WRKY6 was opposite, which gradually increased in physiological after-ripening stage. It is inferred that it is related to release of embryo dormancy and accelerated seed germination.

3.4. Cloning of PgGA2ox Gene of Panax ginseng Seed. The PCR cloning of designed primers was performed using *Panax ginseng* seed cDNA as the template, obtaining a sequence with length of 987 bp. The amplified gene was named PgGA2ox and the nucleotide sequence was submitted to NCBI. GenBank accession number obtained was KT692958.1. The electrophoregram is shown in Figure 5.

3.5. GA2ox Coded Amino Acid Sequence Similarity Analysis and Construction of Phylogenetic Tree. BLASTN analysis was performed on NCBI. It was found that nucleotide sequence of PgGA2ox was similar to gene sequence of *Panax quinquefolius* (KJ802836.1), *Petunia x hybrida* (GU059939.2), and *Camellia lipoensis* (KJ502290.1), with similarity at 99%, 81%, and 80%, respectively. Amino acid sequences coded by PgGA2ox were compared using BLASTP, finding that in terms of amino acid sequence similarity, it was 99% similar to *Panax quinquefolius* (AIL25679.1) GA2ox, 79%, 79%, 79%, 77%, 76%, 73%, 72%, 71%, and 55%, respectively, similar to *Coffea canephora* (CDP06089.1), *Diospyros kaki* (AID65071.1), *Camellia lipoensis* (AHZ13201.1), *Nerium oleander* (AAT92094.1), *Petunia x hybrida* (AFH56955.1)

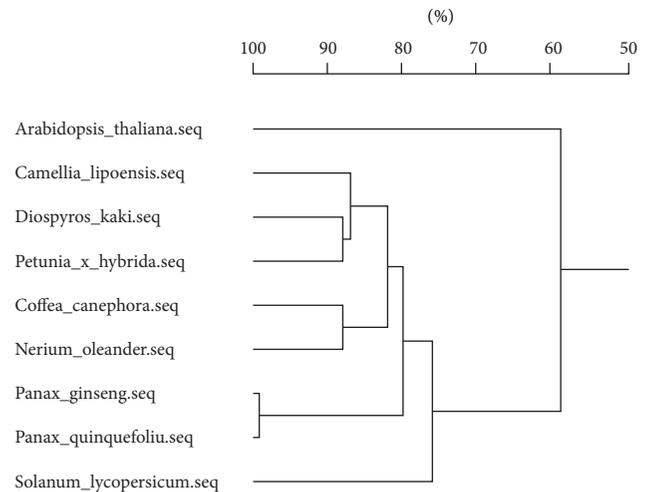

FIGURE 7: Evolutionary analysis of PgGA2ox.

GA2ox, *Cucurbita maxima* (CAC83090.1), *Solanum lycopersicum* (NP_001234752), *Helianthus annuus* (CAS03784.1), and *Arabidopsis thaliana* (NP_174296.1) gene encoding.

GA2ox is a dioxygenase and 2-ketoglutarate substrate in the GA metabolic pathway. The PgGA2ox protein in the *Panax ginseng* contains a conserved binding amino acid site shared by other plants, i.e., a R residue and a S residue bounded to 2-ketoglutarate, located at positions 226 and 228, respectively, and two H residues and one D residue bound to Fe (Figure 6).

In order to analyze the evolution of PgGA2ox encoded proteins, a phylogenetic tree was constructed using the DNAMAN software (Figure 7). According to the phylogenetic tree, PgGA2ox is most closely related to *Panax quinquefolius*, close to persimmon and *Nerium indicum*, which is consistent with BLASTP result of amino acid sequence.

4. Conclusion

The seed after-ripening is an adaptation of the *Panax ginseng* to the external environment in the long-term evolutionary process. In natural conditions, it helps *Panax ginseng* pass through adverse environment, so that its race multiply, but it brings difficulties to cultivation of mankind. In order to expand cultivation area of *Panax ginseng* and further improve economic benefits of *Panax ginseng*, research on after-ripening mechanism of *Panax ginseng* seed is an urgent problem to be solved. *Panax ginseng* seed after-ripening process is very complex, so current domestic and foreign scholars' study on *Panax ginseng* seed after-ripening process focuses on physiological and biochemical dynamic changes within the seed, seed embryo development changes, and changes in hormones and isoenzyme content in the after-ripening period, but little is reported on the after-ripening mechanism of *Panax ginseng* seed.

In this study, we analyzed the expression rules of GA and ABA hormone-related genes and WRKY transcription factor in *Panax ginseng* seed after-ripening, which is the first of its kind in study of *Panax ginseng* seed dormancy.

GA-related genes: Gibberellin acid synthesis regulation occurs mainly in the late transduction pathway. GA20ox can catalyze GA12 and GA53 into active GA1 and GA4. GA2ox, by β -hydroxylation, can convert active GA1 and GA4 into inactive GA13 and GA14 [23]. The expression level of GA20ox (GA synthetic gene) in the physiological after-ripening stage was higher than that in the morphological after-ripening stage, which proved that low temperature could promote GA synthesis and increase expression of GA synthetic gene, which is consistent with the results of Derkx [24]: low temperature can enhance expression of AtGA20ox1 and AtGA20ox1.

ABA-related genes: C40 carotenoid zeaxanthin was oxidized to violaxanthin, which, after forming 9-cis-epoxy carotenoids, turned to C15 xanthohumol after NCED pyrolysis, a key step in ABA synthesis. CYP707A belongs to P450 monooxygenase family and encodes ABA 8'-hydroxylase, which is involved in catabolism of ABA. The expression level of NCED gene and CYP707A gene was not high in the after-ripening stage of *Panax ginseng* seed, both of which decreased gradually during the whole after-ripening stage, which indicated that endogenous ABA synthesis pathway was closely related to seed after-ripening.

WRKY transcription factor: WRKY gene family is a multifunctional gene family. Molecular biological function of its family members is very rich, including regulation of plant resistance to biological stress and abiotic stress, regulation of plant growth and development, morphogenesis, metabolic regulation, and so on. In addition, WRKY

transcription factor is also involved in plant low-temperature response. *Panax ginseng* seeds need to go through low-temperature environment in the after-ripening process. The expression level of WRKY3 and WRKY27 decreased during seed ripening, and WRKY6 was highly expressed in the process of *Panax ginseng* seed after-ripening. Therefore, we speculated that WRKY transcription factor could respond to low temperature regulation, then participate in regulation of metabolism, regulation of gene expression, and finally complete *Panax ginseng* seed after-ripening, which can be further verified in subsequent relevant experiments.

In this study, we cloned for the first time the key gene PgGA2ox for gibberellin acid metabolism during the process of *Panax ginseng* seed after-ripening and obtained GenBank accession number KT692958.1.

The results of this study not only provide a basis for molecular function analysis of PgGA2ox gene but also provide a basis for study on mechanism of after-ripening of *Panax ginseng* seeds.

Based on the interactive food packaging design method based on the user's emotional experience, the specific food packaging design scheme is completed. On the basis of analyzing the current situation of the food industry, this paper discusses the competitive driving factors between the demand side and the enterprise side for food packaging, integrates the user's emotional experience into the reality of food packaging, and focuses on the specific practical solutions based on the user's emotional experience. Incorporating user emotional experience into food packaging design Yuan, 2022 and Liu, 2020 is beneficial to both the impact of food brands and the promotion of product sales. Incorporating user emotional experience has played a very important role in food market competition. At the same time, through practical cases, closely focusing on the user's emotional experience, it innovatively tried to convert users into core designers of product packaging and adopted a small-batch customized production and packaging mode. This plays a certain guiding and reference role for food packaging design. This paper takes the user's emotional experience as the research perspective and interactive packaging as the research object, uses the three-level theory of emotionality as the guide, explores the user's emotional experience path for packaging by means of literature analysis, fieldwork, case analysis, and experiments, and summarizes the design, principles, and methods.

1. Introduction

With the continuous development of the social economy and the advancement of network information technology, people's lives have undergone rapid changes. Social psychologist Maslow once proposed the following. "The development law of human needs is to gradually increase from the lowest level of physiological needs to the highest level of self-realization." When people begin to pursue a high-quality life, consumers' values have also changed, with a desire for more emotional attention. The expectation for commodity packaging [1] has also shifted from simple functional requirements to the emotional experience of commodity packaging [2]. Therefore, it is particularly important to pay attention to the psychology and behavior of consumers to understand their real needs of users [3]. At the same time, the maturation of new media technology, packaging materials [4, 5], and production

technology provides the possibility of innovation in future commodity packaging.

Donald Norman proposed that the affective system consists of three distinct, interconnected layers, each of which affects our experience of the world in a specific way. These three levels are the instinct level, the behavior level, and the reflective level in turn. The instinct layer is responsible for the most primitive instincts of human beings. The behavioral layer refers to the process of achieving an effective goal in the shortest time or with the least amount of behavior. The reflective layer is conscious thinking and learning. These three levels create our emotional experience of things. When these three levels are applied in packaging design, they can, respectively, correspond to the user's instinctive experience of the packaging before purchasing the product, the behavioral experience during use, and the information feedback process after use.

Humans have a relatively rich perception system, and feeling is the simplest and most basic form of reflection when people understand the objective world. "People rely on sensory experience to understand the world. The senses are our connection to memory and the connection of emotion." In instinctive experience, vision, hearing, touch, smell, and taste are in the dominant position. When choosing a product in front of the shelf, the shape of the packaging [6], the texture of the material, and the warmth of the color will bring different emotional feelings to users, which will instinctively trigger emotional reactions, thereby promoting consumption behavior.

In the behavior layer, what is concerned is the user's behavior. The highest requirement of behavioral experience is people-oriented. Understand user behaviors and discover unmet or clearly articulated needs of users. But if the experience is puzzling, it will bring a negative emotional impact on the user, and conversely, good design will produce a positive emotional experience [7].

Good design creates a positive emotional experience. The reflective layer is based on the instinctive layer and the behavioral layer. The focus is on information, culture, and identification with the product or the meaning behind the product. A user's lasting memory of an experience comes from the reflective layer and even affects our future use of a product or service. In packaging design, "the instinct layer, the behavior layer, and the reflection layer are intertwined, influenced, and penetrated." By exploring the emotional experience path of packaging users, we can make packaging design that meets the real needs of consumers [3, 8, 9].

2. Current Situation at Home and Abroad

Since the concept of user experience was first proposed in the 1990s, after decades of development, it has been widely used in different fields and has expanded many related concepts. According to "the authoritative ISO 9241-210 standard, "user experience" is regarded as the response process of people's needs to real-world conditions and the realization of desired products, systems, or services."

Analysis of the research status of foreign user experience shows that most scholars study user experience according to different practical problems, select its constituent elements according to the needs of practical problems, and then conduct classification research one by one [10]. For example, [10] covers the content of user experience as actionable, cognitive, motivating, and enlightening. Morville classifies user experience into usability, usefulness, ease of use, reliability, ease of discovery, satisfaction, and value and then evaluates user experience according to the above categories. [13] encapsulates the components of user experience as pleasure, functionality, usability, and pride. From the above research, it can be seen that user experience can be divided into usability, user emotional experience, and user needs. The research scope of this paper mainly focuses on the user's emotional experience. Emotional design refers to integrating the user's emotional needs in the process of the design construction and applying it to the design process. In order to explore the satisfaction of user experience, Partala [14]

started from the aspects of emotional experience, psychological needs, and interactive environment, respectively, compared the experience data in the experiment, and concluded that autonomy, competitiveness, and self-esteem are more prominent in psychological needs. In marketing and consumer behavior research, there are also many discussions on emotional experience. [15] proposed that when "emotion" acts on the consumption scene, face-to-face interaction is the main reason for affecting the emotional experience. [16] proposed that "in the process of consumption, the complete experience affects consumers' purchasing preferences, and the influence of emotional factors and shopping experience exceeds the product and service itself." According to empirical research by scholars, 85% of consumers decide whether to buy or continue to use a certain brand through an emotional experience, and only 15% of consumers pay relatively little attention to emotional experience.

In the research scope of the user's emotional experience, the measurement method is also very important. Due to the strong subjectivity of user experience, the measurement of subjective emotion has become a relatively common method. In psychological measurement, PAD emotional model, PrEmo scale, semantic difference method, utility scale, hedonic scale, etc. are all commonly used, and most of them are conducted in the form of questionnaires. In addition, a series of qualitative methods such as interviews and observations can be combined for research. However, subjective emotion measurement methods are still not scientific and accurate to a certain extent. Therefore, using experimental methods to quantify physiological indicators can provide scientific data support for emotional research more objectively. For example, facial recognition technology that compares AI and expression databases, brain wave experiments using EEG amplifiers, and eye movement experiments using gaze tracking are gradually being applied by scholars in user experience research in various fields. In the article "Product packaging and consumers' emotional response. Does spatial representation influence product evaluation and choice?", the author uses facial recognition technology to capture the face image of the measurer when viewing the product packaging image and compares the face modeling method with the expression database. Yes, it is found that visual images on product packaging can affect consumers' emotional perception and purchasing decisions, and it is verified that the foreground position of images on the packaging [10, 17] will reduce consumers' psychological distance and increase positive emotional experience.

In our country, the theoretical research of user experience is still in the process of continuous development. Previous scholars have systematically sorted out the concept, composition, measurement, and evaluation of user experience, focusing on in-depth research on measurement and evaluation methods. These discuss the era background and main application fields related to emotionalization, as well as the current research status and future development trends. If prepurchase feelings and product efficacy meet expectations, emotions will suddenly revive and satisfaction will increase significantly, and vice versa. In the process of consumption,

consumers' personal feelings, temperament, knowledge structure, perceptual experience, attitudes, and values will directly or indirectly affect consumers' emotions and emotional responses.

In the process of user research, researchers have different understandings of user experience due to different research perspectives and backgrounds. The research on user experience in our country has just started, and there is still a lack of in-depth and detailed theoretical research, most of which are analyses and enlightenment of foreign research content. User experience has a high degree of attention in the design discipline, and the number of researchers is increasing year by year. However, most of them are widely used in industrial design disciplines, and less in the field of packaging design [18, 19], and most scholars still focus on qualitative research on the measurement method of user experience, which is not scientific and rational in the method. Objectively provide data support for packaging design [20, 21].

By analyzing the user's emotional experience characteristics and the experience path in the packaging, the corresponding three-level design methods are summarized (Figure 1), which are the perception of the instinct layer, the participation process of the behavior layer, and the feedback of the reflection layer.

3. Research on Packaging Design Based on User Emotional Experience

In order to extensively collect the user's emotional experience information about packaging [22], the authors conduct research in the form of questionnaires. By visiting tourist attractions, specialty stores, exhibitions, and issuing online questionnaires, we conduct research on user needs. Through the survey data results, it is known that the user's demand for food packaging is generally divided into the following points, which can reasonably protect the product and meet the functional requirements of the packaging. It can convey national characteristics and show national customs. Interestingly, research has shown that 63% of users say that the interestingness of packaging will affect users' purchase intention.

Graphics are an important part of the packaging. Compared with text, graphics have stronger visual expressive power and are easier to attract users' visual attention [23, 24] and effectively convey the connotation of products. The immersive graphic isomorphism method puts the product itself or partial content into the context, combines the two-dimensional graphic with the product, conveys the form of images and objects that are both real and illusory, breaks the relationship between the picture and the bottom, and integrates the product into the product. At the same time, the dual expression of semantics can also be integrated, and consumers can receive additional brand information or commodity attributes through the presentation of visual graphics. For example, designer Constantin Bolimond (Figure 2) combines the packaging design of nuts with squirrels and forms a complete design by combining the product itself with the packaging pattern. The image of the

squirrel is naive and attractive and metaphorically expresses the invisible meaning of the product.

The realization of any product function is completed by the interaction between people and products, so packaging design should be people-oriented and understand the expectations and usage of packaging by people in all aspects. "Focus on the instinct layer, the user's initial feeling of the packaging, the intuitive feeling of appearance, color matching, material texture, and so on; pay attention to the behavior layer, whether the process of the user using the packaging is simple and easy, and whether the packaging after use can arouse the user's deeper understanding."

Usability is the basic premise of packaging design [25], and it is also the first principle, which can protect the attributes of commodities in the process of commodity circulation. For example, the shape of the food itself will directly affect the structure of the packaging. For example, milk skins, during the production process, in the production process, due to the use of pots and the way the finished product is taken out, most of the unprocessed milk skins are semicircular. The pure milk chews have a thick texture, and a large-caliber short bottle is required when choosing packaging. Milk residue, Bischlager, etc. are all fragile products. In the design of the packaging, it is necessary to take into account the pouch packaging or pressure-resistant packaging. The packaging can only proceed to the next design on the premise of guaranteeing usability. "Sanchun," a dairy food brand in Inner Mongolia, promotes this delicious food as an easy-to-carry food through people-oriented design and packaging (Figures 3 and 4).

On the premise of satisfying usability, ease of use is a further requirement. To measure whether the function and structure of a package are reasonable, through the analysis of the user's psychological needs, physiological habits, and ergonomics, the difficulty of use is determined. Questions such as degree, convenience, and availability for most people come before design [26]. Whether the user's use can be improved in a more convenient way will affect the user's repurchase. Therefore, reducing the time cost for the user's use as much as possible is a high manifestation of ease of use.

After satisfying the principles of usability and ease of use, how to make consumers feel satisfied and happy in the process of selection and use is an important part of pleasantness. Integrate emotional care into packaging, integrate national culture and additional functions, and connect consumers with products through the medium of packaging, thereby generating emotional resonance.

It is very important to add creative graphic elements. In the selection and application of ethnic elements found in the market, most of the graphics are outdated, conservative, and have serious convergence problems. On the basis of retaining the inherent form of ethnic elements, the elements should be simply deconstructed and reconstructed by means of graphic isomorphism, graphic creative expression, etc. to get rid of the convergent packaging of blue sky, white clouds, and green grass and give them a new visual experience [27]. For example, in the kitchen utensil packaging designed by Danish designer Des Jacob Poulsen for Scanwood, the kitchen utensils are isomorphic with the background picture

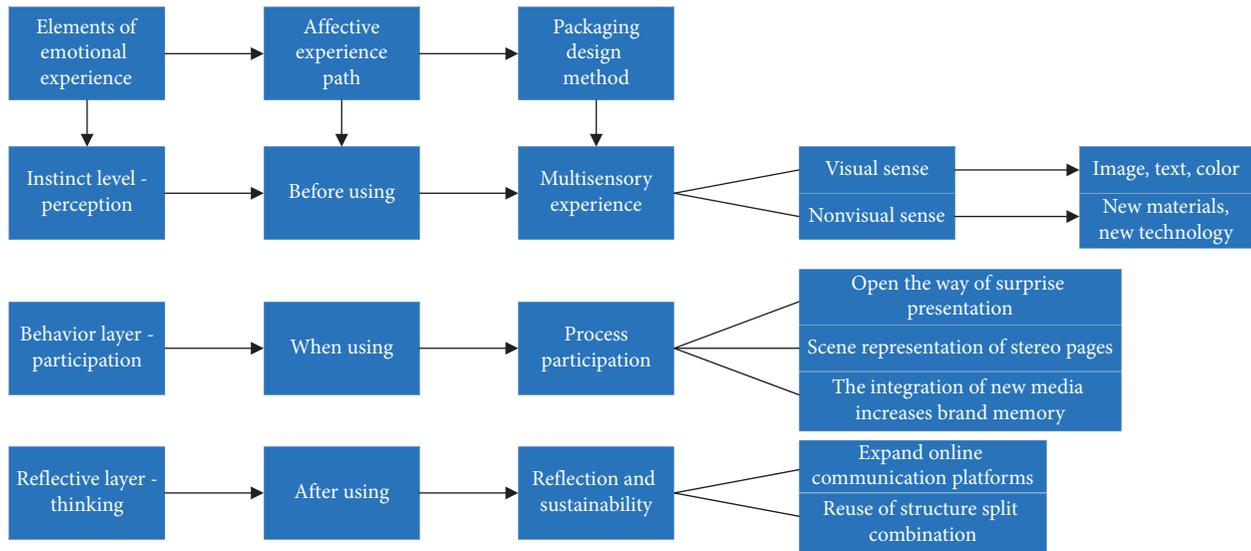

FIGURE 1: Summary of interactive packaging design methods.

FIGURE 2: Nut packaging design.

FIGURE 3: Coffee milk packaging design.

FIGURE 4: Packing design.

in the packaging, which interestingly expresses the natural and pollution-free characteristics of the product.

Emotional color expression is also very important, and the color is more likely to make users form visual memories. Different colors will bring different psychological hints to users. “The rational use of color can not only highlight the functions and attributes of products but also shape the brand

image, expand the effect, gain memory cognition in consumers’ minds, and strengthen the perception [28].” For example, McDonald’s standard red and yellow color matching, Pepsi’s standard blue color, and Sprite’s standard

green have formed the inherent brand attributes in the minds of users. Choosing the main tone and auxiliary color corresponding to the product attributes can maximize the overall artistic effect of the sublimation packaging. The integration and sorting of text information is the key point. Text is one of the elements of commodity packaging. It plays the role of information transmission in packaging and annotates the nature of packaging. It is generally divided into the main text, data text, description text, and advertising text. Text content requires information integration and hierarchical induction. The size and direction of the text, the looseness and tightness of the font area, and the hierarchical relationship of the text will affect people's visual experience. By controlling the spacing, line spacing, and combining text, the hierarchical relationship between different elements is clearly listed, allowing users to quickly obtain the required information in the shortest time. The text information on the packaging of dairy food should take into account the reasonable arrangement of ethnic characters and Chinese characters and the style of expression. For example, by extracting the form of Mongolian characters and combining them with Chinese characters, on the premise of maintaining readability, it can add a touch of ethnic charm to the font style.

4. Optimal Design of Food Packaging

In consumer psychology, if users participate in a certain action, they will strengthen their awareness of the product and will develop a sense of trust with the gradual deepening of their awareness. The design that guides user behavior levels in packaging design is related to the way the packaging is used. The design that pays attention to the way of using the packaging of local specialty food can allow users to relieve stress in the process of using the packaging and have a pleasant, satisfying, and self-identified experience [29].

For example, the design of the way in which local food is used should make the packaging easier to use and more valuable. Good ideas usually emerge from certain behaviors. The packaging of local specialty food is usually discarded by users after use [30]. However, if the packaging design of local specialty food can reflect the value of user experience, feelings, and secondary use, it can effectively enhance users' favorable impression of the product and facilitate the promotion of the product, while also playing a positive role in the protection of the natural environment. Souvenir packaging usually has game functions and secondary utilization functions. Figure 5 shows the sweet corn food packaging designed by VRS WPI Vilnius in Lithuania. The designer has skillfully combined the cutting process in the packaging design so that the images of sloths, flamingos, and owls can be used not only as the visual image symbols of the packaging but also as the main body of the toy. They can create beautiful and unique handmade works. The handmade parts of the three types of packaging can be exchanged and shared, which enhances the fun of the packaging design experience process. While promoting the sales of goods, it also virtually reduces the post-promotion cost of the product.

FIGURE 5: Oho children's sweet corn food packaging.

With the popularization of digital information technology and network, virtual digital packaging has become an inevitable product of the development of modern information technology. Traditional offline consumer groups are diverted by online shopping, and virtual packaging just makes up for the shortcomings of traditional packaging. In recent years, virtual packaging that has emerged one after another not only undertakes the functions of protecting products and displaying goods but also in product promotion and demonstration.

Superimposing virtual images on the original packaging materials through AR technology can expand a large amount of information presentation space and even dynamic display links, allowing consumers to immersively experience the use of products and brand stories through colorful digital content. For example, Baidu joined hands with Yili in December 2015. Through the combination of Baidu's technological innovation and manufacturing and Yili's creation of the global milk industry chain, a brand-new interactive packaging experience can be created[25]. By shooting packaging through mobile phones, global consumers can be led to understanding of all aspects of the global milk industry chain through the form of AR. The living environment, milk processing, and packaging process allows every user to have access to the most authentic Yili. The development of technology has made the application of virtual reality technology in packaging gradually popular, providing technical support for packaging innovation.

Reflecting on the experience of the layer conveys the deep semantics of the product, "focusing on the user's culture, memories, and emotions, increasing the spiritual value and cultural connotation of the product, is a progressive process of user experience from shallow to deep." Also, formulate the next two goals, which are to build an industrial basic innovation system around green packaging, safe packaging, and intelligent packaging. The second is a green production system covering the life cycle of packaging

around cleaner production and green development. This layer focuses on information, culture, and the story behind the product, which is usually an extension of the experience of the product's instinctive layer and behavioral layer.

5. Establishing Packaging Design Patterns

5.1. Brand Positioning and Audience Analysis. Professor Bruce Hanna of the Pratt Institute in the United States once mentioned that designers are all storytellers. The stories told by designers are the behaviors brought out by the design, and the design is the output of the story from a certain perspective. The living background of the light-middle-class people belongs to the era of rational consumption, and they are willing to improve their quality of life and have a greater interest in new things. By 2020, China's light and middle-class population will reach 350 million, becoming the backbone of China's consumer market, while the new middle-class population is still the backbone of urban consumption. In the future, "quality consumption will become the new normal, and the pursuit of high-cost performance will be the main theme of Chinese consumption in the next five years."

5.2. Food Packaging Design. Based on the previous research and experimental data, the author learned that most of the food packaging design uses fashion, gorgeous and creative as semantic phrases to design food packaging and gift boxes.

5.2.1. Instinct Layer. A cultural symbol is a symbolic form of regional cultural connotation and meaning. According to the previous user research and food packaging collection, it is found that most food packaging designs can make users feel the national atmosphere in the shortest time. In the selection and application of ethnic elements, most of the packaging seen in the market has problems such as outdated graphics and conservative and serious convergence. On the basis of retaining the inherent form of ethnic elements, this paper simply deconstructs and reconstructs the graphics to give them a new visual experience. According to the survey, 65% of users believe that when choosing food, whether the original appearance of the food can be presented on the packaging is more important. Therefore, the schematic diagram of the extracted food is used directly in front of the packaging, which is beneficial for the user to obtain the product form through the screen content and reduce the time and cost of purchasing.

5.2.2. Behavior. According to statistics, people will come into contact with at least 30,000 daily necessities in their daily lives and will not leave memories or emotions about each of them in the process. But because of countless repetitions of limbs, it will leave "behavioral memory" during the use of the product. It is necessary to make reasonable use of the user's behavior memory and innovate the packaging under the premise of being easy to use. Look for the features of simplicity, mechanics, and daily from the common

packaging box types and guide users to seamlessly connect when picking up the packaging and using the packaging.

In life, most people have countless experiences using the box-type structure. This experience is not paid attention to, and users can open it smoothly without expending extra effort. The difference is that when the lid is picked up, the surrounding structures automatically descend, presenting a series of contents such as product display screen, eating method, production process, and so on, creating an interaction process different from daily experiences, such as making users feel extremely friendly at the same time and feel a little surprised.

5.2.3. Reflection Layer: Deep Communication of National Culture. The experience of the reflection layer conveys the deep semantics of the product, pays attention to the user's culture, memories, and emotions, and increases the spiritual value and cultural connotation of the product. It is a progressive process of user experience from shallow to deep. This layer focuses on information, culture, and the story behind the product, which is usually the progression of the instinctive layer of the product and the extension of the behavioral layer experience. Based on the user's emotional experience, guided by the three-level theory of emotionality, the practical design of food packaging is completed, providing a new development direction for the packaging of national characteristic products.

6. Conclusion

This paper summarizes the principles and methods of interactive packaging design by exploring consumer perception characteristics and emotional experience paths. According to the three aspects of the user's emotional experience in packaging, three methods of interactive packaging design are summarized, cleverly through the color of the image and the arrangement of the text, the emotional expression of cool and warm colors, the fusion of new technology materials, etc. The interactive experience method when using, including the surprise presentation of the opening method, the scene reproduction of the three-dimensional page, and the introduction of AR technology to enhance the brand memory. For information feedback and reuse after use, including adding QR code recognition and broadening the information dissemination platform, designers should focus on a wider audience. Based on the research of this paper, there are the following possibilities for follow-up research: in-depth analysis of consumers' usage needs, behaviors, and psychological characteristics, and perfect packaging design methods. Continue to expand the research scope of packaging design and deeply explore the possibility of packaging innovation in packaging materials, production processes, packaging, transportation, etc. Continue to explore the application of innovative methods in the packaging of ethnic products and broaden the channels for the dissemination of ethnic culture. In the process of protecting the product, the packaging will cause an emotional experience for the user. Paying attention to the psychology

and behavior of users can better guide the packaging design, promote the mutual communication between users and products, trigger a positive emotional experience while increasing the added value of products, and convey national culture in a subtle way.

Cities need to develop, people's lives need to be improved, and the living environment needs to be enhanced. With the strengthening of the national policy of paying attention to people's livelihood, the speed of development, the increase of the number of cars, and the major demolition and construction of streets are in full swing everywhere. However, traffic congestion has become a serious social problem, which greatly affects economic development and people's daily life. Therefore, the study of signal coordination control of urban traffic arteries has become an urgent problem for all countries. In this paper, after a brief introduction of the basic concepts and related technologies of traffic control systems, we focus on the arterial coordinated control system. The adaptive control model studied in this paper reveals the vehicle arrival dynamics from a microscopic perspective, which helps to improve the adaptive control effect and alleviate urban intersection congestion. The use of traffic information acquisition and control systems can promote the application of vehicle networking technology, while moreover helping to provide important model simulations for future street simulation renovation.

1. Introduction

It is urgent to analyze and propose solutions to the current shortcomings and problems of urban street space design and the current situation of urban streets in China. We should use system theory as an analytical tool and philosophical theory support, from the cultural, human, ecological, ethical perspective to analyze the design of urban street space in China and the current situation of the street problems. Street space is not a long and narrow independent space, closed space, but widely permeated to other types of space, and benign interaction. Street space condenses and carries a large amount of information, involving economic, political, and cultural and social factors and reflects not only value orientation but also social ethics. The transformation process of historical districts often involves different social groups, and one social group often influences another group in order to realize its own spatial practice [1]. Street space renovation design must not unilaterally pursue the expansion of traffic flow while ignoring the reduction of pedestrian space;

unilaterally pursue individual or local economic or commercial interests while ignoring long-term social and overall interests; unilaterally pursue so-called biased visual aesthetics, personal preferences, and a certain style while ignoring the real life and inner feelings of citizens; unilaterally pursue formal novelty and objective prosperity while ignoring the regulation of microclimate. The unilateral pursuit of formal novelty, objective prosperity, while ignoring microclimate regulation and humane care; the unilateral pursuit of verbal ecological green environmental protection and ignore the true meaning of ecological cycle, the true meaning of the green environment, simply because of the so-called international style, while ignoring the unique flavor of the regional personality with a deaf ear. A good street is not only durable but also useable, pleasant, livable, ecological, harmonious, and humane. It is a dynamic open system with all the characteristics of a system that needs to be constantly improved and evolved to meet the needs of the times and to adapt to the development of people. Street space is the window of the city, recording the history of the citizens, and

every detail gives the space a personalized charm, reflecting the comprehensive quality and public spirit of the citizens. The transformation design of street space needs to be preceded by systematic analysis methods and forward-looking theories, and the transformation plan should be made according to local conditions after careful investigation and research of basic information, meticulous and thorough analysis, feedback and evaluation, and many other procedures of combing and borrowing relevant theoretical research results and comprehensive research.

One of the most important points is that urban traffic congestion has become a serious social problem, and how to regulate and manage urban traffic flow in a rational and scientific way is the focus of attention of the global traffic engineering and theoretical communities. Urban residents are increasingly vulnerable to the problems brought by high urbanization, such as traffic congestion, air pollution, and housing tension. Among them, urban congestion is a common problem in major cities around the world, and it seriously affects the quality of life of residents and the operational efficiency of various services. To solve urban traffic congestion, on the one hand, the layout and proportion of residential land and commercial land should be reasonably arranged from the interactive relationship between land use and traffic, so as to solve traffic congestion from planning; on the other hand, the traffic efficiency of roads and road networks should be improved to reduce the probability of congestion. Urban traffic control signal control intersection, as a key node of the road network, is the most likely location to generate traffic congestion, and if its queue of vehicles spreads without limit, it will seriously affect the traffic efficiency of adjacent intersections. Therefore, the signal control strategy of intersections, as an effective method to alleviate their congestion level, is an important research direction for urban road reconstruction in recent years. According to the traffic flow characteristics of urban arterial roads, it has become one of the important research topics of current intelligent traffic control to design advanced adaptive coordinated control systems for urban traffic arterials by using advanced information technology, communication technology, and control technology to improve the operational efficiency of arterial traffic networks. In addition, with the implementation of the concept of bus priority in major cities, the proportion of buses in the road network has increased significantly. In order to improve the efficiency of bus travel, more and more urban intersections are equipped with bus priority signals. However, existing studies and practices show that vehicle-specific signal priority strategies will inevitably lead to increased delays in normal traffic flows. Especially in the case of a general mix of buses and cars, attention needs to be paid to the signal right-of-way allocation for traffic in different directions. Therefore, a reasonable signal control strategy is particularly important to reduce passenger delays. Conversely, if the signal timing scheme does not correctly reflect the characteristics of real-time traffic flow, it may lead to wasted green time, too short cycles, or underestimated turn times, generating unnecessary waiting time. Studies have shown that up to 40% of excess fuel consumption can be generated due to improper

traffic signal timing [2]. It is of practical importance to study and design coordinated signal control systems for urban traffic arterials to solve urban congestion and ensure smooth road flow to promote economic development.

In this paper, after a brief introduction of the basic concepts and related technologies of traffic control systems, we focus on the arterial coordinated control system. With the help of numerical models of arterial traffic delays, we established a set of our own real-time optimization algorithms for arterial coordinated control systems with reference to the current previous control systems. We have collected various literature and technical reports to grasp the current status and development direction of theoretical research in the field of adaptive signal control. In the process of studying the literature, we focused on microscopic simulation-based optimization and control models and organized and summarized the research methods from the perspectives of data collection and traffic flow arrival characteristics. In addition, since developed countries in Europe and the United States started earlier in this field and accumulated rich theoretical foundation and practical experience, this paper pays special attention to the effectiveness of new signal control and optimization methods in comparison with traditional methods based on collecting and organizing relevant data. The phase structure adopted by the signal controller specifies the combination of traffic flow directions for simultaneous release, which will have a certain impact on the final optimization effect. Previous adaptive signal control methods tend to use a four-phase signal structure with simultaneous release of opposing traffic flows, which can only accommodate control requirements where opposing traffic flows are approximately the same. However, in reality, due to the possible deviation of the opposite traffic flow during the peak of the tidal phenomenon, a signal phase structure with higher flexibility in the North American NEMA (National Electrical Manufacturers Association) standard is needed. We then perform adaptive signal optimization and control using a modified dynamic programming (DP) algorithm that is divided into forward recursion and backward recursion. The forward recursive process is combined with the North American NEMA phase structure to invoke a vehicle arrival time prediction model for short-term traffic flow prediction, on the one hand, to estimate the intersection vehicle delay, queue length, and throughput based on the different phase characteristics of vehicles passing through the intersection on the other hand, and finally to determine the optimal green time length and its phase combination for each phase. The optimal phase sequence and duration can be determined through the reverse recursive process, thus completing the optimization of the timing scheme in one go.

The technical route of the research in this paper is shown in Figure 1. The core of the research is an adaptive signal control optimization method for urban intersections based on microscopic simulation. Based on the summary of the current research status, the key issues such as vehicle arrival prediction under microscopic perspective, improvement of traditional dynamic planning algorithm, signal optimization model under the conditions of vehicular network, and

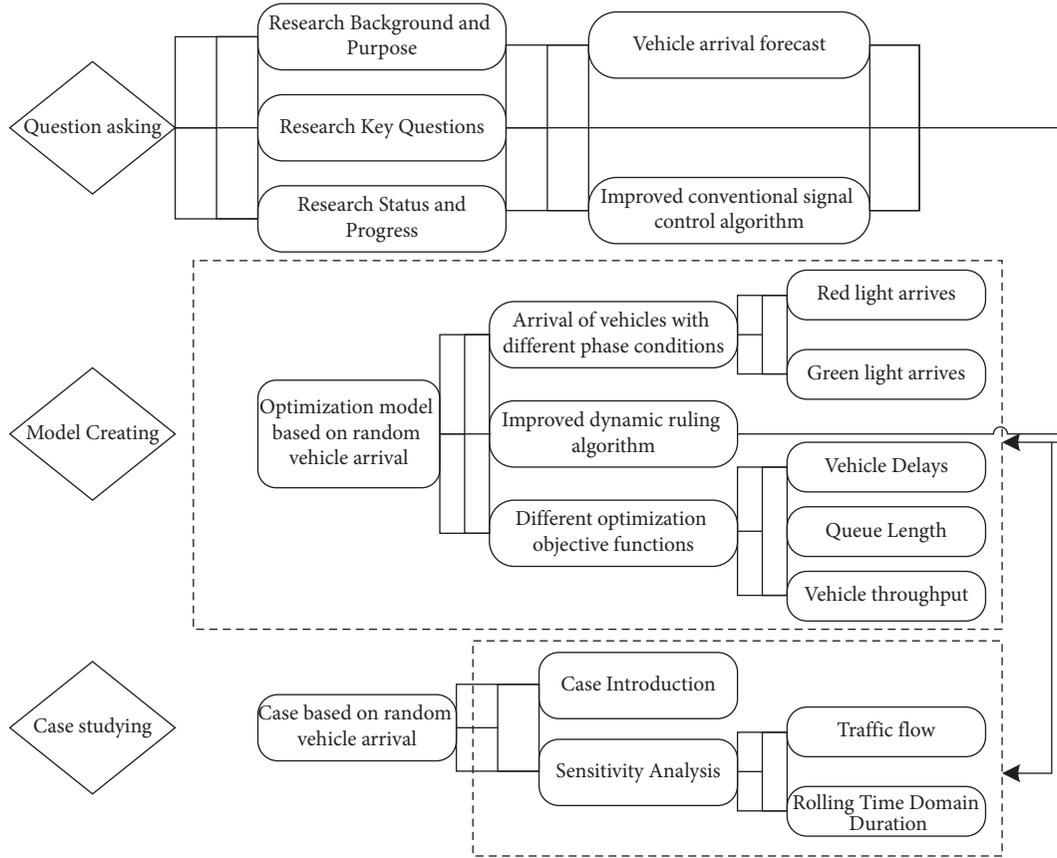

FIGURE 1: Research technology routes.

distributed signal cooperative optimization are focused on. An improved adaptive signal control model based on random vehicle arrival under different vehicle arrival mode conditions is proposed. Finally, based on the secondary developed VISSIM simulation, the proposed model is verified and analyzed using two real intersection cases, respectively, and finally, the research conclusions are drawn.

In order to verify the feasibility of the method proposed in this paper, a secondary development platform is constructed for signal optimization and collaboration using the simulation software VISSIM, a microscopic traffic simulation software developed by PTV, Germany, which can effectively simulate and analyze the operation of vehicles, pedestrians, and rail traffic under various traffic conditions. In the simulation of road network intersections, the general practice is to input the timing scheme in advance and keep the timing scheme fixed during the simulation process. This practice not only cannot realize the information interaction between VISSIM and the optimization model but also is not conducive to the development and validation of new traffic control models. Therefore, it is necessary to link the VISSIM simulation platform with external programs using the COM interface to achieve signal collaboration and optimization. Real-time interaction between external programs and simulation software can be realized through the VISSIM COM server interface technology. The principle of interaction between VISSIM simulation software and programming is briefly described in Figure 2.

2. Adaptive Control Method Based on Traffic Flow Model

Model adaptation (MA for short) has now become a research hotspot in several fields. Its goal is to maximize the performance of the target task using both source training data and target data. As shown in Figure 3, we train a good original model on rich source/training data and adapt the model with additional task-related data in the application phase to get an adapted model (adapted model) to better fit the target task/target data. Model adaptation can be seen as a way of migration learning.

In addition to the signal control methods that have been applied in existing systems, scholars around the world have developed various adaptive signal control and optimization theories based on different characteristics and applicability conditions for adaptive models in road modification signal control. The existing studies generally need to rely on specific traffic flow models and mathematical optimization methods, which can be classified into the single intersection, arterial, and regional cooperative adaptive signal control methods according to their applicability.

In this paper, we introduce many methods and generalize and unify them. Since the introduced and organized articles span a wide range of concepts in terms of time and geography, we have unified the concepts in this article and tried to show our unified concepts in the form of diagrams or formulas.

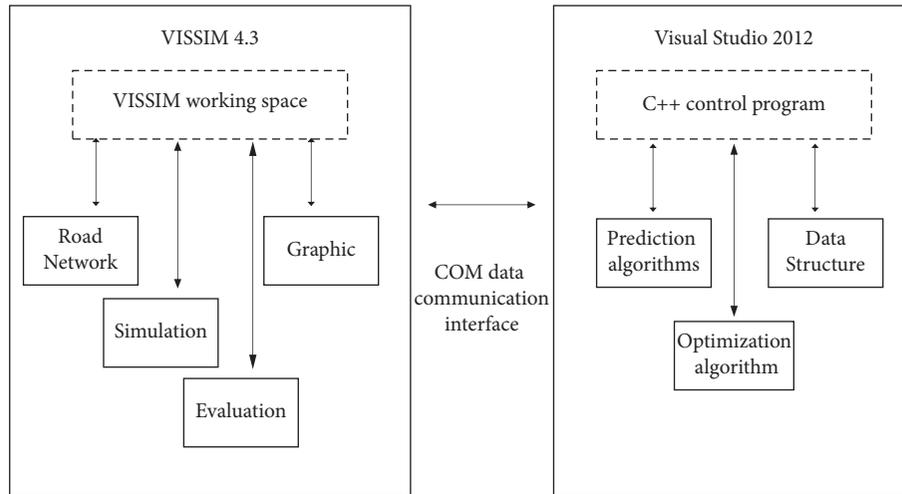

FIGURE 2: Principle of interaction between VISSIM simulation software and visual studio programming environment.

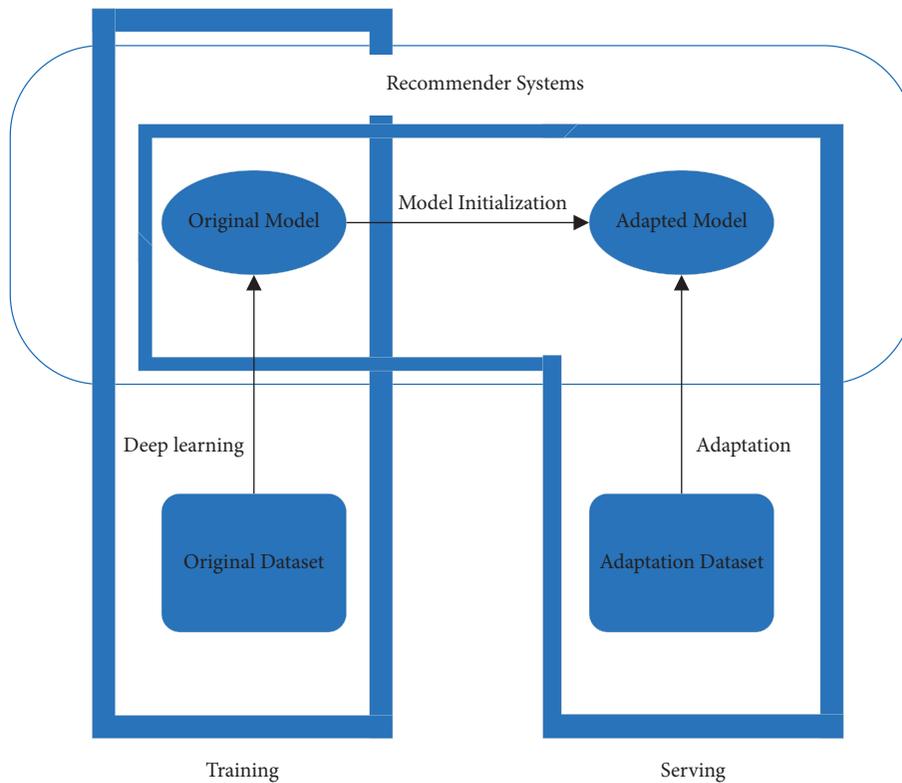

FIGURE 3: General principles of adaptive models.

There are a large number of level intersections in urban roads, which become the convergence and diversion points of traffic flow. In order to make the traffic flow safely into and out of the intersection, some control method must be used to reasonably allocate the right-of-way so that conflicting traffic flows are separated in time and space, thus ensuring the safe passage of vehicles and pedestrians. Planar intersections can generally be divided into cross-shaped, X-shaped, T-shaped, Y-shaped, and multiway intersection shapes. Due to the complicated traffic organization of multiway intersection, it should be avoided as much as possible.

The signal used to direct traffic always changes step by step in a cycle, and a cycle consists of a finite number of steps. The sum of the step lengths of each step in a cycle is called the signal period, or cycle for short, and is denoted by C . If a cycle has n steps, the step lengths are t_1, t_2, \dots, t_n , then the period formula can be shown by the following formula:

$$C = t_1 + t_2 + \dots + t_n. \quad (1)$$

In traffic control, in order to avoid conflicts between traffic flow in all directions on the plane intersection,

usually use the method of time-sharing, that is, in a cycle of a certain period of time, the intersection on a certain traffic flow or several traffic flow has the right of way (i.e., the direction of the signal is green or green arrow), and the conflict with the other traffic flow cannot pass (i.e., the signal in the direction of red). In a cycle, the right-of-way obtained by one or more traffic streams on the level intersection is called the signal phase. A cycle of several signal phases, the signal system is said to be a several phase system. The phase can be represented by a directional line segment, the direction of the arrow direction, and the direction of vehicle movement. If a light-controlled intersection is a four-phase system, the first phase of east-west traffic flows straight ahead, the second phase of east-west traffic flows left, the third phase of north-south traffic flows straight ahead, and the fourth phase of north-south traffic flows left, while all right-turning traffic flows are not controlled. The above phase system is generally known as a four-phase signal and can be represented by Figure 4.

Sometimes, in order to improve intersection utilization, the right-of-way of one traffic flow in one phase can be maintained until the next phase, most often for left-turn traffic flows, as shown in Figure 5. Since the left-turn traffic flow of the second and fourth phases is a continuation of the first and third phases, respectively, the step length can be shorter, for example, a few seconds. Therefore, some people call them “half-phases.” However, the concept of steps and step lengths is quite simple to describe that the above example is actually four steps in a cycle.

The phase difference is an important concept in the coordinated control system of traffic arteries. The phase difference is divided into absolute phase difference and relative phase difference. In the traffic arterial coordinated control system, all intersections on the arterial have the same signal period, and each intersection designates a certain phase to participate in the coordination, called the coordinated phase. With an intersection on the traffic arterial as the reference intersection, the minimum time difference between the start time of the coordinated phase of other intersections lagging behind the start time of the coordinated phase of the reference intersection is called the absolute phase difference; the minimum time difference between the start time of the coordinated phase of any adjacent intersection along the direction of vehicle travel is called the relative phase difference.

Single intersection signal control is the basis for implementing traffic arteries, regional signal control, and distributed control strategies. Regardless of the adaptive signal control strategy, vehicle arrival prediction based on a single intersection is required. Fang and Elefteriadou [3] proposed a vehicle arrival-dissipation prediction model considering intersection queues, which can solve the problem that the conventional PREDICT algorithm [4] cannot accurately predict the intersection approach lane queue length. However, since the model only microscopically simulates the queue arrival under red light conditions, its vehicle arrival dynamics under green light conditions remain to be investigated. Sun and

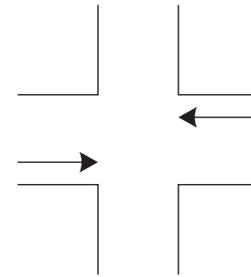

FIGURE 4: 4-phase signal diagram. (a) Phase 1. (b) Phase 2. (c) Phase 3. (d) Phase 4.

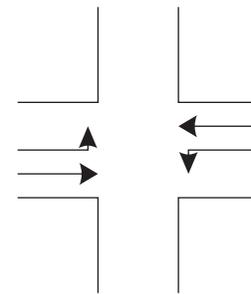

FIGURE 5: Half-phase signal diagram. (a) Phase 1. (b) Phase 2. (c) Phase 3. (d) Phase 4.

Zhang [5] developed a single-intersection vehicle arrival prediction model under triggered signal control conditions, which is not only applicable to NEMA phase structures but can also be extended to multiintersection cooperative control.

The first single-junction-based adaptive signal control strategy was proposed by Miller [6] in 1963, and since then various adaptive signal control strategies have emerged, such as optimization policies for adaptive control (OPAC) [7], PRODYN [8], UTOPIA [9], and controlled optimization of phases (COP) [10]. The aforementioned signal control strategies use dynamic planning algorithms to adjust the green time in real time based on vehicle arrival predictions, among which the COP algorithm is considered to be the best single intersection adaptive signal control algorithm to date because it is not limited by cycle length and phase sequence. The optimization process of the COP algorithm is divided into two main parts: first, a forward recursive step to calculate the vehicle delay time under each alternative scheme and a backward recursive [11] provide a detailed comparison of the performance of various dynamic planning algorithms. Porche and Lafortune [12] proposed the ALLONS-D adaptive signal control theory in 1999, which uses branch constraint method to calculate the optimal timing scheme, while proposing an “implicit coordination” mechanism, that is, optimizes the signal timing schemes of individual intersections sequentially with the predicted upstream traffic arrivals to achieve cooperative control. This approach requires a shorter prediction time (5–15 s), the detector can be placed in the middle of the road, and takes into account the influence of upstream intersection signal control on the prediction results, but the shorter time step places higher

demands on computer performance. Fang and Elefteriadou [13] proposed a single intersection adaptive signal based on the OPAC algorithm and supporting the NEMA phase control strategy. Feng et al. [14] proposed an optimization algorithm based on the COP algorithm and compatible with NEMA phases in 2015, but its performance suffers due to the introduction of the enumeration algorithm in the two-layer model.

From this, it can be found that adaptive signal timing at individual intersections under the framework of a distributed “implicit coordination” control strategy is still necessary for research, first to further improve the short-term vehicle arrival prediction model at the microlevel, while how to improve the algorithmic optimization effect under NEMA phase conditions is still a frontier issue in the field of traffic control. After all, improving the capacity of individual intersections is still the key to achieving smooth traffic flow.

The earliest traffic arterial signal control systems in the world can be traced back to the six-intersection manual signal control system in Salt Lake City, USA in 1917, followed by the development of a 12-intersection cooperative signal control system based on automatic machine timers by the City of Houston in 1922. In contrast, researchers at this stage generally start by maximizing the green wave bandwidth to achieve cooperative control of arterials. The first computational model for bandwidth optimization was proposed by Morgan and Little [15] in 1964, which was able to optimize a fixed signal timing scheme for two-way arterials to maximize the green wave bandwidth. Subsequently, Little [16] proposed a more advanced mathematical planning model to determine the optimal signal cycle length and the recommended travel speed for a given range. Based on this, Little et al. [17] developed the classical MAXBAND model by combining left-turn traffic and queue lengths. The MULTIBAND model was proposed by Gartner et al. [18] in 1995, which can set different bandwidths for traffic arterials to meet specific traffic flow characteristics.

However, the above studies are based on offline methods, and in order to dynamically adjust the signal timing scheme at arterial intersections, Dell’Olmo and Mirchandani [19] proposed the REALBAND optimization model, which uses a decision tree approach to minimize the number of stops and total delays of arriving convoys as the study object, which has been applied through the RHODES [20] system. The real-time, hierarchical, optimized, distributed, and effective system (RHODES) is a distributed adaptive traffic signal optimization system developed by the University of Arizona, USA, using a hierarchical control structure, that is, a network load distribution layer, a network flow control layer, and an intersection control layer. Its traffic flow prediction algorithm obtains vehicle arrival information through detection coils buried in front of the stop line at upstream intersections, and the model system allows for longer prediction times due to possible phase delays.

However, the common drawback of the above models is that they cannot effectively handle the arterial signal coordination problem under saturated traffic conditions. To address the capacity loss caused by vehicle overflow,

Lieberman et al. [21] proposed a real-time cooperative optimal control strategy for oversaturated traffic flow on traffic arterials, which mainly uses Lighthill and Whitham [22], and the traffic flow fluctuation theory proposed by Richards [23] to calculate the fleet depletion time and rate. Hu et al. [24] used the hybrid genetic-simulated annealing algorithm of Li and Schonfeld [25] to optimize the signal timing scheme of traffic arteries under oversaturated traffic flow, including phase sequence, cycle length, and green time, and the results showed that a reasonable phase sequence is crucial to improve the optimization effect.

Given the complexity of the actual system, semiautomatic control has been widely used in the field of cooperative signal control at arterial intersections due to its low installation and usage costs. This signal control strategy is mainly based on triggered control logic that dynamically adjusts the phase difference parameters of key phases at upstream and downstream intersections to achieve cooperative control, and part of the adjustment mechanism is implemented based on offline computation. For example, Jovanis and Gregor [26] improved the traditional optimization method of maximizing the green band by moving the reference point of the phase difference to the end of the straight ahead phase to achieve semitriggered cooperative control. Shoup and Bullock [27] used the travel time of the first vehicle in the passing convoy to dynamically adjust the phase difference parameters. Yin et al. [28], on the basis of a large number of basis, Zhang and Yin [29] proposed a robust optimization model to adjust the cycle time and phase difference, which can effectively deal with the effect of uncertainty in the coordinated phase start time in semitriggered signal control. For the uncertainty of traffic flow, Zhang and Lou [30] proposed an optimization model for semitriggered signal control based on integer programming, which can obtain significant optimization results under lower traffic conditions.

In summary, the research of traffic arterial signal synergy and optimization models generally focuses on the modeling of the phase difference adjustment mechanism based on the traffic flow model, because the signal control parameters set can effectively improve the intersection capacity only when the traffic flow changes are reasonably predicted. However, some of these control models are mainly based on off-line calculations, which cannot well match the real-time fluctuation characteristics of traffic flow. If the traffic flow in different directions can be coordinated, this type of signal control model will be extended to the road network level to achieve larger scale traffic coordination and control.

3. Adaptive Control Model for Random Vehicle Arrival in Urban Roads

The signal period of each intersection in the line control system should be the same so as to ensure the stability of the arterial phase difference. Therefore, the period as the timing parameter of the line control system should refer to the common period of the signals at each intersection in the control model. There are usually two methods to determine the common period: one is to directly take the best period of

the most important intersection in the traffic status of the arterial as the common period; the other method is to calculate the best period of each intersection according to the traffic condition of each intersection and then take the largest value as the common period to avoid the bottleneck effect. This chapter introduces the vehicle arrival model and adaptive signal control optimization method based on a microscopic perspective. The method is mainly applied to traffic signal control in the case of random vehicle arrivals. In order to improve the adaptive signal control algorithm, the NEMA traffic signal phase structure, which is common in North America, is introduced into the original dynamic planning algorithm. In addition, the objective functions of vehicle delay, queue length, and vehicle throughput are established in this chapter. Finally, the implementation framework based on the secondary development of the COM component of the VISSIM simulation software is introduced.

In adaptive signal control, vehicle arrival and dissipation information is an important input variable for the signal optimization algorithm, while the signal timing scheme will conversely affect the changes in traffic dynamics near the intersection. In general, traditional adaptive signal control methods collect vehicle arrival information mainly through upstream detection coils or cameras. If a queued vehicle has not completely left the stop line, whether it starts moving or not, the subsequently detected vehicle travel distance is primarily the distance from the upstream detection coil location to the end of the queue. Therefore, the intersection maximum queue length (distance from the stop line to the end of the queueing convoy) [31] is crucial for estimating the vehicle stopping time. In this section, the trajectory and maximum queue length variation of vehicles arriving at the end of the queue until they leave the stop line are studied from a microscopic perspective to model the vehicle arrival-dispersion process. The proposed model is able to predict the vehicle arrival time at the end of the queue fleet under red light and green light conditions.

3.1. Red Light Arrival. Assume that the distance from the upstream detection coil to the intersection stop line is D . The vehicle passes the detection coil and proceeds at the free-flow speed, vf , and reaches the end of the queue in different lanes according to a certain steering ratio. For simplicity, the deceleration process when the vehicle enters the queue is ignored. The travel time, tt_k , and arrival time, t_k^a , of vehicle k at this distance can be expressed by the following formulas:

$$tt_k = \frac{(D - q_{k-1}^{\max})}{vf}, \quad (2)$$

$$t_k^a = t_k^d + tt_k, \quad (3)$$

where q_{k-1}^{\max} is the maximum queue length after the vehicle $k-1$ enters the queueing convoy; t_k^d is the time for the vehicle to pass the upstream detection coil. The initial maximum queue length can be expressed as $q_0^{\max} = n_0 \cdot S$, where n_0 is the number of queued vehicles in the lane and S is the length of the space occupied by the queue.

In Algorithm 1, T_{st} and T_{end} are the start and end times of the red or green light in the phase, which can be used as the range of vehicle arrival times. The set of the vehicle arrival times at the detection coil is also used as one of the inputs to the algorithm, and K represents the number of detected vehicles. If the calculated vehicle arrival time is within the red light time range $[T_{st}, T_{end}]$, it is recorded and used in the subsequent optimization algorithm. Also, the maximum queue length value is updated after the vehicle arrives. If the vehicle arrival time is greater than the predefined time range or if no vehicle arrives, Algorithm 1 ends. The algorithm will end.

3.2. Green Light Arrival. After the start of the green time, as the traffic dissipation wave [22] passes, the queued vehicles start one by one and at the following speed vq ($vq < vf$) through the stop line. Depending on whether the end-of-fleet vehicle starts or not, the vehicle arrivals can be divided into two categories: Scenario 1, the arriving vehicle arrives and stops before the dissipation wave passes to the end of the queue and then restarts to cross the intersection. Scenario 2, the arriving vehicle catches up with the started vehicle at the end of the queue at free-flow speed vf and passes the intersection stop line at the following speed vq . The details of the two scenarios are shown as follows.

In Scenario 1, similar to the arrival case during the red light period, vehicles join the stationary queueing convoy, and the maximum queue length continues to increase. According to the traffic flow theory, the start time of the vehicles at the end of the queue corresponds to the time when the dissipation wave ends its propagation [32]. Assuming that the speed of propagation of the dissipation wave of the traffic flow after the start of the green light is v_s , therefore, the start time of the vehicle at the end of the queue after the start of the green light can be determined by the following formula:

$$t_s = T_{st} + \frac{q_0^{\max}}{v_s}. \quad (4)$$

If the vehicle arrives before the start time, t_s , at the end of the queue, the start time of the vehicle at the end of the queue increases accordingly due to the increase in queue length Δt_s , which is calculated as follows:

$$\Delta t_s = \frac{S}{v_s}. \quad (5)$$

In Scenario 2, the end of the line starts moving before the arriving vehicle joins the convoy, so the arriving vehicle first moves forward at free-flow speed vf and then joins the convoy at the following speed vq to pass the stop line. For arriving vehicle $k+1$, its arrival process is similar to that of the previous vehicle, the only difference being that the preceding vehicle k has already started at the t_k^a time. In this case, the final value of the arrival moment is calculated as follows:

$$\Delta t_k^a = \frac{vq \cdot [t_k^{a,0} - \max(t_{k-1}^a, t_s)]}{(vf - vq)}, \quad (6)$$

$$t_k^a = t_k^{a,0} + \Delta t_k^a, \quad (7)$$

where Δt_k^a represents the additional travel time required for arriving vehicle k to catch up with the end of the moving queue. The numerator in (6) represents the length of the vehicle $k-1$ traveling forward from the time t_{k-1}^a , and the denominator represents the speed difference. Due to the speed difference between the free-flowing vehicle speed and the following vehicle speed, it is assumed that the arriving vehicle k will catch up and join the convoy at moment t_k^a . The flow of the arrival time and maximum queue length estimation is shown in Algorithm 2.

In Algorithm 2, first initialize the vehicle start time t_s at the end of the queue, the initial value of vehicle travel time tt_1 , and the initial value of vehicle arrival time $t_k^{1,0}$. Vehicle arrivals can be divided into two categories according to the relationship between the magnitude of t_k^a and t_s (Step 3): in scenario 1, the maximum queue length continues to increase; in scenario 2, it is necessary to detect whether the arriving vehicle k can catch up with the convoy before the stop line and pass with the following speed vq . If not, subsequent arrivals will continue and the above process will continue until all arrivals have passed the checkpoint. It can be seen that the maximum queue length and the state of the vehicles at the end of the queue are the keys to estimate the vehicle arrival time in this model.

3.3. Real-Time Signal Control Algorithm. The DP algorithm mainly consists of forward and backward recursion algorithms. The forward recursion is mainly used to calculate the optimal green light time and its corresponding objective function value under different control variables. Backward recursion is mainly used to calculate the optimal signal. Backward recursion is mainly used to calculate the optimal signal timing scheme. The details of the forward and backward recursive algorithms are described as follows.

The forward recursive algorithm in the DP algorithm mainly assigns the phase time length and the alternative traffic direction combinations to each phase group. If a phase in the DP corresponds to two alternative traffic direction combinations, the phase group can be omitted assuming that the minimum control variable, $x_j^{\min} = 0$, which means that the minimum green time is zero; otherwise, the minimum green time is a certain determined value (e.g., 10 s). Under the minimum green light time constraint, the state variable corresponding to phase j can be calculated by the following equations:

$$s_j^{\min} = \begin{cases} s_j^{\min} + h(x_j^{\min}), & j > 1, \\ \max\{x_j^{\min} - x_e, 0\}, & j = 0, \end{cases} \quad (8)$$

$$h(x) = \begin{cases} x + R, & x > 0, \\ 0, & x = 0, \end{cases} \quad (9)$$

where s_j^{\min} is the smallest state variable value in stage j in the DP algorithm, x_e indicates the length of the green time in the end phase of the previous rolling time domain, and R is phase interval, which is the time when there are all yellow or full red light.

In order to simplify the DP algorithm, the maximum green time limit is omitted as it is not often reached in practice. The upper limit of the state variable is T , and the rolling time domain is not bounded by the cycle time. The set of feasible control variables, $X_j(s_j)$, for a given state variable, s_j , can be expressed by the following formula:

$$X_j(s_j) = \begin{cases} x_j^{\min}, \dots, s_j - s_j^{\min}, & \text{if } s_j^{\min} < s_j < T, \\ 0, \dots, T - s_j^{\min}, & \text{if } s_j = T. \end{cases} \quad (10)$$

Using (10), it can be found that each phase in the DP algorithm may correspond to the end phase group of the rolling time domain. If the state variable is equal to the rolling time domain duration, the current phase group may be omitted, and the previous phase group may become the end phase of the current rolling time domain. With supporting variables, c_j is the phase group assigned to DP phase j , which contains two nonconflicting traffic directions; $C_j(i)$ is alternative sets that can be assigned to the two traffic directions in the i phase group. $f_{j(c_j, s_j, x_j)}$ is the objective function value when the state variable is s_j , the control variable is x_j , and the phase group is c_j ; $v_j(s_j)$ is the cumulative value of the objective function from DP stage 1 to stage j . We can then summarize Algorithm 3 as the forward recursive algorithm in the DP algorithm:

The forward recursion algorithm first initializes the cumulative state values. In each stage, the DP algorithm calculates the optimal control variables and the green light phases for each condition. The objective function value can be obtained by the model calculation in the next section. The stopping condition of the proposed algorithm differs from the conventional COP algorithm, that is, the algorithm ends when the minimum value of the state variable is greater than the rolling time domain duration T (step 3) and when the objective function value is no longer varies as the phase group increases.

In the backward recursive algorithm, when the optimal function values of all control variables under each phase of the DP algorithm are known, the optimal phase combinations and green light duration in each DP phase can be obtained by the backward recursive algorithm. When the state variable is T , the DP algorithm can be started from the end phase, to phase J where $x_j^*(T) \neq 0$, in order to obtain the optimal control variables, $x_j^*(T)$.

The reasons why the optimal green light duration can be recursively extended through phase J are as follows: first, the stopping condition in Algorithm 3 ensures that no other phase groups can be added at the end of the rolling time domain. Second, for any phase that $j > J$, its corresponding green time length is 0, which can no longer improve the optimization result of the signal timing scheme. At this point, the backward algorithm can be expressed by Algorithm 4 as follows.

With the four algorithms illustrated before, we can then calculate the objective functions or target variables.

For adaptive signal control algorithms, different objective functions often lead to different control effects. Under specific traffic flow or rolling time domain duration

conditions, some objective functions tend to obtain better signal control optimization results. In this text, $f_{j(c_j, s_j, x_j)}$ represents the objective function corresponding to different measurement indicators, including delay, vehicle queue length, and throughput. The objective function and related variables are calculated as follows:

Objective function 1.

$$\min \sum_{t=s_{j-1}+1}^{s_j} \sum_{p=1}^8 \sum_{l \in L_p} n_l^q(t). \quad (11)$$

Objective function 2.

$$\min \sum_{p=1}^8 \sum_{l \in L_p} n_l^q(s_j). \quad (12)$$

Objective function 3.

$$\min \sum_{t=s_{j-1}+1}^{s_j} \sum_{p=1}^8 \sum_{l \in L_p} n_l^d(t). \quad (13)$$

Objective function 1 denotes minimizing the sum of queue lengths for all lanes from state moment s_{j-1} to s_j for each time step, which is the length of time experienced by all vehicles from the start of the queueing state until they leave the stop line.

Objective function 2 is calculating the minimized queue length, which is the sum of the queue lengths for each lane at the end of each phase group.

Objective function 3 represents the number of vehicles maximized through the intersection, which is the total number of vehicles leaving in each phase. The unit time interval in the above objective function is 1s.

Where l represents certain lane, and L_p is the lane set in phase p , and the relative variables are calculated as follows:

$$n_l^q(t) = n_l^q(t-1) - n_l^d(t) + n_l^a(t), \quad (14)$$

$$n_l^d(t) = \min\{v, n_l^q(t-1) + n_l^a(t)\} \forall l \in L_p, p \in c_j \cap c_{j-1}, \quad (15)$$

$$n_l^d(t) = \begin{cases} \min\{v, n_l^q(t-1) + n_l^a(t)\}, & s_{j-1} + R < t \leq s_j, \\ 0, & s_{j-1} < t \leq s_{j-1} + R, \end{cases} \forall l \in L_p, p \in \frac{c_j}{c_{j-1}}, \quad (16)$$

$$n_l^d(t) = 0, \quad \forall l \in L_p, p \notin c_j, \quad (17)$$

$$n_l^a(t) = A(l, t). \quad (18)$$

In equation (14), the number of vehicles in queue at time t is determined by the number of vehicles in queue, arriving, and departing vehicles at time $t-1$ while departing vehicles could be illustrated by equations (15)–(17). Where v represents vehicle dissipation rate at saturation headway. And $A(l, t)$ in equation (18) denotes the number of vehicles entering the queueing fleet at moment t , obtained mainly based on the vehicle arrival prediction information described in the previous section.

3.4. Implementation Framework and Methodology. This study uses the C++ programming language and Visual Studio 2012 for secondary development of VISSIM simulation software, VISSIM supports C++, JAVA, and VB for secondary development, and compared with other programming languages, using C++ is more convenient to implement various data structures and improve programming efficiency. The following briefly describes the principle of the COM interface of VISSIM simulation software and its application in this study. Figure 6 shows the development framework for implementing the algorithmic model in this section.

In Figure 6, the left side shows the simulation function and interface of the VISSIM simulation platform, and the right side shows the C++ console program of the urban

intersection adaptive model built in this paper, which is called by the VISSIM simulation kernel through the COM interface, including the prediction model and dynamic planning algorithm. In VISSIM version 4.3, the simulation engine contains several simulation categories, among which the Net category contains signal-controlled intersections and traffic elements in the road network, including the SignalControllers category, Links category, and Vehicles category. The SignalControllers category is used to control the signal controllers at all intersections in the network, and for each signal intersection, there is a corresponding SignalController category. The adaptive signal control program built in this paper mainly obtains the vehicle arrival trigger information through the detector category, then collects the implemented timing schemes through the SignalGroup category, and finally returns the optimized signal phases and durations to the SignalGroup category to achieve real-time signal timing control.

4. Signal Control Model Based on Random Vehicle Arrival

First, in order to validate the adaptive signal control optimization method based on vehicle microarrivals, the intersection of Jianchuan Road and Humin Road is used as an

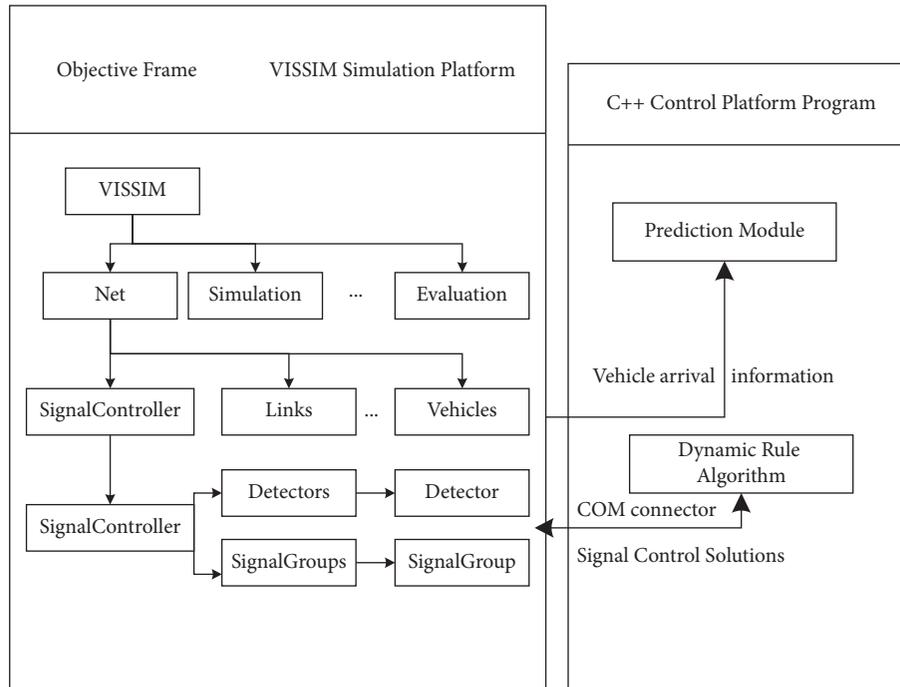

FIGURE 6: Simulation implementation framework.

empirical case and analysis. This intersection is located in Minhang District, Shanghai, and is an intersection with high traffic flow in the region, and the traffic congestion phenomenon is more obvious in the morning and evening peaks, and there is still room for optimization and improvement of its traffic signal timing. Due to the distance from the upstream signal-controlled intersection, the arrival traffic is less affected by the upstream signal timing; at the same time, there are several nonsignal-controlled intersections in the road section, and the vehicle arrival is more random, so this paper uses the random arrival-based adaptive signal control strategy for signal timing optimization. Figure 7 shows the intersection canalization and its corresponding NEMA phase number, where the intersection left-turn lane length is about 150 m, which may generate an overflow phenomenon under oversaturated flow conditions. In order to implement adaptive signal control, it is assumed that a detection coil is buried 500 m upstream to obtain the vehicle passing time and speed for vehicle arrival time prediction.

In this paper, the average stopping distance, the minimum headway, and the desired speed are selected as calibration parameters when establishing the simulation network in VISSIM. Based on the reasonable prediction, the above parameters are set to 3 m, 2 s, and 35 km/h. The C++ console program is written using VISSIM as the COM interface of the simulation platform. The console program contains a prediction module and an optimization module. The prediction module estimates the vehicle arrival time based on the vehicle information collected from the upstream coil at fixed intervals and passes it to the optimization module for calculation, thus realizing real-time control and optimization of the adaptive signal.

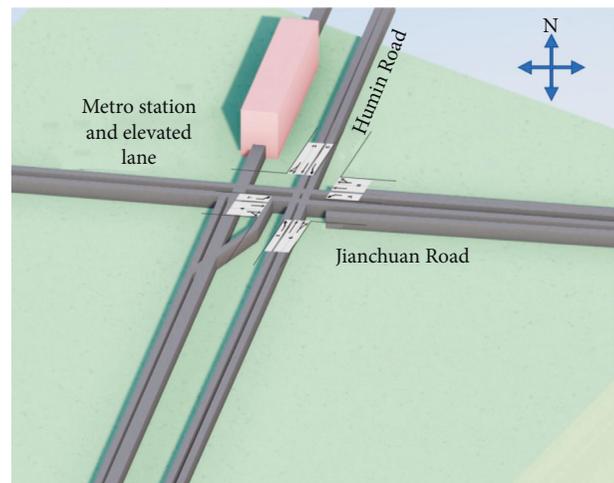

FIGURE 7: Intersection drainage rendering.

Table 1 shows the traffic flow magnitudes for three different congestion levels with intersection saturation levels measured by intersection capacity utilization (ICU) in the traffic signal timing optimization function where the unit is vehicle per hour (vph). The three categories of traffic flow based on different time periods used in this paper cover the low-moderate-high intersection congestion levels, and their traffic saturation rates gradually increase from 58% to 95%. In VISSIM, the vehicle arrival rate obeys a random distribution by ignoring the effect of upstream intersections on the arrival traffic.

The average vehicle delay (s/veh) output from VISSIM is used to evaluate the control effect of the proposed NEMA phase-based DP algorithm, and the optimal fixed signal timing scheme is calculated and compared with the

Step 1 Let $k = 1$, Initialize tt_1 and t_1^a according to the original queue length.
 Step 2 If $T_{st} \leq t_k^a \leq T_{end}$, while $k \leq K$, then record vehicle arrival time, and update $q_k^{max} = q_{k-1}^{max} + S, k = k + 1$; Otherwise end the algorithm.
 Step 3 Use equations. (2) and (3) to calculate the arriving time of vehicle k , and move back to step. 2.

ALGORITHM 1: Define maximum queue length.

conventional four-phase DP algorithm. The conventional four-phase method consists of 1 + 5, 2 + 6, 3 + 7, and 4 + 8 phases of NEMA phases, and the corresponding DP algorithm is similar to the conventional COP algorithm. Assuming that the detection coil is buried in the upstream section 500 m away from the intersection stop line, the vehicle needs about 45 seconds to reach the intersection stop line from the upstream detection coil location under the speed limit of 40 km/h. Therefore, the rolling time domain duration is set to 40 s, so that all vehicles that may reach the end of the queue in the rolling time domain are detected by the upstream coil as much as possible. A sensitivity analysis of the impact of the rolling time domain duration on the performance of the algorithm will be described later.

Table 2 shows the delay data of vehicles passing through the intersection under different signal control strategies, including DP optimization algorithms with vehicle delay, queue length, and vehicle throughput as objective functions, denoted by DP-D (delay), DP-Q (queue), and DP-T (through), respectively. Table 3 shows the comparison results of different adaptive control algorithms with different objective functions and the significance test results at a 95% confidence interval. It is found that the NEMA phase-based DP algorithm proposed in this paper can significantly reduce vehicle delays compared with the four-phase DP algorithm under medium and high traffic conditions, but its optimization effect is not obvious under low traffic conditions.

The simulation results show that the DP algorithm proposed in this paper has different optimization results under different objective functions and traffic flow conditions. Specifically, the DP algorithms (DP-D and DP-T) with vehicle delay and throughput as the objective functions can achieve better optimization results under low traffic flow conditions. However, the optimization results of DP-D and DP-T algorithms gradually decrease as the traffic volume increases. In contrast, the adaptive signal control algorithm DP-Q with queue length minimization as the objective function achieves better optimization results under near-saturation conditions and outperforms the other two control algorithms with the objective function. The reason for this is that under low flow conditions, the queue changes less compared to high flow conditions, so the optimization algorithm as an objective function is not sensitive enough to changes in actual flow, and queue length minimization and queue length minimization are not exactly equivalent to alleviating vehicle delays in all time periods. Combined with the significance test results in Table 3, it can be found that the adaptive signal control algorithm proposed in this paper performs better than the optimal fixed timing scheme except DP-Q under low and medium traffic volumes.

To investigate the variation of the optimal performance of the DP algorithm at different rolling time domain durations, a sensitivity analysis was performed for this case, that is, three DP algorithms with different objective functions were compared under high traffic conditions with rolling times ranging from 20 s to 60 s. As shown in Table 4, the optimization effect of DP-D gradually improves when the vehicle arrival prediction cycle length increases. This is due to the fact that in the longer rolling time domain, the optimization algorithm can effectively evaluate the impact of the signal timing scheme on traffic flow, especially the magnitude of cumulative delay. However, for calculating queue length and throughput, a longer rolling time domain does not lead to improved optimization results. For example, DP-Q mainly uses the queue length at a particular moment as an optimization metric, which requires frequent traffic state updates to obtain better optimization results. dp-t is also insensitive to changes in the rolling time domain, and the data show that it obtains the best signal control results when the rolling time domain duration is close to the travel time of vehicles from the upstream coil to the stop line.

Based on the simulation experiments and data analysis results, the following conclusions can be drawn: first, the DP algorithm proposed in this paper outperforms the optimal signal timing scheme derived from the traditional 4-phase calculation under different traffic conditions; second, the DP algorithm under NEMA phase outperforms the traditional algorithm when the traffic flow is relatively high, and there is an imbalance in the opposite direction. For the three objective functions, the DP algorithms under the principles of minimizing delay and maximizing throughput have similar control effects, while the DP-Q has relatively obvious advantages mainly under saturation traffic. In addition, DP-Q needs to update vehicle arrival data frequently to ensure the optimization results, so it can obtain a better delay control effect under rolling time domain conditions of short time length, so it should be applied in the road sections with adjacent closer upstream and downstream intersections.

5. Conclusion

Leading urban street transformation is conducive to protecting and improving people's livelihood, and providing practical experience for the modeling of street transformation. However, we also find that if road traffic conditions are to be improved. It is necessary to rely on more advanced means of traffic information collection and signal control

Step 1 Let $k = 1$, Initialize t_s, t_1 and $t_1^{a,0}$.
 Step 2 If $T_{st} \leq t_k^{a,0} \leq T_{end}$, while $k \leq K$, then move into step 3. Otherwise, Stop algorithm 2.
 Step 3 If $t_k^{1,0} \leq t_s$, then update $t_k^a = t_k^{a,0}$, and record the time that the vehicle arriving time t_k^a , update the longest queue distance $q_k^{max} = q_{k-1}^{max} + S$, $t_s = t_s + \Delta t_s$. (Scenario 1) Enter Step 5. Otherwise, use equations (6) and (7) to calculate the time that the vehicle arriving time t_k^a , update the longest queue distance $q_k^{max} = q_{k-1}^{max} - \Delta t_k^a \Delta v q + S$. (Scenario 2) Enter Step 4.
 Step 4 If $q_k^{max} \leq 0$ or $t_k^a > T_{end}$. Stop Algorithm 2. Otherwise. Record the time that the vehicle arriving time t_k^a , and enter step 5.
 Step 5 Update that $k = k + 1$, use equations (2) and (3) to calculate the arriving time of vehicle, $t_k^{a,0}$, and move back to step. 2.

ALGORITHM 2: Define travel time while green light.

Step 1 Let $j = 1$, Initialize $v_1(0) = 0$, $s_1^{min} = \min\{x_1^{min} - x_e, 0\}$.
 Step 2 For $s_j = s_j^{min}, \dots, T$. When the objective function is minimizing the delay as well as the queue length: $v_j(s_j) = \min_{c_j, x_j} \{f_j(s_j, x_j, c_j) + v_{j-1}(s_{j-1}) | x_j \in X_j(s_j), c_j \in C_j(i)\}$. When the objective function is to maximize vehicle throughput: $v_j(s_j) = \max_{c_j, x_j} \{f_j(s_j, x_j, c_j) + v_{j-1}(s_{j-1}) | x_j \in X_j(s_j), c_j \in C_j(i)\}$. Record $x_j^*(s_j)$ and $c_j^*(s_j)$ as the best signal timing solution.
 Step 3 If $s_j^{min} < T$, then $j = j + 1$, $i = i + 1$. And return to Step 2. Otherwise stop Algorithm 3.

ALGORITHM 3: Define state variables.

Step 1 Let $s_j^* = T$.
 Step 2 For any $j = J, J - 1, \dots, 2$, $s_{j-1}^* = s_j^* - h(x_j^*(s_j^*))$.

ALGORITHM 4: Backward algorithm.

strategies. Therefore, adaptive traffic signal control methods based on different vehicle arrival characteristics information and collection means remain an important research problem in the field of traffic management and control. Although formed traffic signal control systems are commonly installed in large and medium-sized cities in China, the effect of relieving traffic congestion is still limited, and the control effect of predicting vehicle arrival time from the microlevel to improve the signal timing scheme is not good enough. This paper focuses on how to improve the optimization effect of the control model based on the existing adaptive signal control scheme by using new technologies and concepts. On this basis, this paper draws on the latest foreign research results and establishes a vehicle arrival prediction model and an adaptive signal control method according to different information collection hands and vehicle arrival characteristics, and its main research results are as follows.

Starting from the generation and development of adaptive signal control theory, this paper introduces the latest research progress and challenges of its control models and algorithms. This paper argues that it is an important research direction in the future to make reasonable use of the emerging traffic information collection technology, improve the existing signal control methods, realize the linkage and cooperation of different signal controllers under the condition of reasonable computational complexity, and gradually expand the scope of traffic control and cooperation. For individual intersections with strong randomness of traffic arrival distribution, this paper proposes to collect upstream vehicle arrival data by using a loop coil to establish a microlevel vehicle arrival model to predict the vehicle arrival time under different queuing states. The vehicle arrival time estimation models under red and green conditions are developed separately according to the signal states, and their output vehicle arrival times and numbers are the main input variables of the signal optimization algorithm. Subsequently, the classical algorithm is improved by introducing the North American signal control structure NEMA on the framework of the existing COP algorithm. In addition to the traditional delay metrics, a control model with queue length and vehicle throughput as objective functions is developed in this paper. In order to verify the effectiveness of the model, an adaptive signal real-time control program is constructed in this paper based on the principle of the VISSIM simulation COM component, and simulation tests are conducted using the intersection of Jianchuan Road and Humin Road in Shanghai.

Compared with the existing adaptive signal optimization models, the main innovations of this paper are as follows:

- (1) The vehicle arrival model describes the dynamic process of vehicles arriving at the end of the queue under red light and green light conditions. Combined with the traffic flow fluctuation theory, the arrival time of vehicles entering the queue is quantitatively calculated, which helps to predict the queue length and estimate the delay time.
- (2) The dynamic planning algorithm is improved by combining the characteristics of the NEMA phase structure. The improved optimization algorithm can determine the optimal phase while assigning the green light duration and improve the flexibility of signal control. Meanwhile, based on the objective functions of vehicle delay and queue length, the optimization objective of maximizing the vehicle throughput is proposed, and a better control effect is obtained.
- (3) Based on the arrival-dissipation dynamic characteristics of the convoy at the stop line, the corresponding delay estimation constraints are established, which simplify the model construction methods in previous literature. An implicit cooperative-based regulation mechanism is proposed to achieve distributed control at multiple intersections.

The properties of street space are very complex and show different functional properties in different spatial and temporal environments, which is also a key to study and interpret the city. However, with the intensification of the "car-oriented" street space design, the original outdoor platform for interaction, entertainment, rest, and chatting is gradually deprived, which is a mockery of modern civilization. The study of street space design can be more effective in mastering other spatial design skills. Street space involves social, economic, cultural, ecological, psychological, human, political and other factors, which must be systematically thought, using forward-looking theories, and formulating corresponding countermeasures according to the time and place. There is no one panacea for all streets, and all streets must be considered in a comprehensive manner by investigating regional culture, citizen's lifestyle, street texture, and streetscape characteristics. Second, street space is also the window of the city, most easily remembered and most reflective of the humanistic qualities of the citizens. The transformation of street space is also of practical significance for changing the value orientation, promoting the moral spirit of health and frugality, and maintaining sustainable social development. The starting point of this paper is to establish a new street traffic adaptive model to provide model simulation support for future urban street renovation. However, since the model proposed in this paper is only implemented in the VISSIM simulation platform, whether it can effectively alleviate traffic congestion in the actual road network needs further verification, including calibration and verification of the simulation model. If it can be implemented in the control system, it can also be evaluated by means of hardware-in-the-loop to improve the reliability of the model method.

The upper Tarim River basin is supporting approximately 50 million people by melting the glaciers and snow, which are highly vulnerable and sensitive to climate change. Therefore, assessing the relative effects of climate change on the runoff of this region is essential not only for understanding the mechanism of hydrological response over the mountainous areas in Southern Xinjiang but also for local water resource management. This study quantitatively investigated the climate change in the mountainous area of the upper Tarim River basin, using the up-to-date “ground-truth” precipitation and temperature data, the Asian Precipitation Highly Resolved Observational Data Integration Towards Evaluation of Water Resources (APHRODITE, 1961–2010, 0.25°) data; analyzed the potential connections between runoff data, observed at Alar station, and the key climatological variables; and discussed the regression models on simulating the runoff based on precipitation and temperature data. The main findings of this study were as follows—(1) both annual precipitation and temperature generally increase at rates of 0.85 mm/year and 0.25 °C/10a, respectively, while the runoff data measured at the Alar station shows fluctuating decreasing trends. (2) There are significant spatial differences in the temporal trends of precipitation; for example, the larger increasing rates of precipitation occur in the Karakoram mountains, while the larger decreasing rates happen in the northwestern Kashgar county. (3) The decreasing trends of temperature mainly occur in Kashgar county and its surrounding areas in summer. (4) Seasonal correlations in precipitation and temperature trends are more significant than those on a monthly and annual scale. (5) The regression model in simulating the runoff in the upper Tarim River basin based on radial basis function (RBF) is better than that based on the least-squares method, with the predictive values based on RBF models significantly better (correlation coefficient, $CC \sim 0.85$) than those by least-squares models ($CC \sim 0.75$). These findings will provide valuable information to inform environmental scientists and planners on the climate change issues in the upper Tarim River basin of Southern Xinjiang, China, under a semiarid-arid climate.

1. Introduction

Global climate is changing considerably, characterized by warming over nearly 100 years, and there is a general consensus that increasing average surface air temperature had intensified global hydrological cycles during the 20th century [1–3]. According to the Intergovernmental Panel on Climate Change (IPCC) fifth assessment report [4], by the end of the twenty-first century, the global average surface temperature

will increase by 3.7–4.8°C over the 1750 level, and the global average sea level will rise by 0.52–0.98 m because of CO₂ doubling. Global climate change has accelerated regional water circulation and has caused asymmetry in precipitation distribution and high flood frequencies [5–8].

Spatiotemporal changes in global precipitation and temperature have received increasing attention, and the information on trends of precipitation and temperature is the starting point for the accurate assessment of water

resources, flood control, and drought relief, and the understanding of climate change and effective management of water resources. Meanwhile, natural surface runoff is also vital to maintaining surface water balance. For temporal and long-term runoff, the physical process of runoff yield always has a close relationship with climate variables, such as precipitation and temperature [9–11]. In arid and semiarid regions of vulnerable ecology, a small climate fluctuation may cause large environmental variation when human activity overwhelms the natural carrying capacity [12]. For this reason, addressing the impact of regional climate change on runoff volume will support scientific and technological sustainable development of local water resources.

Xinjiang Province, located in Northwest China, is under an inland, arid, or semiarid desert climate, which is not directly affected by the monsoon system [13, 14]. The Tarim basin in Southern Xinjiang Province is a typical inland watershed in an arid area, and the hydrologic processes of the upper Tarim River basin are typical among those in other regions at mid- and high latitudes of the Northern Hemisphere [11]. Various studies have focused on the impacts of climate change on water resources in the Tarim River basin [15, 16]. They concluded that the temperature and precipitation show an upward tendency during the past several decades and a significant jump has been detected for both the two variables around 1986 [10, 17]. Although the streamflow from the headwaters of the Tarim River shows a significant increase and is sensitive to precipitation [18], the streamflow along the mainstream of the river has decreased. This implies that anthropogenic activities such as irrigation and increased population instead of climate change dominated the streamflow change of the river [19]. Recently, various reports have shown a widespread climatic and hydrologic change in the Tian Shan Mountains during the past few decades [20]. For example, temperature demonstrated a significant rising trend (significant level is smaller than 0.001) at a rate of $0.33\sim 0.34^{\circ}/10a$ during 1960~2010, which is higher than those of China ($0.25^{\circ}/\text{decade}$) and the entire globe ($0.13^{\circ}/10a$) [21]; precipitation increased substantially in most regions especially for the middle and high latitudes, at a rate of $0.61\text{ mm}/a$ [22]; glacier area decreased by 11.5%, and the thickness of snowpack has also decreased [23]. The climate in Northwest China changed dramatically from a warm-dry mode to a warm-wet mode around 1987, and the Chinese Tian Shan Mountains experienced the most dramatic changes during this transition [20].

However, the upper Tarim River basin is relatively unknown in terms of recent climate changes simply due to a lack of meteorological observations in high-altitude areas (Wang et al., [24]. Fortunately, the state-of-the-art dataset (updated in September 2018), Asian Precipitation Highly Resolved Observational Data Integration Towards Evaluation of Water Resources (APHRODITE, $0.25^{\circ}/\text{daily}$ [25]), provided great valuable precipitation and air temperature data in the Asian over the last half century, from 1951 to 2015. And APHRODITE has been demonstrated to replicate “ground-truth” observations very well [26] and represents the best tool for analyzing historical precipitation variability and change. Therefore, this study aims at revealing the in-depth climate

change principles in the upper Tarim River basin and determining the response of runoff to climate change in the region through the analyses of precipitation and temperature.

2. Study Area and Materials

2.1. Study Area. Xinjiang Province of Northwest China accounts for one-sixth of China’s land area and has an inland, arid, or semiarid desert climate that is not directly affected by the monsoon system. Local precipitation of a large spatiotemporal variation is concentrated in mountainous areas [15]. The Tarim River basin in Southern Xinjiang is one of the world’s largest closed drainage hydrographical systems without outflow. The basin is composed of 114 streams belonging to nine river systems: the Aksu River, Kashgar River, Yarkand River, Hotan River, Kaidu River, Dina River, Weigan River, Kuqa River, and Keriya River. The landforms of the Tarim River basin include mountains (47%), plains (22%), and deserts (31%) [27]. The Tarim River lies entirely within a landlocked area and has a mainstream length of 1,321 km. Water has been imported to the mainstream from nine systems throughout history, and the main causes of this import were climate change and human economic activities. The Qarqan, Keriya, and Dina rivers successively lost surface connections to the mainstream prior to the 1940s, as did the Kashgar, Kongqi, and Weigan thereafter. As a result, only the Yarkant River, Akesu River, Hotan River, and Kaidu River have links with the mainstream of the Tarim River. Three tributary river systems (Aksu, Hotan, and Yarkant River) contributing to the Tarim River converge just above the Alar gauging station, while the Kaidu River flows into the Tarim River at the lower reaches.

The study area ($73^{\circ}\text{ E}\sim 82^{\circ}\text{ E}$, $35^{\circ}\text{ N}\sim 43^{\circ}\text{ N}$) is the upper mountain areas of the Tarim River basin (Figure 1(a)). The region is surrounded by high mountains like Tianshan, Eastern Pamir, and Karakoram mountains, which leads to orographic precipitation. Based on the Asian Precipitation Highly Resolved Observational Data Integration Towards Evaluation of Water Resources, the precipitation in the mountainous regions can exceed 300 mm/year in some areas and is mostly in the form of snowfall (Figure 1(b)). However, the average annual precipitation in the region is below 100 mm. The average annual temperatures can range from -12°C to 16°C (Figure 1(c)). The mainstream of the Tarim River is a typical pure dissipation inland river that does not yield water resources by itself and is supplied only by runoff from its upper basin [11, 14, 28]. This runoff is primarily from glacial meltwater and precipitation in mountainous areas. Therefore, hydrologic processes of the mountainous areas are typical of those in other regions at mid- and high latitudes of the Northern Hemisphere [11]. With the backdrop of global climate change, a detailed investigation on changing spatial and temporal features of precipitation will not only help to understand the relationship between climate change and the hydrological cycle, but also be helpful in formulating a regional strategy for water resource management in Southern Xinjiang.

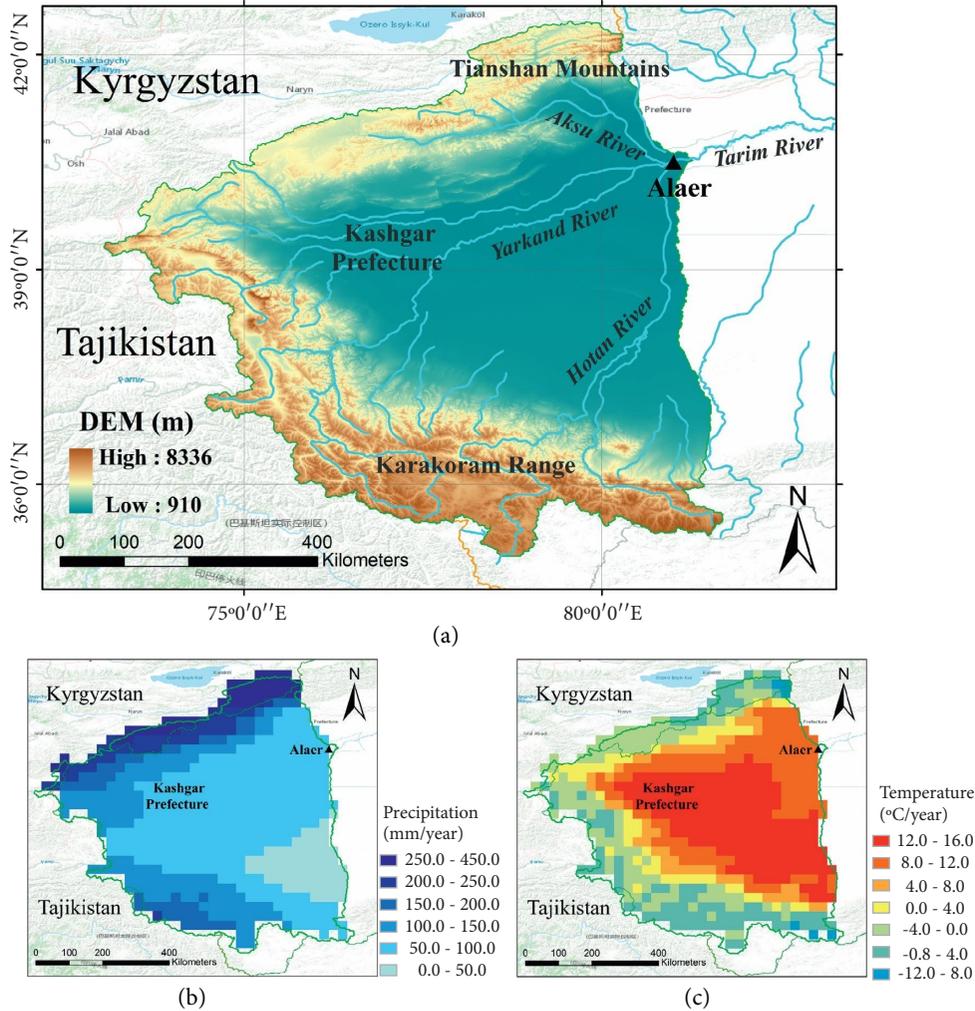

FIGURE 1: (a) The border of the upper Tarim River basin and the spatial patterns of (b) average annual precipitation and (c) average annual temperature over the study area.

2.2. *Data.* This study employed the new state-of-the-art daily dataset with a resolution of 0.25° (updated in September 2018), Asian Precipitation Highly Resolved Observational Data Integration Towards Evaluation of Water Resources [25, 29, 30], which provided great valuable precipitation and temperature data in the Asian over the last half century, from 1961 to 2010, to reveal the in-depth climate change principles in Southern Xinjiang. The APHRODITE project develops state-of-the-art daily precipitation datasets and daily mean temperature datasets with local meteorological/hydrological agencies for Asia. In terms of precipitation, the APHRODITE's Water Resources project has been executed by the Research Institute for Humanity and Nature (RIHN) and the Meteorological Research Institute of Japan Meteorological Agency (MRI/JMA) since 2006. The datasets are created primarily with data obtained from in situ rain-gauge-observation networks [31].

APHRODITE's daily gridded precipitation was presently the only long-term continental-scale high-resolution daily product and has been demonstrated to replicate "ground-

truth" observations very well [26], which was the best tool for studies such as the diagnosis of climate changes, evaluation of Asian water resources, and satellite precipitation estimates. And the APHRODITE data are available online at [http://aphrodite.st.hirosaki-u.ac.jp/download/with_high-resolution\(0.5°_and_0.25°\)_grids_for_Asia](http://aphrodite.st.hirosaki-u.ac.jp/download/with_high-resolution(0.5°_and_0.25°)_grids_for_Asia). Furthermore, measured annual runoff data were furnished by the administration of the Tarim River basin and were collected from Alar stations during 1961–2010. And Alar can be seen as the entrance to the Tarim River. Therefore, the runoff measured at the Alar station was considered to be the runoff of the Tarim River in this article.

3. Methods

3.1. *Regression Analysis.* Rational allocation of water resources is the foundation for the rational allocation of water rights, while the control of runoff prediction in the hydrological site is a prerequisite for the rational allocation of water resources. Therefore, the mathematical model developed to predict runoff timely and accurately for the right to

water management is an extremely important basic job. Runoff prediction is one of the problems in the natural sciences and technology field, and its difficulty is that hydrological changes are subject to various uncertainties and not entirely clear to operation rules. And in mountainous catchments, the quality of runoff modeling depends strongly on the amount and intensity of precipitation and the snow melting.

At present, there are many methods for predicting river runoff such as neural networks, wavelet analysis, and support vector machines. One of the commonly used methods is to calculate the runoff data using statistical methods, and the other is to set up a prediction model according to the evolution of the predicted subject. We used statistical methods including linear regression and nonlinear regression, based on the observed data, to predict and analyze the runoff situations [32–38]. Speaking specifically, based on the monthly runoff data of the upper mountain areas of the Tarim River basin, from the Alar station, during the period of 1961–2010, and precipitation and temperature data in mountainous areas, the influence of the temporal-spatial component of regional precipitation and temperature on monthly runoff was analyzed by using least-squares methods and radial basis function (RBF) neural network.

3.2. Quantitative Error Indicator. In this study, the regression models were established based on the precipitation and temperature data, according to least-squares methods and RBF neural network, and the runoff data were predicted and analyzed by those models. To assess the accuracy of the predictive value of the regression models, four indicators were used in this study: correlation coefficient (CC), bias, root mean square error (RMSE), and mean absolute error (MAE) [39]. Among them, CC is used to measure the correlation between satellite precipitation data and rain gauge data with the value ranging from 0 to 1. Bias evaluates the degree of bias of satellite precipitation data against the rain gauge data. RMSE and MAE are used to evaluate the overall level of satellite precipitation data error within the range of $[0, +\infty]$. The best possible values are $CC=1$, $\text{bias}=0$, $\text{RMSE}=0$, and $\text{MAE}=0$. The equations for the above-mentioned statistics are shown as follows:

$$\begin{aligned}
 CC &= \frac{\sum_{i=1}^n (O_i - \bar{O})(P_i - \bar{P})}{\sqrt{\sum_{i=1}^n (O_i - \bar{O})^2 \times \sum_{i=1}^n (P_i - \bar{P})^2}}, \\
 \text{bias} &= \frac{\sum_{i=1}^n (P_i - O_i)}{\sum_{i=1}^n O_i} \times 100\%, \\
 \text{RMSE} &= \sqrt{\frac{1}{n} \sum_{i=1}^n (P_i - O_i)^2}, \\
 \text{MAE} &= \frac{1}{n} \sum_{i=1}^n |P_i - O_i|,
 \end{aligned} \tag{1}$$

where O_i represents the amount of runoff observed at the Alar station, \bar{O} represents the average observed runoff, P_i and \bar{P} are the estimated values of the regression models and their average values, respectively, and n represents the number of pairs of the two runoff factors in the analysis.

4. Results

4.1. Analysis of Climate Change from 1961 to 2010 in the Upper Tarim River Basin. Generally, a linear regression analysis of precipitation and temperature data from 1961 to 2010 found that precipitation and temperature demonstrated significant increasing trends in the upper Tarim River basin at a rate of 0.85 mm/year and 0.25°C/10a, respectively (significant level is smaller than 0.001; Figure 2(a) and Figure 2(b)). Figure 2(c) shows the temporal patterns of the runoff observed at the Alar station, demonstrating the streamflow along the mainstream of the upper Tarim River basin fluctuating in decreasing trends. In terms of precipitation, it showed a continuously increasing trend, while there were still several years (e.g., 1975, 1985, and 1997) with the smallest precipitation volume around 70.00 mm/year, and the largest precipitation occurred in 2010 with the volume around 210.00 mm/year. In terms of temperature, there was a clear horizontal trend at the beginning from 1961 to 1995, while in the afterward period from 1996 to 2010, the temperature demonstrated a more significant increasing trend at a rate of 0.51°C/10a, with the lowest and highest annual temperature happened in 1974 around 4.00°C and in 2006 around 6.46°C, respectively. In the period from 1961 to 1995, the annual variation in precipitation and temperature demonstrated negative correlations ($CC \sim -0.24$ and $P = 0.168$). And the negative correlations ($CC \sim -0.40$ and $P = 0.142$) were more significant in the period from 1996 to 2010. In addition, the Tarim River runoff showed a continuous decreasing trend, while there were still several years (e.g., 1978, 1995, and 2010) with the largest runoff volume around 220.00 m³/s. In the period from 1996 to 2010, the annual variation in runoff and temperature demonstrated significant correlations ($CC \sim 0.59$ and $P = 0.021$) and the CC value of runoff and precipitation is around -0.27 .

The Aksu River, Hotan River, and Yarkand River are all dominated by snowmelt and precipitation replenishment in the mountain areas. Therefore, changes in precipitation and temperature in the river basin have a direct impact on changes in river runoff. However, the increasing trends of precipitation and temperature in the upper Tarim River basin over the last 50 years conflict with the decreasing trend of runoff, indicating that the Tarim River runoff is affected not only by climate change, but also by human activities. Since the 1960s, land reclamation in the upper Tarim River basin has never stopped. The area of an artificial oasis has been continuously expanded, and the area of irrigation has more than doubled. It can be said that human activities are the dominant factor that causes the Tarim River runoff to decrease.

On a seasonal scale, both precipitation and temperature showed increasing trends in all seasons (Figure 3(a) and Figure 3(b)). As for precipitation, the largest and smallest

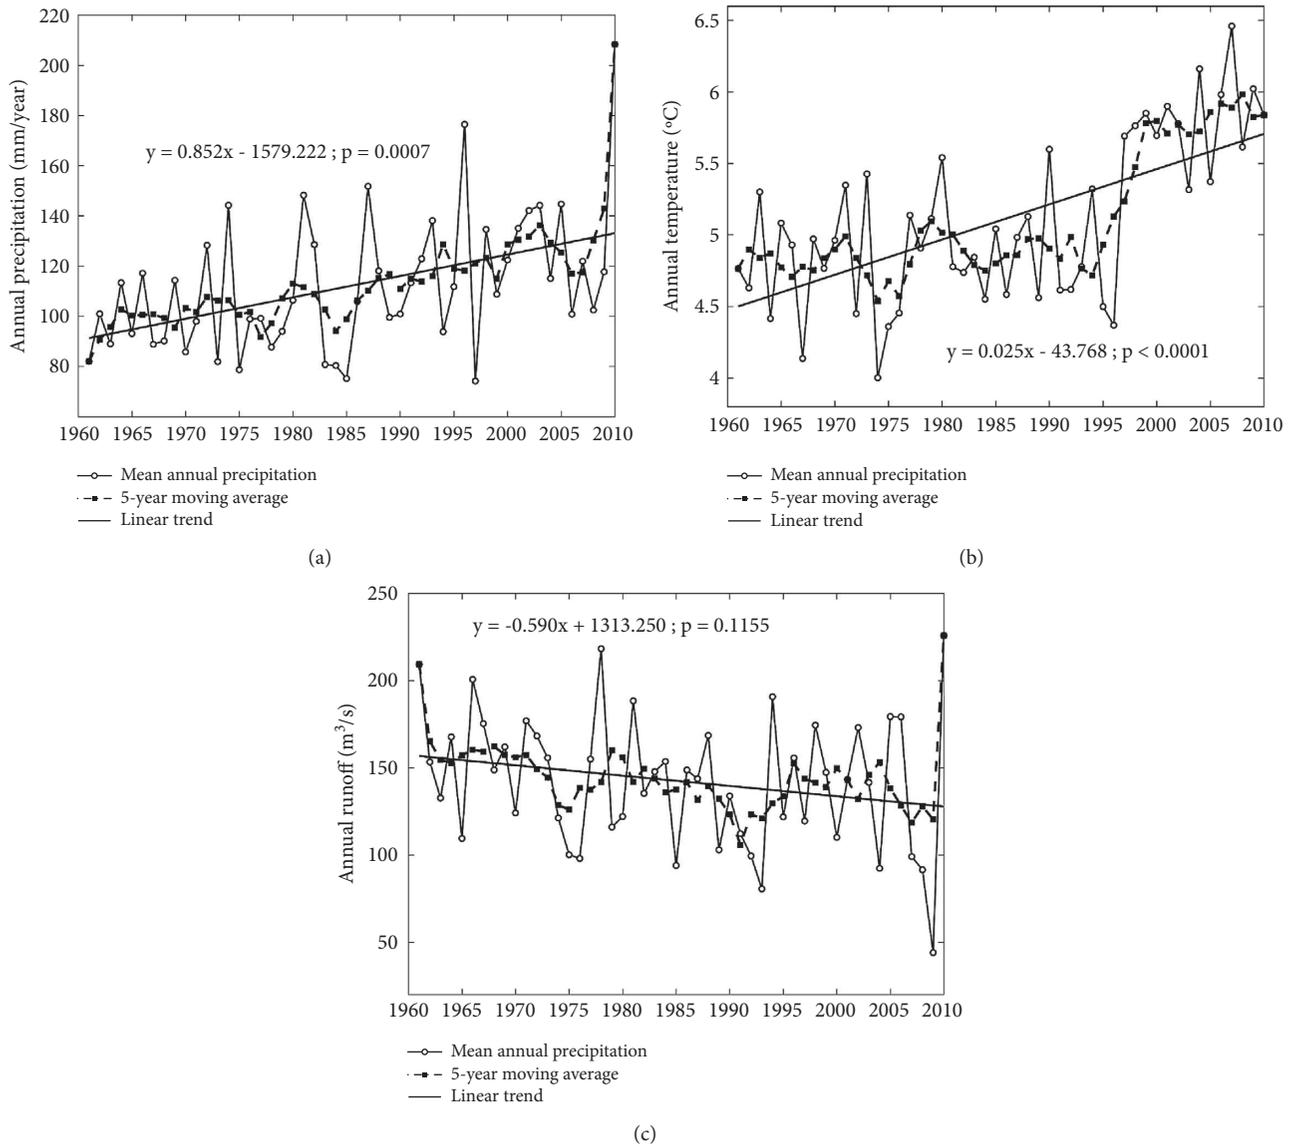

FIGURE 2: Variations in annual mean. (a) Precipitation, (b) temperature, and (c) runoff in the upper Tarim River basin during the period 1961–2010.

increasing rates happened in summer (JJA; June, July, and August, 0.32 mm/year) and spring (MAM; March, April, and May, 0.16 mm/year), respectively. As for temperature, adversely, the largest and smallest increasing rates happened in winter (DJF; December, January, and February) and spring, respectively. The climate changed with the temperature in winter at a rate of $0.36^{\circ}\text{C}/10\text{a}$ in the upper Tarim River basin, which may bring a great threat to the glacier’s accumulations. Meanwhile, the runoff showed decreasing trends in all seasons except spring (Figure 2(c)). The possible reasons are the increase in the arable land area and the continuous expansion of agricultural irrigation areas in the upper Tarim River basin. Although the Tarim River flood season mainly occurs in summer, which is consistent with the period of concentrated water use for agriculture in the basin, a large amount of agricultural water not only occupies the river runoff in summer, but also leads to excessive groundwater

extraction. Even in the autumn and winter seasons, even if agricultural water is reduced, the infiltration of precipitation in autumn and winter directly replenishes the groundwater that is lacking due to severe summer mining. As a result, the surface runoff in the Tarim River basin is still reduced in the autumn and winter seasons when it is not the peak period of agricultural water use.

Table 1 lists the change rates of monthly mean precipitation, temperature, and runoff. Precipitation increased with the largest trend occurring in June at a rate of approximately 0.16 mm/year and demonstrated large increasing trends in July and September with rates larger than 0.10 mm/year, while the smallest increasing trend happened in April with the rate of 0.02 mm/year. In terms of temperature, the largest increasing trend happened not in the winter months but in November at a rate of $0.47^{\circ}\text{C}/10\text{a}$, which was larger than those of the rest months, and the

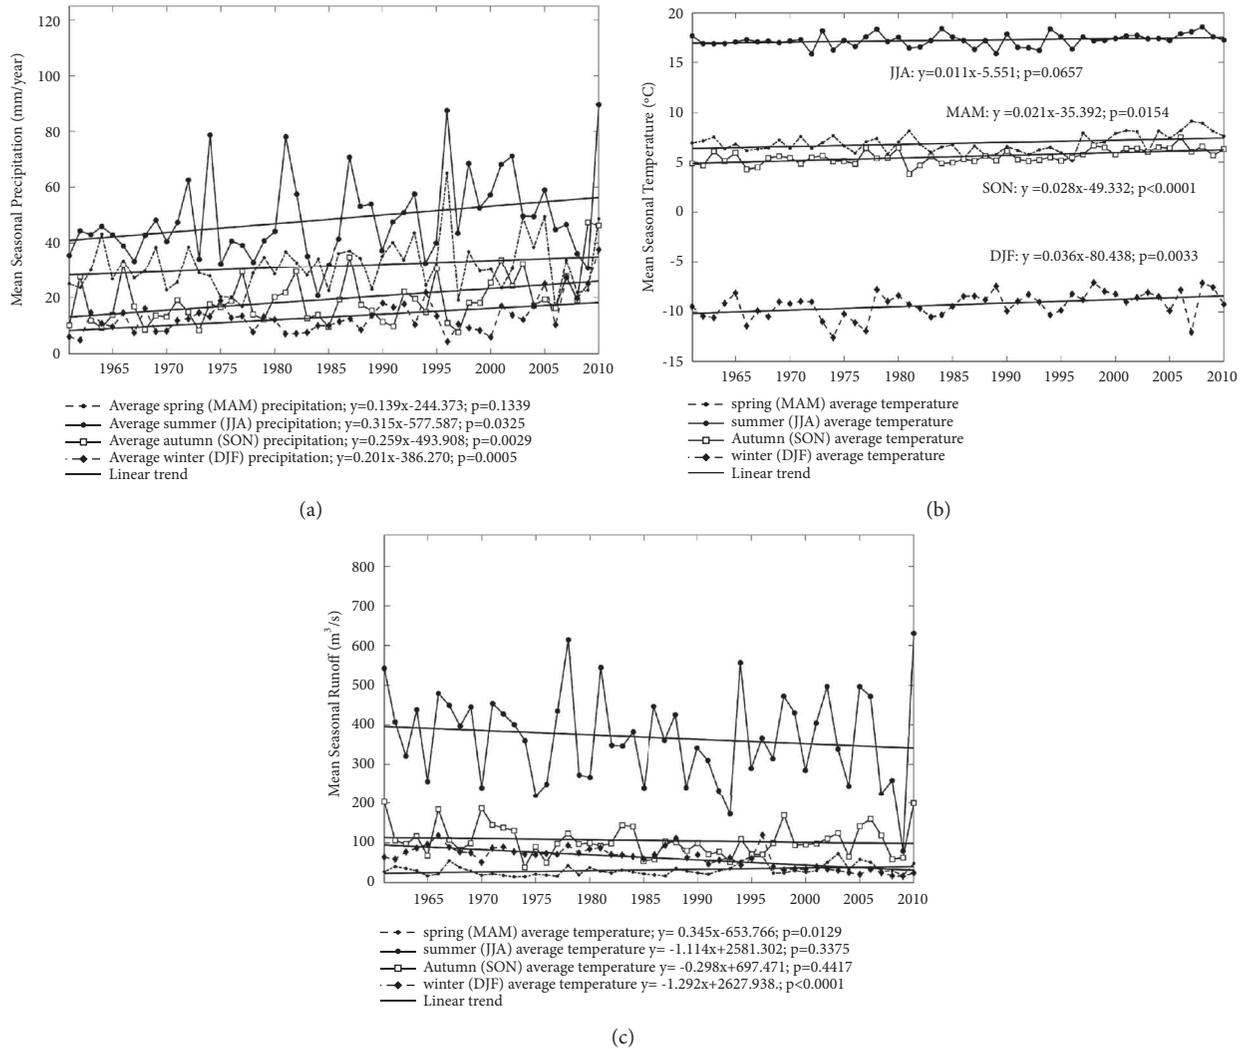

FIGURE 3: Variations in seasonal mean. (a) Precipitation, (b) temperature, and (c) runoff in the upper Tarim River basin during the period 1961–2010.

TABLE 1: Change rates of monthly mean precipitation, temperature, and runoff in the upper Tarim River basin during the period 1961–2010.

Trend	Jan	Feb	Mar	Apr	May	Jun
Precipitation trend (mm/month)	0.052	0.042	0.063	0.019	0.054	0.158
Temperature trend (°C/month)	0.026	0.044	0.029	0.018	0.017	0.012
Runoff trend (m ³ /month)	-1.125	-0.950	-0.324	0.352	1.008	-0.023
Trend	Jul	Aug	Sept	Oct	Nov	Dec
Precipitation trend (mm/month)	0.124	0.033	0.137	0.087	0.036	0.046
Temperature trend (°C/month)	0.006	0.016	0.017	0.019	0.047	0.045
Runoff trend (m ³ /month)	-1.806	-1.515	0.212	0.115	-1.222	-1.801

smallest increasing trend occurred in July at a rate of 0.06°C/10a. Generally speaking, the increasing rates of temperature in cold seasons were larger than those in warm seasons. In addition, the runoff of the upper Tarim River at a monthly scale decreased with the most significant trend occurring in July at a rate of approximately -1.81 m³/s, and it also showed large decreasing trends in January, August, November, and December with rates smaller than 1.00 m³/s, while the largest increasing trend happened in May with the rate of 1.01 m³/s.

Besides, positive trends were observed in April, September, and October.

4.2. Spatial Distributions of the Climate Change and Runoff Trends from 1960 to 2010 in the Upper Tarim River Basin. Figure 4 shows the spatial distributions of precipitation trends, at annual and seasonal scales over the upper Tarim River basin from 1961 to 2010. Overall, the annual

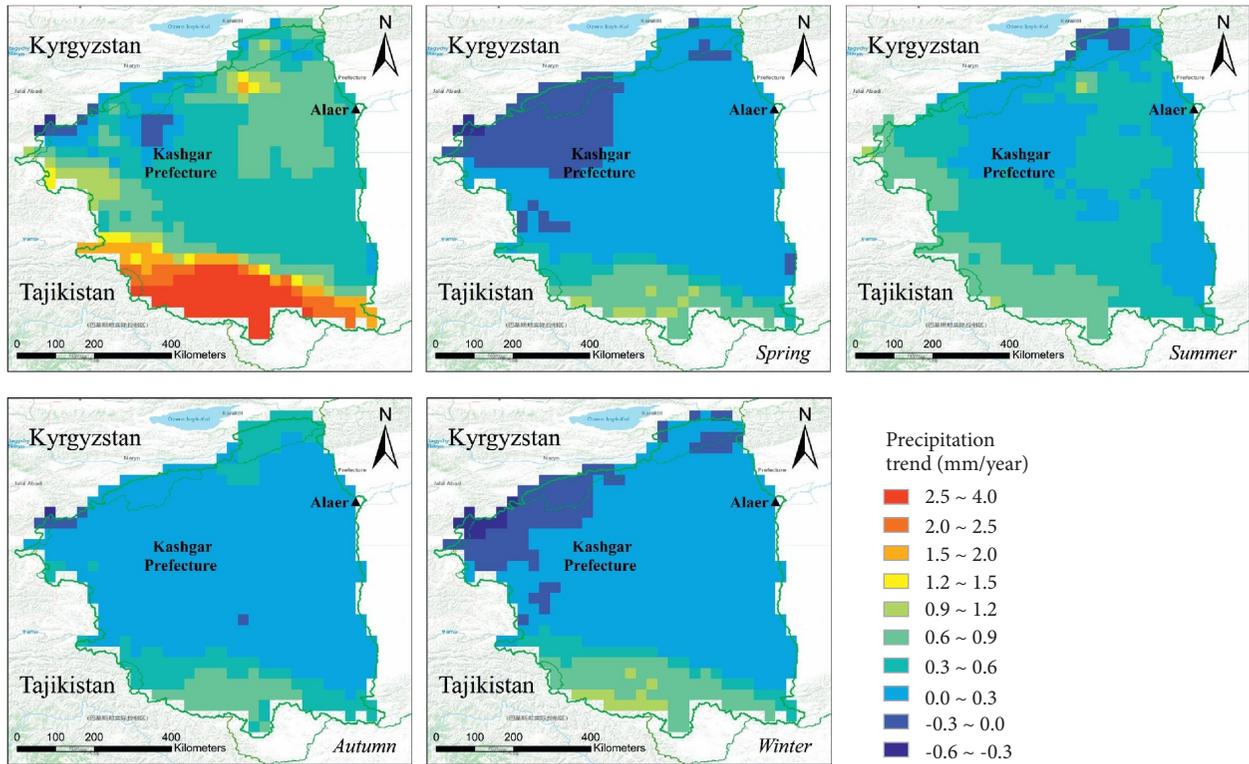

FIGURE 4: Spatial patterns of variations in (a) annual mean precipitation and spatial patterns of variations of precipitation in (b) spring, (c) summer, (d) autumn, and (e) winter, during the period 1961–2010.

precipitation trends generally presented an increasing trend from northwest to south, and the differences in precipitation trends in spatial distributions among the four seasons were significant. The regions with the largest precipitation increasing rates were in the southern region, the Karakoram mountains, in intervals larger than 2.50 mm/year. Although most regions showed increasing trends, the decreasing trends occurred in the northwest edges of the upper basin, with the rates varying from -0.60 mm/year to -0.30 mm/year (Figure 4(a)). On the seasonal scale, the decreasing trends were detected in most regions in spring and winter (Figures 4(b) and 4(d)), and the increasing trends were detected in almost all study areas in summer and autumn (Figures 4(c) and 4(e)). Moreover, the increase in precipitation trends in the Karakoram mountains at all seasons was more significant than that in the other regions.

From 1961 to 2010, the annual average temperature in the upper Tarim River basin showed an overall increasing trend, with the increasing rates varying from $0.00^{\circ}\text{C}/10\text{a}$ to $0.30^{\circ}\text{C}/10\text{a}$ in most areas. And the most significant increasing trends were detected in the southeastern region, with the maximum rate around $0.60^{\circ}\text{C}/10\text{a}$ (Figure 5(a)). On the seasonal scale, the spatial pattern of temperature trends in spring was similar to that at an annual scale (Figure 5(b)). And the temperature in the south, in autumn and winter, showed a clear upward trend (Figures 5(d) and 5(e)). In addition, the temperature in summer dropped slightly in some northern areas (Figure 5(c)).

The correlation coefficients between precipitation and temperature varied both spatially and temporally. The

precipitation and temperature demonstrated higher correlations at the seasonal scale in most regions with the values of CC varying from 0.5 to 0.9, while the correlations on the monthly scale were generally between 0.3 and 0.7. Meanwhile, the spatial distribution of correlations generally presented an increasing trend from south to north (Figure 6(b) and Figure 6(c)). However, on an annual scale, the relationship between the precipitation and temperature was negative in most areas especially in northwestern regions varying from -0.5 to -0.3 , while in the east Karakoram mountains, the correlations were generally fluctuating between 0.3 and 0.5 (Figure 6(a)).

4.3. Analysis of Simulating Runoff Based on Regression Models and Deep Learning Models from 1961 to 2010 over the Upper Tarim River Basin. The spatial distributions of the 50-year average monthly precipitation and temperature over the upper Tarim River basin and the runoff volume observed at Alar are shown in Figure 7. The results show that the runoff of the Tarim River was mainly concentrated in July and August. Considering the precipitation and temperature, the runoff was dominated by snow accumulation in winter, subsequent snow melting in spring, and high precipitation in summer.

Meanwhile, Figure 8 shows the spatial patterns of correlations between monthly precipitation and runoff and those between monthly temperature and runoff for the period 1961–2010. In terms of precipitation, Figure 8(a) shows the correlation coefficients of precipitation and runoff

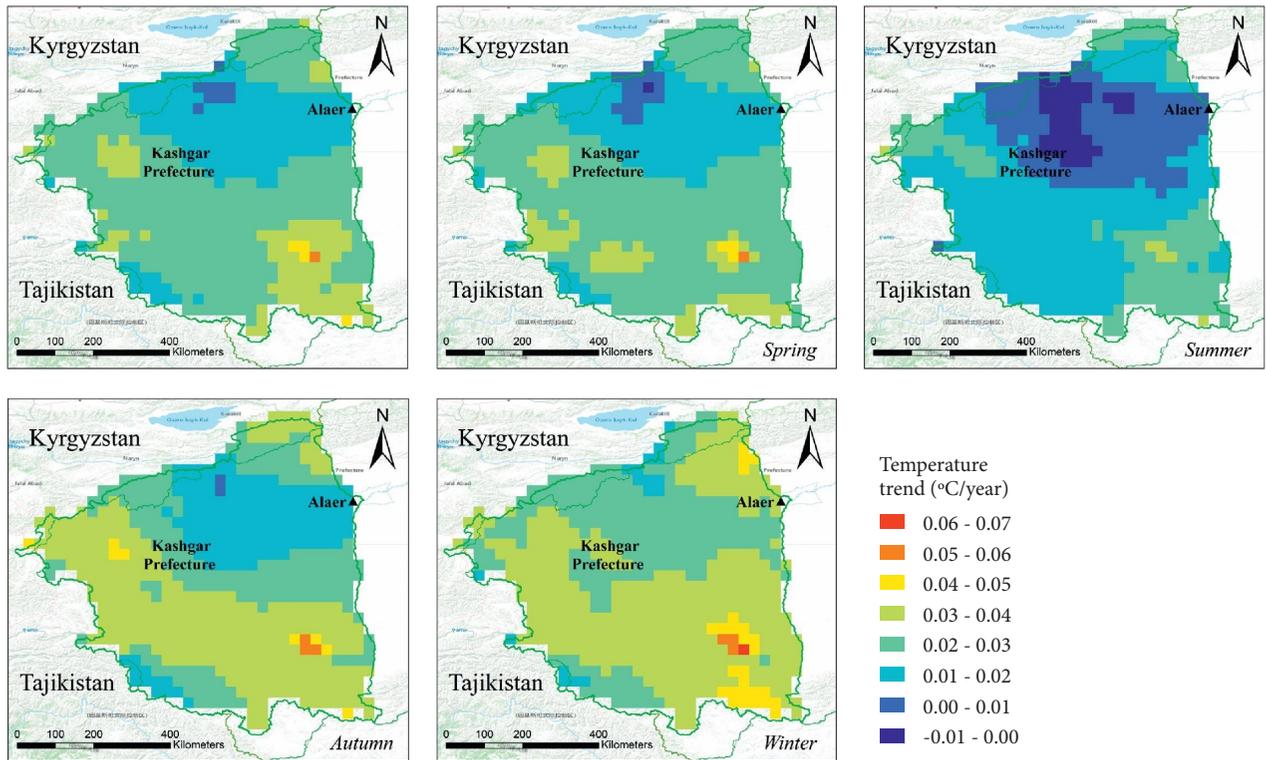

FIGURE 5: Spatial patterns of variations in (a) annual mean temperature and spatial patterns of variations of temperature in (b) spring, (c) summer, (d) autumn and (e) winter, during the period 1961–2010.

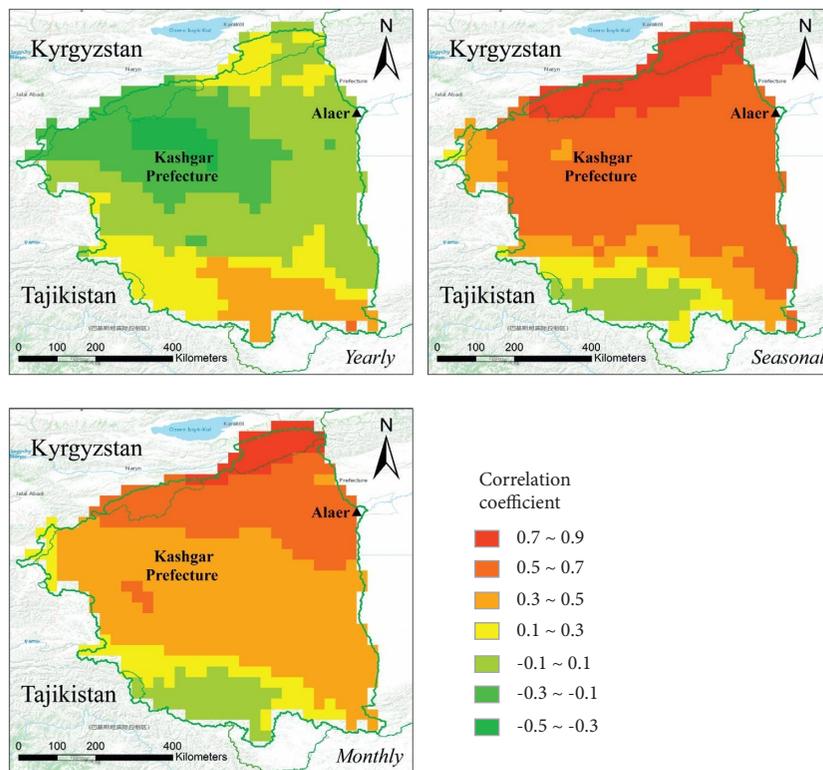

FIGURE 6: The spatial patterns of correlations between precipitation and temperature at (a) annual, (b) seasonal, and (c) monthly scales in the upper Tarim River basin during the period 1961–2010.

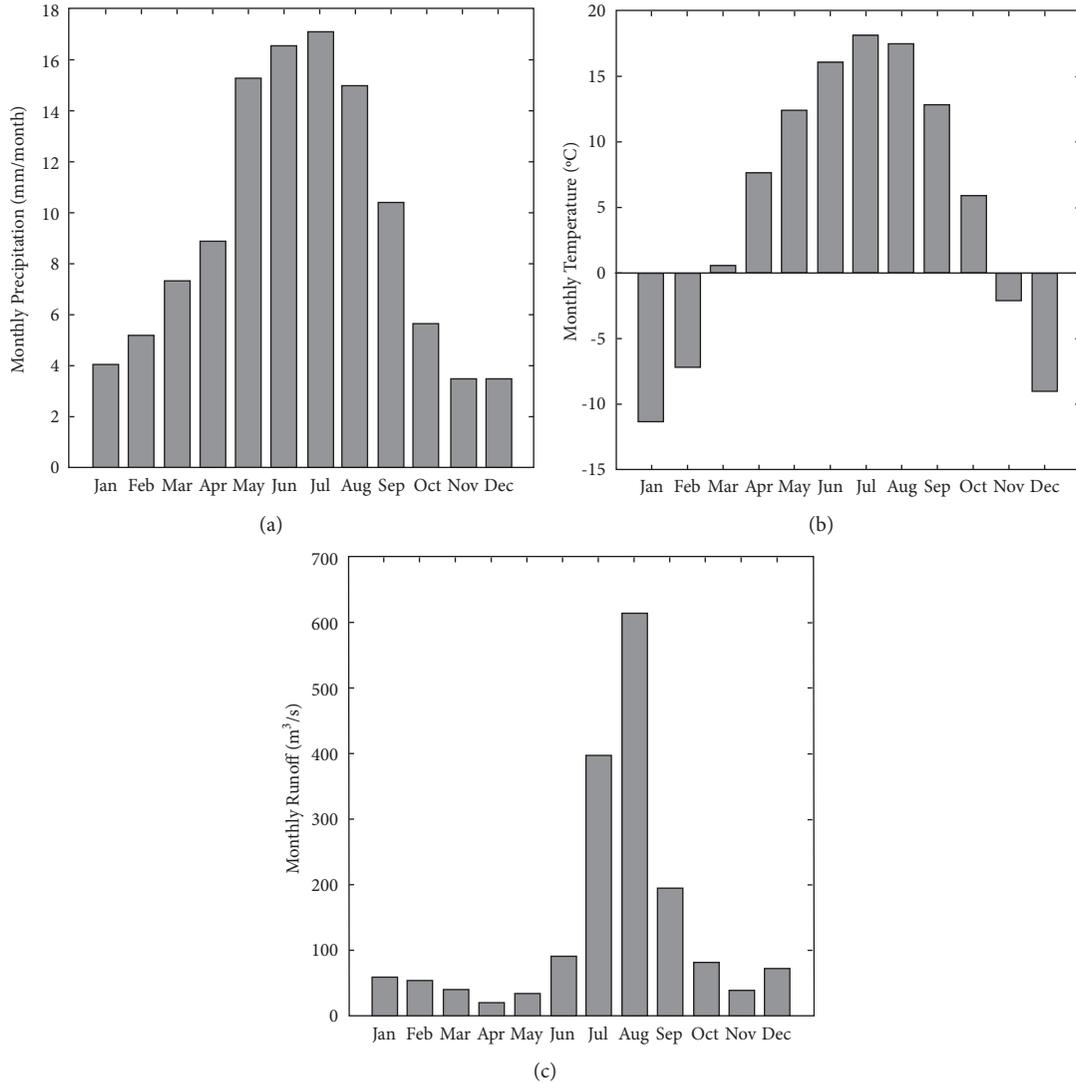

FIGURE 7: Monthly area averages of (a) precipitation, (b) temperature, and (c) runoff in the upper Tarim River basin during the period 1961–2010.

at the corresponding time and the Figure 8(b) shows the correlation coefficients between precipitation and runoff, with one-month delay to the precipitation. The differences in coefficients in spatial distributions were significant, and the coefficients generally presented an increasing trend from south to north. It can be seen that the impact of precipitation, which occurred in the Tian Shan Mountains, had a more significant impact on the runoff than that occurred in the Karakoram mountains. However, the values of correlations shown in Figure 8(b) were larger than those shown in Figure 8(a) demonstrating that the precipitation might have a great potential impact on the runoff with one-month delay at Alar. In terms of temperature, the runoff-temperature relationship exhibited an overall positive correlation. Similar to the relationship between precipitation and runoff, the temperature had larger correlations with runoff with a one-month delay than those of temperature in the corresponding months.

In the present study, another focus was on comparing the least-squares method models with the deep learning models, radial basis function (RBF) neural network models. A training period of 1961–2000 and an evaluation period of 1961–2000 were identified. We regarded the runoff data as the dependent variable, and the precipitation, temperature, and runoff in the current or previous month as the independent variables. And Table 2 lists a total of 12 regression models based on different independent variables and methods. The weighted data were the correlation coefficient of precipitation or temperature and runoff at each grid point as shown in Figure 8.

While comparing the results, it is to be kept in mind that the data used for calibration and verification are the same among different models. The data from 1961 to 2000 were used to build models and validated using data from 2001 to 2010. Figure 9 demonstrated the temporal patterns of monthly runoff at Alar, in the period from 2001 to 2010,

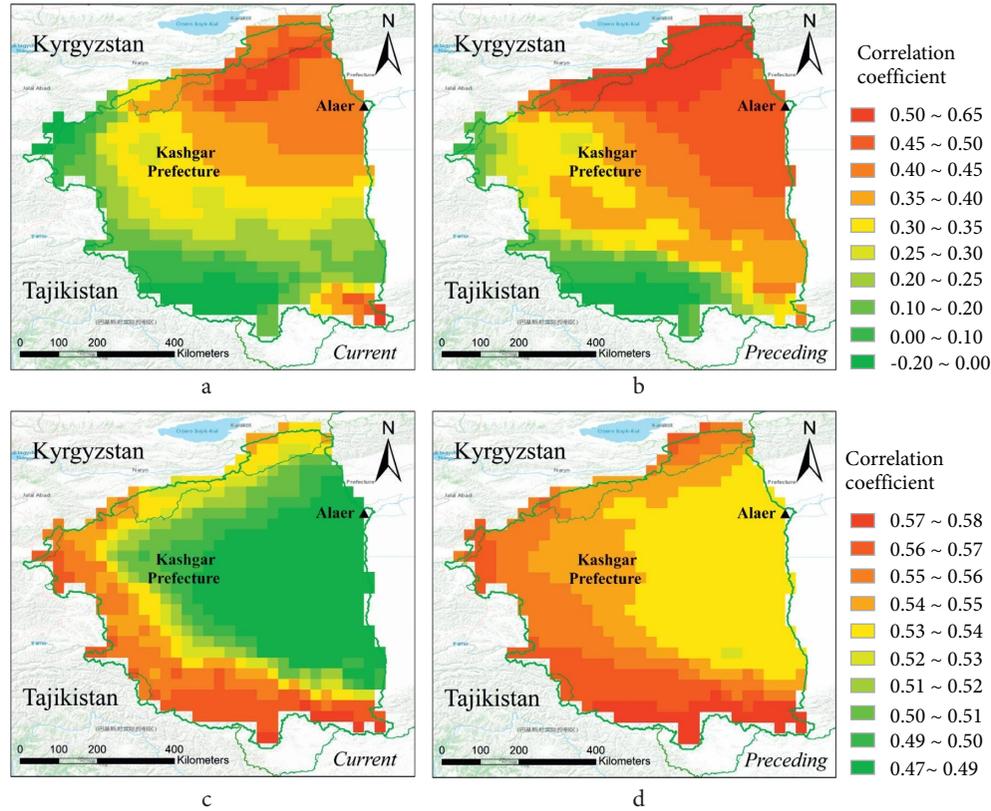

FIGURE 8: The Spatial patterns of correlations between (a) precipitation and runoff in the corresponding months, (b) precipitation and runoff with one-month delay, (c) temperature and runoff in the corresponding months, and (d) temperature and runoff with one-month delay in upper Tarim River basin.

TABLE 2: Summary of models based on different independent variables.

Model	Current		Preceding		Linear fitting		Nonlinear fitting	
	p^{cur}	T^{cur}	p^{pre}	T^{pre}	R^{pre}	Least-squares	Radial basis function	
Cur	√	√	—	—	—	Cur-LS	Cur-RBF	
CurW	√*	√*	—	—	—	CurW-LS	CurW-RBF	
Pre	√	√	√	√	—	Pre-LS	Pre-RBF	
PreW	√*	√*	√*	√*	—	PreW-LS	PreW-RBF	
PreRun	√	√	√	√	√	PreRun-LS	PreRun-RBF	
PreRunW	√*	√*	√*	√*	√	PreRunW-LS	PreRunW-RBF	

*represents weighted data.

based on observations and different prediction models. The least-squares method models significantly overestimated the runoff in winter and spring, and underestimated the runoff in summer especially in August. In terms of accuracy and consistency, the overall performances of the models based on RBF were better than those of the least-squares method models.

Based on different models, the four quantitative error indicators (CC, bias, RMSE, and MAE) of predictions against the runoff observations were also analyzed (Table 3). In terms of least-squares method models, the models using weighted independent variables outperformed the models using unweighted independent variables. In addition, an increase in the number of independent variables improved the accuracy of the models. The CC (~ 0.75), bias ($\sim -17.15\%$),

RMSE ($\sim 136.40 \text{ m}^3/\text{s}$), and MAE ($\sim 89.33 \text{ m}^3/\text{s}$) of the PreRunW-LS model generally performed better than the other models. In terms of RBF models, although the CC value of PreW-RBF (0.84) is less than the CC of Pre-RBF (0.85), the weighted independent variables still improved the models. Unlike the least-squares method, preceding runoff data as one of the independent variables did not significantly improve the quality of the models in terms of quantitative error indicators. Generally speaking, the PreW-RBF model (CC ~ 0.84) outperformed the PreRunW-LS model (CC ~ 0.75). Although the bias value of the PreW-RBF model ($\sim 30\%$) was around two times larger than that of the PreRunW-LS model ($\sim 17\%$), and both the RMSE and MAE values of PreW-RBF were significantly smaller than those of the PreRunW-LS, respectively.

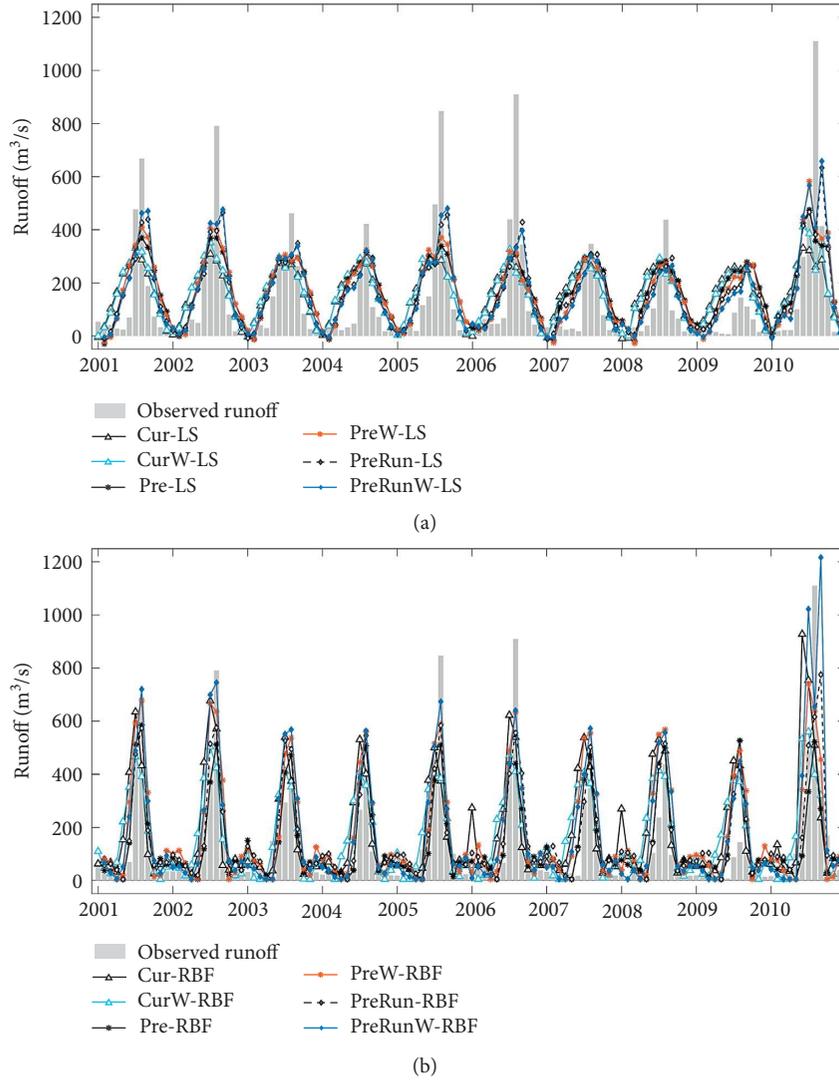

FIGURE 9: Temporal runoff patterns were predicted by (a) least-squares method models and (b) RBF models, against the observed values, in the upper Tarim River basin during the period 2001–2010.

TABLE 3: Summaries of the statistical results based on different models, against the runoff observations, in the upper Tarim River basin during the period 2001–2010.

Model	CC	Bias (%)	RMSE (m ³ /s)	MAE (m ³ /s)
Cur-LS	0.59	14.91	163.85	107.76
CurW-LS	0.62	15.43	160.05	103.01
Pre-LS	0.69	22.90	151.34	104.63
PreW-LS	0.72	20.50	143.61	98.05
PreRun-LS	0.73	19.22	141.45	95.32
PreRunW-LS	0.75	17.15	136.40	89.33
Cur-RBF	0.69	28.17	161.17	104.60
CurW-RBF	0.71	15.95	143.31	90.41
Pre-RBF	0.85	33.68	126.08	84.38
PreW-RBF	0.84	29.61	120.86	82.90
PreRun-RBF	0.82	41.06	146.75	87.95
PreRunW-RBF	0.83	30.19	136.20	75.42

5. Discussions

The Tarim River played a crucial role in the economic and social development of Xinjiang, and the accurate prediction of long-term runoff variation in this basin was important for watershed and flood management. However, frequent floods and droughts in the Tarim River basin were caused by complex forcing factors, so it was challenging to predict when runoff disasters would happen. Many current studies focused on setting up prediction models according to the evolution of the predicted subject. Statistical methods including simple linear or nonlinear methods, in this article, were also considered; it is of great significance for the prediction of runoff in the Tarim River. And the purpose of this study was to be able to quickly predict monthly runoff based on precipitation and temperature data.

Figure 10 demonstrates the temporal patterns of the statistical accuracy indicators evaluating the least-squares method models and RBF models against observed runoff data at the monthly scale. And PreRunW-LS and PreW-RBF models represented the best of the linear and nonlinear models, respectively. The temporal patterns of the CC of least-squares method models and RBF models were different significantly (Figures 10(b) and 10(b)), while the CC values of PreRunW-LS (~-0.20 – ~0.0.5) were significantly larger than those of PreW-RBF (~-0.50 – ~0.50) in winter and spring, especially in February. In terms of bias, PreRunW-LS overestimated the runoff in January and February (as high as ~300%), and PreW-RBF overestimated the runoff in April, May, and October (up to ~350%) against the observed data. However, the bias values of PreW-RBF models were closer to 0.0, in January, February, July, August, and November (Figure 10(d)). As for indicators of RMSE and MAE, the temporal patterns of PreRunW-LS and PreW-RBF were very similar. The RMSE values of PreRunW-LS (~20 m³/s – ~350 m³/s) were much larger than those of PreW-RBF (~10 m³/s – ~200 m³/s), especially in August (Figure 10(f));

similarly, the MAE values of PreW-RBF (~10 m³/s – ~150 m³/s) were also much smaller than those of PreRunW-LS (~20 m³/s – ~260 m³/s). In general, neither PreRunW-LS nor PreW-RBF performed better in summer and autumn than in spring and winter. The possible reason might be that in the upper mountainous basin, when the temperature was much lower than the snow melting temperature, the simple linear or nonlinear models were difficult to fit the relationship between temperature and runoff.

Least-squares models and RBF models used a 40-year training period (1961–2000), and forecasts were conducted for the 10-year validation period from 2001 to 2010. The RBF models exhibited promising predictive skills with the correlation coefficient between the observation and the predicted values close to 0.85, which was better than those of the least-squares models. The results have shown that the PreW-RBF model built with the RBF neural networks had some significant advantages for the long-term prediction of runoff and might provide a new and effective tool for the prediction of drought and flood events in the Tarim River basin.

It should be mentioned that the variability of the Tarim catchment hydrology is not only closely linked with the large-scale atmospheric circulation over Asia but also with headstream snow cover because the Tarim River was fed by the glaciers of the mountainous areas. Thus, in addition to the precipitation and temperature data, snow cover or other anomalies may also be an important independent variable for predicting runoff. And we may conduct a further study in the future to analyze the importance of snow cover to the simulation of the runoff.

6. Conclusions

This study quantitatively investigates the climate change in the upper Tarim River basin, using the up-to-date “ground-truth” precipitation and temperature data, the Asian Precipitation Highly Resolved Observational Data Integration

Towards Evaluation of Water Resources (APHRODITE, 1961–2010, 0.25°) data; analyses the potential connections between runoff data, observed at Alar station and the key climatological variables; and discusses the models in simulating the runoff based on precipitation and temperature data. The main findings of this study are as follows:

- (1) Both annual precipitation and temperature generally increased at rates of 0.85 mm/year and 0.25 °C/10a, respectively, while the runoff data measured at Alar station showed fluctuating decreasing trends.
- (2) There were significant spatial differences in the temporal trends of precipitation, for example, the larger increasing rates of precipitation occurred in the Karakoram mountains, while the larger decreasing rates happened in northwestern Kashgar county.
- (3) The decreasing trends of temperature mainly occurred in the Kashgar county and its surrounding areas in summer.
- (4) The seasonal correlations in trends of precipitation and temperature were more significant than those on a monthly and annual scale.
- (5) The regression model in simulating the runoff in the upper Tarim River basin based on RBF was better than that based on the least-squares method, with the predictive values based on the RBF models significantly better (correlation coefficient, CC, ~ 0.85) than those by least-squares models (CC ~ 0.75).

These findings would provide valuable information to environmental scientists and planners on the climate change issues over the Tarim River basin. [40] [41].

The Sino–Russian Arctic energy cooperation is a successful example based on the comprehensive strategic partnership between the two countries. In order to analyze the impact of Sino–Russian oil and gas resources cooperation in the Arctic on China’s energy security, this paper selects 11 influencing factors such as energy self-sufficiency rate and uses the energy security index method to evaluate the three dimensions of energy supply, demand, and environmental security. The assessment results show that China’s energy security is mainly affected by the over concentration of energy import sources. At the same time, energy demand and environmental security will also have an important impact on China’s energy security. However, relative to energy demand, environmental security factors such as the proportion of clean energy consumption and channel safety factor have a greater impact on China’s energy security. After China and Russia strengthen cooperation in oil and gas resources in the Arctic, China’s energy security index is expected to increase from 0.4419 in 2020 to 0.5412 in 2025. Therefore, China can use technology, funds, scientific research, and other support to carry out all-round cooperation with Russia in the Arctic waterway, oil and gas exploration and development, and Arctic scientific research.

1. Introduction

With the climate warming and the “Arctic amplification” phenomenon [1], the development and utilization of Arctic energy have attracted more and more attention. As a “major stakeholder in the Arctic,” the Chinese government released the first white paper on China’s Arctic policy in 2018, which clearly supports Chinese enterprises to actively participate in the development of Arctic oil and gas resources. The Arctic region is rich in oil and gas resources. According to the estimation of the United States Geological Survey (USGS), the total technically exploitable oil and natural gas resources in the Arctic region are 412 billion barrels of oil equivalent, of which 78% are expected to be natural gas and liquid natural gas. However, China has no geographical advantage in participating in the cooperative development of Arctic energy, and the United States and other countries have restricted China’s influence in Arctic affairs for a long time, which has hindered China’s in-depth participation in Arctic

affairs. In recent years, the scale of Russia’s development of oil and gas resources in the Arctic has been expanding, and its financial and technical support has also increased, which provides an opportunity for China to participate in the cooperative development of Arctic energy. At present, the Yamal natural gas project, in which China and Russia have cooperated in the Arctic region, has been put into operation since 2017, with a total output of 45.8 million tons by 2020. The project plays a leading role in China’s further participation in the development of Arctic energy. Meanwhile, the Sino–Russian Arctic 2 liquid natural gas project under construction will further deepen the cooperation between the two countries in oil and gas resources. The Sino–Russian Arctic oil and gas cooperation not only provides China with the opportunity to jointly develop the Arctic waterway but also on the energy level, the Arctic oil and gas projects have greatly alleviated the need for China’s energy structure adjustment. Therefore, the main research content of this paper is to analyze the potential of energy cooperation

between China and Russia in the Arctic region and evaluate the impact of Sino–Russian Arctic energy development on China’s energy security.

At present, the research on Arctic energy security is not rare at home and abroad. The existing research is mainly carried out from the perspective of energy policy and the environment. In terms of Arctic energy security policy, Zhang and Xing [2] assessed the political and economic role of the Arctic in international relations from the perspective of China’s energy policy strategy. Luo and Li [3] combed the Arctic energy policies of Arctic countries, the European Union, Britain, Germany, Japan, and South Korea and analyzed the game of major powers in the Arctic region and its impact on China’s energy security. Korkmaz (2021) [4] studied the characteristics of China’s Arctic policy and its links with the “Belt and Road” initiative through the white paper on China’s Arctic policy. In terms of the impact of Arctic climate change on China’s energy security, Yang et al. [5] analyzed the possibility of Arctic energy development from the perspective of climate change. Pan [6] analyzed the uncertainties and risks faced by the development of oil and gas resources in the Arctic region and put forward countermeasures for China’s energy security according to the changes in the Arctic climate and environment. However, there is a lack of research on the specific measurement system and evaluation methods of Arctic energy security in the existing literature.

Based on this, this paper studies the current situation of energy cooperation between China and Russia predicts the potential of energy cooperation between China and Russia in the Arctic region and uses the energy security index method to evaluate the impact of Arctic energy development on China’s energy security.

2. Current Situation of Energy Development Cooperation between China and Russia

Among the eight Arctic countries, Russia has the most abundant oil and gas reserves in the Arctic region. According to the USGS assessment, there are 61 large oil and gas fields in the Arctic region, of which 43 are located in the Russian Arctic region, with an oil and gas volume of about 247.4 billion barrels of oil equivalent. In 2017, China and Russia reached an agreement on the construction of the northern waterway and the “ice silk road”. In 2016 and 2018, China and Russia formed two joint investigation teams to complete the scientific investigation of the key waters of the “northeast channel”. In 2019, China–Russia relations will become “strategic cooperative partners,” and China has increased its investment in Russia’s Arctic region.

At present, the oil and gas cooperation projects between China and Russia in the Arctic region mainly include Yamal liquid natural gas project and the Arctic 2 natural gas project. Yamal project, integrating natural gas development, processing, liquefaction, and maritime transportation, is a major oil and gas project in the world. The project is jointly operated by CNPC, China Silk Road Fund, Novatec of Russia, and a total of France, holding 20%, 9.9%, 50.1%, and 20% of the shares of the project, respectively. By 2021, all

four production lines of the project will be put into production, and the annual production capacity of natural gas will reach 19.75 million tons.

The Arctic 2 liquid natural gas project is the second liquid natural gas project developed by Novatec in the Arctic region after the Yamal project. Novatec of Russia holds 60% of the shares in the project, and CNOOC, PetroChina exploration and Development Corporation, a total of France, and Mitsui property-jogmec consortium of Japan holds 10% of the shares respectively. The project is expected to build three natural gas production lines, with a single production line capacity of 6.6 million tons/year and a total annual output of 19.8 million tons. Novatec plans to put the first natural gas production line into production in 2023 and put all three production lines into production in 2025.

According to the data of the world energy network, the actual output of energy cooperation projects between China and Russia in the Arctic region from 2017 to 2020 is shown in Table 1.

3. Analysis of the Potential of Energy Cooperation between China and Russia in the Arctic Region

According to the USGS assessment results, about 30% of the crude oil, 69.3% of the liquid natural gas, and natural gas in the Arctic region are located in Russia. Table 2 shows the technically recoverable oil and gas resources not found in the Arctic region of Russia. From the perspective of resources, the East Barents basin and Timan bochaola basin, which are rich in oil and gas resources, have a low degree of exploration and have broad exploration and production prospects. China and Russia still have much room for cooperation in the Arctic region. From the perspective of Russia’s natural gas exports, Russia’s natural gas exports to Japan, South Korea, and other countries in Asia are decreasing in 2020, but its natural gas exports to China have increased by about 35%. As an important oil and gas exporter of Russia in Asia, Russia is bound to strengthen its energy cooperation with China. At the same time, with the smooth progress of the Yamal project, Russia will strengthen the development of Arctic oil and gas resources. In October 2020, the Russian government approved the national security strategy for developing the Arctic region by 2035. The strategy points out that Russia is expected to significantly increase the Arctic natural gas production from 8.6 million tons in 2018 to 43 million tons, 64 million tons, and finally, to 91 million tons in 2024, 2030, and 2035. At the same time, the strategy also plans to increase the proportion of Russian Arctic oil production in the total oil production, from 17.3% in 2018 to 23% in 2030.

The factors that affect the potential of energy cooperation among countries mainly include the scale of energy cooperation, i.e., energy output, import and export volume, investment in energy technology, equipment, and funds, and the closeness of political and diplomatic relations among countries. However, considering the measurability and availability of data, this paper takes the scale of energy

TABLE 1: Actual total annual production of Yamal 2017–2020.

Particular year	Yamal project	Estimated capacity of a single production line	Actual annual output
2017	In December, the first line was put into operation	5.5 million tons/year	—
2018	In July, the second line was put into operation	5.5 million tons/year	8.6 million tons
2019	—	—	18.4 million tons
2020	—	—	18.8 million tons

TABLE 3: Total annual production from Yamal and arctic 2 2021–2025.

Particular year	Yamal project	Arctic 2 project	Estimated capacity of a single production line	Estimated annual output
2021	Article 4 production line put into operation	—	950000 T/a	2018 million tons
2022	—	—	—	20.62 million tons
2023	—	The first production line is put into operation	6.6 million tons/year	28.46 million tons
2024	—	The second production line is put into operation	6.6 million tons/year	36.47 million tons
2025	—	All three production lines are put into operation	6.6 million tons/year	44.65 million tons

cooperation as the analysis index of the potential of China and Russia oil and gas resources cooperation in the Arctic region.

As the actual annual output of the Yamal project is higher than the estimated annual output, and the annual output has increased, relevant assumptions need to be made when predicting the annual natural gas production capacity of China and Russia in the Arctic region. Assumption: the annual growth rate of natural gas production in China and Russia in the Arctic region is 1.02, and the actual production capacity of the Arctic No. 2 single production line is 7.39 million tons. The reason is that by 2021, all four production lines of the Yamal project have been completed and put into production, and the estimated annual capacity of the first three production lines is 16.5 million tons. However, according to the report of energy world network Moscow, its actual output will be 18.4 million tons/year in 2019 and 18.8 million tons/year in 2020. Considering the actual production capacity of the mining technology, this paper assumes that

the actual annual production capacity of a single production line of the Arctic 2 project is 1.12 times of the estimated annual production capacity. Meanwhile, the first three production lines of the Yamal project will be fully put into production in 2019 and 2020, but the capacity in 2020 is 1.02 times that in 2019, so it is assumed that the annual capacity growth rate of the two projects is 1.02.

Based on the above assumptions, this paper forecasts the output from 2021 to 2025, and the results are shown in Table 3.

4. Selection Basis of Energy Security Assessment Methods and Influencing Factors

4.1. Basis for Selection of Energy Security Assessment Method. Energy security is the core content of a country's national security system. China is relatively short of oil and gas natural resources and has long relied on imports. The long-term stable supply of energy and transportation security has

always been the focus of China's attention. For China, energy security is not just an economic issue of energy supply and demand, but a strategic issue involving energy cooperation and national security among countries. The large-scale natural gas cooperation project between China and Russia in the Arctic region not only stabilizes the overseas supply of China's oil and gas resources but also invests in the construction of the Arctic northeast channel to further expand China's maritime transport channels. But how to quantify its impact on China's energy security is a big challenge. In the existing research, scholars use different measurement methods to quantify energy security. Filipović et al. (2018) [7] used the energy security index (ESI) to analyze and rank the energy security index of EU Member States on the basis of principal component analysis (PCA). Wang et al. [8] proposed a dynamic analysis method of ESI within the framework of FDA (function data analysis), namely *desi*. The improved *desi* can dynamically analyze the change in energy security index over time. Ioannidis and Chalvatzis (2017) [9] for the first time, based on the Shannon Wiener diversity index and the Herfindal Hirschman index, combined the diversity of fuel composition with the dependence on energy imports to assess the security of energy supply. Augustis et al. [10] used the ESL energy assessment method to analyze the energy security of the Baltic Sea. Among many energy security assessment methods, the energy security index (ESI) is a common method for quantitative analysis of energy security. It classifies the data related to energy security, calculates the information entropy, and then combines them into a total value. This method can integrate the information of the Russian Arctic region on China's oil and gas resource supply, energy transport safety coefficient, and so on, summarize China's entire energy system, and reflect the characteristics of energy security. And it has been widely studied in the application of assessing and measuring national energy security, and the research results are relatively reliable.

4.2. Basis for Selection of Factors Affecting Energy Security.

On the one hand, the selection of factors affecting energy security in this paper can integrate the information of China Russia Arctic energy cooperation, on the other hand, the data should be easy to sort out and a weighted summary. In the existing literature, scholars use different influencing factors to evaluate energy security. Matsumoto et al. (2018) [11] assessed the energy security of EU countries, focusing on energy diversity, import dependence, and supply risks. Radovanovi et al. [12] proposed an energy security index covering environmental and social factors, which was applicable to EU countries from 1990 to 2012. Kruyt et al. [13] combed four dimensions such as the availability of energy security and selected influencing factors from the four dimensions. Song et al. [14] proposed China's energy security index, which includes three dimensions: energy supply, energy consumption, and environment. This dimension can be divided from the supply of oil and gas resources, the proportion of China's oil and gas resources consumption, the energy transportation environment, and other factors to

specifically analyze the impact of China Russia Arctic energy cooperation and development on China's energy security. In this paper, the selection of factors affecting energy security is mainly considered from three aspects: first, it can measure the impact of changes in the supply of oil and gas resources on energy security after China's participation in the cooperative development of Arctic energy; Second, it can measure the impact of the utilization of the Northeast waterway on China's energy security; The third is the availability, reliability, and integrity of data. According to the existing literature, this paper selects 11 influencing factors, including 5 energy supply dimensions, 3 energy demand dimensions, and 3 environmental dimensions.

5. Impact Assessment of China Russia Energy Cooperation on China's Energy Security

5.1. Basic Assumptions. In 2018, the first batch of liquid natural gas of the Sino-Russian Yamal project was transported to Rudong terminal in Jiangsu, China, opening a new chapter in Sino-Russian Arctic oil and gas resources cooperation. At the same time, the construction and production of Sino-Russian Arctic No. 2 project will further increase the natural gas delivered to China. However, the specific data that China will import oil and gas resources from the Russian Arctic region after the Arctic 2 project is put into operation is not clear. Therefore, before assessing the impact of Arctic energy development on China's energy security, this paper makes the following assumptions:

Assumption 1. Assumption that China imports oil and gas resources from the Russian Arctic region

China's import of oil and gas resources from Russia's Arctic region accounts for 21% of the total output of bilateral cooperation projects. The reason is that the actual output of liquid natural gas of the Yamal project in 2019 is 18.4 million tons, of which at least 4 million tons will be transported to China, accounting for about 21%. At present, the Sino-Russian Yamal project is progressing very smoothly, and it is also the foundation and important fulcrum for China to participate in the Arctic energy cooperation. The project can also be used as a reference for subsequent cooperation.

Assumption 2. Assumption of influencing factors of energy security

When assessing the impact of the Arctic oil and gas resources cooperation between China and Russia on China's energy security, it is assumed that other factors affecting energy security, except the per capita supply of natural gas, per capita supply of oil and channel safety factors, and maintain the current upward or downward trend. The per capita supply of natural gas, per capita supply of oil and channel safety factors, is evaluated using the data predicted in this paper.

5.2. Accounting and Data Source of Influencing Factors of Energy Security. This paper sorts out the influencing factors of China's energy security from the three dimensions of

energy supply, energy demand, and environment, mainly involving 11 influencing factors such as oil import concentration, energy consumption elasticity coefficient, and channel safety coefficient. It is used to reflect and predict China's energy security from 2010 to 2025. The specific accounting methods and data sources are as follows:

5.2.1. Factors Affecting Energy Supply. The impact of Sino-Russian cooperation in oil and gas resources in the Arctic on China's energy is mainly reflected in the energy supply. The stronger the country's energy supply capacity and the higher the per capita supply, the more its energy security can be guaranteed. In view of this, five factors affecting energy supply security, such as the per capita supply of natural gas, are selected in terms of energy supply security.

- (1) Dependence on foreign oil. The proportion of a country's net oil imports in its domestic oil consumption. External dependence on oil = (total annual oil imports - total annual oil exports) / total annual oil consumption. The higher the dependence on foreign oil, the higher the risks of energy supply.
- (2) Oil import concentration. The proportion of the total export volume of all China's oil import source countries to China's top five oil countries each year in China's net oil import volume. The higher the value, the higher the concentration of China's oil imports and the greater the risk of energy supply.
- (3) Energy self-sufficiency rate. Percentage of domestic energy output to total energy consumption. Indicates the extent to which a country's energy production meets its consumption. The higher the energy self-sufficiency rate, the stronger the domestic energy supply capacity and the higher the energy security.
- (4) Per capita supply of natural gas. The average amount of natural gas per person in the country can be provided for use. Per capita natural gas supply = total annual natural gas supply of a country / total population of the country in this year. The total natural gas supply includes domestic production and foreign net import. Among them, the natural gas import volume of Russia's Arctic region from 2020 to 2025 is predicted in this paper.
- (5) Per capita oil supply. The amount of oil that can be provided for use per capita in the country. Per capita oil supply = annual oil supply of the country / population of the country in the current year. The total oil supply includes domestic production and foreign net import.

5.2.2. Factors Affecting Energy Demand. The energy security of a country is also affected by energy consumption and energy efficiency. High energy consumption means high energy demand, which means that more energy supply is needed to ensure social production and life. The Sino-Russian cooperation on oil and gas resources in the Arctic region has an impact on China's energy efficiency to a

certain extent. The increase in the use of natural gas will improve energy efficiency. Efficient energy consumption and a good energy demand structure can reduce energy waste and ensure the full utilization of energy. Therefore, three factors, such as the proportion of oil consumption, are used to measure the security of energy demand.

- (1) Elasticity coefficient of energy consumption. In China, this indicator is the ratio of the average growth rate of energy consumption in a certain period to the average growth rate of agricultural GDP in the same period. The elasticity coefficient of energy consumption is affected by energy efficiency, economic structure, and other factors. With the improvement of energy efficiency and the optimization of economic structure, the elasticity of energy consumption will decline.
- (2) Energy consumption per unit of GDP. The ratio of total primary energy consumption to domestic GDP. This indicator can reflect the national energy demand level and energy efficiency. Energy consumption per unit GDP = domestic primary energy consumption (ten thousand megajoules) / domestic GDP (ten thousand yuan).
- (3) Proportion of oil consumption. The proportion of domestic oil consumption in primary energy consumption. Oil security is particularly important in energy security. The stability of the oil market has an impact on China's energy security, economic security, and even national security.

5.2.3. Environmental Factors. The stable natural gas supply from the Arctic region to China every year can alleviate environmental pressure and contribute to China's realization of "carbon peak" and "carbon neutrality." At the same time, with the further deepening of energy cooperation between China and Russia in the Arctic region, the commercial and economic value of the Northeast passage of the Arctic is becoming greater and greater. The Strait of Malacca has always been responsible for China's energy transport. The full opening of the Northeast passage of the Arctic can reduce the dependence of energy transport on the traditional passage. Assessing the safety of China's energy maritime transport channels, especially the safety factors of the Malacca Strait and the Northeast channel, can further clarify China's energy security situation. In view of this, China's energy and environmental security is measured by the proportion of coal consumption, the proportion of clean energy, and the channel safety factor.

- (1) Proportion of coal consumption. The proportion of domestic coal consumption in primary energy consumption. This indicator can reflect the energy consumption structure of a country. Reducing the proportion of coal consumption is conducive to the country's optimization of energy structure and improvement of energy efficiency. It is also a practical need to promote China's clean and low-carbon energy transformation.

TABLE 4: Waterway safety impact factors and weights.

Classification	Influencing factors and weight	Arctic passage	Straits of Malacca
Hydrology (0.13)	Current and tide (0.21)	0	1
	Sea ice (0.79)	0	1
Meteorology (0.34)	Wind (0.32)	0	1
	Air temperature (0.25)	0	1
	Visibility (0.43)	0	1
Channel (0.09)	Channel width (0.28)	0	1
	Water depth (0.72)	0	1
Traffic (0.15)	Perfection of national laws and regulations (0.45)	0	1
	Number of accidents (0.55)	1	0
Others (0.29)	Port construction (0.17)	1	0
	Navigation equipment (0.27)	0	1
	Pirates (0.25)	1	0
	Icebreaker (0.31)	1	0

- (2) Proportion of clean energy. The proportion of domestic clean energy consumption in primary energy consumption. The higher the proportion of clean energy consumption in a country, the more friendly its energy consumption is to the environment and the more conducive it is to the long-term stable development of the social economy.
- (3) Channel safety coefficient. Channel safety is an important guarantee for energy maritime transportation. The higher the channel safety coefficient, the higher the overseas supply security of energy. The channel safety factors of ships in the Strait of Malacca and the Northeast channel of the Arctic mainly include hydrological conditions (current and tide, sea ice conditions), meteorological conditions (wind speed, temperature, visibility), channel conditions (navigation width, water depth), traffic conditions (annual traffic accidents, international navigation law), and other conditions (port construction, piracy, navigation facilities). Because the navigation conditions of the channel are fuzzy and complex, the fuzzy analytic hierarchy process is used to measure the channel safety factor. In this paper, five classification conditions are used to form a judgment matrix, and 13 influencing factors are used to form five judgment matrices. The factors in each matrix are compared in pairs, the scaling method is used to assign values, and the weights of each influencing factor are calculated. At the same time, comparing the advantages and disadvantages of various factors in the Arctic channel and the Malacca Strait, the more advantageous one gets a score of 1 and the other 0. The specific weights and scoring results are shown in Table 4.

From the above assessment, the safety factor score of the Arctic channel is 0.2942 and that of the Malacca Strait is 0.7058. The Malacca Strait is superior to the Northeast Arctic channel in sea ice, meteorological conditions, and water conditions, so its final safety factor is also higher than the Northeast Arctic channel. In this paper, the overall safety factor of the channel = the safety factor of the channel of the

Malacca Strait, the proportion of the energy freight volume of the Malacca Strait + the safety factor of the Arctic channel, the proportion of the energy freight volume of the Arctic channel. The energy freight volume data of Malacca Strait is from EIA, and the energy freight volume data of the Arctic channel is from the Norwegian ship owners' Association.

The influencing factors and relevant information used in the energy security assessment are as follows:

5.3. Energy Security Assessment and Result Analysis

5.3.1. Introduction of Energy Security Assessment Method.

Among many energy security assessment methods, the energy security index method is more objective and interpretable, and its application is the most. This paper will use this method to evaluate energy security. As shown in Table 5 in 4.2, the measurement of China's energy security is divided into three dimensions. Each dimension contains the influencing factors related to this dimension, but the influencing factors of each dimension are quite different. Therefore, assuming that the importance of each influencing factor is not distinguished in the same dimension, the subindicators of each dimension are objectively evaluated through information entropy, and then a comprehensive index is aggregated by assigning weights to each dimension. As each influencing factor has different directions for China's energy security, it is necessary to standardize the data of each influencing factor. The specific steps are as follows:

The first step is to standardize the influencing factors of different attributes or scales into a common scale. Generally, the standardized data is between 0 and 1.

Factors that have a positive impact on China's energy security, such as channel safety factors,

$$x_i(t) = \frac{y(t) - \min[y(t)]}{\max[y(t)] - \min[y(t)]} (t_1 \leq t \leq t_{10}); \quad i = 1, \dots, m, \quad (1)$$

where t is the statistical year, m is the number of influencing factors in each dimension, and $y(t)$ is the original value of each influencing factor; $\min[y(t)]$ and $\max[y(t)]$ respectively

TABLE 5: Energy security impact factors and data sources.

Classification	Influence factor	Direction of influence	Data sources
Energy supply	Dependence on oil imports (y_1)	-	BP world energy statistical yearbook 2020 National Statistical Yearbook
	Oil import concentration (y_2)	-	General Administration of Customs of China
	China's energy self-sufficiency rate (y_3)	+	BP world energy statistical yearbook 2020
	Per capita supply of natural gas (y_4)	+	National Statistical Yearbook, predicted value of this article
	Per capita oil supply (y_5)	+	National Statistical Yearbook
Energy needs	Energy consumption elasticity (y_6)	-	National Statistical Yearbook
	GDP energy intensity (y_7)	-	BP world energy statistical yearbook 2020 National Bureau of Statistics
	Proportion of oil consumption (y_8)	-	National Statistical Yearbook
Environment	Proportion of coal consumption (y_9)	-	National Statistical Yearbook
	Proportion of clean energy consumption (y_{10})	+	National Statistical Yearbook
	Channel safety factor (y_{11})	+	EIA Norwegian Shipowners Association

represent the minimum and maximum values of influencing factor I in each dimension.

Factors that have a negative impact on China's energy security, such as energy consumption elasticity,

$$x_i(t) = \frac{y(t) - \max[y(t)]}{\min[y(t)] - \max[y(t)]} (t_1 \leq t \leq t_{10}); \quad i = 1, \dots, m. \quad (2)$$

The second step is to use the function information entropy to measure the proportion of each influencing factor of the operator dimension

$$P_i = \frac{x_i(t)}{\sum_{k=1}^m x_k(t)} (t_1 \leq t \leq t_{10}). \quad (3)$$

The third step is to calculate the information entropy of the influencing factors included in each dimension

$$E_i = [\ln(t_{10} - t_1 + 1)]^{-1} \cdot \sum_{k=1}^m P_i \cdot \ln(P_i). \quad (4)$$

The fourth step is to calculate the weight of influencing factors included in each dimension

$$\omega_i = \frac{1 - E_i}{m - \sum_{k=1}^m E_i} (0 \leq \omega_i \leq 1). \quad (5)$$

The fifth step is the energy security index of each dimension

$$ESI(t) = \sum_{k=1}^m \omega_k(t) \cdot x_k(t), (t_1 \leq t \leq t_{10}) (0 \leq \omega_k \leq 1). \quad (6)$$

Finally, reasonably allocate weights to each dimension, summarize the security indexes of each dimension, and form a comprehensive China energy security index

$$TESI(t) = \sum_d \alpha_d \cdot \left[\sum_{k=1}^m \omega_k(t) \cdot x_k(t) \right], \quad (7)$$

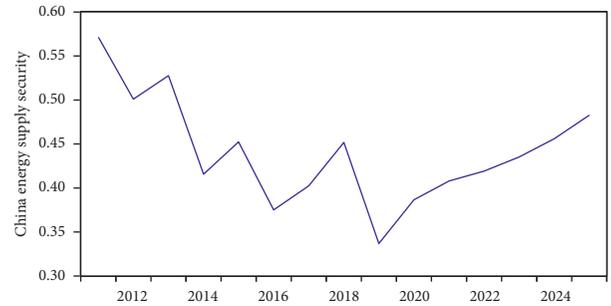

FIGURE 1: China's energy supply security index 2011-2025.

where d represents different dimensions, D represents the total number of dimensions, and α_d represents the weight of different dimensions. According to the research of Ang et al. [15], the weights of energy supply, energy demand, and environment are 50%, 25%, and 25%, respectively. Giving a higher weight to the dimension of energy supply is to emphasize the importance of uninterrupted energy supply. Since all influencing factors have been subject to positive standardization, a larger $Tesi$ (T) means a safer level of energy security.

5.3.2. Energy Security Assessment Results

(1) *Evaluation Results of Three Dimensions of Energy Security.* According to the above calculation method, the energy security assessment [16-22] results of three dimensions are calculated respectively, as shown in Figures 1-3 below. Obviously, the fluctuation of the evaluation results of each dimension is different. The assessment results of China's energy supply security are shown in Figure 1, which shows a downward trend before 2020. This downward trend also reflects that China has always been highly dependent on energy imports, with concentrated sources of energy imports, and a low per capita supply of oil and natural gas. In fact, limited by domestic energy resources, China's dependence on oil imports has reached 73% in 2020, and the

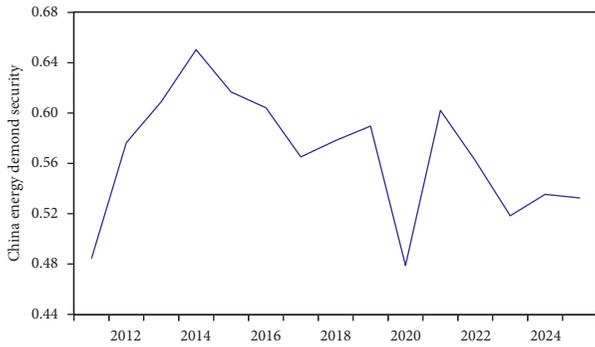

FIGURE 2: China energy demand security index 2011–2025.

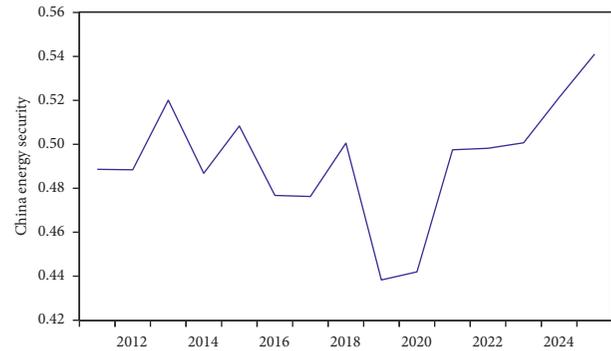

FIGURE 4: China's energy security index 2011–2025.

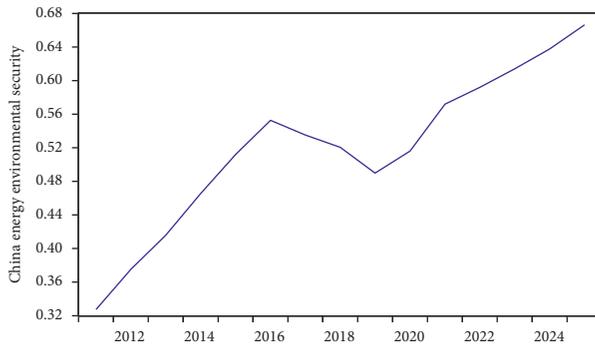

FIGURE 3: China environmental security index 2011–2025.

concentration of oil imports is 57%. China's energy supply faces great risks. After considering the long-term oil and gas resources cooperation projects between China and Russia in the Arctic region, it can be seen from Figure 1 that the energy supply security index has rebounded significantly after 2020 because China's oil and gas resources, especially the import of natural gas, have been protected to a great extent.

The energy demand security assessment index is shown in Figure 2, which fluctuates from 2011 to 2025 and reaches a trough in 2020. After 2014, the energy demand security index has decreased significantly. The possible reason is that in the past, the proportion of oil consumption increased by an average of about 0.2% every year. From 2014 to 2015, the proportion of oil consumption in primary energy consumption increased from 17.3% to 18.4%. Since 2015, the proportion of oil consumption has been relatively stable, and the fluctuation of the energy demand security index is mainly due to the increase of the energy consumption elasticity coefficient (the value in 2020 is 0.96). After 2020, with the further deepening of natural gas cooperation between China and Russia, the proportion of clean energy consumption such as natural gas has increased, and the energy structure has been optimized, which has played a significant role in improving the security of energy demand. But at the same time, the increase in the proportion of oil consumption makes the energy consumption elasticity index unable to rise all the time, so the security of energy demand fluctuates.

The energy and environmental security assessment index is shown in Figure 3, which shows an overall upward trend from 2011 to 2025. Among the three environmental factors,

the proportion of coal consumption has a negative impact on the environmental index, and the proportion of clean energy and channel safety factor have a positive impact on it. With the further deepening of oil and gas resources cooperation between China and Russia in the Arctic region, the Northeast passage of the Arctic has been more utilized, and China's energy transportation has become less dependent on the Malacca Strait. At the same time, the increased use of natural gas has reduced the pressure of energy consumption on the ecological environment. Under the joint action of the two aspects, the growth rate of the energy and environmental security index will increase after 2020.

(2) *Overall Assessment Results of China's Energy Security.* With reference to the predetermined weights, the evaluation results of China's energy security index are obtained by using the final summary formula in 3.3.1, as shown in Figure 4 below. In fact, in 2011, China put forward many favorable energy policies, such as promoting diversified and clean energy development and closing small coal mines, which improved the level of energy security. However, China's domestic energy resources have long been more coal and less oil and gas. In 2019, China's oil import concentration reached 62%, posing challenges to the security of the energy supply, which led to a sharp decline in the energy security factor. With China actively expanding energy channels, strengthening cooperation with Russia on oil and gas resources projects in the Arctic region, and improving energy efficiency, China's overall energy security level has maintained a steady rise. After considering the Arctic energy cooperation with Russia, China's energy security level is expected to rise from 0.4381 in 2019 to 0.5412 in 2025. The continuous promotion of China–Russia Arctic energy cooperation and the construction of the Arctic waterway has reduced China's dependence on energy imports from the Middle East, reduced the constraints of the Malacca Strait, increased the proportion of clean energy consumption, optimized the energy structure, improved energy efficiency, and improved the level of energy security.

6. Conclusion

This study uses the energy security index method to evaluate the impact of oil and gas development cooperation between

China and Arctic countries, especially Russia, on China's energy security. From the final results of the evaluation, it has an impact on China's energy supply security, energy demand security, and environmental security. The specific conclusions are as follows:

- (1) China's energy security risks are mainly affected by the over concentration of energy import sources. Therefore, diversifying energy imports and reducing energy imports from volatile regions such as the Middle East can effectively disperse China's energy supply risks.
- (2) Energy demand and environmental security will also have an important impact on China's energy security. However, compared with energy demand, environmental security factors such as the proportion of clean energy consumption and channel safety factor have a greater impact on China's energy security. Therefore, increasing the proportion of clean energy consumption, reducing the dependence on energy import channels in the Malacca Strait, and diversifying energy import transport channels can effectively ensure China's energy security.
- (3) Strengthening energy cooperation with Russia in the Arctic region can greatly enhance China's energy security. Therefore, with the support of technology, funds, and scientific research, China can carry out all-round and multifield cooperation with Russia in the construction of Arctic waterway, port infrastructure, icebreaker technology, oil and gas exploration and exploitation technology, and Arctic scientific research.

Experimental instructional design is an important pedagogical component of university teaching and learning, an important means of cultivating students' innovative spirit and practical skills, and has an important status and role that cannot be replaced by any other means of teaching and learning. Assessment for learning as learning, assessment for learning, and assessment as learning are three paradigms of educational assessment that complement each other in achieving curricular and pedagogical goals and together form learning-based assessment. As an important component of national science and technology development, measuring the effectiveness of laboratory instructional design in universities and research institutions is of special significance. This paper presents the authors' research on the background, evaluation characteristics, evaluation content, and methods of experimental teaching evaluation in the information technology environment, with examples of their application.

1. Introduction

Experimental teaching is an important teaching content of science and technology teaching is an important means to cultivate students' innovative spirit, and practical ability has an important status and role that cannot be replaced by any other teaching methods and means [1].

Informatization is a symbol of the 21st century, with the process of informatization, the core of modern computer education technology is developing rapidly, laboratory teaching equipment is gradually digitalized, computerized, and networked, and the era of informatization of laboratory teaching has arrived. Make full use of modern information technology educational tools to significantly improve teaching methods, teaching efficiency, and teaching quality [2]. Laboratory teaching informatization, so that experimental teaching from teaching methods [3], teaching effectiveness, and teaching quality has been improved, so that the experimental management to a new level [4]. Obviously,

education, classroom teaching, and experimental teaching in the 21st century are inevitable and necessary for gradual informatization.

Effective teaching in information-based teaching differs from traditional effective teaching in that it refers to effective teaching in the teaching environment supported by information technology. IT-supported teaching breaks the limitations of time, space, and resources in traditional teaching, and can make full use of the advantages of information technology to carry out various teaching modes based on information technology, such as project-based teaching mode, problem-based teaching mode, network collaborative learning teaching mode, and case-based learning mode, which are conducive to the improvement of teaching quality and the full development of students. The application of information technology in teaching does not mean that effective teaching happens. Some studies have shown that the reasons for successful IT teaching should be attributed more to good instructional design and adequate preparation

for teaching. Therefore, to examine whether informationalized teaching is effective, it is still necessary to start from whether teaching accomplishes teaching objectives and promotes students' learning, and to synthesize various factors such as teaching purposes, application of informationalized teaching mode, application of information technology, and teaching process, so as to explore the objective rules of the effectiveness of informationalized teaching.

Educational assessment is the wind vane and baton of educational reform and development [5]. Due to the long-term, generative and delayed nature of education and the indirect, implicit and subjective nature of assessment, the scientific and effective organization and implementation of educational assessment have been a difficult problem in educational teaching practice [6]. Educational evaluation is related to the direction of educational development, and it is gradually shifted to the following direction: improving result evaluation, strengthening process evaluation, exploring value-added evaluation, improving comprehensive evaluation, and establishing a scientific educational evaluation system and mechanism for different subjects and characteristics of different levels and types of education.

Evaluation of laboratory teaching is a necessary method and tool to analyze and recognize the pedagogical quality and efficiency of laboratory teaching. It is also often assumed that the act of measuring memory does not change memory [7], and most educational practices are focused on strengthening the process of students' processing of knowledge, that is, getting it into their heads. Nowadays, the purpose of evaluation of experimental teaching in the informationized environment is to recognize the laws, problems, and shortcomings of experimental teaching in the informationized environment, to provide a basis for the improvement of experimental teaching quality, experimental teaching improvement, experimental teaching research, and experimental teaching development, in order to meet the needs of talent training in universities in the information era. In the study of how students learn [8], there is no mention of a method about retrieval [9]. This method of retrieval memory is still controversial in specific teaching [10]: whether it is effective [11], ineffective [12], or vague [13]. For a long time, universities across the country have invested a lot of human and financial resources in the field of experimental teaching, accumulated rich experience in experimental teaching, and cultivated a large number of talents, and the evaluation system of classroom theory class teaching is relatively mature, but the evaluation system used to evaluate the quality of experimental teaching has been little studied [14]. With the involvement of information technology in experimental teaching and the increasing requirements for the evaluation of scientific teaching concepts [15] year by year, it is urgent to study and develop the evaluation system of experimental teaching in the new situation to evaluate and monitor experimental teaching.

Whenever new media technologies emerge, some researchers are always eager to introduce these new media technologies into teaching, expecting to use the advantages of new media technologies to improve teaching or solve

problems in teaching [16]. However, as the cult of modern media cools down [17], people gradually shift from the blind pursuit of media technology to the research on the effectiveness of information technology teaching applications, but always fall into the awkward mode of "introducing new technology, a successful experiment and a failed promotion." In this era of information technology, what is wrong with the research on the effectiveness of experimental technology teaching application, and why the research results cannot be promoted to the general practice? And now, the integration of a variety of high-end information technology wisdom classrooms into the vision of educational technology researchers, and how we should be sensible to the configuration of various technologies in the wisdom classroom, the wisdom classroom pragmatic introduction to teaching life? There is an urgent need to find a scientific rationale for the pedagogical application of experimental technologies.

Research on the effectiveness of experimental instructional designs often uses a simple two-class comparison experiment, but such comparison experiments are difficult to prove the instructional effectiveness of experimental designs because of the many gaps in empirical research in this way.

1.1. Misplacement of the Research Question. Comparative experiments on technology application generally explore the question of which is superior between teaching with or without the involvement of a particular technology or between teaching with the involvement of different experimental technologies and attribute the advantage to the application of a particular technology. In pedagogical practice, however, the primary task is to apply technology to improve instruction (practical goal) rather than to demonstrate the superiority of a particular technology (theoretical goal). It is the technology that has specific functions, and these objective functions do not need to be tested repeatedly in pedagogical research. In reality, when different people use the same technology, there will certainly be differences in the extent to which the technology functions are used, but this difference is not caused by the technology itself, but by multiple factors outside the technology. For an emerging technology, the acceptance or rejection of it should not be decided by the merits of its performance. Therefore, the basic question of technology application research is not to prove the superiority of a particular technology, but to explore what particular experimental techniques are most applicable and how they can be combined with other pedagogical elements to achieve optimal results. It is the study of the instructional system associated with the technology that is more important than the study of its advantageous functions.

1.2. Poor Definition of the Comparison Item. Contrast experimental research often judges the merits of technology by the good or bad teaching effect, and inadvertently mistakenly takes the technology as a whole (with or without, this or that) as a contrast item to study. However, technology and its products often contain multiple attributes and functions,

and they have completely different effects on teaching and learning, so it is difficult to say what is being compared by using the technology as a whole as a comparison item. Imagine the need to compare visual media and auditory media in terms of the intuitiveness of content presentation. For example, is there a direct comparison between a computer + projector and a blackboard? Comparing technologies in general terms, the conclusions obtained are hardly indicative of the problem. That is, technology products are only meaningful when compared in terms of the same type of information and pedagogical function. Moreover, comparisons of the role of the same technology product in different instructional contexts are interesting, but unfortunately less often done.

1.3. Evidence of Ineffectiveness. The general idea of validity testing of technology instructional applications is to compare the effectiveness of the experimental and control classes and to attribute the improvement in instructional effectiveness to the application of technology. There are two loopholes in this. First, effectiveness here usually refers to the effect of an educational intervention in a specific context, which is actually based on “client satisfaction,” such as improved academic performance, increased motivation, positive learning attitude, and good experience with a technology product [18]. However, “client satisfaction” is not an “objective” effect. Second, the effect of teaching is the result of complex interactions between the elements of teaching activities, which reflects the overall operation of teaching activities and cannot be attributed to any local elements of teaching. Therefore, we cannot conclude the effectiveness of technology application in terms of teaching effectiveness [19]. To take a step back, even if technology is effective, it is only effective in a specific teaching context and does not have a universal applicability out of context. Due to the non-reproducibility of teaching activities, we simply cannot prove the pedagogical validity of technology in the doctrine. In fact, all tests are only tests of the feasibility in a particular context.

1.4. Defective Experimental Design. This phenomenon can be considered to be widespread at home and abroad. Single-factor isogroup experiments are the simplest experimental teaching comparison study experiments, and these experimental designs are still so, and other multifactor experimental teaching comparison experiments are even more seriously flawed in their design. This phenomenon, although directly related to designer literacy, is not essentially caused by the experimental designer, but by the faulty rationale of experimental teaching comparison experiments. Unlike other scientific experiments, teaching experiments with evidence of teaching effectiveness have to consider the individual person as a variable because the individual person as a whole is involved in the experimental process [20]. However, the individual person is in an open self-creation process and cannot be objectified or conceptualized, so we cannot treat the individual person in a teaching experiment as a variable (operationally speaking, i.e., not controllable), and the teaching effect is indeed inseparable from the unique

contribution of the individual student, so with the teaching effect as the grip, the comparison experiment, no matter how strictly the experimental environment is controlled, can hardly show that the achievement of the teaching effect and The use of technology is directly related. Therefore, no matter how the comparison experiment is designed, it will have doctrinal flaws, and no researcher will be able to recover from this research rationale. It is for this reason that the field of education refers to these types of teaching experiments as “quasi-experiments.” Such quasi-experiments have some exploratory research value, but they can only test the feasibility of local methodological elements. Such feasibility, of course, does not require such empirical studies, which are often obvious.

1.5. Treating Quasi-Conclusions as Conclusive. The conclusions drawn from quasi-experiments in teaching should be “quasi-conclusions.” However, both researchers and practitioners have “inadvertently” promoted quasi-conclusions as generalized definitions, which has led to nothing but confusion and dogma in teaching practice. When people experiment with technology applications, they generally delve into the functional characteristics of a particular technology, customize the content for that technology, and provide as much support as possible in terms of resources, funding, and policies, so that the functionality of the technology is brought to a higher or even higher level, with satisfactory results. You can imagine how costly this kind of teaching experiment is. In fact, although this kind of teaching experiment is a teaching experiment in a “real situation,” it is not a teaching experiment in a “natural situation,” because this kind of teaching experiment is a nonstandard teaching practice. The teaching application of media eventually goes back to the routine work of regular cost, and most of the support equipped for the experiment will be withdrawn. So, is the specific functionality of the technology really needed in regular teaching? If so, will its actual utility be as good as it was during the experiment? These are all uncertainties. If we cannot use the quasi-conclusions of the experiment to address these issues in regular teaching, the quasi-conclusion is naturally useless. At best, it tells us that someone has “worked” before.

We can think about this issue from a different perspective: the pedagogical use of technology may indirectly affect the effectiveness of teaching and learning by increasing the “goal-means” coherence of the teaching system, student engagement, or the adaptability of the teaching system under certain conditions. Therefore, research on the use of technology should examine more the actual role and contribution of technology products in conventional teaching and learning rather than proving its pedagogical effectiveness in isolation [21]. Such empirical studies, while not getting bogged down in quasi-experiments, require an information flow-based approach to instructional systems analysis in order to explore the details of the role of technology products in teaching and learning.

Experimental teaching design validity analysis is a very important experimental design issue [22]. The study of the

relative validity of each basic unit facilitates the improvement of the experimental management model and the development of rational planning, thus maximizing the effectiveness of experimental design [23]. Scientific measurement of experimental design validity can reflect the degree of effective subjective efforts to improve experimental design, which can have a motivating effect on each unit [24]. For measuring the effectiveness of teaching experimental design, hierarchical analysis has been used in the past to analyze the good and bad experimental design of each unit. That is, the weight parameters of each research outcome index are determined by hierarchical analysis, and then each index is multiplied by its respective weight and summed, and the result is used as the final comparative score of each unit. Such a measurement method is hardly motivating for the assessment unit. Because the number of indicators of units with good foundation conditions is often higher, the weighted sum is naturally in the upper level, while the units with poor foundation conditions, no matter how hard they work, the results are limited, and the weighted sum is not likely to be in the upper level, which greatly affects the motivation of the subjective efforts of units with poor foundation conditions, or worse, some units with good foundation conditions rest on their laurels and do not think about making progress, resulting in assessment scores are still at the top, while they have actually regressed.

In this paper, the idea of the binary relative effectiveness of measuring the economic efficiency of enterprises is transferred to measuring the effectiveness of teaching experiment design in colleges and universities, that is, the results of the effectiveness of teaching experiment design of each college and university measured by the hierarchical analysis method are taken as a measure of the basic conditions of each college and universities, and it is regarded as an input, while the corresponding current results measured by the hierarchical analysis method are regarded as an output, as the C^2GS^2 model in the Data Envelope Analysis (DEA) method [25] is used to calculate the relative evaluation results among the evaluation units. This relative evaluation result can eliminate the influence caused by the objective base conditions of each university, and it can make the decision units with different base conditions have the same “benchmark” to achieve the purpose of fair and objective evaluation. It truly reflects the validity of the experimental design. We call this evaluation method the second relative assessment method. By using the binary relative assessment method to evaluate the effectiveness of teaching experiment design in each university, universities with different basic conditions can be stimulated. Against the above background, this study focuses on the problems related to the experimental teaching evaluation system in the information technology environment.

2. Establish the General Index System and Participation Parameters

The research on teaching application of technology must go beyond the old idea of comparative experimental research with no benefit as mentioned above, and start from teaching

system analysis to study the teaching function of technology products in normal teaching. At present, there are two main perspectives of teaching system analysis: one is to view the teaching system as a human behavioral system and analyze the behavior of students and the relationship between them; the other is to view the teaching system as an information system with specific functions, inferring the overall properties of teaching from the local characteristics of information flow and revealing the relationship between information flow and teaching functions [26]. The method of analyzing the teaching system from the perspective of behavioral system suffers from the defects of a complicated and confusing coding system, mechanical and arbitrary cut scores, weak interpretation of results, etc. Moreover, it mostly analyzes the external behavior of students and rarely involves technical elements, and even if the technical dimension is involved in the improved scale, it only judges whether a media is used at the operational level, but there is still no way to know what specific role the media information plays for teaching. In addition, understanding or describing the teaching system from the external verbal behaviors of teachers and students ignores the flow of knowledge and information behind the behaviors and fails to establish a link between teaching behaviors and teaching effects, and the research findings are neither supported nor real teaching guidance.

The IIS (Instructional Information Set) diagram analysis method focuses on the relationship between the marked information of IIS output by three types of information processing subjects, namely, teachers, students, and information media, in the teaching system and the teaching function, and infers the overall properties of teaching from the local characteristics of the information flow in these teaching processes. Here, the teaching system refers to a system of information flow among three types of information processing subjects, namely, teachers, students, and information media, which is essentially an information system composed of students, information media, and teachers and their input information and output information plus the IIS expressing socially shared knowledge set. The conceptual model of the teaching system is shown in Figure 1.

Information processing of teacher (IPT), Information processing of learner (IPL), and Information processing of media (IPM) represent the processing of information by teachers, learners, and information media, respectively. $\{X\}$ and $\{Y\}$ represent the input and output of their information processing processes. In the conceptual model, the information output Y from the three information processing subjects is extracted and structured as “input information items” with the representation format “<contributor> <operation> <information type> <representation form> <IIS subgraph> [<information quality>] [<content annotation>]” (as shown in Figure 2), and the set of information outputs Y is abstractly summarized as the Instructional Information Set IIS, which is used to characterize the shared nature of knowledge. Other elements that are not directly related to information processing are categorized as environmental elements of the instructional system, such as

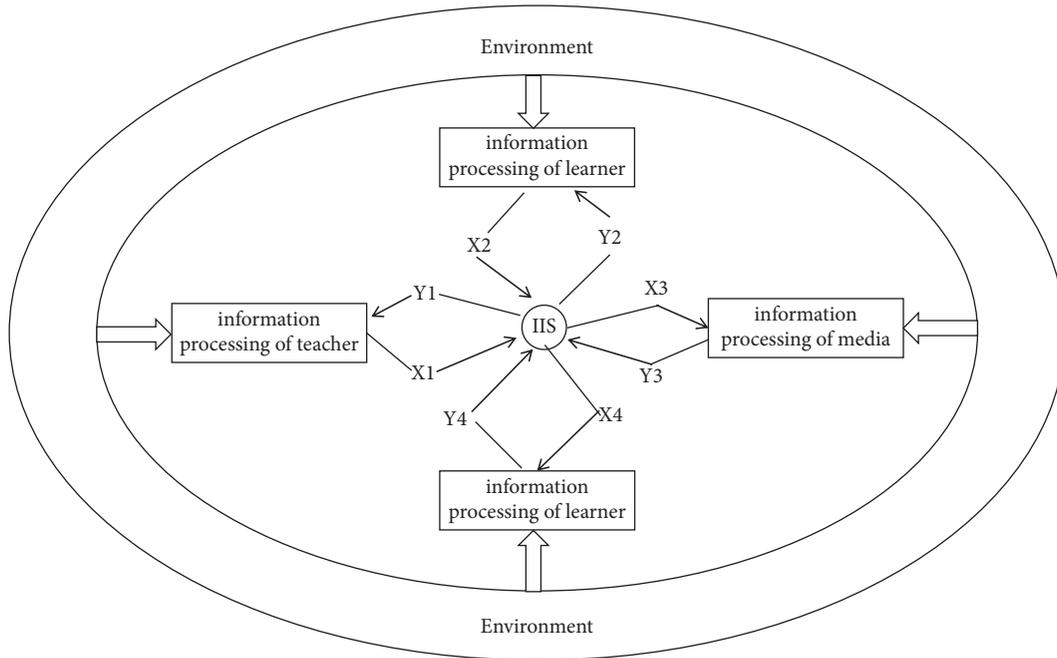

FIGURE 1: Conceptual model of general experimental teaching system.

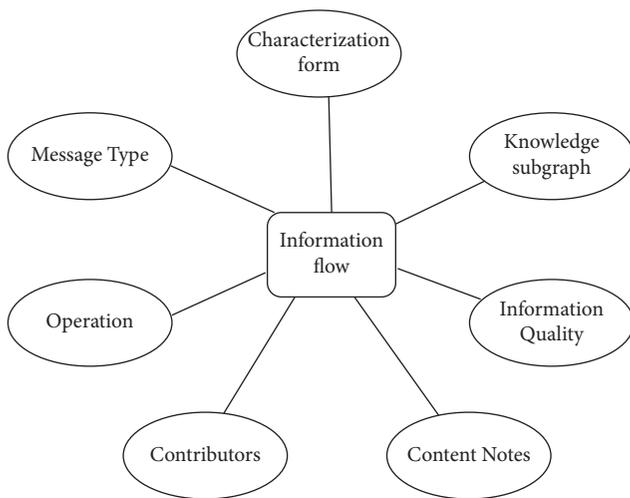

FIGURE 2: General representational structure of information flow for experimental teaching.

students’ prerequisite knowledge skills, teacher-student relationships, and students’ motivation levels. Environmental factors have an impact on the instructional system, but these impacts are ultimately expressed through externalized information output. The conceptual model of the instructional system reflects not only the relationship of information flow among three types of subjects: teachers, students, and information media, but also the contribution of this multi-subject information flow to social knowledge construction, which is reflected in the amount of activation of knowledge points by the information flow. The IIS diagram analysis method specifies that only the information flows of “answer,” “knowledge semantics” and “factual examples” correspond to the IIS knowledge subgraphs, and only the

information flows of Only the subgraphs containing IIS knowledge can contribute to the activation of knowledge points. Although the specific externalized behaviors or verbal information of teachers and students in the teaching process cannot be reproduced, the IIS knowledge subgraph behind the specific behaviors or information flow is an objective graph, and only the information flow that contains the IIS knowledge subgraph has value, and the specific expressions of the information flow have no essential influence on the operation results of the teaching system, so the teaching system in the sense of this information flow is reproducible. This reproducibility of the research object ensures the reproducibility and scientificity of the whole empirical study.

Research on the application of media technologies based on information flow analysis opposes the verification of the pedagogical effectiveness of technologies through comparative experiments and advocates the analysis of the actual pedagogical functions of specific technological products in the context of regular teaching [27]. Therefore, instead of interfering with teachers and students to deliberately use a certain technology in the teaching process, the researcher provides a variety of media technology choices and allows them to make their own trade-offs according to their needs, and then conducts an information flow analysis of the teaching activity process to determine in detail the real role of the selected technology product in the teaching process and the actual dependence of teaching on it [28].

Traditional experimental teaching methods are mostly validation experiments students rely on detailed laboratory handouts to guide each step of the experiment students carefully and cautiously operate inevitably to obtain the expected experimental data thus achieving verification of theoretical learning [29]. However, due to the limitations of

experimental conditions, time, consumption of equipment, equipment integrity, laboratory management, etc. students rely on the teacher's guidance and lack of active thinking, creative thinking, and research on experimental refutation thus the students are trained in experimental ability are less competent. The introduction of computer-assisted teaching with its multimedia, interactivity, and simulation makes the whole teaching process more active and efficient [30]. The use of computer simulation can facilitate the examination of students' design ideas repeatedly modified and optimized and also make many experiments that could not be realized in the laboratory in the past to obtain simulation effects. At the same time, the local area network of experiments, the intelligence, interactivity, and reliability of experimental instruments and virtual instruments to achieve student-oriented personalized teaching reduces the duplication of teachers' work and laboratory management workload makes open laboratories possible and also creates conditions for remote experimental teaching in distance education [31].

The key to the reform of experimental teaching is the reform of experimental teaching mode with students as the main body of the experimental teaching mode of the experimental process to design comprehensive. The design of comprehensive experiments requires students to have strong basic knowledge and wide knowledge with certain innovative abilities. Informatization experimental environment due to the large amount of experimental data storage, experimental program optional, high comparability, experimental data easy to analyze and calculate digital equipment to make the experimental data sampling easy to experiment in the system with a computer to facilitate rapid processing [32]. Based on the above information environment fully mobilizes the enthusiasm, initiative, and creativity of students in the experiments while also providing technical support for the student-led teacher-led experimental teaching design. Of course, to achieve the change of teaching mode must also have the practice and scientific evaluation of the experimental teaching process guided by the theory of learning-based instructional design and other educational technology.

3. Comprehensive Algorithm for Measuring the Validity of Experimental Instructional Design

Before teaching, interviews and questionnaires were conducted with database-related experts, teachers, and former students to understand the learning needs of the database course and to analyze the needs in order to prepare for conducting the effectiveness study. Based on this, we designed the teaching program and prepared the teaching materials according to the available technology and equipment. Then, the first phase of teaching "case study and collaborative web-based learning," i.e., "instructional design," was conducted. During the teaching process, changes and problems were recorded, and after the "instructional design" was completed, research was conducted to understand the effectiveness of the teaching at this stage by means

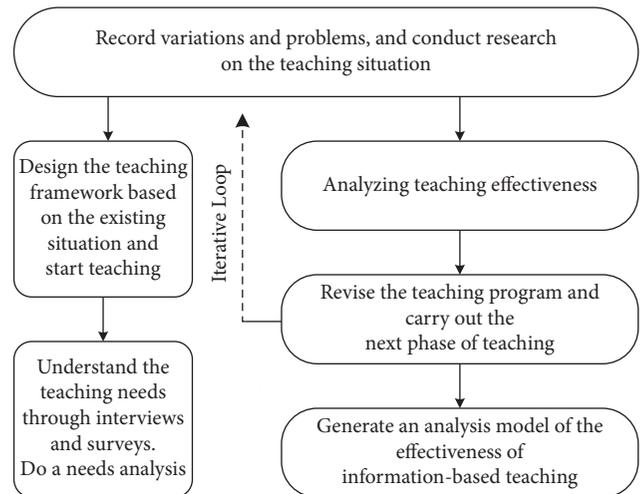

FIGURE 3: Framework for the implementation of data-based informational teaching experiment design.

of interviews and questionnaires. After analyzing the effectiveness of the teaching, the teaching plan is revised and adjusted, and the next stage, i.e., the "multimedia courseware production" stage, is carried out until the end of this stage of teaching. After all the teaching is finished, we summarize the whole teaching and research process and propose a model for analyzing the effectiveness of information technology teaching for undergraduates. The model is shown in Figure 3.

In the study, the effectiveness of stage-specific teaching is mainly understood by means of questionnaires to find out the existing problems and analyze the effectiveness. The analysis of the effectiveness of informatization teaching should comprehensively examine the implementation effect of informatization teaching mode, the application of information technology, and the teaching process to see whether the teaching effect meets the purpose of teaching and whether it effectively promotes students' learning. Based on such considerations, this paper proposes the analysis model of information-based teaching effectiveness as shown in Figure 4 and uses it to analyze the effectiveness of information-based teaching on the basis of questionnaire survey. First, the purpose of teaching is determined according to the learning needs, and the teaching process is analyzed, mainly from examining two aspects: the information technology teaching model and the application of information technology. Then, we analyze what kind of teaching effect is produced after the teaching process and whether it conforms to the teaching purpose. There are many cases between the two extremes of fully conforming and not conforming at all, as shown by the double arrows in the figure. The author divides the teaching effect into five levels, and there are several cases between very effective and completely ineffective such as relatively effective, generally effective, and less effective.

Through the analysis of the effectiveness of experimental teaching, several main factors affecting the teaching effect were summarized: the knowledge and skill reserve before the experiment, the expected results and innovation of the

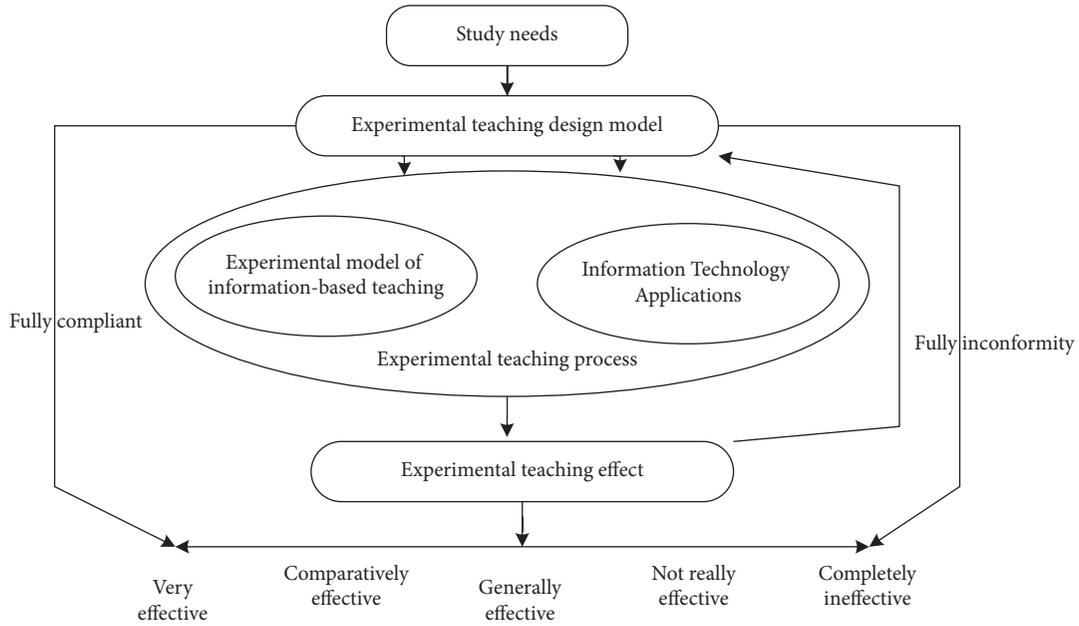

FIGURE 4: Analysis model of the effectiveness of information-based experimental teaching design.

TABLE 1: Findings on the factors influencing the effectiveness of information-based experimental teaching design.

	High impact (%)	Some impact (%)	No impact (%)	N/A (%)
Experiment content	62	26	12	0
Experiment management	4	45	39	12
Experiment results	60	29	10	1
Informational environment	18	25	57	0
Experiment knowledge and skill base	32	43	24	1

experiment, the content of the experiment, the experiment management, the information environment, etc. The specific contents and the results summarized by the questionnaire research are shown in Table 1:

At this point, traditional information technology effectiveness research has come to an end. However, innovative effectiveness measurement must be supported by data or models. Therefore, we reanalyze the data summarized above to come up with a more effective evaluation method. As mentioned in the introduction part of DEA, in this paper we will analyze and summarize the data from the survey results again by using the binary relative evaluations.

The binary relative evaluation method for the analysis of the effectiveness of experimental design teaching in colleges and universities was carried out in two stages. First, the previous and current composite indices of the effectiveness of experimental design teaching in each university are measured by using the hierarchical analysis method, and then they are regarded as input and output, respectively, and their binary relative evaluations are measured by using the data envelopment analysis method. When using the hierarchical analysis method to measure the composite index of the management effectiveness of each university, a system of indicators of the effectiveness of experimental design teaching in universities and selected weight parameters are established. The intent of this method is to establish the system of measuring the effectiveness of experimental

teaching design in universities using the principles of system engineering and hierarchical analysis.

After the analysis of the above-mentioned survey results, some relatively important evaluation factors were determined, but due to the instability and limitation of the survey sample, we made a deeper weighting of the summarized influencing factors through the hierarchical analysis method. The specific method is derived from the following hierarchical analysis. The algorithm of the maximum characteristic root λ_{\max} is shown in equation (1); the consistency index CI is shown in equation (2); the consistency ratio CR is shown in equation (3). The judgment matrix of A-B and the judgment matrix of B-C are shown in equations (4) and (5):

$$\lambda_{\max} = \sum_{i=1}^n [(AW)_i / nW_i], \tag{1}$$

where i is the i -th factor, A is the Judgment Matrix, W_i is the i -th weighting factor.

$$CR = (\lambda_{\max} - n) / (n - 1). \tag{2}$$

The average random consistency index, RI , is obtained by taking the arithmetic mean of the eigenvalues of the random judgment matrix after several iterations of the calculation.

$$CR = CR/RI. \quad (3)$$

When $CR < 0.1$, the consistency of the A-matrix is generally considered to be acceptable.

$$A = \begin{bmatrix} 1 & 1 & 1 & \frac{1}{3} & \frac{1}{5} & \frac{1}{2} \\ 1 & 1 & 1 & \frac{1}{3} & \frac{1}{5} & \frac{1}{2} \\ 1 & 1 & 1 & \frac{1}{3} & \frac{1}{5} & \frac{1}{2} \\ 3 & 3 & 3 & 1 & \frac{1}{3} & 2 \\ 5 & 5 & 5 & 3 & 1 & 4 \\ 2 & 2 & 2 & \frac{1}{2} & \frac{1}{4} & 1 \end{bmatrix}, \quad (4)$$

where $\lambda_{\max} = 6.061$, $CI(6) = 0.012$, $RI(6) = 1.24$, $CR \approx 0.01$.

And the weighting factor is: $W = 0.074, 0.074, 0.074, 0.210, 0.438, 0.130$

$$B = \begin{Bmatrix} 1 & 7 & 3 \\ \frac{1}{7} & 1 & \frac{1}{5} \\ \frac{1}{3} & 5 & 1 \end{Bmatrix}, \quad (5)$$

where

$$\lambda_{\max} = 3.050, CI(3) = 0.025, RI(3) = 0.58, CR = 0.043.$$

And the weighting factor is: $W = 0.649, 0.072, 0.279$

The final structural model and weight parameters of the index system for the effectiveness of experimental teaching design in universities using hierarchical analysis are shown in Figure 5.

In order to give a true reflection of the improvement of the management level of each university due to subjective efforts, each university with different basic conditions should have different reference standards, and the index of the effectiveness of experimental design teaching in each university measured by hierarchical analysis reflects to some extent their different basic conditions, so it can be used as a reference standard to measure the basic conditions of different universities, and we call it the reference index. The current index of the effectiveness of experimental design teaching in each university can also be measured by the hierarchical analysis method, and we call it the current index. We know that the level of experimental design teaching in each university can be fairly measured only in the dynamic change, so we introduce the concept of index state and possible set of index state.

Let x_j, y_j be the reference index and current index of the j -th college, respectively, and call the array (x_j, y_j) the index state of the j th college, called the convex set, T , as in (3)

$$T = \left\{ (x, y) \mid \sum_{j=0}^n \lambda_j x_j \leq x, \sum_{j=0}^n \lambda_j y_j \leq y, \sum_{j=0}^n \lambda_j = 1, \lambda_j \geq 0, j = 0, 1, 2, \dots, n \right\}, \quad (6)$$

where $(x_0, y_0) = 0$.

From DEA model [25], we obtain (4):

$$\begin{aligned} &Max Z, \\ &\sum_{j=0}^n \lambda_j x_j \leq x_{j0}, \\ &\sum_{j=0}^n \lambda_j y_j \leq y_{j0}, \\ &\sum_{j=0}^n \lambda_j = 1, \lambda_j \leq 0, j = 0, 1, 2, \dots, n. \end{aligned} \quad (7)$$

If the optimal value $Z^* = 1$, the university is said to be on the frontier of the set of possible exponential states T . So the binary relative evaluation N of the college can be derived from (5):

$$\eta = 1/Z^* \times 100\%. \quad (8)$$

As $1/Z^* = y/\bar{y}$, the binary relative evaluation represents the percentage of the current index of each university in the maximum current index that can be achieved under the same reference conditions.

4. Results

In this paper, the effectiveness of experimental design teaching in 15 universities from 2014 to 2017 was measured using the above-mentioned binary relative evaluation method. The selected data sources were "2014 National Compendium of Science and Technology Statistics of Higher Education Institutions" and "2018 National Compendium of Science and Technology Statistics of Higher Education Institutions" prepared by the Department of Science and Technology, Ministry of Education and published by Higher Education Press [33]. In order to protect the privacy of local schools and to comply with the relevant protocols, the abbreviated names of these universities are protected in this paper.

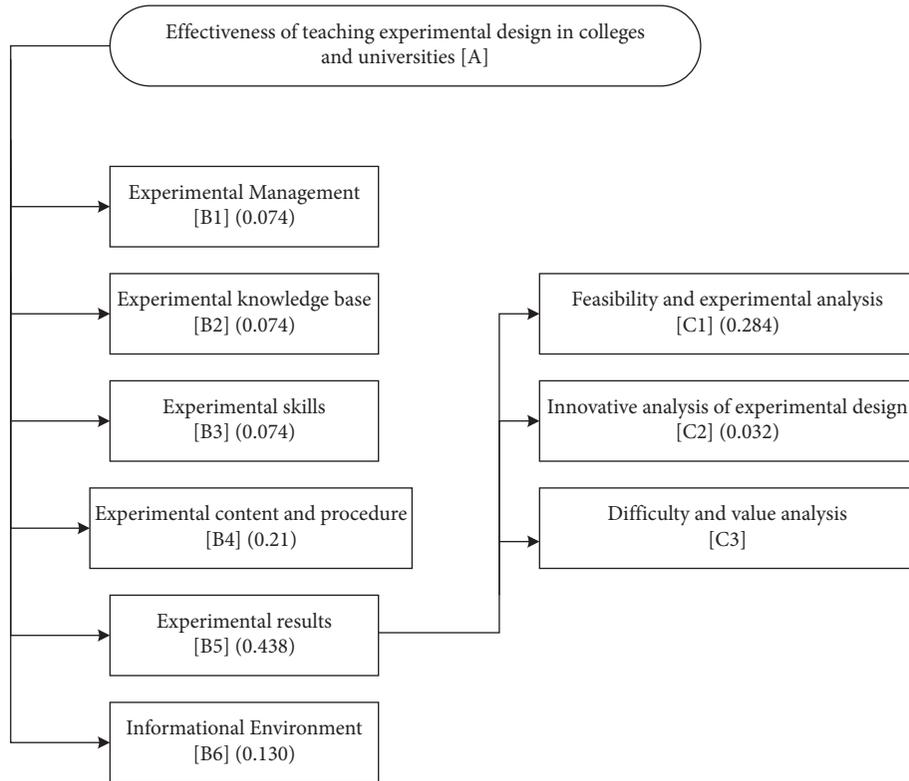

FIGURE 5: Hierarchical structure model and weight parameters of experimental design teaching effectiveness index system in colleges.

15	Q School of Medicine	0.0189	0.0158	0.0153	0.0147	0.0097

However, due to the specificity of the related professions involved, the nature of the terms in the names of the schools is retained. For example, in this paper, the abbreviation of Harbin Institute of Technology, one of the leading industrial institutions in China, is coded as H Technical University. The results of the binary relative evaluation of the effectiveness of experimental design instruction in the 15 target universities in this paper are shown in Tables 2–4.

From the results, we can see that the schools with high binary relative values can be divided into two cases: one case is the schools with high reference index and current index, such as H Technical University. Medicine in 2015, and A University in 2016. The schools with a lower binary relative evaluation can also be divided into two cases: one is a school with a larger decrease in the current index, such as A University of Agriculture in

2017, and the other is a school with a lower reference index and a lower current index, such as M School of Medicine and Q School of Medicine.

5. Conclusion

A teaching process without an evaluation system is unscientific and unlikely to succeed in experimental teaching as well. The study of a more complete, comprehensive, and operational evaluation system is the urgent need for the development of experimental teaching in the information technology environment to improve the quality of experimental teaching testing standards. The scientific evaluation system should be both a certain standard requirements and to meet the actual situation of an evaluation system needs time to establish and improve the need for continuous improvement and development in practice. With the implementation of the evaluation system application evaluation system will continue to be modified and improved.

Higher education laboratory courses due to different professional disciplines experimental content is also different according to the characteristics of the discipline can be applied as above evaluation system.

By using design-based research paradigm to study the effectiveness of informatization teaching, researchers and teachers have a deeper understanding of the factors affecting the effectiveness of informatization teaching. It has some significance to grasp the law of informatization teaching and better use information technology in teaching practice to promote the development of informatization teaching and education informatization. The science of information flow analysis itself is the foundation of teaching analysis research. If information flow analysis is combined with teaching behavior analysis and social network analysis, it must be able to analyze teaching activities in an all-round way.

The strengths of the assessment method described in this paper are: first, it enables students with various characteristics to have the opportunity to be recognized and encouraged because human intelligence is diverse and each student has his or her own superior intelligence; second, it conveys the important idea that learning is complex and that key learning outcomes usually have multiple manifestations and require different skills to be fully demonstrated; and finally, when using performance-based assessment and authentic assessment, it helps to stimulate students' interest and engagement in learning. Improving outcome assessment, strengthening process assessment, exploring value-added assessment, and sound comprehensive assessment necessarily rely on multidimensional assessment methods. It should be clear that the most important concern is the quality, not the quantity, of assessment, and that it is not better to use more assessment methods for a particular concept to be assessed, but rather to choose the assessment methods that match the purpose of the assessment as much as possible. This principle needs to be strictly observed when selecting assessment methods, taking into account the type of learning objectives and their characteristics.

To make the evaluation results highly reliable and comparable, the key issue is to develop a scientific and feasible quantitative index system. When constructing the evaluation index system of information-based teaching, we can draw on the more mature evaluation index systems of other disciplines, then combine the characteristics of computer-assisted teaching to select evaluation indexes, and determine the weight of each index according to its role in teaching, so that the indexes play an objective and comparable role in the process of quantification. At the same time, when selecting the indicators, we should pay attention to the fact that there should not be too many or too few indicators. Too many evaluation indicators are not easy to operate, and too few indicators are not differentiated enough. Therefore, the index system should be improved continuously in teaching practice to avoid the overlapping of index factors and repeated weighting, so that it can be more suitable for the needs of teaching evaluation.

In summary, it can be seen that the reference index is used as the reference standard for the experimental design and teaching effectiveness of colleges and universities. It is more appropriate to use the binary relative evaluation value as an indicator of the effectiveness of the experimental design teaching in various colleges and universities. This can eliminate the injustice to evaluate the effectiveness of experimental design teaching in colleges and universities due to the quality of objective basic conditions. Thus it truly reflects the management effect produced by people's subjective efforts. In addition, the method of binary relative evaluation is used to calculate the effectiveness of experimental design teaching in all colleges and universities.

With the rapid development of the Internet, the new and advanced teaching mode is becoming increasingly popular, which has become a focus in the field of education in recent years. Therefore, the research and development of online teaching platforms have become a hot topic. This article takes international news communication as the research background, aiming at the unclear existing level and weak target. The teaching mode of the single teaching form puts forward the “embedded online intelligent teaching platform.” A set of online innovative teaching platforms for large embedded systems is studied and established. The improved clustering analysis uses the GBKM clustering analysis algorithm to integrate grid clustering and K-means clustering and introduces the new meshing algorithm and the new function to calculate the density threshold. Through theoretical analysis and experimental verification, the superiority of the GBKM algorithm is demonstrated. As the GBKM clustering analysis algorithm is the core algorithm of a personalized smart learning system, it is applied to an online intelligent teaching platform. The experimental results show that the teaching effect of the optimized teaching mode is significantly improved.

1. Introduction

In October 2018, the Ministry of Education of China and the Propaganda Department of the Central Committee of the Communist Party of China issued “Opinions on Improving the Training Ability of Journalism and Communication Talents in Colleges and Universities and Implementing the Education and Training Plan 2.0 for Excellent Journalism and Communication Talents,” strengthening and improving the construction of international journalism and communication in colleges and universities; building first-class global journalism and communication specialty with Chinese characteristics and world level; fully implementing the fundamental task of moral education; educating people with the theory of socialist journalism with Chinese characteristics; and cultivating a large number of high-quality all-media compound

expert news communication reserve talents with national feelings and global vision [1].

Foreign scholars believe that teachers with news work experience must undertake international news communication teaching activities, and experienced teachers must guide students. Educators continue to work hard to cope with the transformation of the media industry, and journalism students in grades 2 and 3 of the University of Missouri have their newspapers in a real community work club [2]. In recent years, foreign news colleges and universities have paid particular attention to data journalism education. From “number one” to “visual first,” news technology has changed continuously, rapidly changing the media pattern, and even the flagship store of the New York Times is trying to keep up with the trend of the times [3].

The traditional theoretical classroom still dominates the shaping of college students’ journalism concept in China.

Domestic scholars have new thoughts on the whole journalism discipline [4]. Some theories of journalism have not adapted to the reality of media diversification, function diversification, and structure diversification. Re-understanding the media and communication will become the key to the teaching and research of news communication [5]. Journalism must make changes in two aspects. Firstly, journalism should not only open up new research fields but also break through the original professional and disciplinary restrictions; learn from and accommodate the research results, research methods, and theoretical systems of other disciplines; and achieve interdisciplinary integration [6]. Secondly, news colleges need to break through the teaching framework of mass communication; adjust the training scheme of news students; and change the curriculum system, teaching mode, and target orientation [7].

Throughout the international journalism and communication professional teaching mode, too old teaching model is not in line with China's national conditions, so they continue to propose new models. This article presents the "personalized intelligence" teaching model—implementing an embedded online intelligent teaching platform. By offering an improved GBKM clustering analysis algorithm, a new meshing algorithm, and a new function to calculate the density threshold, the GBKM clustering analysis algorithm is applied to the online intelligent teaching platform. In this article, a personalized, innovative learning system is designed. The GBKM clustering analysis algorithm is the core performance analysis algorithm. The students' personality characteristics are obtained by clustering analysis of students' performance records. According to the analysis results, the personalized intelligent learning system provides a personalized learning guide for students and achieves a satisfactory 'personalized intelligence' teaching effect. Through theoretical analysis and experimental proof, the superiority of the GBKM algorithm is demonstrated, and the clustering process has achieved good results.

2. GBKM Clustering Analysis Algorithm

K-means is one of the most widely used clustering analysis algorithms and is a classical algorithm to solve the clustering problem [8, 9]. Because of the shortcomings of excessive dependence on the initial clustering center point of k and because of the large amount of computation, it is not efficient in time. At present, there are many improvements to the K-means algorithm. For example, the efficiency of grid clustering algorithms such as the K-means based on genetic algorithm, the K-means with penalty factor, and the PBKP algorithm is very high, and clusters with arbitrary shapes can be found. However, there are also various defects in grid clustering. For example, it depends on the selection of the density threshold. At present, there are many improved grid clustering algorithms, such as bipartite grid clustering, adaptive grid clustering, GCHL, etc [10, 11].

In view of the shortcomings of the above algorithms, this article proposes an improved clustering analysis algorithm based on their advantages. GBKM clustering analysis

algorithm has achieved satisfactory results through data testing and its application to practical systems.

2.1. Basic Concepts of Algorithm. If $A = (D_1, D_2, \dots, D_n)$ is n bounded domains, then $S = D_1 \times D_2 \times \dots \times D_n$ is an n -dimensional space, and D_1, D_2, \dots, D_n is regarded as the dimension of S . The algorithm's input is a set of points in n -dimensional space, defined as $V = \{v_1, v_2, \dots, v_n\}$, where $v_i = \{v_{i1}, v_{i2}, \dots, v_{in}\}$ represents the i -point. $v_{ij} \in D_j$ represents the j -dimensional component of the i -point [12].

Definition 1. Network unit

Assuming that the value on the i dimension is in the interval $[l_i, h_i]$, $i = 1, 2, \dots, n$ each size is divided into p disjoint left-closed and right-open equal-length intervals, so the data space is divided into p^n grid cells. The length of the grid element on the i dimension is $\delta_i = ((h_i - l_i)/p)$, and the j interval on the i dimension can be obtained by the following formula:

$$I_{ij} = [l_i + (j - 1)\delta_i, l_i + j\delta_i], \quad j = 1, 2, \dots, p. \quad (1)$$

Definition 2. Grid unit density

The density $Den(C_i)$ of the cell C_i is defined as the number of data points in the cell.

Definition 3. Density threshold

Set the density threshold $Minpts$, the grid whose density is greater than the density threshold $Minpts$ is "dense unit," and the data in the unit whose density is less than the density threshold is "free data."

Definition 4. Cluster focus

Given the cluster $K_i = (t_{i1}, t_{i2}, \dots, t_{in})$, the mean cluster center is defined as

$$Z_i = \left(\frac{1}{n_i}\right) \sum_{x,y \in K_i} (x, y)^2, \quad (2)$$

where n_i is the number of objects in cluster K_i , and x and y are pairwise different objects in cluster K_i .

Definition 5. Intermediate clustering

The sample space is divided, the unit grid set is defined, the density of the grid unit is calculated, and a grid clusters the dense team. This process, called intermediate clustering, only contains densely distributed points and does not contain all the books. The cluster generated by intermediate clustering is called a medium clustering cluster.

Definition 6. Postclustering

After the intermediate clustering, the center of each medium cluster is calculated as the initial center point, and then the remaining accessible data are K-means clustering. This process is called postclustering, and the clusters are called postclustering clusters.

2.2. The Basic Idea of the Algorithm. Firstly, based on grid clustering analysis, the sample space is divided, and the grid cell set is defined. The object is mapped to the corresponding grid cell, and the density of the grid cell is calculated. The unit with thickness is more incredible than the density threshold r , and the data with a density less than the density threshold r are marked. The adjacent dense units are merged to form an “intermediate cluster,” which does not contain discrete free data. It calculates the center of gravity of the middle group as the initial cluster center [13], calculates the distance between free data and each cluster center, and the accessible data are assigned to the nearest intermediate cluster to form the “postcluster.” The initial clustering center of each postclustering is recalculated. The algorithm terminates if there is no change; if there is a change, the clustering is repeated until the clustering conditions are met [14].

Grid definition itself is a complex problem. Grid size and placement have a significant impact on the clustering results. How to divide the grid is of great significance to the advantages and disadvantages of the algorithm. In the GBKM algorithm, a new function is introduced for meshing: $\delta = ((\sum_{i=1}^n \sqrt{l_i})/n)$ and l_i are the lengths of the i component, $i = 1, 2, \dots, n$.

At the same time, grid-based clustering is very dependent on the selection of density threshold τ . Too large or too small τ will affect the algorithm’s performance. A new algorithm is proposed for determining the density threshold in the GBKM algorithm: $\text{Minpts} = ([\sum_{i=1}^N \text{Den}(C_i)^2]^{(1/2)}/N)$, where $\text{Den}(C_i)$, $i = 1, 2, \dots, N$ is the density value of N dense units with the highest density [15]. The value of N depends on the specific data. In general, $\text{Den}(C_i)$ is arranged in descending order. If $\text{Den}(C_i)$ display density has a significant jump, then $N = I$.

2.3. Steps of the Algorithm. According to a description of the basic idea, the basic steps are as follows:

Step 1: Divide the data space into m disjoint, equal-length grid cells and define the grid cell set;

Step 2: Assign the object to the appropriate unit;

Step 3: Calculate the density of each unit;

Step 4: Mark the grid with a density more remarkable than the density threshold Minpts as “dense unit,” and mark the data in the division with thickness less than the density threshold as “free data.”

Step 5: Repeat any dense unit that is not clustered, merge its adjacent thick units into a cluster until all wide units are clustered to form K “intermediate clusters”;

Step 6: Calculate the center of gravity $Z_i^{(1)}$ of the K intermediate clustering as the initial clustering center;

Step 7: Repeat any accessible data object, calculate the distance between $\text{dis}(x, C_i)$ and k initial clustering centers, where x is the accessible data object, C_i is the first class, if $\text{dis}(x, C_i)$ is the smallest, then $x \in C_i$; until no longer exists free data, forming “postclustering”;

Step 8: Recalculate the center of gravity of the clustering $Z_i^{(1)}$, if $|Z_i^{(1)} - Z_i^{(0)}| \leq \varepsilon$, the clustering ends. Otherwise, continue K-means clustering until $|Z_i^{(i+1)} - Z_i^{(i)}| \leq \varepsilon$ completes clustering.

2.4. Implementation of the Algorithm. The GBKM algorithm is written in Java language, and the editing environment is Eclipse. Eclipse is an open-source extensible application platform which provides a first-class Java integrated development environment for programmers [16]. The implementation of the algorithm is mainly divided into six parts. The first part defines various variables, methods, and classes, among which the most important is to define a public class cluster class, which describes the cluster generated by the clustering process, including the variable of cluster members, the variable of cluster centroid, and the method of updating the cluster centroid. The second part is the definition of the GetData (int cid, int analysis) method, the function of this method is to read data from the database and store it in the array folder after initialization; the third part is the definition of Grid () method. The function of this method is to divide the data space into grids and map the data objects to the Grid one by one. The fourth part is the method of clustering process preCluster (). The fifth part is the method of storing and displaying the clustering results. The sixth part is the main program entry (), which mainly generates the object of the above class and then calls the method of the thing to realize the whole clustering process.

3. International News Communication Intelligent Teaching Optimization

The development of an embedded network intelligent teaching system platform plays a good role in solving embedded professional theory teaching and market demand-oriented application teaching mode optimization. It can quickly improve embedded talents’ training effect and efficiency and solve the bottleneck of market demand for skills. At the same time, it is of great significance to the research and development of international news communication teaching platforms.

3.1. Development Tools and Models

3.1.1. Development Tools. The system used JSP (Java Server Pages) technology framework to generate dynamic, interactive web server applications. JSP technology is the traditional web HTML file (*.htm, *.html) into the Java program segment (scriptlet) and JSP tags, resulting in a JSP file (*.jsp). JSP uses tags and scriptlets to encapsulate the processing logic that generates dynamic web pages, accesses the application logic of resources existing in the server, and separates the web logic from the web design and display. It supports the reusable component-based design and makes developing web-based applications rapid and easy [17].

The web server of this system uses Tomcat 5.0 as a Servlet container, which passes page requests to Servlets and returns the results to users. When a user requests access to a

Servlet, it encapsulates the user's request information in the ServletRequest object, then passes the Request object and Response object to the Servlet requested by the user, and the Servlet writes the results of the response to the ServletResponse object. Then Tomcat transmits the response results to the user.

SQL Use server 2000 is d in the background database, and JavaBean is used to connect the database and query and update the data. Using advanced B/S (Browser/Server) architecture, page design uses the current international popular web production tool Dreamweaver 2004 and EditPlus for editing; the script language is JavaScript; page image processing uses PhotoshopCS and Flash 5.0.

3.1.2. Development Model. This system is composed of people and computers for information collection, storage, knowledge transfer, and use. With the development of science and technology, the expansion of information, and the explosion of knowledge, how to effectively collect information and transfer knowledge has become the development purpose of this system. Therefore, it is imperative to develop a plan that considers the development and operation efficiency and meets the asynchronous real-time processing function. The development of this system uses the MVC model. MVC pattern is the abbreviation of "Model-View-Controller," translated into Chinese as "Pattern-View-Controller." That is, an application's input, processing, and output processes are divided into three layers according to model, view, and controller, namely a model layer, a view layer, and a control layer.

View represents the user interaction interface. For web applications, it can be summarized as an HTML interface. An application may have many different views. The processing of the MVC design pattern for a view is limited to collecting and processing data on the view and the user's request, but not the processing of business processes on the view. Handling of business processes is handed over to model processing. Model is the processing of business processes/states and formulating of business rules. The model accepts the data requested by the view and returns the final processing results. Model design is the core of MVC. When receiving requests from the user, the model is matched with the view and the user's request together without any data processing is completed. The separation of model, view, and controller enables a model to have multiple display views. If the user changes the model's data through a view controller, all views that depend on these data will change. When data changes, the controller notifies all views of the change. Models, ideas, and controllers are updated synchronously according to their relationships and primary functions [9].

The view is in the web tier or client tier in this system. That is, JSP is the page display part. A controller is also in the web tier, implemented by Servlet, the logic part of page display. The model is in the middle tier, implemented with JavaBean on the server side, and implementing logical relationships, as shown in Figure 1.

3.2. Design and Implementation of a Resource Center. As a learning website, providing students with as many learning materials and software download as possible is the proper service function of the website. The resource center module of this website includes nine submodules, as shown in Figure 2: search module, e-book module, curriculum resource module, software download module, learning material module, free resource area module, the latest resource area module, the hottest resource area module, and other resource areas.

Based on the above module system diagram:

Search module: the user inputs keywords, and the system will display the matching records in the database according to fuzzy matching.

Electronic book module: provides users free downloads of electronic books, such as PDF, superstar, and other formats, covering all aspects of embedded learning.

Curriculum resource module: it lets users download free courses or other courses produced by this website. With the curriculum resource center, students can easily find free learning courseware.

Software download module: Module more professional in the embedded aspect can obtain the professional information common download site that does not provide..

Updated resource area: the resources provided by this area are the latest with the help of this website.

Learning material module: the module mainly provides students with more whole, suitable learning materials, such as related technology frontier articles, excellent students' learning notes, etc.

Free resource area: this area provides free downloads to students.

The hottest resource zone: the zone aims to make the most popular resources present in a unique position on the website so that students can understand the current trend of resources.

Other resource areas: it lets users download a window of resources other than free, up-to-date, and hottest resources to display the site's resources more fully on the page.

According to the above description, the logical function of the resource center is clear. First, users select the module after entering the resource center, view the resource information, and then download it online, which can also view the resource's relevant resources and the website's outstanding recommendations.

4. Case Study

One of the main applications of improved clustering analysis algorithms is the personalized intelligent learning system of embedded online innovative teaching platforms. GBKM clustering algorithm is used to cluster the students' scores. According to the clustering analysis results, different learning plans and suggestions are given for international students. At the same time, the results of the analysis are transmitted to the intelligent test paper generation system. The system changes the structure of the following examination paper of the students, truly achieves "individualized teaching", improves the intelligence of the website, and truly

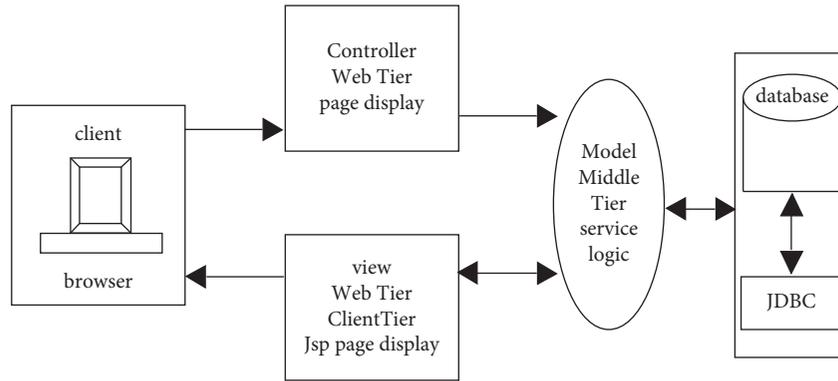

FIGURE 1: The design of the model.

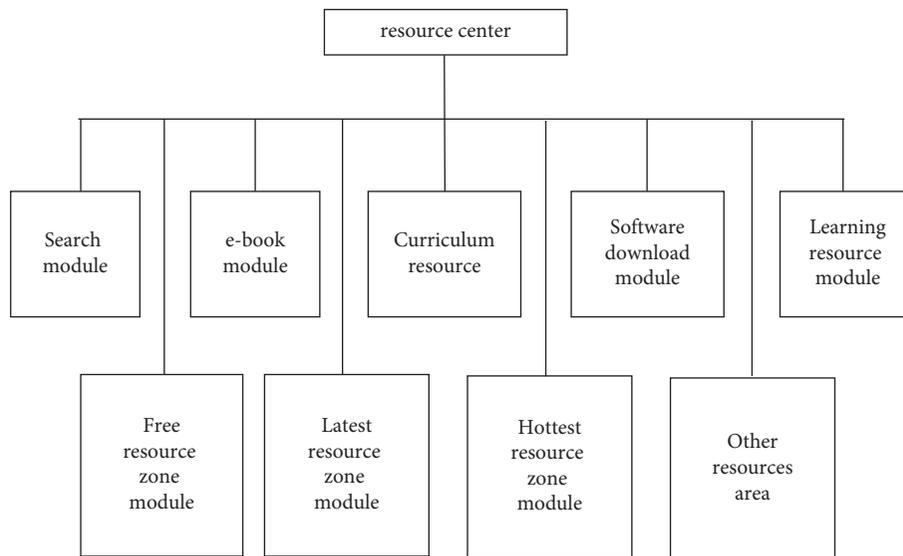

FIGURE 2: The module system of resource center plans.

realizes the “personalized” and “intelligence” of online teaching.

The page display of performance analysis is designed in JSP and CSS style. GBKM algorithm uses Java to compile JavaBean file from Eclipse environment and calls this bean file by JSP page.

In the specific application of the performance analysis system, the GBKM clustering algorithm not only completes the primary function of clustering the relevant data but also completes the analysis of the characteristics of the cluster formed after clustering and how to display it on the page. At the same time, it stores the analysis results in the corresponding database table. The related database table records are updated, such as updating the proportion of each chapter in the testStru table CHAPTERSCORE. For subsequent use, after completing the clustering and analyzing the characteristics of the cluster, the analysis of students’ personality characteristics and the display of various learning suggestions are realized on the JSP page.

Calling a bean file in Jsp is done by introducing the package util where the bean file resides. The specific presented method:

When calling, a GetData object is created in the analysis package and the object is instantiated. Then call various methods in GetData class are called to implement multiple mechanisms. The code segment is as follows:

```

analyse.GetData    gbkm = new    analyse.GetData
(cido,ido);
gbkm.GetData();
gbkm.Grid();      System.out.println    (“main”);
gbkm.preCluster(); gbkm.getPreCluster();
out.print (gbkm.ShowOut());
    
```

The realization of viewing the previous performance analysis results mainly depends on the analysis of the performance analysis result record table. The USERID, COURSE ID, and TEST TIME fields in the table store the student’s latest test time for a specific course. These three fields are consistent with the three fields of USERID, COURSE ID, and TEST TIME in the test history information table. The three fields uniquely identify the analysis results of the previous test and obtain the values of these three fields in the JSP page of analysis. The last examination

TABLE 1: Structure of examination paper table.

Field name	Field ID section	Property	Length	Pkey	Null
Serial number	ID	Int	4	O	O
Course number	SUBJECTID	Int	4		
Category name	STRUTEXT	Varchar	100		
Total number of sections	CHAPTERNUMBER	Char	3		
Chapter scores	CHAPTERSCORE	Varchar	50		

results can be viewed for study and reference by calling the corresponding records in test history.

4.1. Database Table Design. This section mainly introduces the database table design involved in the personalized intelligent learning system, including the test paper structure table, the score analysis result record table, and the test history information table.

Table 1 is the test paper structure table, identified as testStru, and the data source is the change and addition of the background paper structure. This table mainly controls the composition structure of the test paper. CHAPTERSCORE is the proportion of each chapter in the intelligent test paper generation. According to the value of this field, the savvy test paper generation can adjust the structure of the test paper obtained by each savvy test paper generation, namely the proportion of each chapter.

Table 2 is a record of the performance analysis results, which is identified as analysis. The data source is updated after the performance analysis. It records the course number and examination time of the students' last performance analysis, mainly for calling the corresponding information when the students want to view the results of the previous research.

Table 3 is the test history information table identified as test history. The data source is generated automatically by the system after online testing. CHAPTERPER is the proportion of the following test section: CLUSTERED is the student's class number, CLUSTERMEMBER is the class member the student belongs to, and CLUSTERCENTER is the clustering center of the type that the student belongs. SCORE records the examination results, and PNSCORE records each chapter's scores. The table records the information after each examination, including the information obtained from the scoring and the analysis of the result.

4.2. Evaluation of Personalized Intelligent Learning System. In the specific application of the GBKM clustering algorithm in the personalized intelligent school system, as the core algorithm of performance analysis, the corresponding records in the database are successfully read, and the GBKM clustering completes analysis effectively. The characteristics of clusters formed after clustering are analyzed, and the results are displayed on the browser page. At the same time, stored the analysis results in the corresponding database table test history and updated the records of the corresponding database table, such as updating the CHAPTERSCORE of each chapter in the testStru table for subsequent use.

TABLE 2: The pre-analyze table.

Fieldname	Field ID section	Property	Length	Pkey	Null
Serial number	ID	Int	4	O	O
Student no.	USERID	Varchar	4		O
Course number	COURSEID	Varchar	100		O
Test time	TESTTIM	Datetime	3		O

Multiple GBKM clustering analyses were conducted on 78 test records in the database, and the clustering results were roughly the same, as shown in Table 4.

By comparing the characteristics of each class, the course members are very similar to those of the class. In contrast, the differences between the course and the style are significant, and each type's clustering center can represent each class's characteristics. Due to the fast and effective clustering and analysis of the GBKM clustering algorithm, the system can understand the factors of each student's grace and give personalized learning suggestions and guidance according to this feature, increase the system's intelligence, and improve students' learning efficiency and effect. Taking "Introduction to Journalism" as an example, this article compares a series of data. The change of data can better and more intuitively see the transformation of test paper parameters, concluding that the evolution of test paper parameters impacts students' learning.

Firstly, the proportion of original questions in this course is given and then this information is stored in the database table testStru (Table 5).

When students do not perform performance analysis, the structure of the test paper, i.e., the number of points in each chapter, is carried out in following Table 6. The system will set the number of questions according to the specified percentage and will not increase or decrease the number of questions considering students' factors.

Observe the scores of each chapter derived from the database test history table, as shown in Table 6. In this table, the scores of each chapter are expressed in the form of "1 @ 9.5 # 2 @ 9.0 # 3 @ 16.5 # 4 @ 11.0 # 5 @ 11.5 # 6 @ 9.0 # 7 @ 7.0 # 8 @ 9.0 #," where @ is the number of chapters and the equal score of this chapter, for example, 1 @ 9.5 is the score of the first chapter 9.5; # is separated from chapters, such as 1 @ 9.5 # 2 @ 9.0, # is the first chapter, # is the second chapter. In Table 6, the test scores of different students and each student at different times are not the same. That is, different and the same students have different degrees of mastery of knowledge at different times. Suppose all the questions are with the proportion of questions in Table 5. In that case, the examination will lead to different levels of students with different

foundations to test the same topic. The same student always repeats the examination of familiar knowledge points, and unfamiliar knowledge points may not be tested. Therefore, how to change the proportion of questions for different students at different test times to achieve targeted testing has become the focus of the personalized intelligence of this system. Therefore, after the performance analysis, the intelligent learning system will change the proportion of each chapter of the students according to the analysis results. For example, Table 7 shows the proportion of each class chapter after cluster analysis. As Table 6, 1 @ 11% # 2 @ 8% means that the proportion of the first chapter is 11% and the second chapter is 8%.

Table 8 shows the classes of different students and the proportion of each chapter. From this table, we can see the

differences among students and their different balance of questions. The system can carry out individualized intelligent education for international students.

Table 9 shows that students have achieved different results at different test times, belonging to different categories and proportions of questions. Over time, the students’ knowledge of each chapter also changes. The ratio of students’ questions in each chapter also changes, which realizes the function of individual questions.

From the above analysis, the GBKM algorithm is applied to the personalized intelligent learning system and the implementation of personalized philosophical teaching for different students in different periods. It dramatically enhances the intelligence of embedded online innovative teaching platforms.

5. Conclusion

Because the teaching mode of international news communication is too single, the teaching mode and implementation method are improved. The application of cluster analysis algorithms in teaching is studied in depth. GBKM clustering analysis algorithm is proposed to improve the traditional clustering analysis algorithm. Standard tests verify the convergence and effectiveness of the GBKM clustering analysis algorithm, which is successfully applied to the personalized intelligent learning system of an embedded online smart teaching platform. The main innovative work of this article is as follows:

- (1) By studying the implementation of the online teaching platform and related technologies, the concept of "personalized intelligent teaching is proposed," the embedded online intelligent teaching platform is realized using various popular technologies, and the overall style and architecture of the online teaching platform are designed as d .
- (2) The clustering analysis algorithm is studied, and an improved clustering analysis algorithm—GBKM clustering analysis algorithm—is proposed, which overcomes the shortcomings of the traditional clustering analysis algorithm and demonstrates the effectiveness and superiority of the algorithm are d through theoretical proof and experimental verification.
- (3) The improved clustering analysis algorithm is applied to the embedded online intelligent teaching platform to realize the personalized, innovative

learning system of the embedded online smart teaching platform. It reflects the individualized and brilliant teaching concept and dramatically enhances the intelligence of the embedded online intelligent teaching platform. The application of the system also proves the effectiveness and practicability of the GBKM algorithm. It optimized the teaching mode of international news communication.

The traditional ideological and moral education evaluation mechanism in colleges and universities faces many challenges. Among them, the traditional ideological and political theory course evaluation mechanism is difficult to solve the contradiction between the teaching content of the ideological and political theory course and the ideological knowledge of the educated, and the test scores of the ideological and political theory course are difficult to measure the level of students' ideological awareness that has become a prominent problem. The evaluation mechanism of ideological and political education in colleges and universities based on deep learning technology can play a role in the formative evaluation and consequential evaluation of courses, thus forming a new mechanism for evaluating ideological and political education in colleges and universities, and further improving the effectiveness of ideological and political education.

1. Introduction

In 2017, the Ministry of Education issued the “Ideological and Political Work Quality Improvement Project Implementation Outline in Colleges and Universities” [1]. The “Outline” proposed: “Improve the quality evaluation mechanism of ideological and political education in colleges and universities, and study and formulate the evaluation index system of ideological and political work in colleges and universities.” This marks the national optimization and innovation of the quality evaluation mechanism of ideological and political education work in colleges and universities has been brought to a new height. There are three main areas of quality assessment of ideological and political education work in colleges and universities: supply side assessment, demand-side assessment, and management assessment [2]. In general, “supply-side” and “demand-side” are economic concepts. In the quality evaluation system of ideological and political education work, supply side evaluation and demand-side evaluation refer to the evaluation of the educational content of educators and the evaluation of

educated people, respectively. Assessment of learning outcomes. Under the new historical conditions, both educators and educated people have undergone profound changes, and the incompatibility of the traditional ideological and political education work quality evaluation system has become increasingly obvious [3]. Only by establishing new ideas and borrowing new technologies can we realize the optimization and innovation of the quality evaluation system of ideological and political education. In view of this, this paper is mainly based on deep learning technology, one of the core technologies of artificial intelligence, to provide optimization ideas for the evaluation system of ideological and political theory courses in colleges and universities.

The effectiveness of ideological and political theory courses has always been an important concern of ideological educators in colleges and universities because the effectiveness of courses is related to the quality of ideological and political theory courses [4]. In order to maximize the effectiveness of ideological and political theory courses, it is necessary to deal with the contradictions in the teaching of ideological and political theory courses. First of all, the

content to be taught by educators in ideological and political theory courses and the ideological conditions of the educated are a pair of contradictions in the teaching work of ideological and political theory courses [5]. The content taught by ideological and political theory educators is the principles of Marxism and the theoretical achievements of the Sinicization of Marxism, which are scientific theories proved by practice; and the educated are college students, who grew up in a society with diverse values, and they themselves bring There is a diverse knowledge background, and their ideas and concepts are not yet stable, and it is easy to change [6, 7]. To adjust such a pair of contradictions, the designers of ideological and political theory courses must not only ensure the scientific and advanced nature of the content taught by educators but also maintain continuous evaluation of the learning effects of educated people's ideological and political theory courses to ensure Within a certain period of time, the content of the curriculum education will keep pace with the ideological level of the educated. Such "synchronization" requires advanced evaluation mechanisms to assist.

Second, the examination results of the educated ideological and political theory course and the actual behavior of the educated in real life are another pair of contradictions in the teaching work of the ideological and political theory course in colleges and universities. Nowadays, the assessment of ideological and political theory courses is mainly based on the final written examination. Educated students can still obtain high scores by memorizing knowledge points in such an assessment, but such high scores are not the main purpose of ideological and political theory courses. The main educational purpose of the ideological and political theory course is to enable the educated to make correct value judgments in real social practice through the teaching of Marxist theory. However, the fact that an educated person has achieved excellent results in the examination of the ideological and political theory course does not mean that he will also practice the advanced ideas advocated by the ideological and political theory course in social life. Students who achieve excellent grades in the assessment will not necessarily demonstrate the corresponding political and moral qualities in their actual behaviors, nor will they necessarily be able to convert the same excellent grades into positive and positive behaviors in long-term social activities [8, 9]. The key to improving the effectiveness of ideological and political theory courses is to ensure that the educated have achieved a certain ideological change and bring this ideological change into their daily life [10]. This requires educators to grasp the ideological transformation of the educated in the course of teaching ideological and political theory courses and to use the evaluation mechanism to complete the measurement of the level of ideological development. However, "the construction of the evaluation system of ideological and political education in colleges and universities is not perfect, and the evaluation methods and methods are relatively lagging behind." The current traditional evaluation system of ideological and political education in colleges and universities cannot effectively solve the above contradictions [11].

Deep learning is a new technology in the field of artificial intelligence. This concept was proposed by British artificial intelligence expert Professor Hinton and others. It mainly refers to "using the multi-layer abstraction mechanism of the human brain to stimulate the learning process of the human brain through a neural network, so as to realize the abstract expression of a large amount of data in the real world." What's more, "practice has proved that deep learning can capture the underlying essential features or rules within data such as natural images, videos, speech, and music with potentially complex structural rules" [12]. From this point of view, deep learning technology has a technical support function for ideological and political education theory courses. In practice, we can explore the innovation of ideological and political education evaluation according to the evaluation needs of ideological and political courses and the corresponding model of deep learning technology. This paper mainly selects the formative evaluation and the consequential evaluation of the ideological and political theory course as two evaluation methods for model construction.

2. Related Works

Intelligence refers to the ability of people to understand the objective world and use knowledge to solve practical problems. It is concentrated on the depth, accuracy, and completeness of reflecting objective things, as well as the speed and quality of applying knowledge to solve problems. Judgment, association, and creation are manifested. Turing, the "father of artificial intelligence," once conducted an experiment called the Turing test to test whether a computer could not be detected when it communicated with people. Artificial intelligence expert Wisniewski believes that the intelligence of artificial intelligence is reflected in "machines have the ability to learn and understand things, deal with problems and make decisions." Artificial intelligence is a computer program that imitates human intelligence. It relies on massive data and precise algorithms to achieve intelligent applications. For example, Microsoft's machine Xiaoice, Google's AlphaGo, can express its intelligence through image perception, semantic understanding, knowledge expression, and reasoning calculus.

Deep learning provides artificial intelligence with a smarter algorithm, and machines can learn by themselves by optimizing rules and models through data. The earliest research on artificial intelligence can be traced back to 1956, during which it experienced several slumps. An important reason is the lack of data and computing power. Deep learning was proposed by Hinton et al. in 2006, and more advanced algorithms that support artificial intelligence have subsequently emerged. Unlike humans, the second generation of artificial intelligence relies on logical analysis of the causal relationship between things to make decisions and judgments, and discover the correlation between things through deep learning supported by big data. The method it takes is not to analyze the sample survey data, but to analyze the whole data, so as to find the correlation between two or more groups of data [6]. For intelligent robots, the most

important thing is big data and intelligent algorithms. The more and more complete the data, the more accurate and less error-prone decision-making and judgment will be. The cognitive development of machines has made significant progress. For example, machines can look at millions of pictures a day and complete deep learning, while humans have strong intuition and reasoning abilities, and only need to browse and learn a few pictures to grasp the rules [10]. The combination of the machine's deep learning and human reasoning ability is the symbiosis and integration of two types of intelligence, which is the future communion intelligence. The advantages of robots are reflected in speed, accuracy, load-bearing capacity, repetition consistency and operation time, etc., while human capabilities are reflected in thinking and logical reasoning, learning and skill progression, experience and real-time decision-making, interactive collaboration, safety, etc. The combination of the advantages of both humans and robots will exceed the capabilities of a pure human or robot [11]. For example, the expert system in distance education can use its own knowledge reserves to answer students' questions, record, evaluate, and diagnose students' daily learning situations, find problems and errors in students' learning process, and realize individualized teaching. The spiral rise of the SOLO level reflects the development process of individual learning resulting from quantitative change to qualitative change and understanding level from shallow to deep. Pursuit coincides with deep learning. Therefore, from the perspective of the quality level and understanding level of learning, the SOLO taxonomy is related to shallow learning and deep learning. Figure 1 shows an illustration of machine learning and deep learning.

In the field of artificial intelligence, swarm intelligence originally originated from the research on the behavior of many social insect biological groups. Simple individuals, through mutual cooperation and cooperation, emerge such a feature of higher intelligent behavior, which is called swarm intelligence [12]. What is the intrinsic connection between swarm intelligence and artificial intelligence? Classical artificial intelligence represented by symbolic logic and expert systems is rule-driven deterministic intelligence, while artificial intelligence represented by neural networks and deep learning is data-driven uncertainty intelligence [4]. Swarm intelligence is an artificial intelligence composed of two interactive bits of intelligence. The intelligence of our social groups is also driven by interaction to form a joint force to achieve innovation and development. Swarm intelligence can gather human knowledge and wisdom in a wider range than any previous technology, and promote the development of human history.

Deep learning technology obscures the effectiveness of school moral education. On the one hand, technology has brought new measurement standards, which makes it more difficult to measure the effectiveness of moral education content. For example, the emergence of smartphones has changed the relationship between people and changed the individual's perception of the world and self-awareness. McLuhan believes that "the impact of any medium (any extension of man) on individuals and society is due to new

scales; any extension (or any new technology) of our to introduce a new scale into things" [13]. The new scale brought by artificial intelligence technology has become a new standard for measuring the effectiveness of moral education. Therefore, under the background of new technologies, student morality has new development characteristics and laws. However, if schools only emphasize the traditional moral education goals, they ignore the students in the actual technical environment, students will not be able to perceive the real situation of students moral growth, and will not be able to understand the real effectiveness of moral education, thus falling into a passive situation. On the other hand, the complexity of moral education content increases the difficulty of measuring the effectiveness of moral education. On the platform provided by artificial intelligence, students can obtain moral education resources that they care about, and discuss and exchange values with others. Artificial intelligence technology supplements the lack of time and space to teach moral education content in schools and makes up for the actual needs of students. However, in the context of artificial intelligence technology, whether the huge content of moral education is too broad, whether it is in line with the characteristics of children, and how effective is it? It is not easy to observe concretely.

3. Evaluation and Analysis of Moral Education Achievements under Deep Learning

This study defines the meaning of classroom teaching effectiveness as follows: The judgment of classroom teaching effectiveness is not only based on the actual development of students but more importantly, whether students' development level meets the requirements of the curriculum objectives, that is, the achievement of curriculum objectives. Figure 2 shows the relationship between efficiency and benefit in teaching effectiveness.

This research mainly adopts the connotation definition of deep learning defined by scholar Zhang Hao, deep learning is "learners master unstructured deep knowledge and carry out critical higher-order thinking, active knowledge construction, effective transfer application and real problem solving, and then realize the development of higher-order abilities such as problem-solving ability, critical thinking, creative thinking, and meta-cognitive ability." The definition of this meaning can be understood from the following two aspects: First, deep learning is an integral part of students' learning process and a specific way of learning. Deep learning requires students not only to memorize and understand relevant knowledge but also to think critically about the knowledge they have learned and to actively construct and transform it, so as to finally transfer knowledge to real life and solve complex problems question. Second, focus on the development of higher-order abilities and thinking. Through deep learning, the development of higher-order abilities such as problem-solving ability, critical thinking, creative thinking, and meta-cognitive ability can be realized. These abilities can correspond to the four "application, analysis, synthesis, and evaluation" in Bloom's educational goal taxonomy higher cognitive levels. It can be

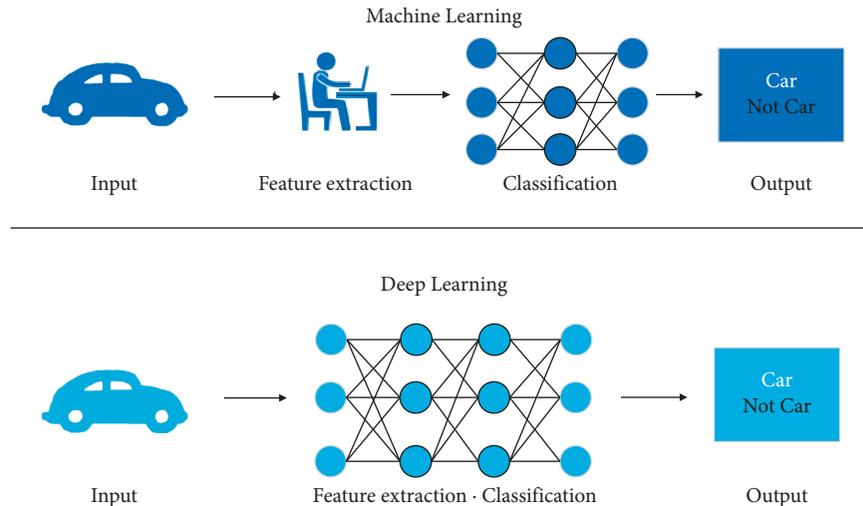

FIGURE 1: Illustration of machine learning and deep learning.

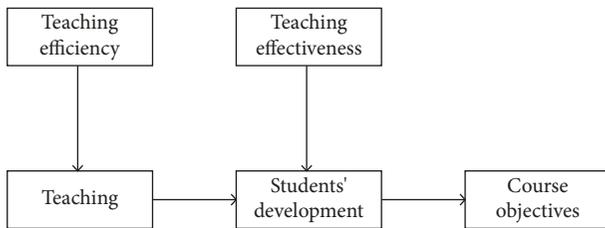

FIGURE 2: The relationship between efficiency and benefit in teaching effectiveness.

seen that deep learning is oriented toward the acquisition of advanced cognitive skills and involves higher-order thinking activities.

3.1. Deep Learning Features. According to the learners' understanding and mastery of knowledge, we can divide learning methods into deep learning and shallow learning. However, deep learning and shallow learning are not separated but interpenetrated. From the perspective of students' learning process, deep learning starts from simple learning with low emotional and behavioral input and gradually turns to advanced learning with high emotional and behavioral input. Therefore, when many scholars in the domestic academic circle express the characteristics of deep learning, they often compare them with shallow learning in the statement and then draw the characteristics of deep learning. For example, Professor Li Jiahou compared the characteristics of deep learning and shallow learning and concluded that the characteristics of deep learning are manifested in three aspects: "understanding and criticism, connection and construction, migration and application." The author uses Li Jiahou's comparative framework for deep learning characteristics. Based on the deep learning characteristics supplemented by other researchers, we select the memory methods, cognitive results, learning motivation, learning behavior, learning effectiveness, reflective state, thinking

ability, and cognition of learners in deep learning and shallow learning. Differences in skills, etc., are compared in more detail.

Through the comparison in Table 1, deep learning emphasizes comprehension memory in terms of memory methods and focuses on the construction and transformation of knowledge in terms of cognitive results. In terms of learning behavior, it is a mixed behavior with high emotion and high behavioral investment. Conduct critical thinking and self-reflection in behavior, focus on transferring the knowledge to memorization life in cognitive skills, show learning as a strong endogenous motivation in learning motivation, and emphasize high effect in learning effect, high efficiency, and high level, focusing on the advanced thinking level in the thinking level, and highlighting the student learning as the center in teaching.

3.2. The Understanding and Transformation of Knowledge Must Go through Deep Learning. In the course of ideological and political theory courses in colleges and universities, college students should first memorize the concepts and knowledge of the basic viewpoints of socialism with Chinese characteristics [13–15]; the second is the consolidation and transformation of knowledge. When college students complete the memorization of this viewpoint of socialism with Chinese characteristics, they will assimilate or adapt this knowledge to clearly repeat the knowledge they have learned; again, it is the transfer and application of knowledge. When asked about the content of basic viewpoint of socialism with Chinese characteristics, college students can quickly retrieve the relevant knowledge to answer. To sum up, through the above three stages, the students' knowledge learning process of the basic viewpoints of socialism with Chinese characteristics is explained. This learning process focuses on understanding and transformation to help students better learn relevant knowledge [16]. Understanding and transformation are high-level cognitive processing and one of the main features of deep learning. Therefore, it can be

TABLE 1: Comparison of deep learning and shallow learning features.

	Deep learning	Shallow learning
Memory	Memorizing on the basis of understanding	Rote memorization
Cognitive results	Build exercises between knowledge and make conceptual changes	Learning scattered or isolated
Learning behavior	Complex activities with high emotional and behavioral input	Simple activities with low emotional and behavioral input
Reflect on state	Critical thinking, self-reflection	Lack of critical thinking and self-reflection
Cognitive skills	Transfer what you learn to your life	Unable to use knowledge flexibly
Thinking level	Higher level of thinking	Lower levels of thinking
Learning motivation	Internal understanding drives learning	Learning driven by external pressure
Learning effect	High effect, high efficiency and high-level	Low effect, low efficiency, low level
Teaching methods	Focus on student learning	Take the teacher's teaching as the center

said that the understanding and transformation of relevant knowledge must go through deep learning. Figure 3 shows generalized knowledge learning stage and classification model.

3.3. The Acquisition of Abilities and Skills Must Go through Deep Learning. In the cognitive stage, first of all, by observing the actions of others using Marxist theory to analyze and solve practical problems, to stimulate situational awareness to form an internal action image as a reference for actual analysis and problem-solving; second, when forming After the image, students combine their own abilities and experience to form operational level expectations, that is, they have self-awareness of whether they can skillfully use Marxist viewpoints to analyze and solve problems. In the connection stage, when students face complex problems, they will know how to use the worldview of Marxist theory to analyze the problem, and at the same time, they will use the Marxist methodology to solve the problem. In turn, the connections that students form in problem-solving become a new round of stimulation.

To sum up, the above three stages explain the acquisition process of students' ability to analyze and solve problems by using the Marxist world outlook and methodology, which is essentially the process of internalizing knowledge into ability. This process focuses on the transfer and application of knowledge, emphasizing the application of the learned knowledge to real life. And this process is one of the main characteristics of deep learning, so it can be said that the acquisition of students' abilities and skills must be carried out by deep learning.

3.4. The Formation of "Three Views" Must Go through Deep Learning

First, know "choices"—make the right choices when faced with situations that conflict with existing values. Various values and cultural ideologies in modern society collide, exclude, and merge with each other, which leads to college students often entering a choice situation premised on moral conflict, and the choice situation is opposite and incompatible. How to make the right choice is a difficult challenge for college students.

Therefore, it is required to teach students to make choices, and to do so when making choices: first, know how to make free choices according to their own values; second, when faced with multiple choices, know how to weigh the pros and cons of these choices; Choose consequences for analysis and thinking in order to make correct and sensible choices [17].

Second, learn to "value"—value your choices and feel content. Many college students have different performances from their predecessors, on and off-campus. From a psychological point of view, this is essential because college students are unwilling to be responsible for behaviors that are not of their own will and without emotional intervention. According to Ruths, he believes that "value comes from the choices we are willing to make," in other words, only on the basis of careful thinking and cherish the results of their choices, college students will be responsible for their choices with words and deeds. Therefore, at this stage, students are required to: first, learn to be satisfied with the choice they have made, and affirm their choice with sufficient reasons; second, be willing to publicly admit this choice.

Finally, put into action, act on that choice, and repeat it as a way of life. College students make rational choices and cherish them when faced with choices, but these cannot make college students form correct values. Laths believes that in order for students to establish a true value system, "the cherished choice must be put into action, so that the action reflects the chosen value orientation." Based on this, at this stage, students are required to: first, put the cherished choices into actions, so that the actions reflect the correct value orientation; a way of life [18]. To sum up, Laths believes that through choice, cherishing, and action, students' value issues have been evaluated and clarified, resulting in correct values. Although the value clarification theory is a Western value education theory, because values are universal in human society, the education methods of values also have certain commonalities, which are the "three views" for middle school students in the ideological and political theory courses in our country's colleges and universities. The formation provides realistic operability.

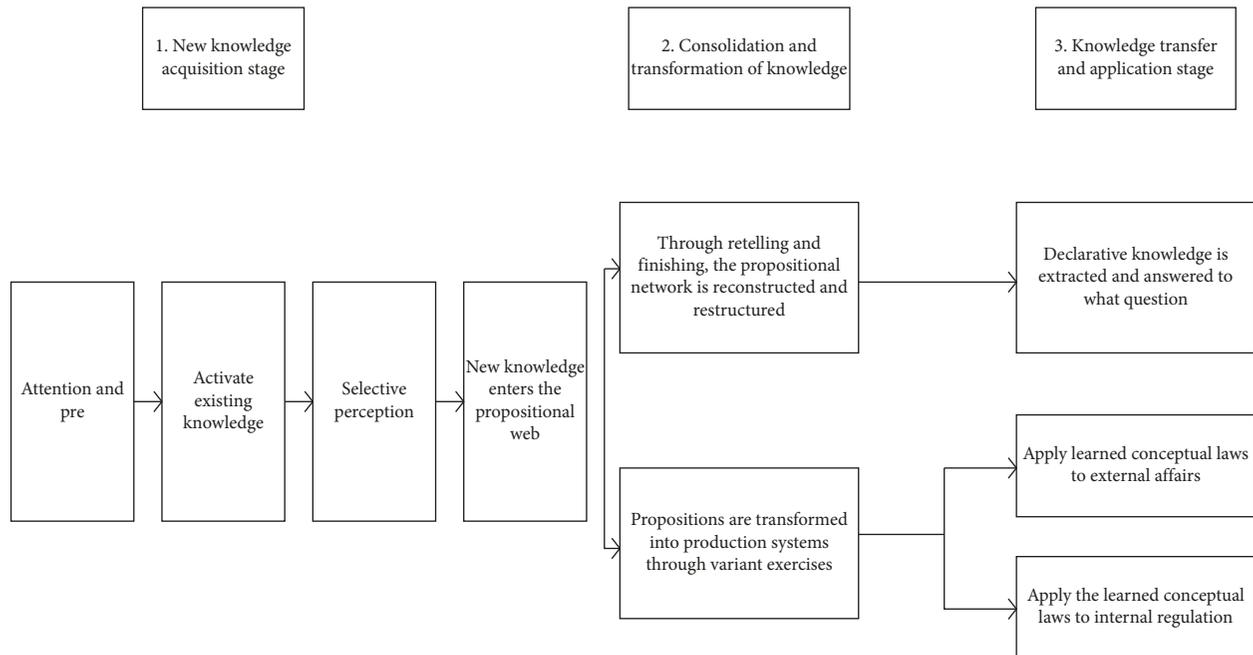

FIGURE 3: Generalized knowledge learning stage and classification model.

4. Survey Design and Implementation

4.1. Investigation Plan Design. Investigating the status quo of the effectiveness of classroom teaching of ideological and political theory courses in colleges and universities is convenient for analyzing the difference between the actual state and the state of classroom teaching of ideological and political theory courses in colleges and universities from the perspective of deep learning, which is the real basis for follow-up countermeasures [19]. In other words, we need to understand the subject and object of the ideological and political theory of classroom teaching behavior in colleges and universities, that is, the teaching and learning behavior of teachers and students, and analyze whether their behavior can contribute to the effectiveness of ideological and political theory classroom teaching. From the perspective of deep learning, we believe that the mark of teachers and students achieving the effectiveness of classroom teaching in ideological and political theory courses is that students have the characteristics of deep learning in the learning behavior of ideological and political theory courses and that teachers can inspire students' deep learning behaviors [20].

Therefore, this study conducted a sample questionnaire survey on teachers and college students of ideological and political theory courses in colleges and universities. To investigate the current situation of classroom teaching in ideological and political theory courses in colleges and universities for teachers of ideological and political theory courses, we mainly understand the occurrence of teaching behaviors that stimulate students' deep learning in the teaching process. The teachers of ideological and political theory courses in colleges and universities are mainly composed of full-time teachers and ideological and political

counselors, so the questionnaire survey objects for teachers are also taken from these two groups [21]. In addition, a survey of the current situation of ideological and political theory courses in colleges and universities was conducted for the students from freshman to senior year, in order to understand the in-depth study of students' ideological and political theory courses. The questionnaire is conducted at the end of the school year, so even the first-year students have already taken part in the ideological and political theory course, which meets the needs of the sample.

Regarding the analysis of survey data, the descriptive statistics function of SPSS software is used to analyze the teaching behavior of college teachers in ideological and political theory courses and the deep learning behavior of students, and use independent sample *T*-test and one-way analysis of variance to understand the group differences of the above behaviors. Table 2 shows a list of the content design of student questionnaires.

After statistics, a total of 135 questionnaires were distributed for teachers, 135 were recovered, 134 were valid, the recovery rate was 100%, and the effective rate was 99.3%; a total of 1,300 questionnaires were distributed for students, 1,254 were recovered, 1,221 were valid, and the recovery rate was 96.5%, the effective rate is 93.9%. The basic information of the samples of the teacher questionnaire and the student questionnaire are shown in Tables 3 and 4, respectively.

Through investigation and analysis, it is found that the learning behavior of college students in ideological and political theory courses basically does not have the characteristics of deep learning behavior. It is mainly manifested in the lack of interest in learning ideological and political theory courses, the basic lack of high-level information

TABLE 2: List of content design of student questionnaires.

Research topic	Survey content	Observation point	Question id
Overall learning	Students' judgment of their overall learning status	Self-judgment of students' overall learning status and academic performance	Q1, Q2
Learn drive	Students' judgment of their own motivation and strength in ideological and political theory courses	Whether the students have the desire to learn the ideological and political theory course and study interest	Q3, Q4, Q5, Q6, Q7
High-level information processing	Students' judgment of their own high-level knowledge processing in the course of ideological and political theory learning	Whether students have the learning characteristics of high-level information processing in the learning process of ideological and political theory courses, and whether teachers have the elements to urge students' deep learning behavior in the course homework arrangement and course examination implementation from the perspective of students	Q8, Q9, Q10, Q11, Q12, Q13, Q14, Q15, Q16
Comprehensive application of knowledge	Students' judgment on their comprehensive use of ideological and political theory courses	The situation of college students' comprehensive use of knowledge in ideological and political theory class teaching and the situation of teachers guiding students to use comprehensive knowledge	Q17, Q18, Q19, Q20, Q21, Q22

TABLE 3: The basic situation of the questionnaire survey sample of the current situation of classroom teaching of ideological and political theory courses in colleges and universities.

	Teacher group			Seniority					Master course			
	Full-time teachers	Counselor	Less than 1 year	1-3 years	4-6 years	7-25 years	26-33 years	Think repair	Outline	Netherlands	Wool	Policies
Frequency (person)	70	64	23	42	33	30	6	70	24	17	19	4
Proportion (%)	52.2	47.8	17.2	31.3	24.6	22.4	4.5	52.2	17.9	12.7	14.2	3.0

processing in the course of ideological and political theory courses, and the lack of comprehensive application of knowledge [22]. See Figure 4 for a horizontal comparison of the mean values of each survey content.

There are also some group differences in the above situation. Whether it is the learning drive of ideological and political theory courses or the level of information processing, girls are worse than boys, and science and engineering students are worse than liberal arts students. From the analysis of the differences in different grades, the first-year students' ideological and political theory courses are slightly better than those of other grades.

By analyzing the current situation of classroom teaching of ideological and political theory courses in colleges and universities, it is found that the classroom teaching behaviors of ideological and political theory teachers are not ideal enough to stimulate students' deep learning [23]. When designing curriculum objectives, teachers do not fully realize the important role they should play in the realization of advanced curriculum objectives; although teachers have

adopted some teaching methods to promote deep learning, the effect is not good; the teacher-student relationship cannot promote information teachers cannot fully and accurately understand the difficulties encountered by students in the learning process of ideological and political theory courses, and it is difficult for students to understand the purpose of teachers to encourage them to conduct classroom discussions; lack of understanding, it is difficult for the course examination to give feedback on the real situation of students' deep learning; the classroom teaching atmosphere of ideological and political theory is not ideal. See Figure 5 for a horizontal comparison of the mean values of each survey content.

Depth learning is the purpose of ideological and political classroom teaching in the new era that emphasizes autonomy, inquiry, and cooperative learning. In order to guide students to learn independently, teachers should change their role as knowledge imparters, and at the same time be a learning theme designers and learning process guidance.

TABLE 4: The basic situation of the questionnaire survey on the current situation of college students in the ideological and political theory course in colleges and universities.

	Gender		Colleges and universities			Professional class		Grade			
	Man	Woman	Synthesis class	Liberal arts classes	Engineering	Liberal arts	In science and engineering	Freshman	Sophomore	Junior	Senior

5. Conclusion

On the basis of analyzing and summarizing the characteristics of deep learning, combined with the current problems in the teaching process of moral education in colleges and universities, this paper proposes a teaching strategy for high school ideological and political classrooms from the perspective of deep learning [24]. In the teaching process of high school ideological and political courses from the perspective of deep learning, under the guidance of teachers, students not only deepen their understanding, grasp, construct, create,

transfer and apply the knowledge they have learned through reflection on the process and results of their own learning activities, but also achieve the knowledge goal of deep learning; it also promotes the development and improvement of related skills, transfers application and problem solving, and achieves the skill goal of deep learning [25].

In the scheme design stage of mechanical products, several design solutions need to be evaluated so that the best design solution can be selected from them. Because the evaluation of mechanical product scheme design is a multilevel, multiattribute and contains many fuzzy models, fuzzy comprehensive evaluation becomes an advantageous model for the evaluation of mechanical product scheme design. In this article, a fuzzy comprehensive evaluation method is constructed, and a combination of the subjectivity of determining weights by hierarchical analysis method and the objectivity of determining weights by entropy value method is used to calculate the weights of evaluation indexes, and a combined assignment method is established to improve the reliability of the evaluation method. Then, the best solution is selected by calculating the comprehensive evaluation value of each product design solution. Finally, the validity, reasonableness, and feasibility of the evaluation model are verified through the evaluation and selection of three design solutions for a gearbox reducer, which also provides a new method for the evaluation and selection of other product design solutions.

1. Introduction

In the conceptual design phase of mechanical products, schematic design is a key aspect of product design, and the quality of the product design scheme directly affects the final product. The product solution design stage is a complex, fully defined, and innovative design reasoning process [1–4]. According to the product demand information, there may be a variety of product solutions designed, and the evaluation of the scheme often involves a variety of technical indicators. How to consider the impact of various uncertainty factors on the weight of the indicators, it is necessary to establish a perfect product design program evaluation model, and comprehensively evaluate many technical indicators. Thus, it can obtain the optimal mechanical product design scheme, which is also the key to ensuring product performance and further design [5–8]. A comprehensive evaluation of mechanical product design solutions can effectively ensure the quality of the design and also enable the designer to

preferably select the best solution among many design solutions that meet the target requirements in all aspects of performance [9–11].

There are various evaluation methods commonly used in product solution design, such as data envelopment analysis (DEA) [12], robust design [13], analytical hierarchy process (AHP) [14], grey correlation analysis [15], artificial neural network [16], analytic network process [17], etc. Chen et al. [18] developed a decision model that combines the design criteria of IF World Design Guidelines and multiattribute decision methods, which can help decision-makers to systematically evaluate and improve the performance of product designs. Yuan et al. [19] proposed a new fuzzy integrated evaluation method for configuration solutions integrating customer requirements based on fuzzy set theory. Li and Zhang [20] proposed a method combining the Kano model (KM), hierarchical analysis method (AHP), and quality function unfolding (QFD) method with intuitionistic fuzzy sets (IFS) to solve the design decision problem of new

product development, and finally the reliability and scientificity of the method were verified by examples. Xu et al. [21] described the evaluation problem of the overall mechanical product design solution as an incomplete multiparameter decision problem and established a decision method for the evaluation of mechanical product solution design by information entropy and ordered weighted average operator. Yumoto [22] established an AHP-based product selection based on the decision rules of a rough set of qualitative evaluation decision support system. Du et al. [23] proposed an improved approach to the traditional quantitative Kano model that facilitates the personalization of products for heterogeneous customer classification groups and can realize accurate marketing. At present, most of the research on the evaluation methods of mechanical product design solutions is done by applying fuzzy theory, fuzzy processing of qualitative indicators, and using methods such as expert scoring to rank the overall evaluation value of design solutions. In the evaluation process, the setting of indicator weights mostly uses empirical methods, which has a strong subjectivity. In this article, the characteristics of technical indicators of mechanical product design solutions are analyzed, hierarchical analysis and information entropy are introduced to describe the uncertainty of indicator weights, the comprehensive evaluation value of design solutions is applied, a preferential model and solution method are constructed for the evaluation of product design solutions, and finally the effectiveness of the method is verified through the evaluation of a gearbox reducer design solution as an example. This evaluation method can not only improve the efficiency by fully scientific design evaluation but also reduce the design cost.

2. Construction of Fuzzy Comprehensive Evaluation Analysis Method

2.1. Fuzzy Comprehensive Evaluation System. Fuzzy hierarchical analysis is an evaluation method formed by integrating fuzzy mathematics and hierarchical analysis. The complexity of the objective world and the ever-changing nature of eternal motion give the world a random uncertainty and a more general uncertainty, that is fuzziness. Therefore, based on the affiliation theory of fuzzy mathematics, qualitative evaluation is transformed into quantitative evaluation, that is, fuzzy mathematics is used to make an overall evaluation of things or objects that are subject to multiple factors [24]. This method can effectively improve the objectivity and scientific nature of the design evaluation, and the specific evaluation process is:

- (1) Determining the set of evaluation indicators U

In order to facilitate weight allocation and evaluation, the evaluation indicators can be divided into m subsets according to the attributes of the evaluation indicators, and each category is regarded as a single evaluation indicator and called the first-level evaluation indicator. The first-level evaluation index can set the subordinate second-level evaluation index,

and the second-level evaluation index can set the subordinate third-level evaluation index, and so on. Denoted as U_1, U_2, \dots, U_s , it should satisfy:

$$\begin{aligned} U &= U_1 \cup U_2 \cup \dots \cup U_s \\ U_i \cap U_j &= \emptyset (i \neq j, i, j = 1, 2, \dots, s). \end{aligned} \quad (1)$$

- (2) Determining the rubric set V of evaluation indicators

The set of rubrics $V = \{v_1, v_2, \dots, v_n\}$ is the evaluation grade standard and the set of rubric grades is composed of the total evaluation results that the evaluator may make to the evaluated object. In this article, the rubric set V is divided into five levels: good, better, average, qualified, and unqualified, and its level score corresponds to 90, 70, 50, 30, and 10.

- (3) Determining the weight vector of evaluation indicators

The weight is a quantitative value that compares and weighs the relative importance of the factors in the evaluated thing as a whole. In the fuzzy comprehensive evaluation, the weights will have a great influence on the final evaluation results, and different weights will sometimes get completely different conclusions.

- (4) Establishing the fuzzy comprehensive evaluation matrix R

The fuzzy comprehensive evaluation matrix composed of the affiliation degree of each evaluation index relative to the evaluation set is:

$$R = \begin{pmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{pmatrix} \quad (0 \leq r_{ij} \leq 1). \quad (2)$$

- (5) Calculating the evaluation vector B of the product design solution

After determining the weights of each evaluation index, the evaluation vector B of the product design solution is obtained by synthesizing the resulting weight vector W of each evaluation index with the evaluation matrix R of the corresponding evaluation indicators.

$$\begin{aligned} B &= W \bullet R = (\omega_1, \omega_2, \dots, \omega_n) \begin{pmatrix} r_{11} & r_{12} & \cdots & r_{1n} \\ r_{21} & r_{22} & \cdots & r_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ r_{m1} & r_{m2} & \cdots & r_{mn} \end{pmatrix} \\ &= (b_1, b_2, \dots, b_n). \end{aligned} \quad (3)$$

- (6) Calculating the comprehensive evaluation value K of product design solutions

The fuzzy comprehensive evaluation matrix \mathbf{B} is transformed into a comprehensive evaluation value K , and different solutions are selected according to their \mathbf{K} values.

$$K = B \cdot V^T. \quad (4)$$

After getting the evaluation value, a comparison of multiple solutions will give an intuitive and quantitative understanding.

2.2. Calculation of Integrated Weights. The methods for calculating the weights of product design evaluation indicators are mainly divided into subjective and objective methods. The final results obtained when applying the subjective method are highly subjective, while the objective method is a method that uses attribute indicators to determine the weights. In order to get more objective and reliable weights of product design evaluation indexes, this article combines subjective and objective methods and proposes a combined weighting method. The subjective method applies the hierarchical analysis method and the objective method applies the entropy value method, then the weights obtained from both are combined, and then the comprehensive weights are derived to provide reliable calculated weights for the subsequent evaluation of product design solutions.

2.2.1. Analytical Hierarchy Analysis to Determine the Weights. In the early 1970s, American operations researcher Professor Saaty proposed the analytical hierarchy process (AHP) [25]. After years of development, this method is now a more mature combination of qualitative and quantitative analysis of multi-criteria decision-making methods. AHP is easy to use, reliable, and practical. It has been widely used at home and abroad after years of development. The principle of AHP is similar to the process of thinking and judging when deciding; when analyzing a problem, the decision-maker has to establish a hierarchical recursive system structure for the influencing factors of the constraint object, so that the decision-maker can rationalize the complex problem.

(1) Construct Decision-Making Indicator System. The establishment of decision indicators is generally determined according to the professional knowledge or engineering practice experience of the evaluator, but the indicators selected in this way are somewhat arbitrary, and the number of decision indicators usually selected is too large, with a serious overlap of information between them and poor representativeness. Therefore, it is necessary to select decision indicators in accordance with the principles of completeness and coordination, scientificity and mutual exclusivity, feasibility and sensitivity, the combination of dynamic and static, the combination of qualitative and quantitative principles, and the decision indicator system of the final constructed product design scheme.

(2) Constructing Judgment Matrix. After the recursive hierarchy has been established, the affiliation between the upper and lower elements is determined. The next step is to determine the weights of the elements at each level. The relative importance of the different indicators is determined by a two-by-two comparison of the indicators at the next level that affects the indicators at the upper level. In this article, the 1 to 9 scale method of hierarchical analysis [26] (Table 1) is used to construct a judgment matrix by comparing each evaluation index in the evaluation system between two so as to calculate the weights corresponding to the evaluation indexes at the criterion level and each sub-criterion level.

(3) Consistency Test of Judgment Matrix. The judgment matrix constructed by a two-by-two comparison does not necessarily have consistency, and a consistency test is required to control the deviation generated by the judgment matrix within a certain range before proceeding to calculate the weights. At present, the maximum characteristic root λ_{\max} of the judgment matrix is generally applied to test the consistency of the judgment. The consistency index is calculated according to the following expression:

$$CI = \frac{\lambda_{\max} - m}{m - 1}, \quad (5)$$

where CI is the consistency index of the judgment matrix, λ_{\max} is the maximum eigenvalue of the judgment matrix \mathbf{A} , and m is the order of the judgment matrix \mathbf{A} .

The average random consistency index RI is introduced to measure the allowable range of inconsistency of judgment matrices of different orders. The RI values of judgment matrices of order 1 to 9 are shown in Table 2.

Determining the allowable range of inconsistency and calculating the inconsistency ratio CR test formula for the judgment matrix \mathbf{A} is performed according to the following expression:

$$CR = \frac{CI}{RI}, \quad (6)$$

where CR is the consistency ratio and RI is the random consistency index.

When the calculated $CR \leq 0.1$, the judgment matrix can be considered consistent, indicating a reasonable weight assignment.

(4) Calculation of Weights. There are many methods to calculate the final weight vector for hierarchical analysis, among which the easiest and most commonly used method is the eigenvector method; so in this article, we choose the eigenvector as the method to calculate the weight vector and has Perron's theorem [27] as its theoretical basis.

Perron's theorem: If $A = (a_{ij})_{n \times n}$ is a positive matrix and $\rho(A)$ is its spectral radius, then the following conditions are satisfied.

- (1) The largest eigenvalue λ_{\max} of A exists, is unique, and $\lambda_{\max} = \rho(A)$;

TABLE 1: Scale value table.

Scale value	The value of a_{ji}
1	Evaluation indicator A is the same importance as B
2	Evaluation indicator A is slightly important than B
3	Evaluation indicator A is slightly important than B
4	Evaluation indicator A is more important than B
5	Evaluation indicator A is obviously important than B
6	Evaluation indicator A is very important than B
7	Evaluation indicator A is fiercely important than B
8	Evaluation indicator A is more fiercely important than B
9	Evaluation indicator A is fiercely important than B

TABLE 2: RI values of high-order average random consistency index.

m	1	2	3	4	5	6	7	8	9	10
RI	0.00	0.00	0.58	0.90	1.12	1.24	1.32	1.41	1.45	1.48

- (2) The normalized eigenvector λ_{\max} corresponding to $\omega = (W_1, W_2, \dots, W_n)^T$ is a positive vector, that is every element of ω is greater than zero.

The relative importance weight vector ω is first obtained by solving the eigenequation of matrix A in terms of the largest eigenvalue λ_{\max} and its corresponding eigenvector and normalizing it.

The eigenvectors are obtained by solving the eigenvalues of matrix A and their corresponding eigenvectors λ_{\max} and then normalizing them to obtain the relative importance weight vector ω .

$$(A - \lambda_{\max}I)\omega = 0. \quad (7)$$

The eigenvector corresponding to λ is

$$\omega = (\omega_1, \omega_2, \dots, \omega_n)^T. \quad (8)$$

The feature vector ω corresponding to the maximum eigenvalue λ_{\max} is the weight vector of the scheme set.

(5) *Multilevel Indicator Weights.* The calculation method of the weight vector in the comprehensive evaluation can obtain the weight of each decision indicator to the upper decision factor layer, the weight of each indicator to the total decision target is needed in the decision, and the weight of the decision factor to the total decision target can be calculated by AHP. Let there be a total of s decision indicators in the decision factor layer and the weight D of the indicators in the factor layer obtained by AHP, then the weight of the final decision indicator on the total decision objective is equal to the product of the weight of the corresponding decision indicator and the weight of the upper decision factor, which is denoted as:

$$\omega_j = \omega_j^e \bullet \omega_j^z, \quad (j = 1, 2, \dots, s), \quad (9)$$

where ω_j^e is the weight of the decision factor C corresponding to the indicator C_j , ω_j^z is the weight of decision factor C to the

overall objective of the decision, ω_j is the weight of indicator C_j on the total objective of the decision.

2.2.2. Entropy Evaluation Method for Determining Weights.

In information theory, entropy is a measure of uncertainty. The greater the amount of information, the smaller the uncertainty and the smaller the entropy; conversely, the greater the entropy [28]. According to the properties of entropy, the randomness and the degree of disorder of a scheme can be judged by calculating the entropy value. The entropy evaluation method (EEM) is an objective assignment method, which determines the index weights according to the size of the information provided by the observations of each index and can reduce the influence of the subjectivity that exists in the hierarchical analysis method on the analysis results [29].

- (1) Constructing the indicator matrix

Assuming that there are n evaluation levels and m evaluation indicators, the evaluation indicators are scored according to the expert opinions, which constitute an $n \times m$ indicator matrix A .

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix}, \quad (10)$$

where a_{ij} is the value of the j th indicator of the i th program.

- (2) Normalizing the indicator matrix

Since the units of measurement of each indicator are not uniform, it is necessary to standardize them before using them to calculate the composite indicators so as to solve the problem of homogenization of the different qualitative indicator values. The indicator matrix A is normalized to obtain the normalization matrix P .

$$P = \begin{bmatrix} p_{11} & p_{12} & \cdots & p_{1m} \\ p_{21} & p_{22} & \cdots & p_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ p_{n1} & p_{n2} & \cdots & p_{nm} \end{bmatrix} \quad (11)$$

$$p_{ij} = \frac{q_{ij}}{\sum_{i=1}^n q_{ij}}$$

$$\text{positive indicators } q_{ij} = \frac{a_{ij} - a_{\min}}{a_{\max} - a_{\min}}$$

$$\text{positive indicators } q_{ij} = \frac{a_{\max} - a_{ij}}{a_{\max} - a_{\min}}$$

$$i = 1, \dots, n, j = 1, \dots, m$$

- (3) Calculating the information entropy value E_j of the j th indicator

$$E_j = -\frac{1}{\ln(n)} \sum_{i=1}^n p_{ij} \ln(p_{ij}) \quad (i = 1, \dots, n, j = 1, \dots, m), \quad (12)$$

where: $0 \leq E_j \leq 1$.

- (4) Calculating the information entropy redundancy D_j

$$D_j = 1 - E_j. \quad (13)$$

- (5) Calculating the entropy weight of each indicator

$$\omega_j = \frac{D_j}{\sum_{j=1}^m D_j}. \quad (14)$$

2.2.3. Determining the Comprehensive Weights of Indicators. The hierarchical analysis method and entropy value method have obtained subjective weights and objective weights, respectively, and it is necessary to recombine the subjective and objective weights to get more accurate comprehensive weights. Then the comprehensive weight of each evaluation index is calculated by the following formula [30].

$$W_j = \frac{\omega_j^{(a)} \cdot \omega_j^{(e)}}{\sum_{j=1}^m \omega_j^{(a)} \cdot \omega_j^{(e)}} \quad (15)$$

$$AHP: \omega_a = (\omega_1^{(a)}, \omega_1^{(a)}, \dots, \omega_m^{(a)})$$

$$EEM: \omega_e = (\omega_1^{(e)}, \omega_1^{(e)}, \dots, \omega_m^{(e)}).$$

3. Fuzzy Comprehensive Evaluation Based on Mechanical Product Design Scheme Optimization

3.1. Establishment of Fuzzy Comprehensive Evaluation System. The article takes the evaluation of a gearbox reducer design scheme as an example, and three preliminary design options are available [31].

- (1) A two-stage reduction: this scheme can make full use of space to reduce the center distance, but it is bound to increase the supporting devices such as shafts, gears, and bearings for the first-stage drive.
- (2) Single-stage transmission, with the clutch arranged in the middle end and the box components divided into two large parts, namely the box and the front cover; the pinion is hollow-set on the long shaft, and the input power is transmitted to the pinion through the long shaft and the clutch closure on it.
- (3) Single-stage transmission, the structure of scheme (2) is partially adjusted: the input shaft adopts torsion shaft transmission, the pinion gear is empty set on the torsion shaft, which makes the reducer have the characteristics of small size; the clutch is arranged

at the rear end, the box combination surface is changed from longitudinal section to transverse section, which improves the assembly and disassembly performance of the clutch parts and output shaft parts; however, the process is more difficult.

By reviewing the information, a total of 2 principles of technical indicators T and economic indicators E were identified as the first-level indicators of the evaluation index system. Performance indicator $T1$, processability indicator $T2$, and service-oriented indicator $T3$ constitute the secondary indicators of technical indicator T , and labor cost $E1$ and time cost $E2$ constitute the secondary indicators of economic indicator E . And center distance $T11$ and weight $T12$ constitute the tertiary indicators of performance indicator $T1$, ease of installation $T21$ and ease of processing $T22$ constitute the tertiary indicators of processability indicator $T2$, and ease of maintenance $T31$ constitutes the tertiary indicators of serviceability indicator $T3$. The processing cost $E11$ and material cost $E12$ are the tertiary indicators of labor cost, and the time of trial production and production start-up $E21$ and design progress $E11$ are the tertiary indicators of time cost [31] (Figure 1).

3.2. Method of Calculating the Comprehensive Weights of the Evaluation Indexes of the Design Scheme

- (1) AHP method to determine the evaluation index weights of gearbox reducer design scheme

For gearbox product development, according to historical data and the experience of relevant engineering designers, two comparisons are made using the 1–9 scale method to construct the judgment matrix of evaluation indicators at all levels, calculate the weights under a single criterion based on the work formulas (5)–(8), and conduct consistency tests on the judgment matrix of order $n > 2$ (Table 3).

- (2) EEM to determine the weight of gearbox reducer design evaluation index

By inviting experts to make a two-by-two comparison of the evaluation indexes at each level of the gearbox reducer design evaluation system shown in Figure 1 using the 1 to 9 scale method, the judgment matrix A of the evaluation indexes at each level is constructed.

$$A = \begin{bmatrix} 1 & 1/7 & 2 & 1/2 & 1 & 1 & 1/2 & 3 & 3 \\ 7 & 1 & 8 & 4 & 7 & 7 & 4 & 9 & 9 \\ 1/2 & 1/8 & 1 & 1/3 & 1/2 & 1/2 & 1/5 & 1 & 1 \\ 2 & 1/4 & 3 & 1 & 2 & 2 & 1 & 5 & 5 \\ 1 & 1/7 & 2 & 1/2 & 1 & 1 & 1/2 & 3 & 3 \\ 1 & 1/7 & 2 & 1/2 & 1 & 1 & 1/2 & 3 & 3 \\ 2 & 1/4 & 5 & 1 & 2 & 2 & 1 & 7 & 7 \\ 1/3 & 1/9 & 1 & 1/5 & 1/3 & 1/3 & 1/7 & 1 & 1 \\ 1/3 & 1/9 & 1 & 1/5 & 1/3 & 1/3 & 1/7 & 1 & 1 \end{bmatrix}. \quad (16)$$

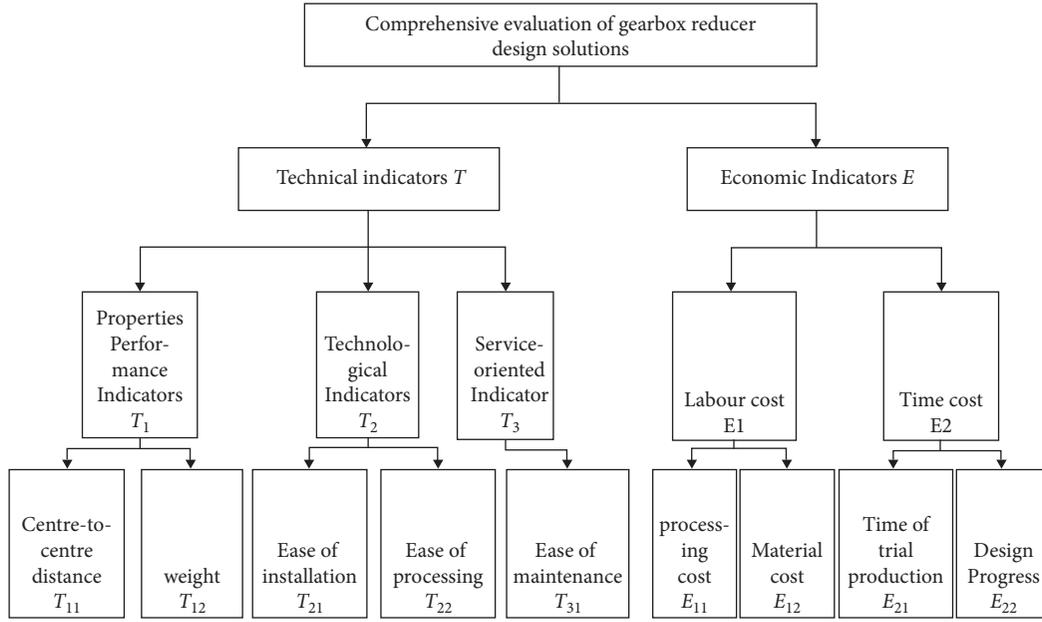

FIGURE 1: Gearbox reducer design scheme evaluation index system.

The entropy and entropy weights of each three-level index under the gearbox reducer design scheme can be obtained by equations (10)–(13) (Table 4).

(3) Comprehensive weight determination of evaluation indicators

The comprehensive weight vector of security principle evaluation indexes can be derived from equation (14) as

$$\mathbf{W}_1 = (0.090, 0.320, 0.069, 0.115, 0.086, 0.082, 0.136, 0.051, 0.051). \quad (17)$$

3.3. *Determining the Affiliation Matrix R of the Product Design Solution.* In this article, the affiliation matrix of the literature [32] on the three design options of the gearbox reducer is directly chosen as shown in Table 5.

3.4. *Determining the Evaluation Matrix B of the Product Design Solution.* The evaluation matrix \mathbf{B} for each gearbox reducer design option can be calculated according to (3).

Scheme 1:

$$\mathbf{B}_1 = \mathbf{W} \bullet \mathbf{R}_1 = (0.1870, 0.0996, 0.0342, 0.3142, 0.3650). \quad (18)$$

Scheme 2:

$$\mathbf{B}_2 = \mathbf{W} \bullet \mathbf{R}_2 = (0.1620, 0.2172, 0.3190, 0.2206, 0.0812). \quad (19)$$

Scheme 3:

$$\mathbf{B}_3 = \mathbf{W} \bullet \mathbf{R}_3 = (0.0966, 0.2934, 0.3606, 0.2494, 0). \quad (20)$$

3.5. *Determining the Comprehensive Evaluation Value of the Product Design Solution K .* According to (5), the evaluation score \mathbf{K} can be calculated for each gearbox reducer design solution.

Scheme 1:

$$\mathbf{K}_1 = \mathbf{B}_1 \bullet \mathbf{V}^T = (0.1870, 0.0996, 0.0342, 0.3142, 0.3650) (90, 70, 50, 30, 10)^T = 38.588. \quad (21)$$

Scheme 2:

Scheme 1	$R_1 = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.2 & 0.8 \\ 0 & 0 & 0.2 & 0.6 & 0.2 \\ 0.4 & 0.6 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0.4 & 0.6 \\ 0 & 0 & 0 & 0.8 & 0.2 \\ 0 & 0 & 0 & 0.8 & 0.2 \\ 0.2 & 0.4 & 0.4 & 0 & 0 \\ 0.8 & 0.2 & 0 & 0 & 0 \end{bmatrix}$
Scheme 2	$R_2 = \begin{bmatrix} 0.2 & 0.6 & 0.2 & 0 & 0.2 \\ 0 & 0 & 0.4 & 0.4 & 0.2 \\ 0 & 0.2 & 0.6 & 0.2 & 0 \\ 0.4 & 0.6 & 0 & 0 & 0 \\ 0 & 0 & 0.2 & 0.6 & 0.2 \\ 0.2 & 0.4 & 0.4 & 0 & 0 \\ 0 & 0.2 & 0.6 & 0.2 & 0 \\ 0.8 & 0.2 & 0 & 0 & 0 \\ 0.8 & 0.2 & 0 & 0 & 0 \end{bmatrix}$
Scheme 3	$R_3 = \begin{bmatrix} 0.4 & 0.6 & 0 & 0 & 0 \\ 0 & 0 & 0.4 & 0.6 & 0 \\ 0 & 0.2 & 0.6 & 0.2 & 0 \\ 0.2 & 0.4 & 0.4 & 0 & 0 \\ 0.2 & 0.6 & 0.2 & 0 & 0 \\ 0 & 0.4 & 0.4 & 0.2 & 0 \\ 0 & 0.4 & 0.4 & 0.2 & 0 \\ 0.2 & 0.4 & 0.4 & 0 & 0 \\ 0.2 & 0.4 & 0.4 & 0 & 0 \end{bmatrix}$

$$K_2 = B_2 \bullet V^T = (0.1620, 0.2172, 0.3190, 0.2206, 0.0812)$$

$$(90, 70, 50, 30, 10)^T = 53.146. \tag{22}$$

Scheme 3:

$$K_3 = B_3 \bullet V^T = (0.0966, 0.2934, 0.3606, 0.2494, 0)$$

$$(90, 70, 50, 30, 10)^T = 54.744. \tag{23}$$

The final rating results of the gearbox reducer design scheme calculated by the above method are $K_3 > K_2 > K_1$, with scheme 3 being the best, scheme 2 the second best, and scheme 1 the worst. This is consistent with the evaluation results of literature [32, 33], and from the actual analysis, scheme 1 uses two-stage reduction, which requires an additional level of transmission system supporting device, while scheme 2 uses a single-stage transmission and scheme 3 is an improved design based on scheme 2, so the evaluation results are also consistent with the actual situation.

4. Conclusions

Evaluation decision plays a crucial role in the design process, and its effectiveness directly affects the direction and results of the design progress. In the decision-making process, when determining the weights of each evaluation index, combining the subjectivity of the hierarchical analysis method to determine the weights and the objectivity of the entropy weight method to determine the weights, the decision-makers can evaluate the design solutions more scientifically and accurately and improve the reliability of the design solution evaluation. The final design scheme, Scheme 3, was preferentially selected after evaluating three designs for a gearbox reducer, which is not only consistent with the literature evaluation results [28, 29] but is also in line with the actual analysis results. This method confirms its scientificity, validity, and reliability, thereby reducing the product development cycle and improving its quality.

Because the English language has always been inaccurate and seemed difficult to correct errors, this development has created a reputation based on improvements to the DWJ algorithm and HMM speech scores and correction mistake. In this paper, different signal characteristics are used using the DWJ algorithm: the Mel frequency cepstrum coefficient compares the standard speech library and the distance between the speech sample and the sample message received. The conversation deciphered the Viterbi code according to the HMM model, which was recognized and evaluated by posteriori probabilities. Finally, the professional data were used to fix the wrong phone to determine, score, and make repair mistakes. The results of the experiments show that the tests used in this article are reliable. The results of the experiment show that the standard English language proficiency in this article is reliable, which can provide students with timely, accurate, and objective assessment and teaching feedback, improving English language proficiency.

1. Introduction

As the most widely used language in the world, it is important to learn and master English. However, learning English has always affected Chinese. Learning, reading, listening, and speaking English on a daily basis is the hardest part. With the advancement of computer science and technology, training, and education, the use of computer-assisted speech technology allows for solving this problem. Technology can transform existing instructional patterns and learning environments and transform information into text by doing, analyzing, recognizing, and understanding them. In combination with other language skills such as fluency, speech technology, and machine translation. English language proficiency systems have been developed to help students correct non-verbal cues on time and without repetition. This will greatly benefit students' English language learning experience and result in significant community and business benefits.

2. Literature Review

The basis of telephone calls is knowledge of speech and speech measurement. Speech recognition technology, or Automatic Speech Recognition (ASR), is the technology of translating information into commands or texts by using automatic recognition and comprehension technology (many are computers) to use interactive communication between man and machine. Thus, speech skills have become a hot topic in recent years [1, 2]. The demands of high-end software, hardware, and procedures for speech signal processing work are due to changes in speech, data signal frequency, volume of speech, in particular, multiple acknowledgments and measures. From the classical dynamic time distortion (DTW) algorithm to the hidden Markov simplified model (HMM) and then to the latent inertia device (ANN), speech recognition has become the norm. *Unprecedented Difficulties*. As a result, it is difficult to improve its accuracy and speed, making it difficult to make a significant impact on knowledge of speech, material, and industry [3].

For the classic speech recognition algorithm, DTW solves the problem of different call length patterns based on dynamic programming ideas. DTW is the easiest and most effective way to identify personal information, as it is virtually no longer included in training. However, it has many shortcomings, especially the ability to recognize an independent speaker, speak fluently, and speak with large words. The main reason is that there is no efficiency for training using statistical procedures, and it is not easy to use simple and advanced instructions for algorithms.

HMM creates a set number of models of speech signal time. The HMM model describes the acoustic model of speech in an appropriate way and uses training techniques in organically blended low-pitched and upper-level speech patterns in cognitive exploration algorithm so a better effect can be obtained. However, HMM also has some limitations [4]. First, the HMM-based approach does not consider the impact of perception. Secondly, large-scale speech corpora need to be collected to train HMM templates of standard speech to obtain robust HMM. Moreover, since call is an aid to second language learning, it involves more nonnative speech recognition. When recognizing nonnative speech, the recognition performance of HMM trained by native speech will be greatly reduced, so it is necessary to carry out self-adaptive nonnative speech recognition. Even so, it is still difficult for the adaptive HMM to achieve good results in nonnative speech recognition. In addition, HMM also has the following problems: the prior statistical knowledge of speech signals is required, the classification decision-making ability is weak, and the Viterbi recognition algorithm has a large amount of computation and Gaussian mixture probability calculation. These shortcomings make it difficult to further improve the performance of HMM model. For English speech recognition with large amount of data and complex pronunciation changes, HMM has more obvious shortcomings, which makes the speech recognition time longer. Therefore, the HMM-based speech recognition method has encountered a major development bottleneck [5].

3. Improved DWT Algorithm

3.1. Speech Recognition Principle. The main idea of knowledge of technology is to bring speech into a product of learning, translating practical information into text that is conveyed through the processes of machine knowledge and understand, and allow the machine to control speech. Speech recognition can illustrate the principle of acceptance as shown in Figure 1. The most important module of speech recognition is to eliminate speech and modify speech patterns.

3.2. Voice Signal Preprocessing. The first step in speaking skills is before the speaking process. The advancement of speech characters is not only the basis of speaking skills, but also an important factor in the development of the characteristics of speech. Only at the prespeaking stage of the speech signal is it possible to subtract the features that

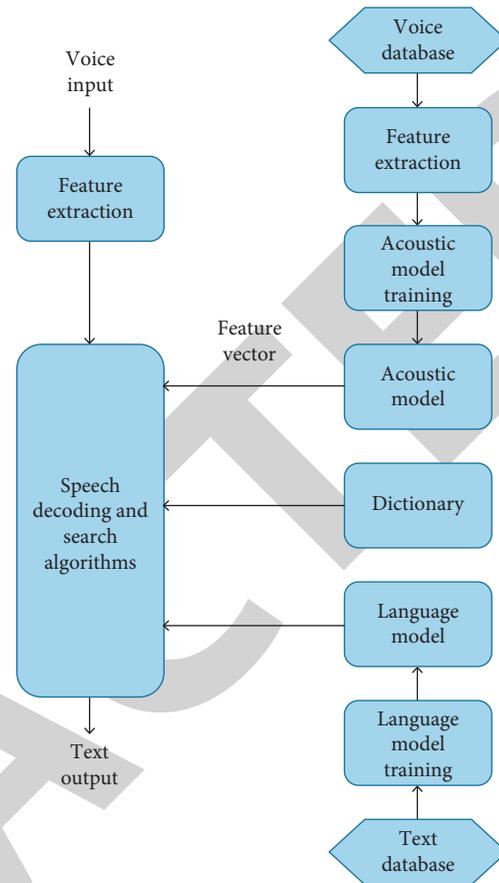

FIGURE 1: Principle of speech recognition.

indicate the speech and then carry out the comparison with the sample to get the result related similarities. The audible signal preprocessing module typically has five steps: digitizing the audible signal, endpoint detection, enclosing, windowing, and preemphasis[6].

3.2.1. Speech Signal Digitization. A loudspeaker signal is a type of clock-changing wave and is an analog signal. However, since computers only receive digital signals, if a computer wants to make a speech sound, it must digitize the speech signal. The process of digitizing spoken characters involves comparisons and quantification. After sampling and quantization, the speech signal becomes a digital signal.

3.2.2. Preemphasis. The first task is to improve the signal frequency, eliminate the frequency signal in the speech signal, and smooth the signal spectrum. In the spectrum of speech signals, the higher the frequency, the lower the amplitude. When the frequency of a speech signal is doubled, its amplitude of the energy spectrum decreases by 6 dB. In order to balance the signal spectrum and facilitate the analysis of the spectrum and other characteristics, it is first necessary to see that the signal is speech signal. High-frequency speech signals and low-frequency speech signals are difficult to obtain. Special attention is paid to solving this

problem. One indicator is the use of digital audio signals through filters with enhanced 6Db/8 frequency characteristics. This is a first-class digital filter, as shown in the following equation:

$$H(z) = 1 - \mu * z^{-1}. \quad (1)$$

If expressed in time domain, the preaccentuated signal $S_2(n)$ is

$$S_2(n) = S(n) - \mu * S(n-1), \quad (2)$$

where μ is 0.9375.

3.2.3. Framing and Windowing. Generally, speech symbols are considered infinite and change over time. However, in the short term, such as 10 ms–25 ms, there is a slight change in the characteristics of the speech signal. We can define this short-term problem as a stable signal, and the characteristics of the speech at this time can be considered as constant [7]. Therefore, it can describe the speech signal using a short time; that is, the speech signal is segmented parallel to the time axis. To achieve the purpose of speech comparison, we subtract the speech signal characteristics for each speech segment and compare them with the segmented speech characteristics. At the same time, the overlap of the frames should be facilitated by the transition of the line adjacent to the speech signal and the continuity of the signal. This overlap is often called the transformation, and the data contained in a ton of speech is called a long line [8].

3.2.4. Endpoint Detection. There is no way to determine the end. Different search processes can be used in different systems. In this form, the system uses a combination of short-term zero interference velocity and short-term momentum to capture the final points. Both methods are time-consuming and the results are reliable and accurate.

The short-term energy is a reflection of the law of change in terms of volume over time. Assume that the long-range magnitude of the X range of the n th energy of the speech signal is indicated by E . then its calculation formula is shown as follows (where N is the frame length):

$$E_n = \sum_{m=0}^{N-1} x_n^2(m), \quad 0 \leq m \leq N-1. \quad (3)$$

We can tell the difference between speech and voice by analyzing the signal strength. The distance between the speaker signal and the pickup will indicate more. Short power consumption, speech signal, and noise can be easily seen in the example of signal-to-noise ratio. However, in a low- to high-pitched environment, the short-wave energy does not exactly distinguish the melody [9].

The short-time zero intersection signal is the number of short-time signals transmitted across the x -axis in the range. The signal recording time for a continuous speech signal is the number of times it crosses over the time axis of the zero intersection reported. If the two values of an example of a

discrete signal are different, it means that they pass through the time axis at once. Therefore, a zero-intersection value can be calculated. We define the short-time zero-crossing rate of speech signal as follows:

$$Z_n = \frac{1}{2} \sum_{m=0}^{N-1} |\text{sgn}[x_n(m)] - \text{sgn}[x_n(m-1)]|, \quad (4)$$

where $\text{sgn}[x]$ is a symbolic function, as follows:

$$\text{sgn}[x] = \begin{cases} 1 & (x \geq 0) \\ -1 & (x \leq 0). \end{cases} \quad (5)$$

Low-energy sound tones have a low cross-sectional area, while high-energy sound tones have a high cross-sectional area. In general, by identifying the zero-crossing speed, it can be seen that the speech segment has a stable zero-crossing speed, but the volume is not the case. Therefore, we can filter the end of the conversation by short-term zero intersection [10].

3.3. Feature Extraction of Speech Signal. Decomposing speech signal features for improved speech reduces system storage capacity, shortens run time, and effectively improves comparison efficiency [11].

Now, after the speech signal has been completed, several measures have been selected for the following characteristics: linear estimated coefficient (LPC), linear hypothesis cepstrum coefficient (LPCC), and Mel cepstrum coefficient (MFCC). These measurements can determine the characteristics of the speech signal. The Mel cepstrum coefficient (MFCC) is stronger for noise operation and more stable than the linear frequency (LPC). Using three negative traits (MFCC, tone, and size) to measure English proficiency, the final experiment showed that MFCC had the highest accuracy [12].

The relationship between Mel scale and frequency can be illustrated by the following equation (where f is the truth rate of the signal):

$$f_{\text{mel}} = 2595 \log_{10} \left(1 + \frac{f}{700} \right), \quad (6)$$

where f is the unit of actual frequency in Hz. MFCC parameter extraction principle's block diagram is shown in Figure 2.

3.4. Dynamic Time Warping (DTW) Recognition Algorithm. Dynamic time distortion is best associated with the principle of dynamic programming by performing time differences between the design and the experimental model. This bends two sentences connected to different clocks on the time axis so that the two points speak better. There are two time series, m and N , and their lengths are h and K . M sequence is the design, n is a sequence model, and the values of each point in the system are the same indicating the value of each column of temporary speech. For example, the sentence of m speech contains the whole H number. The characteristic value of the

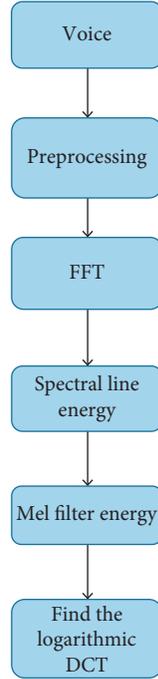

FIGURE 2: Schematic block diagram of MFCC feature parameter extraction.

i -th frame is m_i . The Figure 3 shows data formula (7) of the two sequences:

$$\begin{aligned} M &= m_1, m_2, \dots, m_i, \dots, m_h; \\ N &= n_1, n_2, \dots, n_j, \dots, n_k; \end{aligned} \quad (7)$$

In order to better compare the two speech periods, we need to compare the two periods and create a network of $h * k$ matrices as shown in the figure below. We draw each model audible signal frame on the horizontal axis of the rectangle joint and then draw each sample audible signal frame on the vertical axis of the rectangle joint. The diagrams below are drawn with data from two categories. The intersection of each grid in the figure shows that the distance between m_i and n_j can be marked w_j ; that is, the similarity of each point in m is temporary and each point in n is temporary. The smaller the distance, the higher the similarity. Euclidean sites are usually used. Each term of the matrix (i, j) represents a comparison of the terms m_i and n_j . The DTW algorithm can be scaled down to see the way through multiple points in this network. Content across the network is a parallel content that counts in two sections. The two sequences can be represented in Figure 3 by the two combinations.

From the above analysis, we can define the passage through the lines in the figure according to the method of exploration with the time difference of W . The k -th definition of W indicates drawings of m and n .

From the above analysis, we can determine the way in which the lines in the figure become the means of exploration with time change, shown as W . Conclusion k -th of W is defined as the formula, indicating the sequences M and N . So we have the following formula:

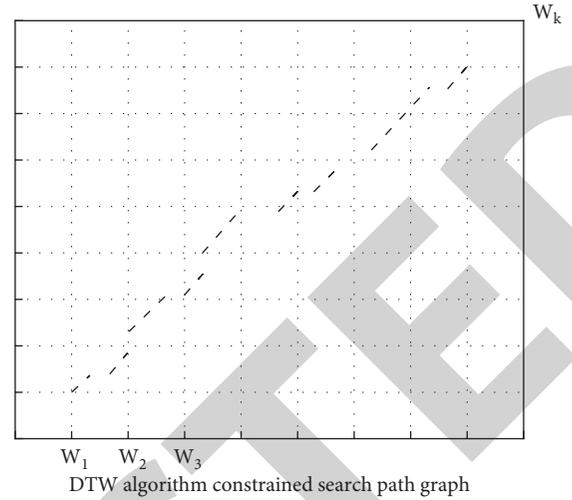

FIGURE 3: DTW algorithm constraint search path diagram.

$$W = w_1, w_2, \dots, w_{k-i}, \dots, w_k; \max(m, n) \leq k \leq m + n - 1. \quad (8)$$

3.5. Improved DTW Algorithm. In the previous section, the DTW algorithm always uses all words as the basis of training and recognition and does not consider the distribution of words. Due to the low slope limit during modification, many points in the network cannot be reached. As shown in Figure 4, it is not necessary to calculate the appropriate frame spacing for the diamond layer mesh content [13]. In addition, it is not necessary to keep the matrix parallelism of all the frames and the matrix components, because only three networks of the previous line are used in the calculation counts for each network point in each row. The combined use of these two functions can reduce computing and storage space [14].

Adjusting multiple lines of the research matrix can affect the required speed. We can control the search area by adjusting the two slopes. If the search is too small, the search speed will be better, more useable methods will be lost, and the comparison will be inaccurate. Changing the search facilities too much may quickly affect competition [15]. Finally, the development of DTW exploration after the experiment did not explore the whole of the matrix data in the figure, but reduced the area of the surrounding parallelogram by two lines with $2/3$ and $3/2$ slopes. It is the last point that works. A field is a parallelogram called an exploration figure. A field is a parallelogram called an exploration figure. In the origin and endpoint of the parallelogram (top right) and the parallelogram formed by the two edges $2/3$ and $3/2$, the following two points Send and X_b finally counted. In such areas, rapid and similar searches are the best options [16]. Improvements to traditional DTW algorithms are aimed at improving the performance of comparison speech. Figure 4 shows the research method for improving the DTW algorithm.

In Figure 4, the actual dynamic bending is divided into three sections: $(1, x_a), (x_{a+1} x_b)(x_{b+1} N)(1, x_a), (x_{a+1} x_b)(x_{b+1} N)$, as shown in

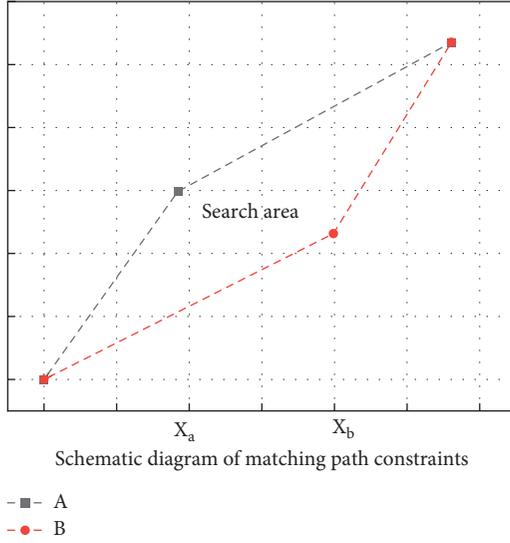

FIGURE 4: Schematic diagram of matching path constraint.

$$\begin{cases} x_a = \frac{1}{3}(2M - N) \\ x_b = \frac{2}{3}(2N - M) \end{cases}, \quad (9)$$

where x_a and x_b both take the nearest integer; thus, the limiting condition formula (10) for the length of M and N is also obtained:

$$\begin{cases} 2M - N \geq 3 \\ 2N - M \geq 2. \end{cases} \quad (10)$$

If the above conditions are not met, the difference between the two is considered to be very good for dynamic bending modification.

It is not necessary to compare each pole on the x -axis with every pole on the y -axis, except the pole on the y -axis. The calculations for y_{\min} and y_{\max} are as follows:

$$y_{\min} \begin{cases} \left(\frac{1}{2}\right)x, & 0 \leq x \leq x_b \\ 2x + (M - 2N), & x_b \leq x \leq N \end{cases}, \quad (11)$$

$$y_{\min} \begin{cases} 2x, & 0 \leq x \leq x_a \\ \left(\frac{1}{2}\right)x + \left(M - \left(\frac{1}{2}\right)(1/2)N\right), & x_a \leq x \leq N. \end{cases} \quad (12)$$

The connecting parts of our three bends are >case. For each front frame of the x -axis, the y -axis ratio is different, but the bending properties are the same, and the distance change is made by the following model:

$$D(x, y) = d(x, y) + \min[D(x - 1, y), D(x - 1, y - 1), D(x - 1, y - 2)]. \quad (13)$$

For each front column of the x -axis, only the storage space of the previous column is required. Therefore, instead of storing the entire distance matrix as a whole, only vectors D and D of the two lines should store the storage space of the previous line and count the storage space of the line now, which has been modified for all forward and post. According to the above model, the storage area D of the previous line and the relative $D(X, v)$ of all the frames of the current line are stored in vector D by calculating the storage location of the current pole and then assigning the new D position to D as the new location stored in the next row. In this way, it goes to the end line of the x -axis, and M meaning of vector D is the parallel to the dynamic curve of the two models.

4. Voice Scoring and Error Correction

4.1. Similarity Comparison Method DTW. At present, there are many methods to measure the pronunciation quality. Our requirements for the scoring algorithm are as follows: high reliability and consistency with experts' scoring only reflect the learners' ability to pronounce Chinese and do not pursue the best similarity with standard pronunciation individuals. Following this study, the HMM-based phoneme probability algorithm was stable and not easily altered due to changes in the learner's behavior or voice channel, indicating similarities between learners' speech and speech patterns.

In speech processing, we cannot simply compare input features with templates directly, because speech signals have considerable randomness. Even if the same person reads the same sentence aloud, it is impossible to have exactly the same length of time. For example, with the faster phonation speed, the length of the vowel stable part will be shortened, while the length of the consonant or transitional part will remain basically the same. Therefore, time regulation is essential. Dynamic time warping is a nonlinear warping technique that combines time warping with distance measure computation. Suppose that the feature vector sequence of the reference template is $a_1, a_2, a_3, \dots, a_m, \dots, a_M$, the feature vector sequence of the input speech is $b_1, b_2, b_3, \dots, b_n, \dots, b_N$, and $M \neq N$. Then, the dynamic regularization is to find a time regularization function $m = w(n)$ and map the time axis n nonlinearly to the time axis m of the reference template, so that

$$D(n, w) \min_{w(n)} \sum_{n=1}^N d[n, w(n)], \quad (14)$$

where $d[n, w(n)]$ represents the distance between the n th and input eigenvectors and the $w(n)$ reference template vector. Obviously, $w(n)$ should be a nondecreasing function. Dynamic time warping aligns the input features with the reference template features in time to eliminate the nonessential differences between them. Figures 5 to 9 show the schematic diagram of the distortion between the two modes in the case of direct matching, linear matching, and nonlinear matching. It can be seen from the figures that when the nonlinear matching method is adopted, it is possible to minimize the nonessential difference between the two modes.

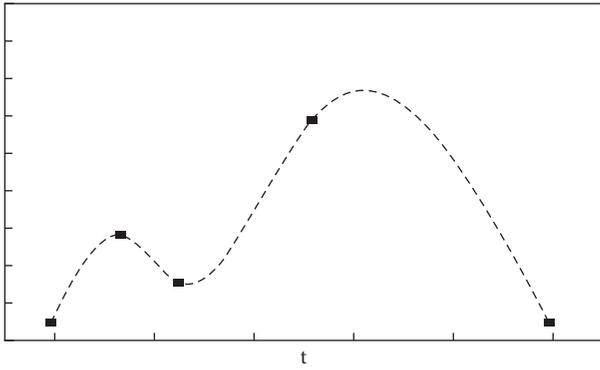

FIGURE 5: Direct matching.

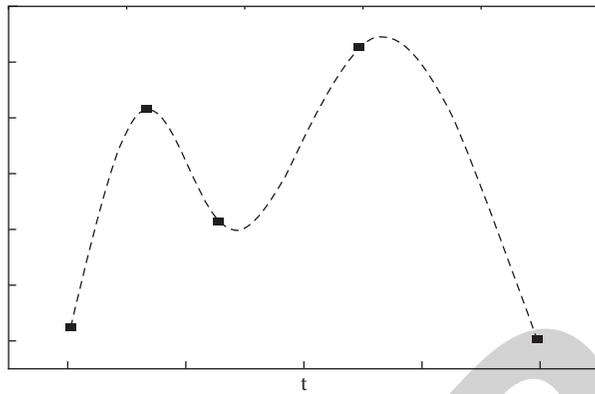

FIGURE 6: Linear matching.

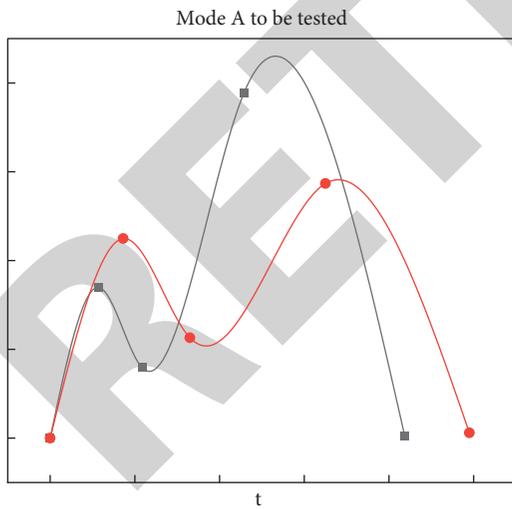

FIGURE 7: Direct matching D1.

Dynamic time warping is an optimization problem. Dynamic programming technology is often used to solve this problem. The concept that local optimization can lead to global optimization is used. The purpose of the solution is to find the optimal time warping function $w(n)$ and the corresponding $D(n, w)$. Recursive formulas (15) and (16) can be derived as follows:

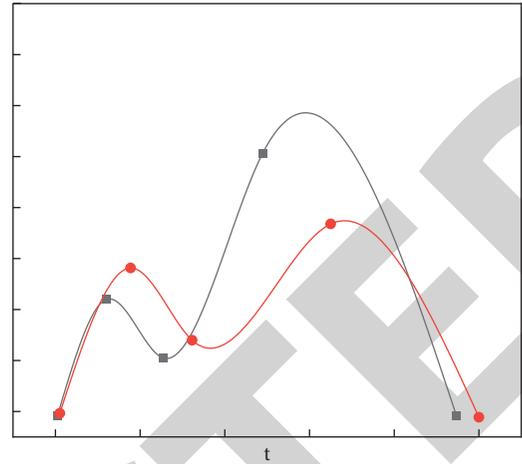

FIGURE 8: Linear matching diagram (D2).

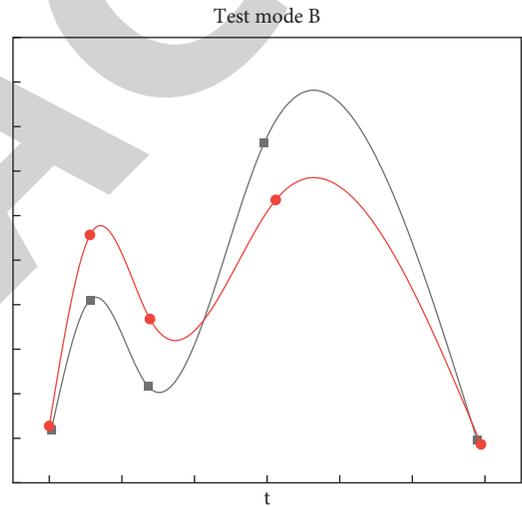

FIGURE 9: Nonlinear matching (D2).

$$D(n + 1, m) = d[n + 1, m] + \min [D(n, m)g(n, m), D(n, m - 1), D(n, m - 2)], \quad (15)$$

$$g(n, m) = \begin{cases} 1, & w(n) \neq w(n - 1) \\ \infty, & w(n) = w(n - 1). \end{cases} \quad (16)$$

Since the calculation of each point $D(n+1, m)$ requires the calculation of all three points D values on the n column, it is very time-consuming to calculate the time regularity using the dynamic programming technique. In pattern recognition, it is often necessary to calculate the distance between features. In speech recognition, the similarity between the reference mode and the input mode is determined by the distortion measure between the two frames [17]. It is a measure that reflects the difference between signal features and is represented by $D(x, y)$. In the calculation of DTW distance, the absolute value average distance equation is used as follows:

$$D(x, y) = \frac{\sum_{i=1}^N |x_i - y_i|}{N} \quad (17)$$

DTW distance cannot be directly used as pronunciation score. We need to find a suitable guide to score from a distance. It is considered a relationship of distance and interest:

$$\text{score} = \frac{100}{1 + a(\text{dist})^b} \quad (18)$$

Obviously, this formula can map the distance to the score range of 0100. To solve the unknown parameters a and B in the formula, we need to know some pairs of fractions and distances. The above parameters can be solved from the scores and DTW distances of some experts in the experiment. Using the formula in this paper, even if the distance is larger or smaller than that in the test, the score can be reasonably converted to the interval of 100 to 0 [18]. As two characteristic parameters are actually used, the actual score estimation formula is slightly more complex than the above formula, and the final score is shown in the following weighted sum formula of the two:

$$\text{score} = w_1 * \frac{100}{1 + a_1(\text{dist}_1)^{b_1}} + w_2 * \frac{100}{1 + a_2(\text{dist}_2)^{b_2}} \quad (19)$$

The unknown parameters in the formula meet certain restrictions: $a_1, a_2, b_1, b_2 > 0$, $w_1 + w_2 = 1$. a_1, a_2, b_1, b_2 are the parameters of converting distance into fraction, and w_1, w_2 are the weights of three features.

4.2. HMM-Based Scoring Method. The competition using the HMM speech model is another alternative to speech competition, starting with voice, and hoping to see the difference between the experimental speech and the acoustic structure and the music and score words accordingly [19].

The flow of the scoring system is shown in Figure 10. Preprepared acoustic modeling and music modeling are used as the answer model using speech recognition technology, and the differences in speech test and models are identified and scored, working with the scoring mechanism [20–28].

The most common method based on the HMM model is to provide telephony. Procedures include logistics scores and postevent scores. Compared to comparison scores, the type of approach for some shows the learner's ability to speak rather than the data that influences the differences between learners and speakers. Its definition is as follows:

$$S_i = \sum_{t=\tau_i}^{\tau_{i+1}-1} \lg[P(q_t|q_{t-1})P(o_t|q_t)], \quad (20)$$

where O_t and q_t are the analysis vectors of phase t and state of HMM. The definition of a model is, then, the result of a change state; that is, A in the HMM model is the resultant distribution of the probe vector, which is B in HMM.

Scoring method for sentences is as follows:

$$s = \frac{\sum W_i S_i}{\sum W_i}, \quad (21)$$

where S is the sentence score, S_i is the sound score, and W_i is the weight song. The advantages of registration do not apply to data. After combining the advantages and disadvantages of the various dialing algorithms, the system uses an HMM-based phoneme-based probability algorithm as a call measurement method.

HMM Back Probability-Based Score: since speaking of sentences for elementary English students is also slow, speech speed should be increased as a significant impact on speech scores. Finally, the score of phoneme duration can be defined as follows:

$$D = \frac{1}{N} \sum_{i=1}^N \lg[p(f(d_i|q_i))], \quad (22)$$

where d_i is the duration of segment i corresponding to phoneme q_i and $f(d_i)$ is the normalization function. Considering the independence of text and speaker, the speech duration is normalized by the measurement of speech rate (ROS). ROS is the number of phonemes per unit time in a sentence or in all utterances of a speaker. Generally, $f(d_i) = \text{ROS} * d_i$ is taken.

4.3. Error Detection. After the recognition and scoring process of forced association of phonemes, MFCC eigenvalues get the corresponding associated phoneme string, phoneme start time and end time, and score. On the basis of these results, we began to detect phoneme errors. According to the results of the most phoneme like judgment, we can roughly divide phoneme reading errors into three categories: misreading, missing reading, and adding phonemes. Define the most phoneme like phoneme as the phoneme formula with maximum HMM likelihood:

$$q'_i = \arg\text{Max}[L_i(q)]. \quad (23)$$

$L_i(q)$ is the likelihood formula of any factor q in time period i :

$$L_i(q) = P(q|Q_i) = \sum_{t=\sigma_i}^{\sigma_{i+1}-1} [P(s_t|s_{t-1})P(o_t|s_t)]. \quad (24)$$

Missed phoneme: q_i is not pronounced, as in the following formula:

$$q_i = \begin{cases} q_{i-1} \\ q_{i+1} \\ \text{SIL} \end{cases} \quad (25)$$

Mispronunciation element: the pronunciation of q_i is so wrong that it sounds more like another pronunciation. It is expressed as q_{i+1} , and it is not a missed phoneme error. At the same time, it is believed that q_i is misread as q_i .

Adding phoneme: there are redundant phonemes in the phoneme recognition result.

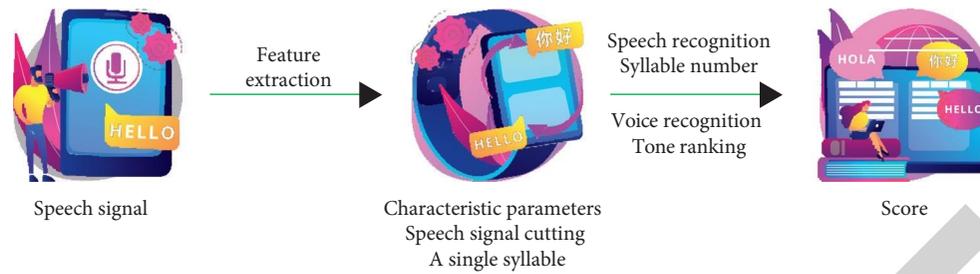

FIGURE 10: Flowchart of scoring system.

The results obtained by the correlator cannot distinguish the three errors. The error detection module can only locate the wrong phoneme according to the phoneme score. If it wants to go further, it needs to get the phoneme recognition results through the recognition process to determine which error it belongs to. Two error detection methods can be designed to meet the above different requirements.

If it is not required to detect the error type, the correlator can first evaluate the phoneme level correlation score of the speech and set the threshold value. When the corresponding phoneme score is lower than the threshold value, the phoneme will be classified as the wrong phoneme. If you need to detect specific types of errors, you need to add a phoneme recognition process.

4.4. Experimental Simulation and Result Analysis

4.4.1. Data Source. These lines use Arabic-language digital data installed in the UCI machine training library developed by the Automatic Alarm Laboratory of Baji-Mokhtar University. This data is called an Arabic number after the MFCC has resolved 13 conflicts in a total of 8800 dialog boxes (88 callers, 10 Arabic numerals, each number repeated 10 times). The call was made by 44 men and 44 women ages 16–40.

The content of this article is about 24 undergraduate students of our college, including 15 boys and 9 girls. The content is recorded using a 16 kHz, 16-bit encoding sampling program, CoolEdit. There are 10 written sentences, which are usually in English.

4.4.2. Recognition Rate Test. Acknowledgment level is the fact that the platform can accept user feedback. This is especially important because it is one of the most important measures in the performance of cognitive skills. On the platform, only the speech test module uses the speech experience. Therefore, only a test run of these models was conducted here to ensure that the training platform was able to recognize the English characters that had been developed in the past. In addition, the ambient noise makes it difficult to get the sound at the time. To perform the test, a sample library of recorded sounds was used in the experiment, namely, 3 true and 3 unrecorded sounds. To reduce the impact of ambient noise, a quiet room is the best place for this experiment. Table 1 provides information on platform level testing.

In the text above, 1 is true and 0 is incorrect. The above tips check if you know the phonetic symbols in English. In terms of acknowledgment, verbal analysis is a great way to measure the accuracy of speech and then learn the English depth of symbols combined with other functions of the platform. Therefore, based on the benefits of the accreditation level of speech screening, we can achieve the training benefits mentioned in this paper.

4.5. Speech Evaluation Experiment. In this paper, the correlation coefficient and the Pearson correlation coefficient are used to illustrate the relationship between the measurement technology and the measurement book.

Depending on the speech characteristics of college students who have different levels of English proficiency, we have different measures (movement, speed, tone, and music) and measured widely, as recommended by English experts. Levels of detailed information and related assessment models are shown in Table 2.

This book was reviewed by two college English teachers. They assessed 10 sentences of English speaking written by 24 high school students one by one, including 4 marks in music, fast, melodic, vocal music, and general measurement. Pearson correlation coefficient is used in this paper to evaluate the reliability of the book review results, because the content of the teachers during the book review will affect evaluation results.

To make it easier to calculate, the levels A, B, C, and D of the scale were changed to 4, 3, 2, and 1, respectively. Pearson's relationship analysis (two experiments) found that the scores of four measures, namely, noise, velocity, noise, and tone, were correlated ($r > 0, P < 0.05$) for each group, regardless of total scores. This suggests that both instructors can follow the same measurement standards during the test and measure the reliability of the test data.

In addition, the results of the two teacher evaluations were averaged (e.g., the average of students' scores on different sentences). The score is the end of the measurement book.

4.6. Inspection of Evaluation Indicators. The procedure described in this paper can measure volume, speed, and intonation of 240 samples in 10 sentences of 24 students. Test results are found in Tables 3 and 4.

TABLE 1: Speech recognition test results.

Test result	Test 1 Correct	Test 2 Correct	Test 3 Correct	Test 4 Error	Test 5 Error	Test 6 Error	Accuracy
<i>i</i>	1	1	1	1	1	0	0.98
<i>u</i>	1	1	1	1	1	1	1
<i>a</i>	1	0	0	1	1	1	0.56
<i>e</i>	0	0	1	0	1	1	0.73

TABLE 2: Artificial evaluation grade and evaluation standard.

Grade	Intonation	Speed of speech	Rhythm	Intonation	Population
A	Complete and correct content, clear and fluent pronunciation, no obvious pronunciation error	Moderate speaking speed	Accurate accent pronunciation, strong sense of rhythm	Accurate and natural intonation	Excellent pronunciation
B	Relatively complete and accurate content, relatively clear and fluent pronunciation, no serious pronunciation error	Speak a little fast (slow)	More accurate accent pronunciation, with a good sense of rhythm	Accurate and natural intonation	Good pronunciation
C	Basically complete and correct content, basically clear and fluent pronunciation, pronunciation errors that affect understanding	Speaking fast (slow)	Ordinary accent pronunciation, with a certain sense of rhythm	Basically accurate intonation, but not natural enough	General grasp of pronunciation
D	Incomplete and accurate content, pronunciation not clear and fluent, and serious pronunciation errors that affect understanding	Speaking too fast (slow)	Accent pronunciation error, too many (less) accents, poor sense of rhythm	Inaccurate and unnatural tone of voice	Poor overall pronunciation

TABLE 3: Evaluation index test results: number of samples.

Index number of samples	Consistent	One-level difference	Two-level difference	Three-level difference
Intonation	206	32	2	0
Speed of speech	197	43	0	0
Rhythm	204	33	3	0
Intonation	193	45	4	1

TABLE 4: Evaluation index experimental results: statistical index.

Index difference level	Consistency rate (%)	Adjacent consistency rate (%)	Pearson
Intonation	87.25	99.58	0.7
Speed of speech	82.08	100	0.493
Rhythm	85.00	98.75	0.543
Intonation	81.00	98.34	0.627

For intonation testing, there were only 207 models with the same level of measurement technology, manual measurement, one-level difference, two-level difference, and no three-level difference. This shows that the machine and manual ratios have a correlation of 87.25%, the adjacent coefficient is up to 99.58%, and the Pearson correlation coefficient is 0.7, indicating that the method in this article is reliable.

For speech speed measurement, there were 197 models at the same level of measurement technology and manual test, 43 models with one-level difference, and two or three with different levels. This shows that the machine and manual speed correlation coefficient are 82.08%, the correlation

coefficient is up to 100%, and the Pearson correlation coefficient is 0.493, indicating the reliability of the velocity measurement.

In terms of test results, there were 204 models of the same stage of machine testing and test manual, 33 models with one-stage difference, and only 3 models with two stages difference, without three-stage difference. This means that the accuracy levels of the machine and manual assembly are as high as 85%, the relative safety rating is as high as 98.75%, and the Pearson correlation coefficient is 0.543, indicating that the measure of consistency is reliable.

For sound analysis, there were 192 models of the same level of measurement machine and manual test, 44 models

with one-level difference, and only 4 models with two-level difference, no three-level difference. This shows that the machine and the manual correlation coefficient are 81%, the cohesive position is 98.34%, and the Pearson correlation coefficient is 0.627, indicating that the correction of this is reliable. In conclusion, the language, speed, atherosclerosis, and intonation assessment methods used in this article are reliable and can be used to improve the English language standard.

5. Conclusion

According to the English pronunciation habits of Chinese people, this paper studies and establishes a targeted corpus. Combined with the needs of Chinese speaking learners, it explains and compares the relevant technologies at each stage in the processing of users' voice. In the speech endpoint detection phase, this paper uses a combination of short-time zero-crossing rate and short-time energy to detect the endpoint of speech. In the speech comparison phase, this paper uses the improved DTW algorithm to recognize the speech similarity. Compared with the traditional DTW algorithm, it speeds up the recognition time and speed, and the recognition effect is better.

The HMM-based phoneme probability algorithm is ideal. It is not easy to change due to changes in students' personal characteristics or sounds and better to show similarities between students' words and speech patterns. HMM-style speech recognition technology is used to determine Viterbi's language, and acknowledgment scores are made with subsequent results. Speech scores based on comparisons and patterns will appear to be studied using techniques such as decomposition of feature parameters, forced coupling, and dynamic distortion time, and some scores mechanisms were studied and their numbers were included in the experiment.

This paper examines the English-speaking skills of college students in China as educational materials, improves the process of measuring the computer English proficiency, and measures various elements such as music, pace, and melody. We performed speed measurement according to the time of speech of the different characteristics of the frequency, noise measurement as a measure of the energy of the short time and the combination, and sound measurement according to the basic frequency. The results of the experiment show that the melody, tempo, rhythms, and musical measurements used in this article are reliable. In addition, taking into account the weight of the above measurements, the retrospective measurement has developed a model for the appropriate measurement and objective of the quality of the quotation. The results of the experiment show that the standard English proficiency test in this article is reliable. It provides students with timely, accurate, and objective analysis and instructional strategies and assists students in identifying differences in their speech and speech patterns, correcting their mispronunciation, and improving the effectiveness of teaching English.

Data Availability

The dataset can be accessed upon request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

With the development of mobile communication technology and the popularization of mobile devices, the connection between people has become increasingly close, the data circulating between them have increased rapidly, and the multidimensional space-time characteristics have gradually entered the stage of the times. The proposal of the basic smart city system is a revolution in the concept of urban construction. A smart city is both an opportunity and a challenge for the urbanization process. By analyzing the multidimensional spatiotemporal feature engineering, this paper studies the development trend of smart cities and discusses how multidimensional spatiotemporal features play a fundamental role in the smart city system.

1. Introduction

The rapid development of today's science and technology, the popularization of the Internet, and the introduction of the Internet of Things have greatly increased people's demand for data transmission. At the same time, the construction of the mobile Internet has increased the number and scale of data transmission. With the development of information technology, the pace of urban informatization has been accelerated, and the level of urbanization has been further improved. Subsequently, urban problems such as environmental pollution, low urban management efficiency, unreasonable industrial structure, and traffic congestion have emerged. In order to solve the increasingly serious urban problems, the construction of smart cities has long been put on the agenda, and it is the application of multidimensional spatiotemporal features that provide the basic conditions [1]. This paper briefly introduces the smart city system and describes the application of multidimensional spatiotemporal features in smart cities with the help of examples. The purpose of multidimensional space-time feature engineering is to develop new or comprehensively utilize existing technologies to process multidimensional space-time features, so as to carry out planning, construction, and operation management of multidimensional space-

time features. The research on multidimensional spatiotemporal characteristics is divided into processing analysis and secondary development. By analyzing this huge amount of data, a lot of hidden information can be discovered, and deep-level information can be mined, so as to propose a processing plan that adapts to the actual situation; dimensional spatiotemporal features carry out operations similar to businesses accepting consumer feedback, adjusting products, and engaging in operation management, so as to achieve their goals. The basis of smart city systems is multidimensional spatiotemporal feature engineering. The development of multidimensional spatiotemporal features affects the construction, development, and operation of smart city systems [2].

There is no doubt that man is wise. Let the city, an inanimate body, be as intelligent as a human being and be able to solve urban problems by itself. This is the construction of a smart city. The construction of a smart city includes many aspects such as government affairs, transportation, medical care, and security. It requires the support of various information technologies such as multidimensional space-time features, cloud computing, and artificial intelligence. It also requires the construction and improvement of infrastructure [3]. A smart city is a new form of urban development in contemporary society, which is of

great significance for improving the government's service and management capabilities, promoting the upgrading of industrial structure and the gathering of knowledge-based talents. The new smart city is characterized by openness, co-construction, and sharing and is committed to achieving equalization of services, eliminating the information gap, and promoting the construction of urban characteristics. The construction and development of smart cities revolves around multidimensional spatiotemporal characteristics. A "smart" city is like a smart person. On the premise of having a complete infrastructure, it should extensively collect information and resources from all aspects of society and analyze and process them, so as to form various complete databases. On the basis of perfect data resources, through the use of advanced information technologies such as the Internet of Things, cloud computing, and multidimensional space-time features, various application platform systems are built to achieve effective prediction and monitoring of economic and social affairs and to assist leaders in making scientific decision-making and improve the management level of the city, so as to provide the public with more intelligent services [4]. During the whole operation process of the city, new data resources will be generated and perceived by the city, which will further promote the improvement of the database and the improvement of processing capacity, thus forming a closed virtuous circle. It can be seen that multidimensional spatiotemporal features play a fundamental role in the construction of smart cities. The building equipment monitoring system is an important part of the intelligent system of the smart community. As the name suggests, the building equipment monitoring system is built for the unified management and monitoring of different equipment in the building, including electrical equipment, HVAC equipment, water supply, drainage equipment, and special equipment [5].

The working principle of the system is as follows: data information is received from various sensors, so that the property can comprehensively and intuitively understand and grasp the operation status of different equipment in the building. For example, according to the pictures taken and transmitted by the camera, we can know whether anyone needs to use the public entertainment area and judge whether the lighting equipment in the area needs to be turned off or whether the temperature of the central air conditioner needs to be adjusted; with the information, judge the actual operation of the power transformation and distribution system and make adjustments in time; and according to the repair and maintenance dates of the equipment in the building, the property management can make appointments for professionals in time. After the system is completed, the information collection, centralized management, and control of all equipment in the building can be realized through the system. Such equipment management and control mode are conducive to the rational allocation of human, material, and other resources and can also save community public resources, thereby improving the energy conservation and environmental protection of smart communities. At the same time, the building equipment monitoring system can be used to realize the timely

and accurate understanding and mastery of the energy consumption of different equipment in the building and provide effective reference information for the reasonable formulation of property energy use indicators and employee KPI indicators [6]. In the smart community, the video intercom system can provide voice and video transmission services for properties and residents, residents and visitors, and visitors and properties. At present, the video intercom system has been used more and more in the construction of smart communities. Many video intercom systems can not only transmit signals to the property owner but also connect with gas alarms, smoke alarms, etc., so that even when the resident is not at home, the property owner can timely discover the hidden safety hazards in the house and realize correctly. Effective control of the risk of household property loss is also conducive to simplifying the property management process and improving the quality of property services. When planning and designing the video intercom system, the property terminal should be installed at the property, the household terminal should be connected to each household, and the visitor terminal should be installed at the public entrance of each residential building [7].

2. Research Method Design

The design of this research method is divided into four parts: data analysis and acquisition, data cleaning and screening, multidimensional big data information fusion, and smart city flow spatiotemporal distribution design. The research technology roadmap is shown in Figure 1.

2.1. Data Acquisition. Frequently used software applications were found through offline questionnaire surveys, such as Weibo check-in, Douyin location sharing, and Mafengwo travel notes, and then the data were divided according to the software characteristics, such as the Weibo check-in data structure contains a user ID, check-in time, check-in location, and other information. Finally, use web crawlers to collect the information generated by tourists using popular software functions near POIID according to keywords, and form an initial data set according to the divided data structure standards for several months [8].

2.2. Data Cleaning. Since the initial data set consists of comprehensive and noncustomized data, which contains a lot of useless data, in order to ensure the scientificity and accuracy of the results, the initial data set needs to be fully cleaned before it can be applied to subsequent analysis [9]. In the data cleaning and screening stage, the deletion method, regression method, mean smoothing method, etc. can be used to preprocess the data first. On the one hand, it can solve the problem of missing data, and on the other hand, it can remove the noise in the initial data. First, data cleaning and screening standards were formulated, then many parameters were obtained through small-scale on-the-spot investigation, and a statistical model was established to perform data mining on the spatiotemporal information in the data and identify tourist groups. Then, according to the

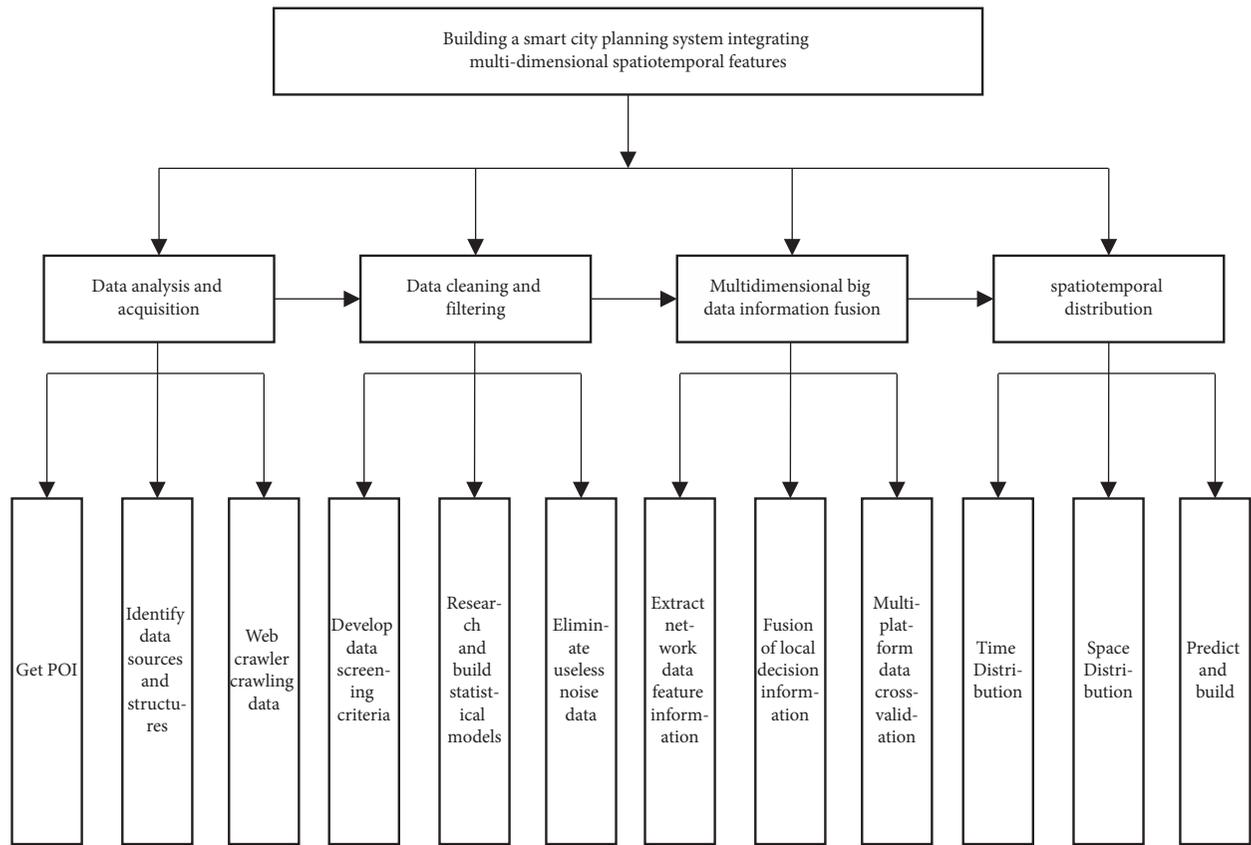

FIGURE 1: Technology roadmap.

user attribute characteristics, unclear geographical source, incomplete information, and the months with incomplete data or fewer data are excluded, and the final remaining data are used as the data basis of this study [10].

2.3. Multidimensional Big Data Information Fusion. Multidimensional big data information fusion has very important value and significance in the era of big data. In the study of smart city flow, there are often more than one factor that affects the spatiotemporal distribution characteristics of smart city flow, so using different data sources can provide important information from different sides and improve the accuracy of data and the reliability of results [11]. D-S or evidence theory, neural network, and other algorithms can be used to integrate and analyze the characteristic information extracted from the data of Weibo, Douyin, and other network platforms and further evaluate or infer the local decision information obtained by further mining the value of the data in order to enhance the role of information and, finally, conduct interactive verification of data on different platforms to exclude abnormal points, improve the confidence of data results, and prevent decision-making mistakes [12].

2.4. Space-Time Distribution Design. This method first integrates the information based on multidimensional big data and uses the time stratification method and software

frequency index to analyze the seasonal, intra-month, intra-week, and intra-day time distribution characteristics of urban smart cities in the flow; then using GIS spatial analysis and kernel density methods, the spatial distribution characteristics of urban smart city flow, such as the “seasonal change” map of urban smart city flow core density and the smart city flow core density map of different attributes, were visualized. A statistical model was established for the analysis of spatial and temporal distribution characteristics of urban smart city flow and a general smart city flow research model to help researchers, city governments, or smart city enterprises re-understand the source market, develop smart city resources in a targeted manner, and design smart city products and smart city lines [13].

3. System Model Construction of Smart City

Models are the most important and most basic tools for studying systems. In order to express the characteristics, properties, or laws of motion of a certain aspect of the entity, the model abstracts the characteristics of the entity at a certain level and expresses them in a certain structural form, so as to help people better understand the characteristics of the object, predict changes, and control the operation or structural design. A system model is a description of the essential properties of a certain aspect of a system, which provides knowledge about the system in a certain form (such as words, symbols, diagrams, and mathematical formulas). A

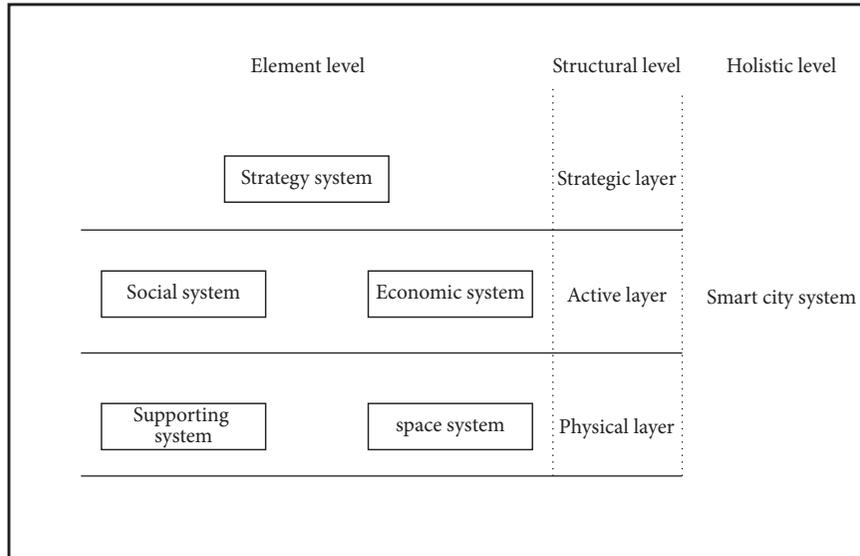

FIGURE 2: Schematic diagram of the elements and structures of the smart city system.

system model is a description, imitation, and abstraction of a real system. It consists of main factors that reflect the nature or characteristics of the system, and it embodies the relationship between these main factors [14]. This part will build a system model of a smart city based on the relevant theories of complex systems, combined with the previous analysis of the elements and structures of the smart city system.

3.1. Smart City System Based on Communication and Control Laws of Complex Open Systems. It can be seen from the above analysis that the smart city system is composed of five subsystems—strategic system, social system, economic system, support system, and space system—as well as three layers—strategic layer, activity layer, and physical layer. From the perspective of the hierarchy of the system, the five subsystems have different degrees of complexity, and the corresponding relationship between the five subsystems and the three levels is shown in Figure 2. As can be seen from the figure, from the structural level, the smart city system is composed of three complex levels: the physical layer, activity layer, and strategic layer; and from the element level, the support system and spatial system of the smart city system are located in the physical layer, the social system and the economic system are located in the activity layer, and the strategy system is located in the strategic layer.

This is how, in the smart city system, the three layers and the five subsystems are organized and connected.

The communication and control rules of the system are important mechanisms for maintaining complex open systems to withstand environmental shocks. In complex systems theory, another group of concepts equally important as the classification and hierarchy of the system is the communication and control of the system, i.e. the maintenance of the system level requires a series of information exchange processes for regulation or control. In other words, a hierarchy of open systems must require communication

and control processes if the system is to survive the shocks dictated by the environment. In a complex system, control is an active action of the controlling subject on the controlled object. The controlling subject obtains, processes, or uses the information to make the controlled object act according to the predetermined purpose of the controlling subject and guide the object to the predetermined purpose [15]. In the control theory of complex systems, according to Ashby's Law of Necessary Diversity, the diversity of controllers must be equal to or greater than the diversity of controlled persons, that is, the diversity and complexity of the "organizational management" performed by the controlling subject must be equal to or greater than the "operational activities" carried out by the controlling subject to achieve the purpose, and the diversity and complexity of "operations" must be equal to or greater than the "objective environment" represented by the controlled object [16].

Corresponding to the smart city system, in order to achieve the purpose of building a smart city by smart city builders, the development strategy and the implementation measures formulated by the builders (control subjects) must be more complex and advanced than the activities of people in the smart city system. The material environment, likewise, the complexity, and the advanced level of human activities must be greater than the material environment faced by the smart city system, so as to effectively realize the transformation of the material environment. At the same time, in order to cope with the diverse changes in the environment, human activities at the active layer also need to play the greatest active role in a certain autonomous way. If the strategic layer restricts the diversity of people's activities in the active layer too much, it will make it difficult for the smart city system to adapt. If the changes in the environment are not well controlled, the development of the system will go with the flow, and the goal of smart city construction will not be achieved [17]. Based on the above analysis, the corresponding relationship between the three levels of the

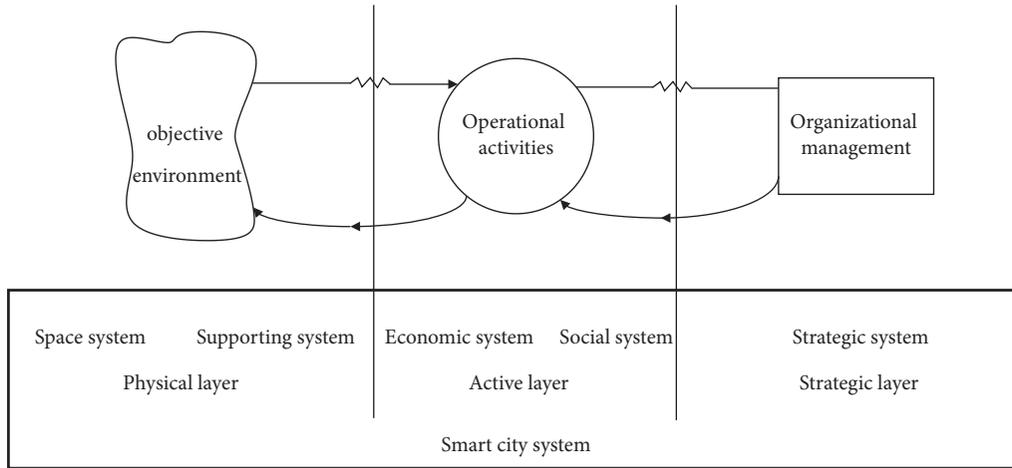

FIGURE 3: Relationship between the elements and structures of the smart city system and the communication and control of the complex system.

smart city system and the control and communication of the complex system is shown in Figure 3.

3.2. *Smart City System Based on Viable System Model.* The communication and control relationship between the three levels and five subsystems of the smart city system can be further analyzed using the viable system model (VSM).

In order to further understand the survival principle governing complex organizational behavior, Bill established a living system model formed by five subsystems connected according to certain communication and control laws, as shown in Figure 4. The model connects the five subsystems through a composite of information and control loops. The survival system model composed of the five subsystems through interconnection and interaction shows various control laws and conditions that are necessary to support the healthy operation of a complex system [18].

In the smart city system, the vital system model reveals the communication and control laws of different subsystems and different system levels of the smart city system.

There is a specific connection between the five subsystems and the three levels of the smart city system and the five subsystems of the living system model and the environment in which the five subsystems act:

- (1) The external environment that is “System 1” in the living system model acts on correspondence to the physical layer of the smart city system. The “overall environment” in the physical layer is the space system of the smart city, which is the accommodation place for people to carry out various activities, has certain physical characteristics, and is reflected in the smart city as an intelligent flow space [19]. The “local environment” in the physical layer is the support system of the smart city. It builds corresponding to smart application systems in different functional areas of the city with emerging information and communication technologies and information infrastructure within a certain spatial

range. In a smart city, these intelligent application systems have become the material and technical carriers that people rely on to carry out various smart forms of economic and social activities. At the same time, in the physical layer, it is precisely because of the extensive application of a large number of intelligent application systems established in the support system that the “overall environment” of the original material from in the space system begins to become intelligent and fluid. The flow space of urban space has brought the decentralized and network development of the physical form of urban space [20].

- (2) “System 1” in the living system model, as well as the adjustment activities of “System 2” and the management and audit activities of “System 3,” which are related to the implementation and operation activities of “System 1” themselves, all correspond to the smart city system’s active layer. In a smart city, according to the different types of people’s activities, the implementation and operation activities of “System 1” can be mainly divided into seven major activities: social and cultural activities, public administration activities, social interaction activities, production activities, circulation activities, consumption activities, and innovation activities. These different types of activities are guided, constrained, and controlled by the corresponding aspects of strategy execution and implementation from the strategy layer. The implementation of the strategy at the strategic level, on the one hand, in accordance with the planning and content of the strategic plan, combined with relevant resources such as funds and talents, organizes and manages the development of the above activities in seven aspects, provides necessary services, and conducts regular assessments to ensure verification of the degree of the intellectual development of different types of activities; on the other hand, it regulates and constrains people’s

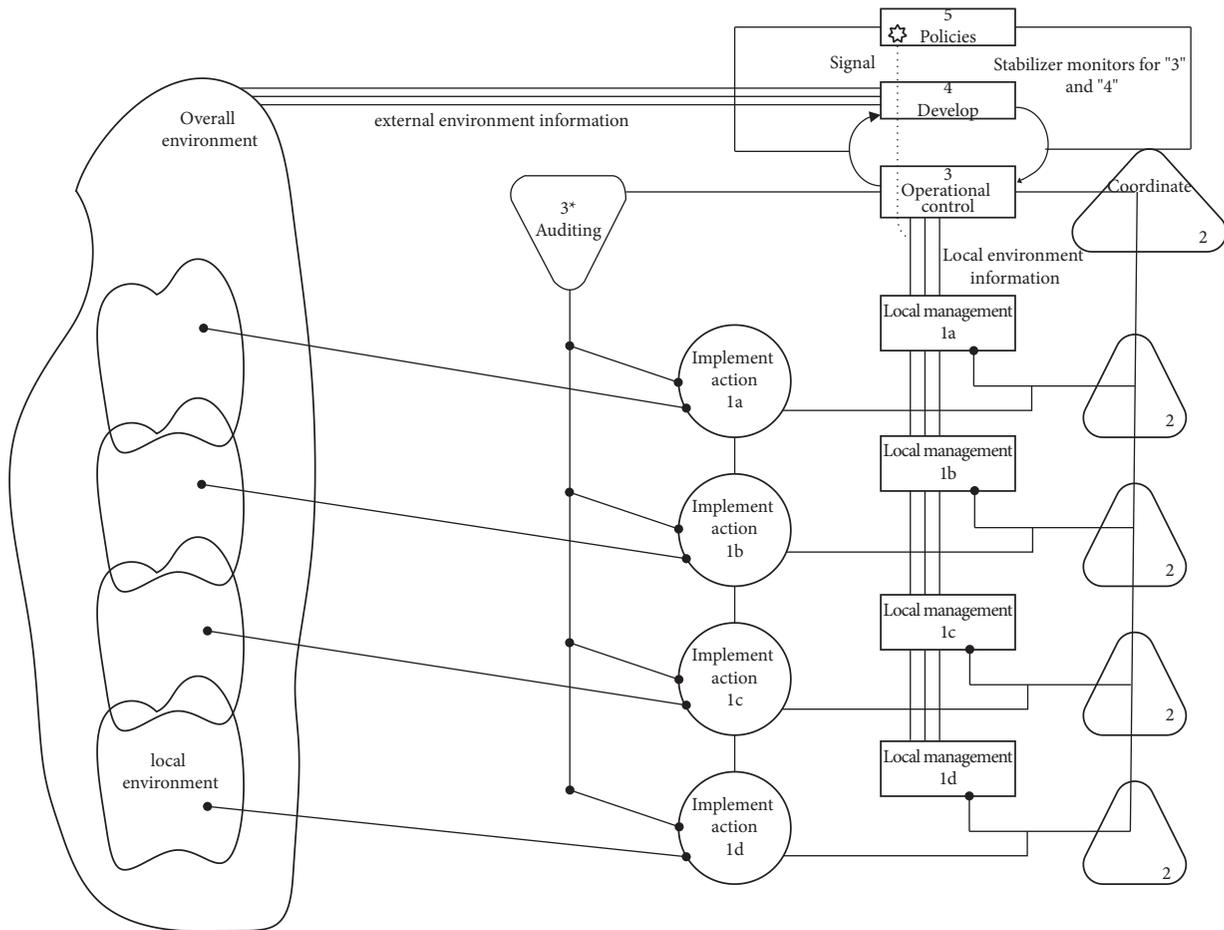

FIGURE 4: Living system model.

various economic and social activities through the supporting policies and regulations, technical standards and specifications, information security requirements and institutional innovation rules in the implementation of strategic planning, so as to ensure that each coordination of class activities. The above seven types of social and cultural activities are integrated with the guidance, restraint, and control from the implementation of the strategy to form a social and cultural system, public administration system, social relationship system, production system, circulation system, consumption system, innovation system. The corresponding economic and social subsystems such as the system, and the corresponding subsystems are further combined to form a social system and an economic system [21].

- (3) "System 2," "System 3," "System 4," and "System 5" in the VSM together correspond to the strategic layer of the smart city system. Among them, "System 2" and "System 3" correspond to the "strategic implementation" of the smart city system strategic layer, "System 4" corresponds to the "strategic research" of the smart city system strategic layer, and "System 5" corresponds to the smart city system "strategic planning" at the strategic level. The strategy

implementation that exerts the control function of "System 3" is connected with the strategic plan corresponding to "System 5." On the one hand, it is accepting and interpreting the basic plan for smart city development in the strategic plan, and on the other hand, it is related to the economic and social situation of the people in the activities. Activities are connected to guide, control, and constrain people's economic and social activities in accordance with the requirements of strategic planning. "System 2" is also an integral part of strategic implementation. As mentioned above, it regulates people's economic and social activities in accordance with policies and regulations, technical standards and specifications, information security requirements, and institutional innovation rules that support and guarantee the implementation of strategic planning. "System 3" jointly ensures the implementation of the strategic plan. The strategic research that exerts the development function of "System 4" fully analyzes the internal and external environment faced by the development of the smart city system through relevant basic research, special research, and case studies and provides necessary information support for the strategic planning and implementation of the

smart city. The strategic planning that exerts the policy function of “System 5” indicates the direction and path for the development of the smart city system by describing the strategic vision of smart city development, formulating strategic goals and strategic tasks for smart city construction, and clarifying the strategic focus of smart city construction, so as to ensure that the smart city system can develop into a city system with “smart” characteristics [22]. It can be seen that the strategic layer and the strategic system are the core of the smart city system, which establish the communication and control mechanism of the entire smart city system and promote the city system to continuously move towards a “smart” city system.

It can be seen that the living system model realizes that different parts of the organization and the entire organization operate according to their own goals through appropriate information flow and communication chain. The operation and development of smart city systems also follow these communication and control laws.

3.3. System Model Description of Smart City

3.3.1. Corresponding Relationship between the Elements and Structures of the Smart City System and the Conceptual Connotation of the Smart City System. The smart city system is an urban system with the characteristics of “smart” formed by the coupling and effect of the intelligence of information technology and the intelligence of people and the urban system. From the analysis of the conceptual connotation of the smart city system above, it can be seen that in the formation and operation of the smart city system, the first is the combination of emerging information technology and the city subsystem to build an intelligent city subsystem, and then the human wisdom and intelligence. The intelligent urban subsystem is combined to form a smart urban subsystem. Finally, human wisdom is combined with various intelligent urban subsystems and smart urban subsystems to build a smart urban system. At the same time, it can be seen from the previous analysis that the smart city system is composed of five subsystems: strategic system, social system, economic system, support system, and space system and also how they reflect the wisdom of people in the smart city system and the intelligent city subsystem and the connection and combination of smart city subsystems.

From the relevant analysis of the elements and structures of the smart city system, it can be seen that the smart city system is composed of three layers: the strategic layer, the activity layer, and the physical layer, and five subsystems: strategic system, social system, economic system, support system, and space system, which are interconnected, interact, and jointly build a smart city system with “smart” characteristics. In the smart city system, the support system and the space system are located at the physical layer, which is the result of the intelligent transformation of the original urban material elements and material forms by emerging information and communication technologies. They are all

intelligent cities with intelligent application systems as the core subsystem. Therefore, the support system and the space system correspond to the intelligent urban subsystems in the smart city system. The social system and the economic system are located in the activity layer, which mainly reflects the intelligent form of people’s economic and social activities. They are constructed by people with the ability to “cognition, judgment, analysis, and action” using information technology under the support of the support system and the space system. Various forms of activities carried out by the intelligent application system and related activities are integrated into the intelligent city subsystem. Therefore, the social system and the economic system correspond to the smart city subsystems in the smart city system. The strategic system is located at the strategic layer. It formulates smart strategic planning with human “insight, foresight, and wise response,” and plans, organizes, guides, and coordinates the construction of smart city subsystems and the development of smart city subsystems. In turn, a more scientific and reasonable development model emerges in the entire smart city system to realize the “smart” development of the entire city [23]. Therefore, the strategic system corresponds to a good combination of human intelligence, intelligent city subsystem, and smart city subsystem in the smart city system.

3.3.2. System Model Design of Smart City. The system model of the smart city is the description, imitation, and abstraction of the smart city system, and it describes the relationship between the elements of the smart city system in a certain structural form. According to the three levels of the smart city system structure and the relationship between the five subsystems, this paper constructs the smart city system model shown in Figure 5. It can be seen from the figure that the system model of a smart city is composed of three layers: strategic layer, activity layer, and physical layer, and five subsystems: strategic system, social system, economic system, support system, and space system. The strategic system is located at the strategic layer, which is at the highest level of the smart city system; the social system and economic system are at the activity layer that is at the middle of the smart city system, and the support system and space system are at the physical layer that is at the bottom of the smart city system. At the same time, the strategic system, social system, economic system, support system, and space system are all interrelated, interactive, and interdependent [24].

The formation, operation, and development of the smart city system are revealed through the interconnection and interaction between the five subsystems in the three layers. Specifically, the formation, operation, and development of the smart city system are realized by the relationship and function of the five subsystems from high to low complexity [25]. Among them, the strategic system is the soul and core of promoting the entire smart city system to present “wisdom”: the construction of information network infrastructure, intelligent application system, and public information platform in the system; the formation of highly intelligent flow space and scientific and rational spatial development pattern in the

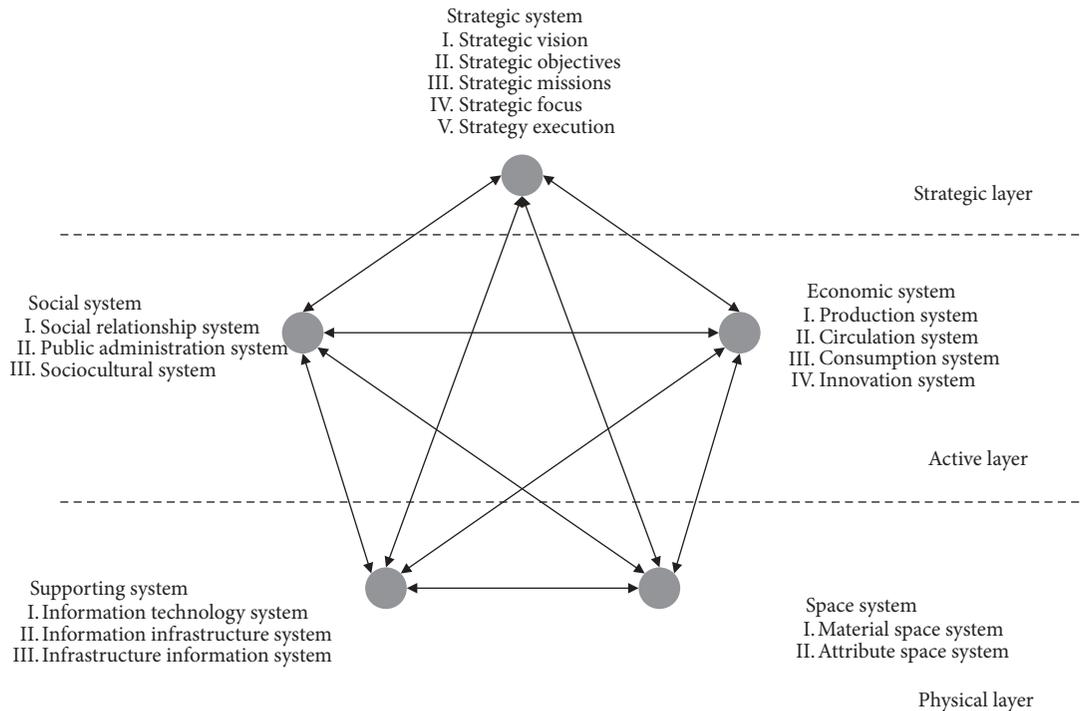

FIGURE 5: Schematic diagram of the system model of a smart city.

space system; and the social environment in the social system that is more in line with the needs of modern people's survival and development. On the other hand, the strategic system realizes the social system, economic system, support system, and spatial system through its restraint, control, and adjustment functions; coordinates and balances development; and then promotes the continuous optimization of the entire urban system. The social system and the economic system are closely related to human activities, and they are the most dynamic and creative system components in the smart city system. Under the guidance and regulation of the strategic system, as well as the support of the support system and the space system, the social system creates a good social environment and conditions to promote the all-round development of human beings. The economic system lays a solid material foundation for the all-round development of human beings by creating more diverse and rich material living conditions and environments, thus creating a social and economic environment in the city that is more in line with the development needs of modern people. The support system and the space system are closely related to the material elements in the city. They are formed in the deployment and implementation of the strategic system and provide the material basis and support place for people's economic and social activities in the smart city. Social activities provide technical and material support, and the space system provides resources, environment, and support sites for people's economic and social activities. It can be seen that the support system and the space system jointly build the basic conditions that are more in line with the needs of modern urban operation and development.

4. Conclusion

In this rapidly developing information age, opportunities and challenges coexist. The combination of informatization and urbanization is inevitable, and so is the construction of a smart city system. Firmly grasp the technical foundation of "multidimensional space-time characteristics" and reasonably solve the problems of security and privacy are of great importance to the construction of smart city systems. In terms of building a smart city, my country has lagged behind for a period of time, with insufficient infrastructure construction, and is competing with many developed countries. It must vigorously develop multidimensional space-time characteristics to solve difficulties and come first. My country's smart city construction should be designed and planned according to local conditions, combined with its own original characteristics, based on multidimensional space-time characteristics, comprehensive use of various science and technology, and strong strategic support to bring urban construction to a new height.

At present, the pouring riser of valve castings is mainly removed by manual cutting, polluting the environment and causing harm to the human body with a low efficiency. Therefore, an automatic cutting pouring riser method using the stereo vision system and manipulator is proposed. The relative position of the valve casting and the end of the manipulator is obtained through the position transformation of the valve casting coordinate system, the manipulator end of the coordinate system, and the camera coordinate system. The spatial motion trajectory of the manipulator is planned, implementing automatic pouring riser cutting of the same valve casting with the same pose. The experimental results show that the position deviation and the angle deviation of the repetitive positioning accuracy and the random positioning accuracy of the visual system are within ± 1 mm and $\pm 1^\circ$; in the pouring riser cutting test, the maximum deviation between the actual cutting trajectory and the theoretical cutting trajectory is 3 mm. In summary, the method shows a good reliability and could meet the requirements of cutting accuracy.

1. Introduction

As a control unit to control medium flow in the pipeline conveying system, the valve which is widely used in petroleum industry, chemical industry, metallurgy, electric power industry, etc., can change the channel section and medium direction to realize the diversion, globe, throttle, check, or the overflow pressure relief, and other functions. Because of the complexity of its internal structure, the major part of valve blank is manufactured by casting [1–4]. The pouring riser which is inevitable in the cast process should be cut out as “excess” for subsequent machining. At present, the pouring riser is cut with a hand-held abrasive cutting machine basically which has high labor intensity and low efficiency [5–7]. Large amounts of metal dust and smoke from cutting process float in the air and cause environmental pollution. In addition, the cutting staff who breathe these kinds of dust is likely to suffer from occupational diseases, such as pneumoconiosis, and this has a negative influence on the social image of enterprises [8–12]. Therefore, it has

become an urgent problem for the valve manufacturers to develop an automatic cutting method and equipment for cutting pouring riser.

With the development and advancement of the industrial robot technology, the robot is gradually used to cut the pouring riser of the valve and other castings. At present, the common way is to clamp the casting onto the mechanism. Cutting tools, such as cutting disc and flame cutter, are installed at the end of the robot. The cutting trajectory is determined by teaching; then, the robot is controlled to move to finish the cutting according to the teaching trajectory. The advantage of this method is that one teaching track could be called for cutting the same casting theoretically. However, in practice, due to the complex shape of blank parts, it is difficult to determine a coarse datum to improve positional accuracy, resulting in overcutting or undercutting. In addition, enterprises would bear a huge manufacturing cost of positioning and clamping devices for different castings. Thus, large time cost for track teaching causes a lower efficiency and cannot meet the production requirements of enterprises.

In summary, developing a universal positioning method and fixture for valve casting is of great significance. Furthermore, the positioning device of valve casting should meet the following two requirements: (1) for different types of valve castings, the same positioning method and device can be fixed on the same positioning clamping device, and (2) for the same valve castings fixed on the clamping device in the same position and attitude, the pouring riser cutting will be completed using the same teaching program after track teaching.

This paper discusses the positioning method and system for automatic cutting pouring riser of valve castings by an integration of machine vision, robot, network communications, artificial intelligence, and information processing technology [13–16], to achieve the same body in the same position, and the posture is clamped on the automatic cutting equipment, with the same program to complete the same valve pouring riser cutting, which laid a foundation for automatic cutting of the pouring riser and solved the urgent problems faced by enterprises. The research and development work has broad application prospects, which can significantly improve the economic benefits of foundry enterprises and achieve good social benefits.

2. Positioning System Composition

The positioning system mainly includes the following: 6-DOF industrial robot, 4 high-precision industrial infrared cameras, computer, positioning disc, and flange. Robots, industrial cameras, and computers are connected to switches to form industrial Ethernet, which uses the TCP/IP protocol for communication.

The positioning disc is positioned and mounted to the end of the robot with the flange. The end of the robot is a flange structure, the end face has a pin hole and a stopper, users can achieve their own process equipment or precise positioning between the actuator and the robot by the pin hole and fixing structure; in addition, there are 8 bolt holes on the end face to facilitate the user to install and fasten the positioning fixture to the robot. The corresponding pin hole and convex platform are designed on the flange plate, the convex platform is loaded into the stopper, and then the pin is installed into the pin hole of the flange and at the end face of the robot to position the flange precisely on the robot. Another pin hole is processed in the center of the flange, and then there are two pin holes on the flange. The positioning plate is processed with two pin holes which are corresponding to the flange plate, and four bolt holes are processed in the circumferential direction and installed on the flange plate after positioning.

When the system is working, we place the body casting into the work space at first and then place three marker balls on the circular convex platform; an infrared camera would measure the coordinates of the marker ball in the camera coordinate system, and a computer would calculate the motion parameters of the robot according to the coordinates of the three marked balls; the robot takes the positioning plate and moves to the top of the body casting according to the parameters (for the same valve castings,

the position and attitude relationship between the positioning plate and valve body should be fixed. In this way, the positioning clamping device on automatic cutting equipment can be ensured with the same position and attitude). After positioning, the operator connects the body casting to the positioning plate by the welding steel for its subsequent installation and positioning on the cutting equipment.

The crucial problem is to solve the motion parameters of the robot according to the position and attitude of the valve casting, to ensure that the position and attitude between the positioning plate and the valve are within the specified deviation range after the same valve robot moves. In this paper, coordinate transformation is used to solve this problem. More detail about the principle of positioning and the method of solving robot motion parameters will be presented in subsequent paragraphs.

3. Positioning Principle and Algorithm

Four coordinate systems ((C), (R), (V), and (P)) are, respectively, fixated on the camera, robot, valve casting, and positioning plate. The main function of the system is to drive the positioning plate from the initial position to move to the upper part of the body and keep it in a fixed attitude relationship with the valve. For the coordinate system, we make the xoy plane of the positioning plate coordinate (P) parallel to the xoy plane of the valve coordinate system (V), the z-axis must coincide, and the origins differ by an adjustable height H. In order to calculate the robot motion parameters to achieve the position and attitude relationship, the transformation relationship between the body coordinate system and the robot coordinate system needs to be established. The following describes how to achieve this principle and model by establishing the transformation relationship between coordinate systems to calculate the motion parameters of the robot.

3.1. Establishment of the Camera Coordinate System (C). The camera system is a multicamera stereo vision system [17–29] composed of 4 infrared cameras, which can measure the object's coordinates in 3D space. Calibration software and calibration devices are provided by the manufacturer. After the camera is installed and the working space is determined, the establishment of camera coordinate system (C) can be quickly completed according to the manufacturer's instructions and software. The establishment process will not be described in detail in this paper. The camera coordinate system (C) is the bridge to link other coordinate systems, the establishment and the transformation relationship of the other coordinate systems are realized by establishing the transformation relationship between the body casting coordinate systems (V) and (C), the transformation relationship between the robot coordinates (R) and (C), and the transformation relationship between the location plate coordinates (P) and (C). The motion parameters of the robot are calculated according to these transformation relations.

3.2. *Transformation Relationship between the Body Casting Coordinate System (V) and the Camera Coordinate System (C).* Three circular convex platforms are casted according to design reference, on which are placed the reflective marking balls A, B, and C; the midpoint of the connection between A and B is O_V , and we make sure that $CO_V \perp AB$ when casting. The coordinates of the three reflective marker balls in camera coordinates were obtained by camera shooting, which were, respectively, denoted as

$$A = \begin{bmatrix} x_A^C \\ y_A^C \\ z_A^C \end{bmatrix} B = \begin{bmatrix} x_B^C \\ y_B^C \\ z_B^C \end{bmatrix} C = \begin{bmatrix} x_C^C \\ y_C^C \\ z_C^C \end{bmatrix}. \quad (1)$$

When the valve casting coordinate system (V) is established, O_V is the origin of coordinates, vector AB is the x -axis, the normal vector of the plane formed by A, B, and C is z -axis, and the y -axis is determined according to the right-hand rule.

The body casting coordinate system (V) can be regarded as the coordinate system which coincides with the camera coordinate system (C) after rotation and translation. Rotation is the change of attitude, which can be represented by a 3×3 rotation matrix, denoted by ${}^C_V R$; translation is the change of the origin, which is represented by a vector of 3×1 , and the origin of the valve casting coordinate system (V) is O_V , which is denoted as O_{CV} in the camera coordinate system (C); then,

$${}^C O_V = \begin{bmatrix} \frac{(x_A^C + x_B^C)}{2} \\ \frac{(y_A^C + y_B^C)}{2} \\ \frac{(z_A^C + z_B^C)}{2} \end{bmatrix}. \quad (2)$$

The unit vector on the x -axis of the body casting coordinate system (V) is denoted by e_{Vx}^C in (C); then,

$$e_{Vx}^C = \frac{\vec{AB}}{|\vec{AB}|}. \quad (3)$$

We connect CA and CB in the camera coordinate system (C) to construct vectors \vec{CA} and \vec{CB} ; then, the vector corresponding to z -axis of the body casting coordinate system (V) in the camera coordinate system (C) is the cross-product of these two vectors, and the unit vector of the z -axis of the body casting coordinate system (V) is denoted by e_{Vz}^C in the camera coordinate system (C); then,

$$e_{Vz}^C = \frac{\vec{CA} \times \vec{CB}}{|\vec{CA} \times \vec{CB}|}. \quad (4)$$

The unit vector of the y -axis of the body casting coordinate system (V) is denoted by e_{Vy}^C in the camera coordinate system (C); then, e_{Vy}^C is the cross product between the two

unit vectors, which are the x -axis and the z -axis of the body casting coordinate system (V) in the camera coordinate system (C) vector; then,

$$e_{Vy}^C = e_{Vz}^C \times e_{Vx}^C. \quad (5)$$

In the camera coordinate system, the unit vector of x , y , and z -axis can be expressed as

$$e_{Cx} = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} e_{Cy} = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} e_{Cz} = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}. \quad (6)$$

Then, the elements in the rotation matrix ${}^C_V R$ can be represented by the dot product between unit vectors e_{Vx}^C , e_{Vy}^C , and e_{Vz}^C and unit vectors e_{Cx} , e_{Cy} , and e_{Cz} , when e_{Vx}^C , e_{Vy}^C , and e_{Vz}^C are the unit vectors of x , y , and z -axis of the body casting coordinate system (V) in the camera coordinate system (C) and e_{Cx} , e_{Cy} , and e_{Cz} are unit vectors of the x , y , and z -axis of the camera coordinate system; then,

$${}^C_V R = \begin{bmatrix} e_{Cx} \cdot e_{Vx}^C & e_{Cx} \cdot e_{Vy}^C & e_{Cx} \cdot e_{Vz}^C \\ e_{Cy} \cdot e_{Vx}^C & e_{Cy} \cdot e_{Vy}^C & e_{Cy} \cdot e_{Vz}^C \\ e_{Cz} \cdot e_{Vx}^C & e_{Cz} \cdot e_{Vy}^C & e_{Cz} \cdot e_{Vz}^C \end{bmatrix}. \quad (7)$$

3.3. *Transformation Relationship between Robot Tool Coordinate System (R) and Camera Coordinate System (C).* The tool coordinate system (R) is at the end of the robot which is formulated by the robot manufacturer. A positioning pin hole and a positioning stopper are at the end of robot, origin of coordinates is the center of the stopper, x -axis is the line between the center of the pin hole and the center of the stopper whose direction is from the center of the pin hole to the center of the stopper, z -axis is the axis direction, and y -axis is determined by the right-hand rule as aforementioned. The robot can be accurately positioned through the convex platform and the positioning pin hole of the flange.

In the stereo vision system, the traditional method to determine the coordinate transformation relationship between the robot and the camera is complicated and difficult to implement; therefore, this paper will adopt the following methods to establish this relationship. A T-type calibration rod is processed and manufactured, the corresponding T-groove, the positioning pin hole, and the thread hole are processed along the x and y -axis of the tool coordinates on the positioning flange. Two marking balls D and E are placed on the T-type calibration rod along the x -axis direction, to ensure that D and E are symmetrically arranged on both sides of the origin of the robot coordinates, and two marking balls are placed along the y -axis. The coordinates of marking balls D , E , F , and G in the camera coordinate system can be obtained with the camera; the transformation relationship between the tool coordinate system (R) and the camera coordinate system (C) is established according to the similar method in Section 3.2.

The robot coordinate system (R) is obtained from the camera coordinate system (C) after rotation and translation. It represents the change of attitude, which can be represented by a 3×3 rotation matrix, denoted by ${}^C_R R$. Translation is the change of origin, denoted by a 3×1 vector, and the coordinates of the origin O_R of the robot tool coordinate system (R) are ${}^C O_R$ in the camera coordinate system (C).

The midpoints of D and E are taken as the coordinate origin O_R of the robot tool coordinate system (R), and the coordinate of O_R in the camera coordinate system (C) is O_{CR} ; then,

$${}^C O_R = \begin{bmatrix} \frac{(x_D^C + x_E^C)}{2} \\ \frac{(y_D^C + y_E^C)}{2} \\ \frac{(z_D^C + z_E^C)}{2} \end{bmatrix}. \quad (8)$$

The unit vector on the x -axis of the robot coordinate system (R) is indicated in the camera coordinate system (C) as

$$e_{Rx}^C = \frac{\vec{DE}}{DE}. \quad (9)$$

The unit vector on the y -axis of the robot coordinate system (R) is indicated in the camera coordinate system (C) as

$$e_{Ry}^C = \frac{\vec{FG}}{FG}. \quad (10)$$

The unit vector on the z -axis of the robot coordinate system (R) is e_{Rz}^C in the camera coordinate system (C); it can be obtained from the cross product of e_{Rx}^C and e_{Ry}^C ; then,

$$e_{Rz}^C = e_{Ry}^C \times e_{Rx}^C. \quad (11)$$

Elements in the rotation matrix ${}^C_R R$ is the dot product between two unit vectors, in which one is the unit vector of each coordinate axis of the robot tool coordinate system (R) in the camera coordinate system (C) denoted by e_{Rx}^C , e_{Ry}^C , and e_{Rz}^C and another is the unit vector of the x , y , and z axes of the camera coordinate denoted by e_{Cx} , e_{Cy} , and e_{Cz} ; then,

$${}^C_R R = \begin{bmatrix} e_{Cx} \cdot e_{Rx}^C & e_{Cx} \cdot e_{Ry}^C & e_{Cx} \cdot e_{Rz}^C \\ e_{Cy} \cdot e_{Rx}^C & e_{Cy} \cdot e_{Ry}^C & e_{Cy} \cdot e_{Rz}^C \\ e_{Cz} \cdot e_{Rx}^C & e_{Cz} \cdot e_{Ry}^C & e_{Cz} \cdot e_{Rz}^C \end{bmatrix}. \quad (12)$$

3.4. Transformation Relationship between the Positioning Plate Coordinate System (P) and Robot Tool Coordinate System (R). The positioning plate is positioned on the flange

through two pin holes; in this way, the position and attitude between the positioning plate and the robot are fixed. We establish the coordinate system (P) of the positioning disk and take the line between the center of the two pin holes of the positioning disk as the x -axis, the vertical orientation of the positioning plate is the z -axis, the y -axis is determined according to the right-hand rule, and the center of the positioning plate is taken as the origin of the coordinates O_P . When the coordinate system of the positioning plate is established in this way, its x and y axes are parallel to the x and y axes of the robot tool coordinate system and their z -axis overlaps. There is only translation between the positioning plate coordinate system (P) and the robot tool coordinate system (R), and there is no rotation of the coordinate axis. The rotation transformation matrix is an identity matrix, denoted by

$${}^R_P R = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}. \quad (13)$$

When the thickness of the position plate is h_p and the thickness of the flange plate is h_f , the coordinates of the origin of the positioning plate coordinate system (P) in the robot tool coordinate system (R) can be denoted by

$$O_P^R = \begin{bmatrix} 0 \\ 0 \\ -(h_p + h_f) \end{bmatrix}. \quad (14)$$

3.5. Transformation Relationship between the Robot Tool Coordinate System (R) and the Valve Coordinate System (V).

The function of the positioning system is to make the robot drive the positioning plate to move from the initial position to the upper side of the valve. At this time, the xy plane of the positioning plate coordinate (P) is parallel to the xy plane of the valve coordinate (V), and the Z axis coincides. The distance of the origins of the coordinates is H , in which $H = h + f$. Then, the translational motion of the robot can be regarded as moving from its initial position to $H + h_p + h_f$ on the z -axis of the body frame (V). Then, only the transformation relationship between the camera coordinate system (C), valve coordinate system (V), and the robot coordinate system (R) needs to be considered.

The robot coordinate (R) overlaps with the camera coordinate system after rotation and translation and then moves again to the origin of the robot coordinate (R) to the point P; its Z axis coincides with the z -axis of the body coordinate system; its x -axis and y -axis are, respectively, parallel to the x -axis and y -axis of the body coordinate system (V), and the x -axis and y -axis are parallel to the x -axis and y -axis of the valve coordinate system (V). Then, the transformation relation between the robot coordinate system (R) and the valve coordinate system (V) can be established.

TABLE 1: The repeat positioning accuracy test.

Times	1	2	3	4	5	6	7	8	9	10
OO' (mm)	0.5	-0.6	1.9	0.4	1.3	1.6	-1.1	-1.2	-0.9	0.2
θ ($^{\circ}$ C)	0.1	-0.12	0.4	0.08	0.26	0.32	-0.23	-0.25	-0.18	0.04

The rotation transformation matrix between the valve coordinate system (V) and the robot coordinate system (R) is denoted by ${}^R_V R$; then,

$${}^R_V R = {}^R_C R \times {}^C_V R = {}^C_R R^T \times {}^C_V R. \quad (15)$$

The coordinate of P in the valve coordinate system {V} is ${}^V P$; then,

$${}^V P = \begin{bmatrix} 0 \\ 0 \\ \mathbf{H} + \mathbf{h}_p + \mathbf{h}_f \end{bmatrix}. \quad (16)$$

The coordinate of P in the camera coordinate system {C} is ${}^C P$; then,

$${}^C P = {}^C_V R {}^V P + {}^C O_V. \quad (17)$$

The coordinate of P in the robot coordinate system {R} is ${}^R P$; then,

$${}^R P = {}^C_R R^T ({}^C P - {}^C O_V). \quad (18)$$

By substituting equation (17) into equation (18), we get

$${}^R P = {}^C_R R^T ({}^C_V R {}^V P + {}^C O_V - {}^C O_V). \quad (19)$$

4. Calculation of the Robot Motion Parameters

According to the transformation relationship between the robot tool coordinate system (R) and the valve coordinate system (V), the motion parameters of the robot from the initial position and attitude adjusting to the same position and attitude with the valve can be calculated.

The adjustment of robot attitude is achieved by rotation angles γ , β , and α around x_R , y_R , and z_R of the robot tool coordinate system; then, positioning between the positioning disc and the valve can be calculated as

$$\begin{aligned} \gamma &= A \tan 2 [{}^R_V R(3, 2), {}^R_V R(3, 3)], \\ \beta &= A \tan 2 \left\{ -{}^R_V R(3, 1), \sqrt{[{}^R_V R(1, 1)]^2 + [{}^R_V R(2, 1)]^2} \right\}, \\ \alpha &= A \tan 2 [{}^R_V R(2, 1), {}^R_V R(1, 1)]. \end{aligned} \quad (20)$$

The robot's translation of x_R , y_R , and z_R along the tool coordinate system (R) is Δx , Δy , Δz .

$$\Delta x = {}^R P(1), \quad \Delta y = {}^R P(2), \quad \Delta z = {}^R P(3). \quad (21)$$

After calculation, the motion parameters of the robot are sent to the robot controller through industrial Ethernet and the positioning between the positioning disc and the valve can be realized according to the motion parameters.

5. Practical Application of the Positioning System

The positioning system is established, including 4 infrared cameras, Kawasaki robot, and computer. As a lot of matrix calculations are involved in the positioning algorithm, MATLAB 2017 software is installed on the computer to realize the positioning algorithm and provide a human-computer interaction environment.

The operation process is as follows: Click "static calibration" button to realize automatic calculation of the rotation matrix ${}^C_R R$ and the translation vector P_{RC} between the robot tool coordinate system (R) and the camera coordinate system (C). During the positioning operation, enter the valve code and the height difference H between the locating disc and the corresponding valve; thickness h_p and flange thickness h_f are automatically retrieved from the Excel table by the system. The "Start" button is used to start the positioning system to read coordinates from the camera, calculate the movement parameters of the robot, and control the robot move to the upper side of the valve to achieve positioning. The "Reset" button is used to reset the robot to its initial position and attitude. Parameters of the new valve or modified parameters of the old valve can be saved into the Excel sheet by clicking "Save" button, and click the "Save" button.

In order to verify the accuracy of the positioning method, a cross laser is installed on the positioning disk and the experiments are as follows: (1) the repeat positioning accuracy test: fix the valve in a certain position, repeat the positioning process for 10 times, and observe the center position of the cross cursor and the deflection angle of the cross line; (2) the random positioning accuracy test: move the valve randomly, change its position and attitude, change the position and attitude of the valve, and observe the center position of the cross cursor and the deflection of the cross line in every motion.

6. The Error Evaluation Method

In order to evaluate the precision of repeat, after the first position, mark the center and the projection line of cross laser on the valve castings (solid lines x and y and point O). The deviation of the projection line and the center (dotted lines \hat{x}' and \hat{y}' and point O') from the first projection line and center was compared in the subsequent positioning.

In the deviation between the cross laser, the translation error is evaluated by the distance OO' and the angle positioning error is evaluated by θ . According to the geometric relationship, it can be calculated as

TABLE 2: The random positioning accuracy test.

Times	1	2	3	4	5	6	7	8	9	10
OO' (mm)	-2.4	-0.06	-1.84	2.37	-2.41	-2.7	0.341	1.6	-1.12	-1.92
θ ($^{\circ}\text{C}$)	-0.49	-0.01	-0.38	0.48	-0.49	-0.51	0.07	0.33	-0.23	-0.39

$$\theta = \tan^{-1}\left(\frac{OO'}{OO_R}\right), \quad (22)$$

where $OO_R = H + h_p + h_f$.

In the test, the thickness of the positioning plate is $h_p = 40\text{mm}$, the thickness of the flange is $h_f = 40\text{mm}$, and the positioning height is $H = 200\text{mm}$, and then $OO_R = H + h_p + h_f = 280\text{mm}$.

The data of the repeat positioning accuracy test are shown in Table 1, and the experimental data of the random positioning accuracy test are shown in Table 2.

The test results show the following: (1) in the repeat positioning accuracy test, the position error is within $\pm 2\text{mm}$ and the angle positioning error is within $\pm 0.5^{\circ}\text{C}$; (2) in the random positioning accuracy test, the position error is also controlled within $\pm 3\text{mm}$ and the angle positioning error is controlled within $\pm 1^{\circ}\text{C}$. The results show that the positioning method is effective.

7. Conclusion

To solve the problem of locating the valve on cutting equipment in automatic cutting of pouring riser after valve casting, a positioning system integrating stereo vision, robot, and information processing technology for automatic pouring riser cutting of valve casting was designed, using the principle and method of coordinate transformation. We establish a coordinate relationship between the rotation and translation by fixing the coordinate system of the valve castings, positioning plate, robot, and camera. We calculated the motion parameters of robot in the working space and realized that the positioning plate can be positioned to the upper side of the same type valve casting with the same position and attitude. The experimental results and the actual cutting show that the proposed positioning method has high positioning accuracy, satisfies the cutting accuracy requirements of valve castings, and has a wide application prospect.

Aiming at the nonlinear, nonstationary, and time series characteristics of power load, this study proposes a load forecasting method based on empirical mode decomposition and particle swarm optimization of the gated recurrent unit neural network. First, the original power load data are decomposed into a limited number of modal components and a residual component by using empirical modal decomposition to reduce the nonstationarity and complexity of the load sequence and decrease the association between different IMFs. The subsequences build prediction models based on the gated recurrent unit neural network, respectively, and use the particle swarm algorithm to optimize the network-related hyperparameters to increase the parameter accuracy of the model; finally, superimpose the prediction results of each subsequence to obtain the final load prediction value. The results of the case study show that compared with the traditional forecasting algorithm, the proposed EMD-PSO-GRU forecasting model method can better dig the trend information of forecasting, fit the load curve better, and have higher forecasting accuracy.

1. Introduction

Accurate load forecasting is an important guarantee for stable operation of power grids, scheduling optimization, and reducing operating costs [1]. Smart grid provides a high-quality and massive database for load forecasting. With the rapid evolution of the energy Internet [2], it is more urgent and important to study algorithms with the ability to process big data and high forecasting accuracy. The accuracy of the model has important significance and high engineering application value [3, 4].

In terms of load forecasting, traditional forecasting models such as autoregression (AR), although fast in operation, have high data requirements and lack the ability to adapt and predict. The robustness is poor, and it is difficult to meet the requirements of load forecasting [5]. In recent years, the development of artificial intelligence technology has provided ideas for solving these problems, but some new

problems are still derived. Xiangyu et al. [6] used a deep belief network to quickly analyze complex influencing factors, which improves the prediction accuracy, but it only targets regional loads and lacks adaptability. Wu et al. [7] used a parallelized multicore support vector machine (SVM) for load prediction, and the prediction error is reduced to a certain extent compared with a single-core SVM, but it lacks the consideration of the correlation between time series data. Shi and Zhang [8] considered the training differences of different algorithms and proposed a stacking load forecasting model embedded with various machine learning algorithms. This model ensures good accuracy in forecasting, but the cost of model integration is too high and the time is long. With the growing development of deep learning, the gated recurrent unit network as a kind of the special RNN model [9, 10] is widely used to predict events in time series due to the introduction of modules with “memory function” in its structure [11], but it has two deficiencies, namely, the

model learning rate and the number of neurons in the hidden layer, which are difficult to determine. Among them, the learning rate determines the training effect of the model, and the number of neurons in the hidden layer affects the fitting effect of the model. Usually, these parameters are determined by experience and are uncertain, which leads to a decrease in the accuracy of the model.

Similar to other neural networks, GRU's model parameters often need to be selected by human experience, and the fitting ability, training speed, and prediction effect of different model parameters are quite different. In order to more reasonably determine the model parameters of GRU and improve the stability of power load forecasting, a method is proposed based on EMD-PSO to optimize GRU network hyperparameters. Through example analysis, the prediction results verify the effectiveness of the proposed model.

2. Model Theory

2.1. Empirical Mode Decomposition. EMD is a decomposition method, which can decompose the signal according to the specific time scale features of the data and adaptively decompose the local feature signals on different time scales to obtain IMF and residual signals with different characteristics. Each IMF component obtained by decomposition has a certain physical meaning. It represents the variable components of various time scales contained in the raw load data, and the residual term represents the basic trend of the load sequence. The specific EMD steps for a given original time series $x(t)$ are as follows [12, 13]:

- (1) Identify maximum and minimum points in the original sequence $x(t)$, use the cubic spline interpolation method to respectively fit $x_{up}(t)$ and $x_{low}(t)$, and calculate the mean $m(t)$ of the upper and lower envelopes.

$$m(t) = \frac{x_{up}(t) + x_{low}(t)}{2}. \quad (1)$$

- (2) Calculate the difference between the original sequence $x(t)$ and the envelope mean $m(t)$, denoted as $h(t)$.

$$h(t) = x(t) - m(t). \quad (2)$$

- (3) Determine whether $h(t)$ satisfies the IMF constraints; if not, use it as a new input sequence, and repeat steps (1) to (2) until the constraints are met; if so, $h(t)$ is the first IMF component, denoted as $c_1(t) = h(t)$, and separates $c_1(t)$ from the original sequence $x(t)$ to obtain $r_1(t)$.

$$r_1(t) = x(t) - c_1(t). \quad (3)$$

- (4) $r_1(t)$ is regarded as a new original sequence, and the abovementioned smoothing steps are repeated to obtain the remaining IMF components and one remaining component. The final result of EMD can be expressed as

$$x(t) = \sum_{i=1}^n c_i(t) + r_n(t). \quad (4)$$

In the formula: $c_i(t)$ is the i -th intrinsic mode function component; $r_n(t)$ is the residual component, representing the trend term of the original series.

By using the empirical mode decomposition method, different components can be decomposed from the load time series to form a series of subsequence components [14]. Compared with the original series, the subsequence has stronger stationarity to improve accuracy.

2.2. Gated Recurrent Unit Neural Network. The GRU network optimizes LSTM's three gate functions, integrates oblivion gates and input gates into one update gate [15–17], and mixes neuronal and hidden states simultaneously. This can effectively mitigate the following problems: GRU addresses the “vanishing gradient” of RNN networks and reduces the training time of the model. GRU network basic structure is shown in Figure 1.

The calculation formula of the internal structure is

$$\begin{aligned} r_t &= \sigma(W_r \cdot [h_{t-1}, x_t]), \\ z_t &= \sigma(W_z \cdot [h_{t-1}, x_t]), \\ \tilde{h}_t &= \phi\left(W_{\tilde{h}} \cdot [r_t \times h_{t-1}, x_t]\right), \\ h_t &= (I - z_t) \times h_{t-1} + z_t \times \tilde{h}_t, \\ y_t &= \sigma(W_o \cdot h_t). \end{aligned} \quad (5)$$

x_t , h_{t-1} , r_t , z_t , \tilde{h}_t , and y_t , respectively, represent the input vector, the state memory variable at the previous moment, the state of the reset gate, the state of the update gate, e -th state of the current candidate set, and the output vector; W_r , W_z , $W_{\tilde{h}}$, and W_o are the weight parameters; I represents identity matrix; $[\]$ represents vector connection; \cdot represents matrix dot product; \times represents matrix product; σ represents sigmoid activation function; and ϕ represents tanh activation function. The mathematical description of σ and ϕ is as follows:

$$\begin{aligned} \sigma(x) &= \frac{1}{1 + e^{-x}}, \\ \phi(x) &= \frac{e^x - e^{-x}}{e^x + e^{-x}}. \end{aligned} \quad (6)$$

GRU networks use update gates and reset gates as core modules. x_t and h_{t-1} at the previous moment is input into the update gate after the sigmoid nonlinear transformation to determine the state of the previous moment. The reset gate controls the amount of information written to the candidate set, stores the information at the previous moment through h_{t-1} times $I - z_t$, and records the information at the current moment through \tilde{h}_t times z_t .

2.3. Particle Swarm Optimization Algorithm. In PSO, each particle has an initial velocity and position, and the fitness value of the particle is determined by the fitness function

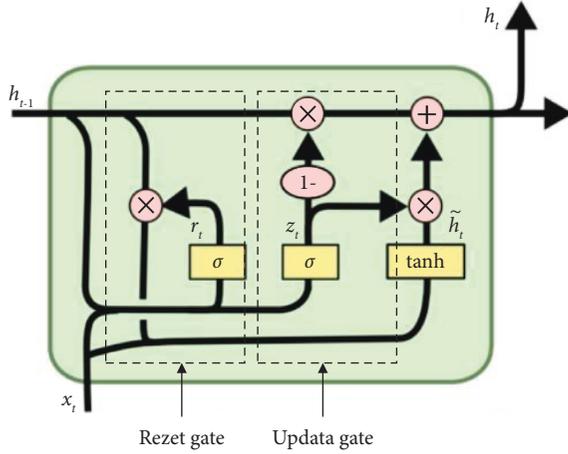

FIGURE 1: GRU network structure.

[18]. In the iteration, each particle can store the searched optimal position, and its velocity determines the direction and distance of flight [19]. The particles update their speed and position by comparing the fitness values, the optimal value detected by the particle itself is the individual extremum, and the optimal solution detected by the entire population is the global extremum [20]:

$$\begin{aligned} v_i(t+1) &= \omega v_i(t) + c_1 R_1 [R_i^b(t) - x_i(t)] \\ &\quad + c_2 R_2 [R_g^b(t) - x_i(t)], \\ x_i(t+1) &= x_i(t) + v_i(t+1). \end{aligned} \quad (7)$$

In the formula, t is the number of iterations; $v_i(t)$ is the speed of the i -th particle in t iterations; ω is the inertia weight; c_1, c_2 are the cognitive coefficients; R_1, R_2 are uniformly distributed random numbers; $Rb/i(t)$ is the individual historical optimal position of a particle i ; $Rb/g(t)$ is the historical optimal position of the group; $x_i(t)$ is the position of the particle in t iterations.

The inertia weight ω is an important parameter of PSO. The larger the weight, the stronger the global search ability of the algorithm; the smaller the weight, the stronger the local search ability of the algorithm [21, 22]. The dynamic adjustment of the inertial weight is adopted.

$$\omega(n) = \omega_{\max} - (\omega_{\max} - \omega_{\min}) \left(\frac{n}{n_{\max}} \right), \quad (8)$$

where ω_{\max} represents the maximum weight, ω_{\min} represents the minimum weight, and n_{\max} is the maximum number of iterations.

3. EMD-PSO Optimizes the Prediction Model of GRU Hyperparameters

3.1. PSO Optimizes the GRU Hyperparameter Model. The PSO algorithm is a random search and parallel optimization algorithm, which has the characteristics of simplicity, good robustness, and fast convergence speed, and has a high probability of finding the global optimal solution to the

problem [23]. The algorithm optimizes the hyperparameters of the GRU and establishes a load forecasting model with higher accuracy. In the GRU model, two hyperparameters have a positive effect on the prediction performance of the model, namely, the number of GRU neurons and the learning rate. Taking these two key parameters as the characteristics of particle optimization, the PSO algorithm is used to adjust and optimize the GRU model. The flowchart of the PSO-GRU load forecasting model is shown in Figure 2.

3.2. EMD-PSO-GRU (EPG) Load Forecasting Model. The load sequence is complex and nonstationary. The decomposed components are input to the GRU model and the PSO algorithm is used to optimize the GRU model hyperparameters. Finally, superimpose the prediction results of each component to get the final prediction value. To improve prediction accuracy, this study proposes the EMD-PSO-GRU hybrid prediction model architecture shown in Figure 3.

The specific steps for building a model are as follows.

- (1) The original load time series is divided into several subsequences by EMD
- (2) Divide each subsequence into a training set and a validation set and normalize the dataset. Since the GRU model is highly sensitive to the data scale, the original data have a large difference in the order of magnitude; in order to avoid that the change of larger value will cover the change in smaller value, it is necessary to constrain the input data to a similar order of magnitude to avoid affecting the effect of power load forecasting due to the large individual input value. The dataset is between [0, 1] to reinforce the convergence speed of GRU.
- (3) Learn the complex relationship between input and output variables in each subsequence by building a GRU network and through the PSO algorithm to determine the optimal GRU network hyperparameters
- (4) Use the trained GRU network to predict the subsequence and deformalize the prediction result to obtain the real prediction value
- (5) Add the prediction results of each subsequence to obtain the final result of the load

3.3. Model Evaluation Metrics. To evaluate the performance of the prediction model, MAPE and RMSE are used as evaluation indicators [24–33], which are defined as follows:

$$\begin{aligned} y_{MAPE} &= \frac{1}{n} \sum_{i=1}^n \frac{|y_i - \hat{y}_i|}{y_i} \times 100\%, \\ y_{RMSE} &= \sqrt{\frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{n}}, \end{aligned} \quad (9)$$

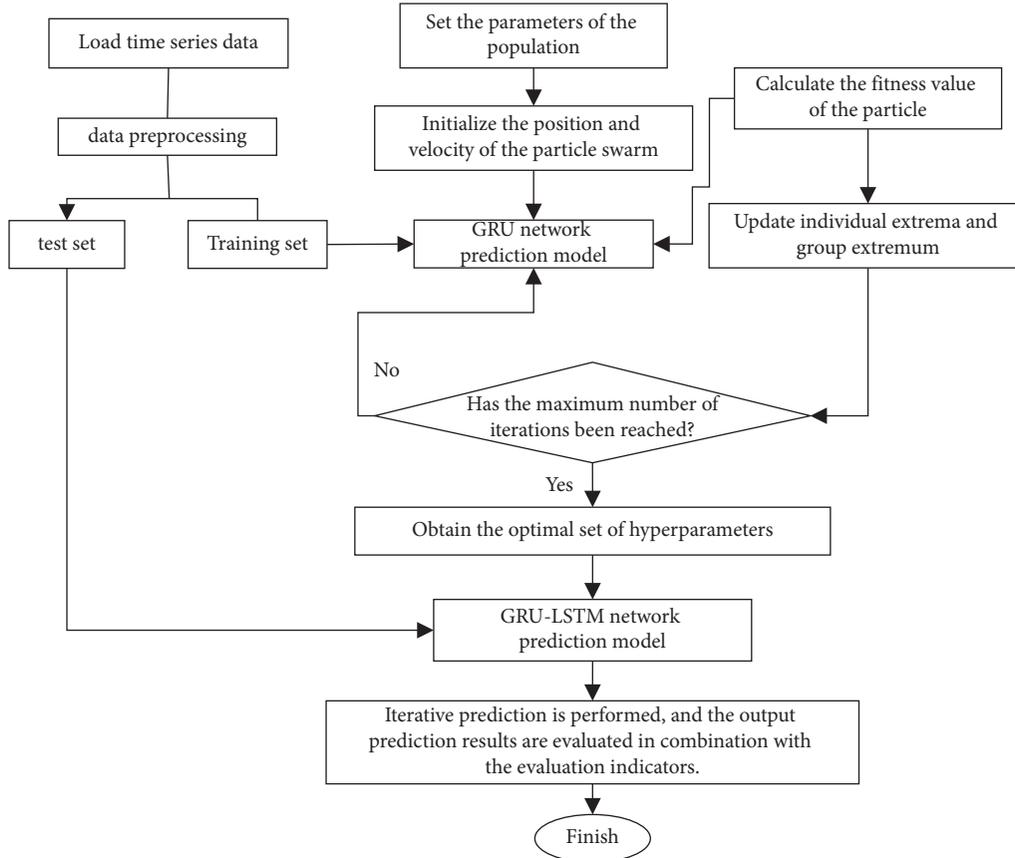

FIGURE 2: Flowchart of the PSO-LSTM load prediction model.

where y_i is the actual load value on the i -th day; \hat{y}_i is the load forecast value on the i -th day; n is the number of samples in the test set.

4. EMD-PSO Optimizes the Prediction Model of GRU Hyperparameters

To verify the scientificity and reliability of the load forecasting model based on EMD-PSO-GRU proposed in this study, the power load data of a specific area from January 1, 2016, to May 8, 2020, are used. Figure 4 shows the raw data of the average daily load, with a total of 1588 data samples divided into a training set and test set with a ratio of 9:1, in which the training set data has 1430 data and the test set has 158 data.

4.1. EMD Decomposition. The load data are decomposed by EMD, and it is decomposed step by step from high frequency to low frequency into 9 IMF components and a residual component. The decomposition result is shown in Figure 5. Compared with the original power load sequence, the decomposed components become more stable in turn. The nine IMF components, respectively, reflect the influence of different influencing factors on the load data at different scales, and the residual component represents the long-term change trend of the load sequence.

4.2. Model Parameter Settings. The number of PSO population sizes is set to 8, the dimension of population optimization is set to 2, the maximum number of iterations is set to 10, the learning factors $c_1=2$, $c_2=2$, and the inertia weights are set to $w_{\max}=1.2$, $w_{\min}=0.8$. The range of the number of neurons is set to $[1, 60]$, and the range of the learning rate is set to $[0.001, 0.01]$.

4.3. Hyperparameter Optimization Results. The predictive performance of a GRU network depends on the choice of parameters for building the network, such as the learning rate and the number of hidden layer nodes. The learning rate and the number of hidden layer nodes in the GRU network are determined by the PSO optimization. Table 1 shows the optimal learning rate and optimal number of hidden layer nodes for the GRU network for each IMF.

In order to verify the superiority of the EMD-PSO-GRU hybrid prediction model, PSO-GRU, GRU, SVM, and RNN models were established under the same prediction process for comparative analysis.

4.4. Load Forecasting Result Analysis. Each model is trained with the data of the training set, the prediction results are compared and verified with the data of the test set, and the MAPE and RMSE evaluation indicators are selected to evaluate the accuracy of the prediction model. The

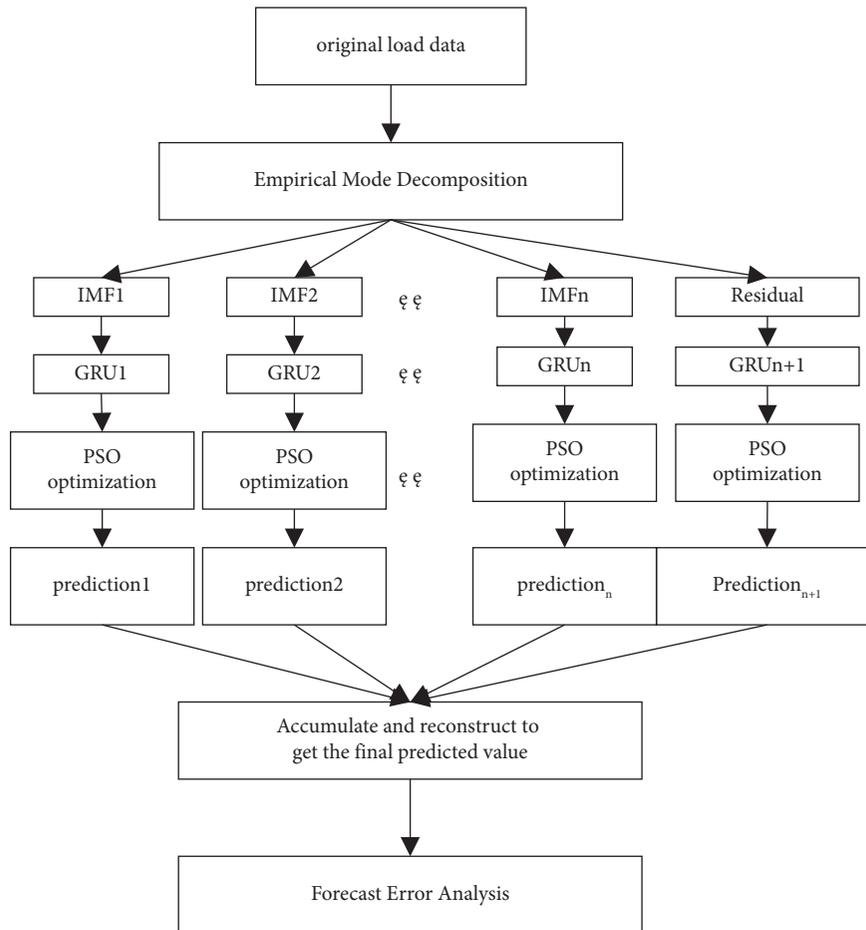

FIGURE 3: EMD-PSO-GRU combined prediction flowchart.

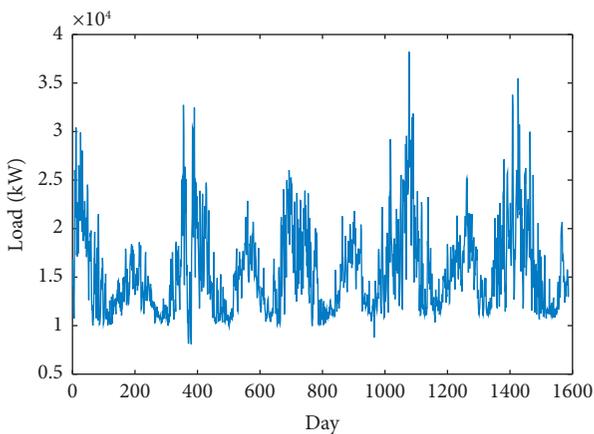

FIGURE 4: Load raw data.

comparison results of the test set are shown in Figure 6. In order to more clearly see the prediction performance of each model, the error rates of the last two months on the test set are selected for comparison, and the comparison chart is shown in Figure 7. It can be seen from Figures 6 and 7 that among the five models of EMD-PSO-GRU, PSO-GRU,

GRU, SVM, and RNN, the overall fitting effect of the EMD-PSO-GRU model and the fitting effect at the peaks and troughs of the waves, The combined effect is better, and the error rate is obviously smaller. It can be seen that the empirical mode decomposition can stabilize the data with strong volatility and then predict it, which can effectively improve the prediction accuracy of the model.

The prediction accuracy evaluation results of each model are shown in Figure 8, and the quantitative indicators of each evaluation result are shown in Table 2. The accuracy evaluation results of the evaluation indicators of the EMD-PSO-GRU model are the best, and the prediction effect of the SVM model is the worst. The MAPE index of the EMD-PSO-GRU model is 1.678%, and the RMSE index is 259.32. Compared with the PSO-GRU prediction model, the MAPE is reduced by 24.92%, and the RMSE is reduced by 28.85%. Strong data stabilization before prediction can effectively improve the prediction accuracy of the model. The MAPE of PSO-GRU is 2.235%, and the RMSE is 364.48. Compared with the GRU model, its MAPE is reduced by 19.78%, and the RMSE is reduced by 25.60%. Due to the influence of experience, adaptively finding the optimal solution of hyperparameters is very important to improve the prediction performance of GRU, which can better improve the prediction accuracy.

5. Conclusions

A load forecasting method based on the EMD-PSO-GRU is proposed. First, the data are subjected to variational modal decomposition, preprocessing, and division of the sample dataset, and then, a GRU neural network forecasting model is established for each subsequence. The PSO algorithm is used to optimize the hyperparameters of the GRU neural network, and finally, the respective sequence prediction results are accumulated to obtain the final load prediction value. The method proposed has the following merits:

- (1) The EMD decomposition method can well mine the essential features such as cycles and trends in the sequence
- (2) Show good advantages of the GRU network in the field of data mining. The GRU network has a unique network structure and strong learning ability for time series data.
- (3) The PSO algorithm has stronger global optimization ability and convergence speed by adding nonlinearly changing inertia weights, avoiding the drawbacks of traditional manual selection of hyperparameters, and

can independently optimize the hyperparameters of the network model

- (4) The prediction accuracy of the “decomposition-prediction-reconstruction” method is higher. The proposed method demonstrates better prediction accuracy compared with the existing artificial intelligence prediction methods.

With the development of economic globalization, the trend of internationalization and alliance of large enterprises is becoming more and more obvious, and the competition and cooperation among enterprises are still continuing. In this new historical stage, it is very necessary to ensure the smooth implementation of financial management and coordination with other systems, in line with the times, to establish, improve, and ensure a scientific and reasonable enterprise financial management model and prove its effectiveness. However, the existing research on the specific implementation of the integrated financial management model based on the theory and case studies is not specific enough, the process tracking is not detailed enough, the implementation effect evaluation theory lacks scientificity and integrity in the establishment of the index system, and the evaluation methods are relatively simple. In view of the above problems, this paper proposes the specific implementation steps and problems that need to be paid attention based on the financial management model for large listed companies, establishes the evaluation index system of enterprise implementation by using the method, and quantifies the listed companies before and after the implementation of integrated financial management. The comparisons give credible results. This paper is of great significance for improving the existing performance evaluation system, responding to national policies, promoting the development of enterprise informatization, and improving the success rate and competitiveness of enterprise integrated financial management implementation.

1. Introduction

With the advent of the digital information age, digital transformation of enterprises is an inevitable choice to adapt to the development of the times, and information technology is an important means to help enterprises achieve digital transformation. Digital management can not only realize the integration of enterprise management information, but also help enterprises to achieve a qualitative leap in their management level. As a tool set beyond the scope of management, the ERP system plays a role in driving the efficient operation of the internal processes of the enterprise and revitalizing the enterprise resources, thereby helping the enterprise to successfully realize the digital transformation [1]. In order to adapt to the development of the digital age, many enterprises have begun to improve their daily operation and management levels by building their own ERP systems and fully implementing ERP systems. When most

enterprises go online with ERP systems, due to the limited management foundation and human resources, they choose to launch ERP subsystems one by one to smoothly realize the transformation of information management. As the most important economic management activity of an enterprise, corporate financial management is essentially a work of organizing corporate financial activities and dealing with corporate financial relations, covering all aspects of the company's economic business. Because the management efficiency and operation effect of the company's daily business are closely related to the overall level of the company's financial management system, therefore, enterprises will choose to launch the ERP financial management system first [2].

During the implementation of the ERP financial management system, the advantages of the ERP financial management system cannot be brought into full play because the internal business processes of the enterprise cannot

be fully integrated with the ERP financial management system, which eventually leads to the failure of the ERP financial management system. According to an Accenture research report, nearly 80% of ERP systems have not achieved the expected results after going online. It shows that the implementation of ERP financial management system cannot be accomplished overnight and the system should be upgraded through continuous evaluation and optimization, so that it is possible to enjoy the benefits brought by information integration [3]. However, most enterprises tend to ignore this point when they build their own ERP systems and fully implement ERP systems. There is often a situation of “emphasizing the system, neglecting evaluation and weak optimization,” which goes against the original intention of enterprises to use the ERP system to improve the efficiency of operation and management. Therefore, it is necessary to discuss whether ERP can be better applied to the financial management model, so that the logistics, information flow, and capital flow can be effectively integrated, and it is necessary to study whether the integrated financial management based on ERP can be successfully implemented, what is the effect of the implementation, and whether it can improve the financial management level of enterprises and meet the requirements of rapid development of enterprises. On the basis of discussing the relevant theories, this paper deeply studies the financial management mode and effect of enterprises based on ERP and establishes the financial management evaluation index system. Quantitative evaluation was carried out, and a practical research was carried out on the refined evaluation method of financial management quality of listed companies based on ERP model.

2. Research Status of ERP Financial Management Evaluation Methods at Home and Abroad

Enterprise Resource Planning, referred to as ERP system, refers to the digitalization of enterprise management through the combination of modern information technology and advanced enterprise management concepts. ERP is essentially a thinking mode of enterprise management, which uses the internal and external resources of the enterprise to provide the optimal solution for the daily operation activities of the enterprise, thereby helping the enterprise to achieve the operation and management goals and improve the actual management level of the enterprise [4, 5]. To evaluate the implementation effect of ERP financial management system, it is necessary to identify the relevant factors that affect the implementation effect of ERP financial management system.

Domestic scholars started late to study the factors affecting the ERP financial management system. Zhang et al. summarized the influencing factors that affect the implementation of ERP systems in enterprises as changes in financial organizations, integration of financial systems, optimization of core financial processes, and a perfect evaluation system [6]. Chen Hu collects relevant information by

means of a questionnaire survey and summarizes the factors that affect the implementation of the financial management system into four factors: business process management, system quality, business standardization, and personnel management. Martin assumed the influencing factors of the ERP financial management system, designed a questionnaire, and used a regression model to verify the correlation between the hypothesized influencing factors [7, 8]. He et al. based on the perspective of process reengineering, take the enterprises that implement financial management systems in China as samples and establish an analysis model of influencing factors. Through empirical methods, it is verified that the factors affecting the financial management system of Chinese enterprises include strategic planning, business process management, and organizational structure design [9–11]. In terms of performance, Miao built the performance evaluation system of the enterprise ERP financial management system, hoping to improve the management level of the enterprise through the construction of the performance evaluation system, so that the enterprise can occupy a favorable position in the fierce market competition [12]. In order to evaluate the performance of the ERP system, Liu optimizes the internal process of the ERP, improves the existing information system, and at the same time improves the efficiency of enterprise management and enhances the competitiveness of the enterprise. By introducing the financial management theory of the balanced scorecard, we can obtain which aspects of the enterprise need to be optimized [13]. Zhang et al. also constructed an ERP system evaluation system based on the balanced scorecard to evaluate and analyze the implementation performance of China Unicom’s ERP system and put forward optimization suggestions after calculating the membership of each evaluation index [14]. Pan used the grey fuzzy correlation method based on the balanced scorecard to analyze the difference in the effect of enterprises before and after the implementation of the ERP system [15]. In terms of influencing factors, after analyzing the main influencing factors of the enterprise ERP financial management system, Li evaluated the situation of the ERP financial management system during the use period and weighted the obtained evaluation results, so as to obtain the time to get the weighted evaluation results. Then, the contribution is evaluated by introducing weights, and finally the financial management system is evaluated based on the dynamic weighted evaluation sequence [16]. Huang et al. built an index system composed of three dimensions: ERP basic operation, comprehensive benefits, and personnel training and growth and used the evaluation system to evaluate the application effect of the ERP system of supply chain enterprises, so as to improve the evaluation ability of supply chain enterprises to the ERP system [17].

In the 1980s, foreign scholars’ research on ERP financial management system gradually deepened. Three scholars including Mudimigh et al. discussed ERP system, financial management, and system integration, respectively, and proposed the fact that ERP financial management system should be based on ERP software in the construction process. Based on the financial data as the core, the integration advantages of the ERP system can be realized [18]. On the

basis of decision support theory, Elisabeth emphasized that the ERP financial management system should meet the process-oriented characteristics and further put forward the view that the system process should be optimized when improving the function of the financial management system [19]. Based on three theories: the urgency of the foundation, the state capability of the national implementation plan, and the technical cooperation between tasks, Trkman proposed the fact that enterprises should continuously improve and optimize the cooperation between business process tasks and management cycles, so as to make the business management reach the best state [20]. In order to make ERP effectively implemented after the introduction, Rajan CA uses TAM (Technical Acceptance Model) to analyze the factors affecting ERP implementation and also tries to analyze the impact of ERP system on performance and work efficiency [21]. Through investigation and research on the types and characteristics of enterprise financial management systems, Zhi proposes how to build an enterprise ERP financial management system based on the ERP environment and the importance attached by senior managers to the construction of ERP financial management systems to promote the development of enterprise financial management. Basic requirements and other viewpoints are found in [22]. Lin analyzes the ERP financial management system in the shipping industry, proposes how to build the ERP-based financial management information management system for shipping companies, and designs its business process in detail. Finally, the designed system is tested [23]. The evaluation of ERP abroad has formed a relatively mature theoretical system, mainly including the ABCD evaluation system and the evaluation of the three parts of the ERP system use purpose, ERP operation problem handling, and factors affecting the success of ERP implementation formulated by the American standardization organization system. ABCD evaluation system mainly includes five research areas: strategic planning, continuous optimization of system quality, development of new products, plan execution, and control. By elaborating the content of each part in detail, explaining the problems involved in this part and the differences in its characteristic attributes between different levels of A, B, C, and D, a more comprehensive problem is drawn, and the questions raised will be discussed and broken down into several components. For example, taking the strategic planning section, first, grade each subquestion of the strategic planning; then divide the strategic planning into four different levels, A, B, C, and D. Level A: strategic planning development and implementation is an ongoing process that drives people's decisions and actions, reflecting a "customer first" perspective. Whether all employees of the company can clearly express the company's purpose, long-term planning and strategic goals is as question. Level B: the formulation and implementation of the strategic plan are a formal matter that should be developed by the company's senior decision makers and middle managers and should be carried out at least once a year. When making decisions based on a strategic plan, the company should enable employees to understand the company's basic purpose and long-term planning. Level C: even though the company

seldom formulates and uses strategic planning to make decisions, it can still smoothly make decisions related to the direction of the company's operations. Level D: the company has never developed a strategic plan. And put forward comprehensive questions to judge whether the enterprise has achieved the expected effect after implementing the ERP financial management system; finally, evaluate each comprehensive problem. The evaluation result here is not the average score for each small problem, but it is to provide the basis for the comprehensive score [24].

From the above research results, it is found that domestic and foreign scholars have carried out certain research on the ERP financial management system and the evaluation and optimization of the ERP financial management system. And it can be found that domestic and foreign scholars' research on ERP financial management system is mostly based on the analysis of its internal structure and how to achieve coordination between systems. Conduct research and develop a relatively complete evaluation system to meet the evaluation needs. However, in the selection of research objects, most of them are large enterprises in developed countries, which generally have the characteristics of large scale, clear process, and standardized management. However, domestic scholars started late, and so far they have not formed an authoritative, systematic ERP financial management evaluation system that can meet the needs of enterprises. Most of the researchers' research on the evaluation system is only in the initial stage. By summarizing the research results of ERP financial management optimization at home and abroad, it is found that foreign researchers pay more attention to explore the reasons for the low success rate of system application and try to formulate scientific and effective solutions from a macroperspective to realize the optimization of ERP system. However, domestic scholars mostly explore the optimization of ERP financial management system from the microperspective of the enterprise level. By analyzing the application status of the system and proposing solutions for the existing problems to achieve system optimization, the solution is more practical.

3. Implementation Analysis of ERP Integrated Financial Management System

ERP financial management system: as far as listed companies are concerned, the accounting module used to integrate financial data is the basis for the normal operation of the financial management system, the fund management module is an important part of the operation of financial management, and budget management is the basis for enterprises to carry out financial management and also is an important means of financial management. In a word, the accounting module, fund management module, and budget management module not only connect the beginning and end of the enterprise financial management work, but also run through the most important components in the ERP financial management system of listed companies: accounting module, capital management module, and the application status of the comprehensive budget management module which is described [25]. Generally, the accounting

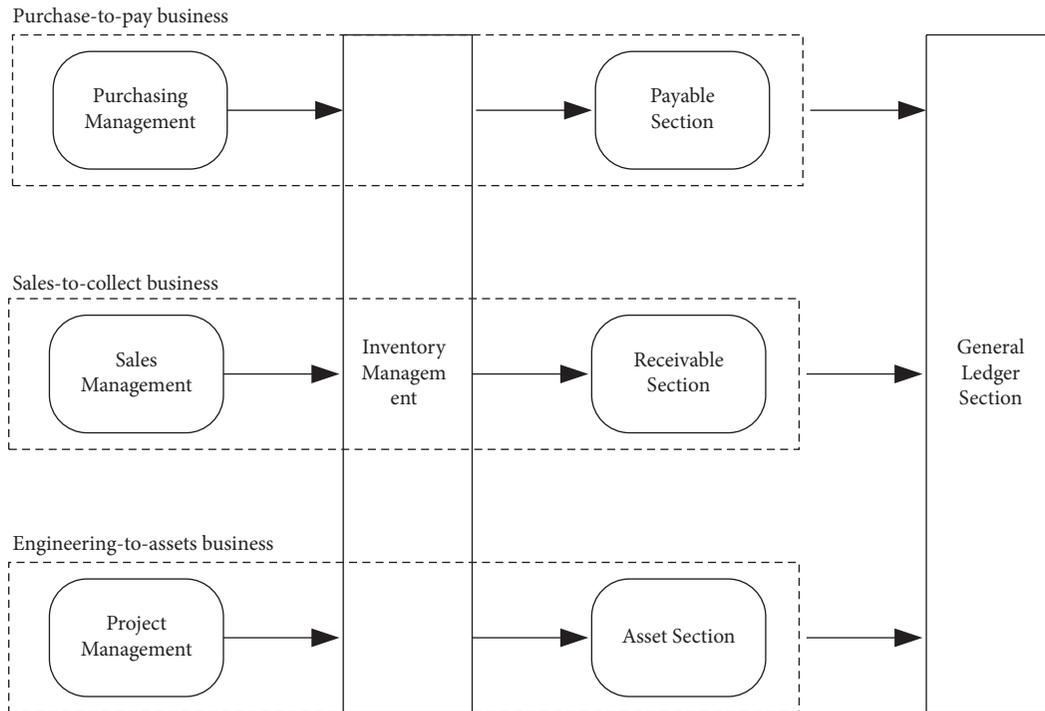

FIGURE 1: Integration diagram of the general ledger section of the accounting module composition.

module of listed companies uses the Oracle suite, which realizes the integration between the module components and the functional upgrade of some blocks. The accounting module includes general ledger, accounts receivable, accounts payable, assets, purchases, and projects. The relationship between these components and the general ledger blocks is shown in Figure 1.

- (1) General ledger section: the general ledger section is the core of the accounting module. Basic elements such as accounting subjects, accounting periods, currency, and book sets in the system are set in the general ledger section. Each submodule will transfer the generated accounting entries to the general ledger block during business processing, generate journals, and update account balances to generate subsidiary ledgers, general ledgers, and various financial statements. Since the financial information of the enterprise will be automatically posted to the general ledger section through the system, and other submodules will also share data with the general ledger section, the general ledger section should be the best platform for querying company information.
- (2) Accounts receivable segment: the accounts receivable section is mainly used to manage the customer's current business, business collection, and settlement business, including the management and preservation of customer data and information, the issuance of sales invoices integrated with the BOSS system, and the management of customer accounts receivable and payment collection information, recording receipt vouchers and controlling the aging of customer

arrears. At the same time, the accounts receivable section can automatically import the data of the business daily report interface provided by the BOSS system into the business accounts receivable invoice and import the bank receipt information into the accounts receivable section through this interface and then batch verification of invoices received.

- (3) Accounts payable segment: for listed companies, dealing with suppliers is a very important business activity for the company. The payable section is used to manage the business dealings with suppliers. The section contains basic information about suppliers such as supplier locations, contacts, and bank accounts. For the invoice management of the business transactions of the enterprise, the invoice needs to be paid after a strict approval process. The payment method can choose single payment or batch payment.
- (4) Assets sector: it is mainly used to manage and account for various assets of the enterprise and is specifically used to process various businesses in the process of enterprise asset management in batches, such as processing the increase and decrease of assets, depreciation and amortization, and provision for impairment. In each accounting period, as long as the financial staff submits the asset processing request, the asset section will automatically accrue depreciation or amortization, transmit the relevant entries to the general ledger section, and automatically update the asset account balance sheet. The asset section is integrated with the accounts payable section and the project section. In the asset section, users can find asset information at any time, such as

the original value of the asset, accumulated depreciation in use, asset age, remaining life, storage location, custodian, and asset status, and can update asset information.

4. Refinement Evaluation Method of EPR Integrated Financial Management Quality Based on ISM-ANP

Because of its unique practicality, the integrated financial management based on EPR has gradually attracted the attention of relevant institutions all over the world and has carried out extensive research. There are few studies on the evaluation of ERP integrated financial management implementation, but it is very important. This paper combines the integrated financial management mode to bring changes to the enterprise compared with the traditional financial management mode, extracts the relevant performance factors, establishes the enterprise implementation evaluation index system, and carries out the weight calculation, trying to quantify the implementation effect of the integrated financial management based on ERP.

4.1. Establishment of ERP Implementation Evaluation Index System. According to the industry situation of electronic manufacturing, after consulting relevant experts and implementing ERP-based integrated financial management, the following indicators of the industry will be greatly affected:

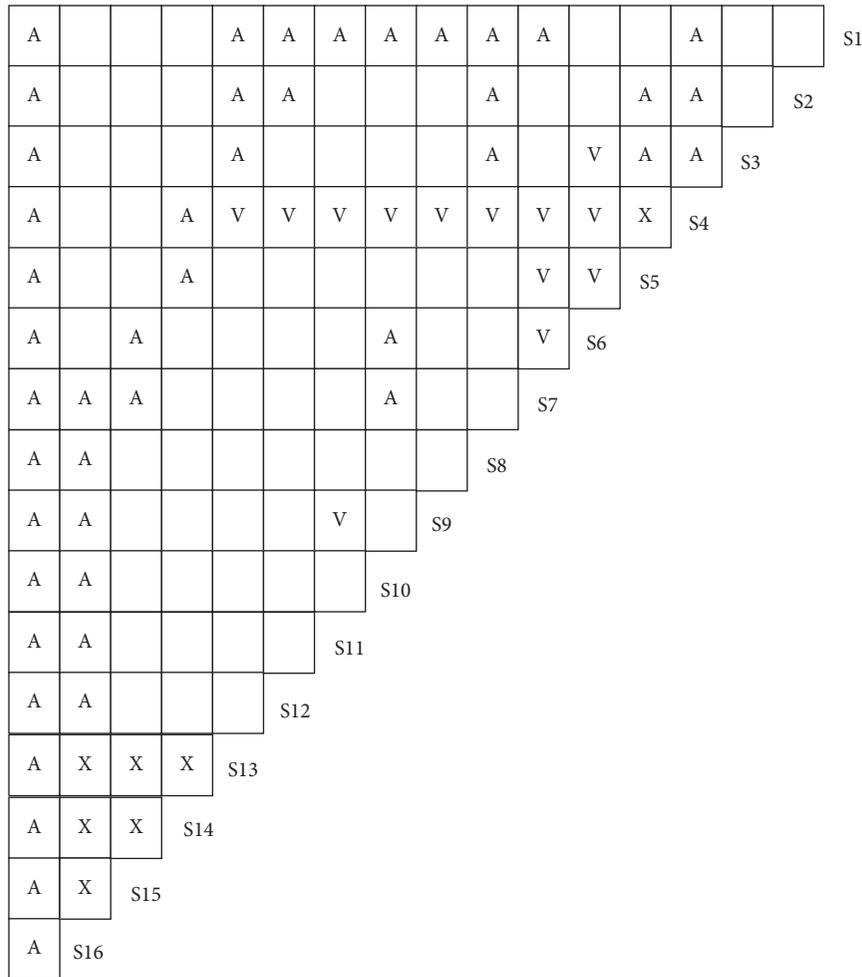

- (1) *Management Benefits.* (1) After the implementation of integrated financial management, the network and software are used to standardize the management of the enterprise, straighten out the management process of the enterprise, and make the inventory cost of the enterprise drop significantly. Through effective daily supervision, the purpose of reducing inventory costs and saving funds has been basically achieved. At the same time, due to the constraints of the network and software, the occurrence of enterprise violations and illegal acts has been effectively prevented, and the work efficiency of employees has been greatly improved, thereby increasing management benefits. (2) The information and data in the system can be used to continuously adjust the ratio of inventory to funds, increase the turnover frequency of products as much as possible, increase the turnover rate of funds, and improve the efficiency of the use of funds. And the credit control module of the system can be used to monitor the accounts receivable and accounts payable in real time, strengthen the analysis of information, prevent the occurrence of "bad debts," and improve the credit of the enterprise. (3) With the development of the project, especially the continuous improvement of the process, it overcomes the randomness of the management behavior of the managers and prompts the employees to gradually change the logic of

dealing with things that they used to think in the past and understand that the work they do is not only about the existing operations. When the process is moved into the system, it is more important to find the unreasonable part of the original work and to integrate the advanced management ideas and methods into the future process. It helps to improve the team awareness of employees and makes the whole company form an excellent management team.

- (2) *Economic Benefits.* (1) After using the system, the entire production process of the enterprise is organically combined, so that the enterprise can effectively reduce the inventory, ensure stable logistics to support normal production, improve efficiency, reduce the enterprise's inventory investment, improve the inventory turnover rate, and effectively reduce capital occupation. (2) Reduce the phenomenon of delayed delivery and improve the level of on-time delivery. From the beginning of the product sales plan, it manages and counts various pieces of information about its sales products, sales areas, and sales customers and makes a comprehensive analysis of sales volume, amount, profit, performance, and customer service. The inventory is steadily reduced, the service level of the enterprise is greatly improved, and the delay rate is reduced, thereby greatly improving the credibility of the enterprise. (3) The procurement lead time is effectively shortened. With timely and accurate production plan information, purchasing personnel can concentrate on value analysis, source selection, study negotiation strategies, understand production problems, can determine reasonable order quantities, excellent suppliers, and maintain the best safety reserves. Provide ordering and acceptance information, track and urge materials purchased or outsourced for processing, and ensure the timely arrival of goods. This shortens the procurement time and saves procurement costs.

After the implementation of ERP-based integrated financial management is completed, the evaluation before and after the implementation is carried out, and the evaluation factors proposed before are comprehensively analyzed, the main indicators are extracted, and a comprehensive performance evaluation system is established. The evaluation factors mainly include capital turnover, work efficiency, management Informatization level, employee quality, customer satisfaction, corporate image, reduction of downtime, shortened procurement lead time, reduction of delayed delivery, reduction of inventory, reduction of management personnel, management benefits, growth benefits, customer benefits, economic benefits, and enterprise integration benefits.

4.2. Implementation Effect Evaluation Based on ISM-ANP. Set up an IMS evaluation structure team, according to the calculation requirements, after expert discussion, the final

Enterprise comprehensive benefit

FIGURE 2: Integration diagram of the general ledger section of the accounting module composition.

indicators will be listed as follows: S_1 capital turnover, S_2 work efficiency, S_3 production capacity, S_4 management information level, S_5 staff quality, S_6 customer satisfaction Degree, S_7 corporate image, S_8 reduce downtime, S_9 shorten procurement lead time, S_{10} reduce backorder, S_{11} reduce inventory, S_{12} reduce management personnel, S_{13} management benefits, S_{14} growth benefits, S_{15} customer benefits, and S_{16} economic benefits and enterprises overall benefit.

According to the suggestions of experts, establish the relationship diagram of the mutual influence of various indicators, as shown in Figure 2. “V” means that the row factor has a direct or indirect influence on the column factor, “A” means that the column factor has a direct or indirect influence on the row factor, “X” means that the row and column influence each other, and blank means that there is no mutual influence between the row factor and the column factor.

Calculating the logical relationship of the mutual influence factors of the enterprise comprehensive evaluation index of the reachability matrix R and L , the adjacency matrix A can be obtained. Let $A_1 = A + I$, $A_2 = (A + 1)^2$, ..., $A_r = (A + 1)^r$. Then, after the Boolean algebra operation rules, $R = A_2$ is obtained, the row and column factors of the

reachable matrix R are the same, and it is a 17th-order square matrix; the arrangement order is S_1, S_2, \dots, S_{17} . The element corresponding to 1 in the new array indicates that the factor of the row has an influence on the factor of the column and the element of 0 means that the factor of the row has no influence on the factor of the column.

The evaluation model is obtained by ISM-ANP method, MATLAB programming, and SD software, S_1 capital turnover, S_2 work efficiency, S_3 production capacity, S_4 management informatization level, S_5 staff quality, S_6 customer satisfaction, S_7 corporate image, S_8 reducing downtime and waiting for materials, S_9 shortening procurement lead time, S_{10} reducing delayed delivery, S_{11} reducing inventory, S_{12} reducing management personnel, S_{13} management benefits, S_{14} growth benefits, S_{15} customer benefits, S_{16} economic benefits, and S_{17} various indicators of comprehensive enterprise benefits. The weights are shown in Table 1.

After the implementation of the integrated financial management model based on the increase of each indicator: $J = R * \omega = 0.3409 = 34.09\%$.

$R = (10\%, 50\%, 30\%, 10\%, 80\%, 50\%, 10\%, 30\%, 50\%, 50\%, 60\%, \text{ and } 30\%); \omega = (0.1776, 0.0959, 0.0763, 0.1216,$

TABLE 1: ERO implementation evaluation model of the final weight of each index.

Name	Normalized by cluster	Limiting
Production capacity	0.50774	0.177629
Work efficiency	0.27419	0.095924
Capital turnover	0.21806	0.076286
Employee quality	0.48486	0.121581
Management informatization level	0.51514	0.129172
Corporate image	0.71118	0.026877
Customer satisfaction	0.28882	0.010915
Management personnel cost	0.17364	0.062792
Inventory cost	0.25569	0.092463
Backorder cost	0.12497	0.045192
Procurement lead time	0.14627	0.052894
Downtime cost	0.18506	0.066920
Manufacturing cost	0.11436	0.041355

0.1292, 0.0269, 0.0109, 0.0628, 0.0925, 0.0452, 0.0529, 0.0669, and 0.041). It can be seen from the above calculation that, after the refined evaluation method of financial management quality based on the ERP model, the comprehensive performance of the enterprise is improved compared with that before the implementation of the model. Factors and the dependence and feedback relationship between factors can be considered, and the effect of implementation can be more clearly defined.

5. Conclusion and Outlook

This paper mainly expounds the basic theory of ERP integrated financial management implementation, the necessity of implementation, the implementation process and safeguard measures, etc., and puts forward the important factors that affect enterprise performance after the implementation of ERP integrated financial management. According to these factors, the evaluation index system is designed, the rationality and scientificity of the index design are verified by MATLAB software, the weight of the evaluation index system is calculated by the ISN-ANP method, and the index is explained and analyzed in detail. Finally, taking a listed company as an example, through the research on the implementation process of the integrated financial management based on the company, it analyzes the existing problems, the process of implementation, and the results of the implementation before the company does not implement it and finally draws the conclusion that the integrated financial management is based on the company's refined assessment method of financial management quality. The experimental results show that the comprehensive performance of the enterprise after implementing the integrated financial management quality refined evaluation method is 34.09% higher than that before the model is not implemented.

5.1. Summary

- (1) The process and safeguard measures for the implementation of integrated financial management are

proposed. On the basis of summarizing the theories of EPR and integrated financial management, this paper expounds the concept and characteristics of ERP-based financial management. These theories will lay a good foundation for the successful implementation of ERP projects.

- (2) ISM-ANP method is used to solve the problem of establishing the effect evaluation system of ERP integrated financial management implementation.

This paper introduces the ISM-ANP method and applies it to the ERP implementation effect evaluation index system. The combination of ISM and ANP can comprehensively consider various clear or unclear factors that affect enterprise performance and can consider the dependence and feedback relationship between factors, which can better solve the problem of ERP implementation effect. In this paper, referring to the industry situation and according to the suggestions of experts, the ISM-ANP method is applied to establish the implementation effect evaluation index system suitable for the electronic manufacturing industry. The use of MATLAB software and SD software for calculation saves time is beneficial to the ISM-ANP analysis method. Further promotion and application provide a reference index system for the relevant listed companies on the refined evaluation method of ERP financial management quality.

5.2. Prospect. Due to the authors' lack of practical experience and limitations of various conditions, although this paper has carried out research in terms of method and empirical analysis, there are still many deficiencies in the implementation process model and implementation evaluation index system of Chen Company, which need to be studied by other scholars' conduct further research.

- (1) Since the factors affecting enterprise performance after the implementation of ERP are quite complex, there are a large number of qualitative indicators, which makes the artificial selection of indicators not particularly objective, and the analysis of the factors related to the implementation effect is relatively superficial, so the evaluation of such indicators is not very objective. Whether the selection can accurately evaluate the implementation effect still needs further research and analysis.
- (2) The evaluation model and data sources need to be further improved. This paper adopts the Delphi method to assign the relationship between the indicators and the relative importance assignment by experts, which may have a certain degree of subjectivity, the reliability of the collected data is not high, and there are defects of subjective factors, which requires follow-up completely.

In the era of the 4G network, the scale and pattern of online music education have been formed, and its necessity and educational achievements have emerged. The 5G network era is coming, and online music education is once again facing new challenges, and it is imperative to make necessary changes. This paper, by expounding on the changes brought about by the 5G network era, combined with the characteristics of online music education in colleges and universities, will summarize and analyze the current work status and problems faced. Improve the level of work and make online music education reach a new height.

1. Introduction

In recent years, my country's higher music education has developed rapidly [1]. The latest data from the Ministry of Education show that the total number of students in various types of higher education in China is nearly 37.8 million. Among them, music education in colleges and universities, as one of the priorities in higher education, has always been highly valued by the party and the state [2, 3]. With the widespread use of 4G network technology, music education has also broken through the traditional single face-to-face mode, gradually introducing new technologies, broadening work ideas, and opening up new positions for online music education, attracting more college students to learn theory and education through online media. The results are remarkable. Recently, with the rapid development of network technology, the 5G network after 4G has achieved trial networking, and a faster and more convenient network era is coming. Under the new situation, the online music education work in colleges and universities will inevitably face new challenges, and the work ideas and methods will also face new changes [4].

The rapid development of network technology and the continuous progress of new media technology have brought

about great changes in people's daily life. Smartphones that can be connected to the Internet have become an important item for everyone to travel. As long as there is a mobile phone, reading and learning, shopping and driving, information query, and even identity verification can be realized. 4G network technology has truly changed people's daily life habits. Traffic and Wi-Fi have become the channel tools for modern people to exchange information with others. Among them, the emergence of new network media has expanded the channels for people to obtain information on a daily basis from newspaper publications and television broadcasts to network news terminals. Text, pictures, audio, and video, as information carriers, are constantly combined on new online media and become links and pushes. No matter at home or abroad, no matter the size of the news, just take out your mobile phone and can know what is going on in the world. The dividends brought by the 4G network era are obvious, the technological innovation is faster than expected, and the 5G network is coming to everyone [5]. In 2014, the transmission network based on 5G technology was interviewed for the first time. After several years of research and development, at the end of 2017, the 5G-phased full-featured standardization was completed. My country also

authorized the three major domestic operators to carry out system experiments in 2018. The technical principles of 5G networks do not need to be repeated, but the changes it will bring cannot be ignored. First, the data transmission speed in the 5G era has increased. The data transmission speed of the 5G network can exceed 1 Gb per second, and the theoretical peak value can reach tens of Gb per second. Compared with the 4G network, the data transmission speed is greatly improved. Second, in the 5G era, more devices and terminals can access the network. In addition to mobile phones, computers, and a small number of other devices, the current devices that can access the network will add more access devices and everyone will also have more smart devices that can access the network. Third, the 5G era will promote the development of big data technology. With more devices connected to the network, more data will be formed. Some scholars say that this will bring about a tsunami and blowout of data. The previous sampling data analysis technology cannot meet the demand, and it is inevitable that more big data technology that can analyze the whole data will be used. The explosive growth of data also puts more demands on big data technology, and the further development of big data technology is in line with the arrival of the 5G era. Traditional music and musical traditions are constantly changing with the evolution of social life, not fixed [6–8]. The relationship between Chinese and Western music has gone through different stages since its birth, and the situation and people's mentality reflected in each stage are different. The research in this area really goes from the analysis and explanation of the abstract idea to the concrete and detailed explanation. In music teaching, when affirming the excellence of traditional Chinese music, it is undeniable that the introduction of Western music has had a historical impact on the development of music in our country. The introduction of music forms does not equal the introduction of culture. The surface form of music culture is very important. It is easy to teach and accept [9, 10], and its psychological form has a deep relationship with a nation's way of life, behavior, and aesthetics in the deep level. What is more important now is to do research on the psychology of music culture. As far as my country's national music culture is concerned, from the point of view of being passed down from generation to generation and having characteristics, traditional music is not only regarded as traditional music in our era but also as traditional music in all dynasties [11]. In addition to historical inheritance, traditional music is especially important for its expressive and developmental nature, and the historical penetrating power that any tradition must have. After generations in the process of historical evolution, it still maintains its vitality and maintains its existence. This requires that the tradition must have the ability to recreate and the internal mechanism of recreation, and have the vigor of continuous reconstruction.

College students are more likely to accept the traditional education model, which requires face-to-face communication between teachers and students, which is conducive to the interaction between teachers and students, and the effect is obviously irreplaceable. The current college students are thoughtful, energetic, and have a strong ability to accept new

things. It is the group characteristics of college students. It has become a reality that college students are proficient in using mobile phones and computers to access information online. In the process of music education, using new media tools such as WeChat, Weibo, and various teaching APPs to communicate ideas with students through the Internet and transmit positive energy will inevitably make college students more receptive and more willing to accept. The network music work has also passed the initial stage of testing the water and has further developed to a mature and high-level stage. The content is more abundant [12]. The rapid development of network technology has profoundly affected people's daily life, and basic needs such as food, clothing, housing, and transportation can be solved by using the network. Among them, obtaining information through the Internet has become the behavioral habit of many people, especially college students, and it is not uncommon to have problems with "Baidu look" and "Zhihu look." Network technology also provides technical support for music education, and the emergence of new network media provides content and platform support for music education. The massive information on the Internet has become an important resource information base for music education [13], and the form of expression is more intuitive. WeChat, QQ, Weibo, etc. are commonly used information interaction platforms. College students are willing to obtain rich music through new online media. The use of the Internet and new media has further improved the effect of music education. Data from December 2018 show that the usage rates of WeChat Moments, Qzone, and Weibo are 83.4%, 58.8%, and 42.3%, respectively. As a group with more access to the Internet, college students often use various social media tools such as WeChat, QQ, and Weibo. Using new media tools and the convenience of the Internet, Si music education can be integrated into all aspects of daily life, which is convenient to create a good campus cultural environment, and is no longer limited by a fixed location and time. Through the effective use of life bits and fragmented time, as an effective supplement to the traditional education model, it is close to the needs and preferences of college students, easy to stimulate their enthusiasm and interest in learning, and increases the diversity of music education work methods. It is easier to achieve the ideal results of smooth acceptance, hydration, and noiselessness [14, 15].

2. Current Situations and Problems

For a long time, in the educational practice of our country, emphasis is placed on science and engineering, ignoring humanities, utilitarianism, ignoring quality, focusing on majors, ignoring foundations, focusing on books, and ignoring practice. The understanding of music education in ordinary colleges and universities is superficial, and the cultivation of college students' aesthetic education emotions has been neglected. However, some leaders in charge of music education in colleges and universities do not pay enough attention to music education. They mistakenly believe that music education is just simple singing and dancing, and think that holding some competitions and cultural

performances is the whole of music education, which leads to the teaching practice of music education in colleges and universities. It is not valued in music, and it is only in form and appearance, so college students' musical aesthetic ability cannot be truly improved and developed. Society lacks a profound understanding of the essence of music education, coupled with the fact that music education cannot bring direct economic benefits, and its role cannot be seen in the short term, to a certain extent, some people despise it and only regard it as a kind of embellishment or decoration, without knowing its value in essence. Therefore, society, schools, or families have given enough attention to music education. In this way, both educators and educated people bury in their hearts the subconscious thought that music education is not important, and its educational effect can be imagined. At present, most of the public music teachers in many colleges and universities come from professional music academies (departments), and their majors are vocal music, instrumental music, or theoretical composition during their studies. Therefore, they only focus on technical teaching in the teaching process, so that students have a good understanding of music. Compared with students majoring in music, students of other majors in colleges and universities have different foundations, different specialties, and different interests and hobbies. Although the teaching object and teaching purpose of the two are different, the teaching content is similar. The music curriculum is very random, the curriculum is scattered, and the phenomenon of people setting up courses can be seen everywhere. In addition, the teaching materials for general music courses in most colleges and universities are very limited, and there are only a few teaching materials recommended by the music education associations of colleges and universities. Compared with the situation where there are dozens of general comprehensive teaching materials for other disciplines and majors, there is a world of difference. The teaching content is separated from the actual needs of ordinary college students in colleges and universities. The public music textbooks are not included in the textbook management system uniformly ordered and distributed by the school. The textbooks used in the teaching are all searched and purchased by the teachers themselves. Therefore, it is difficult to guarantee quality. It can be seen from the survey data and the information inquired that the current situation of music education in ordinary colleges and universities has been greatly improved, but it is not as optimistic as we imagined. It seems that its situation is still dispensable. It is very strong, and some people regard it only as a kind of decoration, which is still in form and appearance and has not been paid any attention fundamentally. "Art education is important in talking, secondary in doing, not in busy." The phenomenon is still widespread. Furthermore, the development of music education in ordinary colleges and universities in my country is still unbalanced. Although a few schools have achieved good results, most of them still have many problems, such as the management organization of music education is not perfect, the teaching management is not perfect; the general lack of teachers and the low level of teachers; insufficient funding; and single teaching materials, teaching content, and teaching forms; the reasons for all

these phenomena are complex. Obviously, some problems cannot be solved by individuals, but only by the government and schools before they can be gradually solved and implemented. This article only analyzes and discusses the problems existing in music education in ordinary colleges and universities, hoping to find out the crux of the existing theory and practice.

- (1) More attention but still insufficient. At present, various colleges and universities have realized the powerful function and importance of the Internet, and many kinds of music teaching workers have also carried out educational and teaching activities through various network media tools, so that the working interface of music education is not only offline but also extended to online and established a solid educational position on the Internet [16]. The emphasis on online music education in colleges and universities has definitely increased, but the degree of emphasis is still insufficient [17]. There are still many websites and web pages and WeChat public platforms in colleges and universities, but the quality is not high. They pay attention to the form of content and despise the connotative value of content. The resource investment in online music education is still not enough. If you only think that online music is just a mechanical transfer of offline music education to the network, or that online music education only needs a few computers connected to the network, it proves that online music education is not enough. There is also a biased understanding [18].
- (2) Rich in content but different in quality. On the network platforms of colleges and departments, especially the WeChat public platform, information is released quickly, and the content covers a wide range of categories. However, there are still actual phenomena of uneven quality of some content published on different platforms or on the same platform. Too much emphasis on whether the title is eye-catching, the number of clicks on a single article, etc., and the lack of strict control of the quality of the content, the phenomenon of fried rice, and stereotypes still occur, and teachers in professional fields use online platforms and new media tools to conduct professional There are still fewer lectures.
- (3) The use of media tools tends to be skilled but the form lacks innovation. After the development in recent years, the number of university network platforms has reached a certain scale, with corresponding influence, and outsiders also know school information mainly through network media. There are more and more teachers and students in colleges and universities who are familiar with the use of new media tools. The website pushes a beautiful and professional layout and has accumulated a lot of operating experience. Information is released quickly, and news information can be released on the same day, which is much faster than traditional

paper media. However, with skill and speed, the atmosphere of music education through new online media is not strong, and most of them are information transmission, which fails to effectively combine music education and information. The newly generated network tools cannot be understood and used in time, which makes the innovation of music education work form insufficient. Figure 1 shows the relationship between music innovation education disciplines.

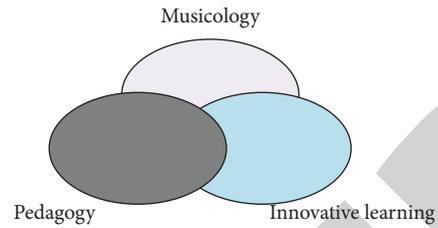

FIGURE 1: The relationship between music innovation education disciplines.

- (4) In quality education, music quality teaching is very important [19]. As an important part of art education, music education has a very high aesthetic education value. It is the most direct university aesthetic education and plays an irreplaceable role in the full implementation of quality education. Pursuing the comprehensive and balanced development of college students' personalities is the basic concept of music education in colleges and universities.

3. Ideas for Music Education Work under 5G

- (1) Establish the awareness of full participation in online music education in the 5G era. With the advent of the 5G network era, the impact of new technologies and the emergence of massive data will inevitably bring about new changes in the network music work pattern in colleges and universities [20, 21]. In colleges and universities, student education is not only the task of teachers but also the work responsibility of student staff, class tutors, and related staff. Similarly, the basic idea of educating people by all staff is bound to apply to the field of ideological and political work. All kinds of people can integrate music education into it based on their own work, form music education into work habits, and reflect music education with practical actions. In the 5G era, the network will pervade life, and the music education work examples of all kinds of people will become valuable materials for online music education, and everyone will become a participant in online music education. Through online sharing and reporting, narration, and guidance, online and offline linkages are formed to create an organic working system for online music education in the 5G era. Colleges and universities should help every worker to establish an important awareness of full participation in online music education through educational guidance and policy support.
- (2) Strengthen the construction of online music educators in the 5G era. Online music education requires a professional workforce [22]. In the 5G era, the emergence of new technologies and the new changes in the network landscape have put forward more and higher job requirements for online music educators. Most colleges and universities have not established a full-time network music education team, and many

workers still undertake a lot of other work. The new job requirements will bring more work tasks, and the establishment of a full-time team will ensure full input of work energy to meet the new challenges. At the same time, the resource investment in the workforce should continue to increase, and the professional quality of the workforce should be improved through the training of theoretical literacy, media technology, educational methods, and frequent exchanges in the Internet industry, media industry, and education industry. In the full-time work team, the theoretical talent team will be further enriched, and finally, a team of network music educators in the 5G era with strong ideas, outstanding abilities, and a combination of full-time and part-time jobs will be formed. The full-time work team combined with the actual work of full participation in online music education will help colleges and universities to ensure the work effect of online music education in the 5G era [23].

- (3) Open up a new frontier for online music education in the 5G era. In the 5G era, network transmission is faster and traffic costs may be lower. Coupled with the emergence of various technologies, the impact is no less than the 4G era. Among the online tools currently used by college students, WeChat, QQ, and Weibo are no longer new, and more media apps such as Douyin and Zhihu have also become online gathering places for college students. Online music education cannot only be satisfied with WeChat, Weibo, and other tools but should quickly adjust to emerging platforms to work. In the future, if the traffic cost is further reduced, the traditional text and pictures may also lose their advantages, and the audio and video will have more room for development. The focus of online music education can also gradually shift from text and pictures to audio and video, using audio and video to share news information and convey correct ideas. At the same time, try to introduce VR technology, big data analysis technology, etc. in online music education, through new technological innovation work mode, data analysis to understand the current state of mind of college students, understand the different needs, and provide a reliable basis for future work design.

Constructive music teaching is a teaching mode based on constructivism theory. The teaching mode of constructivism is “student-centered, teachers play the roles of organizers, guides, helpers, and facilitators in the whole teaching process, and use the learning environment elements such as situation, collaboration, and conversation to give full play to students’ initiative, enthusiasm and initiative, and ultimately achieve the purpose of enabling students to effectively realize the meaning construction of the current knowledge.” In this model, students are the active constructors of the meaning of knowledge, and teachers are the organizers, guides, helpers, and facilitators of meaning construction; the knowledge provided by textbooks is no longer the content taught by teachers, but students actively construct the object of meaning; the media is no longer a means and method to help teachers impart knowledge, but a cognitive tool for students to actively study and explore collaboratively. The more mature teaching methods that have been developed so far include scaffolding, throwing, and random access (also known as random access). These theoretical frameworks are fully applicable to the music teaching process and can be used innovatively.

- (1) Scaffolding music teaching. The scaffold originally refers to the scaffolding used in the construction industry. It is used here to vividly describe a teaching method, that is, students are regarded as a building, and students’ “learning” is a process of actively constructing themselves, while teachers’ “Teaching” is a necessary scaffolding that supports students to continuously construct themselves and develop new problem-solving skills. Taking the Xiangjiao version of the music textbook “Let the World Be Full of Love” as an example, teachers can show students the structure diagram of the whole class (see the figure below) by writing on the blackboard before class, so that students can clarify their learning ideas and goals [24]. On this basis, fill in the detailed content of the section one by one in groups. In the whole teaching, teachers only teach songs through various media and guide students to promote teaching progress one section at a time, while more time is reserved for students to use section thinking to construct to make the world full of love as the theme. The system of emotion and knowledge can achieve the purpose of aesthetic and emotional education for students. Figure 2 shows making the world full of love.
- (2) Throwing-out music teaching. This teaching mode requires that it be established on the basis of contagious real events or real problems. The real events or problems are vividly likened to “sketches,” because once the event or problem is determined, the entire teaching content and teaching process are also confirmed, just like the ship is wrongly fixed. For the music class “Let the world be full of love,” “pin” is “to fill the world with love,” which not only includes the song “Let the world be full of love” but also guides students on how to understand and feel “love.” Love

FIGURE 2: Making the world full of love.

“includes human affection and human love (see the picture below).” After the teacher “breaks down,” the rest of the time needs to be more for teachers to participate in students’ discussions on an equal footing and for students to communicate and share with each other. Different individual students have different understandings of “love” and different feelings about the song. Sharing their experiences of enjoying or feeling “love” in communication can enrich students’ in-depth and diverse understanding of “love,” and deepen emotional cognition. Figure 3 shows understanding and feeling of “love.”

Creative music activity is complex, which requires the fusion of music logic with more left-brain activities and musical intuition with more right-brain activities, so that music innovation education and brain science are linked together, interacting, influencing, and promoting each other. Figure 4 shows the relationship between music creation and brain function.

In the creative music teaching practice, the creative teaching method is the main method, the game teaching method and the technology intervention method are supplemented, and the interactive method, the telling method, and the guiding method are also used comprehensively. The teaching concept basically involves three major music teaching systems, such as letting students create rhythm with rhythm and melody, using Colvin gestures to create melody, and using Orff instruments to improvise an accompaniment. The teaching theme of “Cultivating Musical Ability by Participating in Creative Music Games” is to integrate games into the process of music learning, improve students’ interest in music creation, and encourage creative performance; the teaching target is eighth-grade students who have never been exposed to songwriting. The content is the development and extension of the typical Spanish-style flamenco dance rhythm [25]. First, divide all the students into four groups, namely, rhythm group, transmission group, rhythm group, and singing group; secondly, collectively learn and practice knowledge about rhythm patterns, transmission objects, rhythm, and pitch; and third, groups will cooperate to display the music knowledge they have learned; fourth, creative teaching, requiring students to improvise specific and incomplete melodies, and show their achievements through the students’ creative work session. The teaching steps are as follows: first, import through collective momentum and rhythm imitation games; second, sound creation learning through the students’ understanding of the regular staff, create music for the displayed graphic spectrum. Figure 5 is an example of a graph spectrum.

The arrival of the 5G network is just around the corner, and people’s life will be more convenient. The online music work in colleges and universities will also usher in new changes accordingly, adapt to technological changes, combined with the new work situation, establish a music work

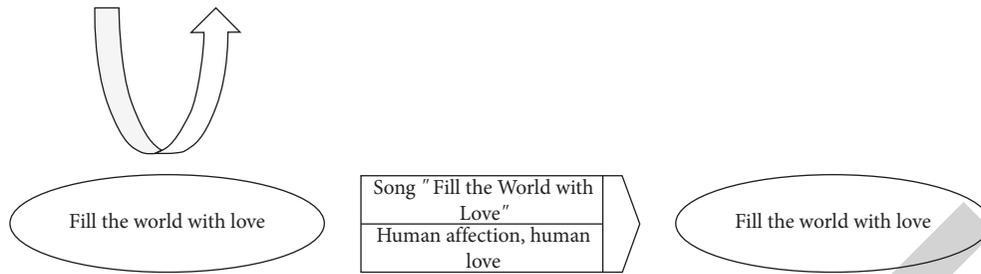

FIGURE 3: Understanding and feeling "love."

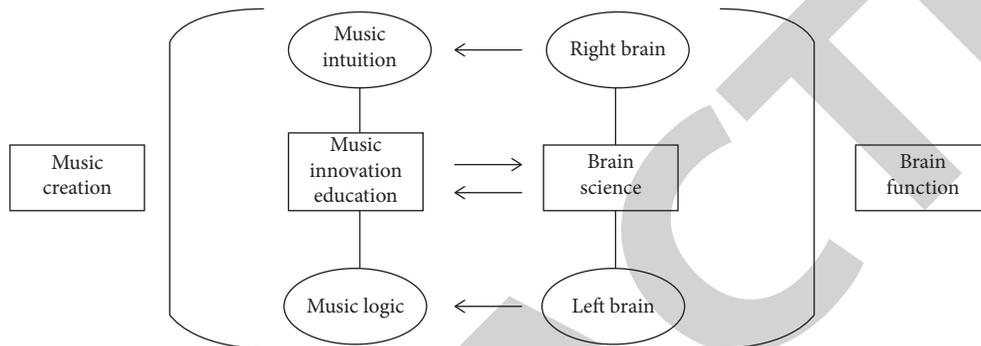

FIGURE 4: The relationship between music creation and brain function.

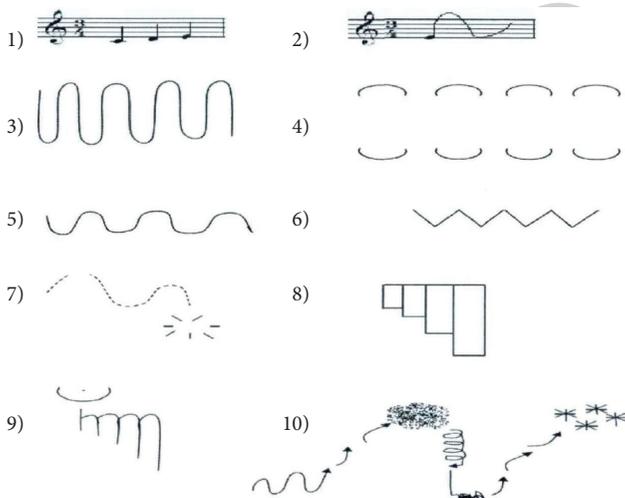

FIGURE 5: Example of a graph spectrum.

awareness in line with the new era of the Internet, constantly broaden work ideas, innovate work methods, and improve content quality by improving content quality, innovating the form of content expression, and introducing new technologies will surely once again enhance the work level of online music education.

4. Conclusion

In short, under the impact of the Internet in today's society, traditional statistical services have been unable to keep up with the times. While the Internet has provided great help, it has also put forward new requirements for traditional

statistical services. The complex and difficult statistical service system will definitely be replaced by the electronic information-based statistical service system. Therefore, it is an inevitable trend in the new era to establish an electronic information-based statistical service file system in the statistical service department. Following the trend, increasing the information management efficiency of statistical services, and establishing an electronic information-based statistical service system in the new era is a major way for our statistical service industry to contribute to society. It is also the technical basis for promoting the comprehensive management of statistical services. Therefore, statistical service departments should fully realize the importance of informatization construction of statistical services, improve the statistical service system, improve the professional quality of statistical service personnel, and promote the informatization construction of statistical services.

School sports is an important part of sports. The participants are mainly school students. Students play an important role in the development of the country. The development of campus sports is particularly important for the future development of the country. With the continuous improvement of the level of sports technology, to achieve higher, faster, and stronger sports goals, the requirements for sports venues continue to increase. To study whether the environment of the school's badminton court meets the requirements of the school's teachers and students to exercise and whether it can achieve the purpose of improving their own sports skills, the above problems are studied. Through the analysis of the light environment in the school grounds, to judge some problems existing in the badminton field of the school, improvement measures are put forward through research, and feasibility analysis of the improvement measures is carried out.

1. Introduction

The light environment is an important indicator that affects the comfort of the badminton court, so a suitable light environment affects the performance of athletes to a certain extent [1]. The impact of the light environment on athletes is mainly manifested as glare, due to inappropriate distribution or range of brightness, or too strong contrast, causing discomfort or visual conditions that reduce the ability to distinguish details or objects. According to the degree of glare's impact on vision, it can be divided into disability glare and discomfort glare. Disabling glare can cause a decline in visual ergonomics, while discomfort glare affects people's visual comfort [2–5]. Generally speaking, the presence of glare in badminton courts is uncomfortable glare. Uncomfortable glare will weaken visual function to a certain extent, affect visual performance and work efficiency, and cause safety hazards in important visual workplaces. Long-term effects

will cause psychological damage, discomfort, and visual fatigue, which in turn lead to physical discomforts such as irritability, inability to concentrate, migraine, and eye diseases. Therefore, uncomfortable glare is an important indicator in lighting design, which is usually evaluated by the UGR system (unified glare value) [6–9]. In addition, there are the VCP method, the cutoff angle method, and the CIBSE LG3 method for reflected glare. The physical term for the light environment is called light intensity, abbreviated as illuminance, and the unit is lux or lx.

2. Experimental Investigation

2.1. Experimental Objects and Instruments. In the badminton court of a university gymnasium, a student was selected as the experimental object, and the serving test was performed in 3 different illumination time periods. An experimental subject is picked, and the skin temperature, heart rate, etc., are recorded before the test, so that the heart

rate is stable, and then, the ball is served in sequence in 7 fields. Make sure that the test subjects are tested when their heart rate is basically stable. The test subjects serve on the side of the court, and then, the data are recorded. The experimental equipment used mainly includes thermometers, black ball thermometers, sports watches, and hula hoops.

2.2. Experimental Method. This study investigates the badminton court in a university gymnasium and mainly analyzes the problems existing in the light environment of the badminton court in the gymnasium of the university. The research methods mainly include survey method, literature research method, simulation method, qualitative analysis method, and experimental summary method.

2.3. Experimental Scheme. The university arranged a total of 7 indoor badminton courts side by side. 7 courts were used as the control group, and only the light environment of these 7 courts was studied. The light environment experiment is mainly divided into two parts. The first part is to test the illumination of each area of the badminton court in the gymnasium of the school. Since each field is large, each field is divided into 12 areas to test the badminton field in groups and test the illuminance of each area of each site. Figure 1 shows the division of badminton test area.

The lighting of the school's gymnasium badminton court consists of two lighting modes: natural light sources and lamps. There are windows on the north and south sides of the venue and a ribbon-shaped skylight on the top. The illuminance test is to test the illuminance of the site at different times, record the illuminance of each site area under different light environments, and conduct statistical sorting and analysis. According to the use time of the venue, the illumination data of each venue will be obtained in six time periods: 9:00, 11:00, 13:00, 15:00, 18:00, and 21:00. The test content includes glare in each area and direct illumination in each area. The second part of the light environment experiment is to analyze whether the light environment of the school's gymnasium badminton court has an impact on sports through experiments.

3. Results Analysis

3.1. Thermal Environment-Related Indicators. In photometry, "luminosity" is the density of luminous intensity in a specified direction, but is often misunderstood as illuminance. The international unit of luminosity is the light received per square meter (called candela in mainland China, Hong Kong, and Macau). Light intensity has a great influence on the photosynthesis of organisms. It can be measured by a light meter [10–15].

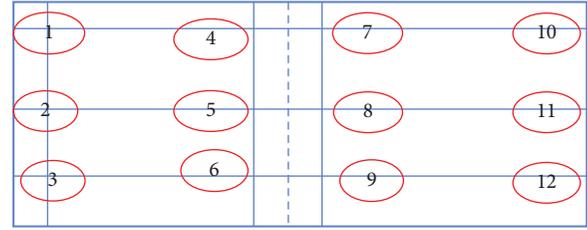

FIGURE 1: Division of badminton test area.

3.1.1. Calculation Formula.

Average illuminance (Eav)

$$\begin{aligned} & \text{total luminous flux of light source } (N * \Phi) \\ & = \frac{* \text{utilization factor (CU)} * \text{maintenance factor (MF)}}{\text{area area}(m^2)}. \end{aligned} \quad (1)$$

(Note: applicable to indoor or stadium lighting calculations).

Utilization coefficient: 0.4 for general indoor use and 0.3 for sports.

Maintenance coefficient: generally, 0.7 ~ 0.8 is taken.

3.1.2. Standard Value. The average illuminance on the work surface or reference plane is maintained, and the average illuminance on the specified surface shall not be lower than this value. It is the average illuminance on a specified surface at the moment when the lighting installation must be maintained, which is the illuminance required to ensure visual safety and visual efficacy at work. The national standard of the People's Republic of China "Architectural Lighting Design Standards" GB50034-2013 specifies the general illuminance standard values for new, renovated, and expanded residential, public, and industrial buildings.

3.2. Illumination Data Analysis of Each Area of the Badminton Court. During the investigation, it was found that the lighting methods of the school's gymnasium badminton court mainly include complete natural lighting, combination of natural lighting and artificial lighting, and complete artificial lighting [16–19]. In most cases, the badminton court in the gymnasium of our school only relies on natural lighting and artificial lighting. In the case of the combination of the two lighting modes, it only exists in the morning and evening with natural light sources but cannot meet indoor lighting. The time is relatively short. This experimental investigation mainly studies the illuminance of indoor lighting under natural light and when the lights are turned on without natural light. In the case of sufficient natural light sources, it can be divided into two situations: curtains drawn and curtains not drawn. Therefore, this survey mainly studies various time periods of natural light, including 9:00, 11:00, 13:00, 15:00, 18:00, and 21:00. According to the illuminance of each area in six time periods, the following

statistical table is obtained according to the calculation formula of average illuminance (Eav) (Table 1).

It can be seen from Table 1 that the illuminance value of the badminton court varies with time, and there are obvious differences in the illuminance of each venue in different time periods. The comfort of the venue is judged by the illuminance value of each venue.

From Figure 2, it can be seen from the broken line graph of the illuminance of the badminton court that the illuminance changes in each venue in different time periods and the illuminance of the draw is also different for different venues in the same time period according to different distribution positions. Combining the statistical table of illuminance values of each venue at different times in Table 1 and the two graphs of the broken line chart of illuminance of the badminton court in Figure 2, it can be clearly found that the illuminance of the venue increases from both sides to the middle under natural light sources, while the illuminance of each area is relatively stable when the lights are turned on. The reason for affecting the illuminance is the use of lamps and lanterns. The survey test tested six time periods, namely, the illuminance of the site under three relatively typical lighting conditions under the condition of sufficient natural light source on sunny days, without drawing the curtain, pulling the curtain under the condition of sufficient natural light source, and turning on the light under the condition of insufficient natural light source. Among them, the test is 9:00, 11:00, 13:00, and 18:00. The four time periods are the data when the curtain is not drawn under the condition of sufficient natural light source, and 15:00 is the area of the venue after the curtain is drawn under the condition of sufficient natural light source. The data of 21:00 are the illuminance of each venue area under the condition that the natural light source is insufficient at night and the lights must be turned on at night. It can be seen from the test that the illumination of each area in the room is the highest when the curtains are not drawn under the condition of sufficient natural light source, followed by the curtains drawn with sufficient natural light source, and the illumination of each site is the lowest under the condition of artificial lighting. Among them, the illuminance is higher at 11:00 and 13:00 in the four time periods when the curtains are not drawn under the natural light source, followed by the time periods of 9:00 and 18:00, and the indoor curtains are shading at 15:00, but the illuminance inside the site is still higher than that in the morning and evening. From the experimental data, it can be seen that the lighting conditions of each site are also different in the same time period, because the installation of indoor windows is asymmetric on the north and south sides, and the installation positions of the windows are different, so the lighting conditions are not the same. The average illuminance on the north side with windows on both sides is higher than that on the south side. Because there are windows on the south side of Nos. 3 and 4, the lighting conditions are good, and there are pillars on the north side of Nos. 3 and 4 to block the light. The southern site is higher than the northern site under lighting conditions. Due to the location of the windows, the north and south sides of Site 1 and Site 7 are walls, so the illuminance under natural lighting

TABLE 1: Statistical table of the average value of illuminance at different times in each site. Unit: lux/m².

Numbering	Time					
	9:00	11:00	13:00	15:00	18:00	21:00

Venue 4	730	977	867	838	772	218
Venue 5	729	1008	866	820	711	255
Venue 6	716	931	851	761	752	131
Venue 7	611	714	744	714	645	243

is the lowest in the entire site. There are no windows on the west side of the No. 2 field, but there are windows on the east side. Therefore, the illuminance of 1, 4, 7, and 10 areas of No. 2 field is lower than that of 3, 6, 9, and 12 areas. According to the illuminance test data when the lights are turned on under the condition of insufficient natural lighting, it is found that the average illuminance of each area is between 250 lux and 350 lux under the condition of turning on the lights. There is a malfunction for some reason, resulting in the failure of normal lighting. Among them, the faulty lights have the first light and the second light on the north side of the east row in the middle of Nos. 3 and 4; the lights on the northwest side between No. 4 and No. 5 are faulty; the two lights on the south side of the row on the side were faulty; the two lights on the southernmost side of the west column between sites 5 and 6 were faulty, and the lights on the east side between sites 5 and 6 were faulty; a row of lights were in the middle of venues 6 and 7. Therefore, the illuminance of some areas is lower than the average value of this time, which leads to areas 2, 3, 7, 8, 9, 10, 11, and 12 of No. 4, areas 1, 2, and 3 of No. 5, and the entire No. 6 illumination in areas 1, 4, 7, 10, and 11 of the site; Site 7 will be affected.

3.3. Analysis of the Experimental Data of the Ground Light Environment of the Badminton Court. There is a control experiment in this experiment. To verify the influence of the light environment on the exercising population, other environmental factors and the personal factors of the experimental subjects should be basically controlled to avoid affecting the experimental results. Their heart rate and skin temperature are tested before each experiment to ensure that the heart rate of each experiment is basically the same, so as to avoid the testers' own physical conditions affecting the experimental results. The different time periods of the experimental illumination are divided into six groups. The illumination conditions in the six groups are the same as the conditions in the illumination experimental data. Each group of experiments is divided into seven times, and seven sites are tested. Test data of badminton court ground illumination environment (Table 1). The variable in the data is the time period of the test, and the ambient temperature in the test will be different due to the different control time period. Therefore, the ambient temperature is also used as a control variable, and both horizontal and vertical analysis are required to avoid as much as possible. Experimental bias:

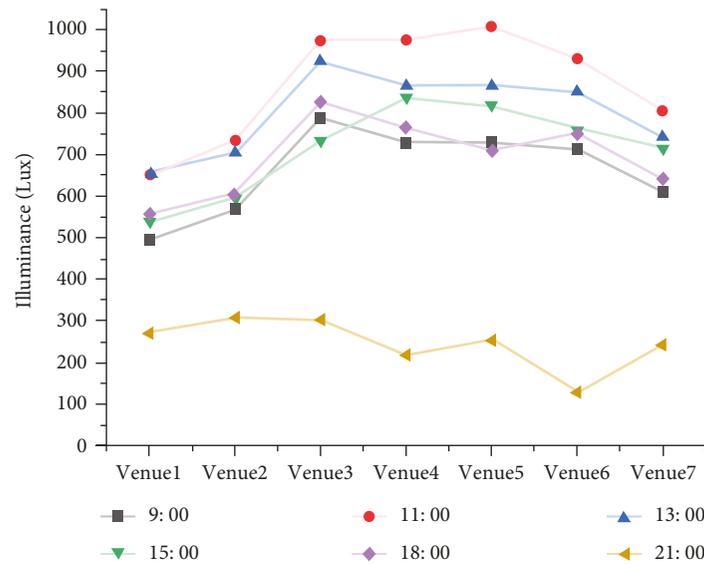

FIGURE 2: Badminton court field illuminance line chart.

To more intuitively see the influence of different temperatures and illuminance on the experimental results in this experiment, the bar graph of the ground light environment test data of the badminton court in Figure 3 is drawn according to the experimental data.

Figure 3 is a bar chart of the ground light environment test data of the badminton court, which can visually display the scores of each venue at different temperatures in different time periods and the scores of each venue at the same temperature in the same time period. Comparing the illumination environment scores of the same venue in different time periods, we can find the impact of different illumination in different time periods on sports performance. Through the difference in the scores of different venues in the same time period, it can be found that the impact of illumination in different venues on sports performance. The bar chart mainly shows the score of each field, and the main influencing factor is the different illumination of each field under different conditions during the test period. According to the experimental data of the badminton light environment, it can be seen that the illumination in each test period is different, so the final experimental result score data will also be different. The temperature during the experiment is also one of the influencing factors of the experimental results. Therefore, to visually see the score data under the influence of the two environmental factors, temperature and illuminance, the origin data analysis software is used to draw a 3D scatter diagram as shown in Figure 3. The three-dimensional scatter diagram is drawn from the test data of the ground light environment of the badminton court, and the three-dimensional scatter diagram obtained by the test data of the ground light environment of the badminton court. In Figure 2, we can see the scores of the experimental objects under the two experimental conditions of X -axis ambient temperature and Y -axis field illumination. Through the line chart and the three-dimensional scatter chart, it can be seen that the badminton court in the school gymnasium has different effects on sports under different time and light

conditions. From the line graph of the ground light environment experiment data of the badminton court in Figure 1, it can be seen that in the six time periods, in these groups of experiments at 9:00, 18:00, and 15:00, the scores of each venue are higher than other time periods; in the experiment at 21:00 (insufficient natural light source, turn on the lights), the low scores of each venue were lower than other time periods. By analyzing the experimental data under the conditions of light and temperature, using the temperature as a quantitative measure, and analyzing the data of the experiment under the same or similar temperature conditions, we can know that for sports, the light intensity needs to be within an appropriate range, and people can exercise to achieve intended purpose, when the illumination is too high or too low is not conducive to physical exercise. The three time periods with the highest scores, 9:00, 15:00, and 18:00, are basically between 500 lux and 800 lux. The experiment shows that when the illumination is between 500 lux and 800 lux, athletes will achieve the best performance.

4. Discussion

4.1. Influence of Light Environment on Motion. Lighting mainly affects the illuminance and glare in the light environment [20–22]. When the illuminance is not enough, it will affect the judgment of the sports people on badminton and causes visual damage. Through the illumination test experiment and the analysis of the light environment experiment, it can be seen that there are many problems in the badminton court in the gymnasium of the school. First of all, the illumination of the indoor badminton court of the school is uneven and there is glare. According to the national standard, the illumination of the badminton court is not less than 300 lux, while the illumination of our school's indoor badminton court is only about 200 lux when the natural light source is insufficient, which is not up to 300 lux. Illumination standard: in the experiment, No. 4 field

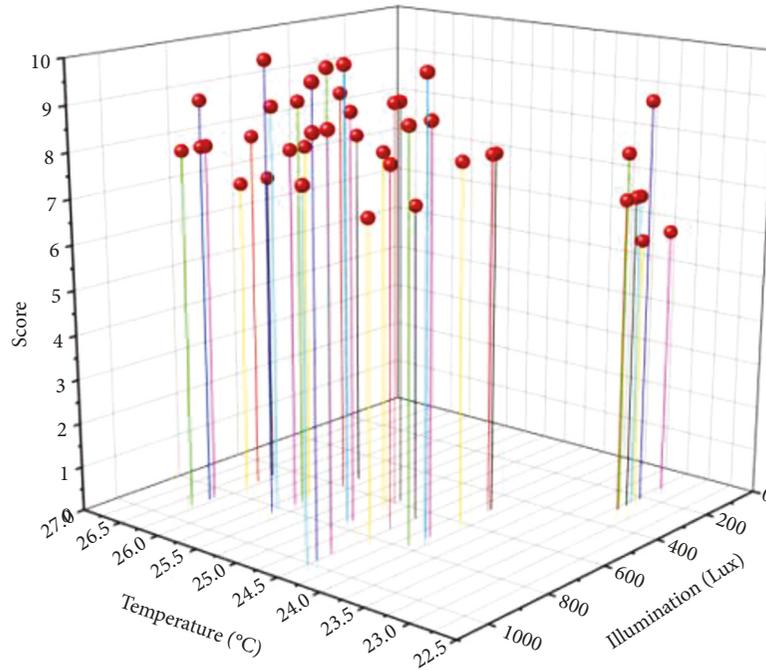

FIGURE 3: 3D scatter plot of the experimental data of the ground light environment of the badminton court.

scored the highest, and No. 4 field had medium illumination in each experiment, neither the highest nor the lowest. In the three experiments, the site with the lowest score data was the site with the highest or lowest illumination during the test during that time period. From the three-dimensional scatter diagram of the ground light environment test data of the badminton court in Figure 2, it can be found that both the illumination and temperature of the environment have a certain influence on the exercise performance, and there is also a standard value when the temperature and illumination affect exercise. In the influence process, it can be found that the influence of light on the movement is mainly in two cases, the illumination is too high or the illumination is too low. When the illuminance reaches a certain range, it is the most comfortable illuminance for exercise. Under this and illuminance conditions, people who are exercising will neither be unable to judge the movement situation because the illumination is too low, nor will they cause glare because the illumination is too high. Through this experiment, it can be found that the most suitable illumination range is in the range of 500 lux to 800 lux, so the final improvement of the stadium badminton court should also reach this illumination range. From the above data analysis, it can be concluded that the illumination has a certain influence on the badminton movement, and the optimal illumination required for the exercise is between a certain value. When the illumination is too high or too low, it is not conducive to sports.

4.2. Improvement Measures for Badminton Court. Through the above experiments and data analysis, it can be found that the problems to be improved in the badminton

court in the gymnasium of the school mainly include insufficient lighting and glare [23–25]. Regarding the problem, we will improve the badminton court in the school's gymnasium. For the problem of insufficient light illumination, higher-power lamps can be selected, and the existing damaged lamps can be repaired, to achieve the effect of increasing the illumination. For the glare problem, the illumination mode of the lamps can be changed and the illumination angle can be adjusted. Aiming at the problem of field illumination, the DIALux lamp modeling software is used for analysis. First, the spatial structure diagram of the badminton court in the gymnasium of the school as shown in Figure 4 is established to carry out the overall simulation analysis.

Figure 4 is a model based on the overall structure of the badminton court in the gymnasium of our school to restore the existing structure of the badminton court of the school, including all doors and windows. In this way, the interior lighting of the venue and the illumination of each area can be simulated under the condition of sufficient natural light sources. Then, the simulated environment is combined and arranged according to the installation method of the existing lamps. After the arrangement is completed, the DIALux software is used for lighting analysis.

As shown in Figure 5, the lighting of the badminton court in the gymnasium of the school is basically arranged around the lamps in the absence of natural light sources at night. The illuminance of the places illuminated by the lamps in a straight line is higher and then gradually decreases to the places where the lamps cannot illuminate. The calculation results show that the average illuminance on the ground of the badminton court in the entire gymnasium is about 150 lux, the maximum illuminance is 230 lux, and the minimum illuminance is 62 lux. The illuminance distribution is not uniform, and the illuminance values are quite

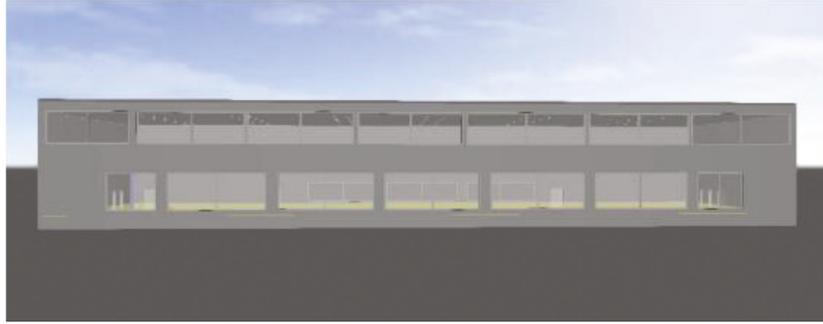

FIGURE 4: Construction of the badminton court model of the gymnasium.

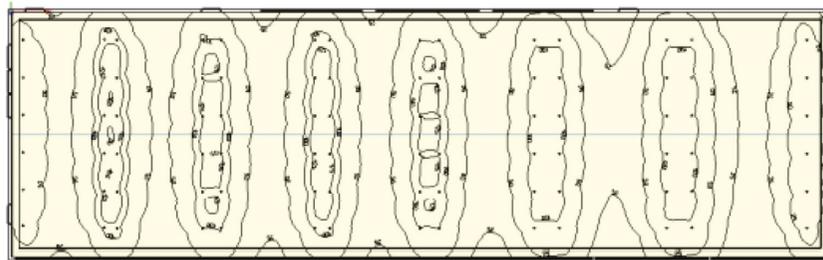

FIGURE 5: Simulation calculation result of the lighting tube of the badminton court in the gymnasium of the school.

different. However, considering that the light distribution method of the badminton court in the school gymnasium is mainly distributed on both sides of each badminton court, the light is irradiated to the middle of the badminton court by playing against each other on both sides, so that although the overall illumination is not uniform, exercising on the badminton court. The area can have good lighting. Therefore, although some areas have low illumination, they are basically dead ends of the movement and do not affect the overall badminton movement.

5. Conclusion

Although the venue as a whole meets the standards, some parts need to be improved. Compared with the standard facilities of the venue, the overall feeling of the sports crowd is also extremely important. Improving sports skills requires not only standard venue facilities but also the subjective feelings of sports people. Through the illumination experiment, it can be found that the illuminance of the badminton court in the gymnasium of the school is different under different illumination conditions and in different areas of the venue. The factors that affect the illumination include the light source and the building structure. Therefore, venue lighting not only needs to consider the selection of lamps but also allocates reasonably according to different venues and arranges lamps reasonably to achieve the desired effect. The ground light environment experiment of the badminton court found that among the lighting factors affecting the sports crowd, the school's badminton court illuminance has a suitable range. When the illuminance is between 500 lux and 800 lux, it is the most comfortable for the sports crowd, and when the illumination is too low, it will affect the sports.

It will affect people's visual effects in badminton, and when the illumination is too high, it is easy to produce glare, so the improvement of the venue should be based on the illumination standard between 500 lux and 800 lux.

Data Availability

With the continuous development of the social economy, people from all walks of life attach great importance to the smart home design of artificial intelligence technology. In the context of the information age, people's requirements for the quality of life are also gradually upgrading, and the requirements for home furnishing have also been upgraded from the traditional requirements of only living places to the expectation that a more intelligent, convenient, smart home has gradually been brought into life by people. The smart home system can integrate all control terminals into one system and implement on-site or remote control of home equipment using the computer terminal and mobile phone terminal, to realize the function of managing home equipment more conveniently and flexibly. Artificial intelligence technology as one of the important links adopts a structured design scheme to control and complete the design of the smart home system. Compared with most smart home systems on the market, this system also focuses on the safety precautions of the residential environment. It adopts infrared detectors for doors and windows and gravity sensing devices for indoor floors. The space-time barriers between home systems optimize and enhance the user's living experience. The article first analyzes the architecture, mainstream technology, and characteristics of computer technology and then discusses the design and implementation of my country's smart home system, providing strong support for subsequent research.

1. Introduction

With the rapid progress of computer technology and the continuous reduction in hardware costs [1, 2], virtual reality (VR) technology has ushered in a new wave of development, and many companies have begun to participate in the research and development of VR technology. Google of the United States developed the Google Cardboard product, Samsung of South Korea developed the Gear VR headset, and Sony of Japan developed the PlayStation headset. However, while the hardware equipment is booming, the lack of content seriously restricts the development and popularization of VR technology. At present, most companies try to expand the research direction and development prospects of VR technology by combining existing experience and new technical theories, especially the application of VR technology in the field of home improvement. The smart home is a new living concept based on the combination of

many technologies [3–5]. As the pursuit of spiritual quality is becoming more and more personalized, the traditional two-dimensional design concept can no longer meet the needs of modern people. Smart home products [6–9] are relatively expensive equipment and show functional characteristics through specific physical objects, which are expensive and difficult to adapt to the individual needs of customers.

The traditional home display method usually uses 3D renderings for visual simulation display [10], but this display method cannot realize the preview of the whole scene, which easily leads to the finished product being less than the customer's psychological expectation. Therefore, more and more people begin to apply VR technology [11] to the home simulation display system. This display method can not only provide users with an immersive home experience but also realize the self-service design of home details such as floors, floor tiles, and wallpaper patterns [9]. In addition, the traditional home display method has a complex design and

low drawing efficiency, while the home display method based on VR technology can be operated in batches, thereby improving work efficiency. To improve the display effect of home simulation [3] and realize immersive home display, this study proposes a home simulation display system based on virtual reality. The system is developed and designed based on HTC Vive VR equipment, fully considering the interaction between home display and users, and realizes personalized home decoration design. The simulation design and implementation results show that the proposed home display system can not only provide users with an immersive home experience but also can carry out modular design to improve the development efficiency.

The basic principle of a smart home [12, 13] is to allow human beings to experience the progress and development of technology and bring convenience to human life. Firstly, the application scenarios of a smart home are analyzed, how the intelligent functions in the home are realized intelligently, and the virtual reality technology is used to express intelligence [14, 15]. Therefore, this simulation system combines 3D modeling, from the user's point of view, and uses virtual reality technology to achieve a 3D demonstration of some functions of the smart home [16] control system. When the user clicks the relevant button, the simulation system will make a corresponding control response. Relying on ordinary residential quarters, this study takes the real simulation of the surrounding environment as the premise, fully excavates the basic needs of the residents as the criterion, fully demonstrates the convenience brought by the home to human beings, and completes a virtual simulation of a smart home with basic function demonstration system [17]. There are also many personalized smart home control methods, and the demonstration platform can be customized according to the user's DIY.

This study uses three-dimensional modeling technology, taking residential quarters as an example, to study the technology of a home simulation system. By collecting data and using SketchUp software to build and optimize the model of the simulation system, a realistic home scene model is constructed. The comprehensive use of the Unity3D rendering engine, combined with the virtual simulation system technology, realizes the intelligent simulation of the internal functions of the home, allowing users to feel the convenience brought by real smart home control on the computer [18]. The simulation system is easy to carry and provides convenience for smart home publicity, and at the same time, compared with the previous home control physical equipment, the simulation system costs less. This simulation system gives full play to the interactivity and autonomy of the 3D visual simulation technology in virtual reality and makes full use of the Unity3D rendering engine combined with the built-in ShaderLab shading language to further improve the rendering effect, creating a more realistic day, night, and indoor and outdoor effects. It improves the user's sense of immersion and simulates various intelligent control functions in the home.

Our work mainly studies the design of the smart home system, by analyzing the architecture of computer technology and the main features of its technology.

2. Overall Function Design of the System

2.1. Simulation System Function Design. To realize the personalized home design, the choice of various types of units, and hardcover rooms, this study proposes a home simulation display system based on virtual reality. The system realizes the roaming display, UI interaction, and scene switching of the rough house and DIY design, as shown in Figure 1. For DIY design, personalized home design can be achieved by implementing functions such as home object interaction, handle prompts, furniture placement, and floor material switching. The establishment of the smart home virtual simulation system [19, 20] has three macroscopic tasks: (1) the planning and construction of the entire scene environment; (2) the interactive realization of indoor scenes; and (3) the interactive realization of outdoor scenes. The 3D scene model is realized by modeling software; the 3D engine design realizes the interactive roaming of indoor and outdoor scenes and the demonstration of indoor home functions. The design of the entire simulation system follows the waterfall model, which is gradually refined from top to bottom. Figure 1 shows the overall functional architecture of the system.

The specific function design of each module is as follows: (1) the basic unit type module realizes the roaming display, UI interaction, and multi-scene switching of the home, and the user can realize the roaming by operating the handle. The purpose of this function is to achieve a global view of the layout of the house and use the UI menu to interact with the details of the home. (2) The self-service design module realizes the functions of personalized home design and user-independent switching of furniture and floor materials, object highlight display, and teleportation. As can be seen from the above figure, the simulation system mainly designs and realizes core functions such as intelligent simulation of internal components of the home in the virtual home scene, interactive roaming of the virtual scene, and dynamic simulation of the work of the housing pipeline.

2.2. Technical Process of Simulation System Implementation. The entire scene technical process mainly consists of three modules: data acquisition, SketchUp modeling, and Unity3D rendering. Firstly, the collected data are abstracted, the scene is set and planned, the house base map is made in AutoCAD, and the scene model is constructed using virtual modeling technology, material, and texture. After that, the construction of the simulation scene is improved in Unity3D, the required special effects are added to the environment, the virtual roaming of the scene is realized, and the program design simulation of the simulation system production is carried out for the functional demonstration in the home, and finally, the real-time rendering of the virtual environment is realized to complete the whole process. Figure 2 is a block diagram of the system technology roadmap.

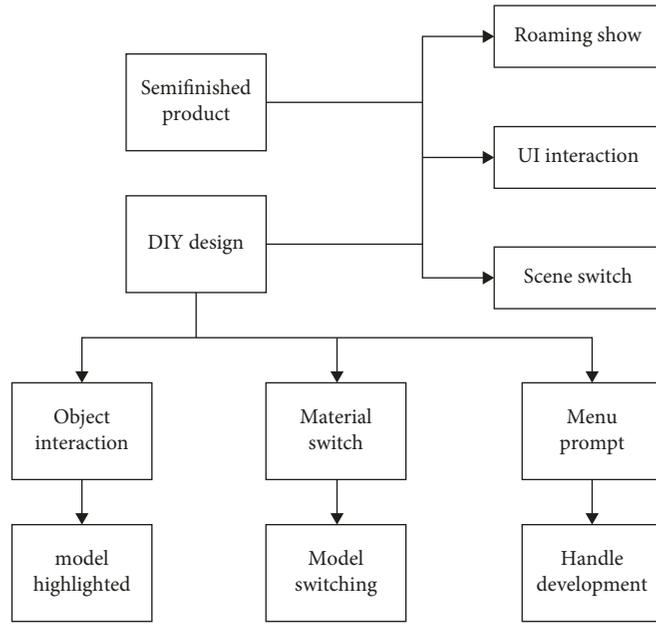

FIGURE 1: Overall functional architecture of the system.

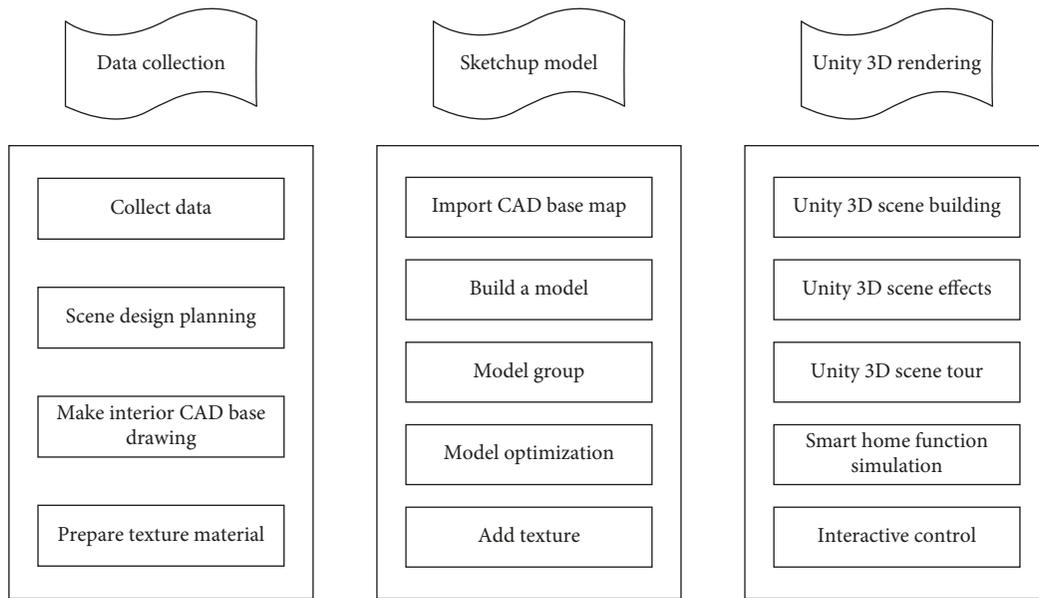

FIGURE 2: System technology roadblock diagram.

The technical route of design and implementation of a smart home virtual simulation system is as follows:

- (1) Carrying out the overall design and planning of the scene, building indoor and outdoor virtual environment models, and determining the scale, implementation route, and development tools of the simulation system development scene
- (2) Planning the area of the terrain; dividing the terrain area, the road interval, the number of street lamps, and the interval between the lamps; and setting the placement position of the home

- (3) The construction of the entire scene, the setting of light effects, the simulation of the natural environment, the construction of indoor object models, etc
- (4) The optimization, grouping, importing, and exporting preprocessing of 3D model to realize roaming interactive system
- (5) Adding sky effects, light sources, trees, fountains, fallen leaves, sun halo, and other environmental special effects to the virtual scene in the Unity3D engine; setting the roaming mode; and realizing the interactive control operation of the home and indoor household facilities

2.3. Selection of System Development Tools. The basis for the establishment of the entire simulation system is the model, and the quality of the model will affect the efficiency of the entire simulation system, so the establishment of the model is very important. At present, in the 3D simulation system, macroscopically, the modeling methods can be divided into two types: preprocessing modeling and real-time modeling. Microscopically, it can be divided into three types: the first is to use 3D software to model; the second is to measure and model through instruments and equipment; and the third is to use images or videos to model.

- (1) Using 3D Software to Model. You can see many excellent modeling software packages in the market, and the more well-known ones are 3D Max, SketchUp, Maya, and AutoCAD. The basic operations are to construct complex geometric scenes by rotating, extruding, stretching, or doing Boolean operations on the solid model. Using modeling software to build 3D models mainly includes geometric modeling, kinematic modeling, physical modeling, object behavior, and model segmentation.
- (2) Modeling with Instruments. 3D scanner is also known as 3D digitizer. It is a device used to analyze a real-world object or environment to gather data on its shape and possibly its appearance (e.g., color). The collected real stereo color data will be used to convert into digital signals that can be recognized by computers, which can then be used to build digital 3D models.
- (3) Modeling Based on Images or Videos. Image-based modeling and rendering (IBMR), referred to as IBMR, is a super-active research field in the current computer graphics community. Using IBMR technology, the information provided by the image is expressed by a three-dimensional model, which makes the entire transformation process convenient and fast.

2.3.1. Selection of Modeling Software

(1) *SketchUp.* The elegance and ease of traditional pencil sketches and the speed and flexibility of modern digital technology are perfectly combined by SketchUp Master. Master Sketcher is completely different from how we usually let the design process match the software too much, and it was specially developed to match our design process. In the design process, we are usually used to start from an inaccurate scale and proportion to start the overall thinking and continue to add details as the thinking progresses. Of course, if you need to, you can easily and quickly make precise drawings. Unlike CAD, which is difficult to modify, Sketch Master allows us to easily solve various modifications that occur throughout the design process according to design goals. Figure 3 shows SketchUp modeling example diagram.

(2) *Blender.* Blender is a free and open-source 3D graphics and image software that provides a series of animated short film production solutions from modeling, animation,

FIGURE 3: SketchUp modeling example diagram.

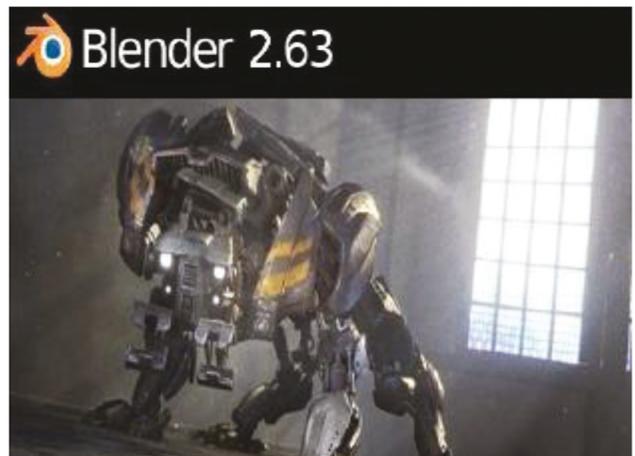

FIGURE 4: Logo of blender.

material, and rendering, to audio processing, video editing, etc. Blender has a variety of user interfaces that are easy to use in different jobs and has built-in advanced film and television solutions such as green screen keying, camera reverse tracking, mask processing, and post-junction compositing. Figure 4 is the logo of blender.

2.4. Realization of Function Display of Custom Home. To achieve an immersive user experience effect, this study uses HTC Vive equipment to build a workstation and combines VR technology to realize the basic unit module and DIY design module. The specific implementation process includes four stages: resource collection and production, environment deployment, application development, and release testing. The specific operation details of each stage are shown in Figure 5.

3. Design and Implementation of the System Model

3.1. System Design. The design of smart home system [21] is mainly composed of security protection function, intelligent control of household appliances, and network communication. Various system operations are carried out by the

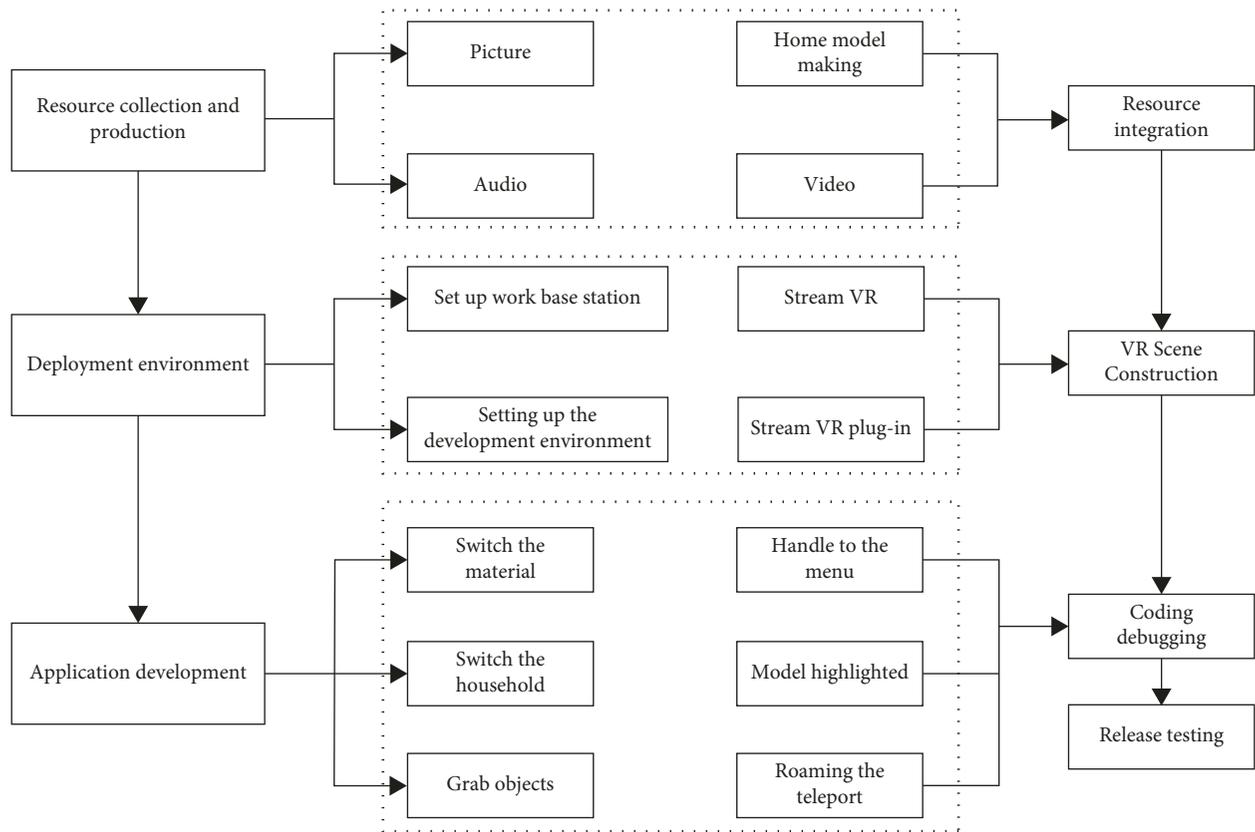

FIGURE 5: System implementation details.

intelligent security module, equipment control module, and wireless transmission module, respectively. The network communication is based on the wireless transmission module. Through the AP mode, the computer, mobile phone, and other devices can control the current mode. The intelligent control of home appliances is to use voice recognition to issue professional instructions to the system first and then control the operation of each system through the matrix keyboard. In terms of safety precautions, technologies such as video capture and human body detection are applied. When a human body passes by, the human body detection template will run immediately, turn on the camera, monitor the behavior and movements of people in the house at all times, save the data information, and transfer the picture to the mobile phone for mobile terminal.

3.1.1. System Hardware Design. In terms of system hardware design, the STM32 development platform is used as the core control of the system, the cloud platform provided by China Mobile and the wireless communication Wi-Fi technology is used as the communication medium, and temperature and humidity, flame sensors, and photosensitive sensors are mainly used in sensing nodes, smoke sensors, and other devices, collecting home environment information in real time, and displaying relevant data through display devices; at the same time, the system controls and links home devices through multiple relays.

The system adopts STM32F103 chip as the main controller, and its minimum system consists of power supply circuit, reset circuit, and crystal oscillator circuit. For the reset circuit, when the system is powered on, due to the existence of the capacitor, the NRST is at a low level. When the capacitor is fully charged, the reset pin (NRST) is at a high level, and the system works normally. After this pin is grounded, the system forms a manual reset. For the crystal oscillator circuit, the internal and external crystal oscillators can be switched, and the system is connected to an external 8 MHz crystal oscillator and a 32.768 kHz crystal oscillator, and the highest frequency multiplier of the system is 72 MHz.

Considering that the system hardware devices are relatively complex and the number is large, this article only introduces some of the hardware. In the display terminal, the hardware design method of the IIC protocol is adopted. Compared with the design of the SPI protocol, this design method reduces the general IO ports of the system and saves hardware resources; in the control terminal, considering that the operating voltage of the system is inconsistent with the operating voltage of hardware devices such as relays. A level converter is designed through the LM393 chip to solve the misjudgment phenomenon caused by inconsistent levels between devices; at the sensing terminal, each sensor node retains direct output (0-1) and analog output. The interface is convenient for system calls; in the transmission terminal, the Wi-Fi module of the ATK-ESP8266 model is chosen,

which has fast transmission speed and stable network and only needs to keep two data interfaces and two power interfaces to work.

3.1.2. System Software Design. In the software design of this system, it is mainly divided into sensor information collection at the perception layer, information transmission at the network layer, and multichannel relay control and data display at the application layer. Finally, the data obtained by the system are processed through a normalization algorithm.

In the design of the main program of the system, the sensor module, display module, control module, communication module, etc., used in the system are first initialized. After the initialization is completed, it is connected to the cloud platform. When connected to the cloud platform, the system will sense that the data of the layer are uploaded to the cloud platform in real time and judged. If there is an abnormality, the system will activate the alarm function. At the same time, the user can issue commands through the cloud platform to control the home equipment and upload the status of the home equipment in real time.

In the wireless communication node, the Wi-Fi module is mainly to perform related mode initialization settings. After the settings are completed, a TCP connection is established with the cloud platform. When the system is connected to the cloud platform, operations such as data uploading and command issuance can be performed.

After the data processing completes the collection of monitoring information, the collected information is pre-processed and classified, and finally, the processed information is learned, the most suitable processing method is calculated, and the data are sent to the user through the PTZ. According to the characteristics of smart home diversity, the data are monitored in a direct and normalized way.

The collected data are classified and processed by MATLAB software, various types of data are represented by graphs, and the size of the collected data and whether it is abnormal can be seen intuitively. At the same time, to ensure that abnormal information can be monitored and pushed to users, the data are analyzed through a normalization algorithm inside the system.

3.2. System Implementation. Nowadays, computer technology and 5G technology are becoming more and more mature, and high technology has gradually been integrated into people's daily life. As an important way to implement computer technology, smart home system is mainly reflected in the three aspects of upper computer, lower computer, and terminal control, as shown in Figure 6.

3.2.1. Host Computer Level. The host computer level includes data interaction, front-end control, Web page control module, and app control module. The back-end Django technology and the front-end Vue.js technology are used to complete Web page development. Being able to produce API objects helps to reduce the complexity of background

management. Window + Frame + Html code is used to implement control, and finally, the communication between the server and API.Ajax is realized, and the information is transmitted to the cloud SVN/GIT server.

3.2.2. Lower Computer Level. The lower computer is composed of a wireless transmission module, manual control module, voice playback module, backup power module, and other components. The single-chip system module is mainly implemented by the STM32F103VET6 single-chip micro-computer, and the voice playback module is completed by the most advanced iFLYTEK module, which constitutes the XFS5152-TTS voice synthesis module. The voice system is controlled. The speech recognition module is based on the Micro Snow LD3320 speech recognition module. The chip used is produced and designed by a specific company. This chip can run independently without the help of other chips. The equipment control module can reasonably control items such as doors and curtains. The driving stepper motor is very different from the voice recognition system. It uses the TB6600HG chip. The construction process of this chip is very complicated, and the current can reach 5 A. The driver has 5 subdivision modes, such as 1/16, 1/81, and 1/1, which can work stably in any environment. The manual control module uses matrix keys, and the keyboard module is mainly based on the 4×4 scale of external expansion and in-line keys, which is more stable than other keys.

3.2.3. Terminal Control. The terminal control module consists of a TFT LCD. It is the main project of ALIENTEK. It has the characteristics of wide viewing angle and low consumption. It can work at ultralow temperature. It can also collect humidity data, light intensity, and air quality in the air through the display camera, which is conducive to user perception.

The system selects the XFS5152-TTS voice module, which can synthesize Chinese and English voices, as well as play and record functions. The stepper motor is driven by a PWM constant current bipolar sine wave micro-stepper motor to drive a single chip, which has a reset function and a standby function, which can protect the parts due to built-in overheating in time. AP mode is like a mobile phone hotspot function, any Wi-Fi-related device can be connected, and it has a lot in common with the network bottom device mode. In this system, ESP8266 mainly uses the USART3 carrier to maintain communication with the microcontroller. It can also use the SSID mode and UDP broadcast mode of the mobile phone Wi-Fi terminal to broadcast. The broadcast uses the ESP8266 module, which can be directly connected to the router to keep the entire network unobstructed, which is conducive to remote control through mobile phones. In addition, the system has upgraded the sensitivity control system and safety protection system. In terms of energy, a backup power supply is added, which is usually used to save data and instructions that have not been saved in time when an unexpected power failure occurs. In terms of antitheft prevention, it not

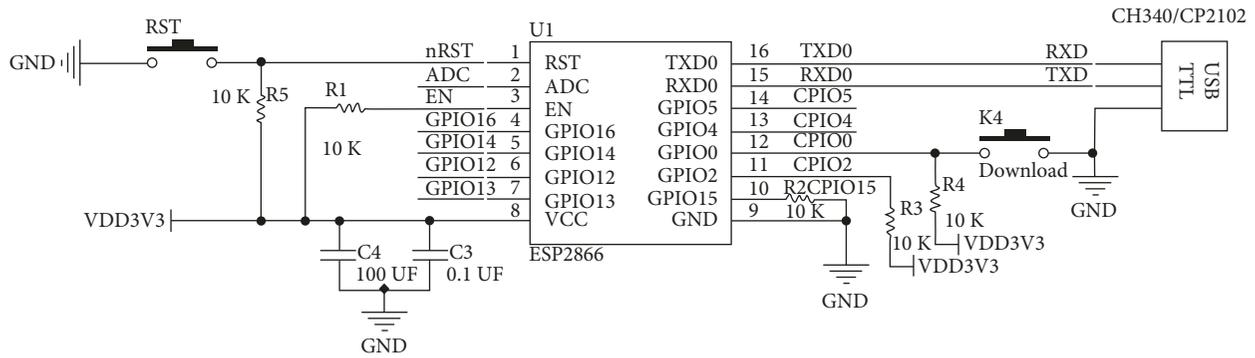

FIGURE 6: Schematic diagram of remote control template.

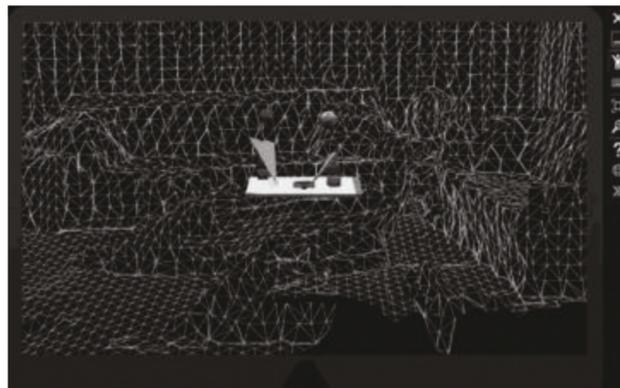

FIGURE 7: Point cloud data collected by the device.

only designs traditional image monitoring technology but also incorporates the latest infrared detection technology and gravity sensing technology. All residential door locks are equipped with face recognition technology, which is convenient for users to enter while saving the traditional key to open the door. In addition, an infrared receiving module and an infrared transmitting module are set above the door panel and on the top ceiling. These two modules are directly connected to the door lock switch. When the door lock is normally opened, the infrared detector will be turned off for a period of time. It will not be activated until the resident reenters, and then, it will enter a state of 24/7 persistent monitoring. If nonresident personnel enter, it is illegal entry, and then, the two infrared modules will not be closed normally. When the door panel is pushed open by an external force, it will directly trigger the security system and issue a special alarm to remind the residents. At the exposed windows of the residence, an infrared detection module is also set up and connected to the alarm system. In addition to the infrared technology in the doors and windows, a gravity sensing system is also placed on the indoor floor to form an all-around protection for the house. When a serious change in gravity is detected, the alarm system will be automatically triggered. The wireless technology module can control the communication Web page in a remote way and can realize remote control on the intelligent terminal.

4. System Implementation and Testing

Since the VR-based virtual reality home simulation system has certain requirements on software and hardware, this article uses HTC Vive equipment to build a workstation and uses the following development environment and tools to realize the functions of each module of the system. The system environment is as follows: Windows 10, 64-bit system, Nvidia GeForce GTX 1080 GPU, and Intel®

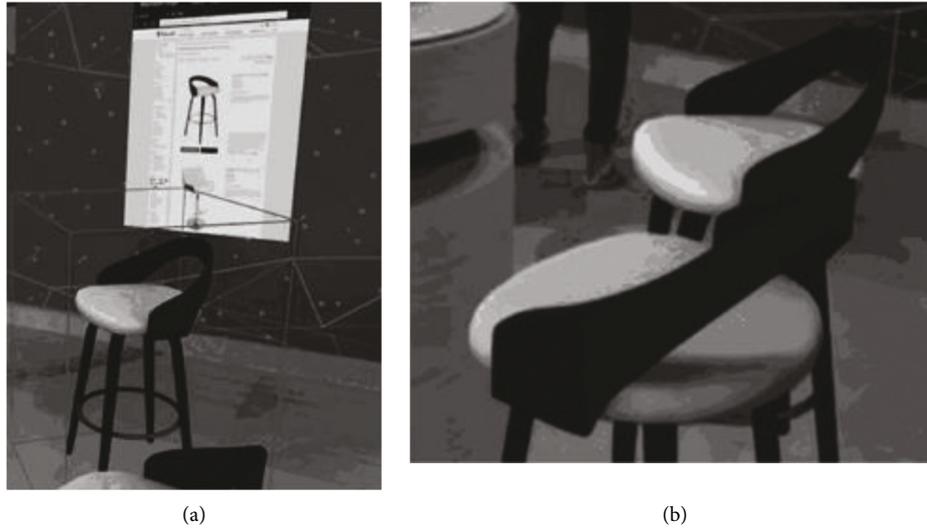

FIGURE 9: User interaction results.

TABLE 1: Comparison of computational events and memory occupied by algorithms before and after optimization of different models.

Number	Model	Memory footprint (MB)	Elapsed time (s)
1	Before optimization	548	1.62
	After optimization	417	1.05
2	Before optimization	433	1.24
	After optimization	359	0.87
3	Before optimization	845	1.97
	After optimization	766	1.84

Core(TM) i7-7700 CPU, VR development kit is DOTween (HOTween v2) 1.1.640, Virtual Reality Toolkit 3.2.1, and SteamVR Plugin 1.2.3.

Figure 7 is a visual display of the point cloud data collected by the device in this study. Figure 8 shows the results obtained after modeling the set of point cloud data.

This study also implements user-defined interactive operations and implementation effects, as shown in Figure 9. Users can interact with the movement, zoom, and holographic projection of the modeling results.

To verify the effectiveness of the model optimization in this study, Table 1 shows the computation time and memory occupied by the algorithm before and after model optimization. As can be seen from Table 1, the optimization can significantly save memory and reduce computation time.

5. Conclusion

This study proposes a computer-based smart home [21] simulation display system to achieve personalized home design, diverse unit types, and decoration choices. The

system uses the interface function module to realize the interaction between the system and the user and adopts the basic apartment type roaming module to realize the apartment type roaming function, and the hardcover model room display module provides the user's self-service design function. The scene rendering function, handle prompt, home placement, and floor material switching based on HTC Vive show that the home display method designed in this study can not only provide users with an immersive virtual home effect experience but also has high drawing efficiency and operational low-cost advantage. To sum up, with the continuous popularization of information technology, computer technology has a huge space for development. It can connect with different items in an intelligent way and finally realize intelligent management and control. At the same time, the complete application of computer technology in smart homes can not only improve the safety of smart homes [22, 23] but also improve people's quality of life. It completely breaks the space and time constraints of traditional home management, better improves the intelligent level of home life, and allows people to enjoy it more comfortably [24, 25].

The teaching quality monitoring and evaluation system in colleges and universities gives the scientific and objective evaluation of school teaching work and effectively optimizes and adjusts the important system of teaching work under the condition of deep excavation of the problems. However, the data on the teaching quality of colleges and universities in the state of static storage has seriously affected the value of data existence and the mining of laws. This paper mainly analyzes the application types of data mining technology in the college basketball teaching quality monitoring and evaluation system and discusses the data mining implementation method in the college basketball teaching quality and evaluation system, hoping to have a certain reference for relevant personnel.

1. Introduction

Today is an era of informatization, and also an era of the knowledge economy. As one of the most active and important factors, talents should be highly valued. As a base for cultivating high-quality talents, colleges and universities should pay more attention to the quality of talent training, provide high-quality talents for various constructions of our society, and realize the high-quality development of my country's economy [1]. In addition, the competition among countries is becoming more and more fierce. The essence of the competition is the competition of talents. If my country wants to occupy a more favorable position in the world, it needs to strengthen the training of talents. The cultivation of talents depends on education, and the quality of basketball teaching is of great significance to the quality of talent cultivation. Colleges and universities should fully recognize the importance of basketball teaching quality, not only to take effective measures to improve the teaching quality but also to take effective methods to monitor and evaluate the teaching quality [2–4], to ensure that the teaching quality of colleges and universities meet the needs of students development requirements.

With the continuous popularization of the Internet, basketball news information, and basketball events have been widely disseminated on the network platform, and the public's enthusiasm for basketball is rising. College basketball teaching is facing many challenges and opportunities. In the online teaching platform, teachers can integrate and disseminate rich teaching resources, exchange and share teaching experiences with other experienced teachers, and even communicate with distant teachers through remote interaction to improve teachers' teaching levels. Under the background of big data, the assessment and management of basketball teaching are more professional and informative, which standardizes the evaluation model of basketball teaching and training, and improves the effectiveness of basketball teaching; colleges and universities can also use digital assessment and management to improve basketball training and teaching. Carry out assessment and management, change the traditional and vague evaluation methods, and continuously optimize the relevant standards and norms of basketball training and teaching, so that basketball learning can achieve the goal of skill, professionalism, and healthy exercise.

There are many methods for monitoring and evaluating the quality of basketball teaching in colleges and universities,

among which data mining technology [5, 6] is a more effective method and has strong practical value. Relevant personnel should conduct in-depth research on data mining technology [7] so that it can play a greater role in the monitoring and evaluation system of basketball teaching quality in colleges and universities so that colleges and universities in our country can cultivate higher-quality talents. The guiding role of data mining [8] in basketball teaching is shown in Figure 1.

Data mining technology can perform data classification and prediction, cluster analysis and association analysis, etc., and can conduct deep data mining, which is an important research field to improve analysis and decision-making capabilities [9–11]. The introduction of data mining technology into teaching quality monitoring, objective analysis of existing performance data, and mining of valuable information will undoubtedly help improve teaching measures and improve teaching quality. At present, there have been related research on the application of data mining technology to teaching management [12]. For example, the literature studies the course association classification model and student achievement prediction algorithm based on frequent pattern spectral clustering; the literature proposes a K-nearest neighbor based local optimal The reconstructed incomplete data imputation method combined with the random forest model realizes the prediction of grades; the literature studies how to use the undergraduate grade data to infer the students' performance during the postgraduate period by means of various prediction and statistical methods. On the basis of learning from previous research experience, this paper uses factor analysis to comprehensively evaluate and analyze the performance of students majoring in computer science and proposes an improved decision tree method to predict student performance. A detailed comparative analysis was carried out, and a method that could better promote the monitoring of teaching quality was found.

2. Related Work

2.1. Data Mining and Knowledge Discovery. The superficial meaning of data mining technology means that when faced with a pile of data [13], it can be well processed, analyzed, and screened over and over again among these many data to select the most useful data. Databases are generally very complex. In this complex database, resources are continuously utilized. Through the study and mastery of data mining technology, the long-term accumulated data can be processed, and some data are random. If it is processed manually, it may increase the difficulty of the work of the staff and make the data cluttered. Users must learn to extract the data so that the data can be better used in people's lives. In the process of learning data mining technology, it is necessary to continuously learn new knowledge, discover new knowledge, follow the local characteristics and rules of different systems, and the data can be updated in time, and the knowledge in the database must be analyzed in detail; this requires A lot of information, the patterns or concepts and laws of this kind of information are different, each has its

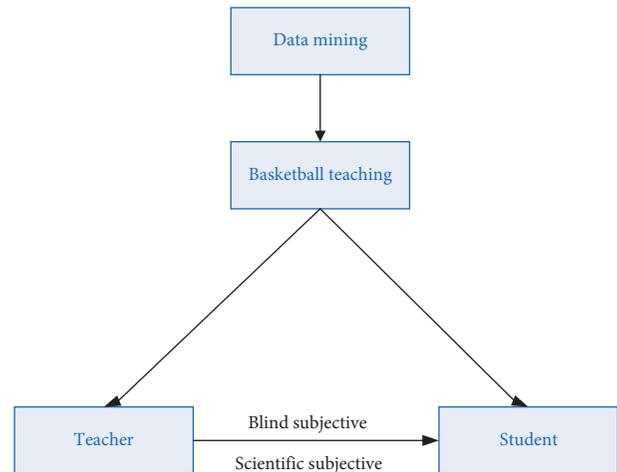

FIGURE 1: The role of data mining in basketball teaching.

own level, has a future prediction direction for the data, and makes decisions at the same time; another point is that data mining technology should be based on different The information of the students should be updated in a timely manner, and the information of the students should be understood in time, so as to have a good guiding effect on the course.

Knowledge discovery (KDD): knowledge discovery is a broader term for the so-called “data mining,” which is to obtain knowledge according to different needs from information represented by various media. The purpose of knowledge discovery is to shield users from the tedious details of the original data, extract meaningful and concise knowledge from the original data, and report directly to the users. There is still confusion between database-based knowledge discovery (KDD) and data mining [14], and the two terms are often used interchangeably. KDD represents the entire process of transforming low-level data into high-level knowledge. KDD can be simply defined as KDD is the specific process of identifying valid, novel, potentially useful, and basically understandable patterns in data. Data mining, on the other hand, can be thought of as the extraction of patterns or models from observational data, which is a general interpretation of data mining. Although data mining is at the heart of the knowledge discovery process, it is usually only a part of KDD (roughly 15% to 25%). Therefore, data mining is only one step of the whole KDD process, and there is no exact definition of how many steps and which steps must be included in the KDD process. However, a general process should accept raw data input, select significant data items, reduce, preprocess, and enrich data sets, transform data into appropriate formats, find patterns in data, and evaluate and interpret findings.

Because the quality of the data mining algorithm [15, 16] will directly affect the accuracy of the knowledge found by KDD, and most of the current KDD research focuses on data mining algorithms and applied technologies, people often do not strictly distinguish between data mining and knowledge discovery in databases both use each other. Generally, it is

called KDD in the field of scientific research, and it is called data mining in the field of engineering [17].

2.2. Data Mining Process. The KDD process is shown in Figure 2. The KDD process can be summarized into three parts: data preprocessing, data mining, and interpretation and evaluation of results.

2.2.1. Data Preprocessing. Data preprocessing refers to the set of techniques implemented on a database to remove noise, and missing and inconsistent data. The different data preprocessing techniques involved in data mining are data cleaning, data integration, data reduction, and data transformation. The need for data preprocessing stems from the fact that real-time data and many times database data are often incomplete and inconsistent, which can lead to incorrect and inaccurate data mining results [18]. Therefore, in order to improve the quality of the data to be observed and analyzed, it can be processed through these four steps of data preprocessing. The more data you improve, the more accurate observations and predictions will be. Figure 3 shows the steps of data preprocessing.

2.2.2. Data Mining. Data mining technology refers to a process of automatically retrieving from a large amount of complex data and automatically sorting out relevant information. To be precise, data mining is the “eye” for discovering knowledge base data, that is, to regularly search for chaotic data in massive data, so as to sort out the information that people need in an orderly manner. In fact, the process of data mining is fully automated, but many experts point out that only 80% of the time and experience in the data mining process is spent in the preprocessing stage. According to objective facts, many preparations need to be done before data mining technology. Even so, data mining technology is very convenient and can maximize work efficiency in practical applications [19]. In particular, teaching quality management using data mining technology in colleges and universities can assist teachers and college administrators in teaching analysis and other work, continuously develop and improve teaching systems and mechanisms, and promote the scientific development of schools. Accelerate the modernization of higher education with Chinese characteristics in the new era.

2.2.3. Interpretation and Evaluation of Results. The patterns discovered in the data mining stage may have redundant or irrelevant patterns after evaluation, and then they need to be eliminated; it is also possible that the patterns do not meet the user’s requirements, then it is necessary to fall back to the previous stage of the discovery process, such as reselecting. The data adopts new data transformation methods, sets new parameter values, and even changes a mining algorithm. Also, since KDD is ultimately intended for human users, it may be necessary to visualize the patterns found, or convert the results into another representation, that is, understandable to the user. Data mining is just one step in the

overall process. The quality of data mining has two influence factors: one is the effectiveness of the data mining techniques used, and the other is the quality and quantity of the data used for mining (the size of the data). If the wrong data or inappropriate attributes are selected, or the data is inappropriately transformed, the mining results will not be good [20]. The whole mining process is a continuous feedback process. For example, the user found that the selected data was not very good during the mining process. Or the mining technique used.

2.3. Methods and Technologies of Data Mining. There are many ways to operate data mining technology. First of all, the genetic algorithm will be introduced. This method is based on the laws of nature, survival of the fittest, survival the fittest, combining different data, evolving, and finally merging together so that it becomes new data information, and the newly established data still needs to have the ability to select the overall situation, integrate the data, and finally become a data system, and then use the data, so that it will be very convenient to use [21]. It makes the arrangement of information more convenient; the second method is a decision tree, which is to first organize and summarize all the data, and then classify the data, organize the data information for branch processing, and search from the middle. The most valuable information, and then clean up the data that does not meet the conditions, because this process is like the process of growing a sapling, so it is called a decision tree. The biggest advantage of this method is that the operation is very simple, The process is also very smooth, and the most important thing is that the work efficiency is very high. This method is very suitable for a large amount of data, which will reduce the pressure and burden on the staff.

The first method is to clarify the management and decision-making problems. If there are problems in the process of education and teaching management, we must constantly summarize and summarize the emergence of such decision-making management problems, and at the same time identify them. Established in time, so that specific data can be turned into goals so that it can be redefined; the second method is to extract the original data, and the data can be managed and customized according to different goals, and because the teaching management information system The establishment of the database and other related teaching functions require the support of a lot of data [22]. In the process of extracting from the database, the noise data must be excluded, and it cannot be interfered with by the vacant data. These data are integrated and transformed for accurate processing; the third point is to design data and continuously mine data. Because of the different goals, for the completion of data mining tasks, various data algorithms should be used to establish a data algorithm. Processing model; the fourth is the refinement of data. With the huge database and the screening of value metrics, this data will have a corresponding mining mode, and at the same time, it must be processed and integrated according to different teaching management needs.

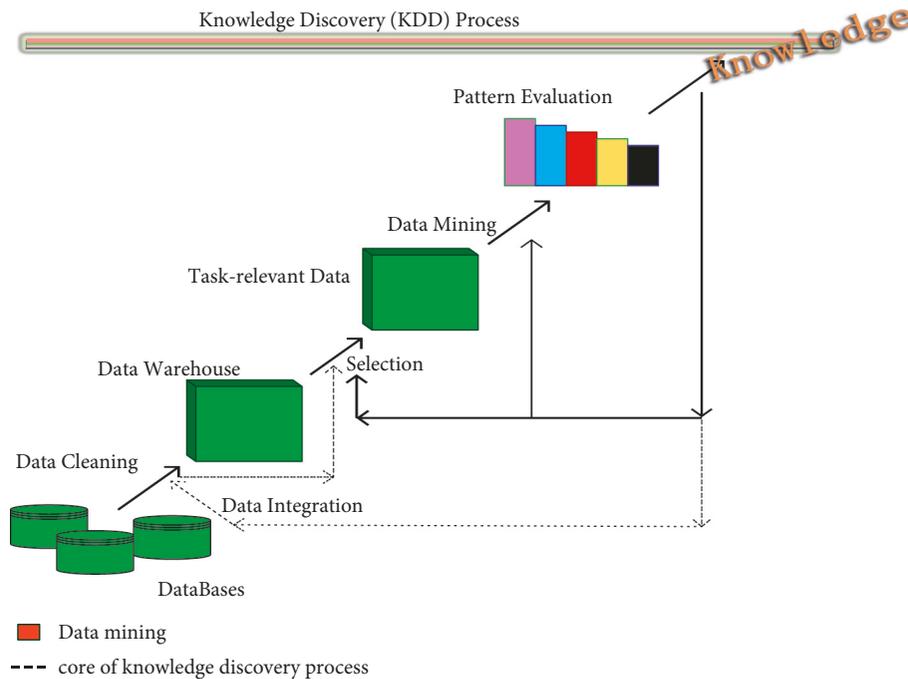

FIGURE 2: KDD process diagram.

FIGURE 3: Data preprocessing steps.

3. Explore the Application of Data Mining Technology in College Basketball Teaching

This chapter mainly explores the application of data mining classification technology in college basketball teaching, puts forward the implementation plan of data mining technology in college basketball teaching application, and introduces the implementation process of the plan by taking the analysis of students' performance in college basketball teaching as an example.

3.1. The Implementation Process of Classification Mining. Data mining is a decision support process and a deep-level data information analysis method. It is undoubtedly very beneficial to apply data mining techniques to the evaluation of teaching. It can comprehensively analyze the hidden internal relationship between test results and various factors connection. For example, through the analysis of the school's student performance-related database system, data mining tools can answer similar questions such as "what factors may have an impact on students' academic performance," which cannot be achieved by traditional evaluation methods? Through data mining and analysis, the evaluation results can bring unprecedented gains and surprises to teaching.

In the past, the database query method was usually used to process a large amount of data information in the teaching process. Here, the author proposes a classification algorithm in data mining, which can convert a large amount of data into classification rules, so as to better analyze these data. Figure 4 is a flow chart of classification implementation.

3.2. Data Collection. In this example, the author can discuss the basic learning situation of students (such as knowledge base, classroom learning effect, students' interest in the course, homework completion, time spent after class, and learning methods used), what factors have an impact on academic performance, and what are the reasons why students' academic performance is excellent or their academic performance is unsatisfactory, and expect to use the obtained analysis results to guide future teaching work [23].

Student achievement analysis is all about finding functional relationships between two or more attributes. To analyze the causes of students' academic performance, we need data from the following aspects:

3.2.1. Basic Information about Students. The data structure is as follows: student number, name, gender, place of origin, department, major, and class. This information is available through the school's student management information system.

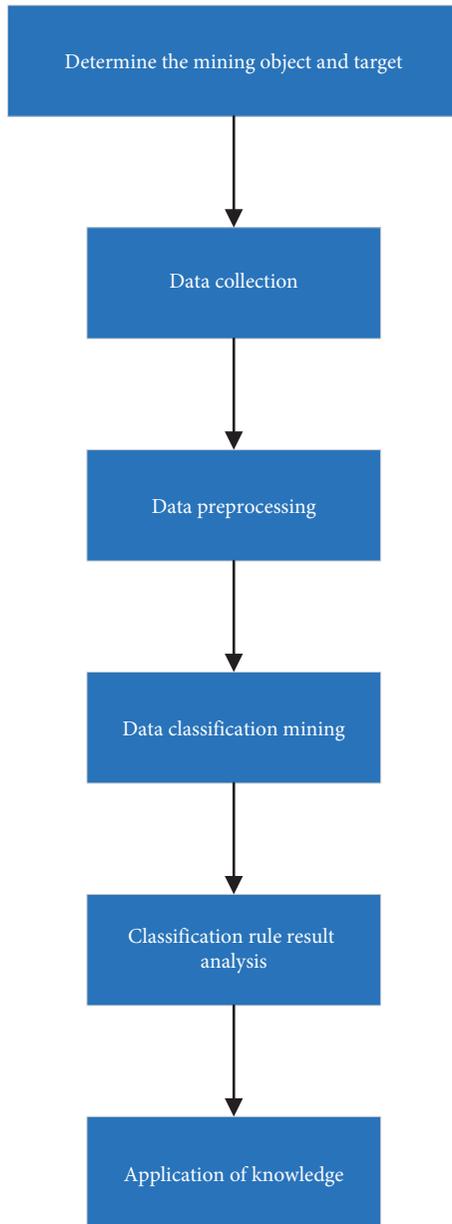

FIGURE 4: The implementation process of classification mining.

3.2.2. Student Survey Information. The content includes the degree of love for the major, the course, the mastery of preschool knowledge, the effect of classroom learning, and learning methods [24]. This information is mainly generated by students filling out surveys.

In the past, these tasks usually required the production of questionnaires. After students filled out the questionnaires, teachers spent a lot of time and energy collecting these data. Because this work is very tedious, it will take up a lot of time. Therefore, many teachers are reluctant to do this work, thus making it impossible to complete the very important work of mastering the basic information of students.

3.2.3. Grade Database. The score database includes students' usual homework scores and course test scores. This database is generated by teachers during the teaching process.

In this example, the method adopted by the author is: that all assignments require students to upload the written examinations to the submission system in the form of electronic documents in the prescribed format and prescribed file name [25]. The basketball movement standard test is conducted in accordance with the prescribed movements and prescribed methods, and the results are registered.

3.3. Data Pre-Processing

3.3.1. Data Integration. It is merging data from multiple data sources together. In this study, the multiple database files obtained by data collection are used to generate the basic database of student achievement analysis by database technology, as shown in Figure 5.

3.3.2. Data Cleaning. The main job of data cleaning is to fill in missing data values.

In the basic database of student achievement analysis, we see that there are some attributes that we are interested in missing attribute values. For these vacancies, data cleaning techniques can be used to fill them.

For these vacancies, data cleansing techniques can be used to fill them. There are many ways to fill in blank values for properties:

- (1) Ignore tuples: this is usually done when the class label is missing or the tuple has multiple attributes with missing values.
- (2) Fill in missing values manually: generally speaking, this method is time-consuming and may not work when the dataset is large and many values are missing.
- (3) Fill in the missing value with a global constant: replace the missing property value with the same constant (e.g., "Unknown"). But if the missing values are all replaced with "Unknown," the mining program might mistake them for an interesting concept, since they all have the same value—"Unknown." Therefore, although the method is simple, it is not recommended here.
- (4) Fill in the empty values with the average value of the attribute.
- (5) Use the mean of all samples that belong to the same class as the given tuple.
- (6) Fill gaps with the most probable values which can be determined by regression methods, Bayesian methods, or decision tree induction.

In this example, the method of ignoring tuples is used to delete records that have not taken the test or that have a large number of vacancies in the online survey data filled out by students. For other individual vacancies, because the total number of records is not too many, and the vacancy values are few, other individual vacancies are filled manually. The filling principle is to use other attribute values of the record as filter conditions to filter in

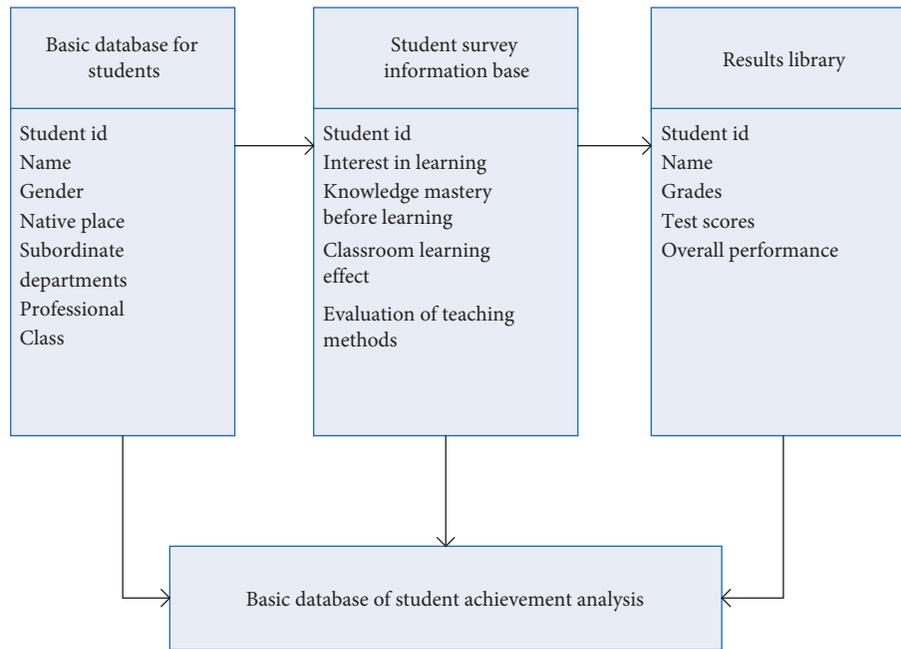

FIGURE 5: Establishment of the basic database for student achievement analysis.

the database. After filtering, use most of the attribute values to fill the vacancy.

3.3.3. Data Conversion. Data transformation is mainly to normalize the data.

This paper uses the concept stratification technique, Continuous-valued attributes can be converted to discrete-valued attributes (i.e., discretized). Histogram analysis is a relatively simple discretization method, which is divided into two categories: equal-width binning and equal-depth binning. Equal-width binning divides attribute values into equal parts or intervals. In equal-depth bins, the values are divided so that each part contains as many samples as possible. Here, using equal-depth binning for discretization, all values of the usual grade attribute are divided into three categories: the grades from 0 to 70 belong to “poor,” 70 to 85 belong to “average,” and above 85 belong to “good.”

3.3.4. Data Reduction. The purpose of data reduction is to reduce the size of the data to be mined, but it will not affect (or basically not affect) the final mining results. Here, the method of dimensionality reduction is adopted, that is, the really useful feature attributes are found from the initial feature attributes to reduce the number of feature attributes or variables to be considered in data mining.

Since there are many attribute fields in the student information table, in order to facilitate the establishment of the decision tree model, this paper selects the after-school practice time, the degree of understanding of the course before learning, the classroom learning situation, and the usual practice situation. The total grade attribute is used as

the basis for establishing the total grade classification decision tree model to analyze the student’s learning situation.

3.4. Data Classification Mining. The purpose of classification mining is to establish a decision tree model for performance analysis.

Based on the characteristics of the dataset, in this classification mining research, in order to make the generated rules easy to understand, the decision tree method is chosen. Since the training set is not too large, you can choose the GongD3 or C4.5 algorithm for classification and mining, and here the Gong3 algorithm is selected for classification.

3.4.1. ID3 Algorithm. The most famous algorithm in the decision tree algorithm is the ID3 algorithm proposed by Quinlan. The ID3 algorithm starts with all training samples at the root node of the tree, selects an attribute to distinguish these samples, and produces a branch for each value of the attribute. Move the corresponding sample subset of branch attribute values onto the newly generated child nodes. This algorithm is applied recursively to each child node until all samples on a node are assigned to a certain class. ID3 algorithm is a greedy algorithm. It uses a top-down, divide-by-recursive approach to construct a decision tree.

Let S be a set containing s data samples, and the category attribute can take m different values, corresponding to m different categories C ($1 = 1' \dots m$). Suppose s_i is the number of samples in category C_i ; then, the amount of information required to classify a given data object is

$$I(s_1, s_2, \dots, s_m) = - \sum_{i=1}^m p_i \log_2(p_i). \quad (1)$$

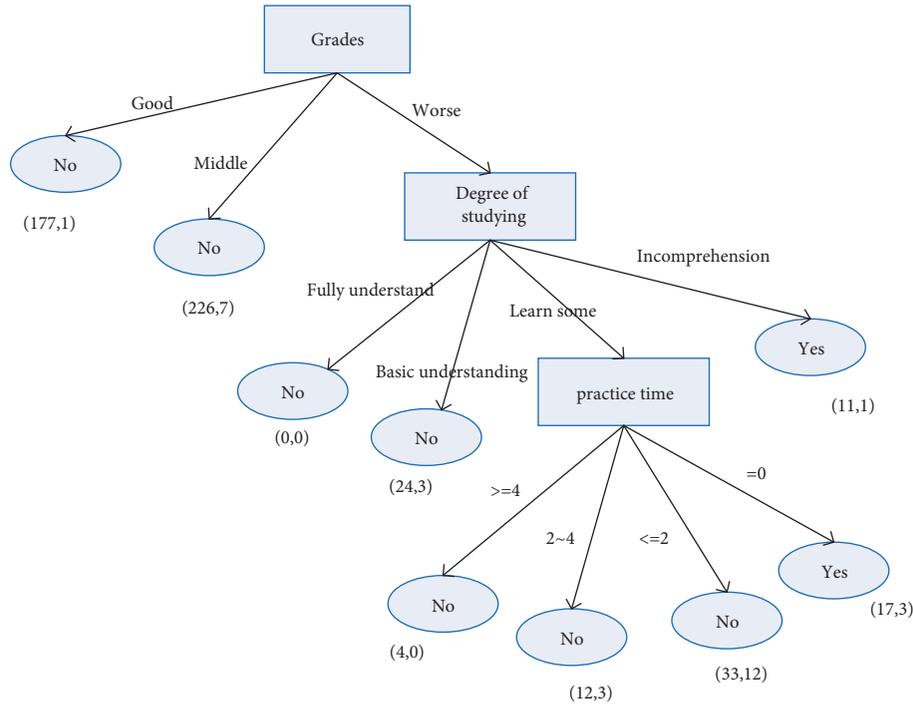

FIGURE 6: Decision tree of whether the grades after pruning fail.

where p_i is the probability that any data object belongs to a category C_i .

Let an attribute A take V different values $\{a_1, a_2, \dots, a_v\}$. Using the attribute A , the set S can be divided into v subsets $\{s_1, s_2, \dots, s_v\}$. Among them, s_j contains the data samples, whose attribute A in the S set takes the value of a_j . If attribute A is selected as a test attribute (i.e., attribute A is used to divide the current sample set), let s_{ij} be the number of samples belonging to category c_i in subset s_j . Then the information required to divide the current sample set by attribute A (the direct descendant) can be calculated according to the following formula:

$$E(A) = \sum_{i=1}^v \frac{S_{1j} + \dots + S_{mj}}{S} I(S_{1j} + \dots + S_{mj}). \quad (2)$$

In this way, the information gain obtained by using attribute A to divide the corresponding sample set of the current branch node is

$$\text{Gain}(A) = I(S_1, S_2, \dots, S_m) - E(A). \quad (3)$$

The information gain of each attribute is calculated by the above formula. Select the attribute with the highest information gain as the test attribute for the given set S , create a node, mark it with this attribute, create a branch for each value of the attribute, and perform sample division.

3.4.2. Using the ID3 Algorithm to Generate a Decision Tree Model. Since there are many attribute fields in the student information table, when establishing a decision tree model for whether the grades are good or not, this paper selects the after-class computer time, the degree of understanding of

the course before learning, and the classroom learning situation. The attribute field of normal work status, whether the attribute is good or not is used as a category attribute. When establishing the decision tree model of whether the grade is failed or not, the attribute of failing or not is used as the category attribute.

3.4.3. Decision Tree Pruning. When a decision tree is just established since many branches are constructed from abnormal data in the training sample set (due to noise and other reasons), the decision tree is too “blooming,” which reduces the comprehensibility of the tree. At the same time, it also increases the dependence of the decision tree itself on historical data, that is to say, this decision tree may be very accurate for this historical data, but the accuracy drops sharply once it is applied to new data. The condition is called overtraining. In order to make the rules contained in the obtained decision tree have a general meaning, the decision tree must be modified. The task of branch pruning is mainly to delete one or more branches and replace these branches with leaves to simplify the decision tree, so as to improve the speed of classification and recognition in the future and the ability to classify and recognition of new data.

There are usually two methods for pruning branches, which are

- (1) *Prepruning Method.* The method is realized by stopping the branch generation process in advance, that is, by judging whether it is necessary to continue to divide the training sample set contained in the node on the current node. Once the branch is stopped, the current node becomes a leaf node. The leaf node may contain multiple training samples of

different categories. Since this pruning is done before branching, it is called prepruning.

- (2) *Postpruning Method*. This approach addresses the problem of overtraining from another angle. On the basis of allowing the decision tree to grow most fully, it cuts off those leaf nodes or branches that are not generally represented in the decision tree according to certain rules. After pruning, the pruned branch node becomes a leaf node, and it is marked as the category with the largest number of categories in the samples it contains.

Prepruning requires more computation time, but the resulting decision tree is more reliable. In this paper, the method of postpruning is adopted. First, the error rate of a fully grown decision tree is calculated, and a maximum allowable error rate is specified by the user. When the pruning reaches a certain depth and the calculated error rate is higher than the maximum allowable value, stop pruning immediately, otherwise, continue pruning. Figure 6 is a decision tree for the classification of failing grades after pruning.

4. Conclusion

Under the background of the increasing development of science and technology in our country, the combination of science and technology with higher education, the application, and research of intelligent information systems, is more conducive to promoting the modernization of colleges and universities. Through the application of data mining technology in the quality evaluation of basketball teaching in colleges and universities, the limitations of traditional basketball teaching management can be effectively improved, and various unfavorable factors that hinder teaching management can be found in time. In the school's teaching, the use of data mining technology in basketball teaching can reasonably collect, analyze and summarize the relevant data of colleges and universities, and then find and solve problems in time, which not only reduces teaching accidents but also makes all aspects of colleges and universities. Management Metropolis eliminates drawbacks, coordinates the overall construction of the school, comprehensively cultivates high-quality talents and innovative ability levels, and promotes the construction of modern teaching in colleges and universities on the basis of improving the quality of teaching, laying a solid precondition for cultivating high-quality talents, and for the realization of lay the foundation for the construction of world-class universities and first-class disciplines [18–26].

With the rapid development of Internet technology, the use and sharing of data have brought great opportunities and challenges to mankind. On the one hand, the development of data sharing and analysis technology has promoted the improvement of economic and social benefits. On the other hand, protecting private information has become an urgent issue in the Internet era. In addition, the amount and type of information data are also increasing. At present, most algorithms can only encrypt a single type of small-scale data, which cannot meet the current data environment. Therefore, it is very necessary to study the privacy protection algorithm of multimodal data fusion. To improve the security of privacy protection algorithm, combined with the idea of multimode, this paper combines the improved traditional spatial steganography algorithm LSB matching method and the improved traditional transform domain steganography algorithm DCT with AES encryption algorithm after modifying the S-box and then combines it with image stitching technology, so as to realize a safe and reliable privacy protection algorithm of multimode information fusion. The algorithm completes the hidden communication of private information, which not only ensures that the receiver can accurately recover private information in the process of information transmission but also greatly improves the security of private information transmission.

1. Introduction

With the rapid development of Internet technology, the use and sharing of data have brought great opportunities and challenges to mankind. Nowadays, people pay more and more attention to their private information. The college entrance examination registration and voluntary filling system provide services to more than 10 million candidates across the country. These candidates' personal information is stored in the college entrance examination registration and voluntary filling system; the national social security system is more about the pension, medical care, employment, and other information of hundreds of millions of people across the country. The development of data sharing and analysis technology has promoted the improvement of economic and social benefits. At the same time, the protection of private information has become an urgent problem in the Internet era. At present, the amount of

information is increasing, and there are more and more types. Most algorithms can only encrypt a single type of small-scale data, which cannot meet the current data environment. Therefore, it is necessary to study the privacy protection algorithm of multimodal data fusion.

In recent years, pin academics have achieved a series of results on traditional modified/embedded information hiding. Literature [1] proposed a data hiding/protection strategy combining PVD (pixel value difference), LSB, and MPE (modification of prediction error) to improve steganographic capacity and resistance to RS steganalysis. The literature [2] uses MSB (most significant bit) to select the best embedding point and combines the AES encryption algorithm to embed the ciphertext in the lowest significant bit of that point. Literature [3] implements a digital watermarking technique based on hybrid multibit multiplication rules by secret key control from the DWT domain.

Meanwhile, the concept of reversible data hiding (RDH) has been proposed from the perspective of whether the original carrier image can be recovered. Reversible data hiding refers to embedding secret information into the “reversible domain” of the original carrier image so that the image can be recovered without distortion after extracting the secret information. This technique is widely used in military, medical, and legal forensic fields. Literature [4] proposes embeddable pixel pairs (EPP, embeddable pixels pairs) as the embedding unit of secret information and achieves reversible information hiding through secret bit extraction and carrier recovery. Although the focus of reversible information hiding is on the lossless recovery of the carrier, the encryption process also inevitably makes modifications to the original carrier.

Zero-hiding techniques guide the change of steganography from embedding to nonembedding. The multilayer partially homomorphic textual information steganography based on zero-hiding proposed in literature [5] achieves a better balance in terms of robustness, security, and capacity. However, in the image domain, zero-hiding follows that although it achieves no modification of the image carrier, it generates other necessary information as the secret key for decoding by the receiver, such as associated documents and secret message extraction files, thus causing additional channel occupation.

At present, the traditional “coding/mapping” approach is more mature, and the evaluation scheme has been established by the academic community in recent years. In [6], the image grid is divided and the image SIFT features are combined with hash sequences to quantize and encode the feature sequences and build an image library, which can be used for indexing. The literature [7] adopts the idea of carrier-free information hiding and uses the brightness features of the material molecular structure for encoding to establish the mapping relationship between binary sequences and image carriers. The literature [8] focuses on image global features, quantization coding the gray gradient coeval matrix to achieve carrier-free information hiding and constructing a high-secure satellite communication model. The classical transformation methods in information hiding are discrete cosine transform (DCT), discrete wavelet transform (DWT) [9], and discrete Fourier transform (DFT) [10]. The literature [11] proposes carrier-free information hiding based on DCT (discrete cosine transform) and LDA (latent Dirichlet allocation, document topic generation model) models.

In summary, information hiding algorithms have been progressing in the process of exploration, and different steganography methods have different focuses on performance evaluation. However, on the issue of “how to hide,” many existing steganographic methods always revolve around the three existing frameworks, while combining various technologies to jointly promote the development of information hiding.

Based on the traditional steganography embedding algorithm, this paper improves the spatial domain steganography algorithm and transforms the domain steganography algorithm to improve the embedding

capacity and antisteganalysis ability of the algorithm. Combined with image stitching technology, the mapping capacity of the noncarrier information hiding algorithm is improved, and the large capacity noncarrier information hiding algorithm is used to hide the key. Joint information encryption method is to achieve multimodal data fusion privacy protection system. The system improves the diversity and security of the system by using the key control steganography algorithm.

2. Multimodal Data Fusion Privacy Protection Algorithm

2.1. Improved Spatial Domain Steganography Algorithm. However, the disadvantage of the traditional LSB algorithm is that when the embedded message is large, it takes a long time, and it can only deal with simple stream format files. So, in this paper, based on the traditional LSB matching algorithm, according to the texture characteristics of the image, the texture complex region is selected to embed the private information into the carrier image with complementary embedding rules. The embedding capacity of the traditional LSB matching algorithm is improved. The traditional LSB matching algorithm is to embed secret information into gray images randomly. At present, color images are generally used in network transmission. Therefore, this paper first divides them into RGB layers, selects regions with complex image textures to embed private information, and embeds them into different color layers in different regions of the carrier image in a complementary, so as to improve the embedding capacity and undetectability of the spatial domain steganography algorithm.

2.1.1. RGB Layered. The color image has RGB three color channels, and the three-channel component diagram is different. When the secret image is hidden in different layers, it is different from the original carrier image. The secret image is hidden in the image carrier of each layer of *R*, *G*, and *B*. In this paper, the *R* channel and *G* channel are used as complementary channels to embed private information, which can achieve better results in this respect and better resists statistical analysis. In this way, embedding private information in two layers can improve the embedding capacity and reduce the change of the statistical characteristics of the original carrier image caused by private information embedding, which improves the capacity and undetectability of information hiding.

2.1.2. Image Grayscale Cooccurrence Matrix. The image gray level cooccurrence matrix can be used to describe the texture features of the image, and the ciphertext is embedded into the complex area of the texture features of the image. The effective steganography of the ciphertext is completed by using the redundant space of the image [12].

In this paper, four parameters (energy, entropy, dissimilarity, and correlation) are derived to describe the texture characteristics of the image gray level cooccurrence matrix in image texture analysis.

$$\text{Energy} = \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} P(i, j)^2, \quad (1)$$

$$\text{Entropy} = \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} P(i, j) \log_2 P(i, j), \quad (2)$$

$$\text{Inertia} = \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} |i - j| p(i, j), \quad (3)$$

$$\text{Coherence} = \frac{\sum_{i=0}^{L-1} \sum_{j=0}^{L-1} (i+1)(j+1)P(i, j) - \mu_1 \mu_2}{\delta_1 \delta_2}, \quad (4)$$

These four features respectively reflect the characteristics of the gray distribution of the image, including uniformity, the thickness of the capacity texture of the carrier image, and the similarity of the elements in the matrix. The matrix is formed by these four features, $T(4) = \{\text{Energy}, \text{Entropy}, \text{Inertia}, \text{Coherence}\}$. Then, the embedding region is determined by selecting parameters.

2.1.3. Embedding of Secret Information. The spatial domain steganography algorithm first extracts the texturally complex subblocks of the original color carrier image. The ciphertext is divided into two groups and the carrier image subblock texture features are used to obtain the embedding position. A set of ciphertext is embedded in the R channel in $+1$ form and a set of ciphertext is embedded in the G channel in -1 form, and the channels are combined to obtain a color image containing the cipher.

2.2. Improved Transform Domain Steganography Algorithm. Based on the traditional modified message hiding transform domain steganography algorithm, this paper divides the color image into three channels of RGB for embedding the ciphertext to increase the embedding capacity. The ciphertext is grouped into two bits and embedded into the more stable intermediate frequency region after the DCT transform. Because digital images are DCT-transformed, the low and medium frequency signals have the highest energy, but the private information embedded in the low and medium frequency signals can easily be observed directly by the human eye; in the high-frequency part, the energy is low and unstable, so the intermediate frequency region after DCT transform is selected for private information embedding. This region can better meet the imperceptibility and robustness of the steganography algorithm.

2.3. Large Capacity Carrier-Free Information Hiding Algorithm. The traditional mapped carrier-free information hiding algorithm has the problem of low steganographic capacity. In this paper, multiple mapped images are reorganized and stitched into one image using image stitching technology to improve the steganographic capacity of the carrier-free information hiding algorithm and realize the

secure mapped steganographic writing of keys and some private information.

By using the features of the image for binary encoding, a binary sequence can be derived without any modification to the image. In this way, the image can form a mapping relationship with the corresponding private information. This mapping relationship requires a one-to-one correspondence between the private information and the images in the image library. That is, if the length of the binary sequence of private messages is n , the image library must have at least 2^n images. The value of n has to be chosen appropriately for the possibility of implementation and the security of mapping hidden information.

The steganographic capacity of carrier-less information mapping is low, and image stitching technology is used to improve the steganographic capacity of the algorithm. Multiple images are similarly spliced to form a complete key image and sent to the receiver. Taking the 2×2 modes as an example, the splicing combination process is shown in Figure 1.

2.4. Multimodal Data Fusion Privacy Protection Algorithm Design. The multimodal data fusion privacy protection algorithm uses two images to steganography the ciphertext (private information encrypted to form the ciphertext) and the key, one using a spatial domain steganography algorithm or a transform domain steganography algorithm to steganography the ciphertext, with the key controlling the choice of the specific algorithm, and the other using a carrier-free information hiding algorithm to steganography the key in a mapped fashion. This design can ensure the safe transmission of private information so that any image cannot be decoded after being illegally intercepted. Even if the two images are intercepted, the interceptor does not know the operation mode of the system and cannot crack the contains secret images.

The information transmitted by the multimodal data fusion steganography system consists of two parts: the ciphered image and the key-mapped image. Due to the long length of the AES encryption key, a 6×6 stitching mode is used and the private information is encrypted by the message encryption technique (AES encryption algorithm after modifying the S-box), and then the ciphertext is embedded in the chosen ciphertext steganography algorithm, where an improved spatial domain steganography algorithm and a transform domain steganography algorithm can be chosen to form the ciphered image. Keymapping image mainly implements mapped hiding of the key; the key consists of two parts, $\text{key} = \{\text{keychoose}, \text{keyencryption}\}$; these two parts are, in order, the ciphertext steganography flag bit and the encryption algorithm key. The coverless information hiding technique uses a 6×6 pattern to stitch the submap into a complete carrier image to form a key mapping image. After receiving the key image, the receiver splits and then deciphers the type of ciphertext steganography algorithm used and the key of the encryption algorithm, respectively. The effect of the secret image is shown in Figure 2. The cryptographic image and the key mapped

FIGURE 1: Splicing assembly process.

FIGURE 2: (a) Secret images. (b) Keymapping images.

image are transmitted, and then the receiver gets the private information in a specific way.

As shown in Figure 2, after receiving the key-mapped image and the cryptographic image, the receiver needs to first segment the key-mapped image according to the rules to obtain 36 subimages. The subgraphs are decrypted separately in mapped form, and the decrypted results are combined in stitching order to obtain the key for the complete encryption algorithm and to determine the type of steganography algorithm using the first-bit flag bit, with the spatial domain steganography selected if the first bit is 0, and the transform domain steganography is selected if it is 1. The ciphertext is decrypted by the corresponding steganographic algorithm on the cryptographic image, and the ciphertext is decrypted by the encryption algorithm key obtained from the key-mapped image to obtain the plaintext.

The process of implementing the multimodal data fusion privacy protection algorithm is shown in Figure 3, where the private information and the key of the encryption algorithm are first encrypted to obtain the ciphertext. The spatial domain steganography algorithm or transform domain steganography algorithm is selected to embed the ciphertext, and the modified embedding algorithm is selected to embed the ciphertext. The secret key containing the type symbol of the ciphertext steganography algorithm and the information encryption key is obtained. The secret key is mapped by the noncarrier information hiding mapping algorithm, and the encrypted image and the key mapping image are generated.

When decrypting, the key mapping image is first segmented and then decrypted by the carrier-free information hiding algorithm. The codes corresponding to the 36

subgraphs are decoded according to the carrier-free information hiding technique; the codes are combined and processed to obtain the key of the encryption algorithm and the ciphertext steganography algorithm type flag. The cryptographic image is then decrypted according to a determined steganographic algorithm to produce the ciphertext. Finally, based on the previously derived key, the private message is decrypted by an encryption algorithm.

3. Algorithm Implementation

3.1. System Implementation. The multimodal data fusion privacy protection algorithm consists of several application forms, the core of which is the data fusion steganography. Click on the image fusion steganography, there are two links for the sender and the receiver, and select the sender. There are three inputs on the transmitter side: the plaintext before processing, the encryption key, and the carrier image selection path. One input, the selection of the ciphertext steganography algorithm, is used to implement the selection of the spatial domain steganography algorithm or the transform domain steganography algorithm. There are 3 output items: the encrypted ciphertext, the mapped image 1, and the encrypted image 2. There are six additional function buttons: Encryption, Key Mapping, Browse, Ciphertext Steganography, Save, and Send. A brief description of each function button is given follows (Figure 4):

- (1) Encryption: encryption of the input plaintext and a key of a specific length to obtain the ciphertext using the AES encryption algorithm with a modified S-box;

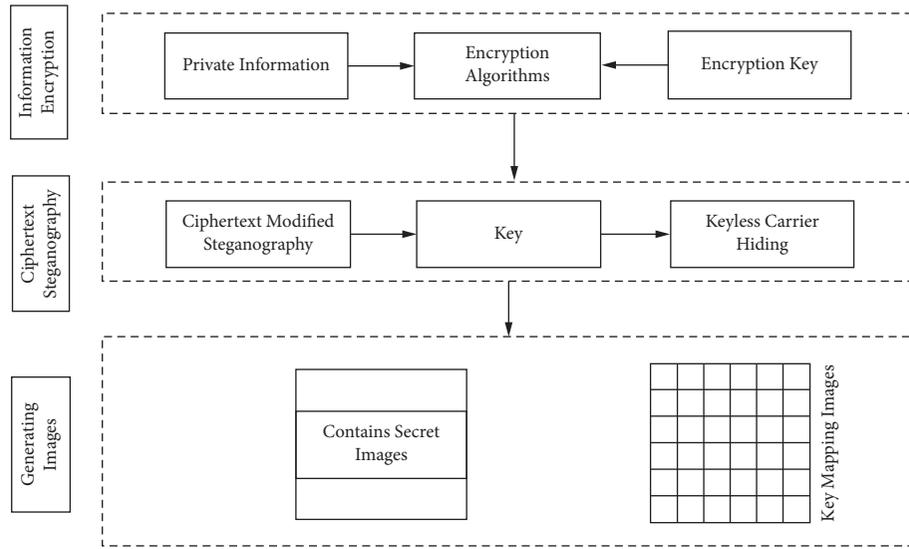

FIGURE 3: The encryption process of multimodal data fusion privacy protection algorithm.

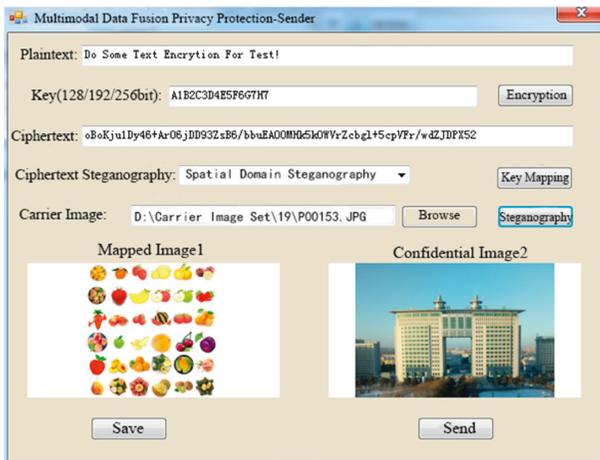

FIGURE 4: Sender-side steganography-spatial domain steganography.

- (2) Key Mapping: based on the chosen ciphertext steganography algorithm and the encryption algorithm key, a carrier-free information hiding mapping steganography is performed to obtain mapped image 1;
- (3) Browse: jump to the image selection page and select the appropriate carrier image for ciphertext steganography;
- (4) Ciphertext steganography: the ciphertext obtained in (1) is steganographically written to the carrier image in (3) according to the selected ciphertext steganography method, and the sender selects the spatial domain steganography algorithm to complete the steganographic effect as shown in Figure 4;
- (5) Save: jump to the image, save the page, and select the save path option to save the mapped image 1 and the encrypted image 2 locally;

- (6) Send: jump to the send page, fill in the recipient's details, and transmit two coded images to the sender.

The multimodal data fusion privacy-preserving-receiver side is shown in Figure 5, with a total of one input item being the path selection of the image containing the secret. The three output items are the mapped image 1, the coded image 2, and the plaintext (private message). Five function buttons are included, namely, Browse, Get Mapped Image 1, Get Confidential Image 2, Decrypt, and Clear buttons. A brief description of each function button is given as follows:

- (1) Browse: it obtains the path to the folder containing the key-mapped image and the ciphertext steganography image;
- (2) Get Mapped Image 1: the system reads the key mapping image in the specified folder and segments the key mapping image, storing the 36 subimages in the order in the program directory;
- (3) Obtaining a Confidential Image 2: the system reads the ciphertext steganography image under the specified folder and displays it in the system interface;
- (4) Declassify: the subgraph obtained from (2) is decrypted by the carrier-free information hiding algorithm mapping, combined, and processed to obtain the ciphertext steganography flag and the encryption algorithm key, the corresponding steganography decryption algorithm is performed on the carrier image 2 to obtain the ciphertext, and the ciphertext is decrypted according to the AES decryption algorithm after modifying the S-box, resulting in the plaintext, and displayed;
- (5) Clear: it clears the cryptographic image selection, the mapped image, the encrypted image, and the plaintext and deletes the split subimage of the key-mapped image stored in the program directory, clears the system cache image, and restores the receiver page to the initial page.

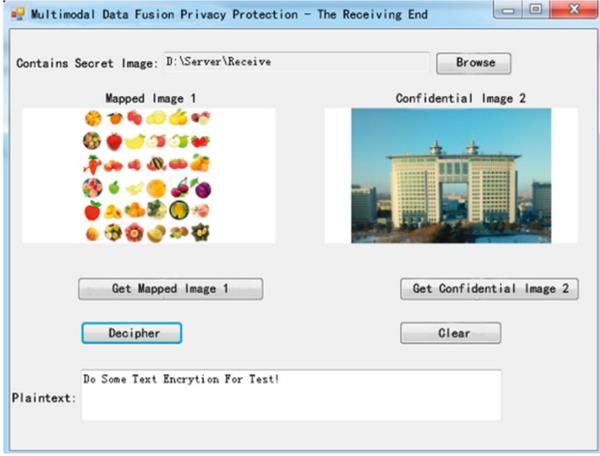

FIGURE 5: Decryption completion page on the receiving end.

As can be seen from the above, this system implements a multimodal data fusion privacy protection algorithm, which encrypts private information by modifying the AES encryption algorithm after the S-box and completes the steganography of the ciphertext and key after the information hiding algorithm (improved spatial domain steganography, improved transform domain steganography, and carrier-free information hiding algorithm). The receiver decrypts the key and the ciphertext according to the two steganographic images in turn and then performs the message decryption operation to recover the private message accurately.

3.2. Non-detectability Analysis. Multimodal data fusion privacy protection algorithms are implemented by three types of algorithms: information encryption algorithms, modified steganography algorithms (improved spatial domain steganography and improved transform domain steganography), and high-capacity carrier-free information hiding algorithms. The proper fusion of these algorithms makes the multimodal data fusion privacy protection algorithm highly secure. The following analysis addresses the undetectability of key-mapped images and ciphertext images in the multimodal data fusion privacy protection algorithm.

The undetectability of the multimodal data fusion privacy protection algorithm is objectively evaluated from the perspective of mathematical-statistical analysis. The key-mapped images before and after steganography are evaluated using root mean square error and peak signal-to-noise ratio, with the root mean square error calculated as shown in equation (5) and the peak signal-to-noise ratio shown in (6).

$$\text{MSE} = \frac{\sum_{x=0}^{N_x} \sum_{y=0}^{N_y-1} [S'(x, y) - S(x, y)]^2}{N_x \times N_y}, \quad (5)$$

$$\begin{aligned} \text{PSNR} &= 101g\left(\frac{\max S(s, y)^2}{\text{MSE}}\right) \\ &= 201g\left(\frac{\max S(s, y)}{\text{MSE}}\right), \end{aligned} \quad (6)$$

TABLE 1: Test results.

Spatial domain steganography ratio	Transformation field steganography ratio	JSTEG detection ratio
0.1	0.1	0
0.2	0.2	0
0.3	0.3	0
0.4	0.4	0
0.5	0.5	0

where $S(x, y)$ is the gray value of the sampled points of the key-mapped images and $S'(x, y)$ is the gray value of the sampled points of the stitched original images. The smaller the MSE value, the smaller the image distinction, and similarly, the larger the PSNR value, the smaller the image distinction. The key-mapped images in this paper are not different from the original images, and the root mean square error and peak signal-to-noise ratio are calculated as shown in the following equations:

$$\text{MSE} = 0, \quad (7)$$

$$\text{PSNR} = \infty. \quad (8)$$

Based on the mathematical-statistical analysis, it can be concluded that the key mapping image of the multimodal data fusion privacy protection algorithm is completely undetectable; in other words, none of the existing steganalysis algorithms can detect the key information in the key mapping image.

The JSTEG method was used to detect the embedding rate of cryptographic images and to verify the undetectability of the steganography algorithm. The detection of the 600×400 pixel cipher laden image was performed using the JSTEG method, which is an information hiding algorithm based on JPEG images, with the steganography ratio incremented from 0.1 to 0.5, and the detection results were obtained as shown in Table 1.

From Table 1, it can be concluded that the detection result of the JSTEG algorithm is 0 for both spatial domain steganography algorithm and transform domain steganography algorithm, JSTEG cannot effectively detect the ciphertext steganography method used in this paper, and ciphertext steganography with multimodal data fusion privacy protection has good effect in resisting dedicated steganography analysis algorithm.

4. Conclusions

This paper designs and implements a multimodal data fusion privacy protection algorithm based on image steganography, joint information encryption algorithms, steganography of encrypted ciphertext by two modified embedding steganography algorithms (spatial domain steganography and transform domain steganography), and mapped steganography of key according to the carrier-free information hiding algorithm. The algorithm has proved through experiments to be a great guarantee of the security of private information.

Future attempts can be made to combine it with deep learning of artificial intelligence technology to further improve the efficiency and algorithmic diversity of the algorithm. In the mentioned image fusion encryption, this paper has not considered the fusion in multiple modes, which needs further research.

The water conservancy project is an important livelihood engineering project, and it is also an important factor to ensure the living water supply, power supply stability, and economic development of the regional population. Therefore, the management of water conservancy projects is particularly important. The core management content is cost control, which can maximize the benefits of the project and avoid the waste of investors' funds. This study studies the whole process control of water conservancy project cost, explains the problems existing in the current domestic water conservancy project cost control, and finally expounds on the whole process control measures, in order to provide a reference for related work. In this study, SPSS software is mainly used to establish a multiple linear regression model to analyze the influencing factors of water conservancy projects. Through the method of model solving, the relationship between hydraulic engineering and various variables is analyzed, and the multi-linear verification is improved, so as to further test the model, optimize the model, and finally manage and predict it accurately.

1. Introduction

In recent years, with the rapid development of my country's water conservancy project construction. Due to the long construction period of water conservancy projects [1], large investment, and many cooperative departments, it is greatly affected by natural resources, topography, geology, hydro-meteorological conditions, as well as local economic development level, transportation, and other resource market conditions [2, 3]. Personality is very prominent. In terms of pricing, water conservancy projects have the characteristics of a single piece, multiple times, diversity of methods, and complexity of basis [4, 5]. These characteristics determine the unique problems in the cost management of water conservancy projects that are different from other construction projects [6, 7].

At present, the cost management mode of water conservancy projects in my country is divided into stages and units, that is, the cost control in the project decision-making

and design stage is completed by the cost professionals of the design unit, and the cost control in the contracting stage is carried out by the project owner who can bid by himself or can bid. The cost consulting unit with the agency qualification is completed, the cost control in the construction phase is completed by the cost professionals of the supervision unit, and the cost control in the completion and post-evaluation phases is completed by the cost consulting unit with the qualification for a price review. Project decision-making and design stage are important stages of cost management. Therefore, doing a good job in the management of water conservancy projects can ensure the daily life of the people [8], and the requirements for project cost management are the highest.

Project cost is an important part of project construction. A scientific and reasonable project cost [9, 10] plays an important role in the construction of the entire project. The construction of a project, obtaining a standard and reasonable project cost, has already made a good start and can

invest in the preliminary project that has a good investment standard. The economic expenditure can be kept within a controllable range so that the construction of the project can be completed quickly and well. In the construction of water conservancy projects, the cost management of the whole process can not only measure the investment in the life cycle of the construction project but also grasp the investment as a whole [11]. In the process of project management, the influencing factors of project cost mainly include financing methods, construction plans and exploration, and other factors [12, 13]. The analysis of all quotation management in the process of water conservancy project construction can make water conservancy projects in the process of construction [14]. As a major construction project in modern society, the water conservancy project needs to pay enough attention to the cost management of the whole process, so as to ensure that the water conservancy project construction achieves the rationalization of capital utilization in the whole process of construction. It also needs to promote the completion of high-quality and high-efficiency water conservancy project construction, and improve the benefits of project construction [15, 16].

The necessity of investment control in the whole life cycle of water conservancy projects: The reason for constructing the investment control mechanism for the whole life cycle of water conservancy projects is to improve the corresponding work at each stage and link the construction system, and effectively implement the staged supervision mode because different stages have unique characteristics. Therefore, only by improving the procedural supervision and management model can the integrity of the management process and the comprehensive level of investment control be improved. The most important thing is to integrate the static control mechanism, dynamic control mechanism, deviation analysis mechanism, and remedial adjustment mechanism in the investment control structure of the whole life cycle of water conservancy projects, so as to establish a really good supervision mode and comprehensive supervision system [17]. In the whole life cycle management of water conservancy projects, to a certain extent, relies on the computer software system of integrated information [18]. The application of BIM (Building Information Modeling) technology (see Figure 1) can fully reflect the physical and geometric characteristics of water conservancy buildings, display project appearance, location, and environmental information in three-dimensional space, and integrate various engineering information of buildings, including progress, material information, and cost information. In the BIM model, all information is provided by a unified data source, and the engineering information is independent, logically related, and consistent.

2. Existing Problems

We mainly use SPSS software to establish a multiple linear regression model to analyze the factors that affect hydraulic engineering. Through the method of model solving, the relationship between hydraulic engineering and various variables is analyzed, and the verification of multi-linearity is

improved. This is to further test the model, optimize the model, and finally carry out accurate management and prediction.

2.1. Problems in the Decision-Making Stage. Judging from the construction situation of water conservancy projects in recent years, some projects have not been completed in strict accordance with the construction period, which means that the investment costs that investors need to bear also need to rise, resulting in the inability to better control the cost of water conservancy projects [19]. The problem that caused this situation is that the basis for the cost estimation in the decision-making stage of the water conservancy project is not sufficient, and it is not considered according to the actual situation, and the construction plan is formulated only after the theoretical approval.

2.2. Design Phase Issues. Engineering design is a prerequisite for the construction of all construction projects. At present, many design institutes have fallen into a misunderstanding when designing water conservancy projects, that is, they think that as long as the quality is strictly controlled, the design scheme can be optimized, resulting in the neglect of engineering costs, to design the overall cost-effectiveness of the program is generally low. Although quality is the core criterion for determining the service life and value of a project, it does not mean that cost is unimportant. Simply considering an influencing factor will lead to deviations in the design scheme and make cost control difficult.

2.3. Project Quotation Problem. The project list quotation method is a cost control method after the construction of most projects in the world. At present, only a few economically developed areas in China use this method, and most areas have not yet implemented it. When using the bill of quantities for quotation, the company chooses the industry quota as the reference value, which makes the cost involved in the bill of quantities only the social average, and does not reflect the actual cost control of the construction unit, resulting in this kind of cost. The means of control cannot be implemented.

2.4. Issues in the Implementation Phase. The main problem affecting project cost management in the implementation stage is the modification of the construction design. At present, in many domestic water conservancy projects [20], investors and constructors randomly modify the construction design, which can directly lead to an increase in project costs. At the same time, there is no domestic law or regulation that is completely aimed at the management of construction costs, which makes the construction contract have many loopholes in the process of signing so that the construction party can make use of loopholes to modify the project quantity, which will seriously affect the water conservancy project and the cost control.

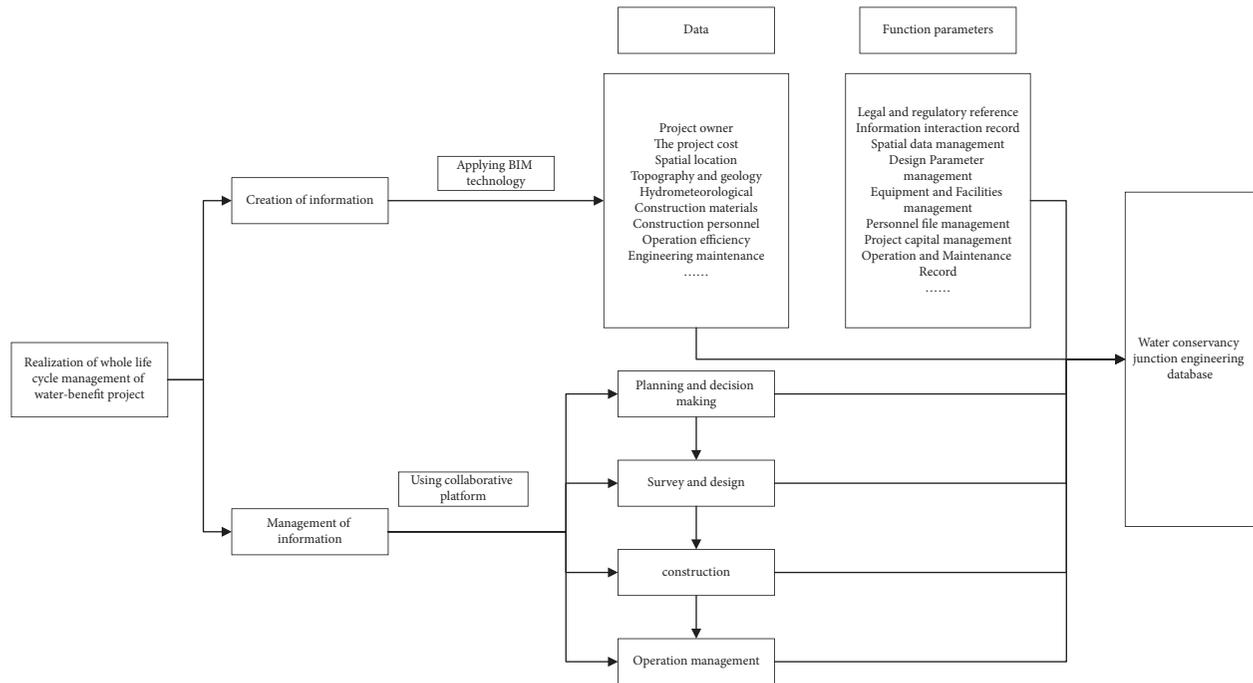

FIGURE 1: Full life cycle management of water conservancy projects.

2.5. *Issues in the Settlement Phase.* There may also be some loopholes in the formulation and signing of water conservancy project contracts, which leads to the situation that the investor and the construction party shirk each other when the project is settled. It is mainly manifested in the fact that the construction party increases the amount of the project cost in the settlement by falsely reporting the construction volume; while the investor bargains with the construction party under the loopholes in the contract clauses, and some construction parties try to avoid this “malicious” bargaining behavior. Therefore, there will be a situation of falsely reporting the project cost. Both parties did not strictly follow the contract settlement method, which made the cost control of the water conservancy project more difficult to carry out, and even could not be settled, so the project could not be put into use, increasing the additional cost in the later period.

3. Number of Control and Management Measures in the Whole Process of Water Conservancy Project Cost

3.1. *Water Conservancy Project Cost Process.* The control of water conservancy project cost is different in different stages such as project proposal, feasibility study report, initial design, bidding and construction, and complete acceptance. The construction of water conservancy projects uses a lot of manpower, material resources, and financial resources. In the process of project implementation, the implementation of good management and control of the whole process of construction cost can save a lot of cost for my country’s economic construction and ensure that the project has good quality and profit. First, have a clear understanding of the concept of water conservancy project cost control and

management, and then explain the management and control involved in water conservancy construction before, during, and after the event, so as to draw powerful measures for water conservancy construction project control and management, and in order to provide effective reference and basis for the management and control of engineering cost of water conservancy construction projects in my country in the future. Therefore, the corresponding preparations should be done in the early stage of the construction project, and the funds should be controlled in the reserved cost and stage coefficient in the investment decision-making stage. The following processes are usually required in the cost of water conservancy construction projects, as shown in Figure 2.

3.2. *Cost Control Measures in the Decision-Making Stage.* In the decision-making stage of a water conservancy project, the investor should communicate with the auditors in the early stage and conduct a comprehensive evaluation of the water conservancy project to be invested in. During the evaluation process, it is necessary to conduct a comprehensive survey of the market and analyze the geological exploration data of the construction site to make the construction period and early cost evaluation results more accurate.

3.3. Cost Control Measures in the Design Stage

- (1) The design institute needs to optimize the design scheme according to the requirements of the investor. The premise of optimization includes not only the quality of the project but also the cost of the project. The design work is carried out on the

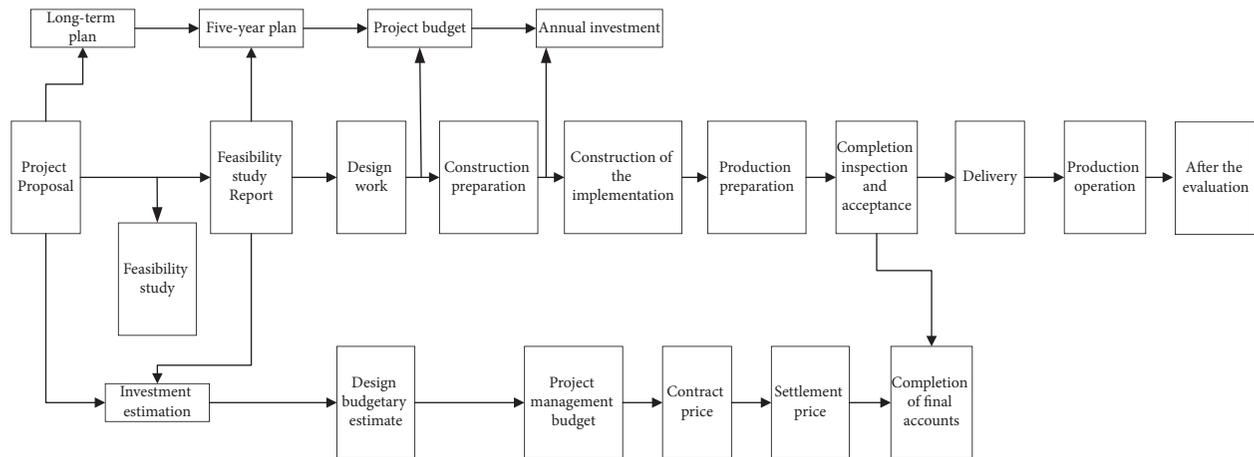

FIGURE 2: Construction flowchart.

premise of engineering quality, and then the economic credibility of the design scheme is evaluated, and at the same time, it is studied whether the architectural function of the design scheme meets the needs of the investor. In addition, the method of limit design can also be adopted, and the investor can directly control the estimated cost of the project within a certain range when communicating with the design institute.

- (2) During the design process, it is necessary to consider the design changes in the construction stage. Designers should comprehensively consider the correlation between design changes and the impact of construction costs. Usually, the earlier design changes occur in the construction stage, the smaller the impact on the overall cost. Therefore, it is necessary to conduct a comprehensive study of the influencing factors immediately after the design is completed, so as to minimize the change in the design scheme.

3.4. Cost Control Measures in the Construction Stage.

First of all, it is necessary to formulate a dynamic and static cost control plan in the construction stage. The static control plan is mainly to be discussed by the construction party, the investor, and the design institute before the start of construction. Modify the process links that the construction unit cannot meet in the plan. At the same time, the investor and the builder should sign a cost pre-limited contract, that is, to formulate a scope of approval for the fluctuation of the project cost, and stipulate the conditions that can affect the cost of the project, and the additional cost caused by other conditions will not be paid. Dynamic cost control refers to the review and compensation management of cost changes caused by modification of the construction design during the entire construction stage, and the reasons for changes in the construction process and the design changes are reported to the cost management department for review. The changes within the scope are approved for revision, while those beyond the contract limit need to be negotiated by the

investor and the construction party for related compensation issues. It should be noted that the limited terms in the contract shall not be arbitrarily changed during the construction stage. If a party unilaterally changes the contract, it shall bear all the additional costs. In the construction stage, where investment mainly occurs, construction site management should be done well, and corresponding management and control should be done to reduce costs and eliminate waste. They should pay attention to the following aspects: 1. Do a good job in investment tracking management. Through effective tracking management, the corresponding problems can be found in a timely and effective manner, and the quality of the project can be effectively grasped in terms of quality, progress, and cost, so as to reasonably save costs and solve problems. Identify the control basis, such as project management budget and the project contract price, etc., through project measurement, control of project changes, etc., according to the actual workload completed by the contractor, and strictly determine the actual project costs incurred during the construction stage. 2. Strictly review the construction organization design. During the construction process, the construction plan that is technically feasible and economically reasonable should be selected as far as possible. According to the nature and scale of the project, the length of the construction period, the number of workers, mechanical equipment, material supply, transportation, geological, climatic conditions, and other specific technical and economic conditions, the construction organization design, construction plan, The construction schedule is optimized, and finally, the most rational use of manpower, material resources, financial resources, and resources is selected. Correctly handle the dialectical and unified relationship between project cost, construction period, and quality, and improve the comprehensive economic benefits of project construction. 3. Control engineering changes. If the corresponding project quantity is changed, it will bring a lot of unnecessary trouble to the original budget investment. In engineering contracting, many common phenomena will occur, due to factors such as construction site conditions, climate changes, changes in construction progress, and

changes, differences, and delays in contract terms, specifications, standard documents, and construction drawings, which will inevitably lead to engineering contracting. Claims arise, which in turn lead to changes in the investment in the project.

3.5. Cost Control Measures at the Completion Stage. The completion settlement report is the most direct data reflecting the actual cost of the water conservancy project, and it is also the core reference data for investors to consider the projected income. In order to control the project cost at the time of completion and settlement, it is necessary to conduct a comprehensive review of the actual construction volume of the water conservancy project, compare the early design drawings, revised drawings, and as-built drawings, and cooperate with auditors to inspect all construction links. Carefully check whether there is any false report of construction volume. At the same time, it is also necessary to refer to the limited terms in the contract when completing the settlement to avoid the problem of “malicious” price reduction by the investor and ensure the economic benefits of the construction party, so as to avoid their fraudulent behavior and make the whole process of cost work more complete and accurate.

4. Multiple Regression Analysis Models

4.1. Introduction to Multiple Regression Models. Multiple regression analysis [21, 22] refers to the establishment of a linear or nonlinear mathematical model between multiple variables by considering one variable as a dependent variable and one or more other variables as independent variables. Statistical analysis methods use quantitative relationships and use sample data for analysis. In addition, there is also a multiple regression analysis that discusses the linear dependence of multiple independent variables and multiple dependent variables, which is called the multiple multiple regression analysis models (or simply many-to-many regression) [23]. Usually, multiple factors affect the dependent variable, and the problem that multiple independent variables affect one dependent variable can be solved by multiple regression analysis [24]. For example, economic knowledge tells us that in addition to commodity price P , commodity demand Q is also affected by factors such as the price of substitutes, the price of complementary products, and consumer income, and even includes the quality variable of commodity brand (Brand Quality variables cannot be measured numerically, and dummy variables need to be introduced into the model). Multiple regression analysis has a wider range of applications. Since linear regression analysis is relatively simple and common, the following first introduces multiple linear regression [25, 26]. On the basis of linear analysis, dummy variable regression and a class of curve regression models that can be transformed into linear regression are gradually introduced.

One of the more famous multiple regression models is principal component analysis, which we use in this article. When using statistical analysis methods to study

multivariate subjects, too many variables will increase the complexity of the subject. People naturally want to get more information with fewer variables. In many cases, there is a certain correlation between variables. When there is a certain correlation between two variables, it can be interpreted that the information of the two variables reflecting the subject overlaps to a certain extent. Principal component analysis is to delete the redundant variables (closely related variables) for all the variables originally proposed, and establish as few new variables as possible so that these new variables are uncorrelated, and these new variables reflect. The information on the subject should be kept as original as possible. The principal component analysis is the basic mathematical analysis method, and its practical application is very wide, such in demographics, quantitative geography, molecular dynamics simulation, mathematical modeling, mathematical analysis, and other disciplines. Analytical method is that the component analysis is a multivariate statistical method that examines the correlation between multiple variables. It studies how to reveal the internal structure of multiple variables through a few principal components, that is, derive a few principal components from the original variables so that they can be as fully as possible. It is possible to retain a lot of information about the original variables, and they are not related to each other. Usually, the mathematical processing is to linearly combine the original P indicators as a new comprehensive indicator.

The most classic way is to use the variance of F_1 (the first linear combination selected, that is, the first comprehensive indicator) to express, that is, the larger the $\text{Var}(F_1)$, the more information F_1 contains. Therefore, F_1 selected in all linear combinations should have the largest variance, so F_1 is called the first principal component. If the first principal component is not enough to represent the information of the original P indicators, then consider selecting F_2 to select the second linear combination. In order to effectively reflect the original information, the existing information of F_1 does not need to appear in F_2 again, which is called F_2 , is the second principal component, and so on, and this way the third, fourth, ..., P -th principal components can be constructed.

4.2. Statistics of Data. Due to its public welfare nature, the construction funds of water conservancy projects are mostly invested by the government. The policies and financial levels of different provinces affect the decision-making of water conservancy project construction. In addition, engineering projects of different times and scales also have a greater impact on decision-making. The author counted a total of 20 initial approvals as samples, from which 17 samples were selected to estimate the regression model, and the remaining 3 samples were used for model testing.

4.3. Data Analysis. The multiple regression function is

$$E(y) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_k x_k. \quad (1)$$

It can be seen from formula (1) that the value of the dependent variable in the model is composed of the linear

function of the independent variable and the random variable of the error term, and the model parameters determine the specific form of the linear relationship between the dependent variable and the independent variable. The key point of using multiple regression analysis is to determine the specific values of the model parameters, then determine the specific form of the multiple linear regression model, and analyze the results according to the results. It is the mean or expected value and zero, and obeys the normal distribution, and it is independent.

The least-squares method is used to obtain the estimator of the regression coefficient, and the normal equation is as follows:

$$\begin{aligned} \hat{\beta}_0 n + \hat{\beta}_1 \sum_{i=1}^n x_{i1} + \dots + \hat{\beta}_k \sum_{i=1}^n x_{ik} &= \sum_{i=1}^n y_i, \\ \hat{\beta}_0 \sum_{i=1}^n x_{i1} + \hat{\beta}_1 \sum_{i=1}^n x_{i1}^2 + \dots + \hat{\beta}_k \sum_{i=1}^n x_{i1} x_{ik} &= \sum_{i=1}^n x_{i1} y_i, \quad (2) \\ \hat{\beta}_0 \sum_{i=1}^n x_{ik} + \hat{\beta}_1 \sum_{i=1}^n x_{ik} x_{i1} + \dots + \hat{\beta}_k \sum_{i=1}^n x_{ik}^2 &= \sum_{i=1}^n x_{ik} y_i, \end{aligned}$$

The dependent variable is the total static investment of the project, and the independent variables are the storage capacity, the irrigation surface, and the dam height. With the help of SPSS software, the estimated quantities of the regression coefficients are: $\hat{\beta}_0 = 51281.672$, $\hat{\beta}_1 = 10.797$, $\hat{\beta}_3 = 1420.701$, $\hat{\beta}_4 = -315.564$.

So the empirical regression equation between static total investment and storage capacity, irrigation surface, and dam height is: $y' = 51281.672 + 10.797x_1 + 1420.701x_1 - 315.564x_3$.

Where y' means Static total investment (ten thousand yuan), x_1 means Reservoir storage capacity (ten thousand m^3), x_2 means Irrigated area (ten thousand mu), and x_3 means reservoir dam height (m).

The accuracy of the estimation depends on how well the regression equation fits the sample data. Usually, the multiple determination coefficient R^2 is used to evaluate the goodness of fit of the empirical equation of the multiple regression model. In order to avoid increasing the independent variable and overestimating R^2 , this study adopts the modified multiple determination coefficient, and its calculation formula is

$$\left(R^2 = 1 - \frac{n-1}{n-k-1} \right) (1 - R^2), \quad (3)$$

where R^2 means modified multiple determination coefficient, n means sample size, and k means the number of parameters in the model.

The regression coefficient of determination is $R^2 = 0.948$ and modified multiple determination coefficient is $R^2 = 0.936$, which show that the goodness of fit of the empirical equation of the multiple linear regression model is good. The histograms and standard P-P plots of regression standardized residuals are shown in Figures 3 and 4, respectively.

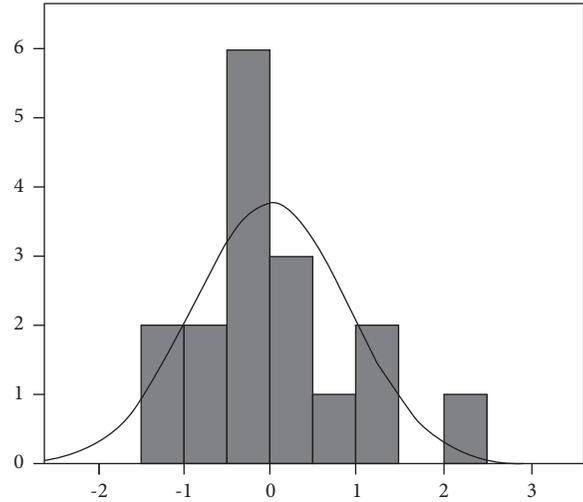

FIGURE 3: Histogram of regression standardized residuals.

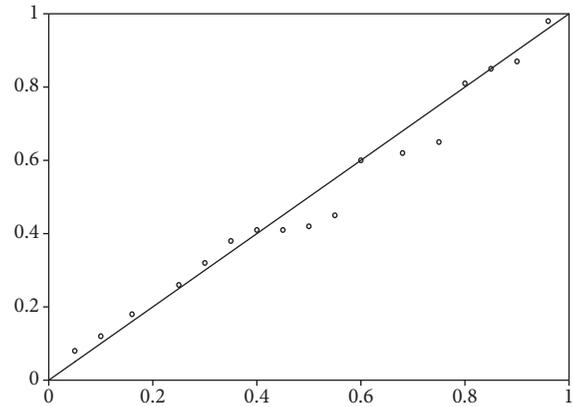

FIGURE 4: Standard P-P plot of regression standardized residuals.

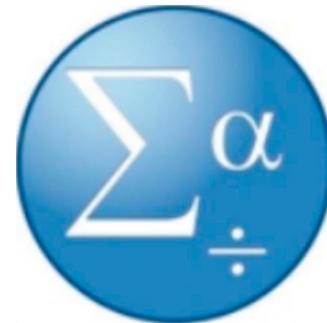

FIGURE 5: Logo of SPSS.

4.4. SPSS Software Application Analysis. Using SPSS software (Figure 5) analysis, the following can be obtained (Tables 1, 2, 3).

The data used in this study is tested by multiple regression estimation models, and through the multiple regression analyses of SPSS software, the regression equation is summarized as $Y = -587.209 + 0.115 + 103.464$.

TABLE 1: Table data obtained after multiple regression analysis.

Model	R	R Part	Adjusted R squared	Errors in standard estimates
1	0.976 ^a	0.953	0.947	388.04391
2	0.987 ^b	0.975	0.967	304.74013

Note: a. Predictor variables: (constant), total floor area; b. Predictor variables: (constant), total floor area, number of floors; c. Dependent variable: total project cost. At this time, the = 0.967 obtained by the regression analysis is relatively close to 1, so the reliability of this regression model is considered acceptable.

TABLE 2: Excluded variables.

Model	Enter beta	t	Significant	Partial correlation	Collinear statistical tolerance
1	Construction layer	0.472b	2.444	0.045	0.678
	Building height	0.298b	1.849	0.107	0.573
	Time limit for a project	-0.478b	-0.879	0.408	-0.315
2	Building height	-0.592c	-1.113	0.308	-0.414
	Time limit for a project	-0.217c	-0.467	0.657	-0.187

Note: a. Dependent variable: total project cost; b. Predictors in the model: (constant), gross floor area; c. Predictors in the model: (constant), gross floor area, The number of building floors thus obtain a regression equation: $Y = -587.209 + 0.115 + 103.464$.

TABLE 3: Coefficients.

Model		Unnormalized coefficient		Normalization coefficient	t	Significant
		B	Standard error	Beta		
1	(Constant)	96.677	300.262		0.322	0.756
	Gross floor area	0.213	0.017	0.976	12.730	0.000
	(Constant)	-587.209	365.957		-1.605	0.153
2	Gross floor area	0.115	0.042	0.528	2.732	0.029
	Construction layer	103.464	42.339	0.472	2.444	0.045

The meaning of this equation is that the total cost of recent engineering projects is greatly affected by the total construction area of the project and the number of building layers.

5. Conclusion

The cost control and management of water conservancy projects should run through the whole process, including engineering decision-making, design, construction, completion settlement, and other stages. Among them, cost control in the engineering design and construction stages is particularly important. In the design stage, the project quality and cost should be used as reference standards to design the optimal water conservancy project plan. The technical and economic demonstration and comparison are an important part of the project evaluation and selection in the feasibility study stage. In this study, the key contents considered in the design of the slope reinforcement scheme are analyzed in detail, and the multiple linear regression is carried out on the important parameter samples that affect the cost. After comparing with the real cost, the model accuracy meets the estimation requirements, and each parameter is easy to obtain in the feasibility study stage, and the model is easy to use. Therefore, this model has strong applicability to the economic comparison and selection of slope reinforcement schemes in the feasibility study stage.

A scoring approach of business English oral training based on a deep neural network is put forward. Based on speech recognition technology, automatic correction technology, deep learning technology, machine learning technology, and the scoring data of business English oral training generated by the general computerized examination platform system, this paper uses the audio data of students' oral expression questions collected by the existing general computerized examination platform, and studies artificial intelligence technology, deep learning technology, and machine learning technology to train the intelligent scoring system, it realizes the intelligent scoring of oral expression questions, which plays a positive role in language training guidance and correction. Finally, the accuracy of the intelligent scoring system is verified by the correlation between the score of the intelligent scoring system and the manual score of teachers. The higher the correlation with manual scoring, the higher the scoring accuracy of the intelligent scoring system.

1. Introduction

With the rise of AI [1–3] to the national strategic level, AI technology has become more and more popular, and AI+ education is also the key research direction of educational technology [3–8]. How to combine artificial intelligence technology [9, 10], deep learning technology [11, 12], machine learning technology [13] and education is a problem worthy of research in the field of educational technology [12–15]. English is a very important subject in the field of education. If artificial intelligence and business English skill training can be combined, it will be of great help to improve students' interest in learning English, correct students' English pronunciation, evaluate students' academic performance, and guide students' learning. Artificial intelligence technology developed to a research climax as early as the 1990s. Recently, with the release of Google's deep learning engine TensorFlow and artificial intelligence technology, it became more popular after alpha dog defeated Li Shishi, which is also expected [16]. TensorFlow brings convenience and ease of use to deep learning and training, and this game also shows that artificial intelligence can still

perform well in this scenario [17–19]. Business English speaking training score plays an important role in Business English teaching. Under the background of artificial intelligence, it is very urgent and necessary to research the scoring of business English oral training based on a deep neural network.

2. Current Situation and Problems of Oral Business English Training

With the rapid development of the Internet, "Internet+ education" has become a trend [20–22]. The business English oral skills training system trains and evaluates English through online learning, so that students have made great progress in all aspects of English listening, speaking, reading, and writing. After years of accumulation, a large number of valuable teaching data are stored in the system. These source data provide a basis for our work. The current situation of oral business English teaching and training is deeply analyzed from four aspects: teaching objectives, content, implementation, and assessment.

(1) Teaching objectives

At present, the formulation of oral English curriculum standards for business English Majors in most colleges and universities is dominated by teaching materials and focused on knowledge. The listed objectives include pronunciation rules, intonation, word quantity, and expressions commonly used in daily life and social life.

(2) Teaching content

Due to the limitations of employing foreign teachers or professional teachers without a business background in China, the teaching content is mainly based on the English teaching content itself, and there is no subject matter of oral English practice for business application background.

(3) Teaching implementation

Due to the reasons of teachers and teaching resources, business English mostly adopts large class teaching, and the number of people in each class is between 35 and 45. In terms of curriculum, oral English is a professional basic course, which is generally set up in the first and second semesters, with 4 class hours per week. Interviews and questionnaires with teachers and professional students in many colleges and universities show that the current teaching methods are mainly teachers' explanation and demonstration (accounting for about 40% of the classroom time) and student group practice (accounting for 50%), with additional personal practice (accounting for 10%). At the same time, the per capita time of students' special oral practice after the class is less than 20 minutes per week.

(4) Teaching evaluation

In Teacher-centered courses, students perform less alone and lack quantitative process records. At the end of the semester, the final assessment will be conducted only in the form of one-to-one oral daily dialogue, question and answer, and monologue.

According to the current situation of oral English teaching and training, combined with the training needs of business English talents, this paper analyzes the main problems existing in the current oral English teaching and training, including (1) the application of teaching objectives is not high; (2) the teaching content is not contemporary enough; (3) lack of pertinence in teaching implementation; (4) the process of teaching evaluation is not strong.

3. Design of Intelligent Scoring System

Oral Business English training includes two parts, English learning and English examination. English learning refers to that students can use the system to conduct self-test and practice relevant English topics when learning English at ordinary times. English test is organized by teachers. Students are evaluated before, during, and at the end of each semester. After the examination, the students will participate

in the questionnaire, which includes learning interests, whether they pass CET-4 or CET-6, the difficulty of the topic, their satisfaction with the examination system, etc. The oral business English training system will collect students' test data, in which the objective question system can directly give scores through the standard answers set in advance, and the subjective questions need to be corrected manually by teachers. This puts forward higher requirements for teachers' energy. The purpose of this study is to save teachers' energy and make subjective questions score automatically.

The topic types of business English oral training include single choice, multiple choice, cloze, oral expression, and English writing. Among them, subjective questions include oral expression questions and English writing questions. English writing can be corrected according to the automatic correction system. The intelligent correction of oral expression questions realizes the automatic scoring of the business English oral training system.

Through the interview with English teachers, the needs for an intelligent scoring system are determined. There are two main aspects of demand as follows:

(1) Accuracy

Since it is automatic scoring, if the accuracy of scoring is not high enough to meet the expectations of teachers, the scoring work will lose its significance. The total score of oral expression questions is 10 points. Compared with the manual score of teachers, the error of no more than 1 point is acceptable and the total score of the whole English test is 100, so the error for the total English score is less than 1%, which can meet the expectations of teachers.

(2) Time consuming

If the time of the intelligent scoring system is too long, which is longer than the time of teachers' manual correction system, it will consume teachers' time longer and lose the significance of saving teachers' time and energy. It takes no more than one minute to batch correct the oral expression questions of about 30 students in a class, which is the ideal automatic correction time for teachers.

3.1. Data Preparation Design. Based on the above demand analysis, the overall design of the intelligent scoring system is shown in Figure 1.

First, the audio data is processed. The corresponding features are extracted from it, then input into the neural network or linear regression model, and finally, the score is output. The language used for all processes is mainly python.

The python language has now become the mainstream language for machine learning programming. This language is more superficial than Java, C++, and C#. It also acts as a "glue" language to "glue" together functional modules written in other languages. Python has a rich software library, which is very helpful for machine learning. NumPy is an essential library in python, which provides some

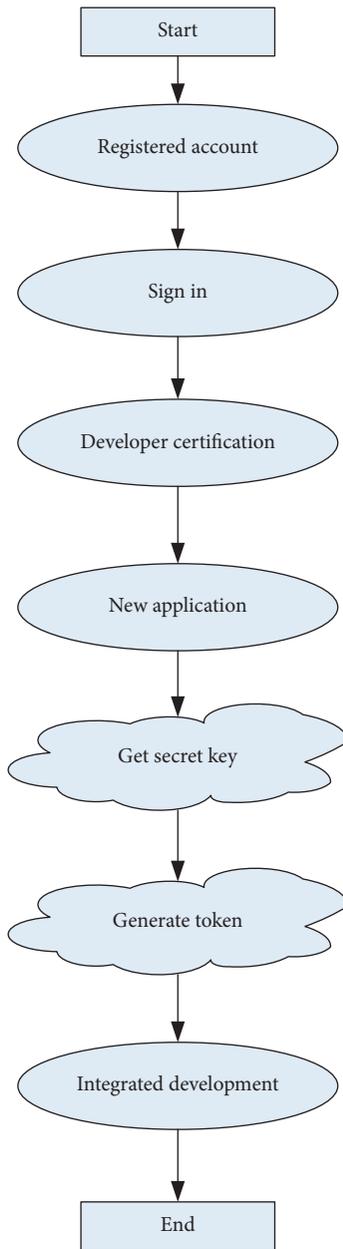

FIGURE 1: The overall design of the intelligent scoring system.

commonly used functions and standard libraries for data calculation. For example, operations related to matrices and arrays can be done using NumPy, and the code is simple and easy to maintain.

3.1.1. Data Processing. The data processing is divided into two parts. One part is processing the oral expression questions answers (audio data), and the other part is processing the data in the system (including student learning data and test data).

(1) Audio data processing

First, the audio data is recognized by speech recognition, and then the text is corrected according to

the requirements of composition correction according to the automatic correction scheme. Natural language processing includes text segmentation, sentence segmentation, construction of dictionaries, and word frequency statistics. The processed data is then subjected to data cleaning in preparation for the subsequent feature extraction. The flowchart of audio data processing is shown in Figure 2.

The flow of natural language processing is shown in Figure 3. The text recognized by the audio is firstly segmented and sentenced through speech recognition, the function words that have no real meaning, such as a and an, are removed, and only actual words such as nouns and adjectives are left. Then, a dictionary is constructed to count the frequency of each word.

(2) System data processing

The system data processing of the college English skill training system is divided into two parts as follows: learning data processing and examination data processing. After the data is extracted, the data needs to be cleaned because the extracted data will have a lot of dirty data and empty data, and these data need to be cleaned so as not to affect the results of subsequent model training. The system data processing is shown in Figure 4.

3.1.2. Feature Extraction. After the feature is extracted, too many features will lead to a complex model. Moreover, some features have little correlation with the target variable, so it is necessary to use the methods of feature transformation and feature selection to extract features.

Feature transformation methods are divided into normalization, discretization, and dimensionality reduction. Feature selection includes filtering, encapsulation, and integration. The definition of feature selection is to select a suitable feature set from many features, making the model make the evaluation index higher in the evaluation stage; that is, the model is more accurate, and the quality is better.

- (a) The first is the filtering method. The filtering method can assign a weight to the feature through some common statistical methods, such as the chi-square test, T -test, information entropy and information gain, correlation coefficient, and covariance. This weight means that the more significant the correlation between the feature and the output result, the greater the impact on the result; the smaller the correlation, the less the effect on the result.
- (b) The encapsulation method refers to selecting different feature subsets among many features. Some features can be excluded according to human experience and combined to achieve different effects. Then, according to different features, the effect to be predicted, the features of each combination of each group are evaluated, and the feature with the best effect is selected. In this way, a subset of features with

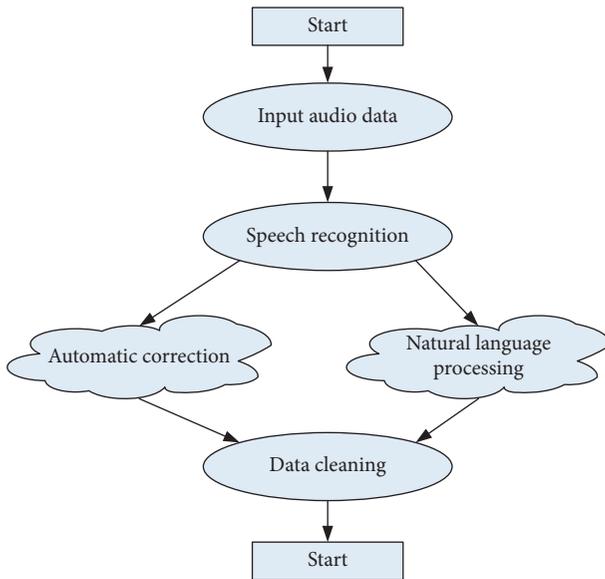

FIGURE 2: Audio data processing.

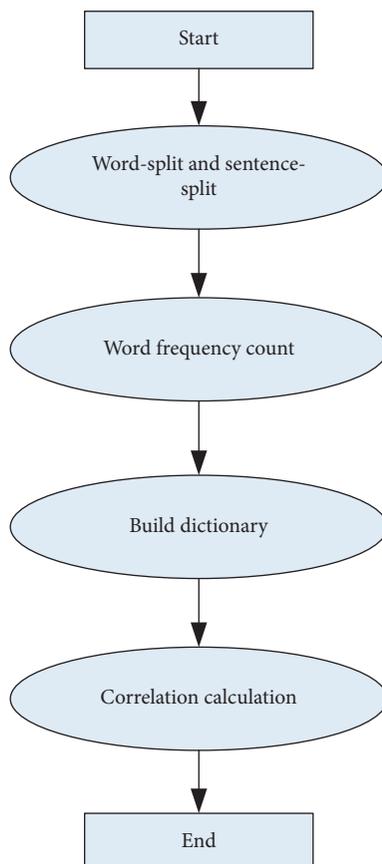

FIGURE 3: Natural language data processing.

better effects can be selected; that is, some irrelevant features are excluded, or features that have less influence on the target result.

- (c) The inheritance method refers to the premise that the model has been trained. Then, the data information

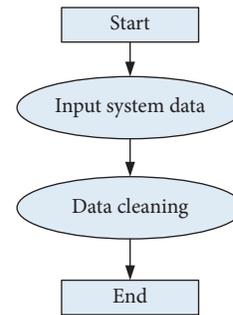

FIGURE 4: System data processing.

is trained through this model to learn the characteristics that make the model accuracy the best. For example, the logistic regression model in the machine learning model can determine the weight of each input feature according to the model to determine the importance of the impact of each feature on the target variable; in this way, the importance of the features can be obtained, and the features can be filtered. The method of feature processing is shown in Figure 5.

The design of the correlation calculation model is shown in Figure 6.

3.2. Intelligent Scoring System Design. The dataset was randomly divided into training and test sets using Python's random method. The training set accounted for 80%, with a total of 3,122 samples, and the test set accounted for 20%, with a total of 781 samples.

3.2.1. Linear Regression Model Design. According to the principle and usage scenarios of linear regression, experiments were carried out using the linear regression model [23–26] as shown in Figure 7.

3.2.2. Deep Neural Network Model Design. There are many mainstream deep learning open source tools on the market [27–29]. TensorFlow was developed by Google and has been widely used in recent years. On GitHub, you can see that TensorFlow has considerable attention and collection. Other deep learning tools such as Caffe and Torch do not have as much attention as TensorFlow, which shows that TensorFlow plays a pivotal role in the minds of deep learning developers and researchers. Many researchers study the training effect of these deep learning tools. Generally speaking, it is not objective. Each deep learning tool has its advantages and disadvantages. The specific situation needs to be analyzed in detail. This research mainly uses TensorFlow to train the neural network model.

The name of TensorFlow has already explained its two most essential components, Tensor and Flow. These two words are translated into Chinese as tensor and flow, respectively, which are explained from the perspective of the data model and calculation model. Tensor represents multidimensional data, that is, the data model. Flow refers to the

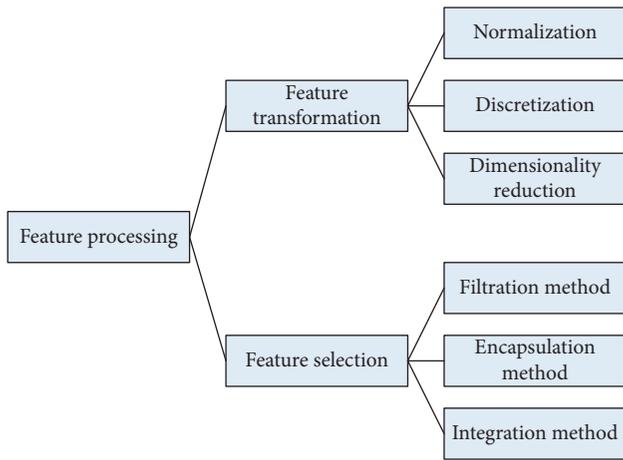

FIGURE 5: Feature processing.

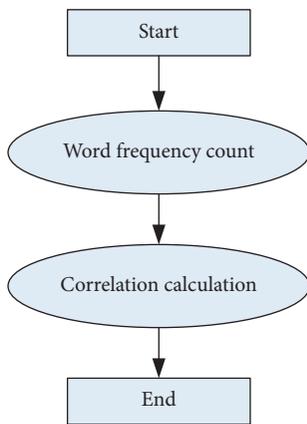

FIGURE 6: Correlation calculation model.

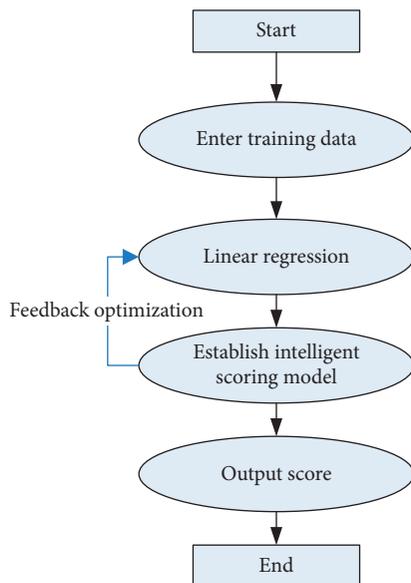

FIGURE 7: Linear regression model.

flow computing performed by tensor Tensor, which means the computing model. Each calculation in TensorFlow is a node on the graph, and the edges between nodes describe the dependencies between nodes.

In Python, “import TensorFlow as tf” is generally used to load TensorFlow. Tf can use TensorFlow more easily in programming. The TensorFlow program is divided into two parts, the first part needs to define all the calculations in the calculation graph, and the second part is to perform calculations.

There are many ways to install TensorFlow, which can be installed using Docker, installing using Pip, or compiled from source code. TensorFlow is divided into CPU version and GPU version. I installed the CPU version; the method used is Pip installation. The following is a detailed introduction to my installation method.

Pip is a small tool for Python that can easily and conveniently install and manage Python packages. Install TensorFlow using Pip - a three-step process. The first step is to install Pip. Select the appropriate version of Pip for your operating system to install. The second step is to find the proper installation package for TensorFlow. Because TensorFlow is divided into CPU and GPU versions, the GPU version requires the computer to support CUDA (Compute Unified Device Archive, a computing platform); I installed the CPU version. Currently, GPU installation still has specific restrictions on the environment. After the first two steps are completed, you can proceed to the third step, install TensorFlow through Pip. During installation, the commands installed will vary slightly depending on the version of Python. The steps of the deep neural network model are shown in Figure 8.

The steps of the deep neural network model (Figure 8) are as follows: input the training data into the neural network, and then use the neural network to train an intelligent scoring model continuously, and then input the test data into the intelligent scoring model to obtain the preliminary results of the intelligent scoring, compare this result with the teacher’s score, and then feedback and optimize the model, improve the model, and finally determine the intelligent scoring model; then input the test data into the intelligent scoring model and finally determine the score and then output it.

3.2.3. Fusion Design of Linear Regression Model and Deep Neural Network Model. The linear regression model and the deep neural network model are respectively assigned a weight and then summed to calculate the fused value. The final weighted prediction results in the experiment are $p = Lr_model * \alpha + dnn_model * \beta$, $\alpha + \beta = 1$, of which Lr_model and dnn_model are the results of the linear regression model and the deep neural network model, respectively. The values of α and β change dynamically during each training and are related to relevant parameters and datasets.

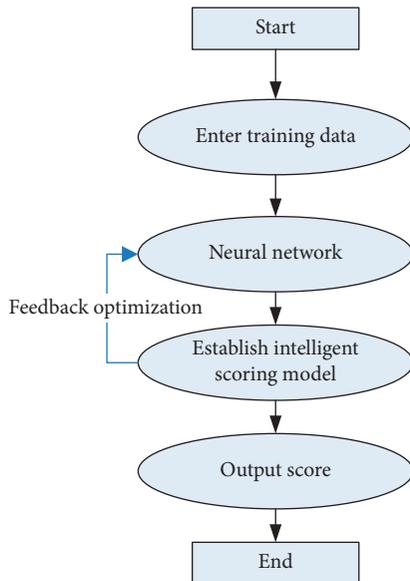

FIGURE 8: Deep neural network model.

3.3. Experimental Results of the Intelligent Scoring System

3.3.1. *Model Evaluation.* The weight value results of the linear regression model are shown in Table 1.

The result of the weight value of the deep network is shown in Table 2.

The weight value results after the linear regression model-neural network model fusion are shown in Table 3.

The dataset is randomly divided into a training set and test set, of which the training set accounts for 80%, with a total of 3,122 samples, and the test set accounts for 20%, with a total of 781 samples. The random sampling is divided into five categories, and the five categories are marked as A, B, C, D, and E, respectively.

There are three models as follows: the linear regression model (lr), the deep neural network model (DNN), and the model after the fusion of the two models (lr_DNN). We calculate the respective Recall and Precision to evaluate the model; the results are shown in Table 4. It can be seen from the table that the Recall and Precision after the fusion of the linear regression model and the deep neural network model are significantly better than the deep neural network model and the linear regression model.

3.3.2. *Evaluation of Scoring Accuracy.* The dataset was randomly divided into a training set and test set, of which the training set accounted for 80%, with a total of 3,122 samples, and the test set accounted for 20%, with a total of 781 samples. The method for judging whether the score is accurate or not is shown in Figure 9.

Among the 781 samples, 711 samples were predicted correctly, and 70 samples were predicted wrong. Therefore, the calculated accuracy rate is 91.04%, and the formula for calculating the accuracy rate is as follows:

Accuracy rate = (accurate number of scores/total number of scores) * 100% = 91.04%

The main reason for the accuracy of the predicted samples is that the established intelligent scoring model can objectively describe the students' verbal expression ability, and teachers' scores are relatively concentrated, generally ranging from 7 to 9 (10-point scale). The main reason for the inaccuracy of the predicted samples is that the usual grades of some students cannot reflect their learning situation. For

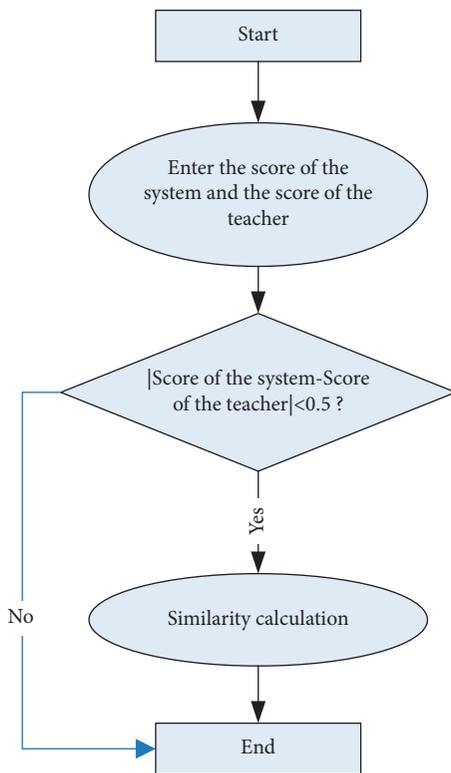

FIGURE 9: Evaluation of scoring accuracy.

example, student A is not interested in English but has a higher score on the oral English expression question. It is usual for the prediction results to have a certain error. Due to the diversity of samples, it is acceptable for the accuracy of a certain model to have the error within a reasonable range.

4. Conclusions

With the deepening of China’s opening to the outside world, business English majors put forward higher requirements for oral application ability. Making full use of various educational information technologies to promote the normalization, informatization, and networking of oral teaching and training is an important measure to improve the oral application ability of business applications. Based on the analysis of the current situation of applied oral English teaching and training, this paper combs the prominent

problems in the current teaching, such as low application of objectives, insufficient timeliness of the content, insufficient pertinence of implementation, and weak evaluation process, and puts forward a scoring method of business English oral English training based on deep neural network.

This paper explores a new teaching mode. Focusing on business application, this model promotes the transformation of teaching objectives from knowledge to ability, introduces scene application and other rich teaching contents, promotes the implementation of “online and offline” hybrid teaching, and implements curriculum formative assessment and evaluation, so as to promote student-centered teaching reform and improve students’ oral application ability. After one academic year’s pilot application in many business English application courses, the new model has better results in classroom effect, student investment, performance assessment, innovative practice, and practice.

Although it is based on the student’s oral test data in the business English oral skill training system for speech recognition, automatic correction, machine learning modeling, and neural network modeling, there will still be many problems in the actual operation process. The limitations of this study are as follows: inaccurate speech recognition results, inaccurate oral score, and limitations of the deep learning model.

- (1) Although speech recognition has been claimed to have an accuracy of more than 95% in the official documents, in the actual process, the output results of speech recognition will be affected by the examination environment, the influence of surrounding students, and the noise nearby. If the speech recognition result is not accurate, it will have a certain impact on the oral score.
- (2) At present, most oral evaluation still adopts the subjective evaluation of teachers, and the oral evaluation itself is a difficult problem to overcome. Different teachers have different scoring standards, and there are differences in the scores between teachers. Most of them take the form of average scores to calculate the student’s scores. Therefore, in the process of automatic recognition of oral scoring, there will be a difference between the system scoring standard and the teacher scoring standard. In short, it is difficult to quantify teachers’ scoring standards, and it is difficult to reach an agreement between the scoring standards of the automatic correction system and teachers’ scoring standards.
- (3) The following research can optimize the scoring model and select the most appropriate model with the in-depth study of neural networks. Moreover, with the gradual increase of the computing power of CPU and GPU, the model can be more complex. In this way, even if the complexity of the model is increased and the amount of calculation becomes larger, the results can be calculated quickly.

Evapotranspiration (ET) is the main process parameter of the land surface heat and water balance. Evapotranspiration remote-sensing inversion can be divided into two types of methods, process-driven and data-driven, according to the model power. This paper presents a comprehensive and systematic review of the research progress of data-driven ET remote-sensing inversion methods and their products; reviews the basic principles, advantages, and disadvantages of related methods/products from three perspectives: empirical regression, machine learning, and data fusion; and finally indicates the development direction of data-driven ET remote-sensing inversion research.

1. Introduction

Evapotranspiration (ET) is the process by which surface water is transferred to the atmosphere, including evaporation of water trapped from water bodies, soils, and vegetation surfaces and transpiration by plants. As an important vehicle for water transfer and energy conversion in the land-air system, accurate estimates of evapotranspiration are essential for understanding global climate change, ecological and environmental issues, water cycle, and hydrological processes, as well as for mixing and irrigation of water for agriculture, monitoring agricultural droughts, and improving agricultural water use efficiency. To obtain complete spatial and temporal information on land surface ecosystems, two different scales of research tools are needed, namely ground-based observations and remote sensing. Currently, more than 400 stations and 2,000 ground-based flux observation sites have been constructed worldwide. In China, a network of 45 stations has been initially built to cover the major ecosystem types in Central Park. To capture the spatial heterogeneity, scale effects, and uncertainties of surface evapotranspiration and to provide ground truth measurements at scale for developing and validating remote-

sensing estimation models of evapotranspiration, the Integrated Heihe River Basin Ecological/Hydrological Processes Remote-Sensing Experiment constructed a dense three-dimensional flux observation matrix consisting of vorticity correlators, large-aperture scintillators, and automatic weather stations. However, the above observations are all station-scale based, and the spatial heterogeneity of large scale and nonuniformity of hydrothermal transport lead to the poor spatial representation of station-based observations, while intensive observations at large scale with multiple stations are usually time-consuming and laborious. Remote sensing, due to its macroscopic nature and large observation range, can overcome the spatial scale scaling problem involved in station-based observations, and a series of remote-sensing-based ET inversion models have been constructed [1]. Due to the low spatial resolution of geosynchronous satellites, which is difficult to meet the realistic demand, data from polar-orbiting satellites are usually used, and the time coverage period of polar-orbiting satellites is generally one week (e.g., Landsat at around 10: 00 a.m., MODIS Terra at around 10: 30 a.m., and Aqua at around 13: 30 p.m.), and the ET estimated based on these data is instantaneous ET. Daily, monthly, yearly, or even annual time

series of evapotranspiration are more useful than instantaneous evapotranspiration. For example, daily evapotranspiration is needed for meteorology, hydrology, and global atmospheric modeling; the dynamics of water consumption in agricultural fields during the growing season require estimation of the corresponding time-series evapotranspiration, and watershed water balance studies require estimation of time-series evapotranspiration. Therefore, it is necessary to explore the expansion of the time scale of remote-sensing inversion evapotranspiration and derive the cumulative daily to monthly values from the instantaneous values at the time of satellite transit to meet the research and application needs in the fields of climate, ecology, hydrology, and agriculture. With the development of satellite remote-sensing technology, surface parameters closely related to surface water and heat fluxes such as surface temperature, vegetation index, and soil moisture can be obtained by remote-sensing inversion, and remote-sensing inversion of evapotranspiration has become an effective method to obtain the spatial and temporal distribution of evapotranspiration at regional and global scales with high accuracy and timeliness. Due to the spatial heterogeneity of the subsurface surface, complex near-surface meteorological conditions, and the dynamics of hydro-thermal transport processes, the spatial and temporal variability of surface evapotranspiration varies greatly, and the accurate estimation at the regional scale still faces great challenges [2].

Existing methods for remote-sensing inversion of evapotranspiration can be classified into conductivity-based and temperature-based methods according to the principle mechanism [3] and into methods based on shortwave band data, thermal infrared band data, and microwave band data according to the driving data. In this paper, we classify them into two major categories according to the model drivers: process-driven physical inversion methods, such as energy balance residual methods and methods based on Penman–Monteith or Priestley–Taylor formulas; and data-driven inversion methods, including empirical regression methods, machine learning methods, and data fusion methods. Process-driven methods are based on theories and assumptions of photosynthesis, canopy conductance, and respiration in the biosphere and use simplified ecosystem processes and components to form established model structures that simulate the carbon-water-energy exchange of ecosystems. This type of approach has a better physical basis and can achieve high estimation accuracy when high-precision input data are available. However, regional surface heterogeneity, complexity of impedance parameterization, and cumulative data errors make the process-based physical methods complex and limited in their estimation results when applied to regions, and their regional extension is limited by the lack of high-quality input data, making it difficult to obtain the desired regional estimation accuracy.

The data-driven remote-sensing inversion method for evapotranspiration is a method to obtain evapotranspiration estimates by establishing the relationship between evapotranspiration-driven data (observed fluxes or existing evapotranspiration products) and their closely related

characteristic parameters. In this paper, we classify the data-driven methods into empirical regression methods, machine learning methods, and data fusion methods (Figure 1). Empirical regression methods and machine learning methods estimate actual evapotranspiration by directly constructing empirical relationships between remote sensing, meteorological and hydrological variables, and ET reference true values (e.g., observed fluxes), while data fusion methods improve ET accuracy or spatial and temporal resolution by fusing ET products with the same or different spatial and temporal resolutions. Related studies have found that complex physical and analytical methods do not necessarily have higher accuracy than simple empirical and statistical methods, while the diffusion and application of machine learning methods have greatly improved the accuracy of surface parameter estimation. The advantage of data-driven methods lies in the ability to capture data relationships sensitively and to construct well-fitting regression relationships with low errors to estimate steam emanation by relying on data alone. Unlike the traditional physical model, it does not need to predict the physical mechanisms of evapotranspiration processes or to obtain all variables that have an influence on them. It is only necessary to construct relationships between the obtained remote sensing, meteorological and observational flux data to obtain highly accurate estimation results.

With the development of the global flux observation network, more and more flux observation data have been shared and acquired, and data-driven methods have been developed rapidly. This paper presents a comprehensive and systematic review of the research progress of data-driven remote-sensing inversion methods and products at home and abroad; summarizes the basic principles, advantages, and shortcomings of related methods/products from three aspects: empirical regression, machine learning, and data fusion; and finally indicates the future development direction of data-driven remote-sensing inversion of evapotranspiration.

2. Data-Driven Inversion Method for Remote Sensing of Evapotranspiration

2.1. Experience Regression Method. Early empirical regression methods estimated surface evapotranspiration using a non-linear relationship between ground gas temperature difference and evapotranspiration and net radiation. With the long-term and continuous acquisition of observation data, the empirical regression method no longer relied only on the difference in ground gas temperature but estimated evapotranspiration by directly constructing linear or non-linear relationships between evapotranspiration and various climate or remotely sensed invertible parameters that are closely related to it. Later, in order to construct empirical models with higher applicability and accuracy, it was gradually developed to combine physical models and construct empirical regression relationships using globally distributed multisite flux observations.

Since the 1970s, with the advent of handheld infrared radiometers, researchers have begun to study the relationship between crop canopy temperature and plant

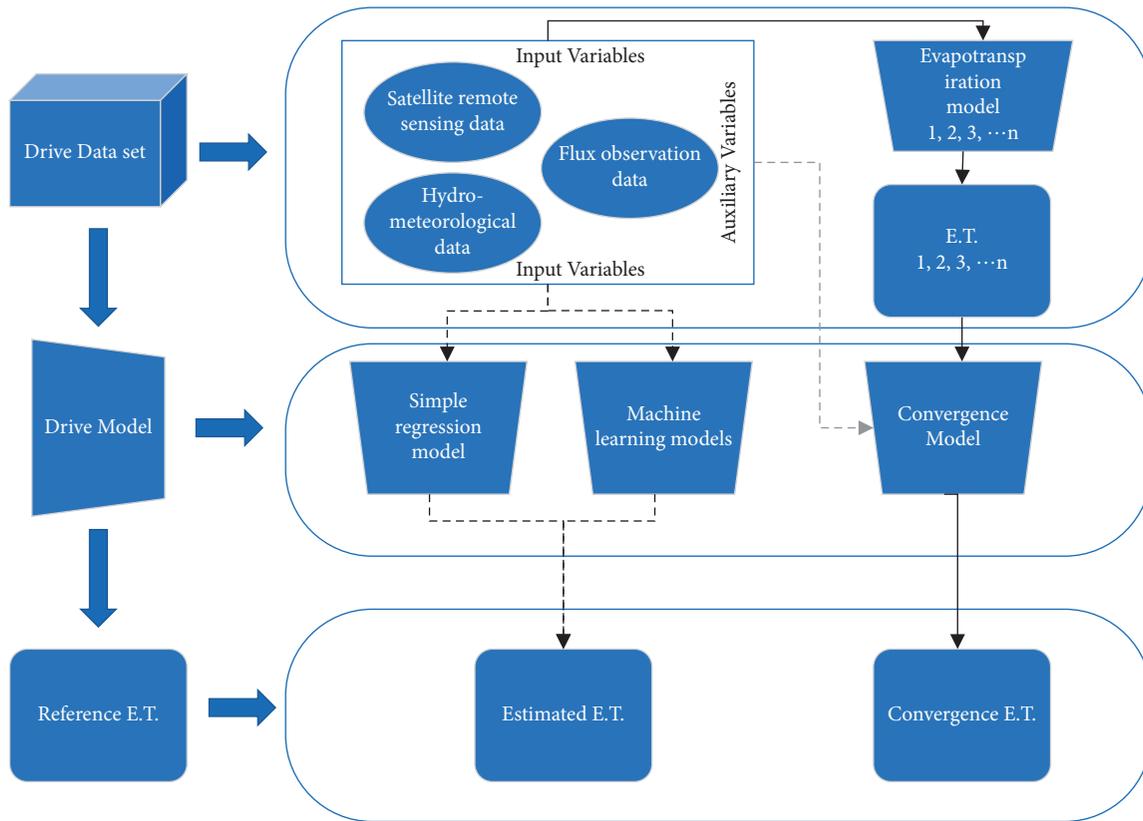

FIGURE 1: Integral flowchart of the data-driven remote inversion method for evapotranspiration (ET).

evapotranspiration. Jackson et al. [4] constructed an empirical model based on the relationship between instantaneous surface temperature at noon and the temperature difference between the reference altitude and daily evapotranspiration. The development of remote-sensing satellite detection technology, such as the early TIROS satellites (Television and Infrared Observing Satellite), NOAA satellites (National Oceanic and Atmospheric Administration), and HCMM satellites (meteorological satellite), has made it possible to estimate evapotranspiration on a large scale. With the progress in understanding and the availability of more satellite data, a series of time-scale extension methods have been proposed by different scholars. The idea of these methods is to obtain the daily evaporation by temporally extending the instantaneous latent heat flux based on parameters that remain constant with time or vary with a certain pattern. Interpolation and data assimilation methods are used to obtain connected long time series of evapotranspiration. Currently, some representative time-scale expansion methods include empirical model, sinusoidal relationship method, evaporation ratio method, reference evaporation ratio method, surface impedance method, astronomical radiation ratio method, and data assimilation method.

Empirical models (also known as statistical models) determine daily evapotranspiration by fitting latent heat LE , sensible heat H , net solar radiation R , and soil heat flux G under certain assumptions using instantaneous remotely sensed observations and ground truth values. This method

was first proposed by Jackson et al. and has since been widely adopted [5]. Jackson et al. calculated daily evapotranspiration from the difference between daily net radiation and instantaneous remotely sensed land surface temperature (LST) and surface air temperature during daytime (usually at 13:30–14:00), as shown in the equation in Table 1. Seguin and Itier [6] found that daily evapotranspiration was also related to vegetation cover, surface roughness, wind speed, temperature stratification, and atmospheric stability and changed the above equation to an exponential form as shown in the equation in Table 1. Subsequently, Carlson [5] found that B and n vary with wind speed and surface roughness but are more sensitive to NDVI (normalized difference-vegetation index) and vegetation and proposed a simple method, as shown in the equation in Table 1. The method uses the difference between the LST at the time of satellite transit and the air temperature at 50 m height above the ground to calculate the daily evapotranspiration. The method is relatively simple and practical, but the coefficients B and n vary with the vegetation cover, introducing some cumulative error to the calculation results. Rivas and Caselles [7] estimated regional reference evapotranspiration based on LST and local meteorological data at the time of satellite transit, as shown in the equation in Table 1. The advantage of this method is that it has few parameters and high accuracy, and the disadvantage is that it is not universal and requires refitting the values of a and b with the PM equations based on local meteorological data when the regions are different.

TABLE 1: Summary of commonly applied empirical regression methods.

Methods	Parameter meaning	References	Remark
$LE_d = R_{n,d} - G_d - B_1(T_{1s} - T_{1a})$	LE_d is daily evapotranspiration, $\text{mm} \cdot \text{d}^{-1}$. $R_{n,d}$ is daily net radiation flux, $\text{MJ} \cdot \text{m}^{-2}$. $d^{-1}G_d$ is daily soil heat flux, $\text{MJ} \cdot \text{m}^{-2}$. $d^{-1}T_{1s}$ and T_{1a} are ground surface temperature and the temperature at 1.5 meters above the ground surface, at 13:30–14:00 local time, $^{\circ}\text{C}$ B_1 is lysimeter empirical parameters for regression of observed data	Jackson et al. [4]	(1)
$LE_d = R_{n,d} - B_2 T(\text{rad}13 - T_{a13})^{n_1}$	$T_{\text{rad}13}$ and T_{a13} are radiated ground surface temperature and the temperature at 2 meters above the ground surface, at 13:00 local time, $^{\circ}\text{C}$ B_2 and n_1 are calibration parameters based on surface roughness and atmospheric stability	Seguin et al. [5]	(2)
$LE_d = R_{n,d} - B_3(T_{\text{rad}} - T_{a50})^{n_2}$	T_{rad} and T_{a50} are radiated ground surface temperature and the temperature at 50 meters above ground surface, at 13:00 local time, $^{\circ}\text{C}$ B_3 is average overall conductivity of daily apparent heat flux n_2 is correction parameters for non-neutral static stability	Carlson et al. [6]	(3)
$ET_{r,d} = a - T_{\text{rad}} + b$	$ET_{r,d}$ is daily reference evapotranspiration, $\text{mm} \cdot \text{d}^{-1}$, a, b are parameters fitted using the PM formula based on local meteorological data	Rivas and Caselles [7]	(4)

The empirical model can obtain high-precision evapotranspiration throughout the day by remote-sensing observation of LST, temperature, and net daily radiation only once a day at noon under the condition of sufficient moisture supply and relatively stable surface atmosphere, which is very convenient for large-scale remote-sensing applications and can be of great use in irrigation management and crop yield estimation. The evapotranspiration during the rainy period needs to be obtained by interpolating the evapotranspiration of consecutive sunny days. The parameters B and n for different regions need to be determined by empirical regression and are not universal.

Solar radiation provides the energy source required for evaporation; soil moisture can directly provide water for soil evaporation, and its deficiency has a coercive effect on evaporation; surface temperature difference (difference between surface temperature and near-surface air temperature) is the temperature condition that allows evaporation process to occur, and surface temperature can indicate information such as surface soil moisture condition. Wind speed, vegetation index, vegetation cover, leaf area index, and so on can provide information about the heterogeneous condition of the ground, such as roughness and impedance, which can influence the evapotranspiration process [8, 9]. The estimation of evapotranspiration can be considered as a complex non-linear regression analysis of several meteorological and remotely sensed variables, and its general form can be summarized in the following equation, in conjunction with the equations provided in Table 1:

$$ET = f(R_n, R_s, T_s, T_a, VI, WS, RH_{da}, dVP_i \dots), \quad (1)$$

where R_n represents net surface radiation, R_s represents incident shortwave radiation, T_s represents surface temperature, T_a represents air temperature, VI represents vegetation index, WS represents wind speed, RH_{da} represents daily average relative humidity, and dVP_i represents water vapor pressure inverse difference.

In the twentieth century, when remote-sensing inversion theory and ET research were less mature, such methods

played an important role in estimating ET over small areas and could provide reliable information for moisture availability in practical applications [6]. Due to its dependence on ground-based observations, it is difficult to be applied to ET estimation over large areas.

Eddy covariance systems (EC) allow for more accurate ground-based flux observations, and with the establishment of a flux observation network based on eddy correlation (EC) system, long-term and continuous large-scale acquisition of observation data becomes possible. In particular, the sharing of open data from projects such as Fluxnet and ARM, have led to the emergence of regression statistics methods in various manifestations, and the combination of remote-sensing products, meteorological data, and flux observations to invert vapor combining remote-sensing products, meteorological data, and flux observations to invert the vapor has been well developed [10]. The empirical regression method no longer relies solely on the difference in ground temperature but estimates evapotranspiration by directly constructing linear relationships between evapotranspiration and its various closely related meteorological or remotely sensed reversible parameters. It was found that in the absence of a large number of meteorological observations, the evapotranspiration of image elements can be estimated from only a small number of remotely sensed reversible parameters, such as surface temperature, vegetation index, and surface albedo. However, the regression relationships constructed using meteorological and flux observation data from a few stations have large uncertainties in regional transplantation and require re-evaluation of empirical coefficients, while it is relatively difficult to construct empirical models with high applicability and accuracy. For this reason, research on empirical regression methods has been gradually developed to construct empirical regression relationships based on physical models using globally distributed multistation flux observation data [11]. Wang et al. [9] divided surface evapotranspiration into radiative and aerodynamic terms, introduced wind speed to calculate aerodynamic impedance, and combined ground

observation data, meteorological, and remote-sensing data to propose an empirical regression relationship based on the Penman–Monteith equation-based empirical regression relationship with certain physical significance for various surface types and confirmed that the accuracy of the empirical algorithm should be higher than that of the general model algorithm by re-fitting the coefficients for different land types separately, as shown in Figure 2. Yao et al. [12] proposed a simple hybrid empirical evapotranspiration estimation model based on a two-source model and validated by ground observations, which can be used for global surface evapotranspiration estimation. Yao et al. [13, 14] established an empirical estimation method based on Priestley–Taylor equation using 240 Fluxnet sites worldwide and determined the coefficients for different land classes. The empirical coefficients of the Priestley–Taylor equation were re-parameterized by replacing the available energy at the surface with the more readily available incident shortwave radiation.

Because thermal infrared surface temperatures are affected by clouds, simple regression methods applicable to large regions or the globe tend to use more readily available air temperatures as model inputs, Table 2, with calculated root mean squared error (RMSE).

There is also a trapezoidal eigenspace method based on the CWSI (crop water stress index) water deficit index for estimating regional surface evapotranspiration, as shown in Figure 3.

Based on the concept of CWSI (crop water stress index), Moran et al. [15] introduced the water deficit index (WDI), defined as the ratio of actual evapotranspiration to potential evapotranspiration, based on the Ts-VI trapezoidal space to estimate regional surface evapotranspiration and water deficit, and extended the CWSI applied in the total vegetation cover area to the partial-vegetation cover area. The CWSI applied in all-vegetation areas was extended to partial-vegetation areas. The input of surface observations for the trapezoidal method includes water vapor pressure, air temperature, wind speed, and maximum and minimum stomatal impedance. The trapezoidal method assumes that Ts-Ta on the wet and dry edges varies linearly with vegetation cover. To calculate the WDI at each image point in the trapezoidal space, the values of the four vertices of the trapezoid are obtained by combining the CWSI theory with the Penman–Monteith equation, that is, (1) the top of full vegetation cover with good moisture, (2) the top of full vegetation cover under water deficit, (3) the top of saturated bare soil, and (4) the dry bare soil.

2.2. Machine Learning Method. From constructing empirical relationships with observations from a few stations to constructing empirical relationships with observations from globally distributed stations, simple empirical statistical methods are becoming increasingly difficult to meet the high-precision needs of practical applications. Due to the excellent classification and regression prediction capabilities, machine learning methods are beginning to be used in studies of evapotranspiration estimation. Machine learning methods construct empirical models based on patterns

contained in data without specifying any functional form; have good data adaptability [16]; can significantly improve regression prediction accuracy; can also mine new information from data to facilitate the generation of understanding of new mechanisms [17]; and have been widely used in geological fields, such as surface parameter inversion, groundwater studies, downscaling, remote-sensing image fusion, and so on [18]. The results have been widely used in the field of geology, such as surface parameter inversion, groundwater studies, downscaling, and remote-sensing image fusion [18].

A study by Genaidy et al. [19] was one of the first studies that received wide attention on the use of neural networks for evapotranspiration estimation. Yang et al. [20] used a support vector machine approach to successfully estimate the evapotranspiration for the contiguous United States at 8 d using surface temperature, enhanced vegetation index, and surface cover in combination with incident shortwave radiation based on remotely sensed data and observations from 22 AmeriFlux sites. Jung et al. [21] used a support vector machine approach to estimate the evapotranspiration at 8 d scale evapotranspiration. The study by Jung et al. [21] published in *Nature* is one of the most influential studies in recent years using machine algorithms to estimate evapotranspiration, which used the model tree ensemble (MTE) approach to integrate surface meteorological data, remote-sensing data, and flux site data to assess monthly evapotranspiration at the global scale. Since then, especially in the past 5 years, a large number of related studies based on machine learning have emerged. Although these studies mainly focus on the comparative evaluation of different machine learning algorithms, the estimation results of different machine learning methods do not differ much, as confirmed by the study [22]. The accuracy of the estimation results between different machine learning methods is comparable after adjusting the parameters to obtain the optimal parameters [23]. The advantage of machine algorithms is that the model construction incorporates observed data, similar to encapsulated complex empirical algorithms, and high model simulation accuracy, and the disadvantage is that the model accuracy depends on the data, including data quality, data processing methods, data representativeness, and data scale issues. The focus of this paper is to summarize the application of machine learning methods to the inversion of evapotranspiration rather than to present the principles of each machine learning method, and information about the methods can be found in the above references.

The existing studies on regional evapotranspiration estimation based on various machine learning methods are summarized, and the existing studies are divided into two categories: one is the estimation of regional image-scale evapotranspiration through site-liter scale expansion, and the other is the estimation of regional image-scale evapotranspiration through image or watershed scale expansion.

(1) The regional evapotranspiration model is constructed with in situ observed flux data as the image element true value, combined with remote-sensing products and climate information. Depending on the source of the driving data,

Reference	Input	Time span	Station	Time scale	Results
Wang and Liang [8]	$VI, WS, R_s, RH_{da}, dVP_i$	1982–2002	International 64 flux observation sites	16 days	$R^2 = 0.94$; RMSE = 17 W/m ²
Yao et al. [12]	R_n, T_a, VI	2000–2008	12 ARM sites, 7 Fluxnet sites, 3 China flux observation sites	16 days	$R^2 = 0.84$; RMSE = 14.74 W/m ²
Yao et al. [13]	$VI, T_a, R_n, RH_{da}, dVP_i$	2000–2009	240 Fluxnet sites	1 day	Daily: $R^2 = 0.68 - 0.87$; RMSE = 11.5 – 20.9 W/m ² Monthly: $R^2 = 0.80 - 0.96$; RMSE = 4.3 – 18.1 W/m ²
Yao et al. [14]	R_s, VI, RH_{da}	2000–2009	100 Fluxnet sites	1 day	Daily: $R^2 = 0.42 - 0.81$; RMSE = 15.8 – 28.2 W/m ² Monthly: $R^2 = 0.58 - 0.86$; RMSE = 11.7 – 23.9 W/m ²

two types of models can be built: one is to combine the ground frame flux observation data with all-remote-sensing products as the model driver; the other is to combine the ground frame flux observation data with climate and weather information and remote-sensing products as the model driver. The method effectively utilizes the observation data of the global flux observation network, gives full play to the powerful regression prediction capability of machine learning technology, fuses the accuracy error of the driven data, and improves the accuracy of remote-sensing inversion of surface evapotranspiration. The method effectively utilizes the observation data of the global flux observation network,

gives full play to the strong regression prediction ability of machine learning technology, and fuses the accuracy error of the driving data to improve the accuracy of remote-sensing inversion of surface evaporation. However, most studies ignore the spatial scale differences between the source area of flux observations and gridded gas data or moderate resolution remote-sensing products. Such methods use in situ observed flux data as image element true values to construct models and combine remote-sensing products with climatological and meteorological information to obtain regional evapotranspiration. Various machine learning methods, such as neural networks, kernel function methods, and tree

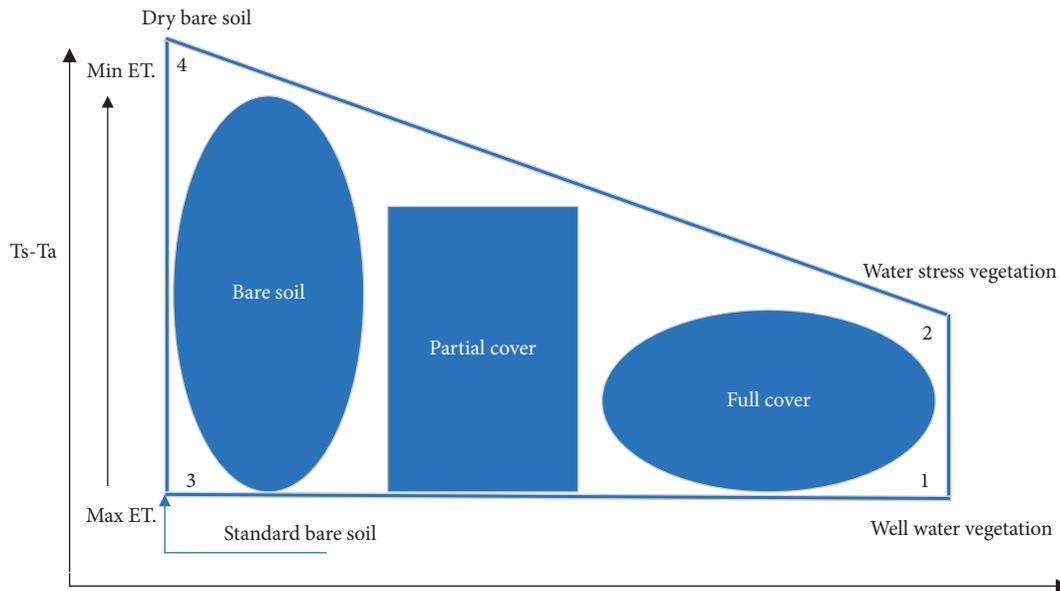

FIGURE 3: Schematic diagram of the terrestrial temperature difference-vegetation cover trapezoid relationship.

models, are used to obtain the spatial and temporal distribution of evapotranspiration at high scales in the observed regions and even globally. Depending on the source of the driving data, they can be divided into two categories. (i) Combination of ground-based observations and all-remote-sensing products as model drivers. Based on Moderate Resolution Imaging Spectroradiometer (MODIS) surface products, or in combination with Global Land Surface Satellite (GLASS), Global Energy and Water Exchanges-Surface Radiation Budget (GEWEX-SRB), Cloud and Earth Radiation Energy System (CERES), or the Japan Aerospace Exploration Agency (JAXA), researchers can use multiple remote sensing metrics as driving data to invert regional surface evapotranspiration through machine learning upgraded models [17, 20, 22]. (ii) Combining ground observation data with meteorological and climate information and remote-sensing products as model-driven data. Regional meteorological indicators are obtained from meteorological reanalysis data or weather station interpolation, and the combination of MODIS and GLASS remote sensing can invert surface parameters to drive model upscaling and estimate regional surface evapotranspiration [16, 22]. Comparing these two types of methods, the uncertainty of remote sensing combined with meteorological data-driven models is greater than the uncertainty of all-remote sensing as a data-driven model due to the inherent uncertainty of meteorologically driven data sets [22]. The advantage of remote sensing combined with meteorological data-driven models is that the input of meteorological data makes it possible to invert to obtain spatiotemporally continuous daily surface evapotranspiration, but it also reduces the spatial resolution of the inversion results. Meanwhile, its low spatial resolution cannot effectively take into account the spatial scale differences between the source area of site flux observations and gridded meteorological data or medium-resolution remote-sensing products, which reduces the inversion accuracy.

In addition, surface temperature and ground temperature difference, which are important parameters in traditional physical models for evapotranspiration estimation, are less applied in machine learning methods (Figure 4). Only a few studies have considered the effect of thermal infrared surface temperature as a driving factor in global applications [24, 25]. Thermal infrared surface temperature can provide valuable information such as surface soil moisture status for estimating evapotranspiration [26], and Jimenez [24] showed that the sensible and latent heat flux accuracy is significantly reduced when there is no thermal infrared surface temperature input. Although there are still some shortcomings, under the existing conditions, the site upscaling approach effectively utilizes the observed data from the global flux observation network, takes full advantage of the machine learning technology with powerful regression prediction capability, incorporates the accuracy error of the driving data, and improves the accuracy of remote-sensing inversion of surface evapotranspiration.

(2) Combine the existing shelf model flux products or re-analysis products to construct the relationship between remote-sensing variables and fluxes at image scale to obtain regional evapotranspiration directly or construct the relationship between watershed variables and watershed evapotranspiration to obtain evapotranspiration at image scale by downscaling. These methods can effectively solve the problem of matching spatial scales. However, the model construction of the image-scale scaling method uses the land surface model flux products or re-analysis products as the real values, and there is no set of products with fully reliable accuracy, so there is great uncertainty in the regional evapotranspiration obtained using this method. The Global Soil Wetness Project-2 (GSWP-2) compared global evapotranspiration estimates from 15 models and found global annual evapotranspiration variability ranging from 272 to 441 mm/a [27]. By comparing 41 global surface evapotranspiration (GSE) product data sets from 1985 to 1995, the

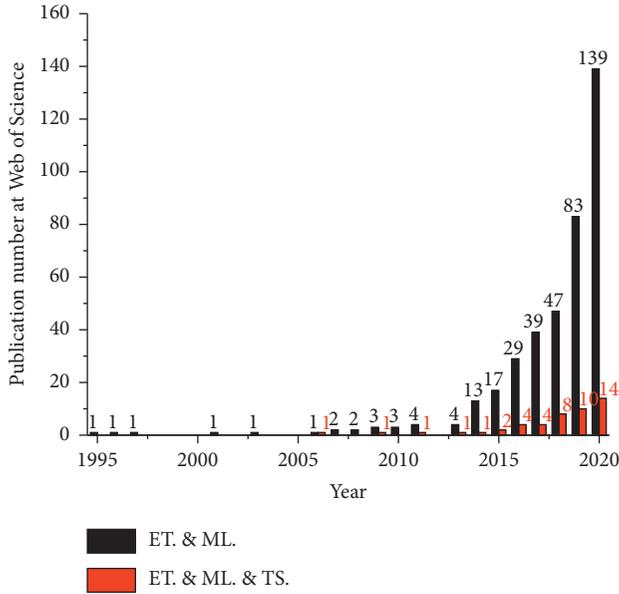

FIGURE 4: Number of articles published in 1995–2020 on topics that include evapotranspiration and machine learning (ET and ML) and evapotranspiration, machine learning, and surface temperature (ET and ML and TS; based on a web of science platform).

study found that the global average annual surface evapotranspiration was about 1.59 ± 0.19 mm/d (46 ± 5 W/m²). Simulated values are lower than the reference data set as of IPCC AR4 (IPCC Fourth Assessment Report), whose standard deviation is 0.16 mm/d (4.6 W/m²), while the standard deviation of 0.12 mm/d (3.6 W/m²) for the GSWP LSMs (the Global Soil Wetness Project land surface models) dataset is even lower than the standard deviation of IPCC AR4 [28].

There is also a method for estimating regional evapotranspiration at the watershed downscale. This method is to construct the relationship between basin variables and basin evapotranspiration in combination with basin evapotranspiration, downscaling to get like meta-scale evapotranspiration. Lappen and Schumacher [29] based on surface water balance method from rainfall data from rain barrel observatory, river runoff from the hydrological observatory, combined with gravity recovery and climate experiment (GRACE) and Terrestrial Water Storage Anomaly (TWSA) data to obtain monthly-scale evapotranspiration from 95 watersheds worldwide, and used a model tree integration approach to relate variables such as radiation, temperature, rainfall, wind speed, and vegetation index to monthly-scale watershed evapotranspiration to estimate monthly-scale using spatialized meteorological and satellite data global evapotranspiration using spatialized meteorological and satellite data. This method effectively solves the spatial scale matching problem and can obtain high-precision basin-scale monthly evapotranspiration, but it cannot describe the spatial and temporal (e.g., between different days and between different grids) heterogeneity of evapotranspiration in the basin and cannot accurately obtain high-precision daily evapotranspiration.

2.3. Data Fusion Method. ET estimation based on data fusion can be divided into two categories, that is, fusion with the same spatial and temporal resolution and fusion with different spatial and temporal resolutions.

(1) Same spatial and temporal resolution fusion is the fusion of ET obtained from models with multiple spatial and temporal resolutions with flux observations or ET products as reference true values to obtain higher accuracy ET estimates. This approach combines the advantages of physical models with solid physical mechanisms and data-driven methods with strong regression prediction capabilities, combining the advantages and disadvantages of various algorithms. The problem is that the fusion accuracy is limited by the accuracy of the individual model being fused. The fusion accuracy is limited by the accuracy of the individual models being fused. Depending on whether the fused ET models and the fusion method used can be explicitly expressed, they can be subdivided into two types: multimodel ET explicit fusion and multimodel ET implicit fusion.

Considering that different algorithms have their own advantages and disadvantages, the study of multialgorithm fusion has become a new trend in the study of quantitative remote sensing of vapor distribution in order to improve the accuracy of vapor emission. For example, models such as simple averaging, Bayesian averaging, empirical orthogonal function method, Taylor fusion model, and machine learning methods have been applied to multimodel ET fusion studies of evapotranspiration [30, 31]. The data-driven multimodel ET fusion method combines the advantages of physical models with solid physical mechanisms and data-driven methods with powerful regression prediction capabilities and combines the advantages and disadvantages of various algorithms to directly fuse the observed data, avoiding the problems of missing physical mechanism or low accuracy caused by using only data-driven methods to invert ET. It avoids the problem of missing physical mechanism or low accuracy caused by inversion of evapotranspiration using only physical models and can obtain more reliable evapotranspiration estimation results, while the estimation accuracy is improved to some extent.

Explicit multimodel ET fusion means that both the ET model to be fused and the fusion method used can be explicitly expressed. As the name implies, explicit fusion is characterized by the fact that the fusion model (including the model to be fused and the fusion method) can be expressed in an explicit formula that is easy to manipulate and replicate. The fusion of process-based physical models and data-driven empirical regression models using simple averaging, Bayesian averaging, or simple Taylor's method is currently a common approach for the explicit fusion of multiple models [30]. Bayesian averaging or simple Taylor fusion is essentially a weighted average method, where the scores of the different models to be fused are weighted according to the evaluated Bayesian or simple Taylor models. Its general expression is as follows:

$$ET = w_1 ET_1 + w_2 ET_2 + \dots + w_n ET_n, \quad (2)$$

$$ET_n = f_n(v_{n1}, v_{n2}, \dots, v_{ni}, \dots, v_{nm}), \quad (3)$$

where w_n denotes the weight of the n -th model to be fused, ET_n is the n th model to be fused, f_n denotes the equation expression of the n -th model to be fused, and v_{ni} denotes the i -th model driver of the n th model to be fused. When using this approach for multimodel fusion, the selection of multiple models is more important, and a balance is needed to select the number of over- and underestimated models. The advantage of this approach is that it can balance the overestimation and underestimation of different algorithms, reduce their overestimation or underestimation, and improve the accuracy of the algorithm; the disadvantage is that the fusion accuracy is highly dependent on the accuracy of the fusion models themselves, and the uncertainty of the weight ratio of the fusion models inherently limits its wide application.

Implicit fusion of multimodel ET means that the fused ET model or the fusion method used cannot be expressed explicitly, that is, the fused model includes estimation methods that cannot be expressed in explicit formulas (e.g., machine learning methods, assimilation methods, pattern methods, etc.) [14, 32] or methods that cannot be expressed in explicit formulas (e.g., machine learning methods, etc.) as fusion methods for process-based multimodel fusion studies of physical or empirical regression models [31], or neither the model being fused nor the fusion method can be expressed explicitly. The essence of multimodel implicit fusion is product fusion, that is, multiple models to be fused need to be used to obtain their respective ET values, and then fusion methods are used to fuse site or regional products. The general expression is as follows:

$$ET = f(ET_1, ET_2, \dots, ET_n), \quad (4)$$

where ET_n is the n -th model to be fused estimation result and f denotes the fusion method. Compared with the traditional physical model and display fusion, the implicit fusion method improves the estimation accuracy; compared with the empirical regression method and machine learning method, this type of method is more reliable than the empirical regression method and machine learning method when the area is scaled, especially in the area where the observed data are lacking or difficult to obtain. Meanwhile, the model fusion approach can still obtain reliable ET estimates with good accuracy for regions where vegetation cover is poor and it is difficult to obtain reliable and high-precision ET estimates using machine learning site upscaling alone. The shortcomings of this method are similar to the multimodel ET explicit fusion; the fusion accuracy is still limited by the accuracy of the fused algorithm itself and the dissimilarity between the selected models; and the complex structure of the fused model also affects its computational efficiency.

(2) The fusion of different spatial and temporal resolutions refers to the data-driven approach to establish the linkage between data to achieve spatial and temporal fusion or downscaling of evapotranspiration products to obtain ET products with high spatial and temporal resolutions, so as to effectively solve the problem of not being able to directly obtain high spatial and temporal resolution surface

evapotranspiration from single-source remote-sensing data under the existing conditions. The disadvantage is that the fusion accuracy is highly dependent on the accuracy of the low-resolution ET products. Without a high accuracy single-source remote-sensing ET product, the uncertainty of data-driven spatiotemporal fusion or downscaling ET results will be directly increased. Spatiotemporal fusion and downscaling processes are similar [33], both of which are centered on establishing connections between data, and the advantage of the data-driven approach is that it can better capture and construct the relationships between data.

ET spatiotemporal fusion is the fusion of ET products with high temporal resolution and low spatial resolution and ET products with high spatial resolution and low temporal resolution to obtain ET products with high spatiotemporal resolution (Figure 5(a)). At this stage, there are few studies that directly fuse surface evapotranspiration products with different spatial and temporal resolutions; unlike slowly changing parameters such as surface reflectance, surface evapotranspiration is dynamically changing and its spatial and temporal fusion is difficult [34]. Data-driven ET downscaling research uses specific methods to elevate the high spatial resolution drivers to coarser scales; uses data-driven methods (e.g., machine learning methods) to establish a non-linear relationship between evapotranspiration at coarse scales, that is, low spatial resolution, and the drivers; and then applies this non-linear relationship to the high spatial resolution drivers to obtain the high spatial resolution evapotranspiration.

ET downscaling is to establish the relationship between the high spatial resolution process parameters and the low spatial resolution ET products and then downscale to obtain the high spatial resolution ET products (Figure 5(b)). Ke et al. [35] combined spatiotemporal fusion methods and machine learning downscaling methods to construct three spatiotemporal downscaling method schemes to obtain the actual evapotranspiration products of 30 m for 8 days. The three methods are (1) the Landsat-scale vegetation index at moment t_2 is obtained by the fusion of Landsat, MODIS at moment t_1 , and MODIS surface reflectance at t_2 . We obtained the Landsat surface temperature at moment t_2 by combining fusing Landsat, MODIS at time t_1 , and MODIS surface temperature at t_2 . And combine with the MOD16 ET product, the evapotranspiration at Landsat scale at t_2 moment is obtained by machine learning downscaling method. (2) The Landsat-scale vegetation index at moment t_2 is obtained by fusing the Landsat-scale vegetation index at moment t_2 after inversion of Landsat, MODIS, and MODIS surface reflectance at different resolutions at moment t_1 and moment t_2 , respectively, and the rest of the steps are the same as (1). (3) The vegetation index and surface temperature at moment t_1 are obtained by inversion of Landsat at moment t_1 ; the MOD16 evapotranspiration product at moment t_1 is obtained; the Landsat-scale evapotranspiration at moment t_1 is obtained by using the machine learning downscaling method; and then the Landsat-scale evapotranspiration at moment t_2 is obtained by combining the MOD16 evapotranspiration products at moment t_1 and moment t_2 .

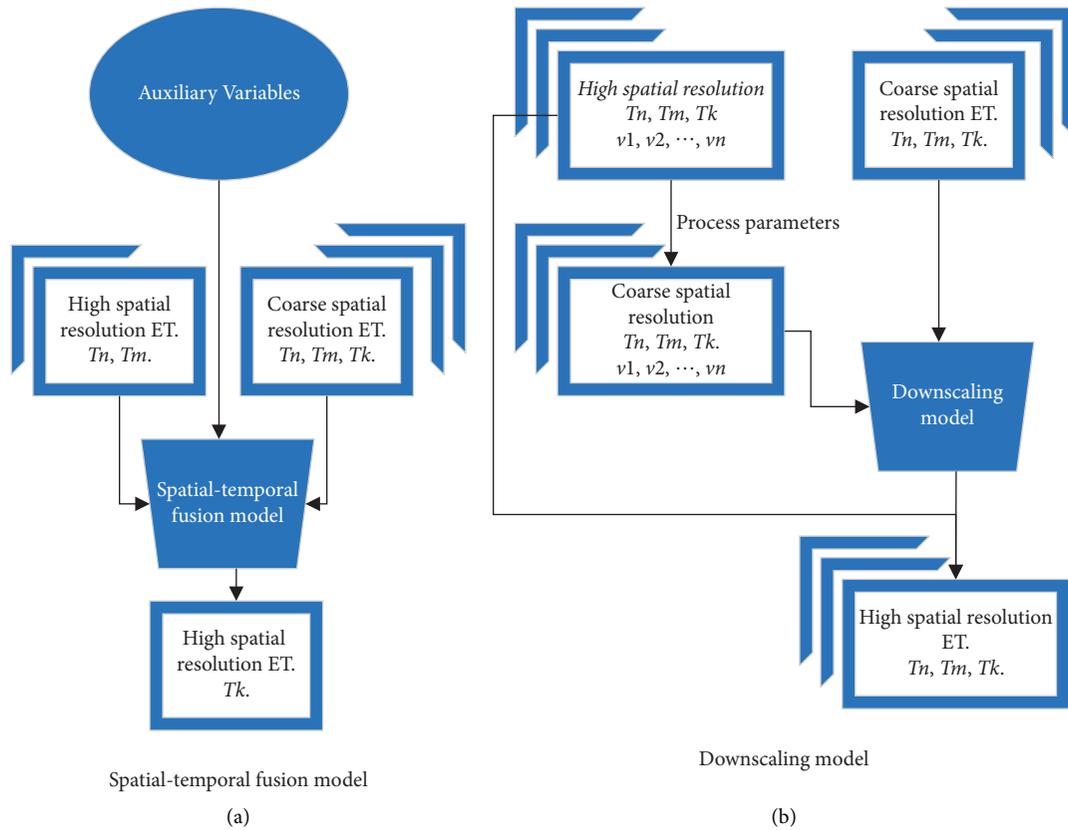

FIGURE 5: Schematic diagram of the principle of fusion of evapotranspiration (ET) data with different spatial and temporal resolutions: (a) spatialtemporal fusion model and (b) downscaling model.

2.4. ET Products Based on Data Fusion. The GLASS ET product is a spatially continuous latent heat flux remote-sensing product covering the global land surface, generated based on a Bayesian multimodel fusion approach, combining AVHRR, MODIS, and MERRA reanalysis data. Reference [30] used Bayesian averaging for different land surface coverage types, fusing two Penman–Monteith-based process models, two Priestley–Taylor-based process models, and a data-driven semiempirical model as the formal algorithm for the GLASS product land surface evapotranspiration. The product has a temporal resolution of 8 d, a maximum spatial resolution of 0.05° for the AVHRR-based product, and a maximum spatial resolution of 1 km for the MODIS-based product. Compared to the five fused evapotranspiration algorithms, the accuracy of the GLASS evapotranspiration product is significantly improved by the fusion of different ground classes and is closer to the ground truth. Compared with the machine learning-based product, the advantage of this product is that the fusion model has a physical mechanism and is relatively reliable in areas without flux observations; the disadvantage is that the fusion accuracy is limited by the accuracy of the fusion algorithm.

Hi-GLASS ET product is a high spatial resolution global land surface latent heat flux remote-sensing product based on the Taylor capability weight fusion method, combined with Landsat and MERRA reanalysis data. Yao et al. [36] used the Taylor capability weight approach, fusing a

Penman–Monteith-based process model, a dual-source model, two Priestley–Taylor-based process models, and a data-driven empirical model, as the formal algorithm for land surface evaporation flux generation for the Hi-GLASS product. The product has a temporal resolution of 16 d and a spatial resolution of 30 m. The accuracy of the Hi-GLASS evapotranspiration product is better than that of the fused single algorithm. The advantages and disadvantages of this product are similar to those of the GLASS algorithm.

Synthesis ET product, is a monthly-scale, 1 km resolution remote-sensing combination data set produced by the simple averaging plus combination approach. Elnashar et al. [37] selected 12 sets of evapotranspiration products and constructed an evaluation matrix for ground validation of the selected products using eddy-related observations from 645 flux observation sites worldwide and sort selection based on accuracy.. The remote-sensing model with the best performance in terms of accuracy was selected for simple averaging and product combination. Finally, the NTSG product (downscaled to 1 km by nearest neighbor resampling) was selected for 1982–2000 (Table 3); MOD16A2 (V105) and NTSG products were simply averaged and selected for 2001–2002; 2003–2017; simple averaging of the PML product (upscaled to 1 km by image element averaging) and the SSEBop product, with the SSEBop product were selected for 2018–2019. Combine them together to constitute the final Synthesis ET product. This product combines the

TABLE 3: Existing multimodel fusion products for global evapotranspiration.

Product	Reference	Methods	Accuracy	Temporal resolution	Spatial resolution	Time span (year)
GLASS ET	Yao et al. [14]	Bayesian	$R^2 = 0.72$ RMSE: 42.2 W/m ²	8 d	1 km	2000–2018
Hi-GLASS ET	Yao et al. [36]	Taylor skill fusion	$R^2 = 0.65$ RMSE: 23.8 W/m ²	16 d	30 m	2013–2018
SynthesisET	Elnashar et al. [37]	Simple average and combination	RMSE: 20.95–20.12 mm/month	1 month	1 km	1982–2019

advantages of several integrated products and provides users with a set of integrated products with relatively reliable accuracy that can be used directly without comparison; however, the products with different spatial resolutions have different spatial scales represented by their image elements, and the accuracy ranking by direct verification comparison without considering the flux observation source area lacks rationality.

3. Discussion and Conclusion

Although the data-driven methods have become more and more diverse in the past decade, from the initial non-linear relationship with temperature difference and net radiation to estimate surface evapotranspiration, to the construction of semiempirical regression relationships based on physical models with a large amount of observation data, to the widespread use of machine learning and deep learning methods, the data-driven methods have become more and more diverse, and the accuracy of data-driven evapotranspiration inversion has been gradually improved, and a variety of data-driven global evapotranspiration products have emerged, but there are still some urgent problems to be solved.

- (1) Lack of evaporation products with high spatial and temporal resolution. The existing data-driven products are difficult to combine both high temporal and high spatial resolution features: for the full remote-sensing-driven inversion method, there is a lack of accessible remote-sensing data with high spatial and temporal resolution and spatial and temporal continuity; for the products that rely on gas data, the existing reanalysis products have a coarse resolution. The existing data-driven products have difficulty in combining both high temporal and high spatial resolution features; only the yet-to-be-released Hi-GLASS-ET product has a high spatial resolution (30 m) but a low temporal resolution (16 d), while the product with the high temporal resolution has a coarse spatial resolution (0.5°), and most of the remaining products have a coarse spatial and temporal resolution (8 d 0.05° and above). For the all-remote sensing-driven inversion methods, there is a lack of accessible remote-sensing data with high spatial and temporal resolution and spatial and temporal continuity; for products relying on meteorological data, the coarse resolution of existing

global reanalysis products reduces the spatial resolution of estimation results; the variability of different meteorological data and the uncertainty of regional meteorological data also increase the uncertainty of estimation accuracy.

- (2) The problem of spatial scale mismatch. The spatial scale difference between the source area of site observation and satellite image elements reduces the inversion accuracy. Most of the existing studies are based on EC observation data and establish the relationship between observation flux and meteorological observation or medium-resolution remote-sensing products to obtain national or global scale evapotranspiration. The low spatial resolution of remote-sensing and meteorological driven data makes it impossible to effectively consider the spatial scale difference between the source area of site flux observation and gridded meteorological data or medium-resolution remote-sensing products.
- (3) Physical mechanisms are inadequate and spatial scalability is limited. Due to global climate differences, topographic relief, and surface heterogeneity, a limited number of stations cannot represent all surface conditions globally. For example, the estimation accuracy cannot be guaranteed in regions where there is a lack of observation data such as deserts and wetlands. Empirical methods or machine learning methods construct models based on a limited number (several hundred) of station observations, and the accuracy is better in regions where observation data are available, but the lack of data representativeness limits the generalization of the model, making its spatial scalability to be investigated.
- (4) The important drivers of evapotranspiration, such as surface temperature and soil moisture, are not sufficiently considered. The existing methods mostly consider moisture input factors such as water pressure deficit and relative humidity and mostly use remote-sensing variables such as vegetation index, which can better reflect long-term changes in evapotranspiration but cannot monitor short-term changes. The thermal infrared surface temperature can provide valuable information such as surface soil moisture state for estimating evapotranspiration, and can better indicate the spatial and temporal

heterogeneity of evapotranspiration. Microwave remote sensing can provide soil moisture information directly. Existing methods mostly consider moisture input factors such as water vapor pressure deficit and relative humidity and do not effectively consider soil moisture information that has a direct impact on evapotranspiration.

- (5) Observation data quality problem. The data-driven approach mostly uses flux observation data to drive the model, and the global application of the flux of EC observations has the problem of energy non-confinement. It is still controversial whether energy balance closure correction is needed when using data-driven methods to invert ET.
- (6) Lack of data-based evapotranspiration separation methods. The separation of soil evapotranspiration and vegetation evapotranspiration is more scientifically relevant and useful than the global approach, but there is still a lack of data-driven evapotranspiration separation methods.

This paper summarizes the advantages and problems of existing data-driven remote-sensing inversion methods for evapotranspiration in terms of both methods and available global products, from empirical regression, to the wide application of machine learning, to data fusion and downscaling. In today's big data era, where information is being collected much faster than we can understand, extracting and interpreting information is the challenge of the moment, and data-driven methods based on data are the opportunity within the challenge. Although data-driven inversion models can obtain high accuracy of vapor emission, they cannot replace physical models. Some physical models are more sensitive to specific input parameters than data-driven models, and it is more difficult to obtain high-precision input parameters on a global scale, which makes it difficult for physical models to surpass data-driven methods in terms of estimation accuracy. Compared with physical models, most data-driven methods lack the ability to explain the evapotranspiration process, which makes the analysis of estimation results limited in terms of interpretability. Ultimately, the core problem of data-driven inversion of remotely sensed evapotranspiration is still a problem of data. On the one hand, due to the powerful regression capability of data-driven (machine learning) methods, good accuracy estimation results can be obtained even if the driving data are wrong; on the other hand, when the spatial and temporal representativeness of the data is extremely limited, it is difficult for a clever woman to cook without rice. Considering that data-driven (machine learning) based methods can substantially improve the regression prediction accuracy, an important development direction is the deep integration of data-driven methods with physical models, which is severely lacking in the existing data-driven methods. Although existing data-driven fusion methods for evapotranspiration with the same spatial and temporal

resolution have been combined with physical models to conduct multimodel fusion studies, the strength is still insufficient, mainly from the external combination, that is, using machine learning methods as fusion models to integrate physical methods, and lack of internal combination, that is, using machine learning methods to estimate input parameters that are difficult to obtain in vapor dispersion physical models and improving the accuracy of physical models by improving the estimation accuracy of complex parameters (e.g., surface roughness) in physical models.

Under the current situation of scarcity of high-precision and high spatial and temporal resolution driving data, data-driven methods and physical models should be closely combined to complement and promote each other so that mechanism and high-precision can coexist and jointly improve the accuracy of evapotranspiration remote-sensing inversion to obtain evapotranspiration remote-sensing products with high accuracy and good scalability.

The noise in the marine engine room has always been a major cause of disturbance and damage to sailors' physical and mental health; however, the antinoise countermeasures were being ignored by the industry. To further reduce the noise in the marine engine room, the system structure of active noise control (ANC) and the theoretical basis of the least mean square (LMS) and filtered X least mean square (FXLMS) algorithm are studied. Based on the FXLMS algorithm ANC system, the simulation study of active noise control in the marine engine room of a multigas carrier is carried out. According to the simulation results by the diagrams plotted on the time domain and spectrum, the ANC systems with the FXLMS algorithm can effectively reduce the noise in the marine engine room by about 20 dB, especially for the peak low-frequency range of 20–500 Hz with a large antinoise effect.

1. Introduction

To deal with the global energy crisis and fulfill the demand for “low-carbon,” the global power engine has set off a wave of electrification. This electric engine is not only a little more efficient than the traditional internal combustion engine, but also has the advantages of zero pollutant emissions and low noise. But ocean-going ships, which are the main vehicle for global trade, are still far away from real electrification. It means that the internal combustion engine will remain the main driving engine or generator for ships. Although the internal combustion engine has the advantages of high efficiency and high reliability, its noise has been troubling the physical and mental health of the crew, reducing the safety and comfort of the ship. Some studies have pointed out that a crew exposed to high noise for a long time is more likely to feel tired, also can easily lead to inattention and reduce work efficiency even lead to safety accidents [1, 2]. What is more serious, it may be deleterious to cardiovascular, endocrine, and nervous systems, and it is associated with neuropsychiatric disorders [3, 4]. To keep the crew away from heavy

noise on board, the 90th meeting of the International Maritime Safety Committee (MSC) in May 2012 approved the draft revision of the Noise Level Rules, which set higher requirements for the noise reduction performance of ships [5]. The shipbuilder and class should take reasonable means to control the cabin noise of ships.

Traditional noise control solutions are focused on passive noise reduction methods. Zhu indicates that semiactive mufflers can control exhaust noise effectively [6]. Liu studied the flow and noise control performance of a compressor silencer [7]. Liang concluded the floating floor of the vessel's engine room can reduce the vibration and noise [8]. Some researchers studied the fuel injection and control strategy from the perspective of the combustion side to reduce the combustion noise of engines [9, 10] while the speed and frequency variations challenge to passive noise reduction. Researchers pay more attention to controllable magneto-rheological damping with linear or nonlinear system control methods for better vibration and noise control [11–13].

Because of the huge cost and less controllable flexibility of passive vibration and noise control methods, more and

more industries are starting to use active noise control methods in specific regions [14–16]; those applications indicate the good potential of the active noise control method. The active noise controller recognized the reference noise frequency and then output the opposite amplitude to achieve the effect of reducing the noise. For different kinds of noise resources and applications, lots of different algorithms and solutions of ANC systems have been studied and applied during the past decades [17, 18]. Zeb simulates the improvement of active noise control for the vehicle by the filtered-input recursive least squares (FxRLS) algorithm [18]. Jiang evaluated the performance of the modified hybrid active noise control system (HANC) which combines the strengths of narrowband ANC and broadband ANC systems on vehicle noise reduction [19]. Even though many ANC solutions have been adopted for small space room applications, the studies of active noise control on large vessel engine rooms have almost not been reported before. Due to the good convergence and stabilities of the FXLMS algorithm, it has been adopted in this article to design the active noise controller for marine engine room noise control. Hence, the noise in the marine engine room has been identified, and the preliminary results of ANC control were reported in this article. The research in this article will provide some beneficial foreshadowing for further ANC applications applied on the vessel.

2. Materials and Methods

Active noise control is a noise control method that adds noise reduction by a control signal which is released by a secondary sound source during the initial noise signal propagation route. The interference theory of sound waves shows that two sound waves with the same frequency and opposite phase overlap each other in the propagation path to produce the interference phenomenon so that the acoustic amplitude of the original noise signal cancels each other. The active noise control achieves the purpose of controlling the noise by achieving the attenuation of the sound energy by interfering with the acoustic wave. In the interference phenomenon of sound waves, the phase and amplitude of two columns of interfering sound waves are two key factors that determine whether the sound energy can decay. In practical application, the reverse phase offset acoustic wave can be auxiliary generated by matching the adaptive digital processor and the electroacoustic device, and the effective suppression of primary noise can be realized. Figure 1 shows the schematic diagram of the noise signal superposition principle.

Primary noise is the original noise signal, and secondary noise is the noise generated by the speaker which is used to offset the original noise. When the system works normally, the output signal of the speaker interferes with the original noise signal in a specific space. To form a stable interference, the two-column waves need to meet the following three conditions: (1) the propagation direction is the same, (2) the phase difference remains constant, and (3) the vibration frequency is the same.

Analysis from the perspective of mass point displacement: Let the noise signal be represented by equation (1), the

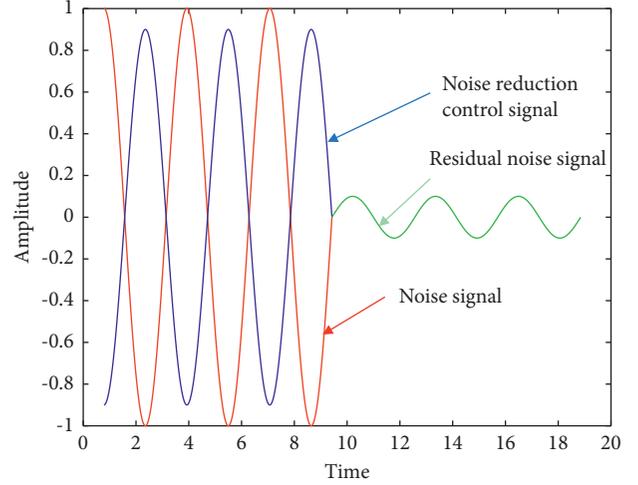

FIGURE 1: Schematic diagram of noise signal superposition principle.

cancellation signal be represented by equation (2), and the signal superimposed in the specified noise reduction area be represented by equation (3).

$$E1 = A_1 \sin(\omega_1 t + \varphi_1), \quad (1)$$

$$E2 = A_2 \sin(\omega_2 t + \varphi_2), \quad (2)$$

$$E3 = E1 + E2 = A_1 \sin(\omega_1 t + \varphi_1) + A_2 \sin(\omega_2 t + \varphi_2). \quad (3)$$

The superimposed waveform stability is poor when the frequency ω_1 is not equal to ω_2 . When the difference between the amplitude of A_1 and A_2 is large, the superimposed waveform amplitude cannot reduce the final noise compared with the original noise signal. When ω_1 is equal to ω_2 ,

$$E_3 = A * |2 + 2 \cos(\varphi_2 - \varphi_1)| * \sin(\omega_1 t + \varphi_1). \quad (4)$$

For the positive noise reduction effect, the phase difference of φ_1 and φ_2 should be in the order of $[2n\pi + 3/3\pi, 2n\pi + 4/3\pi]$, or the interference phase length phenomenon will occur; therefore, the noise reduction system cannot play a noise reduction effect in this condition. The adaptive process of the ANC noise reduction system is to adjust the initial phase of the cancellation signal to meet the phase requirements of the system. In the active control of noise, due to the time-change of the noise signal and environmental factors, an adaptive controller is needed to effectively control the accurate tracking of noise signal under the premise of system stability. The filter in the adaptive control system realizes the real-time signal processing function by adapting to the environmental changes of the adaptive algorithm. The adaptive controller consists of a digital filter and a corresponding adaptive algorithm for adjusting the filter parameters, which are the main focus of the controller design work. The objective of the adaptive algorithm is to set an objective function, which is to make the result approach a target value by constant iterative computation.

2.1. Active Noise Control System. The active noise control system usually consists of sensors, controllers, and speakers. The sensor can be divided into a reference signal sensor and an error sensor. The acoustic sensor, speed sensor, or acceleration sensor can be used as input signals. The controller mainly includes the signal processing hardware and the control function of the software programs.

The active noise control system is divided into a feedback system and a feedforward system. The feedforward system usually selects the noise source to collect the noise source in the reference signal selection, and the controller sends out the control signal after processing the input reference signal. The feedback system is often used when the control system cannot collect the initial reference signal.

2.1.1. Feedforward Active Control System. The system equivalent diagram is shown in Figure 2. In the figure, $p(n)$ is the noise signal, $W(z)$ is the controller, $H_1(z)$ is the primary path transmission function, and $H_2(z)$ is the secondary path transmission function.

The reference signal sensor picked up the signal $x(n)$ which was released by the noise source, and then the speaker played the control signal $y(n)$ which was processed by the controller algorithm. The error sensor picks up the error signal $e(n)$ after interfering with the noise source noise and the control signal emitted by the secondary sound source interferes and transmits it to the controller. The controller adjusted the weight coefficient by using the design algorithm to reduce the error signal until the system has become stable.

2.1.2. Feedback Active Control System. The controller responds to the signal feedback by the error sensor when the feedback system processes the noise signal. Because the signal is picked up by the feedback control system through the error sensor and then used as the controller input, it is easy to be disturbed by other noise and reduces the stability of the system, which has a certain impact on the system noise reduction effect. In the feedback active noise control system, the signal processing takes an error signal as its input signal. The equivalent control system diagram is displayed in Figure 3. Compared with the feedforward active noise system, its noise reduction performance is poor and rarely used.

The symbol definitions in Figure 3 are omitted here as the same symbols were used in Figure 2.

2.2. LMS and FXLMS Algorithms for ANC System. Because of the time-varying characteristics of the noise signal, it is difficult to predict in advance and makes the noise difficult to be tracked in real time. ANC technology requires tracking the time-varying noise signal by adjusting the controller to make the generated secondary noise signal minimize the original noise signal. An adaptive filter can track the time-varying signals well and continuously by adjusting the required control signals to produce them through some optimization error criterion.

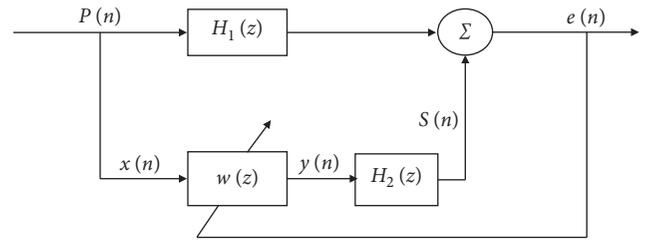

FIGURE 2: Feedforward active control system equivalent diagram.

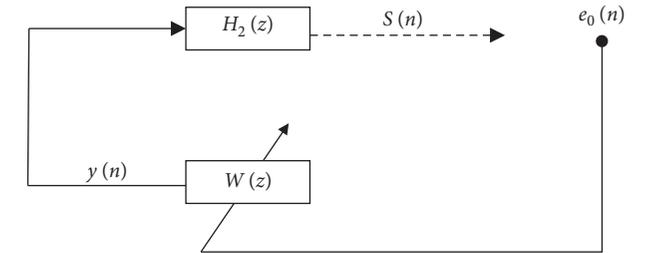

FIGURE 3: Feedback active control system equivalent diagram.

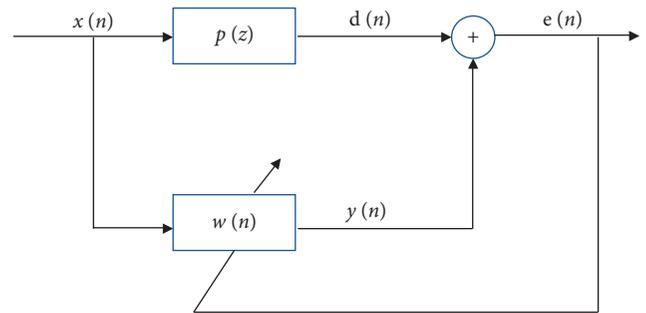

FIGURE 4: Block diagram of noise LMS algorithm active control system.

This optimization error criterion belongs to the ANC algorithm. The adaptive LMS algorithm and FXLMS algorithm are widely used.

2.2.1. LMS Algorithm. The equivalent diagram of the LMS algorithm is shown in Figure 4.

The noise signal $x(n)$ is processed by the primary path transmission function $P(z)$ and then becomes as the primary noise signal $d(n)$. The noise signal $x(n)$ and the error signal $e(n)$ are transmitted to the adaptive filter to update the weight coefficient, and the adaptive filter outputs $y(n)$ making the error signal $e(n)$ gradually reduce.

Symbol definition: $x(n)$: noise signal; $P(z)$: primary sound source transmission path; $d(n)$: initial noise signal of the error sensor; $e(n)$: error signal; $w(n)$: the LMS adaptive filter; and $y(n)$: output signal of the LMS adaptive filter.

The input signal at time n gets a response by a filter of order L :

$$X(n) = [x(n), x(n-1), \dots, x(n-L+1)]^T. \quad (5)$$

The vector of the filtered weight coefficient at time n is expressed as

$$W(n) = [w_1(n), w_2(n), \dots, w_L(n)]^T. \quad (6)$$

The filter output signal $y(n)$ can be expressed as

$$y(n) = X^T(n)W(n) = W^T(n)X(n) = \sum_{i=1}^L w_i(n)x(n-l+1). \quad (7)$$

The error signal at time n is

$$e(n) = d(n) - y(n) = d(n) - w^T(n)x(n). \quad (8)$$

Using the minimum mean-variance error optimization criterion,

$$\begin{aligned} J(n) &= E[e^2(n)] = E\left[\left(d(n) - w^T(n)x(n)\right)^2\right] \\ &= E[d^2(n)] - 2W^T(n)E[d(n)X(n)] \\ &\quad + W^T(n)E[X(n)X^T(n)]W(n), \end{aligned} \quad (9)$$

delimit R and P as the equations below.

$$\begin{aligned} R &= E[X(n)X^T(n)], \\ P &= E(d(n)X(n)). \end{aligned} \quad (10)$$

R is the autocorrelation matrix of the reference signal and P is the intercorrelation matrix between the expected signal and the reference signal.

Then formula (9) is reduced to

$$J(n) = E[d^2(n)] - 2W^T(n)P + W^T(n)RW(n). \quad (11)$$

$J(n)$ is the quadratic function about W , and to realize the minimum error signal, the gradient obtained by equation (11) is indicated by

$$\begin{aligned} \nabla(n) &= \frac{\partial J(n)}{\partial W} \Big|_{W=W(n)} = \left[\frac{\partial J(n)}{\partial W_1}, \frac{\partial J(n)}{\partial W_2}, \dots, \frac{\partial J(n)}{\partial W_L} \right] \\ &= 2RW(n) - 2P. \end{aligned} \quad (12)$$

The above equation is made equal to 0, and then the filtering coefficient W_0 for the minimum error signal is obtained, namely, the Wiener solution.

$$W_0 = R^{-1}P. \quad (13)$$

Returning to the formula (11),

$$\begin{aligned} J_{\min} &= E[d^2(n)] - 2P^T R^{-1}P + [R^{-1}P]^T R R^{-1}P \\ &= E[d^2(n)] - P^T W_0, \end{aligned} \quad (14)$$

$$J(n) = J_{\min} + [W(n) - W_0]^T R [W(n) - W_0].$$

When the autocorrelation matrices R and P are known, the adaptive filter algorithm can calculate the W_0 , that is, it only needs to know the autocorrelation matrix R and the intercorrelation matrix P to obtain the best filter weight coefficient. In practice, P and R are not necessarily certain; however, the minimum mean square algorithm does not require an autocorrelation matrix, it still can obtain the best-

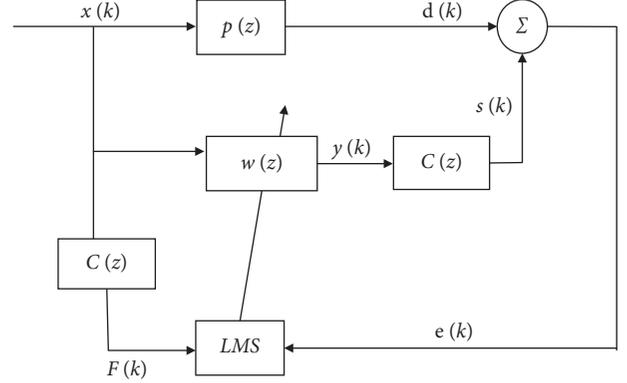

FIGURE 5: Block diagram of noise FXLMS algorithm active control system.

filtered weight coefficient through the steepest descent method.

From the steepest descent theory, the filter weight vector at the next moment can be expressed as $w(n+1)$.

$$W(n+1) = W(n) - \mu \nabla(n). \quad (15)$$

In the equation (15), μ is the convergence step and $\nabla(n)$ is the gradient of the n -th iteration.

Taking the gradient in the LMS algorithm from the square root of the error signal as an unbiased estimate of $\nabla(n)$,

$$\hat{\nabla} = \frac{\partial e^2(n)}{\partial W} = -2e(n)X(n), \quad (16)$$

$$W(n+1) = W(n) + 2\mu e(n)X(n). \quad (17)$$

2.2.2. FXLMS Algorithm. The FXLMS equivalent diagram of the active noise control system is shown in Figure 5.

In practice, the LMS algorithm ignores the existence of the secondary path $C(z)$, that is, the control signal $y(k)$ from the speaker can bring the error signal close to zero, but the signal $y(k)$ after passing through the secondary path $C(z)$ does not necessarily make the error signal close to zero. Because the electrical signal emitted by the speaker transmits through a series of digital-analog conversions to the microphone, there is a certain time difference with the reference signal, which can easily lead to the instability of the system. Based on this, Morgan [20] proposes to place the same filter in the reference signal path to realize the weight update of the LMS algorithm, thus realizing FXLMS's algorithm. $C'(z)$ can estimate the statute of $C(z)$ precisely which is required in the algorithm, and the two are approximately equal. Adding the estimation $C'(z)$ of the secondary path transmission function improves the LMS algorithm and indeed becomes the essential difference between FXLMS and LMS algorithms [21–30].

Symbols definition: $x(k)$: noise signal; $P(z)$: primary sound source transmission path; $P(k)$: primary path transmission function; $d(k)$: initial noise signal of the error sensor; $C(z)$: secondary sound source transmission path;

$C(k)$: secondary path transmission function; $e(k)$: error signal; $w(z)$: self-adapting filter; $y(k)$: output signal of the adaptive filter; $s(k)$: secondary noise signal passing through the secondary path; $C'(z)$: estimated secondary path; and $F(k)$: noise signal generated through the estimated secondary path.

The desired signal is transmitted through the primary path and can be represented as a convolution of the reference signal with the primary path transmission function.

$$d(k) = x(k) * P(k). \quad (18)$$

Similarly, the secondary noise signal emitted by the speaker may be expressed as

$$s(k) = y(k) * C(k). \quad (19)$$

The filter weight coefficient and the algorithm input signal vector are

$$\begin{aligned} W(k) &= [w_1(k), w_1(k), \dots, w_L(k)]^T, \\ F(k) &= [f(k), f(k-1), \dots, f(k-l+1)]^T = X(k)C(k). \end{aligned} \quad (20)$$

The output of the filter of L order at time k in the FXLMS algorithm is

$$y(k) = X^T(k)W(k) = W^T(k)F(k) = \sum_{l=1}^L w_l(k)f(k-l+1). \quad (21)$$

To delimit $r(k)$ as the filtered signal, which is the convolution of the reference signal and the secondary path transmission function can be expressed as

$$r(k) = X(k) * C(k). \quad (22)$$

The derived error signal is

$$e(k) = d(k) + s(k) = d(k) + r^T(k)W(k). \quad (23)$$

The relation of the filter weight can be derived by equation (17).

$$W(k+1) = W(k) - 2\mu e(k)r(k). \quad (24)$$

R is defined as the autocorrelation matrix of the reference signal, by which its orthogonal matrix can be expressed as Q .

$$R = Q\Lambda Q^T. \quad (25)$$

Λ is the diagonal matrix composed of the eigenvalues of the R ,

$$\Lambda = \text{diag}(\lambda_1, \lambda_2, \dots, \lambda_L),$$

$$W(n+1) = [I - 2\mu Q\Lambda Q^T]W(n) + 2\mu P, \quad (26)$$

$$E[W(n+1)] = Q[I - 2\mu\Lambda]^{n+1}Q^{-1}E[W(0)] + 2\mu P.$$

In the above formula, $W(0)$ is the initial value of the filter weight; thus, the convergence conditions of the above formula are

TABLE 1: Engine parameter for sampling noise signal in the marine engine room.

Items	Unit	Value
Bore	mm	400
Stroke	mm	1770
Speed	rpm	125
Cylinder number	—	6
Power	kW	4950
Firing order	—	1-6-2-4-3-5

$$|1 - 2\mu\lambda_{\max}| < 1. \quad (27)$$

Equation (27) can be transformed as

$$0 < \mu < 1/\lambda_{\max}. \quad (28)$$

λ_{\max} is the maximum eigenvalue of the positive definite matrix R , and the adaptive filtering weights converge when the convergence step size factor μ satisfies equation (28). Usually, the autocorrelation matrix R is unknown but the reference signal is available, and the mean square value of the reference signal and the autocorrelation matrix R satisfy the following relationship:

$$\begin{aligned} \text{Tr}[R] &= \sum_{i=0}^N \lambda_i = \sum_{n=1}^L E[x^2(n)], \\ \lambda_{\max} &< \text{Tr}[R]. \end{aligned} \quad (29)$$

Therefore, the convergence step length μ satisfies the following relationship:

$$0 < \mu < \frac{1}{\sum_{n=1}^L E[x^2(n)]}. \quad (30)$$

The sum mean square of the reference signal is known, and the value range of the convergence steps can be prejudged by the reference signal.

3. Results

3.1. Noise Sampling. This article collects the cabin noise as a reference noise signal on a multigas carrier. The noise source of the marine engine room is mainly derived from the noise of a 6-cylinder two-stroke low-speed engine, and its main parameters are shown in Table 1.

Usually, for a certain type of engine, the engine room noise is greatly affected by the engine speed and power. The higher the speed, the greater the power, and the more obvious the corresponding noise. The position of the microphone of the noise reference signal is located on the top of a 1 m distance of the exhaust manifold between cylinder 3 and cylinder 4. The sampling frequency of the reference signal collection is 8 kHz, under the condition that the engine speed of 125 rpm, the power is 3715 kW, which corresponds to a 75% load operating condition. All the generators are stopped, and the electric power consumption on the vessel is provided by the main engine shaft belt generator. Figure 6 shows the actual drawing of the low-speed engine in the engine room. The main noise in the

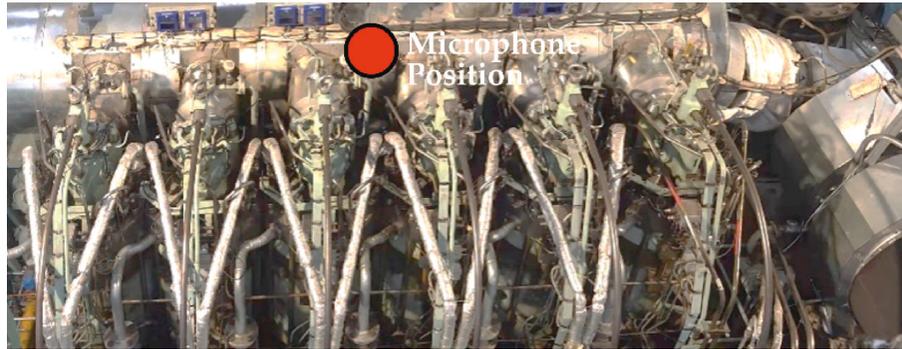

FIGURE 6: Schematic diagram of reference noise signal picking up position in the marine engine room.

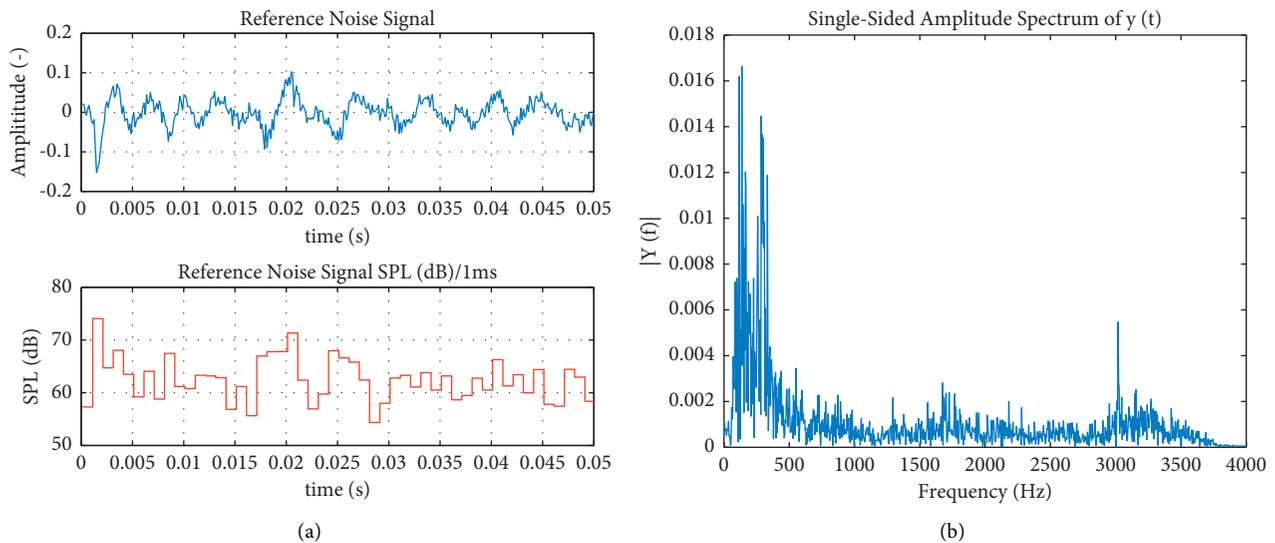

FIGURE 7: Characteristics of the noise signal in the marine engine room. (a) The time domain diagram of reference noise signal; (b) the spectrum diagram of reference noise signal by fast Fourier transform (FFT).

engine room comes from the friction, vibration, air transmission, and combustion noise of the two-stroke engine.

3.2. Signal Processing and Modeling. Figure 7 is the characteristics of the noise signal in the marine engine room. Figure 7(a) shows the time domain map of the reference signal after being analyzed. The engine running noise in the engine room shows obvious periodicity, so the acquisition signal within 50 ms is selected as an input, and the analytical spectrum map shows that the frequency at the peak noise is concentrated between 80 and 400 Hz, which is displayed on Figure 7(b). These low-frequency noises are difficult to eliminate by the passive noise reduction method.

The active noise reduction calculation model of engine cabin noise with the FXLMS algorithm has been established on the MATLAB platform. White noise is used as an excitation to identify the secondary path transmission function $C'(z)$ offline. It is assumed that the characteristics of $C'(z)$ are variable and unknown at the first. The offline estimation method can be used to identify the secondary path transmission function, and the identification coefficient of $C'(z)$

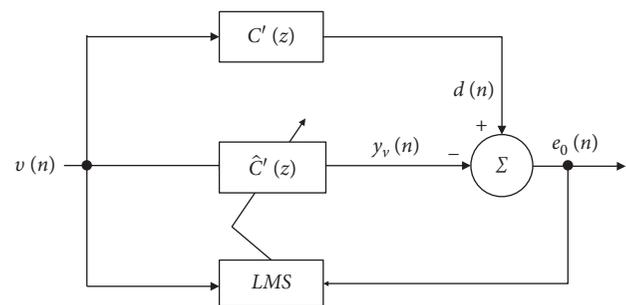

FIGURE 8: The block diagram of offline identification for secondary transmission path function.

is used as the fixed coefficient of the FXLMS algorithm. The steps of offline identification are shown in Figure 8.

A white noise signal in the n moment is $v(n)$, the secondary path output value is $d(n)$, $y_v(n)$ is the value of the white noise through the secondary path identification, and $e_0(n)$ is the error value between the secondary path output value and secondary path identification value. It can be considered that the secondary path identification function

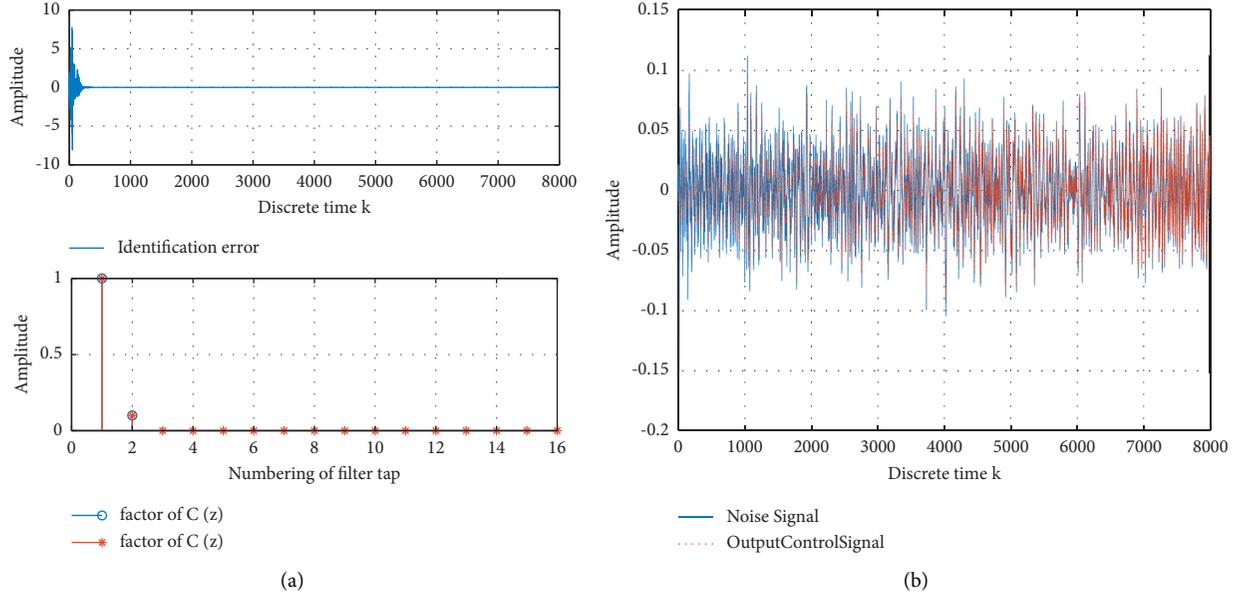

FIGURE 9: Offline identification results for secondary path transmission function and output control signal. (a) The simulation results of offline identification by LMS algorithm; (b) the output control signal of FXLMS ANC systems.

$\hat{C}'(z)$ is closer to the secondary path function $C'(z)$ when the error value $e_0(n)$ is close to zero through the LMS algorithm's constantly iterative update.

Offline identification is a system identification independently separated from the ANC system, which will not increase the operation burden of the ANC system, and also will not damage the robustness of the ANC system. If the secondary path transmission function of the ANC system remains unchanged, offline identification has certain advantages.

During the simulation tests, the primary and secondary transmission functions are set as equations (31) and (32).

$$p(z) = z^{-1} - 0.07z^{-3} + 0.006z^{-4}, \quad (31)$$

$$C(z) = \frac{1}{(z + 0.1)}. \quad (32)$$

The filter order of the FXLMS algorithm N was set as 16, the convergence step factor μ was 0.1, the sampling frequency was 8000 Hz, the total simulation discrete sampling data was 8000, and the whole simulation time was set within one second.

3.3. Disclosed Results. Figure 9 shows offline identification results for the secondary path transmission function and output control signal. The offline identification error and the iteration coefficient of the secondary path transmission function are shown in Figure 9(a). After the two-order iteration and the simulation discrete step length of 600, the offline system identification error tends to be zero. It shows that the LMS algorithm is accurate and efficient for the offline identification of the secondary path transmission function. As shown in the simulation calculation results in Figure 9(b), the control signal of the adaptive output of the speaker agrees well with the reference noise signal after 4000 iteration steps.

The residual noise continuously drops under the action of the active noise reduction system quickly, and gradually stabilizes to a low error value of 0.01 after 5000 steps, and no divergence phenomenon occurs. Comparing the signal amplitude and sound pressure level on the time domain diagram, the blue curve in Figure 10 is the original noise reference signal, and the red curve is the error signal processed by the FXLMS algorithm ANC noise reduction system, indicating that the ANC system significantly reduces the active noise reduction of marine engine room noise. From the perspective of SPL degrees, it shows that the maximum SPL is reduced by about 20 dB at the end of the simulation.

The noise reduction effect was evaluated from the perspective of power, and Spectrum Analyzer was used to analyze the input noise signal and the output error signal by frequency spectrum. The analysis results are shown in Figure 11. As can be seen from Figure 11, the error signal which is colored in blue is generally lower than the input noise signal which is colored in yellow in the full frequency range, and the noise reduction effect at the peak frequency of 125 Hz and 300 Hz is about 20 dB. It is obviously noticed that the ANC system has a better noise reduction effect in the low-frequency range of 20-500 Hz. The ANC system based on the FXLMS algorithm has a good active control effect on the cabin noise of the periodic, low-frequency, and high-intensity noise signal.

When considering the impacts of the different convergence step factors μ , three sets of different μ have been studied. The noise reduction performance is shown in Figure 12 for $\mu = 0.1, 0.5,$ and 0.9 , respectively.

The results show that the noise reduction performance is linearly improving with the decreasing with the convergence step factor μ . In Figures 12(a) and 12(b), when $\mu = 0.9$, the maximum SPL decrease is about 10 dB, not also a large

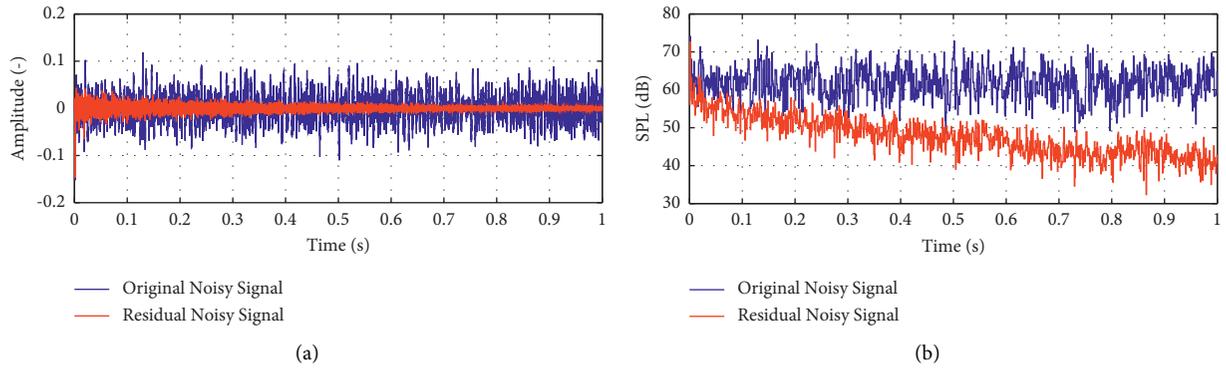

FIGURE 10: The time domain collation map diagram of the amplitude and SPL between reference noise signal and residual noise signal by FXLMS ANC system. (a) Amplitude comparison. (b) Reference noisy signal SPL (dB) 1 ms.

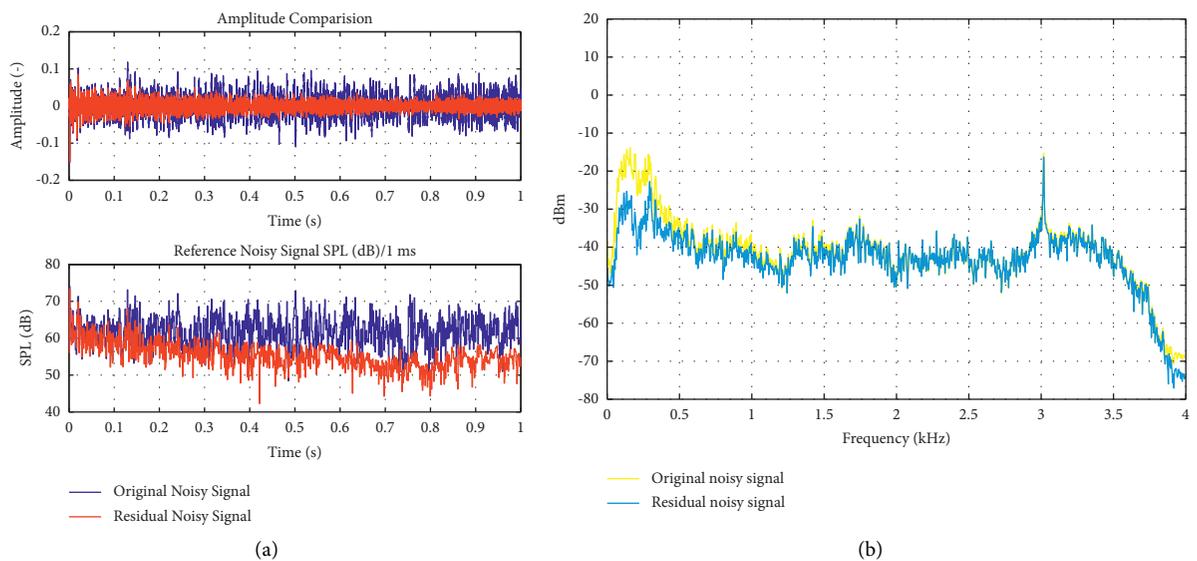

FIGURE 12: Continued.

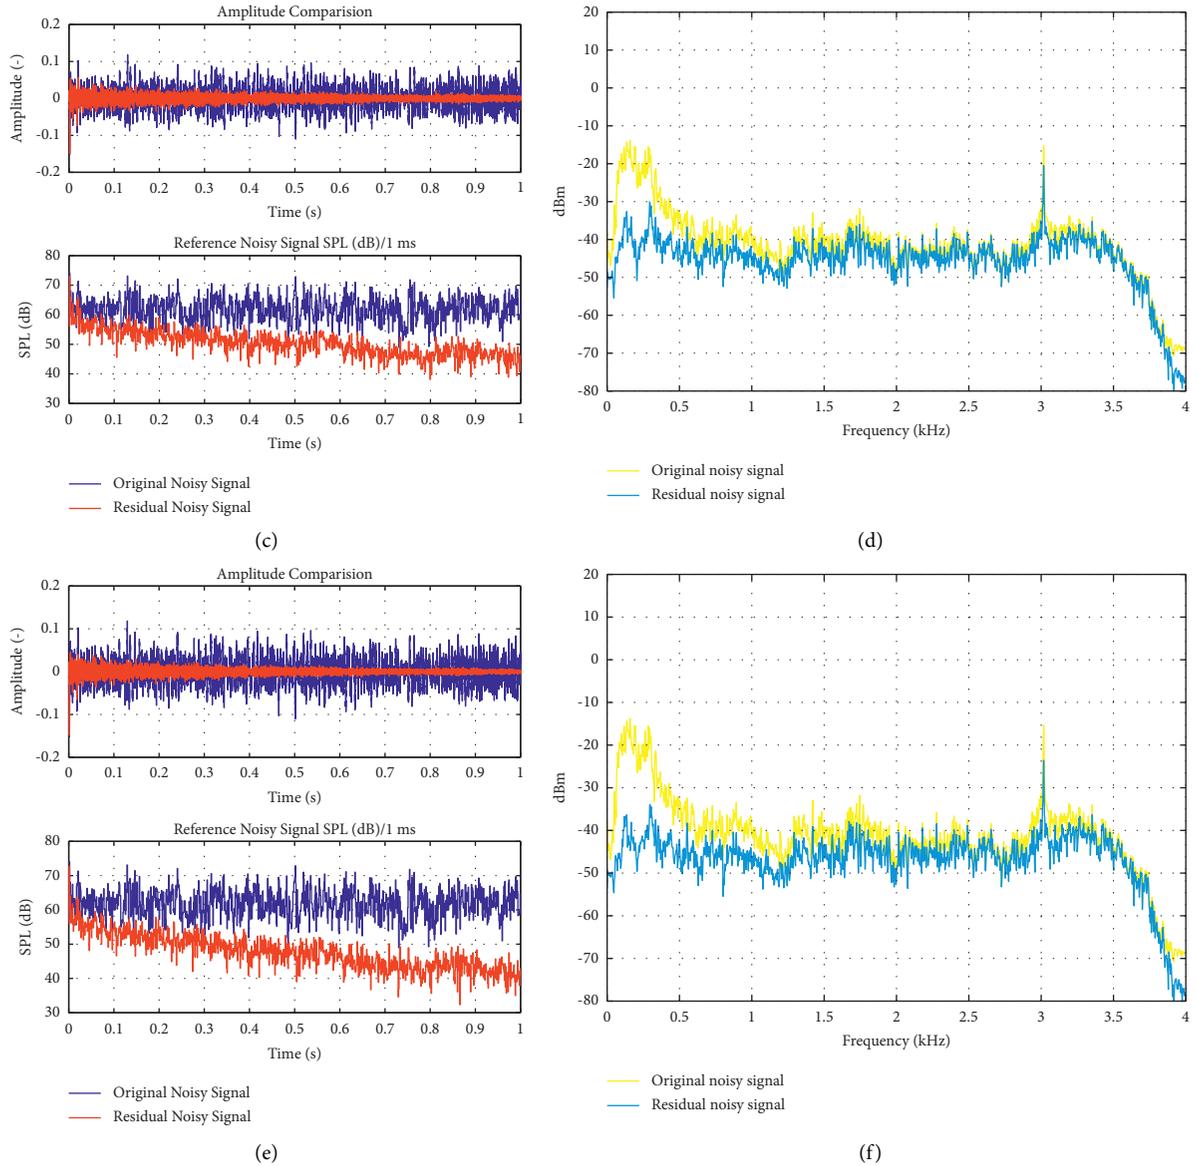

FIGURE 12: Noise reduction performance for different convergence step factors μ . (a) The time domain diagram for $\mu = 0.9$; (b) the spectrum analyzer diagram for $\mu = 0.9$; (c) the time domain diagram for $\mu = 0.5$; (d) spectrum analyzer diagram for $\mu = 0.5$; (e) the time domain diagram for $\mu = 0.1$; (f) spectrum analyzer diagram for $\mu = 0.1$.

fluctuation for the final residual noise signal but also a weak or even bad noise reduction performance for the frequency range of 1.5-4 kHz are observed. As a comparison for $\mu = 0.5$, the results in Figures 12(c) and 12(d) show a better noise reduction performance, the maximum SPL decrease is about 15 dB; for $\mu = 0.1$, the results in Figures 12(e) and 12(f) show the maximum SPL decrease is about 20 dB. The results show that the convergence step factor has great importance for the ANC workings.

4. Discussion

This article studied the significant noise reduction performance in the marine engine room for ANC systems with the FXLMS algorithm. The first part of the article explained the

composition of active noise reduction systems and the modeling theory basis of LMS and FXLMS algorithms. The latter part of the article introduced the simulation conditions, ANC modeling, as well as the disclosed results. In detail, the reference marine engine room noise signal from a gas carrier has been imported and analyzed, which indicated that periodic and peak low frequency are the main characteristics of the noise signal. An ANC system with an FXLMS algorithm was designed to control the sample noise. The model calculation shows that the ANC system based on the FXLMS algorithm significantly suppressed the marine engine room noise. During the entire one-second simulation time, the residual marine engine room noise signal after active control is significantly lower than the input noise signal, as well as the SPL drops by about 20 dB. The controlled marine

engine room noise is generally improved over the input noise over the full frequency range, especially a drop of SPL by about 20 dB for the peak low frequency at 125 Hz and 300 Hz which can be concluded on the spectrum analyzer diagram. While the noise reduction performance for ANC system with FXLMS algorithm has important variations on the convergence step factor. The residual signal error increases linearly with the convergence step factor when compared to the results for different convergence step factors 0.1, 0.5, and 0.9. It shows some limitations in the performance of ANC systems with FXLMS algorithms. When considered, the engine room noise is always stable and can even continue throughout the ship's life cycle; the limitations can be minimized by the initial optimum for the convergence step factor. Further research will focus on multipath ANC systems design and variable convergence step factor optimum for ANC systems [31].

Based on the high-frequency price data, this article estimates the extent of price stickiness, identifies the pricing model, and applies the micro-results to analyze the dynamic characteristics of inflation. The results show that the price moves downward steadily during the COVID-19 epidemic. Secondly, the commodity price displays low stickiness, and the pricing model shows the time-dependent pricing (TDP) model in general. Finally, the inflation inertia is negative, indicating the macro-control is effective on COVID-19 epidemic and has the feature of contradiction to the economic cycle. And inflation inertia mainly comes from food commodities, which means that the anchoring object of the policy should be food commodities during the COVID-19 pandemic.

1. Introduction

In recent years, epidemics have affected human health and social stability. The COVID-19 epidemic that outbreaked at the end of 2019 posed a great challenge to economic and social development. It has broken the original balance between supply and demand and directly affected macroeconomic stability. Therefore, it is increasingly important to ensure effective macro-control measures when we face the impact of the outbreak.

Price stickiness refers to the fact that price does not react to market in time, making price sticky [1]. Price stickiness is usually observed in daily life. However, it is not individual commercial price stickiness but aggregate price patterns and inflation that affect the macroeconomic operation [2], which lead to discussions on the pricing model and the relationship between price stickiness and inflation. Previous studies have shown that price stickiness is closely related to price adjustment [3–5]. At present, price adjustment mainly falls into two models: One is the time-dependent pricing (TDP) model, that is merchants adjust the price in a fixed time which price changes are exogenous. The other is the state-dependent pricing (SDP)

model, that is the adjustment of commodity prices by merchants depends on the market. The price changes are endogenous.

There have been abundant researches on price stickiness. In the early stage, due to the difficulty in obtaining price data, they mainly focused on specific categories of commodities. Based on this, scholars concluded that commodity prices had high price stickiness [6, 7]. Moreover, menu cost [8, 9], sticky information [10], and consumer sentiment [11] were the main causes of price stickiness. With the development of e-commerce, the sample range was expanded. Bils and Klenow found that price changes were frequent, and the price lasted less than 4.3 months when they investigated 350 sorts of goods price from the Bureau of Labor Statistics [12]. Similarly, Klenow and Kryvtsov detected that the price lasted 3.8 months, and the pricing model adopted the time-dependent pricing (TDP) model on the basis of the data from BLS from 1988 to 2003. The web crawler technology further enriched the commodity category and frequency [13]. Cavallo held that the pricing model was the combination of SDP and TDP by capturing daily online commodity data of five countries [14]. Jiang et al. supported this view. They also found that the price lasted 2 months or less, and the price

adjustment model was the combination of SDP and TDP by the data from China’s high-frequency goods price [15].

Some research on price stickiness found that it was related to inflation inertia. Lunnemann and Matha studied the price data of 15 EU countries and found that the price stickiness of service price and regulated service was positively correlated with the inertia of service price inflation [16]. Mato reached the same conclusion based on Brazilian commodity prices [17]. In contrast, Cecchetti and Debelle found that the higher the price stickiness, the lower the inflation inertia [6].

It can be seen that price stickiness is closely related to the pricing model, and there are differences in price setting behavior, resulting in changing the inflation inertia. Moreover, there is no unified conclusion about the relationship between price stickiness and inflation inertia. At the same time, empirical research on price stickiness under the outbreak is still very scarce. Therefore, this article uses online high-frequency price data to study the price stickiness during COVID-19, observes the pricing model and inflation inertia, and provides more reliable empirical evidence for macroeconomic models.

The purpose of this article is to investigate the price stickiness during COVID-19. Compared with the previous literature, the contributions are mainly as follows: Firstly, we use web crawling technology to get the daily commodity prices on COVID-19. The micro-results are used to analyze inflation inertia for the first time, which effectively connects the micro-basis with the macro-application. Secondly, we attempt to measure the price stickiness when the epidemic outbreak. At the same time, the variance decomposition method is used to judge the pricing mode. This article finds that price performs low stickiness, and the pricing model is state-dependent pricing on COVID-19. Finally, we construct an AR model to analyze the inflation inertia and find that inflation inertia is negative, which means the effectiveness of macro-management during the outbreak. And inflation inertia mainly comes from food commodities, which means that the anchoring object of the policy should be food commodities on COVID-19.

The rest of the article is organized as follows: Section 2 introduces data acquisition and data processing; Section 3 shows the measurement results of price stickiness; Section 4 analyzes inflation inertia based on the results of price stickiness; and Section 5 obtains conclusions.

2. Data

2.1. Data Collection. This article collects the commodity price from Taobao platform with the web crawling technology [18, 19]. The data acquisition process is as follows: The first step is to access the Taobao platform with Python to obtain information such as product names, classification, links, and others and store the commodity information in the MySQL database. The second step is to retrieve the product links from the database and matched them on a price comparison website to acquire the historical prices of commodities. The final step is to process the price data with

TABLE 1: Data sources.

Observations	7712415
Product number	48073
Date	2019/12/16–2020/8/22
Product information	Brand, ID, selling price, product link
Retailer information	Name, ID, location

Python and measure the price stickiness to further analyze the inflation.

Compared with offline data, online data are used to study price changes with certain advantages. Firstly, online data increase the frequency of price analysis, and daily data could reflect the price changes more flexibly. Secondly, more enterprises select online sales as an alternative to offline sales when they consider the segmented domestic market. Thirdly, online and offline data are the same about 72% of the time, and online data have a good representation.

2.2. Data Source. The data collected in this article covers 48,073 sorts of commodity information on Taobao from December 2019 to August 2020, with a total of 7,712,415 observations. We match the commodities with eight categories that are divided by State Statistics Bureau (NBS) to facilitate the subsequent analysis. We divided the goods category into food; clothing; residence; household equipment; transport, post, and telecommunication; culture, education, and recreation; medicine and health care; and other goods and services. The data description of commodity is shown in Table 1.

2.3. Data Preprocessing. This article refers to the existing literature and preprocesses the original data in combination with the characteristics of online price as follows:

2.3.1. Missing Value Processing. This article uses daily price data to analyze price stickiness. Some random factors (i.e., software problems, message interrupt, etc.) might result in the missing of price information on a certain day or period, which is required to add the missing information. Therefore, we use the price of missing values in the previous period to replace the missing price until the new price appears [19, 20].

2.3.2. Outlier Processing. The abnormal fluctuations in price will affect the measurement of price stickiness and interferes with the price changes. This article defines the values that the price increased by over 500% or the price decreased by over 90% as outlier value, according to the former research [21]. We choose to eliminate the outlier value to ensure the reliability of results, considering a small number of abnormal values in the dataset.

2.3.3. Period Processing. The sample period referred to the time span from the first appearance of the price to its last time [22]. This article gets rid of the sample periods of less than 7 days to warranty the measurement feasibility.

This article ultimately selects 47,219 commodities and 7,709,816 observations by processing the missing value, abnormal value, and sample period.

3. Measurement of Price Stickiness

3.1. Price Index. The price index is an index that reflects price changes. This article measures the price index by indexing the commodity price obtained by Taobao. We use the Jevons geometric index formula to calculate the commodity price index.

Firstly, we calculate the relative price of each commodity i in period t , pcr_{ti}

$$pcr_{ti} = \frac{p_{ti}}{p_{t-1i}}, \quad (1)$$

where p_{ti} is the price of commodity i at day t , and p_{t-1i} is the price of commodity i at day $t-1$.

Secondly, the relative prices of all commodities are geometrically averaged in period t , pcg_{tz}

$$pcg_t = \sqrt[n]{pcr_{t1} * pcr_{t2} * \dots * pcr_{tn}}. \quad (2)$$

Finally, using equation (2), the first day of the sample period is set to 100 to obtain the commodity price index, pci_t

$$pci_t = pcg_t * pcg_{t-1} * \dots * pcg_1 * 100. \quad (3)$$

Figure 1 shows the trend of commodity price index, in which the green dotted line indicates the outbreak time of COVID-19 in China: January 20, 2020. We can see that the price moves downward steadily during the COVID-19 epidemic.

In order to further study the changes of commodity prices on COVID-19, we analyze eight categories of commodities that are divided by NBS. The results are shown in Figure 2.

3.2. Descriptive Statistics. This section makes the descriptive statistics of price changes. The statistical results are reported in Table 2. We find that 81.24% of the commodities generally change price during the sample period, price adjustments of a commodity are 15.70 times, and commodity price shows low price stickiness. In the meantime, commodities of price increased account for 34.65%, while the decreased goods are 65.35%. It can be drawn that the majority of commodity price is changed and the price moves downward during COVID-19. Then we further classify the commodities into eight categories, and the results are similar to the above.

3.3. Frequency and Period. This section evaluates the price stickiness by calculating the frequency and period of price changes. On the one hand, the price frequency refers to the number of price changes during the sample period. We figure up the price frequency based on the methods of Gopinath and Rigobon (GR methods) [23]. The detailed methods are as follows:

We calculate the price frequency of commodity i in category d $dfreq_{di}$:

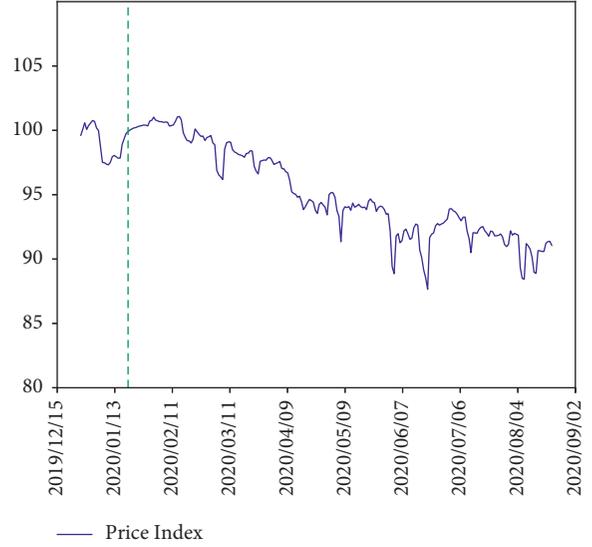

FIGURE 1: Price index.

$$freq_{di} = \frac{npc_{di}}{obs_{di}}, \quad (4)$$

where npc_{di} is the price change times of commodity i in category d . obs_{di} denotes the numbers of observations. Using (4), we divide the commodities into eight categories that are provided by NBS and calculate the price frequency of each category by using the median method, $freq_d$:

$$freq_d = \text{median}(freq_{di}). \quad (5)$$

In order to get the overall price frequency, we calculate the change frequency of eight categories of commodities by the weighted average method where the weight of eight categories of goods is based on the method of He [24]. The overall price frequency is:

$$freq = \sum w_d * freq_d, \quad (6)$$

where w_d is the relative weight of goods i . In order to ensure the robustness of the results, we adopt the BK method to measure the price adjustment frequency. The BK method was used by Bils and Klenow. They calculated the arithmetic mean of each category of goods based on a single good price frequency and got the overall price frequency by the weighted average method. On the other hand, price period refers to the duration of the price until it changes. We obtain the price period according to the method of Jin et al. (4), which is

$$\text{period} = \frac{1}{\ln(1 - freq)}. \quad (7)$$

It can be seen that there is a negative relationship between price frequency and period, that is to say, the higher the price frequency, the shorter the price period, indicating that the price stickiness is higher. The specific results of price frequency and period are shown in Table 3.

The price stickiness is low during the COVID-19 epidemic as shown in Table 3. According to the GR method and BK method, the overall price frequency is 7.85% and 9.65%,

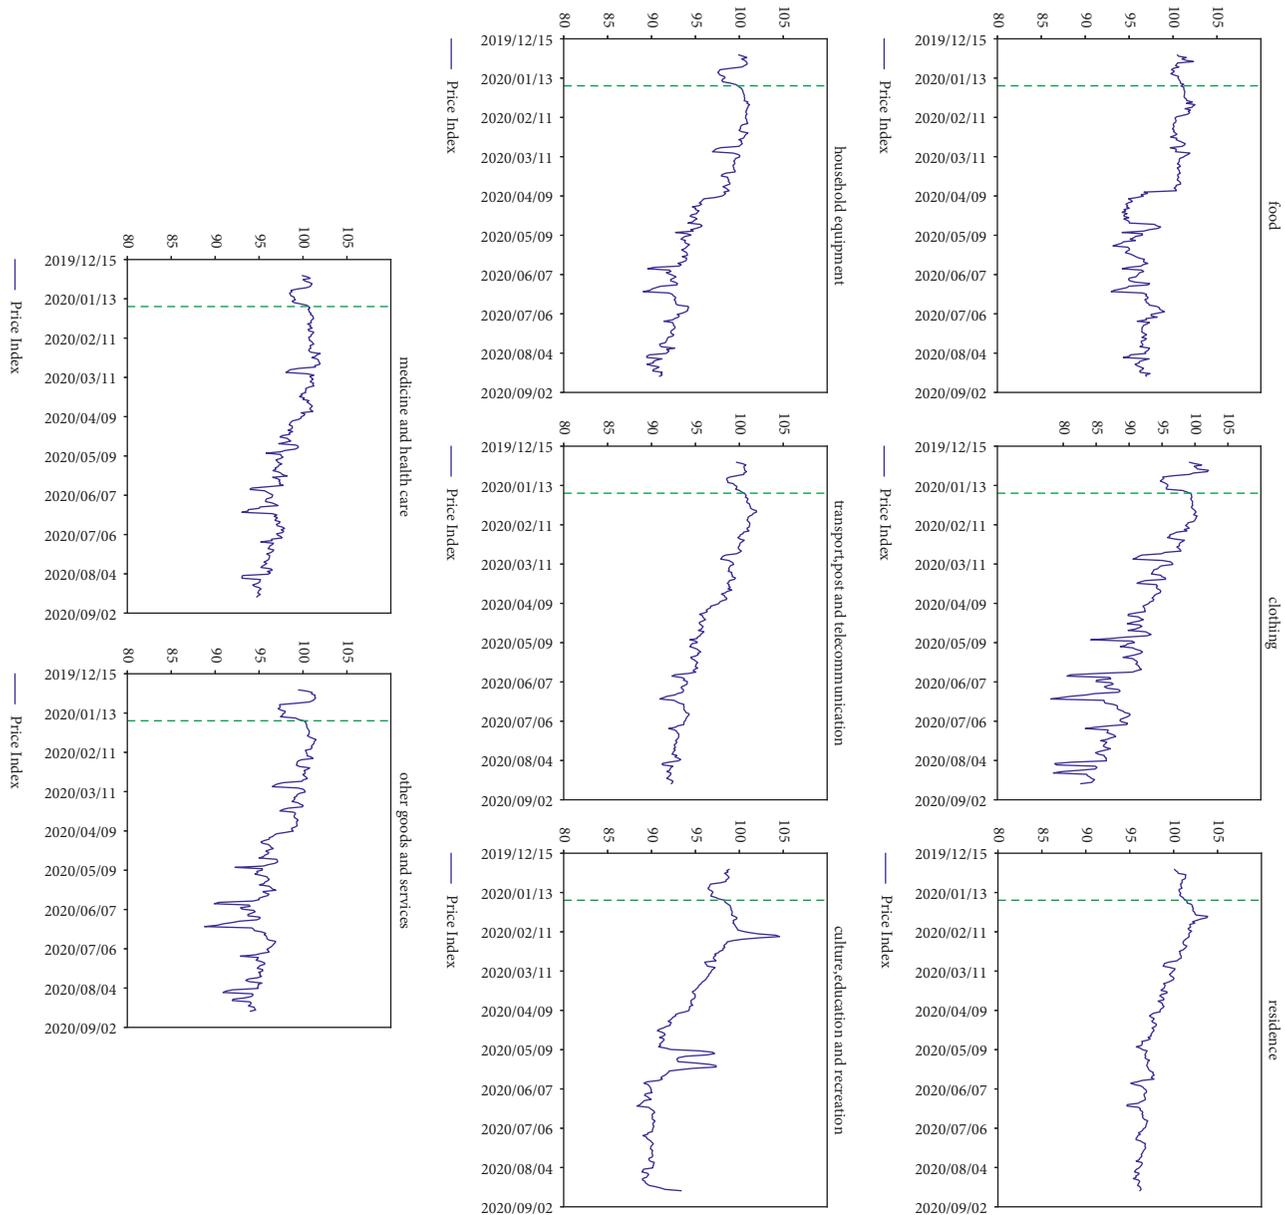

FIGURE 2: Price index of eight categories.

respectively, and the overall price period is 12.23 days and 9.86 days. The extent of price stickiness is far lower than the result of existing studies. Jiang et al. (2020) discovered that the price frequency is 2.24% (GR method) and 3.39% (BK method). As shown in Table 3, the results show that the price period is shorter and price adjustment is more frequent during COVID-19.

We find that there are differences in the price frequency and period among eight main categories. The extent of price stickiness is ranked from low to high: clothing; other goods and services; household equipment; transport, post, and telecommunication; culture, education, and recreation; medicine and health care; food; and residence. It can be drawn that clothing goods have the lowest price stickiness, whose price frequency is 13.50% and the price period is 6.90

days. The results explain that the commodities that change the price make up 13.50% and price adjustment cycle is 6.90 days. Residence goods have the highest price stickiness. Its price frequency is 4.17% and the price period is 23.48 days, which prove that commodities of clothing are best sold during the COVID-19 epidemic. The results are similar to the findings of Jin (2013).

3.4. Price Size. The preceding section discovers that the price stickiness is low during the COVID-19 epidemic by estimating the price stickiness in terms of price frequency and period. In order to further observe the price stickiness, this section measures the size of price changes. The detailed processes are as follows:

TABLE 2: Statistical description of price change.

Index	(1) Price change (%)	(2) Adjustment time	(3) Price rise (%)	(4) Price down (%)
All	81.24	15.70	34.65	65.35
Food	75.03	12.63	46.49	53.51
Clothing	80.14	16.96	28.88	71.12
Residence	34.24	5.41	43.93	56.07
Household equipment	84.79	17.32	30.86	69.14
Transport, post, and telecommunication	79.64	12.50	33.35	66.65
Culture, education, and recreation	84.71	15.32	38.72	61.28
Medicine and health care	74.45	11.26	39.03	60.97
Other goods and services	83.10	18.75	35.55	64.45

Notes: Column 1 shows the percentage of observations that have changed prices. Column 2 is the number of price adjustments. Column 3 has the percentage of observations that price is increased during the sample period. Column 4 shows the percentage of observations that price is decreased during the sample period.

TABLE 3: Price frequency and period.

Index	GR		BK	
	(1) Price frequency (%)	(2) Price period (day)	(3) Price frequency (%)	(4) Price period (day)
All	7.85	12.23	9.65	9.86
Food	7.92	12.12	10.18	9.32
Clothing	13.50	6.90	14.79	6.25
Residence	4.17	23.48	5.56	17.49
Household equipment	10.00	9.49	11.64	8.08
Transport, post, and telecommunication	9.09	10.49	10.90	8.67
Culture, education, and recreation	8.75	10.92	9.91	9.59
Medicine and health care	8.75	10.92	11.21	8.41
Other goods and services	12.08	7.77	13.49	6.90

Notes: Columns 1 and 2 match the price frequency and price period by the BR method. Similarly, Columns 3 and 4 report the results by the BK method.

We calculate the price size of commodity i at t in category d , $size_{di}$:

$$size_{di} = \left| \frac{p_{dit}}{p_{dit-1}} \right|, \quad (8)$$

where p_{dit} is the price of commodity i at day t in category d . p_{dit-1} denotes the price of commodity i at day $t-1$ in category d . Using (7), we divide the commodities into eight categories that are provided by NBS and calculate the price size of each category by using the GR method and the BK method, $size_{m,d}$ and $size_{a,d}$ are

$$size_{m,d} = \text{median}(size_{di}), \quad (9)$$

$$size_{a,d} = \text{mean}(size_{di}). \quad (10)$$

In order to get the overall size of price change, we calculate the size of eight categories of commodities by the weighted average method. The overall price frequencies based on eq (9) and (10) are

$$\begin{aligned} size_m &= \sum w_d * size_{m,d}, \\ size_a &= \sum w_d * size_{a,d}. \end{aligned} \quad (11)$$

Based on the results of Table 4, during the COVID-19 epidemic, the scale of price change was small, and the difference between the scale of price increase and price decrease was not obvious. The size of price changes is 13.62%

and 13.18% by calculating separately with the GR and BK methods, which is less than the results of previous studies. Jin found that the price adjustment range was 24.90%. Jiang et al. found that the median of commodity price adjustment is 19.49% and the arithmetic average is 20.07%. Meanwhile, we find that the difference between the price size increased and that decreased is 0.04%, indicating that the price change is symmetrical during COVID-19. Combined with the results in Table 1, we find that the times of price reduction are greater than that of price raise. Therefore, we obtain that the price moves downward steadily during the COVID-19 epidemic. One cause is that the pricing behavior of merchants will consider consumer sentiment in accordance with fair pricing theory. The abnormal fluctuation of prices causes the consumers' negative emotion, which would influence the partnership between merchants and consumers [25, 26]. Therefore, merchants do not arbitrarily change price during the epidemic, when they will consider the consumer feelings that merchants should deliver the altruism to consumers.

We find that there are differences in the price size among eight categories of goods which are divided by NBS. The size of price change is ranked from low to high: residence; other goods and service; household equipment; transport, post, and telecommunication; medicine and health care; culture, education, and recreation; food; and clothing. The commodity of clothing has the maximum difference in the price increase and decrease, which is 1.06%. Residence goods have the minimum difference, which is 0.06%. The size of price changes among

TABLE 4: Price size.

Index	GR			BK		
	Size change (%)	Size rise (%)	Size down (%)	Size change (%)	Size rise (%)	Size down (%)
All	12.79	13.62	13.18	20.17	24.58	18.09
Food	16.44	18.43	17.47	23.37	28.95	22.05
Clothing	14.99	15.52	16.58	18.73	21.06	19.66
Residence	9.96	9.69	9.75	21.03	25.79	16.77

Other goods and services	10.06	10.52	10.60	13.88	15.85	13.49

Note. Columns 1, 2, and 3 match the size of price change, size of price increase, and size of price decrease, respectively, by the GR method. Columns 4, 5, and 6 report the results by the BK method.

eight main categories of commodities has no significant difference, explaining that the price changes are relatively symmetrical. Thus, this article discovers that the prices of eight categories of commodities move downward stably.

3.5. Pricing Model. Based on the price frequency and size, this article finds that the price moves downward steadily during the COVID-19 epidemic. We inspect the pricing model with the variance decomposition method (short for KK method) proposed by Klenow and Kryvtsov in order to further analyze the source of price fluctuations. KK method decomposes the variance of price changes into time-dependent pricing (TDP) terms and state-dependent pricing (SDP) term and compares the variance contribution rate between the two, so as to obtain the pricing model. The details are as follows:

Let I_{it} represents an indicator of a price change for commodity i in day t :

$$I_{it} = \begin{cases} 1, & p_{it} \neq p_{it-1}, \\ 0, & p_{it} = p_{it-1}, \end{cases} \quad (12)$$

where p_{it} denotes the log of price of commodity i in day t . We use the following equation for aggregate inflation, $\pi_t :=$

$$\begin{aligned} \pi_t &= \sum_{i=1}^N w_{it} (p_{it} - p_{it-1}) \\ &= \left(\sum_{i=1}^N w_{it} I_{it} \right) * \left(\frac{\sum_{i=1}^N w_{it} (p_{it} - p_{it-1})}{\sum_{i=1}^N w_{it} I_{it}} \right) \\ &= fr_t * dp_t. \end{aligned} \quad (13)$$

As shown, eq (13) represents that the aggregate inflation can be expressed as extensive margin and intensive margin. fr_t is the fraction of the commodities' changing price changes in day t , that is the numbers of merchants adjusting price when inflation occurs. dp_t signifies the weighted-average magnitude of adjusting price in day t , that is the

magnitude of price changes by merchants when inflation occurs. According to the model of Klenow and Krystov, the external environment could influence the pricing behaviors of merchants when inflation (π_t) is relevant to fraction (fr_t). Instead, pricing behavior cannot be influenced when inflation (π_t) is irrelevant to fraction (fr_t). Therefore, we reach that the pricing model is the time-dependent pricing (TDP) model if inflation (π_t) is uncorrelated with fraction (fr_t). When inflation rate (π_t) is relevant to magnitude (dp_t) and fraction (fr_t), the pricing model is the state-dependent pricing (SDP) model. The results are shown in Table 5.

We find that coefficients of π_t is negative and small in Table 5, indicating that there exists low inflation phenomenon on COVID-19. Meanwhile, the overall inflation decomposition result of all commodities price displays that π_t and dp_t have a higher relevance degree where the correlation coefficient is 0.601, and the regression coefficient of dp_t is significant at 1% level. The correlation coefficient of π_t and fr_t is 0.095, and the regression coefficient of fr_t is not significant. The results show that the pricing model fits the time-dependent pricing (TDP) model during the COVID-19 epidemic, which explain that most merchants can flexibly change price based on the market environment. In addition, we get that the pricing models of eight categories of commodities are heterogeneous. The correlation coefficient of clothing goods is 0.286. At the same time, the regression coefficient of fr_t is significant. It indicates that the pricing model of clothing goods is state-dependent pricing (SDP) model where fr_t and dp_t are highly related to π_t and regression results are significant. However, the pricing model of other category goods is time-dependent pricing(TDP) model where regression between π_t and fr_t is not significant at the 1% level. It shows that the price changes of these commodities are limited during the COVID-19 epidemic.

Then, the variance decomposition of the inflation (π_t) is made to clarify the contributions of time-dependent pricing (TDP) term and state-dependent pricing (SDP) term. The first-order Taylor expression is carried out on (13):

TABLE 5: Correlations and regression results.

Index		(2)		
		(1) Correlation	Coefficient	P value
All	π	1.00	—	—

	dp_t	0.540	8.143	0.001
Other goods and services	π	1.00	—	—
	fr_t	0.132	0.944	0.064
	dp_t	0.800	4.001	0.001

Notes: Column 1 shows correlation coefficient between inflation (π_t), fraction (fr_t), and magnitude (dp_t). Column 2 is the regression coefficient and p -value that inflation (π_t) regress on fraction (fr_t) and magnitude (dp_t).

$$\text{var}(\pi_t) \approx \underbrace{\text{var}(dp_t) * \overline{fr_t^2}}_{\text{TDP term}} + \underbrace{\text{var}(fr_t) * \overline{dp_t^2} + 2 * \overline{fr_t} * \overline{dp_t} * \text{cov}(fr_t, dp_t)}_{\text{SDP term}}, \quad (14)$$

where fr_t denotes extensive margin, and dp_t represents intensive margin. When the TDP model is dominant, $\text{var}(fr_t)$ and $\text{cov}(fr_t, dp_t)$ are equal to 0 that the inflation variance is decided by the TDP term. However, when the SDP model is dominant, $\text{var}(fr_t)$ is not equal to 0, that is the SDP term has an influence on the inflation variance. The results of the inflation variance decomposition are shown in Table 6.

The variance decomposition results are reported in Table 6. We discover that proportion of TDP term is far more than that of SDP terms, which verify the results in Table 5. However, TDP terms of clothing goods exceed 100%. The reason might be that the mean of fr_t raises the TDP term and the variance of fr_t lowers the SDP term when we consider the high frequency of price changes during the COVID-19 epidemic.

As we know, commodity prices move downward steadily; meanwhile, the low inflation phenomenon exists during the COVID-19 epidemic. The overall pricing model is time-dependent pricing model, and the pricing models of categorized commodities are heterogeneous. The results led to problems that whether macro-policies should respond to

price changes during COVID-19. If so, what commodities should policy anchor? An analysis of the dynamic characteristics of inflation is required to answer these questions. Zhang (2008) supposed that the key to understand the dynamic characteristics of inflation was to identify the inertial characteristics, namely inflation inertia [27]. The next section analyzes the dynamic process of inflation by measuring the inflation inertia.

4. Inflation Inertia

4.1. AR Model. Inflation inertia refers to the duration which inflation deviated from the equilibrium state due to being disturbed by random factors [28]. As a general rule, the greater inflation inertia is, the more obvious hysteresis effect of policies is. Therefore, it is of great significance to policy regulation by accurately measuring the inflation inertia. By referring to the existing literature on the measurement of inflation inertia [27, 29], we evaluate the inflation inertia by making use of the sum coefficients in the AR model. The AR model is as follows:

TABLE 6: Variance decomposition.

Index	(1) cov(fr, dp)	(2) TDP term (%)	(3) SDP term (%)
All	-0.000667	85.64	14.36
Food	-0.000363	97.86	2.14

Other goods and services	AR(2)	-0.152	-0.199

Notes: Column 1 shows inflation inertia coefficient using median unbiased method to estimate the AR model. Column 2 is inflation inertia coefficient using least square method to estimate the AR model.

$$\pi_t = c + \sum_{i=1}^n \rho_i \pi_{t-i} + \varepsilon_t, \quad (15)$$

where π_t is the inflation rate, and $\sum \rho_i$ represents the sum of coefficients in the AR model, which measures the inflation inertia. Considering the collinearity caused by the lag of explanatory variable, OLS will result in deviations of estimated results [30]. Therefore, this article takes the median unbiased estimation that was proposed by Roy and Fuller [31] in order to ensure the robustness of the results.

4.2. Empirical Results. The estimated results are reported in Table 7. It can be seen that the overall inflation inertia is less than 0. The main reason is that the economy is at the low inflation state during the COVID-19 epidemic. We use the Jevons geometric index formula to process price index according to the method of Guo [32]. The overall commodity price index is 96.83, which contribute that the inflation inertia is reversal. The results are similar to the research of Chen [33]. It illustrates that macroeconomic policies are featured by going against the economic cycle, and macro-management is effective [34]. Food commodities has a higher inflation inertia than non-food commodities. It can be sure that the inflation inertia mainly comes from food commodities during the COVID-19 epidemic. The reasons may include that food commodities have the largest weight that reach nearly 1/3 among the eight categories of commodities, and the proportion of food expenditure is

relatively high that achieves 30.16%. The fluctuation of food price caused by the COVID-19 epidemic will directly affect the dynamic characteristics of inflation.

Further, the impact of COVID-19 may cause the structural mutation of model estimation. When the outbreak happened at the initial stage, people would be in a greater demand for some commodities that improves the price of these commodities. With the outbreak is to be gradually brought under control, the demand for commodities will weaken. The commodity price will go through a significant adjustment, bringing out the structural mutation of the AR model during COVID-19. On this account, we conduct a structural breakpoint test by referring the method of Zivot and Andrews [35]. As shown in Table 8, commodities of clothing and culture, education, and recreation did not have obvious structural mutations, while the other commodities have significant structural breakpoints. In order to get more accurate estimation results, we divided the time series into two stages based on the structural breakpoint and held that commodities of food still have great inflation where coefficients are -0.208 and -0.684% , respectively. Meanwhile, this article discovers that there is a great difference among commodities of food, residence, household equipment, and medicine and health care.

The above results show that the demand for commodities of food, residence, supplies and services, and medical services greatly increase during the early period of the COVID-19 epidemic and the price of that is increased. However, with the gradual control of COVID-19, the demand for such

TABLE 8: Structural mutation of inflation inertia.

commodities is reduced, and the accumulation of commodity supply makes the inflation inertia larger.

5. Conclusions

Based on the online high-frequency price data, this article measures the price stickiness of commodities during the COVID-19 epidemic and analyzes pricing models and inflation inertia, which provide the micro-basis for macro-policy. The main conclusions are as follows:

Firstly, the commodity price moves downward steadily during the COVID-19 epidemic. On the whole, most commodities of price shows a downward trend during the sample period. In the meantime, the commodities of price has a minor change size, and the difference between the size increased and that decreased is not obvious. The price of eight categories of goods is similar to the aggregate price performance. The reason lies in that merchant will formulate pricing strategy based on consumer sentiment. The abnormal fluctuations of prices cause the consumers' negative emotion, which would influence the partnership between merchants and consumers. Therefore, price moves downward steadily under the consumer sentiment.

Secondly, the commodity price displays the low stickiness, and the pricing model shows time-dependent pricing (TDP) model in general. We find that most commodities show a time-dependent pattern through eight commodity classification and only clothing commodity belongs to state-

dependent pricing (SDP) model. The results show that the price adjustment of most commodities is limited during the COVID-19 period.

Thirdly, we construct AR model to estimate inflation inertia and clarify the dynamic characteristics of inflation. The results show that the inflation inertia is negative, which means that the macro-control is effective during the COVID-19 epidemic and has the characteristics of going against the economic cycle. It indirectly indicates that COVID-19 is a short-term market shock, and inflation inertia mainly comes from commodities of food, which means that government should regulate the inflation by aiming at food goods during the COVID-19 epidemic.

This article affirms the price stickiness of commodities during the COVID-19 epidemic and thus has practical significance. However, there are still some limitations that need to be further studied. Firstly, we just consider the price stickiness during the COVID-19 epidemic, ignoring the control of other emergencies and limiting the scope of application of our conclusions. Secondly, the data have not been fully mined, and the processing method of high-frequency data still needs to be further improved. Thirdly, the sample data need to be expanded. For example, Amazon and JD can be added as research objects, but it is difficult to obtain and match cross platform commodity information. This is a key issue that needs to be solved in subsequent studies.

This paper takes the village in the city as a case study, through the investigation of the basic information of the village in the city, such as housing construction, construction quality, property rights characteristics, and so on. We use GIS technology to evaluate the construction and reconstruction cost of the plot. This paper puts forward different transformation schemes and explores the application of GIS technology in the transformation planning of urban villages. Finally, this paper designs a GIS-based spatial experience system for micro-transformation of urban villages.

1. Introduction

At present, urbanization is an inevitable trend of social and economic development in the world [1–5]. With the strong impetus of reform and opening up and the development of the market economy, China's urbanization process continues to accelerate. In 1978, China's urbanization rate was 17.9%. In 2011, it reached 51.27% and exceeded 50%. In 2017, China's urbanization rate reached 58.52%. From the perspective of urbanization development laws in the world, when the urbanization rate exceeds 50%, it means that urbanization has entered a rapid development stage, which will inevitably lead to profound social changes. What follows is that the urban spatial structure, industrial positioning, urban planning, urban management, and other aspects will face new development. However, in the process of China's rapid urbanization, a universal and unique phenomenon—village in city has emerged. The village in the city is the product of urbanization under the urban-rural dual system in China and has developed into a typical problem gathering place in the process of the evolution of the urban-rural dual system to the unification. At present, the focus of China's reform and development is to reform the urban-rural dual system. Among them, dealing with the problem of villages in cities is an important content related to the overall

development of China's urban and rural areas and the formation of a new pattern of urban-rural integration. It is also the key to solving the urban-rural dual system.

The essence of urbanization in developing countries is the process of constantly breaking the urban-rural dual structure and gradually realizing urban-rural integration [6, 7]. China's urban-rural dual system was formed in the planned economy era. It is undeniable that in that special historical period, this economic system played an important role in China's economic and social development at that time. However, with the development of the times, China has turned from a planned economy to a market economy. The progress of industrialization has accelerated the development of urbanization. The urban-rural dual system, which once played a role in promoting China's economic and social development, has not only become a stumbling block to the development of urbanization. At the same time, it has also become one of the adverse factors restricting the development of the whole society and has been intensively reflected in the villages in the city. Under China's urban-rural dual management system, although urban villages have already belonged to cities and towns within the geographical scope, they are still rural systems and rural organizational systems in terms of the management system. Although the villagers in urban villages no longer engage in agricultural

production, they cannot enjoy the same social security as urban residents in terms of education, medical treatment, and health care. Nowadays, a series of environmental, social, and economic problems caused by villages in cities have not only become one of the most difficult problems in urban transformation and urban governance in large and medium-sized cities in China, but also become a bottleneck restricting urban development. It can be said that the emergence of urban villages is an inseparable knot in the process of urbanization. Most Chinese cities, large and small, are facing the problem of urban villages. The transformation of urban villages has become a major event that the local government must pay attention to. However, in the actual process of urban village reconstruction, no matter which city or place in China has encountered great challenges, such as insufficient funds for urban village reconstruction and the inability to guarantee the legitimate interests of villagers in the process of reconstruction.

The village in the city is the form of urban material space in the process of urbanization in China. It is the product of the imbalance between urban and rural areas and has deep and complex social problems. From big cities to small- and medium-sized cities, there are many urban village problems involving economy, society, environment, and so on, which has become a chronic disease that seriously puzzles the healthy, harmonious, and sustainable development of cities. In order to promote the healthy development of China's urbanization and improve the quality of urbanization and urban quality, we must take reasonable and effective control measures to transform villages into cities and actively promote the healthy development of urbanization.

At present, the phenomenon, existing problems, and formation mechanism of the village in the city have been thoroughly revealed by the academic circles, and the idea of the transformation of the village in the city has gradually become clear, but the implementation effect of the case study and planning scheme of the transformation is not very ideal. The research on urban village reconstruction planning mainly involves two aspects: system reform and material space transformation. In the process of promoting the transformation of urban villages, many places first adopted the reform of the administrative management system, and the research also relatively focused on the contents of registered residence, land, management, grass-roots organizations, and the operation of the village collective economy. On the one hand, the research on the transformation of material space is a theoretical discussion, involving transformation ideas, operation modes, technical schemes, demolition compensation and resettlement, economic analysis, social analysis, system and policy support, etc. On the other hand, it is the empirical study of transformation planning, which is mainly manifested in the planning and design scheme of urban villages. Although the scientificity and operability of the planning scheme are closely related to the complexity of the transformation of urban villages, the lack of in-depth research on the basic situation of urban villages and insufficient application of technical methods in the planning process are also important reasons for the lack of feasibility of the planning scheme. The application of GIS

technology [8–13] can establish a detailed basic database. Through the statistical analysis function of GIS, planners, and reconstruction implementers can clearly grasp the difficulty of reconstruction of urban villages, the reasonable sequence of reconstruction, the arrangement of demolition and resettlement, etc. The application of GIS technology will provide a powerful technical guarantee for the reconstruction planning of villages in cities.

2. Related Work

2.1. Urban Village. Village in the city is a special phenomenon in the process of rapid urbanization under the urban-rural dual system in China. Compared with China, the phenomenon of urban villages in some developed countries is relatively rare. In addition, urban villages appeared relatively late. Therefore, scholars have not conducted much special research on urban villages in China. However, urban problems similar to the characteristics of “village in city” have also appeared in the urbanization process of some developed countries, especially the urban sprawl in the United States after 1950, and the slums in Latin America, Asia, and other developing countries in the process of rapid urbanization and excessive urbanization. Although the formation mechanism of these phenomena in some developed countries is different from that in China, the theoretical basis for the transformation of urban villages in China can be found from the western urbanization theory and the research on urban fringe. The scholar who first proposed and used the concept of urbanization was a serda, who defined the concept of urbanization in the book *Basic Principles of Urbanization* published in 1867 [14]. In the mid-eighteenth century, the rise of the industrial revolution accelerated the pace of urbanization. With Britain as the representative, under the influence of the industrial revolution, France, Germany, the United States, and other countries have successfully completed the industrial revolution. With the substantial improvement of labor productivity and productivity, the industry of these countries has developed rapidly, while the development of industrialization has also led to the rapid development of urbanization in these countries, and emerging cities continue to appear.

The industrial revolution not only promoted the development of industrialization, but also prompted more and more rural people to gather in cities. With the continuous expansion of urban scale, coupled with the lack of scientific and reasonable urban planning, urban spatial layout was disordered, and social security and residents' living standards were getting lower and lower. In the mid-nineteenth century, some western industrial cities represented by London, England had different problems one after another. The emergence of this phenomenon has attracted more and more western scholars' attention to the direction of urban development. During the discussion on the direction of urban development, two completely different views were formed. One was represented by the British scholar Howard, who advocated that the future direction of urban development should be an idyllic city [15]. The other is represented

by Le Corbusier, who advocates that the future direction of urban development should be modern cities [16]. Compared with the view of developing modern cities, although the idea of developing garden cities is somewhat idealistic, the idea of urbanization that garden cities focus on pursuing low density in regional space and advocating that life should return to green nature provides a certain theoretical reference for China's sustainable urban development and effective land use. The modern urban theory put forward by Le Corbusier argues that cities must be concentrated if they want to develop. Only when cities are concentrated can they bring power to urban development. Cities also need to build a large number of high-rise buildings to make the population concentrated in the city, and the traffic, housing, environment, and other problems caused by population concentration can be solved by other technical means. Le Corbusier's modern urban thoughtfully embodies the concept of intensive land use and advocates that the expansion of urban scale should take the road of connotation development.

Scholars began to systematically study the urban internal spatial structure very early. For example, in 1826, von Thunen, a German economist, published the book "the relationship between agriculture and national economy in isolated countries," in which he put forward the famous agricultural location theory. The theory points out that the level of economic development and its productivity determine the type of agricultural land use and the degree of intensification of agricultural land use, and further points out that the distance between agricultural production land and the agricultural product market has a greater impact on the type of agricultural land use and the degree of intensification of agricultural land use. In 1909, the German economist Weber put forward the famous Weber's industrial location theory in his book on industrial location. The theory chooses the industrial production activities of the three basic links of production, circulation, and consumption as the research object, scientifically analyzes and accurately calculates the relationship between factors such as transportation and labor agglomeration, and puts forward the principle of minimum cost, that is, for industrial products, the lowest point of production cost is the most ideal location for industrial enterprises. From the development of location theory, the early location theory did play a positive role in the scientific and rational use of land, but this theory also has its limitations, such as single research object, pure theoretical derivation, and lack of practicality. After that, with the proposal of concentric circle theory, fan theory, and multicore theory, the location theory has been further developed. These three theories profoundly reveal the general laws of urban land use and functional zoning and emphasize the leading role of CBD in urban development and functional zoning, which has a positive guiding significance for the planning and construction of Chinese cities.

Urban fringe and urban village have different meanings, but they are closely related. From a regional perspective, the urban fringe is a transitional zone between the periphery of the urban built-up area and the rural area. Its boundary is not very obvious, and it also has dynamic characteristics. The

village in the city is a construction area within the urban built-up area and the fringe, and it is a "point" of the urban fringe. From the aspects of land use, economic characteristics, and social structure, the two have certain similarities. They are both in the process of obvious transformation from rural to urban. Compared with the urban fringe, the urban village has more urban characteristics. Therefore, the research theories and methods on the urban fringe can be used for reference in the study of villages in cities in China. The first scholar to put forward the concept of "urban fringe" is German geographer L. Louis. At the same time, his explanation of this concept has also been widely recognized by scholars all over the world. In 1936, Herbert Louis studied Berlin, a large European city, from the perspective of morphology. In his study of the regional structure of Berlin, he found that some areas that were originally located on the edge of the city were gradually surrounded with the continuous expansion of the city and eventually became part of the urban area. Herbert Louis called this surrounded area the urban fringe.

Since the 1970s, there have been more and more studies on the urban fringe in some developed countries, and most of them focus on the rapid development of urbanization. The research content has also changed from the initial spatial form to the research on the development law, influencing factors, and dynamic mechanism of the urban fringe. In the research on the characteristics of regional structure, Golledge believes that there are seven differences between the urban fringe and the rural and urban areas. They are a small amount of agriculture in the urban fringe, intensive crop production, flexible and changeable population, medium density, rapid expansion of new residential areas, and widespread provision of incomplete services, public facilities, and speculative housing. In the study of suburban characteristics, R.E. Boll discussed from a sociological point of view that the urban fringe has the suburban characteristics of living tendency according to class, selective immigration, frequent commuting, weakened geography, and social hierarchy. Adedayo Adesina takes Nigeria as the research object, analyzes the social structure characteristics of urban-rural fringe in developing countries, and points out the potential impact of informal economic activities on government policies. In the study of urban-rural integration, he emphasized the concept of continuous unity between urban and rural areas, analyzed the relationship between changes in real estate structure, land use structure, agricultural structure, and social and community structure, and found that there were environmental differences in the process of such regional transformation between different cities. In the study of land use difference, the urban fringe is divided into inner edge zone and outer edge zone according to the nature and intensity of land use. The inner edge area means that the land use has been in the advanced stage from rural to urban. The outer edge area refers to the agricultural land use as the main landscape, but the land use has obvious suburban characteristics.

In developing countries, slums generally refer to informal settlements, where urban poverty is most evident. Although there are different names, different land tenure

systems and different building structures, overcrowding, unsafe living conditions and the lack of clean water, electricity, sanitation, and other basic living services are common characteristics of slums. The rapid growth of urban and rural migrants, growing poverty, and unsafe land tenure have led to the continuous emergence of slums, and the most important factor is the large-scale migration of the rural population to cities. Since the 1950s, the rural population in developing countries has decreased by an average of 25%. Compared with a large number of rural to urban migrants, the construction of urban planning and urban management system has been slow, which has accelerated the formation of slums and led to the growing scale of slums. Some experiences and lessons can be learned from the practice of slum reconstruction in some developed countries.

2.2. GIS Technology. With the development of computer technology, it has been applied in various fields [17–20]. In the process of using GIS spatial data, better analysis ability can be obtained [10–13]. With the assistance of GIS spatial data, it can ensure that the planning and design personnel can simulate the current planning scheme, and make an objective evaluation of the scheme content under the condition of reasonable screening, so as to obtain better planning decision-making content. Under the support of GIS spatial data, the buffer area can also be superimposed in the form of layer superposition, and the best planning path can be selected in the form of automatic matching. Based on this form of spatial analysis, the perfection of the planning area setting is guaranteed from many different levels, such as residential area, Park Square, public facilities location, pedestrian and vehicle route selection, and the best arrangement, and gradually replaced the traditional form of planning and design methods. In addition, in the process of using the GIS system, it can comprehensively consider the social development, economic growth, natural conditions, and other factors within the scope of the urban planning area. In the case of multiple factor superposition analysis, it ensures the comprehensiveness and objectivity of the prediction and evaluation and further makes an accurate prediction of the economic development trend within the planning area on the basis of the planned urban land grade. The application of GIS technology in the field of urban planning industry can not only improve the overall design efficiency in the process of planning and design, but also obtain better planning and design results and improve the implementation quality of urban planning and design under the condition of shortening the design cycle. In the process of managing data information with the help of GIS technology, it can not only expand the storage capacity of data information, but also improve the data maintenance and updating ability of the system with the help of a variety of different types of spatial data, provide convenient support for the display of data query, superposition, clustering, network proximity, spatial information, and other functions, and make the urban planning and design scheme gradually transform toward the rational direction.

In the process of using GIS to carry out management work, it is necessary to comprehensively analyze the specific application requirements of urban planning and design, so as to ensure that in the process of using traditional surveying and mapping technology, it can avoid the impact of other interference factors and reduce the adverse effects on urban planning and design. The system operation mode based on GIS technology needs to take the satellite system as the basic support within a specific range. In the subsequent use process, the detection work should be carried out for the satellite data information system to ensure the convenience of the detection work. Due to the special nature of relevant external factors, it is necessary to take effective application measures through the rational use of GIS technology in various regions to ensure the visual characteristics of measurement links and provide support for the update of Surveying and mapping technology.

In the process of accelerating urbanization construction, higher requirements are put forward for software surveying and mapping management, which needs to be based on the concept of strictness and rigor, in the form of manual measurement and with the help of the actual utility of measuring instruments, to ensure the accuracy of the finally measured data information, so as to ensure the timeliness of data information update. In addition, there are relatively many types of interference factors caused by the degree of measurement results, which puts forward higher requirements for the traditional surveying and mapping work, and it is necessary to ensure the perfection of the satellite detection process setting. It is necessary to take GIS technology as the basic guarantee to ensure the effectiveness of satellite detection after the completion of satellite detection. In the implementation stage of the actual measurement work, it is necessary to process the collected information to ensure the timeliness of information processing, set the range according to the existing value, and reduce it to the minimum within a limited time. In addition, during the implementation of measurement, the main purpose is to ensure the accuracy of data information, ensure the accuracy of satellite positioning, and enable it to operate stably in orbit 120 km away from the Earth.

When surveying and mapping the ground area based on GIS, it is necessary to strictly follow the specific requirements of signal reception, so as to preset and process the relevant devices, and adjust and evaluate the relevant technical information based on the fully automatic observation form. In addition, in the process of introducing relevant surveying and mapping instruments, it is necessary to ensure the effectiveness of the use of instruments, take this aspect as the focus of the surveying and mapping link, strengthen the management of various types of instruments and equipment, lay a good foundation for the sustainable development of surveying and mapping operations, ensure that the actually obtained surveying and mapping information has the characteristics of detail, and draw the topographic map in an intuitive form. It can not only reduce the use of labor costs, but also ensure the feasibility and operability of GIS mapping mode on the basis of improving work efficiency. Comparing the GIS surveying and mapping

technology with the traditional human light surveying and mapping method, it can be seen that in the process of using GIS technology to carry out surveying and mapping work, it can effectively improve the actual surveying and mapping efficiency and can be used under complex environmental conditions. In full combination with the actual situation, it ensures the effective implementation of Surveying and mapping work and management work and meets the specific requirements of urban planning and design work.

3. Research on the Application of Urban Village Reconstruction Scheme

3.1. Research Framework. The working process of urban village reconstruction planning is as follows: (1) investigation and analysis of the basic situation. Through the on-the-spot survey, questionnaire survey, personal interview, literature reading, and other means, we mainly understand the basic information of urban villages, such as population, housing and land income, policies, and systems. (2) Collection and analysis of basic data. Establish GIS analysis database to collect basic data including land cadastre (topographic map, house cadastre data, etc.), house conditions (structure base area, floor height, house property right, building quality, etc.), and social and economic factors (house cost, demolition cost, population, etc.). (3) Analysis and evaluation of transformation ideas. Through GIS technology, this paper studies the scheme of urban village reconstruction, the method of demolition and resettlement, and the sequence arrangement of reconstruction and reconstruction. (4) Form a preliminary plan and ideas. Through communication and coordination with villagers, local managers and reconstruction implementers, the reconstruction scheme is revised. (5) Preparation of planning scheme (as shown in Figure 1).

3.2. Data Collection. The data collection of the GIS database is mainly based on the following sources: (1) the topographic map is imported to form the GIS base map, which digitizes the basic information such as roads, river waters, and houses, including the house base range and area, floating platform range and area, floor height, and other house information. (2) According to the house cadastre and property rights data of the Housing Administration Bureau, confirm the property right information of all houses in the reconstruction area and enter it into the attribute of the house object in the GIS database. (3) The construction quality of all houses is determined through on-site investigation, which is divided into four grades: A, B, C, and D. At the same time, the buildings with historical protection value shall be determined.

3.3. Evaluation and Classification of Existing Buildings. In general, three different technical schemes can be adopted for the transformation of Urban Villages: first, overall transformation, which refers to the comprehensive transformation from the overall pattern to individual buildings, but some historical buildings may also be retained, mainly for

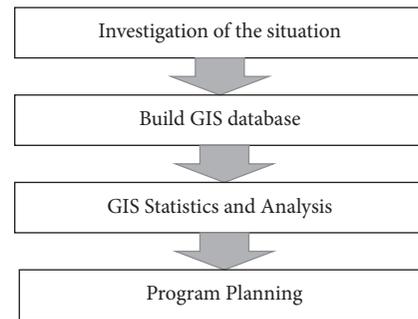

FIGURE 1: Preparation of the planning scheme.

urban villages with poor overall human settlements. Second, local transformation refers to the key transformation of local areas and key elements without major adjustment of the overall pattern, mainly aiming at the villages in the city where the problems are not prominent. The third is to retain the renovation, which means that the internal environment of urban villages is renovated without adjustment of the overall pattern, mainly for urban villages with mild problems and good living environment. What kind of transformation plan should be adopted for the transformation of urban villages? Not only the living environment of urban villages, but also the economic feasibility of the transformation should be considered. The reconstruction of urban villages involves the demolition compensation of the original houses and the relocation and resettlement of the original residents after the reconstruction, which increases the cost of house demolition and resettlement compared with the general real estate development. Therefore, the economic cost and investment income of the transformation should be considered in the selection of the transformation scheme of urban villages. Therefore, it is necessary to evaluate the plot ratio, building quality, property rights, and rental benefits of urban villages. Figure 2 presents the research idea map.

3.3.1. Plot Division. There are obvious differences between the buildings in the East and the west of the village in the city, so it is necessary to adopt different transformation strategies according to local conditions. Firstly, according to the natural geographical environment (such as ponds and rivers), road conditions, and architectural characteristics, the village in the city is divided into 17 plots of similar size.

3.3.2. Statistical Analysis. By using the statistical analysis function of GIS, the basic building conditions of each plot are obtained.

3.3.3. Cluster Analysis. According to the building conditions of each plot, the index values that can best reflect the building characteristics, such as building area, building floor area ratio, average floors, and building quality index, are selected as variables for hierarchical cluster analysis. After testing, the method of sum of squares of Wald's deviation is the best for classification and can analyze the building conditions of each group:

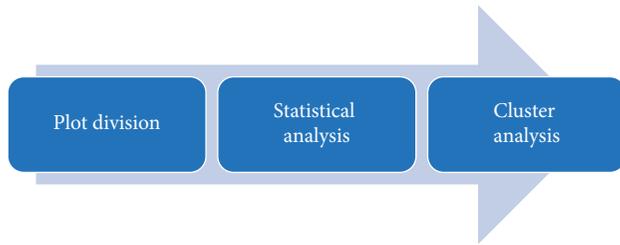

FIGURE 2: Research idea map.

The first group is a low-density building area. The main feature is that the natural landscape in the plot is good, there are large ponds and waters, and the building density, building floor area ratio, and the average number of floors are relatively low. It is a low-cost or high-efficiency reconstruction area. However, the building quality of each plot varies greatly. The plots with a good living environment should be retained and renovated, while the plots with a poor living environment should be listed as key reconstruction areas.

The second group is a medium-density building area, which belongs to a typical traditional rural settlement type. The main characteristics are that the building density in the plot is high, the living environment is relatively poor, and the building quality, floor height, and floor area ratio are general. It is an area in urgent need of reconstruction.

The third group is high-density building areas. The main features are that the average number of floors of buildings in the plot is relatively high, the building quality is relatively good, the building plot ratio is relatively high, and the reconstruction cost is large. It belongs to a local reconstruction area.

3.4. Establishment of Thematic Map and Analysis of Influencing Factors. The above statistical analysis is aimed at the economic evaluation of the amount of housing reconstruction and demolition, which provides a fundamental basis for the determination of the reconstruction scheme. However, it still stays at the level of the mathematical analysis method, and more objective factors must be considered in determining the transformation plan. With the application of GIS technology, the planning can establish thematic maps according to these factors for analysis, and finally achieve the purpose of comprehensive consideration.

Because the original rural planning and management system is not perfect and the villagers' legal meaning is weak, illegal buildings in urban villages are quite common. Therefore, for the houses that have been planned and legally built, the planning should be retained as far as possible. The vast majority of houses in Dongxifang, a village in the city, have incomplete formalities. The main purpose of urban village reconstruction is to improve the environment of urban village. Therefore, the quality of housing construction and the overall construction landscape should become the main evaluation factors of urban village reconstruction.

4. System Design and Application Platform Based on GIS Architecture

With the putting forward of the GIS concept, GIS application terminal is developing toward miniaturization and mobility. GIS Server is developing toward a cross-platform and service-oriented architecture and supports minicomputer, mainframe, cluster, and other applications. The new generation t-c-v three-tier software architecture (terminal cloud virtual), a GIS application model for cloud services proposed by MAPGIS, a large domestic GIS manufacturer, provides users with a cloud GIS basic platform suitable for geographic information services. T-c-v architecture is a loosely coupled software architecture [21–23]. The three layers refer to the terminal application layer, cloud computing layer, and virtual device layer, respectively. Based on the concept of service orientation, each layer is connected by standard service interfaces to provide all-round sharing of data, functions, and services, as well as aggregation and migration of services; replace the current small and medium-sized computing mode with the super large-scale computing mode. The framework can solve the problems of isolated services and difficult integration, make data integration and mining easier, improved data storage organization and management capabilities, and provided users with fast, convenient, and broader information service capabilities. The terminal application layer provides users or developers with standard interfaces to access, so as to facilitate the construction of various terminal applications. Table 1 presents the T-C-V three-layer software architecture.

4.1. Virtual Device Layer (V Layer). The virtual device layer refers to the organization of software and hardware devices such as computers, network facilities, storage devices, and large databases at the bottom based on virtualization technology, shielding the heterogeneity of different computers, networks, and storage devices, managing all software and hardware resources in an integrated manner, virtualizing them into corresponding logical resource pools, and providing a unified and efficient operating environment for cloud computing layer applications. The virtual device layer is the foundation to support cloud computing and cloud GIS services. Users can use various terminal devices to obtain GIS services at any place and at any time.

4.2. Cloud Computing Layer (C Layer). The cloud computing layer combines the current cutting-edge cloud computing technology and the characteristics of geospatial information to establish a framework for massive geographic information data, functions, resource management, and service system. On the basis of supporting super large-scale and virtualized hardware architecture, a massive GIS data, function and resource management, and service system framework are established, and services are established according to the idea of “plug and play” and the concept of aggregated services. The cloud computing layer deploys the cloud GIS services provided by GIS application developers and end users. Among them, basic GIS platform developers can

TABLE 1: T-C-V three-layer software architecture.

Layer	Specific structure
V layer	Virtual device layer
C layer	Cloud production center Cloud service warehouse Cloud management center
T layer	Terminal application layer

provide basic GIS function services, GIS application software developers, and other end users from all walks of life can provide GIS function services of different granularity that can form various applications. The energy source of the cloud computing layer constantly generates new resources and expands the cloud, while ensuring that other resources can be smoothly connected to the cloud. The cloud service warehouse is mainly used to manage various cloud GIS services. The cloud management center is used to manage the registration, discovery, scheduling, and security of all services in the cloud and ensures the normal operation of online transactions of cloud services.

4.2.1. Cloud Production Center. One of the important roles of the cloud computing layer is to generate various cloud resources for users to customize. In order to ensure that all cloud resources can be connected to the cloud for global users and that these resources can be aggregated and reconstructed. Map GIS 10 has launched the development mode of “framework + plug-in.” All applications in this development mode are composed of frameworks and plug-ins. These frameworks and plug-ins are independent of each other. They are connected through certain standards and specifications. As long as the frameworks and plug-ins contained in applications that meet the same standards and specifications can be freely aggregated and reconstructed. At the same time, MAPGIS 10 provides powerful runtime support and can easily access third-party applications. Users can directly customize, aggregate, and reconstruct the application system based on the rich kernel resources provided by MAPGIS 10 and use the existing framework and plug-in resources. They can also customize the development functions based on unified development standards and development processes based on various end application development runtime and API resources provided by MAPGIS 10 to form cloud service resources.

4.2.2. Cloud Service Warehouse. The cloud computing layer is also the cloud GIS Service Center, and the cloud service warehouse is the window to share cloud GIS services to various users. All cloud services managed in the cloud service warehouse are built based on unified service standards, which ensures that third parties can make arbitrary calls according to the unified call standards, so as to facilitate the global sharing of cloud services. MAPGIS 10 adopts a floating flexible architecture and uses a function warehouse and a data warehouse to manage function services and data services respectively, so as to ensure that functions and data can be completely separated, thus ensuring the “drift,

aggregation and reconstruction” characteristics of cloud services.

4.2.3. Cloud Management Center. The cloud computing layer is also the cloud management center, providing the whole process management and monitoring of cloud GIS services from discovery, registration, and invocation; unified management of all resources of cloud environment operation, including management of cloud online use, delivery, security, and other contents. According to the cloud business model, it restricts the online transaction and payment, security, as well as the registration, discovery, and invocation of cloud services, so as to provide a good operating environment for the cloud.

4.3. Terminal Application Layer (T Layer). The terminal application layer provides users with standard access interfaces, and users can build various terminal applications. It allows users to access the cloud and obtain resources through various terminal devices such as PC computers, intelligent terminals, various monitoring devices, and various application software with distinctive applications running on these devices. Through the cloud services provided in layer C, terminal applications can be freely scalable, customized, expanded, and developed to meet various public and private cloud applications from individuals, groups, enterprises, the public, the government, and so on.

5. Conclusion

GIS technology provides an effective analysis tool for data and graphics processing for urban research. It is widely used in urban planning management, urban information system, and other fields and is mostly combined with transportation research, land use, and other research. At present, the domestic GIS technology mainly focuses on the macro problems of physical space, while some developed countries begin to pay attention to the micro-level analysis of social, economic, and psychological factors, which has been widely used in the reconstruction of old cities. The task of urban village reconstruction in many cities in China is urgent. However, due to the lack of collection of basic data and the application of advanced technical methods, the urban village reconstruction schemes are often lack scientificity and operability. As a means of quantification and visualization, GIS analysis is a good tool for observing and analyzing the construction of urban villages. It is helpful to establish a data database for transformation analysis and to help planners analyze and study the social and economic factors of urban villages. In the future, it can be seen that the application of GIS in urban village reconstruction project provides strong analytical support for the determination of the reconstruction scheme, the implementation of the reconstruction sequence, and the evaluation of investment income.

The emergence of Internet technology has changed the technological innovation path and knowledge acquisition paradigm of enterprises and promoted the construction of digital technology, digital platform, and digital infrastructure. A large number of companies have begun to create brand communities and obtain suggestions for product improvement and innovation from the communities. However, obtaining innovative opinions and inspiration through the community to the final realization is not achieved overnight. It needs to go through the process of knowledge sharing to user interaction, from user interaction to knowledge creation and discovery and from knowledge discovery to innovation contribution. To study the efficiency of Internet community innovation, it is necessary to decompose the innovation process into two parts: problem adoption and problem solution, and then analyze them separately to get the influence combination and path. Taking Xiaomi (one of the world's largest mobile phone manufacturers) online community as an example, this article decomposes the process of issue solution into adoption stage and solution stage by crawling the relevant data of posts through web crawlers, takes the adoption efficiency and problem-solving efficiency as antecedents, and uses fuzzy set qualitative comparative analysis method to analyze the combination of conditions that affect the former two. It is of great significance to improve the knowledge sharing and innovation research of the open innovation community.

1. Introduction

With the increase in the number of manufacturers and the types of goods in the market, consumers have higher requirements for purchasing products. In order to cope with the changes in the market, enterprises maintain the original market by improving the shortcomings of their products and constantly carry out technological and product innovation, expecting to expand the market scale. The emergence of new and powerful Internet technology promotes the construction of digital technology, digital platform, and digital infrastructure, and changes the path of technological innovation and knowledge acquisition paradigm of enterprises to a great extent, so that enterprises cannot carry out closed innovation as in the past. They should refer to external ideas while seeking technological progress. Chesbrough calls this new model open innovation. NASA, Toyota, P&G, IBM, Xiaomi, Starbucks,

Haier, and other enterprises have realized the importance of open innovation, and began to put the technical problems encountered by enterprises on the platform, hoping that third-party personnel can provide solutions; or absorb users' product opinions on the platform, and constantly improve old products and develop new products that meet users' preferences. Therefore, at the moment when open innovation is widely used, the efficiency of adopting and solving the opinions provided by users of the research platform plays an important role in improving products, accelerating innovation, and developing products that meet the needs of consumers.

2. Literature Review

Digital technology and tools have penetrated into modern business, and have been applied in a variety of companies [1]. The use of digital technology has a significant impact on

the innovation process, redefining the creation of products and services [2]. Chesbrough proposed that companies in the new century should not innovate in a vacuum, but should carry out open innovation, and can refer to external opinions when seeking technological progress [3]. With the rapid advancement of information technology, Internet-based user-generated content continues to emerge, providing sufficient knowledge resources for enterprises' open innovation. In order to make full use of user-generated content to improve corporate innovation capabilities and maintain competitive advantages, more and more companies have begun to create and use Internet-based user-generated content platforms, that is, open innovation communities, and have gradually become an important platform for companies to gather innovative resources. At present, innovation platforms with relatively mature systems have been established at home and abroad. InnoCentive platform in the United States is the world's top place for discussion and solutions to problems. Toyota, P&G, and NASA have launched research and development problems on this platform. Starbucks' mystarbucks idea platform has accumulated 150,000 ideas from users in 5 years [4]; one-third of the R&D innovation of Xiaomi company comes from fans, and 80% of the modification opinions of MIUI system come from users of Xiaomi community [5]; Haier has realized significant financial and innovation benefits through open innovation through the hope platform [6]. Therefore, it is necessary for enterprises to carry out open innovation.

At present, the research on open innovation platform includes the following aspects:

- (1) Research on the connotation of open innovation communities: in 2003, Chesbrough introduced the concept of closed and open innovation platform, which defined open innovation as a model. In the open new era, enterprises can use external ideas when seeking technological progress, and combine internal and external ideas into an architecture and system according to the needs of business model [3]. Open innovation community has become an important platform for enterprises to gather innovation resources. Many enterprises relied on the Internet to build a content production and release platform to attract users to directly or indirectly participate in innovation-related activities such as the creativity, R&D, and promotion of enterprise internal products, and carried out high-quality user-generated content creation [7]. Obviously, open innovation community is a platform concept, and its most important constituent element is "knowledge." Through the combination of external knowledge and internal knowledge, new knowledge is generated, and then enterprise science and technology innovation can be accelerated [8]. In addition, some scholars believe that innovation elements are not only limited to knowledge, but also include a variety of innovation resources. For example, Laursen and Salter [9] believe that the important point of open innovation

community is to connect internal and external innovation resources of enterprises, and "user" is also one of the important elements of knowledge collaborative innovation in the open innovation community. The process of technological innovation is no longer completed by enterprises alone. The enterprise can guide users to participate in the innovation of products or services, and promote the innovation of products or services through sharing among users [10].

- (2) Through the perspective of social network and social capital, some scholars studied the behavior and motivation of platform users. For example, some scholars have studied the relationship between open innovation network structure and social network caused by user interaction. Starting from the structural dimension, relationship dimension, and cognitive dimension, there is an article that attempted to explore the relationship between three dimensions of social network and its impact on the user innovation participation behavior, and then analyzed its impact on the utilization of enterprise innovation knowledge points, and constructed a relationship model of user participation in innovation and enterprise innovation performance based on social network [11]. From the perspective of social networks, there was an article taking innovation community members as the research object, incorporating them into the social network analysis framework, and describing customer participation in the context of innovation communities from the three dimensions of network characteristics, network behavior, and network capabilities [12].
- (3) Research on the main body of open innovation platform. Some scholars have studied that the construction of an open innovation platform for small and medium-sized enterprises under the Internet+ should rely on the external environment and professional management and operation teams, and make full use of the resources of large enterprises [13]. Z.Zhenggang and J.Silong [14] studied the construction of innovation platforms for industrial clusters and classified the platforms according to the role played by the government in the process of platform construction and operation. In the context of digital and open innovation, the most significant change in innovation network is that "customer" or "consumer" has become one of the main bodies of the innovation network. These consumers form clusters, surpassing enterprises, universities, and scientific research institutes, and they provide more and more extensive elements for innovation [15].
- (4) Research on platform user behavior. Some scholars analyzed the influencing factors of users' continuous knowledge-sharing behavior in the open innovation community. It showed that the degree of users' self-presentation, available social learning opportunities, recognition of enterprises, and recognition of users

FIGURE 1: The process of internet open innovation.

with creative sharing experiences had a significant positive impact on users' continuous creative sharing behavior [16]. Some scholars used data mining to obtain platform data and studied the impact of quantity, quality, and emotion on individual innovation contribution in the open innovation community [17]. Li et al. [18] conducted theoretical research on the characteristics of leading users in open innovation communities, and proposed three characteristics: demand leadership, active expression, and community influence. Then based on the improved weblog method, the qualitative weblog and quantitative data analysis were combined to construct theoretical steps to identify leading users.

- (5) Research on platform knowledge sharing and collaborative innovation. The latest research progress in this area has examined how the factors of platform users' collective or community level affect the actions and decisions of individuals and enterprises in different ways and under different backgrounds. Versteegen et al. [19] combined the analysis of the individual and collective levels of the use of digital technology within the platform, and explained how collective promotion (i.e., the possibility of target-oriented action by multiple members of the group) is implemented by a group of heterogeneous participants. Zhou et al. [20] studied the influencing factors of user knowledge sharing in the open innovation community, and believed that innovation self-efficacy, result expectation, social identity, and community influence have significant positive effects on user knowledge-sharing behavior. Ren [21] and others have studied the factors influencing innovative users' knowledge sharing in the community under the open innovation paradigm, and explored the development path of their knowledge sharing. These studies indicate that by examining the interaction between individual-level factors and community- (or collective-) level factors, it is expected to have a more detailed understanding of the innovation process of digital platform.

As shown in Figure 1, the Internet open innovation is a process from knowledge sharing to user interaction, from user interaction to knowledge creation and discovery, and from knowledge discovery to innovation contribution.

The current research mainly focuses on the first half of the knowledge innovation process, focusing more on the motivation and behavior of knowledge sharing, the influencing factors of knowledge discovery and user behavior, etc. The research framework and the selected influencing factors and indicators mainly point to the behavior and motivation of users participating in knowledge sharing, and the research on the efficiency of problem-solving in the open innovation community is very limited.

However, it is of great significance for innovation platforms and communities to discover problems from the final solution of problems in products. Only when users get feedback on problems and convey their opinions to enterprises through the platform, the role of innovation communities can form a closed loop, enabling users to play a role in product design and upgrade the final effects. Therefore, the main research work of this article is to analyze the combination of factors affecting the efficiency of problem-solving in the open innovation community, identify the combination of factors contributing to the current efficiency in different situations, and put forward suggestions to improve the efficiency of problem-solving.

3. Research Design

3.1. Research Objects and Data Acquisition. This article chooses Xiaomi community as the research object. Xiaomi Company was founded in April 2010. In only 1 year, its annual income has exceeded 100 billion yuan. In the rapid rise of Xiaomi Company, its unique business model has played an important role. One year after the company was founded, Xiaomi community began to build. In the early days of its establishment, the influence of Xiaomi community was limited, but with the increase of content and functions, it began to play a role in product development, new product promotion, paid rush purchases, and other activities, and became an important bridge connecting companies, products, and users. It is a typical and successful open innovation platform. The crawler is used to crawl the post data in the Xiaomi community forum. The crawled data content includes post type, number of replies, number of approvals, number of views, time of issue creation, time of issue establishment, time of issue development, and time of issue optimization. The time of data extraction is December 2020. After preliminary integration, this article chooses to crawl the relatively complete content of notebook circle, mobile phone manager, router, Redmi note88pro, network signal, cloud service, control center, super power saving, Xiaomi health, Xiaomi Bluetooth headset, and Xiaomi extreme 10 data for analysis.

3.2. Path Identification Method and Variable Setting. This article chooses the fuzzy set qualitative comparative analysis method to identify the combination of conditions that affect the efficiency of the problem being adopted and solved. At first, we introduce the process of the issue solution as shown in Figure 2.

Qualitative comparative analysis first appeared in Ragin's book "Comparative Methods." As a case-oriented research, this method is based on mathematical theories such as sets and Boolean algebra, and it realizes an organic combination of quantitative and directional optimal characteristics [22].

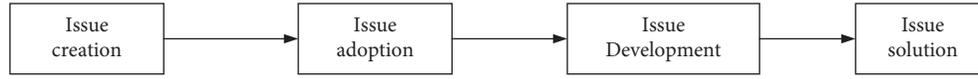

FIGURE 2: The process of issue solution in Xiaomi Community.

Qualitative comparative analysis methods include multivalued set, clear set, and fuzzy set. According to the theory of fuzzy sets, the relationship between sets in reality is not as clear as that in the traditional set theory [23]. According to the concept of fuzzy set, the membership score of a set may be any number between 0 and 1. In a fuzzy set qualitative comparative analysis, each case is regarded as a combination of attributes [24], abandoning the net effect of a single variable, and looking at the problem from the overall perspective and configuration thinking. Different attribute combinations correspond to the results.

After the users put forward questions, only a part of the issues can be adopted by the platform and put on file for settlement, and the settlement time of different issues on file is not the same. Therefore, the fuzzy set qualitative comparative analysis method is used to scientifically reveal the combination of conditions that affect the efficiency of the adoption and settlement of issues, and to deeply analyze under what circumstances the issues will be first adopted and put on file, and what are the characteristics of issues that need less time to solve. Table 1 shows the variable setting of issue adoption efficiency.

As shown in Table 1, issue adoption efficiency is measured by the time difference between question creation and project establishment as the result variable of the analysis; the antecedent variables include the number of dynamics in the circle, the number of employees stationed in the circle, the number of answer groups composed of platform users, the type of post, the number of posts, the number of approvals, and the number of views. There are two types of posts: help and suggestions. The number of posts refers to the number of posts that users reply to in the question posts that have been adopted for filing. The number of approval and the number of views, respectively, indicate the data of approval and views of the adopted issues.

As shown in Table 2, problem-solving efficiency refers to the difference between the time of question creation and the time of solution. When problem-solving efficiency is analyzed as a result variable, the adoption efficiency of the issue needs to be increased in the antecedent variables. The shorter time for the issue to be adopted, the more attention the enterprise pays to the issues, and it will inevitably give relatively more human resources and material resources to improve and solve the issue. Therefore, when we analyze the combination of conditions that affect the efficiency of the issue solution, it is necessary to consider the adoption efficiency put into the antecedent variable.

4. Data Processing

4.1. Descriptive Statistical Analysis. Before in-depth analysis of the data, in order to understand the distribution of the data, the descriptive statistical analysis is carried out first as shown in Table 3.

TABLE 1: Variable setting of issue adoption efficiency.

Variable type	Variable name
The result variable	Issue adoption efficiency
The antecedent variable	The number of dynamics in the circle
	The number of employees stationed in the circle
	The number of answer groups composed of platform users
	The type of post
	The number of posts
	The number of approvals
	The number of views

TABLE 2: Variable setting of issue solution efficiency.

Variable type	Variable name
The result variable	Issue solution efficiency
The antecedent variable	The number of dynamics in the circle
	The number of employees stationed in the circle
	The number of answer groups composed of platform users
	The type of post
	The number of posts
	The number of approvals
	The number of views
	Issue adoption efficiency

From the results of descriptive statistical analysis, it can be seen that the dispersion degree of dynamic variables is the highest, the communities where popular products are located usually have more dynamic, while the dynamic number of products with small audience is limited, so the dynamic will be less. And the standard deviation of other variables is not different, which indicates that the data distribution of these variables is relatively concentrated and the range of change is small.

In this article, the post type variable is treated as a 0–1 dichotomous variable, in which 1 corresponds to the help post and 0 corresponds to the suggestion post. The descriptive statistical analysis of the dichotomous variable is of little significance. Through simple statistics, it is found that the vast majority of post types are help type, and a small part are suggestion type.

4.2. Data Calibration. The calibration reported below and the set relation analysis was performed using the fuzzy set/QCA 3.0 program [25]. Data calibration is to set up three critical points: complete membership point, cross membership point, and complete nonmembership point, and use fsQCA software to convert the data to 0–1. When selecting the critical point, according to the existing theory and knowledge, combined with the data and quantile points, this

TABLE 3: Descriptive statistical analysis of variables.

Variable name	Mean	Std	Min	Max
The number of dynamics in the circle	27038	1591.72	1132	84000
The number of employees stationed in the circle	38	3.01	11	135
The number of answer groups composed of platform users	74	3.30	17	155
The number of posts	81	14.39	1	1334
The number of approvals	29	18.92	0	3933
The number of views	189	22.00	1	1560
Issue adoption efficiency	19	2.96	0	327
Issue solution efficiency	31	3.55	0	332

TABLE 4: Data calibration.

Variable name	Complete	Cross	Complete non
The number of dynamics in the circle	1132	20000	63000
The number of employees stationed in the circle	11	17	135
The number of answer groups composed of platform users	17	79	155
The number of posts	1	8	541.4
The number of approvals	0	2	42.6
The number of views	1	48	941.6
Issue adoption efficiency	0	4	114.4
Issue solution efficiency	1	11	139.8

article refers to the calibration methods of Wei et al. [26] and Fiss [27], and defines 95% as the full membership point, 50% as the cross membership point, and 5% as the complete nonmembership point.

4.3. Necessity Analysis. Since the post type is a dichotomous variable, the data itself is already between 0 and 1 (Table 4), so it is not necessary to calibrate the data, so it can be used directly [28].

After the data calibration, the data need to be checked for necessity. If a necessary condition appears in the antecedent variable, the parsimonious solution obtained by software processing data will eliminate the necessary condition, but only when the condition appears in the condition combination, the result will occur. Therefore, the necessity of checking variables is an essential step. Generally speaking, if the consistency is greater than 0.9, it is considered as a necessary condition.

4.3.1. Necessity Analysis of Adopting Efficiency as an Antecedent Variable. As shown in Table 5, for the results of the necessity of adoption efficiency, it is found that the consistency of post type is as high as 0.97, which indicates that the type of help or suggestion has a significant impact on whether the topic is adopted. Therefore, it is necessary to eliminate the necessary condition of post types in the subsequent data processing.

4.3.2. Necessity Analysis of Solution Efficiency as an Antecedent Variable. As shown in Table 6, for the results of the necessity of solution efficiency, it is found that the consistency of post types is as high as 0.98, which indicates that whether the post is a help or a suggestion type also has a significant impact on whether the issue is implemented.

Therefore, it is necessary to eliminate the post type in the subsequent data processing.

4.4. Sufficiency Analysis. Sufficiency analysis is needed after the necessity test. Different from the above necessary condition analysis, configuration analysis attempts to reveal the sufficiency analysis of the results caused by different configurations composed of multiple conditions [29], that is, to discuss whether the set composed of multiple antecedent conditions is a subset of the result set. The same as the necessity test is that it is necessary to set a minimum consistency threshold to check the sufficiency. The minimum recommended threshold of consistency is 0.75. The previous articles on the qualitative comparison of Fuzzy Sets set different thresholds for consistency, Zhang Ming sets the threshold value to 0.76; Zhao sets the threshold value to 0.75; and Zhang Weiguo sets the threshold value to 0.8. After the analysis of the test threshold, 0.85 is selected as the consistency threshold, and the case threshold is set to 1 [28, 30, 31].

Through the qualitative comparative analysis of fuzzy sets, we can get the parsimonious solution, intermediate solution, and complex solution. The parsimonious solution includes all the logical remainder, but does not consider whether the logical remainder is reasonable, so the parsimonious solution often deviates from the fact; the complex solution does not include any logical remainder, only observes the solution formed by the case data; and the intermediate solution includes the theoretical remainder which is in line with the expectation of the theoretical direction and verified evidence. Some articles choose different solutions to analyze the results. Wan and Wang chose to analyze the complex solutions; Zhang reported the intermediate solutions supplemented by the simplified solutions; Wen and Fiss [27, 28] choose to analyze the intermediate solutions. Due to a large number of paths, in order to better

analyze the characteristics of each path and the relationship between paths, we choose to interpret only the intermediate solution.

4.4.1. Sufficiency Analysis of Adopting Efficiency as an Antecedent Variable. As shown in Table 7, for the sufficiency analysis [32–38], the abbreviation of the variable will be used below. We use DY (dynamics) to replace the number of dynamics in the circle, use ES (employees stationed) to replace the number of employees stationed in the circle, use GOA (group of answer) to replace the number of answer groups composed of platform users, use PO (posts) to replace the number of posts, use AP (approval) to replace the number of approval, and use VI (views) to replace the number of views.

Since the variables of dynamic, employees stationed, and answer group are platform-level variables, and the variables of post number, the number of approval, and views are issue-level variables, different paths can be classified and analyzed according to the level of function. It can be seen from the

Table 7 that the overall consistency of the obtained path is 0.834, which is greater than the set threshold, indicating that the antecedent condition of the corresponding case composition is the sufficient condition for the occurrence of issue adoption. The overall coverage rate of the path is 0.785, which shows that the results of this article can explain 78.5% of the cases.

There are only two ways to act through the issue level. Among them, the core function is the number of views and posts, which measures the user's attention to the problem. Even if the platform variable does not play a significant role, the more likely the problem will be adopted as long as there are enough customers who pay attention to the issue and the number of views on the topic reaches a certain scale. If the general and significant defects of the products cause a lot of attention, the possibility of the issue being adopted will increase.

There are two paths that work through the platform level. The core variable in the first path is the answer group, and the core variable combination in the second path is dynamic and employees stationed. From the comparison of the two

TABLE 7: Sufficiency analysis of adoption efficiency.

Function level	Conditional combination	Raw coverage	Consistency
None	$\sim DY^* \sim ES^* \sim AP$	0.357	0.902
Issue	$\sim DY^* \sim ES^* VI$	0.480	0.886

paths, it can be concluded that when the issue-level variables do not play a role, the interpretation group variables and dynamics, and the variable combinations of employees stationed can replace each other to improve the efficiency of topic adoption. This path is suitable for companies that already have obvious improvement directions and optimization plans for their products, and file a case after a small number of customers have put forward optimization requirements.

Through the dual level of platform and issue, there are six paths, of which five paths have more than or equal to two core variables at the platform level, and three paths have all variables at the platform level, which shows that the factors at the platform level can more affect the adoption of problems. In the combination with platform variables, the approval number appears three times, the number of posts appears two times, and the number of views appears one time. The approval number and the number of posts often have clear optimization and improvement needs, which can promote the adoption of problems better than the number of views. This path

describes that the enterprise itself has the intention of optimization. After a large number of customers have clear optimization requirements for a product at the same time, it promotes the platform to pay attention to the problem and take optimization actions.

4.4.2. *Sufficiency Analysis of Solution Efficiency as an Antecedent Variable.* Table 8 shows the results of the sufficiency analysis [39–45] when the solution efficiency is taken as an antecedent variable. Using the same classification method, the results are divided into three categories. It can be seen from Table 7 that the overall consistency of the obtained path is 0.859, which is greater than the set threshold, indicating that the antecedent conditions of the corresponding case composition are sufficient conditions for the occurrence of issue adoption. The overall coverage rate of the path is 0.735, which shows that the results of this article can explain 73.5% of the cases.

Among the six paths at the issue level, the core variable combinations of the two paths with higher coverage are adoption efficiency, the number of posts, adoption efficiency,

and the number of views. At the same time, the adoption variable appears three times, the number of views appears three times, the number of approval appears two times, and the number of posts appears two times in these six paths. From the summary of the characteristics of the path: whether the topic is adopted or not is the key to whether the problem can be solved. Therefore, the company pays attention to the issue, and the issues that are filed will definitely respond later; meanwhile, the characteristics of path variables are the same as those in the adoption stage, and the number of views and posts are high-frequency variables, which indicates that the attention of a large number of users not only improves the enterprise's attention from the beginning of the problem establishment, but also promotes the platform interaction. In the process of problem-solving, continuous attention can also supervise the efficiency of enterprise problem-solving. This path corresponds to the implementation of the problem that has been filed by the enterprise and has a large number of views.

In one path at the platform level, dynamic and employees stationed are its core variables, which play a significant role in promoting the implementation of issues. However, the coverage rate of this path is relatively low, indicating that most of the problems in reality cannot be solved by platform alone.

There are seven paths formed under the dual effects of platforms and issue, and the number is slightly more than the first type. At this level, the highest frequency of platform variables is the answer group, which refers to the group of question-answering users in the circle. The larger the size of the answer group, the more likely the problem is to be solved. The second highest frequency variable is dynamic, which refers to the active state of users in the circle. A circle with more dynamics indicates to a certain extent that the number of users who use the product and follow the product is large. The variables that appear more frequently in the issue level are the number of approval and the number of posts. Users can convey clear modification opinions through posting or expressing opinions. Therefore, this group of paths describes the situation that has been concerned by a large number of users, and the problems that have put forward clear opinions or have been concerned by a large number of users, and in the circle where the questions are located, the larger scale of the answer group are executed more efficiently.

4.5. Robustness Test. Robustness testing can be done from two perspectives: set theory and statistical theory. From the perspective of set theory, the robustness test is realized by changing the calibration threshold and increasing or decreasing variables; from the perspective of statistical theory, the robustness test is realized by changing the data time span and other methods. In this article, the robustness test is carried out from the perspective of set theory. After changing the threshold of the adequacy test to 0.86, the path is basically consistent, which proves that the results are robust.

5. Research Conclusions and Prospects

5.1. Research Conclusion. By collecting various data on posts in the Xiaomi community, the fuzzy set qualitative

comparative analysis method is used to identify the combination of conditions that affect the efficiency of issue adoption and solution.

First of all, in the necessary analysis, the consistency of post type is as high as 0.97, which is the necessity index. So, we need to delete this variable in the sufficiency analysis. In this article, when processing the data, the assignment of the post type for help is 1, and the suggested assignment is 0. Usually, when users have found that the product has problems hindering their use, the help-seeking type of post appears and users will seek help from enterprises through the platform. While the suggestion type of post is often that the product itself does not have problems hindering the use, and users hope to get a better sense of use by improving a certain aspect of the product for more convenient use. When the product is improved, it is generally updated on the basis of the normal use of the product, so the help type post will have higher efficiency in adoption and implementation than the suggestion type post.

Secondly, from the path analysis of adoption efficiency and solution efficiency, we can see that the most common path is the combination of platform-level variables and issue-level variables. This shows that in the whole process from the emergence of problems to the solution, what we need is the cooperation of the platform and the users. Only when the users actively raise problems and the platform actively cooperates to deal with problems, can we more effectively promote the problem solution. We can find that there are two paths through the issue level, two paths of the platform level, and six paths of the platforms and issue level when adoption efficiency is an antecedent variable. There are six paths through the issue level, one path of platform level, and seven paths for the two-layer interaction of issues and platforms when solution efficiency is an antecedent variable. From the adoption stage to the solution stage, the number of paths through the role of the issue-level increases significantly, and a single issue level variable as the core variable can become a path of the solution stage, which indicates that the fluctuation of the issue-level variable can significantly affect the process of the issue implementation.

Thirdly, in general, the coverage of paths with fewer core variables is higher than that with more core variables. The greater the number of core variables, the higher the requirements for corresponding cases, and the fewer cases corresponding to them.

5.2. Shortcomings and Prospects. In this article, the data obtained from the Xiaomi community is limited. At present, the data only includes the platform level and the issue level. If we can increase the personal information data of platform users and the related data of different circles, we can establish a more reasonable structure. We can analyze the influencing factors of problem adoption and problem solution from the three levels of platform, circle, and issue, and carry out more in-depth research. If we can get more relevant data about the appropriateness of problem solution methods, we can also study the combination of variables to promote the generating of high appropriateness solutions.

With the development of the intelligent and interactive power system, the elements of distribution network planning continue to increase. The distribution network connects the transmission system and individuals, directly affects the individual's power consumption experience, and is a key link in the power system. A reasonable planning scheme can not only improve the power supply capacity and reliability of the distribution network but also fully apply the data of each system in the distribution network to realize the optimal planning of the medium-voltage distribution network driven by data. Firstly, this paper constructs the CIM model and the distribution network topology model and establishes the wiring pattern recognition feature library. The network reconstruction and planning method research was carried out for the target line, and a typical operation scenario of the distribution network was generated. At the same time, based on the time period network loss index, the distribution network reconfiguration optimization model and distribution network expansion planning model are established, and the solution method of the distribution network reconstruction and expansion planning model is expounded. A reconstruction optimization scheme with the best overall network loss performance is in the network operation scenario. The experimental results of the final example show that based on the proposed time period network loss index, the overall operation loss of the distribution network in a period can be calculated more accurately, and the optimized planning scheme is more suitable for the load power consumption characteristics of the region, and the method has certain feasibility.

1. Introduction

Since the reform and opening up, my country's economy has matured rapidly, people's living criteria have been constantly heightened, and the demand for electric energy has continued to rise. With the continuous acceleration of my country's socialist modernization handle, electricity plays an increasingly important role in all fields of society. Electricity supply and safety have become the basis for national, social, and economic development and are related to national security issues. With the rapid construction of modern allocation net and the construction of power big data platform, the informatization and automation level of allocation net have been greatly improved. The wide application of allocation net GIS system, production management system, operation management system, and allocation net automation system makes the data analysis between different

systems of the allocation net easier, and provides a solid foundation for the application of big data to the planning and optimization of the allocation net. Base. In 2016, my country's electricity "13th Five-Year Plan" clearly stated that it is necessary to increase the construction of the allocation net. The "13th Five-Year Plan" period, a modern allocation net that is compatible with a well-off society, will be basically built [1]. The implementation of the "13th Five-Year Plan" for electric power has significantly accelerated the transformation and construction of my country's allocation net system, and the power supply capacity, safety, and reliable of the allocation net have been greatly improved. However, there are still many problems in the current allocation net operation, such as the speed of social development is too fast and the load is not balanced, resulting in heavy overload problems in allocation net lines and station areas [2]. Therefore, the optimization plan and structure of the

allocation net still need to be improved. The 10 kV medium-voltage allocation net is the core component of the allocation net, which directly affects the individual's power experience and is also a key link in the power system. A suitable allocation net grid planning optimization scheme should not only have good performance in uncertain scenarios but also improve the power supply capacity, reliability, and equipment utilization of the network, which is more conducive to social and economic development [3]. If there are defects in the planning and optimization scheme of the allocation net grid, it may lead to unstable network operation, poor power supply capacity and reliability, and even detrimental to the long-term development of society [4]. Therefore, it is necessary to study the optimization planning method of 10 kV medium-voltage allocation net.

The identification of the wiring pattern of the allocation net feeder is an important part of the distribution planning and optimization work. This work mode, which mainly relies on the manual judgment of planning staff to screen and integrate different system data and problems, and then propose corresponding planning and construction projects based on experience, and then carry out corresponding calculation and analysis and comparison, not only has a huge workload but also because of the data. The lack of calculation and analysis tools leads to the remediation plan relying more on manual experience and lack of rigorous calculation and analysis. In the previous allocation net optimization planning work, extreme situations are often considered, which may not match the actual situation. So as to make the allocation net optimization planning scheme more suitable for the actual allocation net, it is more necessary to consider the actual operation scenarios of the regional allocation net. With the gradual deepening of the construction of the big data platform, the allocation net planning has the opportunity to obtain more sufficient operation data than before, so that based on the data-driven idea, according to the allocation net GIS system, production management system, allocation net automation system, and operation comprehensive analysis of data from various systems such as management systems. We realize the analysis and simulation of the typical operation scene of the allocation net under the data drive. By considering typical operation scenarios, combined with the existing structural requirements of the power grid, the network can be more reasonably optimized to improve the network operation performance and better arrange the investment of capital resources. With the more and more extensive application of artificial intelligence algorithms in practical work, the work that could only be done manually in the past can be realized through intelligent discrimination and analysis of computers.

2. Research Status of Optimization Planning Methods for Distribution Network at Home and Abroad

With the rapid construction of the modern allocation net and the construction of the power big data platform, the informatization and automation level of the allocation net

have been greatly improved, and the wide application of GIS systems, production management systems, power marketing systems, and allocation net automation systems makes the data analysis of the allocation net easier and lays a solid foundation for the data-driven optimization planning of the allocation net. With the more and more extensive application of artificial intelligence algorithms in practical work, the work that could only be done manually in the past can be realized through intelligent discrimination and analysis of computers. In the actual allocation net optimization planning work, the export and comprehensive analysis of the allocation net historical data are mainly done manually, and the comparison of the implementation effects of different planning schemes requires a lot of manual calculations. This work mode, which mainly relies on the manual judgment of planning staff to screen and integrate different system data and problems, and then propose corresponding planning and construction projects based on experience, and then carry out corresponding calculation and analysis and comparison, not only has a huge workload but also because of the data. The lack of calculation and analysis tools leads to the remediation plan relying more on manual experience and lack of rigorous calculation and analysis.

2.1. Research on Optimization and Reconfiguration of Distribution Network. Distribution network reconfiguration is an allocation net optimization method that enables the allocation net to achieve the optimal operation mode by changing the opening and closing states of the segment and tie switches in the allocation net, on the premise that the allocation net is connected and radiated. The optimization goals of allocation net reconfiguration usually include balancing the load, reducing network losses, and improving power supply reliability [5–7]. On the time scale, we aimed at optimizing the network structure for the manipulation of the allocation net, while dynamic reconfiguration takes into account the time scale, and reconfigures and optimizes the manipulate of the allocation net within a period of time. Static reconstruction generally takes the typical load of a certain period as the object to optimize the allocation net structure, and the research focuses on the improvement of the optimization algorithm [8, 9]. In the literature [10], the inertia weight is introduced into the traditional firefly algorithm, and chaos is used. Theoretical adjustment of algorithm parameters, and the addition of an elite retention strategy to solve the problem of reconfiguration of allocation net with DG, improves the calculation speed and global performance of the algorithm. Dynamic reconstruction studies the real-time and dynamic optimization of the network structure during the manipulation of the allocation net. Usually, the specific operation modes of each time period are reconstructed, respectively [11, 12]. Reference [13] uses the interval number to DG and continuous load forecasting, uses the improved FCM (Fuzzy c-means) algorithm to divide the time period of the reconstruction, and uses the decimal particle swarm algorithm to solve the static reconstruction problem to achieve dynamic reconfiguration of allocation net.

The main problem of static refactoring is that refactoring in the face of a single typical operating scenario does not necessarily guarantee the optimal refactoring target for the entire period. The traditional typical scenario construction handle lacks scientificity and is often formed by using the maximum operation mode of the allocation net or the distribution transformer capacity combined with the load coefficient. Therefore, allocation net reconstruction scheme makes it to perform the best in the entire action period of allocation net. Strictly speaking, traditional allocation net reconfiguration belongs to the category of operation optimization. However, in recent years, power grid companies have put forward indicators of capital utilization efficiency and equipment utilization, and more reasonable arrangements for planning funds and planning project progress have become one of the very important considerations for planning departments. Due to the limitation of investment scale and project construction period, through reasonable transformation of distribution network, the power supply capacity of existing distribution network framework is fully explored, load distribution is balanced, network loss is reduced, and voltage level is improved. It is effective in the utilization rate of funds with equipment utilization to solve the weak links of the existing power grid.

2.2. Research on Distribution Network Planning. The research on distribution network planning develops with the development of society. The early research on allocation net planning is mainly about the location and capacity of power supply and the planning method of grid. From the perspective of time, load considerations can be divided into static load planning and dynamic load planning. From the perspective of planning objects [14–16], planning can be divided into subsystem planning and overall system planning [17–19]. Static load planning regards the load of the network as constant and considers the network planning in a relatively single scenario; dynamic load planning considers the load changes of the network and usually divides the planning into multistage planning. Subsystem planning is the planning for a single system of the allocation net, which can usually be divided into power subsystem planning and grid planning. The overall system planning is the planning for the overall system of the allocation net. The relationship is between the power supply and the grid. In the static programming model, the literature [20] used the 0, 1 mixed integer model for the first time in the circuit planning of the allocation net. In the dynamic programming model, reference [21] uses the dynamic load planning model to plan the allocation net substation, and the model solves the problems of the capacity, location, and construction time of the substation. In addition, the current allocation net planning model research includes economic model, reliability model, comprehensive model, and research on practical engineering application of allocation net planning. Reference [22] established a planning model with the goal of maximizing the annual comprehensive income of DG operators, the smallest annual comprehensive cost of power distribution companies, and the largest annual comprehensive income of

individuals participating in demand-side response. Reference [23] added reliability cost calculation to the established multistage planning model and considered constraints such as energy storage charging and discharging constraints and extreme load scenarios. Reference [24] is oriented to the allocation net problem and designs a method for automatically generating planning schemes for solutions to different problems in the allocation net, and quantitatively forms an automatic generation method for various typical problems. The planning method is based on the established planning model. In terms of planning algorithms, the use of allocation net optimization planning algorithms can be roughly divided into mathematical optimization algorithms and heuristic algorithms. Because there are usually a large number of integer decision variables in the allocation net planning problem, there are often linear and nonlinear objective functions and constraints in the planning model. When solving large-scale system decision-making combinations, mathematical optimization algorithms are prone to the “curse of dimensionality” problem, so it is difficult to use traditional mathematical optimization methods to solve them directly. By contrast, heuristic algorithms are now also called artificial intelligence algorithms, which solve problems by simulating the evolution and development of things in life.

3. Building a Data-Driven Distribution Network Operation Scenario Method

A large amount of historical load data of the distribution network records the load operation characteristics of the allocation net. If an allocation net optimization planning scheme that is more in line with the regional load power consumption characteristics is required, the operating feature of the allocation net should fully considered. In this paper, the generation method of typical operation scenarios is introduced. Based on this, a period network loss exponent is put forward to assess the overall network operation wear and tear manifestation of the scheme in the whole scheduled time. The not-alike load amalgamation and each node of the allocation net are called the operation scenarios of the allocation net. Because the load points in the allocation net are different, the load type operation scenes of the allocation net are very large. Directly taking the node load value as the node load feature is able to rashly write the action scene of the allocation net at a fixed time hint, no more than its troublesome to depict the operation scene of the allocation net in a fixed time hint interval. To fully consider the historical operational site of the allocation net and reduce amount of calculation, this paper proposes a period network abrasion index in light of the typical operating scenarios obtained by clustering and the proportion of the duration of the scenarios, to achieve a practical overall evaluation of the reconstruction scheme. The allocation net is divided into several types of typical operation scenarios and their time proportions in a period of time. A network loss evaluation index is established as follows:

$$H_i = f_{si}(x)t_{si}, \quad (1)$$

$$H = \sum_{i=1}^K H_i. \quad (2)$$

In formulas (1) and (2), f_{si} is the network fray count function in the i typical operating script, which originates from the propulsion spread calculation equation, x is the allocation net reconstruction scheme, the switching condition vector, t_{si} is the time occupation the i operational site ratio, K is the quantity of representative scene, H_i is the network loss index of the i scenario, and H is the network loss index of the entire period, all in power units.

Since the calculation of the time period network loss index requires the calculation of the network loss index of each typical scenario, the accuracy of the network loss index of each scene is the premise of the validity of the time period network loss index. To verify the validity of the proposed network loss index during the period, the load data of an allocation net for 30 days is analyzed and calculated in the scenario. The network loss of all actual scenarios in various scenarios is used as a comparison, and the calculation results are shown in Table 1.

The actual network loss in the scenario in Table 1 is the precise network loss obtained after the power flow calculation for all the monitoring sections classified in the typical scenario, which requires a large amount of calculation. The scenario network loss index comprehensively considers the network loss and its time proportion corresponding to typical scenarios, which is different from the network loss. However, the data in the table show that the use of the time-scenario network loss index can correctly characterize different scenarios while reducing the calculation scale. The relationship between the sizes of the network loss shows the effectiveness of the index to characterize the network loss of the allocation net.

4. Reconstruction of Distribution Network and Model Planning

Based on the idea of comprehensive analysis of distribution network representative scene, combined with time period network abrasion index, a mathematical model of allocation net reconfiguration optimization and planning is established. Due to the high global requirements of the algorithm to solve the model, a relatively mature genetic algorithm was selected to optimize the model. The algorithm coding method and the method of judging the effective solution were introduced, and the feasibility of the method was verified by an example analysis.

4.1. Distribution Network Reconstruction and Planning Based on Operation Scenario Analysis. The flow chart of distribution network expansion planning in this paper is shown in Figure 1. Through the work in the previous chapters, the current status information data of the allocation net have been obtained, including the topology structure of the allocation net and the historical load of the allocation net. On

this basis, according to the installation information reported by individuals, the analysis and construction of the future allocation net are carried out, and feasible lines are pre-established. A planning model with the lowest comprehensive cost is established, and the genetic algorithm is finally used for optimization. Allocation net expansion planning refers to the reasonable expansion and optimization of lines and substations under the premise of satisfying regional development and current operation to further improve the power supply capacity and reliability of the network [25].

To improve the efficiency, the cost of the planning scheme should be reduced as much as possible while meeting the requirements of the expansion plan. In actual projects, the cost of allocation net expansion planning mainly includes the cost of new lines and the cost of operating losses after the lines are built. The goal of the allocation net expansion planning in this paper is to reduce the cost of new lines and operating losses, and establish a mathematical model with the lowest comprehensive cost as the planning optimization goal.

4.2. Genetic Algorithm for Distribution Network Reconfiguration and Planning. The distribution network reconstruction problem is a large-scale nonlinear mixed integer programming problem. It is easy to converge to the local optimum when solving so that the algorithm jumps out of the local optimum and calculates to the global optimum solution hot spot. The methods for solving nonlinear optimization problems can generally be divided into mathematical optimization algorithms and heuristic algorithms. Among them, the mathematical optimization algorithm is prone to the “curse of dimensionality” problem when solving larger system decision-making combinations. Therefore, the heuristic algorithm is more widely used in comparison, such as the use of the following algorithms: the experimental design of the three groups: the allocation net reconstruction modus in the light of the used to gain reconstruction scheme 1 as group 1, an average load scenario is established, and the reconstruction scheme 2 is solved as group 2 and is used for comparison as group 3. We calculate the period network loss index of each group of reconstruction schemes and the homologous equivalence net wear and tear power calculation, the homologous equivalence net wear, and tear power calculation under the power. The obtained reconstruction optimization scheme and corresponding index calculation are shown in Table 2.

The calculation results of the total network loss of each group of schemes are shown in Table 3.

The average voltage in the node period of the allocation net under each scheme is shown in Figure 2.

It can be seen from Figure 2 that the reconfiguration optimization scheme obtained by the method proposed in this paper makes the average voltage of each node more balanced during the period, and the network operation is improved. Table 3 shows that the reconstruction scheme 1 has taken many by optimizing the network loss index of the scheme period. Compared with the reconstruction scheme 2,

TABLE 1: Comparison of network loss scenarios.

Scenes	Scenario duration	Duration ratio (%)	Scenario network loss	Scenario network loss index	Scenario actual network loss amount
1	161	22.36	127.96	28.61	20.86
2	147	20.42	591.66	120.80	87.49
3	159	22.08	40.49	8.94	6.56
4	147	20.42	201.85	41.21	29.85
5	106	14.72	358.51	52.78	38.32
Sum	720	100	1320.47	252.34	183.08

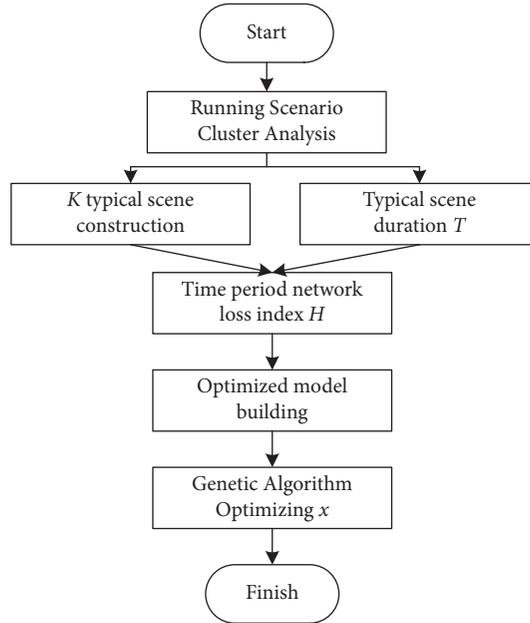

FIGURE 1: Process of allocation net reconfiguration.

TABLE 2: Reconfiguration solutions and corresponding performance.

Group	1	2	3
Reconstruction plan	9,14,28,33,36	7,9,14,28,32	33,34,35,36,37
Network loss index H during the plan period	154.76	173.8	307.93
Network loss P under the average load scenario	146.67	139.98	246.84

TABLE 3: Calculation results of total network loss of each solution.

Group	1	2	3
Quarterly actual total network loss	343.95	386.49	685.37
Equivalent total network loss for scenario analysis	341.71	383.75	679.91
Calculation error	2.24	2.74	5.46
Equivalent total network loss for average load scenarios	323.85	309.08	545.02
Calculation error	20.1	77.41	140.35

the performance is better in the whole period, and the actual quarterly total compared with scheme 2, the network loss is decreased by 42.54 MWh. Compared with scheme 3 without the optimization of allocation net reconstruction, the grid power scheme 2 is decreased by 298.88 MWh. From the calculation of the indicators of each scheme in Table 2, scheme 1 also shows simply using a single average load value. Instead of load characteristics, it is impossible to obtain the

optimal reconstruction scheme within the allocation net. The simulation of the example verifies the feasibility of the allocation net reconstruction and planning method based on the analysis of the operation scenario. The lack of calculation and analysis tools leads to the remediation plan relying more on manual experience and lack of rigorous calculation and analysis. The results of the example show that the reconstruction and planning scheme considering the regional

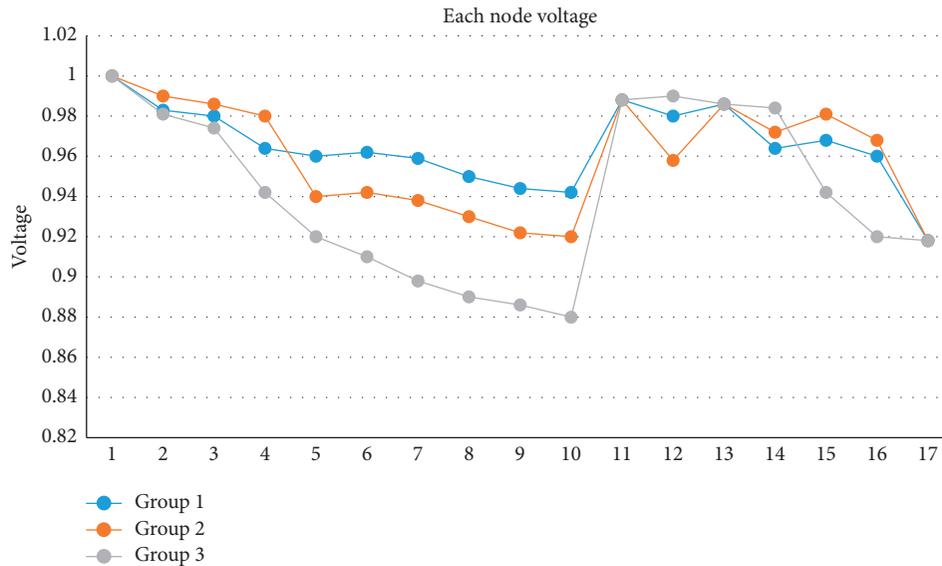

FIGURE 2: Node voltage under each solution.

allocation net operation scenario can be more effective than considering a single operation scenario. It fits the load power consumption characteristics of the region, and the overall performance is better.

5. Conclusion and Outlook

This paper mainly studies and applies the data of each system in the allocation net, and carries out the research on the optimization planning of the medium-voltage allocation net, including the identification of the wiring pattern of the medium-voltage allocation net and the optimization and expansion planning of the network frame reconstruction. The data of the method study come from the allocation net GIS system, production management system, operation management system, metering system, and allocation net automation system, based on the CIM model obtained by each system, regional historical load data, load increase, and decrease report data research. The topology analysis and wiring pattern recognition of allocation net based on CIM are realized.

5.1. Summary. Aiming at the related problems in the optimization and planning of allocation net reconfiguration, an allocation net data-driven allocation net operation scenario generation method is introduced. The typical operation scenarios of allocation net reconstruction are generated. In the region and the information of industrial expansion and installation, the planning scene of the allocation net is generated, and the effectiveness of the scene generation is analyzed. The mathematical model and solution method of allocation net reconfiguration and planning are introduced, and the mathematical model of allocation net reconfiguration and planning for operation scenario analysis is established based on the time period network loss index. Since the mathematical model has high requirements on the global convergence ability, a relatively

mature genetic algorithm with strong as algorithm, and coding method of the genetic algorithm and the effective solution judgment method are introduced. The data-driven allocation net optimization planning method is as follows. Through the allocation net topology analysis and wiring pattern recognition, the wiring to be optimized with heavy overload problems is found, and the reconstruction optimization solution is given priority. We make expansion plans. The simulation of the example verifies the feasibility of the allocation net reconstruction and planning method based on the analysis of the operation scenario. The results of the example show that the reconstruction and planning scheme considering the regional allocation net operation scenario can be more effective than considering a single operation scenario. It fits the load power consumption characteristics of the region, and the overall performance is better.

5.2. Prospect. Although the research has achieved certain results, there are still many problems that need to be improved. The research prospects are as follows:

- (1) The historical load data from the allocation net and how to make full use of the historical load data to construct a more realistic operation scenario can still be deeply considered and studied, in the planning research of this paper; although a certain load margin is reserved in the setting of the allocation net planning requirements, there are still many uncertain factors in the actual allocation net operation, such as the uncertainty of the future load. The research considerations such as the uncertainty of electricity prices and electricity prices are still not in-depth enough.
- (2) In the proposed method for optimization, reconstruction, and expansion planning of allocation net operation, the optimization algorithm used is the

widely used genetic algorithm, but when applied to large-scale networks, local optimal results may still occur. Improvements in use can still be studied.

Artistic graphic design is the aesthetic result of the designer's fusion of various elements, with a high degree of independence. Considering the lack of significant visual design scope and aesthetic indicators of graphic design, our research aims to build an upgraded network model that can categorize different types of artistic graphics with labels and realize the free combination of graphic solutions. We realize the scheme reorganization of artistic graphic design from the perspective of computer vision and propose the artistic graphic design method based on memory neural network. We built a computer vision environment and reconstructed the computer vision network to set up an independent deep camera vision range calculation law. Considering the artistic graphic region segmentation problem, we propose the self-attentive mechanism, which can quantitatively segment different artistic graphic regions according to temporal features, before arranging them in a sequence to obtain the graphic region feature vector. We also add the LSTM structure based on the attention mechanism to match with the self-attention features of the graphical region segmentation module and pass the matched attention feature vector to the LSTM network to extract the labeled text feature information of the graphs. To test the effectiveness of our method, we build a database of artistic graphics and set up an adaptive training process. We also compared deep learning methods of the same type, and the experimental results proved that our method outperformed other deep methods in artistic graphic design by keeping the scheme reorganization accuracy and quantitative evaluation of artistic models above 90%.

1. Introduction

The most critical purpose of art graphic design is to solve the positioning solution and emergency plan of the product in the complete solution. During the establishment of the final solution of the product, different design processes and emergency measures need to be presented in visual communication in real time [1, 2]. Based on the artistic design needs of the client's feedback, the appearance and approach are reconstructed in terms of appearance, methodological improvement, and style review on different levels such as screen, space, structure, and logic. In the field of visual design, textual language is active in another way in the coordination of solutions. Professional artists and design will communicate textual elements to the audience in visual form according to the client's perception of the product, and this creative design style is the key point of figuration of artistic graphic design [3]. The representation of artistic graphics is shown in Figure 1.

The elements of art graphic design consist of both static and dynamic, and for all artistic design, graphic design applies to a range of disciplines such as painting, sculpture, and drawing. Graphic design as a basic discipline is widely used in various art industries and is also used in industry. Selecting independent design elements, building perceptual logic models, and constructing visual environments according to different design principles are all part of artistic graphic design. Considering the high professional requirements of artistic graphic design for manual labor, many researchers started to study automatic combination systems for artistic graphic design [4–7]. This research requires the integration of an artistic graphics database, computer vision unit, deep learning algorithm unit, data preprocessing unit, etc. Many researchers have already started their work accordingly.

Artistic graphic design solutions generate many unstable situational factors when it comes to human-environment communication scenarios. When dealing with image key

FIGURE 1: Expression of artistic graphics.

issues feature extraction, most researchers take the approach of fusion of different algorithms. Behavior recognition algorithms are mainly justified for personal graphic design, and image recognition algorithms are mainly utilized for environmental static buildings [8, 9]. Combining the two algorithms, dynamic features of the person and static features of the environment can be obtained separately, and matching the appropriate classifier can subdivide the person's action features and map them with static features. Most researchers in artistic graphic designers prefer to use deep learning methods in the experimental phase [10–14]. Deep neural networks can capture different types of graphical features, and in artistic scene construction, different levels of combinations can be generated in the design scheme depending on the database coverage of the graphics. Each combination has independent network training parameters with generalizability. In the early visual communication research, researchers tried to construct 3D scenes using deep cameras, using deep learning algorithms to learn pixel elements in the scenes, and embedding the trained models into the artistic graphic design system, which can automatically match different scene combinations according to the customer's needs. Customers can choose the corresponding graphic design solutions according to their needs. The application of deep learning accelerates the speed of scenario design and reduces the complexity of scenario design. In convolutional neural network weight screening, the training parameters and weights can be specified within a specified threshold according to the complexity of the original graphic data, and the model with the best graphic design is used in the test results.

The current character recognition algorithms cannot achieve nodal feature connection at the temporal level, resulting in missing longitudinal features between nodes at

the time of acquisition. In the process of predicting behavior, artistic graphic design requires the dynamic coexistence of character features and environmental features, but the spatial information error is impossible to compensate for at the temporal level, which causes the problems of time consuming, inefficient, and low accuracy in image design solution generation [15–17]. To meet the special needs of different artistic graphic designs, some researchers have adopted 3D scanners for scene reconstruction and then used motion capture methods to reconstruct characters and environments on demand. Such an approach enables directed scene reconstruction for different graphic design projects, and researchers who adopt this method mostly use RGB images in the selection of behavior recognition data. Although this method has high timeliness and low experimental cost, it is the preferred method for most researchers. However, the method requires a certain experimental environment, and the graphical design scheme can be miscombined in the case of unstable nonstructural factors. To solve this problem, some researchers have used an approximate linear method to optimize the data minimization problem and extracted to generate predefined templates on the scene reconstruction combination problem to prevent combination errors that lead to system whiteout [18, 19].

Considering that the graphic design contains skeletal information of each node in the character model reconstruction, there is a directional problem between the normalization of skeletal information and vector information transfer, which reduces the generalization of the character graphic design. The extraction of temporal level behavioral features from skeletal information becomes exceptionally difficult under the dual effect of nonstructural factors [20]. To solve this problem, some researchers strictly control the input of experimental conditions to reduce the influence of nonstructural factors. The depth camera is used as the only channel for depth information extraction, and the correlation between temporal convolution features and behavioral labels is obtained by matching the data video frame rate with the temporal convolution layer. In the matching of skeletal points with skeletal joints, some researchers try to create multiple spatial dimensions to match from different measures as a way to obtain the maximum match. The results of reasonable graphical design tests can be filtered according to the set range of criterion values [21–24]. When setting the graphic windows dynamically, all the dynamic windows are set to a uniform size to avoid the problem of inconsistent output features, and it is the deep neural network that can flexibly identify multiple skeleton sequences when receiving skeletal point feature data to increase the robustness of the model. We analyzed the visual effects and principles of composition of artistic graphic design. Considering the differences and independence of art graphic design, we realize the scheme reorganization of artistic graphic design from the perspective of computer vision and propose a memory neural network-based artistic graphic design method.

The rest of this study is organized as follows. Section 2 presents the history of research and research results on the intelligent design of artistic graphics. Section 3 describes in

detail the principles and implementation process related to visual memory neural network-based art graphics design. Section 4 shows the related experimental setup, the experimental data set, and the analysis of the experimental results. Finally, Section 5 summarizes our research and reveals some further research work.

2. Related Work

In the process of character graphic design, artists and technicians have different requirements for the effect of the dynamic presentation of characters, and there is a gap between the overall retention effect of graphics and the effect achieved by deep neural network models. To balance the requirements of both artistic design and technical processing, some researchers try to use RGB graphic data as the input of the scheme combination, and for the requirement of optical flow information in the scheme, graphic design artists require full traversal of still life appearance and dynamic character features. Some of the node-tracking information is often lost in the implementation process of technicians, and the behavioral linear resolution cannot be completed for dynamic character features. Therefore, some researchers have treated the above features separately, with the study in literature [25] oriented toward still life contour feature acquisition and the study in literature [26] oriented toward dynamic character skeletal point optical flow information feature capture. In addition, researchers in the literature [27] proposed a dense trajectory extraction algorithm for still life feature classification, which is based on the SVM algorithm and classified by feature association, and the efficiency of this classification method is experimentally proven to be excellent. Researchers in the literature [28] optimized the former study based on the addition of RGB cameras to capture optical flow features and optimize the bad trajectory data by matching the trajectory information co-generated by optical flow features with dense trajectories. Traditional RGB algorithms require manual labeling of behavior types and preprocessing management of data labels to prevent behavior label overlap. The biggest drawback of the RGB algorithm is that it relies too much on manual label classification design, and cannot freely combine solutions according to feature types in the graphical design combination scheme.

Traditional graphic design solution combination methods do not perform well at the level of accuracy and speed, and the graphic solution classification and frame rate processing effects cannot achieve real-time results. Some researchers have tried to optimize the visual graphic design solution combination using deep learning methods. Deep neural networks for graphic design can process the visual effects brought by graphic design solutions from the pixel level, and different visual presentation effects are easier to achieve at the pixel level according to the specific needs of the customer. Researchers in the literature [29] proposed a two-layer CNN algorithm when dealing with graphic design optical flow features, and the method can obtain deep pixel features between combinations of graphic schemes. Researchers in the literature [30] optimized based on dual-

stream neural networks and proposed an independent frame feature fusion convolution algorithm, which was designed to achieve feature optimization and compensation in the deep convolution of graphic features in the first and second layers, and the experimental final output of the graphic design model was tested with better efficiency.

A convolutional neural network, as the most basic network structure for image recognition, is more relevant for video data with continuous frames. Compared with single-frame data processing, graphic contextual feature information is more easily linked. If a series of natural language processing neural networks are to be adopted for graphic sequences, they will be more closely related to the integration requirements of data sequences. Recurrent neural networks were the initial adaptive training model used in this study to complete the pretraining of primary combinatorial solutions for graphic design. As graphic design became more demanding at the artistic level, the researcher gradually focused his research on the complementarity of the strengths between different neural networks. In the literature [31], a recurrent neural network and a memory unit network were fused in dealing with the graphic design sequence problem, and an ordered graphic sequence integration was accomplished with the assistance of attention mechanisms. The literature [32] utilized computer vision to complete the directed graphical visual scene reconstruction in advance, and the method was also directly cited as a template by subsequent studies, which reduced the time cost and experimental cost and improved the efficiency of visual reconstruction. The literature [33] proposed a two-layer network nesting structure, where the authors selectively arranged some structures of RNN and LSTM algorithms in a spatial network in a flashback manner, and the graphical input was also RGB data. Researchers in the literature [34], on the other hand, proposed a new and improved LSTM approach, where the authors proposed the model for dense graphical target labeling and segmentation, where the input and output times are automatically ordered according to the matched image sequences in the design of the attention mechanism. To address the influence of unstructured factors, some researchers try to represent the graphical design in 3D space with RGB three channels as the width of feature extraction, and the method is experimentally proven to work better in the face of graphical design schemes with depth information. Some researchers extract interference information in the original graphic data and realize label mapping linkage through interference information and unstructured factors, which can directly filter out most unstructured factors during the model training process. The method works better in subsequent experimental demonstrations but is more dependent on manual processing of the raw data, which is more workload.

3. Method

3.1. Computer Vision Reconstruction. In graphic reconstruction design, the mapping relationship between pixel distances and realistic distances of graphic designs is usually determined from a two-dimensional graphic pixel

coordinate system. To ensure the accuracy, most researchers use the camera calibration method, through which the graphic elements under the pixel coordinate system can be converted to the world coordinate system by the camera calibration operation. The system of automatic combination of schemes for artistic graphic design is to realize automatic extraction of artistic graphic features, an automatic combination of schemes, etc. For this purpose, we designed a computer vision reconstruction mathematical equation as follows:

$$\begin{aligned} x'_{ii} &= f_1(x_{ij}), \\ y'_{ii} &= f_2(y_{ij}), \end{aligned} \quad (1)$$

where f represents the mapping association between real coordinates and pixel coordinates, and the automatic transformation of the projection matrix can be done given the predetermined pixel coordinates.

According to the art graphic design requirements, the corresponding heights and nodes of different design patterns can be obtained according to the camera calibration. For irregular geometric art graphics, we can zone the graphics and subdivide them into rectangles, squares, triangles, and so on. Rectangles and squares are relatively easy to calculate and can be directly brought into the mathematical equation. For triangular clusters, trigonometric functions need to be added to the original equation to calculate the node distances and feature vector information of the art figure. The computer vision system is built as shown in Figure 2.

For a given graphic design target, dimensional mapping and pixel coordinate positioning can be done within the first line of action. In a real scene, the dynamic movement distance can be accurately measured in the projection and camera angle as long as the range of the graphic design target is within the range limit. The area between the first action line and the second action line belongs to the maximum distance where the depth information of the depth camera acts, and within this area, it can be used for 3D graphic design, and the spatial information of each graphic node can be accurately recorded in the detailed vector information due. Those beyond the second action line belong to the invalid region. According to the calculation equation of the triangle function, we can get the information of camera angle, action line angle, action range angle, and the angle of nodes inside the graphical target. The mathematical equation of the clip angle calculation is shown below.

$$\begin{aligned} \alpha &= \arccos\left(\frac{d_{aj}^2 + d_{ak}^2 - d_{jk}^2}{2d_{aj} \times d_{ak}}\right) - \arcsin\left(\frac{d_{jd} \times \sin \angle ajk}{d_{ad}}\right) \\ &\quad - \arcsin\left(\frac{d_{ek} \times \sin \angle ajk}{d_{ae}}\right). \end{aligned} \quad (2)$$

3.2. Self-Attentive Based Neural Network for Artistic Graphic Design. We refer to many literature on the construction of neural networks for graph design, and according to our need

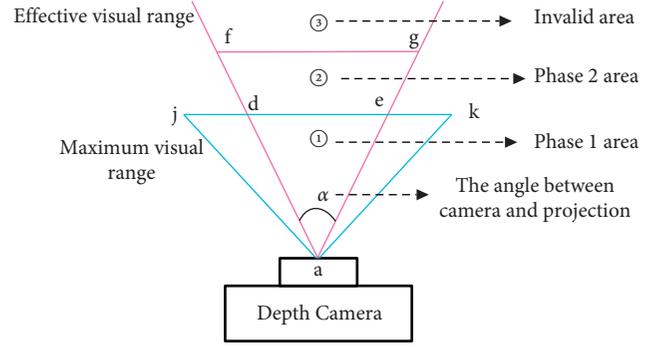

FIGURE 2: Computer vision system construction.

for graph design solutions with only combinations, we use the partial structure of convolutional neural networks and temporal convolutional networks. In the temporal convolutional network part, we divide the graphics into different regions, all of which will be arranged in a certain order, assuming that the input sequence is $X = (x_1, x_2, \dots, x_n)$, n represents the number of graphic design time regions division, and x_i represents the pattern node data in the i th feature acquisition stage of the art graphics, which is represented as a projection matrix with dimensions $T \times M \times D$ dimensions, where D represents the graphic design dimension, T represents the temporal label of the region, and M represents the number of graphic nodes. In the structural design of the temporal convolution layer, we use a $3 \times 3 \times t$ filter as the initial feature extraction, set the pooling layer to $3 \times 3 \times 1$, and the rest of the initial convolution layer dimensions are set to $3 \times 3 \times 3$. The last graphical temporal convolution result will come with the temporal depth information of all the previous convolution layers, and according to the temporal depth range obtained from the test, the best temporal convolution result can be retained for each feature [35].

We segment the art graph into regions and then combine the node vector features of each region into different sequences, each sequence will also be subjected to pooling operation and batch normalization after the initial convolution calculation. Finally, n feature vectors of different time regions of the art graphics at the time level will be obtained. Each set of sequences represents a combination of art graphics in an independent period. The scale of each graphical feature is $X \in R^{N \times M \times K}$, where K represents the feature dimension of each time region node. On top of this, we add an attention mechanism to weight the weighted features of each art-graphic region. To migrate the self-attentive weighted features to the original art graphics, we reshape the region nodes in the attention network. Assuming that the expression of the region node X after reshaping is $Y = [y_1, y_2, \dots, y_m]$, where $y_i \in R^{NK}$, by forwarding propagation network we define the self-attention weighting calculation a_i as the following equation:

$$a_i = \sigma(W^a \times y_i + b_i^a), \quad i = 1, 2, \dots, m, \quad (3)$$

where W^a and b_i^a denote the self-attentive parameters with matrix bias and $\sigma(\ast)$ represents the activation function. We denote the mathematical equations of the self-attentive

model as $s_{att} = [s_1, s_2, \dots, s_m]$ in the artistic graph input matching $X \in R^{N \times M \times K}$. To ensure the generalization of the input graphics in, we denote the attention graph as $A \in R^{N \times M \times K}$, where K represents the artistic graphics features after K feature extractions. Finally, we weight all the previously obtained features for conversion, and the mathematical equation is as follows:

$$\begin{aligned} f_n &= A \cdot X, \\ f_n^{(1)} &= (FNN(\text{MultiHead}(f_n^{(0)}, f_n^{(0)}, f_n^{(0)}))), \end{aligned} \quad (4)$$

FNN stands for feed-forward neural network and $f_n^{(1)}$ features of node sequences in art graphics regions.

3.3. Attention-Based LSTM. To facilitate the traversal and association of temporal convolutional features, we used the LSTM algorithm as an association network, and to the LSTM, we added an attention mechanism to associate with the self-attention layer in the temporal convolutional network. Our proposed visual memory neural-based art graphics design network is shown in Figure 3.

In the above figure, γ represents the comprehensive fusion output of the attention feature vector, and ρ represents the average weight fusion output of the attention feature vector. During the reorganization of the art graphic design scheme, we assigned a different focus of attention mechanism to each graphic area. In the face of different art styles, each art style was evaluated under the artist's assessment with multiple indicator scores according to the differences in expression. For example, the difference between color art and rule art, color art mainly emphasizes RGB pixel intensity and establishes the assignment point of color art attention mechanism based on the local pixel threshold response. The contour intensity is mainly used as the threshold response for rule art, and the attention mechanism assigns weights based on the response threshold. In each period, the improved LSTM network can extract feature vectors of the same dimension from the same attention mechanisms. In this way, different dimensional features are extracted in batches, and finally, the global graphic combination scheme features are obtained in the final class.

Suppose the art graphics data has N feature sets $f = [f_1, f_2, \dots, f_n]$, each of which is obtained in the dual association role of temporal convolutional network and long short-term memory network. When the feature sets are used as input, the inverse network of the temporal convolutional layer receives only one fused feature graph at a time, and the first half of the network can output a high-level feature graph at any time under the action of the LSTM network, and the outputs of the different dimensional attention mechanisms are calculated as shown below.

$$\begin{aligned} h_i &= g(f_i), i \in (1, n), \\ Q &= [h_1, h_2, \dots, h_n], \\ \alpha &= \text{softmax}(w^T \tanh(Q)), \\ r &= Q\alpha^T, \end{aligned} \quad (5)$$

where g denotes the extraction method of LSTM network in artistic graphic region features. Q represents the combination of temporal features in different dimensional outputs. If the feature outputs in the same dimension are used as local feature sequence inputs, the forgetting gate will not be able to filter useful features due to the existence of blank features between periods. α denotes the attention of n features in the predicted output of the memory network unit. r denotes the weighted sum of attention of all time dimensions. To solve the problem of the inconsistent combination of multiple artistic graphics schemes and uncoordinated input dimensions, we also propose a graphics feature compression method based on variable pooling operations. This method can compress the attention of different dimensions according to uniform dimensions and decompress the uniform features at the graphical design combination network layer, and each network layer has a built-in data preprocessing layer to avoid the problem of confusing data formats. The variable pooling feature compression network is shown in Figure 4.

4. Experiment

4.1. Training. Artistic graphic scheme free combination model for scheme requires huge graphic database support. For the creation of the database, the database classification can perceive the differences in art graphics in drawing style, color, and contour, to extract the different features of each type in the deep neural network. We map the depth information in the depth camera to the pixel coordinates, to obtain the representation of the contour nodes in space according to the graphic contour extraction algorithm. The pixel coordinates and depth information will produce information mapping in two different data sequences, and to check whether the graph and combination classification are unified, we set independent region thresholds. It has an excellent scheme combination effect for still life graphics. In the model training process, we plan a reasonable training process according to the demand for artistic graphics combinations, as shown in Figure 5.

4.2. Data set. At the initial stage of the art graphics database creation, we invited professional art aestheticians to evaluate art graphics for aesthetic indicators, object emphasis, color harmony, balance elements, motion blur, and other indicators and developed an independent evaluation system. In the art graphics design data collection, we manually labeled the art graphics that have generated economic benefits, and the labeled information contains graphic size, artistic category, combination direction, etc. For the database sequence classification, we adopted the rule of thirds and experimentally reconstructed a quantitative evaluation model. In the quantitative evaluation model, the art graphics' ease of use, aesthetics, balance, and contrast remain the performance evaluation benchmarks for the automatic art graphics combination model. In all art graphics data sets, we set 80% of the training set and 20% of the test set. In the experimental implementation of the art graphics data set, we defined only

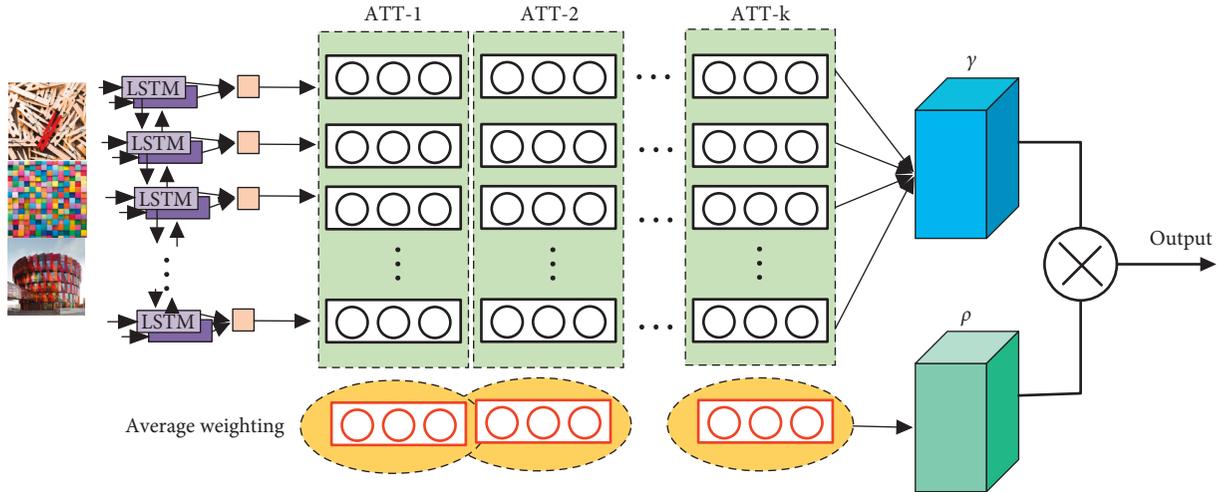

FIGURE 3: Visual memory neural network.

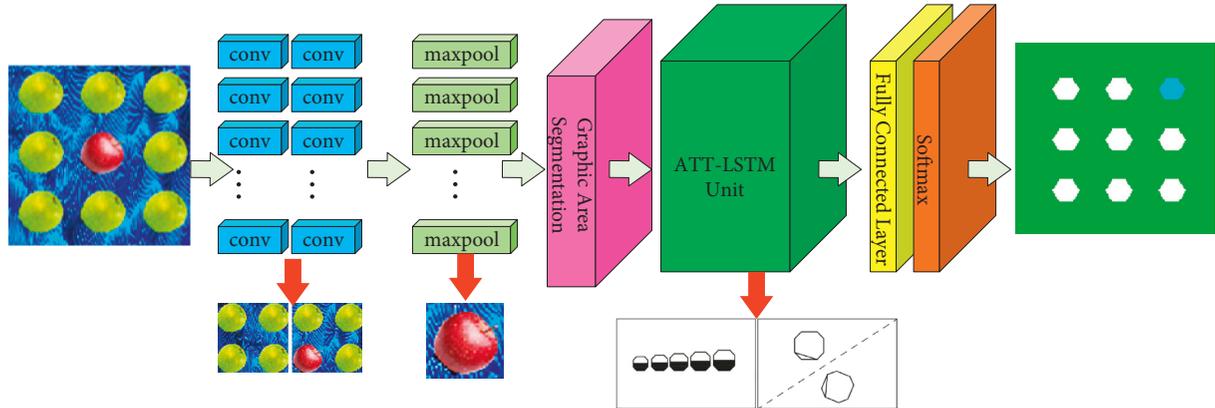

FIGURE 4: The variable pooling feature compression network.

three categories of artistic graphics at the beginning of the study, namely color category, regular combination category, and multiple arrangement category. The details of the art graphics data set are shown in Table 1.

4.3. Analysis. In the prior experiments, we found in the method validation experiments that machine learning methods have poor accuracy in the visual communication of artistic graphics and cannot achieve real-time requirements. Deep learning methods perform better in the scheme combination of artistic graphics; therefore, in the later experiments, we use deep learning methods as the base reference. In the first stage of experiments, we compare the effect of three methods, CNN [36], RNN [37], and LSTM [38], on the combination of artistic graphics. The first phase experiments are evaluated in terms of precision (P) and recall (R). The experimental results are shown in Table 2.

According to the experimental data in Table 2, it is clear that the combination of artistic graphic design solutions performs better in the image-based deep learning approach. However, the image-based deep neural network method cannot access the information contained inside the artistic

graphic labels and cannot achieve the fusion and generalization of data features at the textual level. The accuracy of CNN-like methods stays around 80% in the three types of artistic graphic scheme combinations. Our method incorporates not only CNN methods but also LSTM methods. The structure of the dual network makes up for the model's feature capture of textual information of art graphics, and the joint mapping of pixel features and textual features can effectively compensate for the shortcomings of the pure image-like methods. Therefore, the experiment proves that our method can keep the accuracy above 90% in all the art graphics combinations, which is significantly better than other methods.

In the second phase of the experiment, we validated the artistic graphic aesthetic index. Based on the opinions of professional art aestheticians, we chose three important indicators for validation: Balance Element (BE), Color Harmony (CH), and Object Emphasis (OE). The balance element is to verify the visual balance of art graphics after reconstruction. Color Harmony is to verify that the artistic graphic features are fully captured at the pixel level. Object Emphasis is to highlight the art graphics in similar combination schemes. The results of the experiments are shown in Table 3.

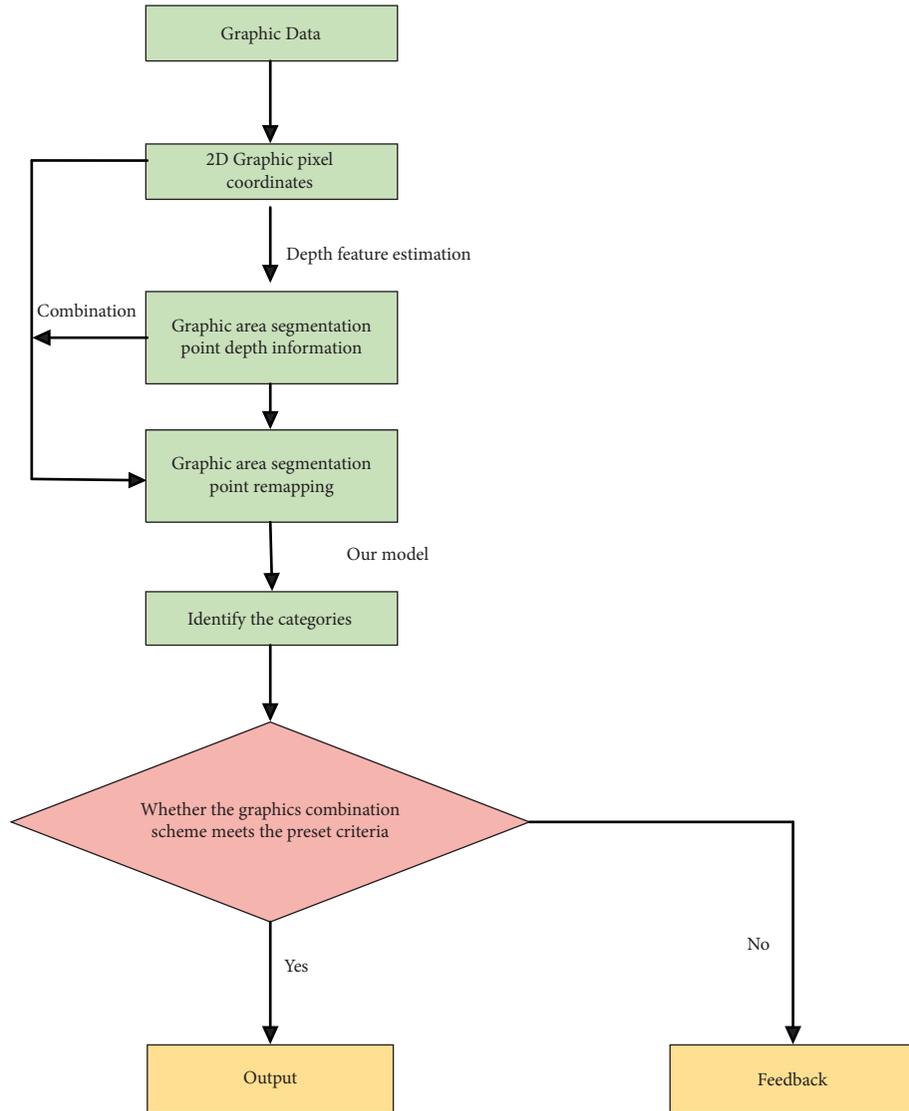

FIGURE 5: Art graphic design model training process.

TABLE 1: The detail of art graphics data sets.

	Data sets		
	Color	Regular combination	Multiple arrangement
Train	42880	34880	53040
Test	10720	8720	13260
Total	53600	43600	66300

TABLE 3: Experimental results of the accuracy of aesthetic indicators of art graphics.

	Color	Regular combination	Multiple arrangement
Balance element	0.89	0.87	0.92
Color harmony	0.96	0.81	0.90
Object emphasis	0.92	0.96	0.95

TABLE 2: Experimental results of combining the accuracy of different art graphics schemes.

	Color		Regular combination		Multiple arrangement	
	<i>P</i> (%)	<i>R</i> (%)	<i>P</i> (%)	<i>R</i> (%)	<i>P</i> (%)	<i>R</i> (%)
CNN	73	83	85	86	80	83
RNN	66	75	61	74	69	76
LSTM	77	76	79	77	71	79
Ours	93	89	95	90	90	89

The experimental data in Table 3 shows that the best performing type of art graphics among the balanced elements is the multiple arrangement art graphics, which is more advantageous when evaluating the balanced elements because of the multiple arrangement graphics with different combinations of elements. In the color harmony, the best effect is in the color art graphics, and the color harmony index is not good enough because the regular combination and multiple arrangements pay more attention to the outline and space planning. Target emphasis performs well in all

TABLE 4: Experimental results of different methods of quantitative evaluation model.

	CNN	RNN	LSTM	Ours
Graphics design ease of use	0.7	0.7	0.8	0.9
Graphic combination balance	0.7	0.8	0.8	0.9
Graphic category aesthetics	0.8	0.7	0.8	0.9

three art types. This shows that we should fully consider the role of color harmony and balance elements when classifying database categories. Our method maintains an accuracy rate of 80% in both evaluation indexes, and the experimental data are more accurate in the actual test, thus showing the high efficiency of our method in the experiment.

In the third phase of the experiment, we validated the art graphics quantitative evaluation model, and we tested the experimental performance in the three phases according to the three aspects of art graphics design ease of use, graphic combination balance, and graphic category aesthetics, and the experimental results are shown in Table 4.

From the above experimental results, it can be seen that CNN and RNN methods are not stable enough in the quantitative evaluation model. The LSTM method keeps above 0.8 in the quantitative evaluation model, and due to the memory units embedded in the LSTM network, the under-conditioned feature vectors can be selectively screened in the quantitative evaluation model through the forgetting gate. Our method achieves 0.9 in the quantitative evaluation model, which shows that our method outperforms other deep learning methods and proves the superiority of our method.

5. Conclusion

In this study, we analyze the visual effects and principles of composition of artistic graphic design. Considering the differences and independence of artistic graphic design, we realize the scheme reorganization of art graphic design from the perspective of computer vision and propose the method of art graphic design based on memory neural network. Referring to numerous deep learning methods such as CNN, RNN, and LSTM, we experimentally validated each method and finally designed a two-layer network structure based on CNN and LSTM networks. We built a computer vision environment and reconstructed the computer vision network to set up an independent deep camera vision range computation law. Considering the artistic graphic region segmentation problem, we proposed a self-attentive mechanism, which can quantitatively segment different artistic graphic regions based on temporal features, after arranging them in a sequence to obtain the graphic region feature vector. In the last part of the network structure, we propose the LSTM structure based on the attention mechanism to match with the self-attention features of the graphic region segmentation module and pass the matched attention feature vector to the LSTM network to extract the labeled text feature information of the graphics. To test the effectiveness of our method, we build a database of artistic graphics and set up an adaptive training process. We also

compare deep learning methods of the same type, and the experimental results demonstrate that our method outperforms other deep methods in artistic graphic design in terms of scheme reorganization accuracy and quantitative evaluation of artistic models.

Intelligent design of art graphics is a very complex study, where visual scene construction and graphic area segmentation are key point technologies. In the research of this paper, we only choose three simple art categories as research, in fact, there are more complex art categories. In future research, we will try more art types and use the two-layer LSTM algorithm to enhance the feature capture range of the model and improve the generalization of the model.

Load training is an important part of the daily training of aerobics athletes. Therefore, the research on the characteristics of aerobics movement of athletes in load training has been paid extensive attention by teaching units. Deep learning algorithm in artificial intelligence algorithm is used to study the characteristics of calisthenics teaching and training, which is a beneficial exploration to improve the scientific of calisthenics training programs. The basic principles of the neural network algorithm and implementation process are described. After the basic structure and characteristics of the network are analyzed, a comprehensive solution to optimize and improve the regularized deep belief network algorithm is proposed. The results show that compared with other learning algorithms, the feature classification error rate of the optimized regularized deep belief network algorithm is 6% lower than that of other algorithms. Although the training speed of the model decreases, the convergence period of the deep neural network algorithm can better achieve the extraction accuracy of abstract features of training data when the deep learning period increases. Being less affected by input parameters, the algorithm will have better stability and be more conducive to extracting the features favorable to classification. In the field of deep learning, the advantages of the deep neural networks can effectively classify the training characteristics of aerobics athletes and provide scientific decision-making basis for subsequent teaching and training.

1. Introduction

Artificial intelligence algorithms supported by machine learning, deep learning, and other theories, with the help of computer-aided platforms, better realize accurate and efficient rule classification and feature mining of large amounts of data. In the training of aerobics, a lot of functional training is needed, so it is necessary to effectively improve the level of aerobics skills. In the past, the research on feature data of functional training mainly relied on artificial means, and the analysis period was often long and the analysis effect was not very ideal. In this paper, the deep neural network is introduced to carry out feature classification research on the load characteristics of aerobics teaching and training, aiming to find out the movement characteristics of athletes' functional aerobics training accurately and to provide scientific

and accurate data support for the optimization of subsequent training programs. The main direction of this research is to discuss the feasibility of neural network algorithms in deep learning theory by analyzing the basic theory of artificial neural networks. Based on the deep belief model, the regularized deep belief network algorithm with batch normalization is constructed. The simulation results show that the optimized regularized deep belief network algorithm has advantages in the accuracy of feature classification and algorithm iteration.

A deep neural network plays a very good supporting role in feature extraction, pattern recognition, and other aspects. The principle of a feature extraction algorithm based on a deep neural network is to select important feature information from research data by simulating the information characteristics of the biological nervous system. In this

paper, the study focuses on the neural network algorithm, pays attention to the latest achievements in the field of in-depth learning, analyses the basic modules, model structure, and implementation process of the in-depth neural network, explores how to better improve the advantages of the in-depth neural network algorithm, and helps to effectively classify the characteristics of athletes' load training in Aerobics Teaching and training.

The deep learning theory is introduced to the basic artificial algorithm. Based on the need of extracting load training features, which are optimized to improve the accuracy and robustness of the deep neural network in mining training features. For the analysis technology of the basic principle and process of the artificial neural network, insufficient training of traditional deep belief network, combined with batch normalization algorithm, a batch orthodoxy classification method is proposed, and the modified optimization algorithm is applied to the classification of aerobics load training characteristics. Experiments show that the optimized deep belief network effectively enhances the classification and mining of large-scale and complex training data by the neural network algorithm and provides real and reliable data support for the subsequent optimization of the aerobics teaching program.

The main contents of this paper are as follows: Section 1 discusses the advantages of deep neural network algorithm in data feature classification and how the artificial intelligence algorithm based on computer technology can effectively and accurately analyze complex data. Section 2 describes the principle and advantages of the deep neural network algorithm and puts forward the original intention of this paper. The principles and implementation process are described. Section 3 gives the design flow of the deep neural network algorithm. The reliability of the batch normalization algorithm of the basic depth confidence network algorithm for data feature classification is introduced. Section 4 introduces the optimization strategy and performance characteristics of the hybrid algorithm which combines the batch normalization algorithm and the depth neural network algorithm. Section 5 summarizes the research content of the optimized depth neural network algorithm and analyses the future research direction of aerobics teaching classification and training data mining.

2. Related Work

Research on neural networks by scholars at home and abroad have been well applied in many industries and fields. In the research on GPS positioning, Sun et al. proposed a hybrid algorithm to improve the selection of optimal satellite combinations. The accuracy of satellite positioning is improved by improving the accuracy of geometric dilution. [1]. In Wozniak and Giabbanelli's research on forest data recognition, the way to improve the accuracy of recognition and classification by BP neural network is discussed. The clustering algorithm is introduced to optimize the BP neural network, which makes up for the slow convergence of the BP neural network algorithm [2]. Tian et al. introduced an optimized BP neural network to solve the reliability problem

of excessive noise data by using a new executive [3]. In the application of gesture recognition, Li et al. discussed how to improve the BP neural network algorithm to search for local minima. By introducing the chaos principle, a hybrid algorithm model of genetic algorithm and BP neural network is constructed, which improves the quality of the optimal solution of the algorithm [4]. Wang and Jeong discussed the feasibility of optimizing the BP neural network by using wavelet transform theory and discussed back propagation characteristics [5]. Li et al. explored the application of optimization in the comprehensive error compensation of multi-axis machine tools. By updating both the read factor and amplification factor, the convergence effect of the algorithm is improved. In practical application, an error prediction model of machine tool processing accuracy is constructed [6]. In Song et al.'s study on forest data recognition, the way to improve the accuracy of BP neural network recognition and classification is discussed. The clustering algorithm is introduced to optimize the BP neural network, which makes up for the slow convergence of the BP neural network algorithm [7].

In academic research in recent years, Liu explored how to use visualization tools to help users better interpret depth models in recent years [8]. By developing and deploying an interactive visualization system based on improved ActiVis and constructing multiple coordinated views, the results of deep neural network models at various levels, such as instances and subexample, can be studied [9]. Ahn et al. studied how to classify driver's head data using a depth neural network, and proposed a multitask learning depth neural network based on the small gray images. The multitask learning to monitor accurately by using the multiview pictures transmitted by sensors under different environmental conditions such as illumination, vehicle vibration, driver's posture change, and external occlusion [10]. Sharma et al. focused on how to reduce the operating bandwidth and maintain the classification accuracy of the algorithm. By constructing a bit-level processing element array, the operating bandwidth of the deep neural network is dynamically fused, so that the accuracy of the algorithm is not affected under the finest granularity computing conditions [11]. Lubbers et al. introduced a layered interactive particle deep neural network to study the molecular characteristics of two-character computational data sets. The deep neural network achieves the most advanced prediction performance on organic molecular data sets. It can also identify the uncertain regions of the model while realizing the limited and accurate prediction of energy [12]. Zhu et al. explore how to effectively apply depth neural network in image classification. By constructing a training model using features, the performance of the algorithm is effectively improved [13]. Groene et al. studied the variance of human behavior and brain measurement interpretation by building three feature models. Among them, the deep neural network was used to simulate the advanced visual features of human eyes. Experiments show that the depth neural network can effectively classify scenes, which is very similar to the function of the human eyes [14]. In the research of computer single-layer scanning data, You et al. explored the use of denoising model

by the deep neural network, to improve the effective classification of images. Experiments show that this scheme can improve the reliability of information retrieval and has a good application prospect in clinical medicine [15].

Through the analysis and application of artificial neural networks and depth neural networks, it can be seen that there are many good results of intelligent algorithms in image classification, prediction models, image retrieval and positioning, real-time picture monitoring, and other applications. However, under the support of current big data, it is still a worthwhile research area to improve the intelligence level of aerobics teaching and training by studying the characteristic data of aerobics symbol load training. Therefore, in this paper, the deep neural network algorithm will be optimized, and it will be explored how the optimization algorithm model can provide strong data support for feature classification in aerobics load training [16].

3. Methodology

3.1. Neural Network Algorithms. To solve the problem of nonlinear separability, multilayer functional neurons need to be used. Therefore, one or more hidden layers are usually added between the input layer and the output layer. Both hidden layers and output layers are functional neurons with activation function and threshold. More generally, the common neural network is the hierarchical structure shown in Figure 1. There is no same-layer connection or cross-layer connection between neurons. Such neural networks are usually called multilayer feedforward neural networks. BP algorithm is a typical learning algorithm with tutor guidance. The basic idea is to learn a certain number of sample pairs (input and expected output), that is, the input of the sample is transmitted to each neuron of the network input layer. After being calculated by the hidden layer and output layer, each neuron of the output layer outputs the corresponding expected value [17]. If the error accuracy between the expected value and the expected output does not meet the requirements, the error is propagated back from the output layer (note that the error is propagated) and modified through the modification formula of weight and threshold, so that the error between the output of the whole network and the expected output is continuously reduced until the accuracy is met. In other words, the BP network attributes the error between the network output and the expected output to the fault of weight and threshold. Backpropagation apportions the error to each functional neuron. The adjustment of weight and threshold should also be adjusted along the direction of the negative gradient, which is the fastest decline of the error function.

The learning and training of the BP neural network mainly include two processes: forward propagation and error backpropagation. In the forward propagation process, the external data variables are input from the input layer, processed by the neural nodes of each hidden layer, then transformed nonlinearly, and finally output information from the output layer [18]. In this paper, an output error prediction model of a parallel mechanism based on virtual experiments and a BP neural network is constructed. A fast

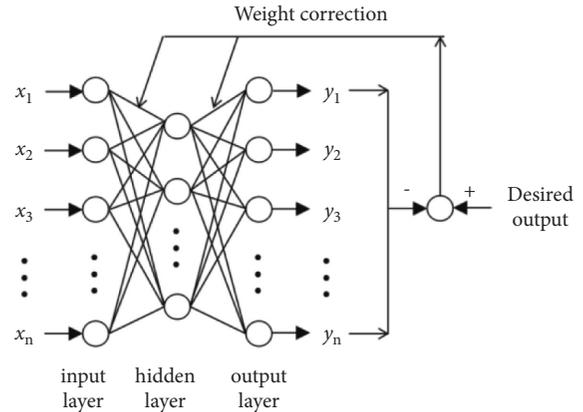

FIGURE 1: Structure of BP neural network.

prediction method for output error of parallel robot mechanism is proposed. Considering the hinge installation error and hinge axis error of the parallel mechanism, a virtual prototype model containing the above input errors is established. The output error of the mechanism is solved by virtual experiment simulation. It is assumed that the errors of mechanical components in mass production obey normal distribution and multiple groups of input error data subject to normal distribution are constructed [19]. Then, the BP neural network prediction model of the mechanism is established. If the actual output result of the output layer deviates greatly from the expected target value, the error backpropagation is carried out. In this process, the error will be backpropagated to each layer of BP neural structure one by one, and the error value will be shared with all neural nodes. Each neural node takes this information as information to continuously and repeatedly adjust the connection weight between the input layer and the hidden layer, the connection weight, and threshold between the hidden layer and the output layer. Until the error is reduced to an acceptable level or until the preset number of learning times. Its structure is shown in Figure 1.

From the above knowledge, the perceptron has only one layer of functional neurons (the so-called functional neurons are neurons with a threshold, and the input layer has no threshold). It has poor learning ability and can only solve linear problems, or even nonlinear separable problems such as XOR.

To solve the problem of nonlinear separability, multilayer functional neurons need to be used. Therefore, one or more hidden layers are usually added between the input layer and the output layer. Both hidden layers and output layers are functional neurons with activation function and threshold. More generally, the common neural network is the hierarchical structure shown in Figure 2. There is no same-layer connection or cross-layer connection between neurons. Such a neural network is usually called multilayer feedforward neural network. The BP neural network learning algorithm flow is shown in Figure 2.

The convergence speed is affected by the variety of error surface distribution in two-dimensional space. The factors

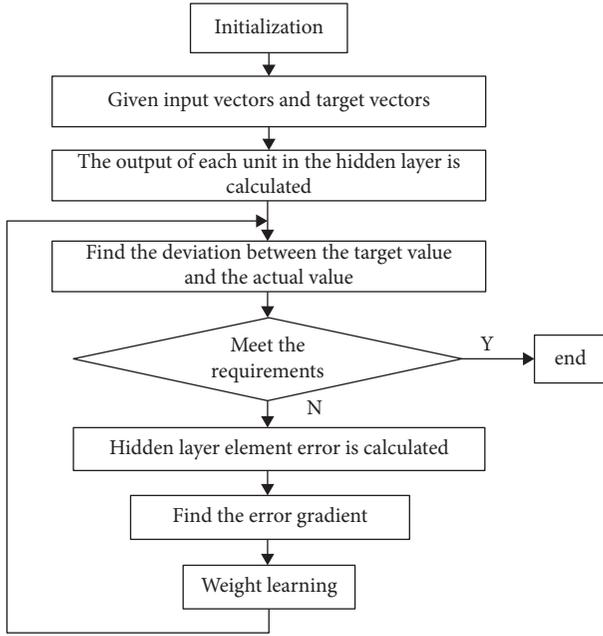

FIGURE 2: Algorithm flow chart.

that affect the stability and speed of nonlinear convergence are mainly related to the model—mainly the structural stiffness. For some structures, from a conceptual point of view, it can be considered as a geometrically invariant stable system. However, if the stiffness of several main members with similar structures is very different, it may lead to large errors in numerical calculation. The gridding method is essentially a method of using known point values for dimensional space interpolation. The main differences between different methods are the range of sampling points and the weight of known points. The difference in sampling point range is global interpolation and local interpolation, and the difference in known point weight lies in the difference in weight function (basis function). Because the multiple regression method is a trend surface mapping method, and the local polynomial interpolation method can also be regarded as the local trend surface method, that is, using a surface to fit the known data can adopt different powers, which is mainly used to distinguish the regional field from the local field, so the method itself plays a role in removing the fine structure. Although the number of hidden layers can enhance the network's ability to deal with negative

linearity, it will also bring too complex technical problems. It is not right that the more the hidden layer is, the better the situation will be. After it exceeds a certain number, the number of hidden layers needs to be determined by experiments (Figure 3).

3.2. Deep Neural Network Algorithms and Their Optimizing Strategies. The deep learning here mainly comes from the deep learning model theory. It is to understand the number of nonlinear operation combinations obtained in the neural network learning from the level of multilayer flying linear function relations. The common shallow structure of the neural network and deep structure of neural network often use fewer neurons to get better generalization performance. Figure 4 is a deep neural network structure with three hidden layers. Deep learning makes good use of the learning characteristics of deep neural networks. At present, there are three main structures of deep neural networks. The first is the generative depth structure, which is used to describe the joint probability distribution of the research object and the high-order correlation characteristics of the data. The second is the discriminatory depth structure, which is to discriminate and judge the pattern classification and describe the posterior distribution of the data. The third is a hybrid structure, which is a combination of generative and discriminatory structures, which can effectively distinguish data.

It is a deep neural network superposed by a restricted Boltzmann machine (RBM). Because of its multilayer structure, it has advantages in obtaining compression coding of data sets. Figure 5 is the construction process diagram of the deep belief network. In the pretraining stage, a greedy unsupervised learning algorithm is used to train each RBM from bottom to top, so that an unsupervised deep belief network can be obtained through repeated iterative training. The gap between the output structure of the money box transmission and the label data can be obtained. In another word, supervised learning from top to bottom is used to fine-tune the deep belief network of unsupervised learning.

The output of the previous RBM in the figure is the input of the latter RBM. If the deep belief network contains one hidden layer, the joint probability distribution of the model can be shown in formula (1). Here, when h_{i+1} is known, which is the probability distribution of the deep belief network,

$$\begin{aligned}
 P(v, h_1, h_2, \dots, h_i) &= P(v | h_1)P(h_1 | h_2), \dots, P(h_{i-2} | h_{i-1})P(h_{i-1} | h_i) \\
 &= P(v | h_1) \left(\prod_{i=1}^{i-2} P(h_i | h_{i+1}) \right) P(h_{i-1}, h_i). \tag{1}
 \end{aligned}$$

In practical applications, deep belief networks are often undertrained. Therefore, the BN is a deep belief network. The batch regularization algorithm uses an independent

regularization method to process the scalar features, which is the batch processing of input data samples. In the fine-tuning of traditional deep belief networks, the distribution of input data at each level is affected by the variation of

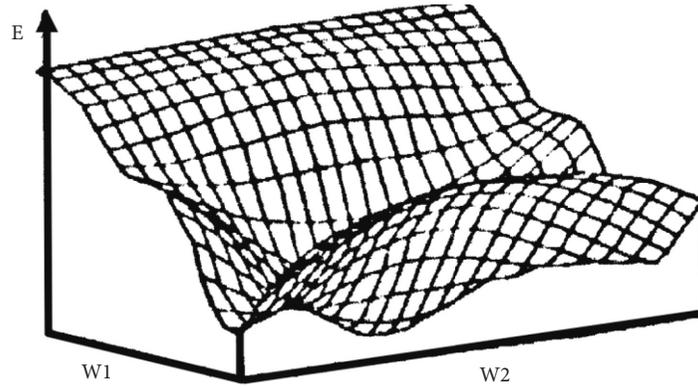

FIGURE 3: Distribution in two-dimensional space.

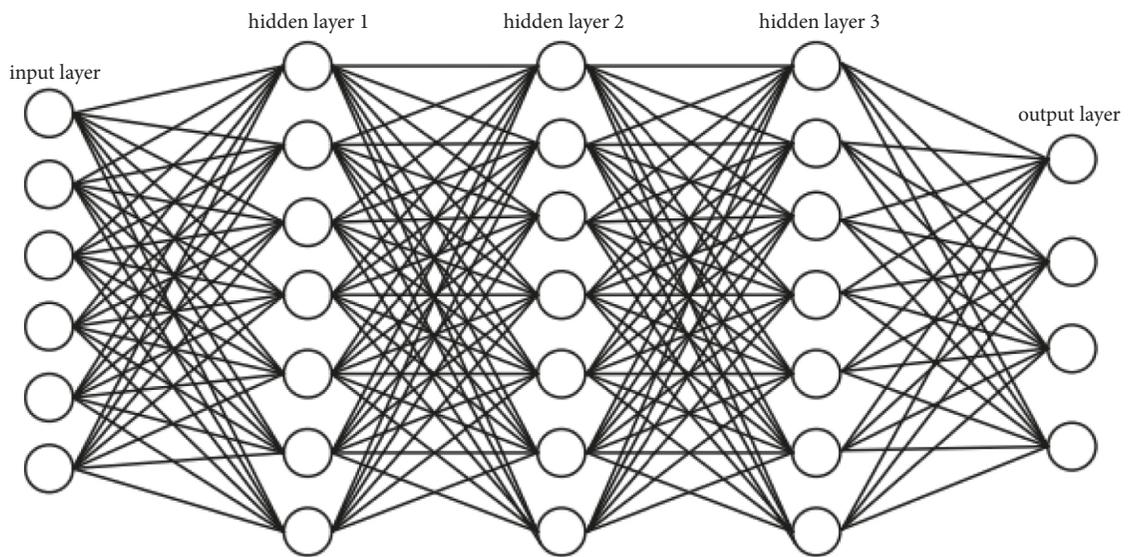

FIGURE 4: Deep neural network structure diagram with three hidden layers.

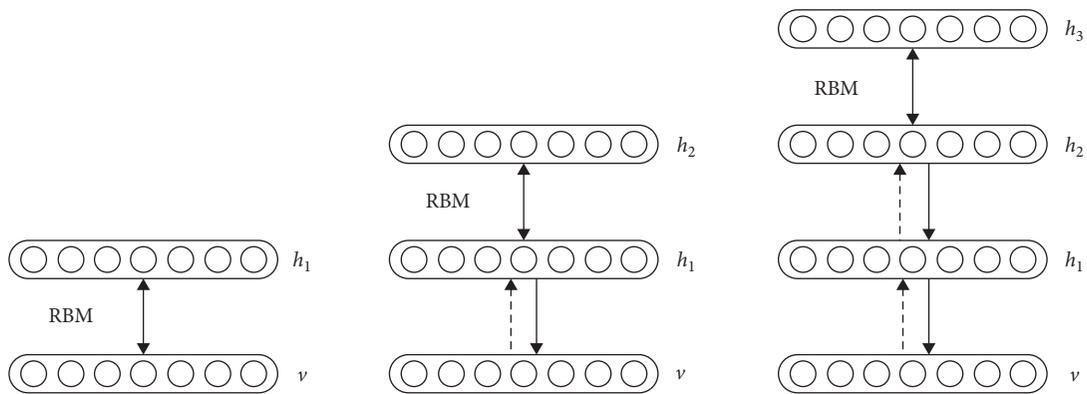

FIGURE 5: The construction process diagram of deep belief network.

parameters. Under this condition, the complexity of networks is very high. If the activation function is used to map the output value as the input data to the latter layer, the distribution of the input data will not change significantly in

the training. In another word, the optimization goal of making the deep belief network run more stable can be achieved. Based on this optimization idea, the batch regularization is in the fine-tuning stage. The structure of the

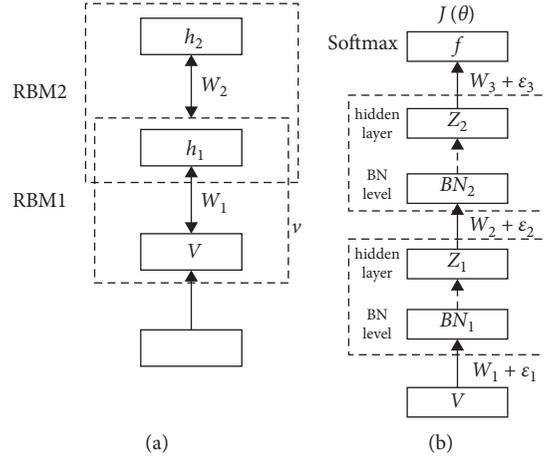

FIGURE 6: BN-DBN structural drawing. (a) Pretraining. (b) Further optimization.

batch regularized depth belief network (BN-DBN) is shown in Figure 6.

Figure 6(b) uses the batch regularization algorithm to process the input features of the batch regularization algorithm (BN) layer and then deactivate the function layer as the input value. In BU processing of a deep neural network with hidden layer 1, formulas (2)–(4) will be used. Each batch of training samples is $D\{x_1, \dots, x_m\}$. The input value of a k dimension x is expressed by $x^{(k)}$. The sample set is D , the mean is μ_B , and the variance is σ_B^2 . Each dimension of the input value x is regularized with \hat{x}_i .

$$\mu_D^{(l)} = \frac{1}{m} \sum_{i=1}^m x_i^{(l)}, \quad (2)$$

$$\sigma_D^{(l)2} = \frac{1}{m} \sum_{i=1}^m (x_i^{(l)} - \mu_D^{(l)})^2, \quad (3)$$

$$\hat{x}^{(l)} = \frac{x_i^{(l)} - \mu_D^{(l)}}{\sigma_D^{(l)}} = \frac{x_i^{(l)} - 1/m \sum_{i=1}^m x_i^{(l)}}{\sqrt{1/m \sum_{i=1}^m (x_i^{(l)} - \mu_D^{(l)})^2}}. \quad (4)$$

Batch regularized deep belief network (BN-DBN) mainly uses scale transformation and translation transformation parameters to make the model more expressive. In this way, the gradient propagation of the deep belief network will not be affected if some layer of the network has parameters to be transformed. When the weights of new parameters are too large, the gradient of the whole model will be reduced by using scale transformation. This method can realize that the whole batch regularized depth belief network (BN-DBN) is always in a stable state during parameter training.

4. Batch Regularized Deep Belief Network (BN-DBN) Performance Experiments

4.1. Experimental Conditions and Parameters. The hardware condition of this test is Windows 10 operating system, with 4.00 GB memory and MATLAB R2014a tool. The database

used in the experiment is the characteristic database of the aerobics training team of M University in 2017. It contains 50,000 training samples and 12,000 test samples. The experimental data collected in this database are randomly obtained, using 5000 training samples and 1500 test samples. The parameters selected in the experiment are based on the parameters obtained after a large number of experiments. In the unsupervised learning stage, without considering the batch regularization algorithm (BN), the number of hidden dangerous layers of the network is 2, and there are 100 neuron nodes in each layer. The batch size is 120. When the number of iterations exceeds 10, the momentum parameter is set to 0.85. When the number of iterations is less than 10, the momentum parameter is set to 0.65. The maximum number of iterations is 200. The initial learning rate of the supervised stage is set to 0.05, and the maximum initial value of fine-tuning times is 100. In the experiment, the batch regularized deep belief network is compared with the original model, and the performance advantages are discussed. The experiment adopts the contrast method. The other feature extraction algorithms are basic depth belief network (DBN) of an automatic encoder (AE) and dropout-DBN.

4.2. Stability Experiment of the BN-DBN Algorithm. The setting of the initial learning rate in traditional DBN will directly affect the stable operation and convergence speed of the algorithm. It often needs a lot of practical experiments to select the appropriate learning rate. In the experiment, it is needed to verify the stability of the BN-DBN algorithm. When other parameters are fixed, the learning rate should change between 0.0005 and 0.05. Based on the characteristic data set of aerobics athletes' weekly load training in 2017, the BN-DBN algorithm was compared with ANN, K-nearest neighbor algorithm (KNN), basic depth belief network (DBN), and dropout-DBN. The results are shown in Figure 7. Under the curve operation of BN-DBN and other algorithms, the classification error rate is 0.6% lower than that of the dropout-DBN algorithm. The results show that the algorithm has high stability.

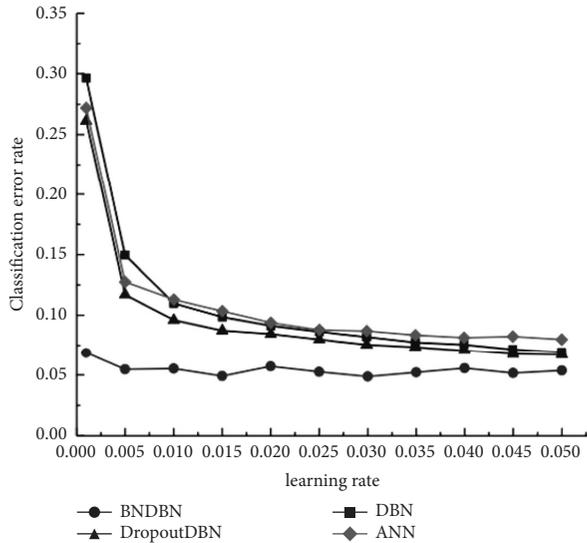

FIGURE 7: Comparison of classification error rates of four algorithms under different learning rates.

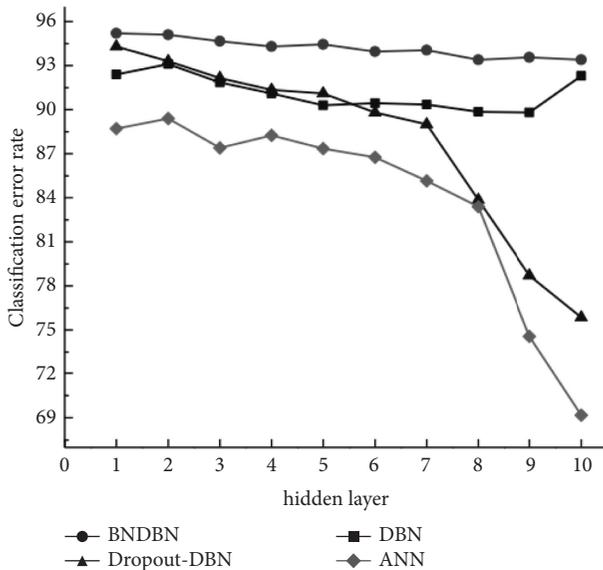

FIGURE 8: Comparison of classification accuracy of four algorithms with different numbers of hidden layers.

4.3. Performance Experiment of BN-DBN Algorithm. Compared with traditional neural network algorithms, the greatest advantage is depth. The algorithm is more likely to exhibit overfitting phenomenon. To verify the performance of the BN-DBN algorithm proposed in this paper on a deeper level, it is needed to assume that other parameters are fixed, which will increase slowly, up to 10 hidden layers, or to use aerobics training data as experimental data. This is the performance of the classification accuracy of the BN-DBN algorithm and other algorithms under the change of hidden layer (Figure 8).

The experimental data above show that, in the training of feature extraction, the statement that the performance of the network will be better if the number of hidden layers

increases is not right. With the same data scale, if the number of hidden layers increases continuously, the classification curves of the four algorithms are in a downward trend. This is mainly because the hidden layer has to extract sample features at different levels in each different layer. The more the number of hidden layers is, the richer the concept of feature expression will be, which will reduce the classification. But the abstraction effect of the BNBDN algorithm is better, which means that although the parameters will change constantly, BNBDN runs well and is more suitable for feature extraction.

5. Conclusion

ANN is an artificial intelligence algorithm that simulates the neural structure of the human brain to reproduce the thinking ability. It has a good application prospect in the research of prediction, classification, and feature extraction. The general deep learning process refers to inputting the feature vector into the neural network. After the operation of the internal code, the neural network outputs the results we need. Different from ordinary programs, the scale of the neural networks is larger, and it can process a large amount of data and get results more quickly. To achieve what a single program cannot do, the premise of the use of the neural networks needs a lot of data for training, that is, it takes longer to create a neural network. A deep belief network algorithm is proposed, and the algorithm is optimized and updated according to the need for aerobics load training feature classification. BN is introduced to optimize the deep belief network. The algorithm and the scalar features of each layer in the neural network are processed by the independent regularization method of the batch regularization algorithm, which is the batch processing of input data samples. This paper has a 0.6% lower classification error rate than dropout-DBN when it is optimized. The BN-DBN can extract the characteristics of data more accurately, and the algorithm has high stability. The abstraction effect of BNBDN algorithm is better, and it is more suitable for feature extraction. However, the study still has some limitations. BN-DBN algorithm still has room for improvement, so building a hybrid model structure is the direction of future research.

The Internet of Things manufacturing technology is an important symbol for measuring the level of a country's scientific and technological development. Enterprises that apply the Internet of Things manufacturing technology represent the level of a country's industrial development to a large extent. However, the introduction of IoT manufacturing technology will not automatically generate benefits. It needs to be matched with a suitable organizational structure to maximize the advantages of IoT manufacturing technology. The enterprise organization structure has always been the focus of enterprise organization research and management research. From the linear system to the network organization, the innovation of enterprise organizational structure has never stopped. Therefore, the research on the organizational structure innovation of IoT manufacturing technology enterprises has strong theoretical and practical significance. This study conducted an empirical study on the impact of organizational innovation climate and individual innovation behavior on organizational structure innovation in IoT manufacturing technology enterprises in the form of a questionnaire survey. The structural equation model of organizational innovation climate and personal innovation behavior is proposed, the data and questionnaires are statistically and factorially analyzed by software such as SPSS 18.0 and AMOS 7.0, and the hypothesized structural equation model is verified.

1. Introduction

Since Schumpeter put forward the theory of technological innovation in 1912, innovation research has been a hot topic in academic circles. Early research on innovation was mainly carried out from a macro perspective, looking at innovation from a highly macro and abstract perspective, viewing enterprises as participants in the economic system, and focusing on the output of the economic system rather than the performance of the enterprise. With the change in environment and the rise of organizational theory, organizational structure innovation has become a research topic. In the late 1980s and early 1990s, the American manufacturing industry first proposed the concept of IoT manufacturing technology to enhance its own competitiveness and promote national economic growth based on the opportunities and challenges it faced. In the following years, there was a wave

of applying IoT manufacturing technology around the world. New industrial countries such as Europe, America, Japan, and China have listed IoT manufacturing technology as a national high-tech and key development project. Manufacturing is the pillar industry of China's national economy. About a quarter of the population is engaged in this industry, creating great material wealth. Therefore, it is the core of China's national economy and the driving force of industrialization. China has introduced the Internet of Things manufacturing technology for more than 20 years, which has played a good role in promoting its economic growth because the theory of organizational innovation at home and abroad is not very unified and perfect. In addition, with the gradual formation of the global economic integration development model, for enterprises applying IoT manufacturing technology, the challenges faced by organizations in their operation are becoming more complex and

diverse, which inevitably requires organizational theory. Keep up with the times. In particular, the global financial crisis in 2008 had a great impact on our country. The downward pressure on the domestic economy was increasing. The state proposed to strengthen technological transformation, accelerate the industrial adjustment of technological innovation, and put forward higher requirements for the application of Internet of Things manufacturing technology [1–5].

This paper studies and analyzes the dynamic system of enterprise organizational innovation applying IoT manufacturing technology, describes the entire emergent process of IoT manufacturing technology enterprise organizational innovation, and proposes an organizational innovation process model with adaptive robust control links according to the emergent characteristics. At the same time, a questionnaire survey was carried out on the employees of enterprises applying the Internet of Things manufacturing technology to investigate the organizational innovation atmosphere and personal innovation behavior, and empirical data were obtained. SPSS 18.0 was used to conduct a statistical analysis of the data and questionnaires. By using AMOS7.0 to verify the hypothetical structural equation model of organizational innovation climate and individual innovation behavior, the relationship between the two is obtained, which is a useful tool for IoT manufacturing technology enterprises. Achieving a higher degree of organizational structure innovation provides a valuable reference.

2. Related Work

At the end of the twentieth century, with the emergence of the new economy and the development of the theory of enterprise innovation, the theory of organizational innovation began to appear. There is no unified definition and classification of organizational innovation, and the similarities and differences between it and organizational structure innovation are unclear. For example, many scholars define organizational innovation as the organization adopting a new idea or behavior, where innovation refers to a new product, a new service, a new technology, or a new management practice. Alasoinni defined organizational innovation as a change in the division of labor and interactions within functions, between functions, and between organizations. Knight divided organizational innovation into four categories: product or service innovation, production process innovation, structural innovation, and people innovation. Michael Hammer and James Champy put forward the theory of process reengineering and enterprise reengineering. BPR became a new method of business organization that emerged in the United States in the early 1990s. They gave a precise definition of BPR: BPR is a fundamental rethinking of business processes and a complete overhaul to achieve dramatic improvements in business performance measures such as cost, quality, service, and speed. This definition contains four keywords: radical, thorough, dramatic, and flow. At the same time, Peter Senge, a professor at the Massachusetts Institute of Technology in the United States and a famous management scientist, pointed

out the management concept of Learning Organization, stating that today's society has entered the information age, and enterprises must remain in the social reform and market economy tide. Inevitably, becoming a learning enterprise organization is a development trend. Based on the basic principles of system dynamics, he specifically conceived some basic characteristics of future enterprises, including flat organizational structure, organizational informatization, more open organization, and the relationship between employees and managers gradually shifting from subordination to work. Correspondingly, for IoT manufacturing technology, in the 1960s, Joan Woodward studied the impact of technology on organizational structure. Lee and Leonard found that self-guided trolleys changed the nature of employees' work in a low-volume manufacturing environment; scholars such as Samson believed that the successful implementation of IoT manufacturing technology should carefully consider organizational and human resource issues such as responsibilities, recognition of changes, positions, and skills. Ghani et al. proposed that necessary organizational changes must be made in the application of IoT manufacturing technology to obtain higher performance. Saraph and Sebastian reviewed numerous studies and concluded that the failure of IoT manufacturing technology is mainly due to the neglect of key human resource factors. Gerwin and Kolodny believed that IoT manufacturing technology has led to many changes in human resource management and practice and further suggested that human resource development should be integrated with the design of new technologies in manufacturing companies. Scholars such as Mital proposed that the purpose of enterprise application of IoT manufacturing technology is to enhance the reliability and flexibility of production and improve product quality and economy, pointing out that the key to the successful implementation of IoT manufacturing technology lies in the human factor. Mohammed Zhari published the paper "The Role of Total Quality Management on Organizational Innovation," which provided new ideas for organizational structure innovation [6–11].

3. The Characteristics and Process of the Innovation Power of the Organizational Structure of the Internet of Things Manufacturing Technology Enterprises

3.1. IOT Manufacturing Technology Enterprise Organizational Structure Innovation Power Mode and Relationship. Foreign scholars attribute the power source of enterprise organizational structure innovation to technology power source, market power source, government power source, and transaction cost source. Chinese scholar Zhang Gang drew on the viewpoints of other scholars at home and abroad and summarized the main contents of six aspects of the dynamic mechanism of enterprise organizational structure innovation, that is, six possible main sources of power for organizational structure innovation: the introduction of new technologies in enterprises and the orientation of enterprise strategies. Changes in corporate value orientation and the

company's own development needs are the triggers for social, political, and economic changes. This paper believes in the innovation of enterprise organizational structure as a new organizational form for enterprises to adapt to environmental changes and productivity development requirements based on advanced manufacturing technology (Internet of Things manufacturing technology). The core innovation power of enterprises can be roughly divided into three modes. (1) Technology is the driving force of the organizational structure innovation model of the induced enterprise. From the perspective of the power source of innovation, the driving force of the technology-induced organizational structure innovation mainly comes from the development of new technologies for the enterprise. For enterprises in the fast "high-tech" industry, they have no choice but to innovate because to achieve market leadership, only continuous innovation and daring to take risks will enable enterprises to have better development opportunities. Therefore, the technology-induced enterprise organizational structure innovation model is the most important driving force for the organizational structure innovation of advanced manufacturing technology enterprises [12]. (2) The innovative power of the strategic-oriented organizational structure mainly comes from the change in the strategic orientation of the enterprise. For example, the senior leaders or managers of the enterprise make advance judgments on the changes in the internal and surrounding environment of the enterprise or make quick responses according to the existing changes. The specific performance is that according to the actual situation of the external environment and internal conditions, the corresponding material and organizational resources are concentrated to determine the organizational vision, clarify the goal of planning, adjust product structure, and realize strategic innovation. Subsequently, structural and cultural innovations are started along with strategic innovation and proceed simultaneously to realize the dynamic matching of the enterprise's strategic, cultural, and structural innovation and achieve the purpose of promoting enterprise organizational structure innovation [13]. (3) The driving force of market pressure-oriented organizational structure innovation mainly comes from the pressure of market competition. The increasingly fierce competition environment pressure in the market makes enterprises have to consider innovative changes to deal with the problems of survival and development. The competition with competitors, the competition of products or services, the competition of product quality, the competition of capital strength, the competition of marketing and public relations require enterprises to use new technologies to develop and improve products and, at the same time, adjust their organizational structure to achieve the purpose of reducing enterprise costs and enhancing competitiveness [14].

Therefore, the market competition is more intense. Companies are more inclined to adopt new technologies and restructure efficient organizations to build competitive advantage. The development of new products and changes in organizational structure and systems, among others, aim to continuously provide high-quality goods and customer

service. The combined effect of the three innovation power modes brings continuous power support to the innovation of organizational structure. The pulling effect caused by their interaction also provides favorable support and traction for their respective innovation models. Enterprises integrate the industrial structure through technological induction and accordingly need to adjust the department setting, resource allocation, and responsibility structure in the enterprise structure. The change in structure will inevitably lead to the innovation of structure, which will lead to the subtle change of corporate culture, that is, the change of corporate values and behavioral norms. Gradual changes in structure and culture, in turn, induce further changes in corporate strategy. Therefore, the innovation of the organizational structure of enterprises driven by technological induction is through structural innovation to cultural innovation and finally affects strategic innovation. The market pressure-type organizational structure innovation mainly promotes the change in enterprise strategy through changes in the external environment, thereby affecting the adjustment of the industrial structure of the enterprise or directly inducing the enterprise to enhance its competitiveness by introducing new technologies. It can also be seen from the innovation of strategic-led organizational structure that the changes in corporate culture and structure are carried out simultaneously and appear interactively under each innovation mode. Therefore, under specific circumstances, the various modes are mutually reinforcing and mutually inducing relationships, as shown in Figure 1.

3.2. General Innovation Process Model of IoT Manufacturing Technology Enterprise Organizational Structure

3.2.1. Process Model of General Organizational Structure Innovation.

As an important content of modern enterprise management, organizational structure innovation is carried out based on the process. Lewin proposed a three-stage model of the organizational innovation process of unfreezing-change-refreezing. On the basis of Lewin's three-stage model, Kotter proposed an eight-stage model of the organizational innovation process (establishing crisis awareness, forming a guiding team, creating a vision, communicating between leaders and organizational members, empowering relevant personnel to make changes, planning goals to create short-term effects, consolidate achievements and deepen reforms, and institutionalize new achievements and new methods). Scheinti put forward the "adaptation cycle" theory of the organizational innovation process. He believed that organizational innovation is a continuous cycle process (insight into changes in the environment, research changes, implementation of changes, stability of changes measures, output changes results). The specific performance of organizational innovation activities is the orderly progress of each stage or the effective connection of each link. In other words, each stage and each link can fully explain that organizational innovation is a process composed of a series of activities with corresponding functions. Based on the

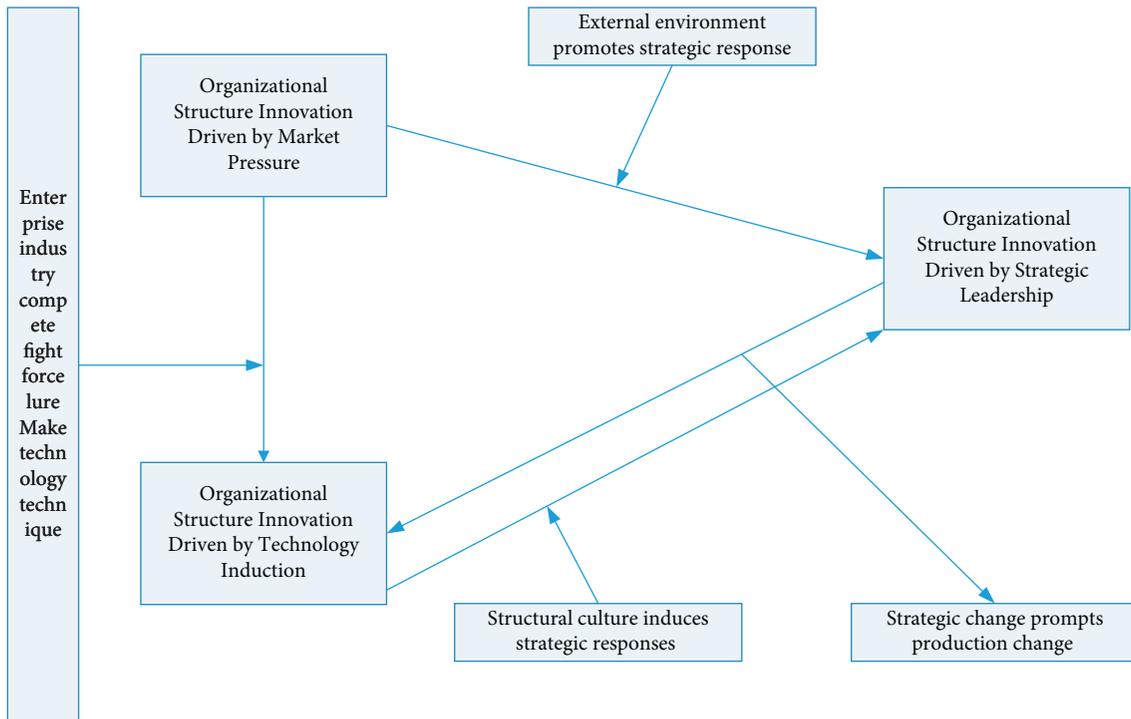

FIGURE 1: Interrelationships among the three innovation dynamic models.

viewpoints of scholars at home and abroad, we generally divide the specific implementation process of organizational structure innovation activities into two major stages. Action to make a choice the second stage is the organization implementation stage, which puts the selected action plan into practice to guide the organization and individual behavior [15]. The specific links included in these two stages are as follows: Figure 2.

- (1) Organizational structure innovation formulation stage. (1) The occurrence and determination of problems: at this stage, the managers of the organization need to consider the development and changing trends of the internal and external environment of the organization and find out the problems that the organization faces or will face at this stage according to the actual situation of the organization. For example, strong market pressure or the mismatch between organizational structure and product structure, according to which the goal of enterprise organizational structure innovation is formulated. (2) The problem is included in the organizational agenda. This stage is the feasibility analysis and demonstration stage of the innovation goal of the enterprise organizational structure. For all activities with the process, the process must be carried out under restricted conditions, so the process of organizational structure innovation must also be carried out in a specific organizational

structure innovation environment. The problem that enterprises should consider is whether the goal of organizational structure innovation can be successfully achieved under the existing environmental conditions of the organization. If the result of the demonstration is that the goal of enterprise organizational structure innovation cannot be achieved under the existing organizational environment of the enterprise, then the enterprise needs to redefine the goal of organizational structure innovation according to the demonstration situation. Many enterprise organizational structure innovations end in failure, most of which are due to the lack of feasibility demonstrations of organizational structure innovation, which leads to the establishment of organizational structure innovation goals that are out of the actual situation of enterprises and organizations, resulting in increased risks of organizational structure innovation. (3) Organizational planning and preassessment: this stage is the design and selection stage of the company's organizational structure innovation plan. Enterprises design several alternative organizational structure innovation plans according to the established organizational structure innovation goals and inherent resource conditions of the organization. Enterprise decision-makers select the best plan for implementation through a comprehensive evaluation of the

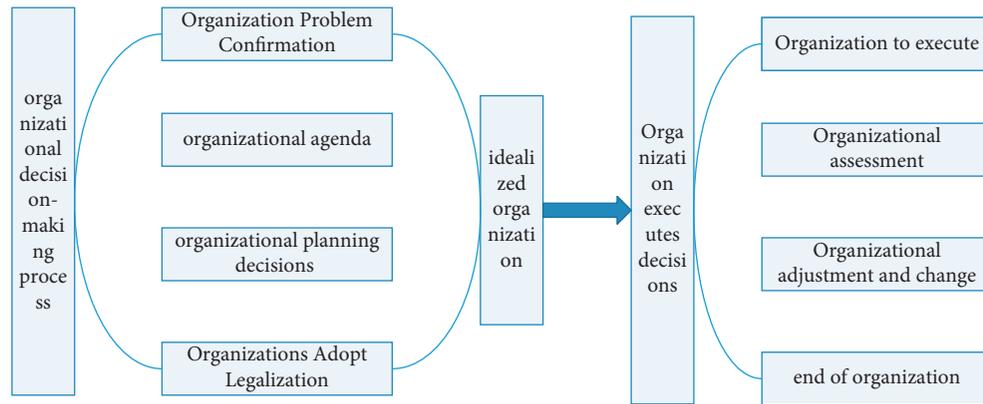

FIGURE 2: Organizational structure innovation process.

alternative plans. In addition, the value tendency and risk preference of organizational decision-makers, the actual resource conditions possessed by the enterprise organization, and the coordination of various interests within the organization are also important factors that affect the choice of innovative plans for enterprise organizational structure.

- (2) Organization and implementation stage. (1) Organizational execution: the implementation of organizational structure innovation by the enterprise is the final confirmation of the innovation plan by the entire organization and is transferred to a controlled release. The specific content includes the acquisition of resources, the preparation of relevant documentation and manuals, and the training of organizational members. The final and crucial step is implementation because no matter how excellent an organization structure innovation plan an enterprise chooses, the implementation of the innovation plan largely determines whether the plan can achieve the ideal goal of organizational structure innovation. (2) Organizational evaluation: this stage evaluates the innovation effect of enterprise organizational structure. Enterprises need to generate a complete and effective evaluation index system according to the ultimate goal of organizational structure innovation, use this as a standard to make accurate value judgments on the effect evaluation of the organizational structure innovation process of enterprises, and provide feedback information according to the judgment for future improvement. The evaluation content in this process mainly includes the following aspects: suitability of organizational goals; input-output efficiency of organizational structure innovation; adequacy of organizational performance; actual performance of organizational structure innovation; resource input quality and allocation; the evaluation of the situation; the fairness of the organization's formulation and implementation; the coordination of the internal interests of the organization; and the impact on the overall development of the enterprise. (3) Organization

adjustment and improvement: this stage is the consolidation and adjustment of the innovation process of the enterprise organizational structure. Consolidate and adjust the organizational structure innovation of the enterprise according to the evaluation of the organizational structure innovation effect. If the effect of the organizational structure innovation is more significant and achieves the corporate organizational structure innovation goal set in advance, then the existing innovation achievements will be consolidated. If the organizational structure innovation effect is not very good, then the organizational structure innovation plan must be carried out. Improve and adjust, and then implement the improved and adjusted program. If the final organizational structure innovation result is far from the original target, it is impossible to achieve the goal of organizational structure innovation through timely improvement and adjustment of the organizational structure innovation plan. Implement new innovation activities under the newly formulated organizational structure innovation goals. (4) The end of the organization means the end of organizational structure innovation activities. To sum up, the general organizational structure innovation is divided into two stages, and each stage has four subprocesses. The first is the decision-maker's process on what action to take for the organizational problem, which includes four subprocesses in the first stage: the occurrence and identification of the problem; the problem included in the organizational agenda; organizational planning and change; and organizational adoption and legalization change. Then, an idealized organizational structure innovation is formed through organizational formulation; then, it is transferred to the organizational execution stage of organizational structure innovation. The four subprocesses of this stage are organizational implementation, organizational evaluation, organizational adjustment and change, and organizational termination. The specific process is shown in Figure 2.

3.2.2. Characteristics of Organizational Structure Innovation Process. Through the general process model of organizational structure innovation, we can see that organizational structure innovation is a cycle with dynamic, systematic uncertainty and regular changes in the process of risk. Therefore, the process of organizational structure innovation has the following characteristics: (1) organizational structure innovation is a reciprocating and cyclical process. The organizational structure innovation process is different from the previous production process. It is often through repeated cycles between several steps in the innovation process to finally achieve the goal of improving organizational efficiency that the enterprise expects. (2) The process of organizational structure innovation is dynamic and systematic. The process of enterprise organizational structure innovation is dynamic and changes with time. Enterprises in different life cycle stages have different organizational characteristics. In different life cycle stages, the innovation of enterprise organizational structure needs to be adjusted accordingly. In addition, in the process of organizational structure innovation, members of the organization organically combine a series of resources in the enterprise and the organization to achieve the purpose of preorganizational structure innovation. This involves all aspects of the enterprise co-organization system. The process of structural innovation is an uncompromising complex system engineering. (3) The process of organizational structure innovation is uncertain and risky. Because, in most cases, the environment of organizational structure innovation is not static and there are many uncontrollable factors within the enterprise organization, such as the way of thinking and code of conduct of the people inside the organization, and because people's cognitive ability to things is limited, we cannot fully understand and recognize the innovation process and cannot fully and effectively solve various problems in the innovation process. It has also been affected to varying degrees [16].

The process of organizational structure innovation is not only a simple change in the organizational structure or organizational procedures of an enterprise, but a reasonable and stable arrangement of human, material, and financial resources and their structure in the enterprise or organization, which means the combination of enterprise resources. The change of the method requires breaking the internal balance of the original organization, and the breaking of this balance can easily lead to the loss of control of enterprise management, coupled with the uncertainty of the process of organizational structure innovation itself, which means that the process of organizational structure innovation is full of risks for businesses.

4. An Empirical Study on the Impact of IoT Manufacturing Technology Companies on Organizational Structure Innovation

4.1. Study Design and Research Methods. This study used the empirical research method of a questionnaire survey. The content of the questionnaire is the organizational innovation climate scale and the personal innovation behavior scale. The

organizational innovation climate scale is mainly based on the KEY scale of amabile and borrowed from the revision of the KEY scale based on the Chinese background by Jian Qiu Haozheng, Sun Rui, and Liu Yun, among others. The personal innovation behavior scale was designed based on Scott and Bruce's three-stage model of innovation behavior and Janssen's scale on innovation behavior. Questionnaire scores of the two scales are through the summary, induction, sorting, testing, item analysis, exploratory factor analysis, and confirmatory factor analysis. Among them, the organizational innovation climate scale contains six dimensions and 24 items, and the personal innovation behavior scale contains eight items. The formal measurement items passed the reliability and validity test, which proved that the organizational innovation climate in the background of advanced manufacturing technology enterprises could be improved by colleagues support (CS), supervisor support (SS), organizational philosophy (OV), resource provision (RS), task characteristics (TC), knowledge support (KS), and other six aspects are measured and evaluated. The personal innovation behavior of employees in IoT manufacturing technology enterprises can be measured and evaluated in two aspects: the generation of innovative ideas ($F1$) and the implementation of innovative ideas ($F2$). The research questionnaire showed good reliability and validity. Both the organizational innovation climate questionnaire and the personal innovation behavior questionnaire are designed in the form of a five-point Likert scale because, in most cases, the five-point scale is the most reliable, and if the options exceed five points, it is difficult for ordinary people to distinguish enough. The three-point scale limits the expression of moderate and strong opinions, and the five-point scale can express the difference between moderate and strong opinions. The respondents choose according to their actual situation in the enterprise and the degree of agreement for each item. In the innovation climate questionnaire, "1" means strongly disagree, "5" means strongly agree, "1" in the innovation behavior questionnaire means never innovating, and "5" means very frequent innovation. At the same time, the questionnaire adopts the method of filling in the blanks and selection and also collects the personal background information of the respondents, including age, gender, education, position, and tenure of service.

4.1.1. Sample Selection and Data Sources and Distribution. The research object of this research is knowledge workers in enterprises applying advanced manufacturing technology. According to the principle of improving the efficiency of questionnaire recovery as much as possible and meeting the required samples, the formal questionnaire survey was conducted by two methods. One is to distribute questionnaires to colleagues through familiar students working in companies that apply advanced manufacturing technology. Good relationships among colleagues and ease of contact ensured high questionnaire recovery rates and questionnaire validity. The second method is to collect questionnaires by sending web-mails to enterprises applying advanced manufacturing technology. This method is inefficient and

has poor recovery. The validity of the questionnaire is also high. The questionnaire survey was carried out from August to September 2010. A total of 200 questionnaires were distributed by the first method, and 175 valid questionnaires were recovered. The effective recovery rate of the questionnaire was 87.5%. A total of 100 questionnaires were distributed by the second method, 34 valid questionnaires were recovered, and the effective recovery rate of the questionnaires was 34%. A total of 300 questionnaires were distributed, and 209 valid questionnaires were recovered, and the effective recovery rate was 70%.

4.1.2. Questionnaire Test Method

- (1) Correlation Analysis of questionnaire items: each variable measurement item in this paper reflects related constructs and concepts, so item scores should be moderately related to each other. If an item has a very low correlation coefficient with all or most other items (often with < 0.03 as the criterion), then the item cannot be part of the scale. If one item is highly correlated with most other items (often by > 0.70), then it is questionable as an independent measure of the scale (Tang, 1999). In this study, 0.70 was used as the criterion for selecting topics. Item-total correlation analysis (Corrected Item-Total Correlation, CITC for short) is one of the methods to purify measurement questions. The CITC analysis follows the following principles: all the items whose CITC is less than 0.40 and which can increase Cronbach's alpha coefficient should be deleted (Tian, Bearden, and Hunter, 2001). Therefore, we use 0.40 as the critical criterion to decide the choice of measurement items.
- (2) Reliability analysis of questionnaire items: the commonly used information test method in the Likert attitude scale is Cronbach's alpha coefficient method. For item selection, the internal reliability of each subscale is mainly measured by the degree of change of the α coefficient before and after item deletion to test whether the items are really the theoretical constructs that are intended to measure the design and to what extent are all items that measure the same constructs internally consistent. The larger the Cronbach's alpha value, the better the correlation between the questionnaire items and the higher the reliability of internal consistency. In general, Cronbach's alpha values greater than 0.8 indicate excellent internal consistency, values between 0.6 and 0.8 indicate good internal consistency, and values below 0.6 indicate poor internal consistency. The scholar Gay (1992) believed that the reliability coefficient of any test or scale above 0.90 means the reliability is very good. Scholars have different opinions on the acceptable minimum reliability coefficient, such as 0.70 (De Vellis, 1991; Nunnally, 1978) and 0.80 (Bryman and Cramer, 1997). However, most believe that if the reliability is

below 0.60, it is appropriate to revise the research tool. In this study, the standard of Cronbach's alpha was set to 0.70.

- (3) Exploratory factor analysis of questionnaire items: exploratory factor analysis is to test whether all items theoretically belonging to the same dimension can clearly form a common factor with the largest extraction variance ratio so that the connotation of this dimension can be expressed and conceptualized. In this study, the KMO (Kaiser-Meyer-Olkin) measure and Bartlett's sphericity test were used to judge whether the samples were suitable for factor analysis. The KMO value is used to judge the standard as shown in table 1, and the Bartlett sphericity test generally only needs to reach a significant level. Then, the principal component analysis method and the maximum variance method are used to rotate and solve the common factor, the eigenvalue is greater than 1, the gravel diagram determines the number of factor extractions, the factor loading is less than 0.50 as the topic selection scale, and the cumulative variance explanation rate of the extracted factors is not less than 50%. At the same time, the item with cross-factor loading exceeding 0.40 (Gorsuch, 1983) is not allowed. Otherwise, the item will be deleted, as shown in Table 1.
- (4) Questionnaire item validity analysis: the construct validity of the questionnaire was analyzed by confirmatory factor analysis. It can test the stability of a scale structure and can also simplify the items obtained by exploratory factor analysis. Judging whether a model and data are well fitted is usually judged by combining absolute fitting indicators and relative fitting indicators. Absolute fitting indicators include χ^2/df , GFI, AGFI, NCP, ECVI, RMR, and RMSEA; relative fitting indicators include CFI, NFI, IFI, TLI, and RFI. In this study, the indicators of χ^2/df , RMSEA, IFI, TLI, CFI, and GFI will be combined to judge the degree of model fit [17–20].
 - (1) χ^2/df (view fit index): the fit index χ^2/df value refers to a statistic that directly tests the similarity between the sample covariance matrix and the estimated covariance matrix and can be used to measure the overall fit of the model and try to correct the model with a low degree of fit. It is generally believed that when $\chi^2/df < 3$, the model fits better; the closer the χ^2/df value is to 1, the better the model fits, $\chi^2/df > 2$ is an ideal result, $2 < \chi^2/df < 5$ indicates that the overall model is acceptable; $\chi^2/df > 5$ indicates that the observed data do not fit the model well, $\chi^2/df > 10$ indicates that the observed data does not fit the model, and the model is very poor.
 - (2) Root Mean Square Error of Approximation (RMSEA) is more sensitive to the error model and easily explains the quality of the model; the RMSEA index is less affected by the sample size and is a widely used fitting index in recent years

TABLE 1: KMO indicator standards.

KMO value	>0.90	0.80–0.90	0.70–0.80	0.60–0.70	0.50–0.60	<0.50
Standard	Very suitable	Suitable	Generally	Barely fit	Not suitable	Unacceptable

one. The variation interval of RMSEA is between 0 and 1, and it is generally believed that the closer to 0, the better. When RMSEA is less than 0.05, it indicates that the model fits very well; if it is greater than 0.05 and less than 0.08, it indicates that the model fits well; and if it is greater than 0.08 and less than 0.1, the model is acceptable.

- (3) Incremental Fit Index (IFI) is generally in the range of 0 to 1, and the closer to 1, the better the fit. It is generally believed that greater than 0.9 indicates a good fit, and if IFI is greater than 0.8, the model is considered acceptable.
- (4) Tucker–Lewis index (TLI), a nonstandard fitting index, is generally in the range of 0 to 1. The closer TLI is to 1, the better the fitting degree is. It is generally considered that a TLI greater than 0.9 indicates a good fit, and a TLI greater than 0.8 indicates that the model is acceptable.
- (5) Comparative Fit Index (CFI): the variation range of CFI is between 0 and 1. The closer it is to 1, the better the degree of fit is. If the CFI is greater than 0.9, it is considered that the model has a good fit. When the CFI is greater than 0.8, the model is considered acceptable.
- (6) Goodness of Fit Index (GFI): the variation interval of GFI is between 0 and 1. The closer it is to 1, the better the degree of fit is. If the GFI is greater than 0.9, it is considered that the model has obtained better results. If the GFI is greater than 0.8, the model is considered acceptable.

4.1.3. Structural Equation Model of Organizational Innovation Climate and Individual Innovation Behavior. Most studies believe that organizational innovation climate has a positive predictive effect on individual innovation behavior, whereas some studies believe that organizational innovation climate has no relationship with organizational innovation behavior. This paper focuses on the organizational innovation climate and organizational innovation behavior of IoT manufacturing technology enterprises. The relationship is further explored, and the following assumptions are made:

Hypothesis 1. Colleague support has a positive impact on individual innovative ideas.

Hypothesis 2. Colleague support has a positive effect on the implementation of individual innovative ideas.

Hypothesis 3. Supervisor support has a positive impact on individual innovative ideas.

Hypothesis 4. Supervisor support has a positive effect on the implementation of individual innovative ideas.

Hypothesis 5. Organizational philosophy has a positive impact on individual innovative ideas.

Hypothesis 6. Organizational philosophy has a positive impact on the implementation of individual innovative ideas.

Hypothesis 7. Resource supply has a positive impact on individual innovative ideas.

Hypothesis 8. Resource supply has a positive impact on the implementation of individual innovative ideas.

Hypothesis 9. Task characteristics have a positive impact on individual innovative ideas.

Hypothesis 10. Task characteristics have a positive impact on the implementation of individual innovative ideas.

Hypothesis 11. Knowledge support has a positive impact on individual innovative ideas.

Hypothesis 12. Knowledge support has a positive impact on the implementation of individual innovative ideas. By combining the above 12 assumptions, the structural equation model of the two groups of variables can be shown in Figure 3.

4.2. Questionnaire Test Results

4.2.1. Construct Validity Analysis of Organizational Innovation Climate Scale. According to the output results of the AMOS fitting model analysis, we summarize the main indicators in the validity analysis as shown in Table 2. The structural validity of the organizational innovation climate questionnaire is acceptable.

As shown in the results, after the confirmatory factor analysis of the factor structure model, the fitting indexes all reach the ideal level. Therefore, goal orientation can be divided into six clear dimensions: peer support, supervisor support, organizational philosophy, resource supply, task characteristics, and knowledge support, as shown in Figure 4.

4.2.2. Analysis of the Construct Validity of the Personal Innovation Behavior Atmosphere Scale. According to the output results of the AMOS fitting model analysis, we summarize the main indicators in the validity analysis as shown in Table 3. According to the above-mentioned main indicators and each indicator judgment standard, the

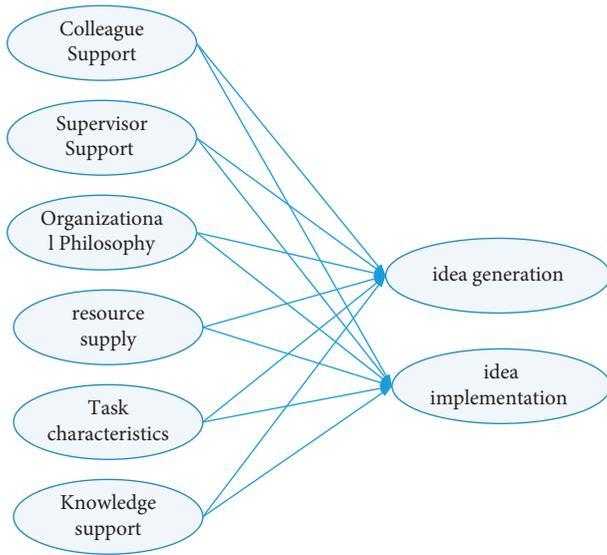

FIGURE 3: Hypothetical model.

TABLE 2: Confirmatory factor analysis of organizational innovation climate.

Variable	Fit metrics					
	χ^2/df	RNSEA	IFI	TLI	CFI	GFI
Six-factor structure	1.617	0.064	0.862	0.834	0.875	0.821

RNSEA value reaches 0.100, and the minimum requirement is the personal innovation behavior questionnaire. Construct validity is okay.

As shown in the results, after the confirmatory factor analysis of the factor structure model, each fitting index has reached the ideal level. Therefore, goal orientation can be divided into two clear dimensions: the generation of innovative ideas and the implementation of innovative ideas, as shown in Figure 5.

4.3. *Verification of the Organizational Innovation Atmosphere and Individual Innovation Relationship Structure Model of IoT Manufacturing Technology Enterprises.* Based on the previous analysis, we use AMOS 7.0 to verify the hypothesis model of the relationship between organizational innovation climate and individual innovation behavior, as shown in Figure 6. The fitting index of the model is shown in Table 4. From the fitting index, it is assumed that the fitting degree of the model is good.

According to the verification results of the hypothesis structural equation model by the AMOS 7.0 software, as shown in Figure 6, in the IoT manufacturing technology enterprise, for hypothesis 1, the nonstandard regression coefficients of CS and F1 are 0.52, indicating that the support level of each colleague is 0.52. With an increase of one unit, the generation of individual innovative ideas will increase by 0.52 units; for hypothesis 2, when the nonstandard

regression coefficients of parameters CS and F2 are 0.47, it indicates that for each unit increase in the support level of colleagues, the implementation of individual innovative ideas will increase by 0.47 units; for hypothesis 3, the nonstandard regression coefficients of parameters SS and F1 is 0.38, indicating that for each unit of supervisor support, the generation of individual innovative ideas will increase by 0.38 units; for hypothesis 4, the nonstandard regression coefficients of parameters SS and F2 are 0.25, indicating that each unit of supervisor support will increase individual innovative idea implementation students by 0.25 units; for hypothesis 5, the nonstandard regression coefficients of OV and F1 are 0.44, the generation of individual innovative ideas will increase by 0.44 units; for hypothesis 6, the standard regression coefficients of OV and F1 are 0.32, indicating that, for each unit increase in organizational concept level, the implementation of individual innovative ideas will increase by 0.32 units; for assuming hypothesis 7, the nonstandard regression coefficients of RS and F1 are 0.48, indicating that, for each unit increase in resource supply level, the generation of individual innovative ideas will increase by 0.48 units; for hypothesis 8, the nonstandard regression coefficients of RS and F2 is 0.50, indicating that, for each unit increase in resource supply level, the implementation of individual innovative ideas will increase by 0.50 units; for hypothesis 9, the nonstandard regression coefficients of TC and F1 are 0.43, indicating that, for each unit increase in task characteristic level, the generation of innovative ideas will increase by 0.43 units; for hypothesis 10, the nonstandard regression coefficients of TC and F2 are 0.52, indicating that, for each unit increase in the task characteristic level, the implementation of individual innovative ideas will increase by 0.52 units; for hypothesis 11, the nonstandard regression coefficients of KS and F1 are 0.40, indicating that, for each unit of knowledge support, the generation of individual innovative ideas will increase by 0.40 units; and for hypothesis 12, the nonstandard regression coefficients of KS and F2 are 0.36, indicating that, for each additional unit of knowledge support, the implementation of individual innovative ideas will increase by 0.36 units. [21–24].

To sum up, the organizational innovation climate has a significant positive impact on the innovation behavior of individuals in the organization. All 12 hypotheses have been verified, indicating that, in IoT manufacturing technology enterprises, people who are the main body of innovation, regardless of the factors that affect innovation in the organization, will have a certain impact on their innovation behavior. In particular, the stimulation, encouragement, and support of individuals' innovative behaviors by enterprises, to a large extent, determines whether the organization can successfully develop its innovative ability and dynamic adaptability. Therefore, the higher the organizational innovation atmosphere, the greater the promotion of individual innovation behavior, and the improvement of individual innovation ability has a positive effect on organizational structure innovation through the function of seeking maximum consistency in organizational management. The greater the promotion effect, the more conducive to improving the organizational structure innovation of IoT manufacturing technology enterprises.

5. Conclusion

In recent years, there has been a wave of research and application of advanced manufacturing technology around the world. With the wide application of advanced

manufacturing technology in China, many enterprises have obtained better benefits. However, many enterprises still fail when implementing IoT manufacturing technologies. The fundamental reason is that the traditional organizational management model of Chinese enterprises cannot well match the manufacturing technology of the Internet of Things, which restricts the development of the manufacturing technology of the Internet of Things. In order to maximize the benefits brought by IoT manufacturing technology, enterprises must learn to transform the traditional organizational management structure to adapt to the production requirements of advanced manufacturing technology. It is imperative to innovate the organizational structure of IoT manufacturing technology enterprises. The research of this paper not only has important theoretical significance for the development and enrichment of the theory of organizational innovation power and process theory of IoT manufacturing technology enterprises but also provides information on factors such as organizational innovation atmosphere and innovative behavior with others that affect the organizational innovation of IoT manufacturing technology enterprises. Empirical analysis research has strong practical application value. It provides a theoretical basis and useful reference for the organizational innovation practice activities of IoT manufacturing technology enterprises. The main points and conclusions are as follows.

This research conducted a questionnaire survey on the innovation atmosphere of enterprise organizations and individual innovation behavior among employees of enterprises applying advanced manufacturing technology, obtained empirical data, and used SPSS 18.0 to conduct statistical analysis on the data and questionnaire. Exploratory factor analysis, reliability analysis, and confirmatory factor analysis are mainly used to analyze the factor structure of the questionnaire, and each factor structure has good reliability and validity. Using AMOS 7.0 to verify the structural equation model of the hypothetical corporate organizational innovation climate and individual innovation behavior, it is concluded that the corporate organizational innovation climate has a significant positive impact on people’s innovation behavior in IoT manufacturing technology enterprises. Organizational innovation climate plays a role in organizational structure innovation through the positive influence of individual innovation behaviors in an organization. The positive relationship between organizational innovation climate and individual innovation behaviors means that IoT manufacturing technology enterprises can achieve a higher degree of organizational structure. Innovation provides a valuable reference.

Investors pay more and more attention to the issue of climate change information disclosure of listed companies. Whether the company can effectively deal with the impact of climate change on its own operations and make reasonable information disclosure will undoubtedly affect the value of the enterprise. Aiming at this, an analysis model based on big data is designed for the impact of carbon information on enterprise value. This study selects the sample stocks of the Shanghai Stock Exchange responsibility index every year as the research sample, counts the carbon information through the social responsibility reports of listed companies, and uses the index method to score the carbon information of each company to measure the quality of carbon information disclosure. Firstly, it analyzes the situation of carbon information disclosure in China through descriptive statistics and then constructs relevant models to conduct an empirical analysis on the impact of carbon information disclosure on enterprise value.

1. Introduction

Enterprise environmental information includes many aspects, and carbon information is also an important aspect, including enterprise carbon emission reduction strategy, carbon emission accounting standards and methods, and so on. The carbon disclosure project (hereinafter referred to as CDP) is an independent nonprofit organization, which aims to open up a special disclosure channel for climate change and provide information support for investors, nongovernmental organizations, and policymakers [1–4]. Among the enterprises that have accepted the CDP questionnaire and disclosed carbon information to them, the enterprises in Europe and the United States have always been in the leading position, and their carbon information disclosure in the CDP questionnaire is more specific and perfect, and the degree of disclosure is relatively high [1–5].

The high-quality carbon information disclosure of these foreign enterprises has been actively promoted by investors and local laws and regulations [6, 7]. The US government

promulgated the mandatory greenhouse gas reporting system in 2009, which stipulates that certain special industries and companies that emit more than 25000 tons of greenhouse gas per year must report to the EPA. In the UK, regulations related to mandatory information disclosure are also under discussion. Japanese government departments, Canada, and Australia began to implement the system of reporting greenhouse gas emissions to relevant departments in 2004 and 2007, respectively [8–10]. Based on the above information, we can see that the government continues to put forward and improve the management system to continuously improve the information disclosure level of enterprises, and at the same time, the business risk of enterprises will also increase [11–15]. This situation will not only affect the specific response measures for enterprise emission reduction but also affect the enterprise value and future development path.

People pay more attention to climate change and have a deeper awareness of environmental protection [16]. Investors and stakeholders have begun to pay attention to whether

the products and services of enterprises are low-carbon, the company's carbon footprint, carbon trading, etc. The regulatory risks, product risks, technical risks, and physical risks related to climate change will have an impact on the company's asset portfolio and cost level [17–19]. The global economy is slowly changing into a low-carbon form, which will have a great impact on the competitiveness and long-term valuation of enterprises, which is gradually realized by people in the capital market. After disclosing carbon information to the public, the company will send a signal to the capital market, representing that the company will carry out management activities related to carbon emissions, which will have an impact on the value of the enterprise. After experiencing this series of situations, the resources in the market will be redistributed among the successful and neglected enterprises.

At this stage, the level of carbon information disclosure of Chinese companies is not high, and it is still in the initial stage. Among all the listed companies, there are not many companies that disclose carbon information. Even among the enterprises that disclose carbon information, the disclosure content lacks standardization and comprehensiveness. The research of this article can make enterprises aware of the significance of carbon information disclosure so as to improve the level and quality of carbon information disclosure in Chinese enterprises. In this way, the company's image has been well packaged, and the international competitiveness and social status of Chinese enterprises have also been strengthened. The research content of this article can provide suggestions on carbon information disclosure for government regulators and relevant policymakers. By analyzing the current situation of carbon information disclosure in China, this article puts forward some suggestions that the carbon information disclosure of Listed Companies in China can be integrated with the mainstream reports and formulates relevant laws and regulations to improve the content and form of carbon information disclosure, which can make carbon information disclosure more standardized and decision-making more effective.

2. Analysis Model Design

2.1. Sample Selection and Data Sources. This article selects A shares listed on the Shanghai Stock Exchange (SSE), uses the constituent stocks of the Shanghai Stock Exchange Social Responsibility Index each year as a research sample, and retrieves their social responsibility reports disclosed in 2012–2015. The SSE Social Responsibility Index takes the stocks of companies listed on the Shanghai Stock Exchange that have performed better in social responsibility in the corporate governance sector as constituent stocks, then the index thus compiled. In the research process, this article conducts the following screening on the research samples:

- (1) Excluding the financial industry.
- (2) The sample companies in this study require complete data in all aspects, so companies with incomplete disclosure data are excluded.

After screening, a total of 337 pieces of eligible data were found. The annual composition of the sample companies is shown in Table 1.

The sample data are from CSMAR and WIND, and the social responsibility report is searched and downloaded from <https://www.cninfo.com.cn>. The explanatory variable carbon information disclosure index (CDI) is scored manually from the social responsibility reports downloaded by each sample company.

2.2. Variable Selections

2.2.1. Explained Variables: Enterprise Value. Many indicators can measure enterprise value, and the key is to divide them into accounting and market indicators. Since enterprise value is a long-term dynamic concept. However, accounting indicators are only historical indicators, and the reflected information is not comprehensive. If accounting indicators are used to measure the value of an enterprise. It is easy to produce short-sighted situations, and it is easy to make inaccurate estimates of the future risks and development status of enterprises. Accounting indicators are relatively unstable, easily manipulated, and easily affected by relevant accounting data. Judging from the above situations, the accounting indicators cannot accurately and comprehensively reflect the real operating conditions of the enterprise. Therefore, it is not suitable as an indicator to accurately reflect an enterprise value.

As a market indicator, Tobin's Q reflects the relative value of an enterprise [20, 21]. Tobin's Q is not easy to manipulate and avoids fluctuating stock prices. EVA, which is also a market indicator, also needs to be calculated, which is relatively complicated and relatively difficult to determine.

2.2.2. Explanatory Variable: Carbon Information Disclosure Index. When designing the CDI score table, this study takes the stakeholder theory as the theoretical basis, combined with previous scholars' research on environmental information disclosure and the content of carbon information disclosure in the CDP questionnaire. At the same time, combined with the actual situation of my country's listed companies, a carbon information disclosure evaluation system suitable for Chinese enterprises is constructed.

Most scholars use the index method when studying environmental information disclosure. It was indicated that the index method could more accurately describe and evaluate social responsibility information. And many foreign scholars have used this method in their studies. The main point of attention in using the index method is first to classify the information to be studied, divide it into several major categories, and then subdivide each significant category into multiple subitems. Then you can start to score each item specifically. After each item has been scored, the sum of all scores is the variable indicator to be studied.

CDP China's questionnaire is an important reference for this article. In CDP China's questionnaire, carbon information disclosure is divided into three categories: strategic management, risks and opportunities, and greenhouse gas

TABLE 1: Annual composition of sample companies.

Year	Number of sample companies	The same number of companies as in the previous year
2012	85	
2013	85	77
2014	86	74
2015	82	72

emissions. Then, under these three categories, we continue to distinguish 12 subindicators such as risks and opportunities brought by climate change and strategic management of carbon emission reduction. The CDI scoring table in this article combines the actual situation of Chinese enterprises and the situation of carbon information disclosure in the corporate social responsibility report. Some deletions and additions are made to the contents of the CDP questionnaire to make it more in line with the actual situation of listed companies in my country. The carbon information disclosure in this article is divided into four categories: strategies for addressing climate change, climate change governance systems and policies, carbon emission reduction measures and actions, and carbon accounting emissions. Then each category is refined and subdivided into 17 small projects, such as corporate emission reduction strategies, and some projects can be divided into qualitative disclosure and quantitative disclosure. Each item is scored against the corporate social responsibility report, with 2 scores for quantitative disclosure, 1 score for qualitative disclosure, and 0 for no disclosure. The total score for the 17 items is 27 scores. After scoring, the total score of each item is CDI. The CDI score judges the detailed level of carbon information disclosure.

After scoring, some scholars will also consider the weight of information and assign different scores to corresponding information according to the different degrees of importance of the information. This study argues that although there may be some differences in the importance of different information, there is also a lot of subjectivity when assigning weights. In this way, the score may be subjectively influenced by the scorer to a large extent. Therefore, the following research did not consider the weight problem but directly added up the scores.

The CDI score table of this study is shown in Table 2:

2.3. Control Variables. According to the previous research of many scholars at home and abroad, it can be learned that many aspects may impact carbon information disclosure. In the following empirical research, we will consider controlling some factors, which will help reflect the impact of carbon information disclosure on corporate value to a greater extent.

2.3.1. Company Size. Social public pressure refers to attracting too much attention from the public, which will bring pressure on oneself. And this pressure is very likely to be affected by the company's expansion. If the company expands, the enterprise scale will be more significant.

Therefore, the larger the company expands, the greater the pressure on the public to bear because the more significant the scale of the company, the easier it is to attract attention from all walks of life.

After a series of scientific studies has proved that a series of consequences of climate change will adversely affect enterprises and individuals because it will lead to problems such as resource shortage and air pollution. With the public's attention to this issue, the company began participating in related low-carbon activities. This article's research uses the degree of enterprise development to represent the pressure mentioned above. Because the bigger the company is, the more people related to its interests and other aspects are, and the easier it is to receive attention from the outside world. Therefore, this article believes that the larger the enterprise develops, the more willing to disclose its carbon information to the outside world.

Company size is a variable often used by domestic and foreign scholars to study enterprise value. This article uses the natural logarithm of the company's total assets at the end of the year to measure the company's size. It takes the company's size as a control variable that affects its value, denoted as SIZE.

2.3.2. Ownership Concentration. So far, the academic community has not reached a clear conclusion on whether the impact of equity on enterprise value is positive or negative. This article selects the sum of the top ten shareholders' shareholding ratios in the corresponding annual reports each year to measure the shareholding concentration and control the impact of the shareholding structure on the enterprise value.

2.3.3. Profit Capacity. Investors pay attention to a company's profit capacity before investing in a business. A company's profit capacity also affects many aspects of the business, such as asset liquidity. Based on the existing research, this article regards ROE as a control variable at the end of each year and adds it to the regression model for the calculation to represent profit capacity.

2.3.4. Company Growth. The ability of a company to grow is conducive to enhancing its value. For investors, a company's growth is an essential basis for their investment decisions. The higher the company's growth, the better the future development prospects. In this way, the company's investors will have a good expectation for the company's future stock price. It can be seen from this that the stronger the company's growth, the higher the value of the company in general. Many indicators can measure the company's growth. Combined with some previous studies by scholars, this article uses the operating income growth rate to measure the company's growth.

2.3.5. Industry Attributes. The public expects industries with high-carbon emissions to fulfill more social responsibilities. The nature of the industry to which the company belongs is

TABLE 2: Carbon information disclosure index (CDI) score.

	Carbon information disclosure project	Introduction
Climate change strategy	(1) Identification of opportunities and risks related to climate change	1 score for disclosure, no score for nondisclosure
	(2) Integrating low-carbon development into business strategies	1 score for disclosure, no score for nondisclosure
	(3) Proposing the concept of low-carbon development	1 score for disclosure, no score for nondisclosure
	(4) Enterprise emission reduction strategy	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(5) Responsibility for climate change	1 score for disclosure, no score for nondisclosure
Climate change governance and policy	(6) Setting up a management organization	1 score for disclosure, no score for nondisclosure
	(7) Establishing a reward and punishment incentive mechanism	1 score for disclosure, no score for nondisclosure
Carbon reduction measures and action	(8) Carbon reduction targets	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(9) Participation in carbon trading	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(10) Publicity and training on carbon emission reduction	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(11) Use of low-carbon products and services	1 score for disclosure, no score for nondisclosure
	(12) Enterprises use new technologies to reduce carbon emissions	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
Carbon accounting and emissions	(13) Standard and method of carbon emission surface calculation	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(14) Carbon emission performance (emission history, emission intensity, emission reduction)	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(15) Energy consumption (energy consumption energy saving, and energy intensity (energy consumption per unit of output value))	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(16) Rewards and punishments received by the environmental protection department	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure
	(17) Carbon emission reduction costs	2 scores for quantitative disclosure, 1 score for disclosure, and no score for nondisclosure

different, and the level of carbon information disclosure is different. At the same time, the industry attribute may impact the relationship between carbon information disclosure and corporate value. In addition, industry differences may affect the level of carbon information disclosure of enterprises.

According to the list of carbon emissions released by the Chinese Academy of Sciences, the top five industries with carbon emissions are defined as high-carbon emission industries, and the remaining industries are low-carbon emission industries. In this study, the industry attributes are assigned a value of 1 for companies in industries with high-carbon emissions and 0 for companies in industries with low-carbon emissions.

2.3.6. Nature of Ownership. Generally speaking, there is a relatively close relationship between state-owned enterprises and the government. Because of such a relationship, the public believes that state-owned enterprises should shoulder more environmental responsibilities than nonstate-owned

enterprises. Our country's state-owned enterprises are different. Compared with other enterprises, they may fulfill more energy conservation and emission reduction responsibilities, and the disclosure of carbon information will be more comprehensive. This study uses the ownership nature of the firm as a control variable. If the state controls the company, then set this item to 1. Otherwise, it is 0; see Table 3.

2.4. Model Construction. This article uses a linear regression equation in an empirical study to examine the impact of a company's carbon disclosure on corporate value. The model used in this article is as follows: in the research, some frequently used variables are selected as control variables in the empirical analysis, such as enterprise size and ownership concentration, using CDI as an independent variable in the model results from scoring the carbon information disclosure index. Tobin's Q was used as the dependent variable in the study [20, 21]. Model 1 is constructed to study the impact of carbon information disclosure on corporate value.

TABLE 3: Description of research variables.

Variable type	Variable type	Variable symbol	Metrics	Calculation method
Explained variable	Corporation value	Q	Tobin's Q	Tobin's Q value = market capitalization at the end of the year/total assets at the end of the year
Explanatory variables	Carbon information disclosure level	CDI	Carbon disclosure index	Score table
	Company size	SIZE	Total assets	Company size = logarithm of total assets at the end of the year
	Ownership concentration	OCN	Shareholdings of the top ten shareholders	Ownership concentration = the sum of the shareholding ratios of the top ten shareholders
	Profit capacity	ROE	Return on equity	Return on equity = profit after tax/Owner's equity
	Company growth	GROWTH	Operating income growth rate	Company growth = (operating income at the end of the current period - operating income at the end of the previous period)/operating income at the end of the previous period
Control variable	Industry attributes	IND	Virtual variable, whether it is a high-carbon emission industry	According to the list of carbon emissions released by the Chinese Academy of Sciences, the top five industries with carbon emissions are defined as high-carbon emission industries, and the remaining industries are low-carbon emission industries. Companies in industries with high-carbon emissions are given a value of 1, and those with low-carbon emissions are given a value of 0
	Nature of ownership	STATE	Virtual variable, whether state-owned	1 for state, 0 for nonstate
	Year	YEAR	Virtual variable, set by year	In 2012, 2013, and 2014, set Y1, Y2, and Y3, respectively, set the current year to 1, and set the rest to 0

Model 1.

$$Q = \beta_0 + \beta_1 CDI + \beta_2 SIZE + \beta_3 OCN + \beta_4 ROE + \beta_5 GROWTH + \beta_6 STATE + \beta_7 YEAR + \epsilon. \tag{1}$$

At the same time, the model more deeply verifies whether the industry in which the company operates will have an impact on the relationship between the two. Therefore, the factor of IND is added to the interaction term of CDI.

Model 2.

$$Q = \beta_0 + \beta_1 CDI + \beta_2 CDI * IND + \beta_3 SIZE + \beta_4 OCN + \beta_5 ROE + \beta_6 GROWTH + \beta_7 STATE + \beta_8 YEAR + \epsilon, \tag{2}$$

where β_0 is the constant term in the regression equation, β_i is the coefficient evaluated for each explanatory variable, and ϵ is the random disturbance item.

3. Empirical Analysis

3.1. Correlation Analysis. To eliminate the influence of individual effects on the correlation between variables, the average value of each variable is calculated with the company as the unit. Then the correlation analysis is carried out. In this article, SPSS 19.0 [22, 23] is used to test the correlation of each variable in the model, and the test results are shown in Table 4.

From the correlation test, we can see a correlation between enterprise value and other variables, but the correlation between the respective variables is not exceptionally high.

3.2. Multiple Linear Regression Analysis. Since the sample companies from 2012 to 2015 are not the same, and the short time is only four years, the four-year sample is aggregated as cross-sectional data for regression analysis. Table 5 shows the multiple regression [24–29] results of the impact of carbon information disclosure on corporate value. It can be seen from Table 5 that the overall fitting degree is 0.336, indicating that the selection of explanatory variables in the model is reasonable. The variance inflation factor VIF of each variable is less than 2, meaning no multicollinearity problem among the variables.

Analysis of the regression coefficient shows that the correlation coefficient between the CDI and the enterprise value is 0.035, the significance is 0.037, and it is significantly positively correlated at the 5% level, which verifies that carbon information disclosure has a positive effect on corporate value. The correlation coefficient between the interaction term CDI * IND and corporate value is 0.086, with a significance of 0.002. It is also significantly positively correlated at the 5% level, indicating that industry factors can significantly impact the relationship between carbon information disclosure and corporate value.

In addition, enterprise value and company size are significantly negatively correlated. It shows that the expansion of the company's scale in this study is not

necessarily conducive to improving corporate value. On the contrary, the larger the company's scale is, the more likely it is to be exposed to risks and the more likely it is to be pressured by the outside world, which is not conducive to the growth of corporate value. The equity concentration and enterprise value are positively correlated at the level of 1%, indicating that increasing the equity concentration is conducive to the centralized management of enterprises and has a positive effect on enterprise value; enterprise value and profit capacity ROE are significantly positively correlated at the level of 1%, indicating that the higher the profit capacity of the enterprise, the greater the enterprise value.

3.3. Comparative Analysis by Industry. In this article, through group regression [28], the sample data of the high-carbon emission industry group and the low-carbon emission industry group are, respectively, substituted into Model

1 to examine the impact of carbon information disclosure in different industries on corporate value. The regression results are shown in Table 6.

It can be seen from Table 6 that the regression coefficient of the carbon information disclosure index and an enterprise value of high-carbon emission industries is 0.259, which is significantly positively correlated at the level of 1%. Still, the correlation coefficient between the level of carbon information disclosure and enterprise value in low-carbon emission industries is 0.025. The significance is 0.237, which is greater than the significance level, indicating that the CDI [30–33] of the sample of low-carbon emission industries does not correlate with the enterprise value.

The empirical analysis results show that the carbon information disclosure index of the overall sample enterprises is significantly positively correlated with the enterprise value. The same conclusion was drawn from the analysis of high-carbon emission sample enterprises. However, the

analysis results of low-carbon emission sample enterprises show no correlation between the two, which can indicate that industry factors impact the relationship between carbon information disclosure and enterprise value. Compared with low-carbon emission industries, the positive correlation between carbon information disclosure and enterprise value in high-carbon emission industries is more significant.

4. Conclusions

This study creatively combines the legitimacy theory, the effectiveness theory of the capital market, and other related theories with carbon information disclosure and takes these classical theories as the basis to study the impact of carbon information disclosure on enterprise value, which provides a reference for China's research on carbon information disclosure and a new idea for researchers' in-depth research in this field. First of all, it makes a descriptive analysis of the relevant quantitative characteristics of carbon information disclosure and analyzes the quality of carbon information disclosure between different years and different industries. Then, we carry out multiple linear regression to analyze the impact of carbon information disclosure on enterprise value. Then, the industry factors are added to the regression to verify whether the carbon information disclosure of high-carbon emission industries has a greater impact on enterprise value than that of low-carbon emission industries by setting the carbon information disclosure level and the industry multiplier.

Globally, the problems caused by the deterioration of the climate and ecological environment are becoming more and more serious. Therefore, energy conservation and emission reduction are currently a very important task for both relevant government departments and individuals in the society because this environment is closely related to and inseparable from everyone. The company is a major emitter of greenhouse gases, so it should bear more responsibility for energy conservation and emission reduction. There are many ways to strengthen the awareness of enterprise carbon information disclosure, such as low-carbon publicity and training of internal employees on low-carbon development. Let enterprises take the initiative to disclose carbon information to promote green and low-carbon development. Nowadays, China is facing severe ecological and environmental problems, so it is very important to disclose carbon information on time and comprehensively. The government has many tasks to shoulder. It needs to find ways to improve the awareness of carbon information disclosure of enterprises and give clear rewards or punishments to relevant enterprises. Only in this way can the overall situation of carbon information disclosure in China be improved.

With the rapid development of the knowledge economy, learning that stays at a shallow level is no longer able to meet the challenges of the times and deep learning has come into being. The key to deep learning is to develop students' critical thinking, information integration, communication and collaboration, and constructive reflection skills, which can be cultivated in the process of problem solving. By exploring the theories of deep learning and problem solving, the basic elements of deep learning theory are incorporated into the design system of problem-solving teaching, and the problem-solving teaching model based on deep learning is proposed in conjunction with the content of elementary school mathematics, so that students can further develop their core literacy based on acquiring deep learning skills.

1. Introduction

The concept of deep learning was proposed by American psychologists Ference Marton and Roger Saljo in the mid-1950s, and in 2005, Professor Li Jiahou's research team introduced the concept of deep learning in a more systematic way for the first time [1, 2]. The concept of deep learning advocates that when building resources, we should pay attention to both explicit subject knowledge and implicit thought and culture, which highlights the cultural characteristics in deep learning and shows that deep learning is indeed intrinsically related to teaching subject culture. At present, the more concentrated research areas are mainly deep learning teaching (learning) model and strategy research, environment design research, and resource construction research. Among them, there are fewer research results on microscopic deep learning strategies and deep learning research focusing on classroom context recreation, which have certain limitations in guiding the teaching of front-line teachers and the learning of students in primary and secondary schools. Deep learning is a new integration and growth point for mathematical culture classroom teaching [3, 4]. This paper intends to explore the structure of

elementary school mathematics classroom teaching from a new perspective based on microscopic deep learning strategies, resource development, and classroom context recreation, in an attempt to contribute their own new thinking on the cultivation of moral and core literacy in mathematics subjects.

2. Introduction to Deep Neural Networks

2.1. Deep Learning Model. The deep learning model, also known as the deep neural network model, is a classical nonlinear machine learning model whose design is inspired by the neural networks in the biological brain [5, 6]. During the continuous exploration of the biological brain, it was found that the basic unit of the biological mechanism of the brain is the neuronal cell. The basic structure of neuronal cells is shown in Figure 1, and each neuronal cell differentiates upstream and downstream into dendritic and axonal structures, respectively. When a nerve signal is transmitted, a chemical is released from the upstream neuron cell, which is captured by the dendritic structure as an input signal, processed by itself, and then transmitted to the downstream neuron cell through the axon by releasing

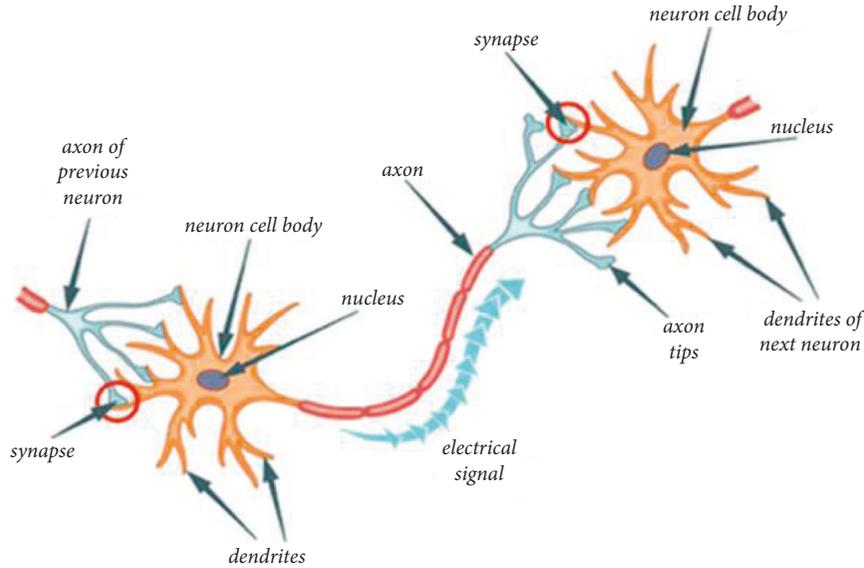

FIGURE 1: Neuronal cells.

the chemical. The neuronal cells release output signals that require the sum of the received input signals to reach a certain strength in order to be activated.

In Figure 2, the input of the j -th output neuron is $\beta_j = \sum_{i=1}^p w_{hj} b_h$; the input to the h -th hidden layer neurons is $a_h = \sum_{i=1}^a v_{ih} x_i$. In Figure 2, the neuron model is divided into three levels: “input layer,” “hidden layer,” and “output layer.” Each “circle” represents a neuron, and the neuron in the “input layer” has only axon endings, the neuron in the “output layer” has only dendrites, while the neuron in the “hidden layer” has both dendrites and axon endings. The neurons in the “hidden layer” have both dendritic and axonal endings, and the lines between neurons represent the transmission of information [7, 8]. It is easy to see that the neuronal model perfectly simulates the process of biological understanding of the world: first, $x_i (i = 1, \dots, d)$ in Figure 2 represents a number of input data, which is also the data to be transmitted from the “input layer” to the “hidden layer.” Second, $v_{ih} (i = 1, \dots, d; h = 1, \dots, q)$ represents the “weight” of the information transmitted from the i -th neuron in the “input layer” to the h -th neuron in the “hidden layer.” “Third, $b_k (k = 1, \dots, d)$ denotes the data obtained by the k -th neuron in the “hidden layer.” If this data reaches a preset “threshold,” the neuron will be activated and the b_k data can continue to be transmitted to the “output layer”; if the “threshold” is not reached, the b_k will not be transmitted to the “output layer.” If the “threshold” is not reached, kb will not be transmitted to the “output layer”; fourth, similarly, w_{hj} and $y_i (j = 1, \dots, l)$ can be understood. In an ordinary neural network model, the input data $x_i (j = 1, \dots, l)$ and the output data $y_i (j = 1, \dots, l)$ are known, and a large amount of training data is used to determine the “weights” between the layers. Once all the “weights” are obtained, the artificial neural network model is built, through which the machine can simulate

the human way of understanding the world to perform clustering, recognition, and optimization. When the “hidden layer” has multiple layers of neurons, a “deep learning” model in computer science is obtained (Figure 3).

2.2. Deep Learning in Education. If deep learning in computer science is to achieve intelligence by activating neurons and calculating weights among neurons, deep learning in education is to achieve teaching goals by activating students’ knowledge and clarifying the relationship between old and new knowledge in teaching practice [9, 10]. It is clear that the “model” of deep learning in computer science corresponds to the teaching process based on deep learning in pedagogy, and there is a clear correspondence in terms of objectives, methods, and focus (see Table 1).

From the abovementioned correspondence between the two fields of deep learning, differences can be obtained [11, 12]. These are mainly reflected in the following aspects.

Firstly, machines do not have the ability to build models on their own, while one of the goals of deep learning in pedagogy is to enable students to explore the connections between knowledge on their own, which is the most essential difference between “human” and “machine.”

Secondly, for machines, the modeling is roughly the same for the same input and output. However, for teaching, each student often has different knowledge constructs in the face of new knowledge, and the activated knowledge may be different.

Finally, although the implementation process of deep learning in these two fields is roughly the same, in computer science, deep learning requires the use of “sea of problems” and a large amount of data to get the model; while in pedagogy, teachers should pay more attention to the activation of students’ knowledge and should not give students too much practice.

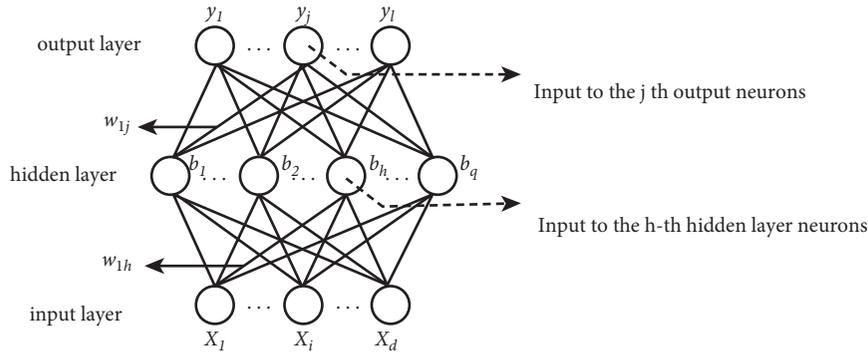

FIGURE 2: Neuronal model.

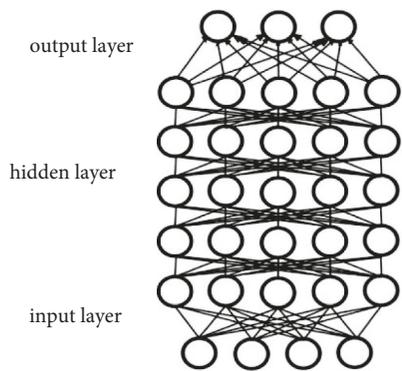

FIGURE 3: The deep learning models with multiple hidden layers.

3. Teaching Practices of Elementary School Mathematics Based on Deep Learning

The teaching practice of deep learning revolves around the core content of the subject, which requires teachers to create contexts suitable for deep learning so as to promote the overall development of students [13, 14]. Based on the understanding of the meaning of deep learning, the teaching process of deep learning should include setting learning tasks, actively exploring and activating knowledge elements, acquiring the essence of mathematics, consolidating the connections between knowledge elements, and summarizing the learning process.

3.1. Assigning Learning Tasks. The purpose of assigning learning tasks is to enable learners to carry out independent learning with the tasks. The learning tasks should be chosen to meet the requirements of the teaching objectives but also to be appropriately challenging for the students. These tasks can be mathematical knowledge itself or can be derived from real life, rich and complex teaching contexts created by the teacher.

3.2. Active Inquiry and Activation of Knowledge Elements. This component refers to students' deep inquiry into the learning tasks set by teachers and their active construction of their own problem-solving approaches and methods

[15, 16]. The core content of a subject is the carrier for carrying out deep learning, a class of core content is composed of several learning units, a learning unit is composed of several knowledge points, and these basic constituent elements can be called knowledge elements. The process of active inquiry is student-oriented, and students are expected to make connections between new knowledge and old knowledge and activate as many existing knowledge elements in their cognitive structure as possible. The more knowledge elements students activate, the more likely they are to approach the essence of mathematics.

Take the process of proving the “butterfly theorem” for an arbitrary quadrilateral as an example. As shown in Figure 4, the main content of the “butterfly theorem” is for any quadrilateral, there is $S_1 : S_2 = S_4 : S_3$ or S_1, S_2, S_3, S_4 (where $S_1, S_2, S_3,$ and S_4 are the areas of four triangles).

The proof of this theorem is as follows: first, the magnitudes of the areas of the four triangles are $S_1 = 1/2 \cdot OD \cdot h_1, S_2 = 1/2 \cdot OB \cdot h_1, S_3 = 1/2 \cdot OB \cdot h_2,$ and $S_4 = 1/2 \cdot OD \cdot h_2$. Second, it can be observed that $\triangle AOD$ and $\triangle AOB$ are two triangles of the same height, and their area ratios are $S_1 : S_2 = OD : OB$. $\triangle COD$ and $\triangle BOC$ are also two triangles of the same height, and their area ratios are $S_4 : S_3 = OD : OB$. Finally, the two equations are equivalently substituted, i.e., $S_1 : S_2 = S_4 : S_3$ or $S_1 \times S_3 = S_2 \times S_4$.

In fact, the proof of “butterfly theorem” is not very difficult, but there are many knowledge elements that need to be activated in the process of proof, such as ratio and proportion, calculation of triangle area, letters for numbers, simple equations, and equivalent substitution, which are all knowledge elements that students may activate in the process of learning the lesson. Only by activating the knowledge elements behind the “butterfly theorem” can students successfully acquire the essence of mathematics [17, 18].

3.3. Acquiring the Essence of Mathematics. This is the part where students are guided by the teacher to use the activated knowledge elements to acquire the essence of mathematics. If students cannot complete the deep learning through independent inquiry, the teacher can guide appropriately by prompting students which knowledge elements the task is related to and then allowing students to activate them,

TABLE 1: The correspondence of deep learning in the two domains.

	Deep learning in computers	Deep learning in teaching science
	Input layer (initial data)	Challenging learning tasks
Model	Hidden layer (transmitting between neurons in the brain, processing information, contains multiple layers of neurons) Output layer (output-processed information) Inspection model	The existing knowledge in the cognitive structure The essence of mathematics Persistent evaluation
Goal	Get the machine to be able to learn	Promote students to have the ability of deep learning, independently explore the connection between knowledge, from “learn” to “learn” can “learn”
Method	Use a large amount of training data to determine the model	Under the guidance of teachers, students complete tasks, activate more knowledge elements, and independently explore the relationship between knowledge elements
Keynote	Training process, neuronal activation, and determination of the weights	Students’ thinking process, the activation of knowledge element and the relationship between knowledge element

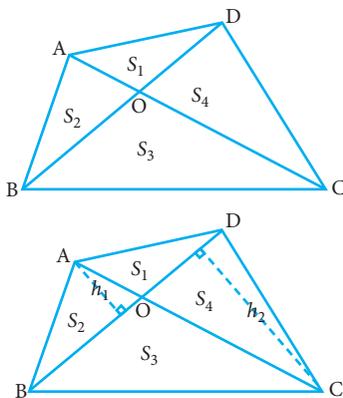

FIGURE 4: Butterfly theorem for arbitrary parallelograms.

unifying student independent inquiry and teacher guidance. This process is teacher-led and is intended to help students acquire the true essence of mathematics. Take the proof of the butterfly theorem as an example [19, 20]. For elementary school students, the mathematical essence of the theorem can be summarized as follows: one is the use of letters to represent unknown quantities and the use of letters to perform operations; the other is the use of the formula for the area of a triangle to convert the ratio of the area to the ratio of the “base.” Therefore, teachers can guide students from these two aspects in the actual teaching process, prompting them to activate the relevant knowledge elements and then letting them use the activated knowledge elements to obtain the essence of mathematics.

3.4. Consolidating the Connections between Knowledge Elements. This component can also be called “continuous assessment,” i.e., multiple assessments to determine whether students have “learned” something [21, 22]. Scientific continuous evaluation can improve teachers’ teaching and professional development; it can optimize students’ in-depth learning and promote their overall development. The assessment can be done by practicing postlesson exercises, taking unit tests, etc. For the proof of the butterfly theorem

for any quadrilateral, the teacher can ask students to complete the following task after the proof is completed.

For example, the diagonal AC of quadrangle ABCD compares to BD compared to point O.

If the area of the triangle ABD is equal to $1/3$ of the area of the triangle BCD, and it is $AO = 2$ and $DO = 3$, then how many times the length of the CO is the length of the DO (Figure 5).

The problem is the ratio of CO and DO. Since AO and DO are known quantities, the ratio of CO and DO can be converted to the ratio of AO and CO. From the diagram, we can see that AO and CO are in two triangles with the same base, which is in line with the essence of the butterfly theorem. Through the above example, teachers can guide students to further understand the process of proving the butterfly theorem, and let them apply the theorem to solve problems, consolidate the connection between knowledge elements, and finally achieve the purpose of in-depth learning.

3.5. Summarizing the Learning Process. Summarizing the learning process means that students can review the meaningful learning process they have participated in [23, 24]. Teachers can determine whether students have integrated new knowledge with old knowledge based on their summaries, which simply means that they “know how to learn.” The deeper goal is to prepare students for learning new knowledge, encourage them to develop the habit of summarizing the learning process, and take the initiative to learn in depth, hoping that they will achieve the goal of “knowing how to learn.” The above teaching practices correspond to the process of deep learning in computer science as shown in Table 2.

4. Teaching Strategies for Elementary School Mathematics Based on Deep Learning

4.1. Stimulating Positive Emotional Experiences and Cultivating Interest in Mathematics Learning. Teachers cause empathy between teachers and students through effective and positive communication with them in the teaching process. Give full play to the positive role of emotional

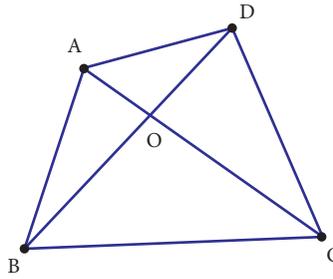

FIGURE 5: Any quadrangle “butterfly theorem” exercise diagram.

TABLE 2: Computer science summarizes the implementation process comparison of deep learning and deep learning teaching practice.

The implementation process of deep learning in computer science	Deep learning teaching practice
Determine the input initial data	Assign learning tasks, and lead to the main content of classroom teaching
Determine the neurons of the “hidden layer”	Actively explore and activate the knowledge meta
Through the training data, the weights and the activated neurons were determined	Get the essence of mathematics and guide students to recall the learned knowledge
By evaluating the model, by verifying the data	Consolidate the connection between knowledge yuan, test whether students firmly grasp knowledge
Finally determine the model	Summarize the learning process, and gradually form a good learning habits

factors in teaching activities, so as to promote teaching with emotion, teaching with emotion [25, 26]. With the help of multimedia to make mathematics teaching more intuitive and visual, to break the students’ fear of mathematics and gradually cultivate students’ interest in learning mathematics. Teachers try to connect the knowledge points learned in class with students’ life, so that students can feel the existence and charm of mathematics in real life. Connecting mathematics with real life creates a lively, relaxed and interesting learning atmosphere so that students really love mathematics and take the initiative to learn mathematics.

4.2. *Students Fully Participate in Teaching and Learning to Achieve Depth of Thinking.* Master the laws of mathematics in a hands-on way. Piaget’s cognitive development stage theory that children between the ages of 7 and 12 years old are in the concrete operation stage, the children of this stage of concrete operation thinking cannot leave the support of concrete things, has not yet formed the ability to abstract thinking. Psychological research shows that the more senses involved in collecting information, the more information is obtained, and the more solid knowledge is learned [27, 28]. Therefore, for students who are still in the concrete arithmetic stage, the use of multiple senses is conducive to the mastery of mathematical laws and the deepening of mathematical knowledge.

The development of mathematical thinking is promoted in cooperative learning. The exchange of ideas with each other produces two or even more ideas. This is also true in elementary school mathematics. In the process of learning knowledge, each student has a different way of thinking when faced with the same problem because of their individual differences and motivational characteristics, as well as their life environment and emotional and attitudinal differences.

Through group discussion, each member of the group has the opportunity to express his or her own views and to exchange experiences and emotions with other members. Through group discussions, students incorporate the experiences and knowledge structures of others into their own knowledge structures and continuously promote self-reflection so that their own knowledge spirals upward and in the process students’ mathematical thinking develops and deepens.

4.3. *Breaking the Boundaries of Disciplines to Integrate Learning and Building a Mathematical Way of Thinking.* In today’s world, it is difficult to rely on the knowledge of a single discipline when students need to mobilize a wide range of knowledge, abilities, and methods to solve the complex problems of tomorrow’s society [29]. Therefore, it is important to integrate the knowledge of other disciplines in the teaching and learning process of mathematics and to develop interdisciplinary thematic learning, not only to deepen students’ understanding of mathematics and promote deeper learning of mathematics but also and more importantly, to develop students’ comprehensive thinking skills and the ability to transfer knowledge, which is an important ability to solve complex problems across disciplines. Teachers break the limitations of their own subject knowledge in the mathematics teaching process and collaborate with teachers of other disciplines to create an integrated, multidisciplinary curriculum that fosters students’ ability to think in multiple, holistic, and innovative ways and promotes the transfer of knowledge and skills.

4.4. *Timely and Positive Assessment to Develop Students’ Self-Confidence in Mathematics.* Learning assessment is an essential part of teaching and learning activities [30–38]. For

students at the elementary school level, affirmative and positive assessment from teachers can stimulate students' intrinsic motivation to learn. The logical and abstract nature of mathematics makes it a subject that is not easy for students to master. In the process of learning, students will inevitably make mistakes, even some simple mistakes that teachers often emphasize, and when students make mistakes, they should not speak harshly, but should be "kind" to them. We should find out the weaknesses of students' knowledge and provide them with targeted individual counseling.

5. Conclusion

Deep learning is a hot topic of research and practice in the field of learning science, and it is important for understanding how people learn and how learning is best achieved. The ultimate goal of deep learning is to enable students to learn basic mathematical knowledge, explore the connection between related knowledge and understand the essence of mathematics, and finally move from "learning" to "knowing." As front-line teachers, they need to design challenging learning topics under the guidance of deep learning theory, so as to create good conditions for students to realize deep learning. According to the above discussion, teachers should pay attention to the following aspects.

First, the need for students to engage in deep learning is determined by mathematical knowledge itself. When mathematical knowledge is limited, the teaching process is much like the implementation of an artificial neural network, with few meta-connections in the "hidden layers" of knowledge. However, as students learn more mathematics, the teaching process should be based on the implementation of deep learning in computer science, and the connections of knowledge elements in the "hidden layer" become more and more complex. For example, in the lesson "position and direction," rays, angles, measures, number pairs, etc., are all knowledge elements in the "hidden layer," and their connections should be understood by students during the lesson.

Second, students' ability to learn in depth is not a task of one lesson, but a long-term process. In the middle and lower grades, teacher guidance may play a key role, as teachers can take the initiative in guiding connections to what students have already learned, but they should also give students as much time as possible to think on their own. In the upper grades, the key role should gradually shift to students, emphasizing interknowledge connections, multiple solutions to problems, and adequate communication.

Third, teachers should try to let students construct their own knowledge system and form the habit of independent learning during the teaching process. When summarizing the results of a lesson, students should not only be asked "what they have learned," but also "what they have used," so that they can recall the learning process. Only in this way can students gradually "learn" mathematics.

Point cloud local feature extraction places an important part of point cloud deep learning neural networks. Accurate extraction of point cloud features is still a challenge for deep learning networks. Oversampling and feature loss of point cloud model are important problems in the accuracy of image point cloud deep learning network. In this paper, we propose an adaptive clustering method for point cloud feature extraction—adaptive optimal means clustering (AOMC)—and apply it to point cloud deep learning network tasks. This method solves the problem of determining the number of clustering centers in the process of point cloud feature extraction so that the feature points contain the whole point cloud model and avoid the problem of losing detail features. Specifically, according to the loss characteristics of point cloud clustering, AOMC selects a different number of clustering centers for various models. Moreover, in light of the density distribution of the point cloud, the radius of the clustering subset is determined. This method effectively improves the accuracy of the point cloud deep learning network on object classification and parts segmentation. Our method reaches demand on Modelnet10 and shapenetcore_partanno_segmentation_benchmark datasets. In terms of deep learning network optimization, it has good performance. Additionally, our method has high accuracy and low algorithm complexity.

1. Introduction

With the rapid development of point cloud intelligence, researchers have paid much attention to the application of deep learning networks in point cloud recognition [1–3]. Moreover, machine learning algorithms are gradually being applied to improve the performance of point cloud recognition. Point cloud intelligence is widely used in surveying mapping, machine recognition, model design, virtual reality, and other fields [4–8].

Point cloud intelligence algorithm based on a deep learning network mainly focuses on object classification, object detection, parts segmentation, and semantic segmentation [9, 10]. Point cloud deep learning networks gather different functions in the same network to realize the integration of various tasks [11–15]. Figure 1 shows the main task and processing flow of the point cloud deep learning network, which includes two main parts: point cloud feature extraction and deep learning computing. The aim of point

cloud feature extraction is to extract effective features from the point cloud model. The extracted features are used for analysis to meet different task requirements. The deep learning network is composed of different convolution kernels. The purpose of convolution is to use features to optimize the loss function, so as to realize the segmentation and classification of the point cloud model.

For the shape analysis task based on the point cloud, it is a fundamental problem to realize the effective representation of local shape features (normal, curvature, etc.). The representation of local shape features is affected by many interference factors, including noise, dynamic sampling density, complex geometric details, and defective parts. These interference factors undoubtedly affect the local shape feature representation of the point cloud and then affect the performance of related applications. To solve this problem, we usually use the local neighborhood estimation of each point in the point cloud to establish an implicit surface representation to realize the simulation of local features.

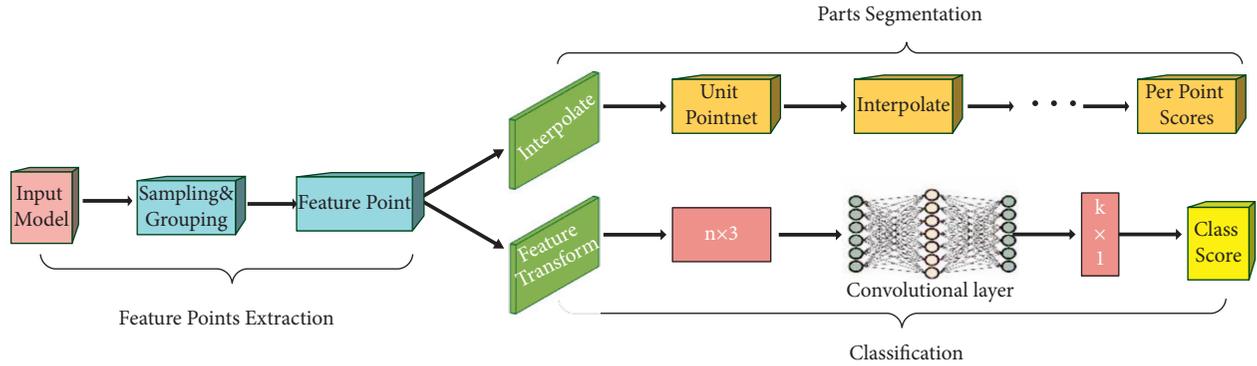

FIGURE 1: The architecture of point cloud deep learning network.

Because point cloud is of disordered and irregular data structure, unlike 2D data, it is impossible to simply use convolutional neural networks (CNN) for feature extraction. Before deep neural networks were envisioned, three-dimensional operators were commonly used to achieve point cloud parts segmentation [16, 17]. To capture finer structures and more accurate boundaries, numerous refinement strategies have been proposed. In 2015, the VoxNet model was presented based on the voxelization model [8]. At the same time, a multiview convolutional neural network (MV-CNN) was proposed based on the multiview sampling method [18]. However, none of these methods can directly act on point cloud data to extract the features of the point cloud.

Clustering is a typical unsupervised learning algorithm. The main idea is to divide the data set into different subsets according to the different attribute features of the undetermined data [3]. The main way to evaluate the clustering effect is to see if objects of the same category are classified into the correct subcategory. Compared with objects between groups, objects within groups have a high degree of similarity, while objects between different groups are very different. For 2D and 3D data, a clustering algorithm can realize effective segmentation of objects, which includes segmentation between different categories and segmentation of parts within objects.

Figure 2 shows the process of feature extraction of the 3D point cloud deep learning network. Firstly, the feature center of the point cloud is carried out. Then, taking the feature center as the center of the sphere and selecting the radius to extract the hierarchical feature points of the point cloud, the purpose is to obtain the local features of the point cloud model. Finally, the extracted feature points are input into the deep learning network to realize the task of point cloud classification and parts segmentation.

Figure 3 shows the process of point cloud feature extraction; if the feature center is not selected reasonably, it will lead to the loss of local features of the point cloud, which will affect the accuracy of the point cloud deep learning network [19, 20]. In practice, supervised learning and unsupervised learning can be used to select feature points of the point cloud [21–23]. However, the time complexity of some methods is high, and the accuracy of other methods is too low. Moreover, the algorithm parameters are not reasonable

for the point cloud category, which leads to the waste of computing resources [24, 25]. Therefore, it is very important to propose a point cloud feature extraction method with low computational complexity, high accuracy, and adaptability for the optimization of the point cloud deep learning network.

In this paper, we primarily consider point cloud classification and parts segmentation, two model tasks in the point cloud processing world. We propose a feature extraction method based on unsupervised learning. The number and radius of clustering are determined according to different cloud types by statistical method. The adaptive feature extraction of the point cloud is realized by parallel optimization. This method not only can ensure the complete coverage of the point cloud range but also can avoid the occurrence of repeated sampling and missing sampling. Moreover, compared with the traditional adaptive clustering method, this algorithm has lower algorithm complexity and higher practicality in parameter settings.

This method includes the process of determining the number of clustering centers and feature points extraction of the point cloud model. The purpose is to achieve accurate feature extraction of the point cloud model and avoid the loss of detail feature points. And we apply the feature points in the training process of the point cloud deep learning network, improving the training speed and accuracy of the network.

Compared with the existing clustering methods, this method has some advantages. We also compare the convergence speed of the deep learning network during the training process to evaluate the effect of how this algorithm improved the process of network training. Experimental results show that this method has a certain effect on the optimization of the point cloud deep learning neural network. In summary, our major contributions are as follows:

- (i) We propose a point cloud feature extraction method based on clustering and adaptive optimization. When extracting the feature points of point cloud models, it not only can keep details of the local feature but also can reduce the complexity of the algorithm.
- (ii) Our method sets different sampling centers and sampling radii for different point cloud types. The

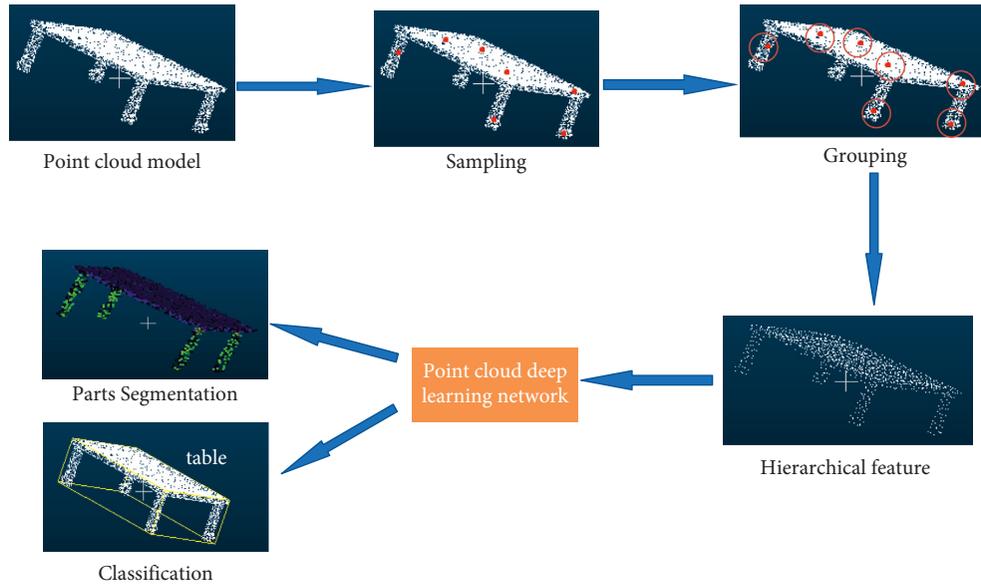

FIGURE 2: Hierarchical feature extraction process of point cloud deep learning.

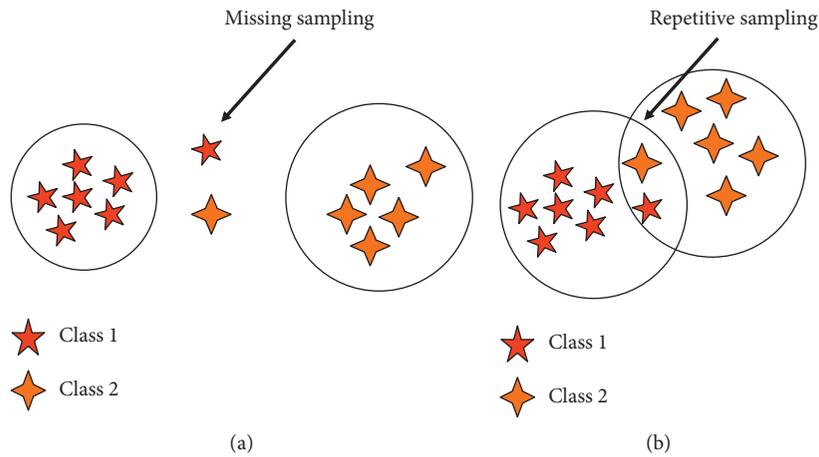

FIGURE 3: Problems in hierarchical feature learning of point cloud: (a) the sampling area does not cover the whole point cloud model and (b) the overlapping of sampling space leads to repeated feature extraction.

purpose is not only to cover the whole range of the point cloud and avoid missing detection but also to ensure that the overlapping part of the clustering subregion is small and prevent resampling.

- (iii) We conduct comprehensive experiments on several benchmark data sets: Modelnet10 [26] and shapenetcore_partanno_segmentation benchmark [27], to validate the effectiveness and efficiency of our proposed method for point cloud classification and parts segmentation tasks. In the point cloud deep learning network optimization, it has a significant effect.

This paper is organized as follows. In Section 2, we provide an overview of the literature on point cloud feature extraction. We propose an adaptive point cloud clustering method in detail in Section 3. Section 4 shows the detailed experimental results. Finally, Section 5 concludes this paper.

2. Related Work

In the process of point cloud feature extraction, machine learning algorithms, including supervised learning [1, 2, 28, 29] and unsupervised learning [3, 30, 31], are widely applied. And the feature points are used to train deep learning networks [27, 32]. Point cloud feature extraction affects the performance of the deep learning network.

2.1. Supervised Learning. Supervised learning is to adjust the parameters of the classifier according to the class label of the sample space. Typical supervised learning includes SVM, naive Bayesian model (NBM), decision tree, and so on. In three-dimensional space, supervised learning determines the classification plane according to the category of the point cloud, so as to ensure the generalization ability of the classifier [28, 29].

Yu and Yang proposed a point cloud sampling method based on the k-nearest neighbor algorithm (k-NN) [1]. The k-NN algorithm determines the center of the sampling based on the category of point cloud data and calculates the radius of the sampling area. The algorithm fully considers the category attributes of each point in the point cloud and makes full use of the distribution of points in the point cloud.

But, for not categorized point cloud data, the k-NN algorithm cannot be used. At the same time, the amount of point cloud data collected by point cloud acquisition devices such as LiDAR is very large [12–14], and the amount of input data for training deep learning networks is also very large. Therefore, it is impossible to label the category of each point. Besides, the algorithm ignores the sparse degree of point cloud distribution, lacking certain self-adaptability. In addition, for point cloud models with more complex distributions, this algorithm increases the number of sampling points that increases the computational complexity of the deep learning network.

2.2. Unsupervised Learning. Unsupervised learning is an algorithm that divides the classification space without prior knowledge. Typical supervised learning includes PCA [30], agglomerative clustering, density-based spatial clustering of applications with noise (DBSCAN), and so on [31]. In the three-dimensional space, the clustering method can divide and extract the target of the point cloud without knowing the classification of the point cloud.

Han studied the point cloud clustering segmentation algorithm based on k-means [3]. This method is implemented based on a certain number of cluster centers, which lacks self-adaptability for different types of point clouds. At the same time, the k-means algorithm needs to initialize the cluster center number before clustering. Therefore, if the cluster center is not well selected, it will have a great impact on the k-means algorithm, which will lead to negative effects such as poor clustering or slow convergence speed.

There is a problem with unsupervised learning. Without knowing the exact number of samples, it is impossible to select the best number of clustering centers. If the number of feature points is too small, the feature information of the point cloud will be lost [33], and the task of point cloud recognition is impossible. If the number of feature points is too large, the complexity of the network will be too high, and the computing resources will be wasted [34, 35].

The unsupervised learning clustering algorithm has some limitations for unknown data. If the initial point of clustering is not selected well, it may affect the convergence effect of the clustering algorithm [9, 16]. Therefore, it is very important to select the initial points, which can cover the whole point cloud model for point cloud feature extraction [8, 10].

At the same time, for different point cloud categories, the value of the cluster subset number is different [1]. For the point cloud model with simple distribution, fewer clustering centers can cover the whole point cloud model. For the point cloud model with complex density distribution and more detailed features, uniform feature extraction is needed to achieve effective feature extraction.

Although DBSCAN clustering algorithm can determine the number of clusters center according to the classification of point cloud [36, 37], in practical application, it is necessary to determine the distance between core points and the minimum number of sample points (MinPts) in the classification subset. Sometimes, due to the accuracy of point cloud computing, the actual application effect of the DBSCAN algorithm needs to be improved. And DBSCAN algorithm has high complexity.

2.3. Point Cloud Deep Learning Network. In 2017, Qi et al. proposed a network model: PointNet [28], which directly targets disordered point clouds. At the same time, in order to obtain hierarchical features such as the CNN model and extract the local features of the point cloud, Qi et al. then proposed a point cloud deep learning network using hierarchical feature learning: PointNet++ [29]. PointNet++ network uses the farthest point sampling and ball query method, which fully covers all the points in the point cloud to avoid outliers in the sampling process. An array of improved algorithms are gradually applied to a deep learning network [38–41] in the past several years. Their main thought is to improve the effect of point cloud feature extraction for developing the performance of a deep learning network.

In the basic PointNet++ network, point cloud feature extraction uses the farthest point sampling and the ball query method, which has a certain degree of randomness and ignores the distribution features of the point cloud. Therefore, the feature clustering method is used here to extract and sample the feature of the point cloud. And the time complexity ($O(N^2)$) of farthest point sampling is high. At the same time, due to the random selection of sampling centers, there may be overlap between different sampling points areas, causing repeated sampling. In addition, the sampling radius of the basic algorithm is of fixed value, which will cause the lack of self-adaptability of sampling, and it is impossible to sample reasonably according to the specific situation of the point cloud distribution.

3. Our Method

We propose a novel point cloud sampling method based on unsupervised learning: adaptive optimal means clustering for point cloud feature extraction (AOMC), which improves the clustering effect of nonmeans clustering. It can be roughly divided into two steps: cluster center number determination and adaptive optimal cluster. Figure 4 shows the process of AOMC.

Firstly, our method determines the number of clustering centers for different categories of point cloud according to the change of the within-cluster sum of squared errors (SSE), raising the adaptability between the selection of the number of cluster centers and the point cloud category. The density of point cloud distribution is different among point cloud models. And various objects have different details, so it is a significant way to select suitable clustering center numbers for each of the point cloud models. Then, adaptive clustering

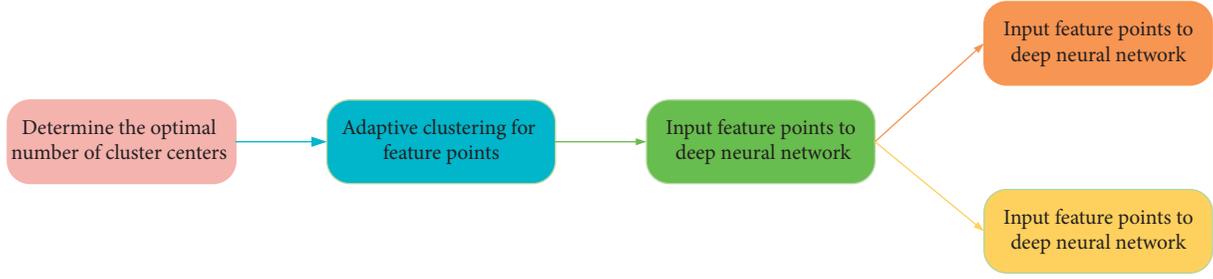

FIGURE 4: Adaptive optimal means clustering for neural networks.

is carried out. The requirement of clustering is not only to realize the uniform distribution of feature points in the point cloud model but also to avoid the loss of detail feature points. At the same time, AOMC avoids the repeated sampling caused by the excessive overlap of each subclass. AOMC makes the clustering centers reasonably and evenly distributed in the point cloud model, so as to improve the clustering effect. After sampling feature points, we input them into the deep learning network. CNN-based deep learning network can learn hierarchical features to achieve the parts segmentation and object detection tasks for point cloud models. The method is applied to the PointNet++ network. By the point cloud classification accuracy and parts segmentation tasks, the degree of improvement of the point cloud deep learning network by this algorithm is analyzed.

Figure 5(a) reflects the effect of common point cloud feature extraction. Because the number of clustering centers is uncertain, the position of the clustering center is unreasonable. Meanwhile, the cluster radius of different cluster subsets is the same, which leads to repeating sampling and missing sampling. The above factors will lead to the loss of point cloud features, which will affect the performance of the deep learning network.

Figure 5(b) is the result of adaptive point cloud feature extraction. Points are divided into two categories according to their distribution position. Each category has its own clustering center. According to the distance from the cluster center to the farthest point of the cluster subset, the radius of each cluster range is determined. It can be seen from Figure 4 that the adaptive clustering algorithm can effectively reflect the distribution features of the point cloud model. Therefore, the point cloud feature extraction through clustering can effectively reflect the structural features and distribution features of the point cloud. The loss of detailed features of the point cloud caused by randomness is avoided. The method we proposed is to use adaptive clustering to improve the performance of the deep learning network.

3.1. Number of Cluster Centers Generation. The error of the cluster algorithm is measured by SSE, where $\mu^{(j)}$ is the center point of the cluster j ($j \in \{1, 2, \dots, k\}$). It is generally considered that the clustering solution process is a problem of optimization (minimization) of the SSE. We set the number of clustering samples as n . If the sample $x^{(i)}$ ($i \in \{1, 2, \dots, n\}$) belongs to the j_{th} cluster, then $w^{(i,j)} = 1$; otherwise, $w^{(i,j)} = 0$.

$$SSE = \sum_{i=1}^n \sum_{j=1}^k w^{(i,j)} \|x^{(i)} - \mu^{(j)}\|_2^2. \quad (1)$$

Based on the visualization tool of SSE, the optimal number of cluster centers is estimated for a given task. The basic method to determine the elbow point is to find the parameter of the cluster center when the clustering deviation increases abruptly. If the curve attenuation is gentle and there is no obvious elbow point, is the best sampling value when the SSE is set to be a threshold, usually less than 300.

We can draw the clustering deviation diagram with different values of the cluster center and observe the position of the elbow point.

Figure 6 is an image in which the SSE of the clustering changes with the number of cluster centers. It can be seen that the SSE decreases with the increase of cluster center number. When the number of cluster centers is three, the curve of Figure 6(b) presents an obvious elbow shape, which is called the elbow point. Therefore, three is a better choice for this set of data in Figure 6(a). The selection of elbow points should not only consider the degree of error change but also consider the absolute size of the error. If the error changes more gently with the increase of cluster centers or the elbow point appears in the place with a large error, the number of cluster centers with a small error should be selected as the best parameter.

3.2. Adaptive Optimal Clustering. After obtaining the optimal clustering center of each point cloud model, we then determine the location of the cluster center and divide the point cloud model into different subsets.

The main idea of AOMC is that the mutual distance between the initial cluster centers is as far apart as possible. We set the point cloud model as a set x . Our aim is to obtain a set of clustering results x_{cluster} . Initially, the point cloud model is a set of n sample points. We take μ to record each selected cluster center point.

We set an empty set M to record the selected cluster center points, then randomly select the first center point $\mu^{(1)}$ from the input sample, and add it to the set M .

For each sample point $x^{(i)}$ ($i \in \{1, 2, \dots, n-1\}$) outside the set M , we calculate the shortest Euclidean distance $d(x^{(i)}, M)^2$ between each sample point and the current cluster center set M . According to the distance, the probability distribution $d(x^{(i)}, M)^2 / \sum_i d(x^{(i)}, M)^2$ is constructed.

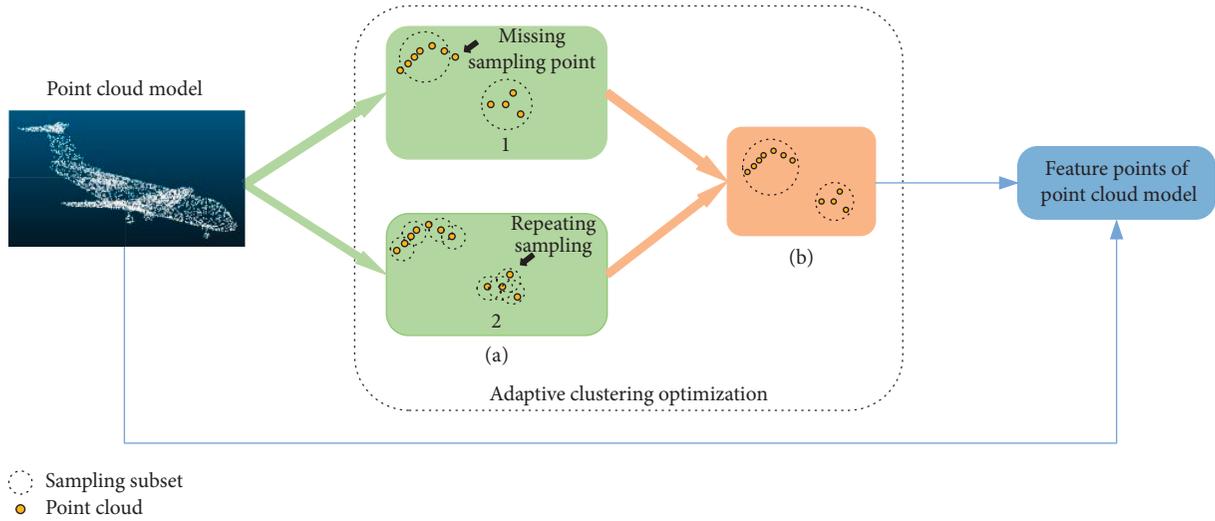

FIGURE 5: Comparison between common feature extraction and adaptive feature extraction: (a) common point cloud feature extraction and (b) adaptive point cloud feature extraction.

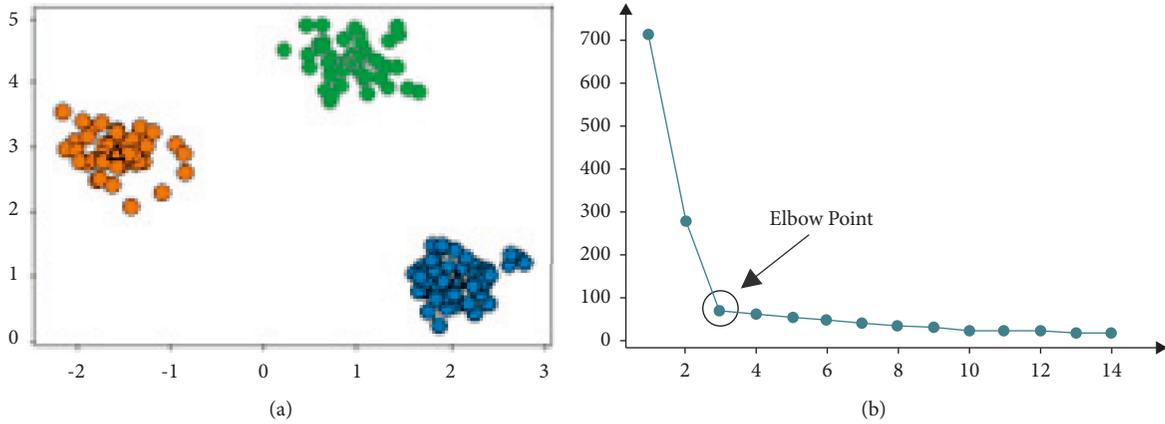

FIGURE 6: Elbow point selection schematic: (a) two dimensional of three cluster centers and (b) the relationship between the change of clustering number centers and SSE in (a). When the number of cluster centers is 3, the curve appears obvious “elbow point.”

Then, based on the weighted distribution of distance, generate a probability value p between 0 and 1 and select the next central point $\mu^{(p)}$ from $x^{(i)}$ to M . In light of the probability distribution, the point in a set of $x^{(i)}$ farther away from M is more likely to be selected as the next cluster center $\mu^{(p)}$. This ensures the uniform distribution of the initial cluster centers in the point cloud model.

By repeating the above steps, the initial adaptive cluster centers are obtained. Compared with the random selection of initial cluster centers, the AOMC method ensures that the distance between the initial cluster center points is longer, and the distribution is uniform in the point cloud model.

The remaining points of x are classified into the cluster subsets corresponding to the cluster centers in M and initialize the SSE value of M . Then, set a threshold value for SSE. Based on the distribution of the points in the subset, the sample center of the subset is updated as the new cluster center in M . Update the current SSE of the point cloud model clustering result. Finally, when SSE is less than the threshold, we get the cluster result x_{cluster} .

The adaptive optimal means clustering (AOMC) algorithm is summarized in Algorithm 1:

3.3. Determination of Feature Points and Loss Function. After dividing the point cloud model into different adaptive clustering subsets, we then sample the data points of each subset. Sampling radius and loss function are defined as follows:

Sampling radius. We carry out cluster sampling of point clouds according to different types of point clouds. First, in order to prevent the occurrence of outliers, the maximum coverage is the entire sample space. The sampling radius is defined from the center point to the farthest point in the class:

$$r_j = \sqrt{\|x_{jf} - \mu_j\|_2^2} \quad j \in \{1, \dots, k\}. \quad (2)$$

Loss function. In the point cloud deep learning network, the maximum cross-entropy function is used as the

```

ALGORITHM 1: AOMC: adaptive optimal means clustering for point cloud feature extraction.

measurement of the loss function. As shown in formula (3), it is the maximum cross-entropy function.

First of all, the input class of the neural network is normalized here, which is defined as follows:

$$L_S = \frac{e^{S_i}}{\sum_{i=1}^k e^{S_i}}, \quad (3)$$

where S_i denotes the output value of the multilayer perceptron for each point cloud class and k represents the number of point cloud classes in the sample. This operation is equivalent to the softmax layer function and \dots is output as a vector form. Next, the cross-entropy calculation is carried out between the output and the label, which is defined as follows:

$$L = -\frac{1}{k} \sum_{i=1}^k y_i \ln(L_{S_i}), \quad (4)$$

where y_i is the actual label of each point cloud class; the label of each point cloud class is multiplied by the natural logarithmic form output by the normalization layer, and finally, the mean loss of the point cloud class is calculated by means of the mean value as the loss function of the deep learning network.

4. Experiments

4.1. Data Sets. We conduct the experiments on two benchmark data sets. ModelNet10 contains 4,899 meshed CAD models from 10 categories. Each point cloud contains 10,000 coordinate points. Each point consists of three-dimensional position coordinate information (x , y , and z) and normal vector information (N_x , N_y , and N_z).

Shapenetcore_partanno_segmentation_benchmark data set includes 16,846 point cloud models from 19 types. Each point cloud contains about 2,500 coordinate points. Each point consists of three-dimensional position coordinate

information and part segmentation information, whose purpose is to compare the prediction results of a deep learning network with real value.

Figure 7 is the example of the point cloud model in this research. As can be seen from Figure 7, the point cloud model has a large amount of data, and features need to be refined; otherwise, the processing algorithm will be time-consuming. Point cloud data is measurable. It can directly obtain three-dimensional coordinates, distance, azimuth, and surface normal vector on the point cloud and can also calculate the surface area and volume of the target expressed by the point cloud. Due to the limited laser penetration, the point cloud obtained by LiDAR scanning basically reflects the surface condition of the target, and there is almost no internal information about the target.

4.2. Evaluation Metrics. We use shapenetcore_partanno_segmentation_benchmark data set to test the network performance, randomly select 10 point cloud classes from them, and carry out parts segmentation analysis. We use mean intersection over union (mIoU) to evaluate the effect of a deep learning network on parts segmentation of point clouds [20–22].

$$mIoU = \frac{1}{k+1} \sum_{i=0}^k \frac{P_{ii}}{\sum_{j=0}^k P_{ij} + \sum_{j=0}^k P_{ji} - P_{ii}}, \quad (5)$$

where i represents the real value, j is the predicted value, P_{ij} is the probability that i is predicted to be j , and k is the number of categories in the sample. The larger the mIoU is, the more parts that prove that the predicted value coincides with the real value, the better the effect of network segmentation.

In order to verify the classification effect of this algorithm, the mean class accuracy (mAP) is used to evaluate the overall performance of network classification:

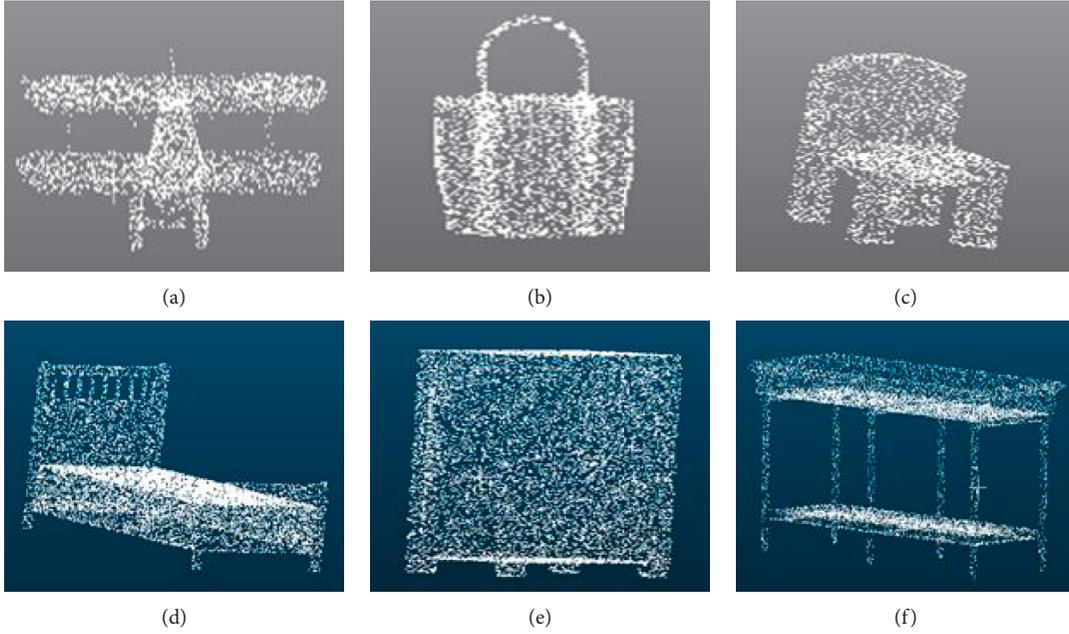

FIGURE 7: Examples of our point cloud model (top: shapenetcore_partanno_segmentation_benchmark and bottom: Modelnet10): (a) airplane, (b) bag, (c) chair, (d) bed, (e) dresser, and (f) table.

$$mAP = \frac{1}{k} \sum_{i=1}^k AP_i, \quad (6)$$

where k represents the number of point cloud classes and AP is the classification accuracy of each point cloud class.

4.3. Evaluation of Feature Point Extraction. The first two parts have already introduced the flow of the AOMC algorithm. Next, we use these methods to extract feature points from different types of point clouds. We use the Modelnet10 data set for analysis.

As shown in Table 1, the “elbow point method” is used to select the best clustering center number for 10 different types of the point cloud model in the data set.

Figure 8 illustrates the point cloud feature sampling using the AOMC algorithm, compared with the random feature sampling method, and the AOMC point cloud sampling points are more evenly distributed and can better capture local feature information, which achieves the purpose of improving the accuracy of point cloud deep learning network.

4.4. Overall Performance and Parameter Analysis of the Proposed Method. To better explain the benefits of the proposed AOMC clustering method, we make a comprehensive analysis from run time (time complexity), mAP , and $mIoU$. We compare and analyze the AOMC algorithm and other cluster methods, including farthest selection [27], random selection [34], DBSCAN [42], k-means [3], and agglomerative clustering [43]. Table 2 shows the performance of the combination of time complexity. What’s more,

Table 3 indicates the $mIoU$ of each method on every point cloud model. Table 4 displays the comparison of mAP of various methods.

We evaluate the run-time performance of our method with a GTX 2080TI GPU, Core i9-9900K CPU, and 32 GB memory.

4.4.1. Run-Time Comparison. Run time is an important measure of algorithm complexity. Here, we calculate the run time of different point cloud feature extraction algorithms. In the Modelnet10 data set, there are 4,899 point cloud models. Each cloud model consists of 10,000 points. We set different feature points to comprehensively analyze and compare the time complexity of different feature extraction algorithms.

As can be seen from the data in Table 2, compared with the farthest selection, the algorithm complexity of AOMC is relatively low. In the actual experiment, due to the uneven density and dense arrangement of point cloud samples, it is difficult to adjust the parameters of the DBSCAN ($O(N * Eps)$, where Eps means the spending time finding each neighborhood point) algorithm, and the actual application effect is limited. The algorithm complexity of agglomerative clustering ($O(N^3)$) is the highest among them. Random selection has the highest sampling speed ($O(1)$), but it has a large loss of local characteristics of the point cloud. In practice, the time complexity of AOMC is slightly longer than that of k-means ($O(N * \log(N))$). The main reason is the determination of the number of cluster centers.

4.4.2. $mIoU$ Comparison. Next, we analyze the performance of the feature extraction algorithm in parts segmentation tasks by comparing the $mIoU$ of different point cloud models.

TABLE 1: Selection of cluster number of different point clouds based on “elbow point method.”

Class	Bathtub	Bed	Chair	Desk	Dresser	Monitor	Nightstand	Sofa	Table	Toilet
Number of cluster centers	17	13	9	11	12	12	15	11	11	16

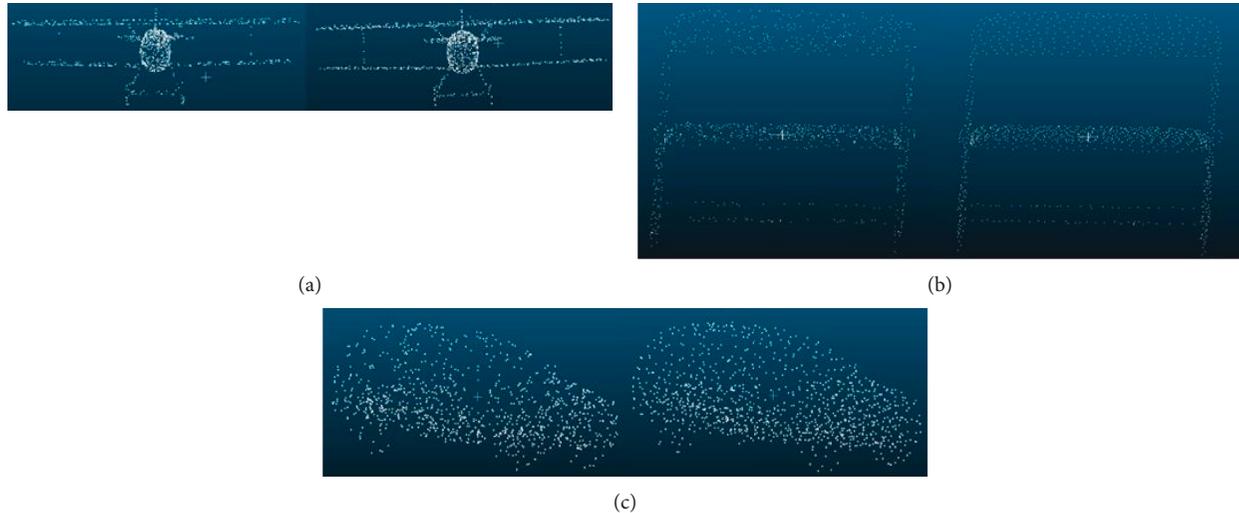

FIGURE 8: Comparison of point cloud feature sampling point between AOMC and random sampling. A total of 10m24 feature points are collected for each point cloud model; the left is random sampling; and the right is using AOMC to sample feature points. (a) Details of the wing are lost by random sampling. (b) and (c) Point cloud distribution of AOMC is more uniform than random sampling. (a) Airplane, (b) chair, and (c) car.

TABLE 2: Comparison of run time on local feature point extraction.

Feature points number	1,024	1,536	2,048
Farthest selection	1.51 s	3.56 s	5.83 s
Random selection	7×10^{-4} s	1.11×10^{-3} s	15×10^{-3} s
DBSCAN	0.07 s	0.08 s	1.01 s
k-means ($k=10$)	0.32 s	0.36 s	0.47 s
Agglomerative clustering ($n=10$)	2.91 s	2.96 s	3.01 s
Ours	0.55 s	0.58 s	0.64 s

TABLE 3: Comparison of mIoU on parts segmentation task. The best and the second-best methods are highlighted in red and green colors, respectively.

Method	Mean intersection over union (mIoU)										
	Avg (%)	Airplane (%)	Bag (%)	Chair (%)	Laptop (%)	Knife (%)	Mug (%)	Rocket (%)	Cap (%)	Table (%)	Earphone (%)
Farthest selection	81.60	82.40	81.10	90.70	90.60	86.10	95.10	54.50	89.90	82	68.50
Random selection	78.80	80.30	80	91	89	83.10	90.10	51.40	87.70	73	62
DBSCAN	79.70	79.20	78	89	90	83	95	56	82	80	65
k-means ($k=10$)	80.70	83.10	74	88	91	84	87	57	90.10	81	72
Agglomerative clustering	79.30	81.40	73	83	84	83.40	91	59	88.40	80.40	69.40
Ours	83	84	79	91.70	89.40	89.90	94.30	61	83	84	74

It can be seen from Table 3 that AOMC, the method we proposed based on adaptive point cloud clustering feature extraction, is applied in the task of point cloud model parts segmentation. The mIoU of some point cloud models parts segmentation is improved.

We can see that AOMC obtains an average of 1.4% improvement over the second-best method: farthest

selection. Compared with the random selection sampling method, AOMC has the best relative performance, which is about 4.2% enhancement. Although agglomerative clustering has the highest time complexity, its performance of parts segmentation is not better.

As shown in Figure 9, it is the effect of point cloud parts segmentation. The interior of the point cloud model is

TABLE 4: Comparison of the map on the classification task. The best and the second-best methods are highlighted in red and green colors, respectively.

Method	Mean intersection over union (mIoU)										
	Avg (%)	Airplane (%)	Bag (%)	Chair (%)	Laptop (%)	Knife (%)	Mug (%)	Rocket (%)	Cap (%)	Table (%)	Earphone (%)
Farthest selection	81.60	82.40	81.10	90.70	90.60	86.10	95.10	54.50	89.90	82	68.50
Random selection	78.80	80.30	80	91	89	83.10	90.10	51.40	87.70	73	62
DBSCAN	79.70	79.20	78	89	90	83	95	56	82	80	65
k-means ($k=10$)	80.70	83.10	74	88	91	84	87	57	90.10	81	72
Agglomerative clustering	79.30	81.40	73	83	84	83.40	91	59	88.40	80.40	69.40
Ours	83	84	79	91.70	89.40	89.90	94.30	61	83	84	74

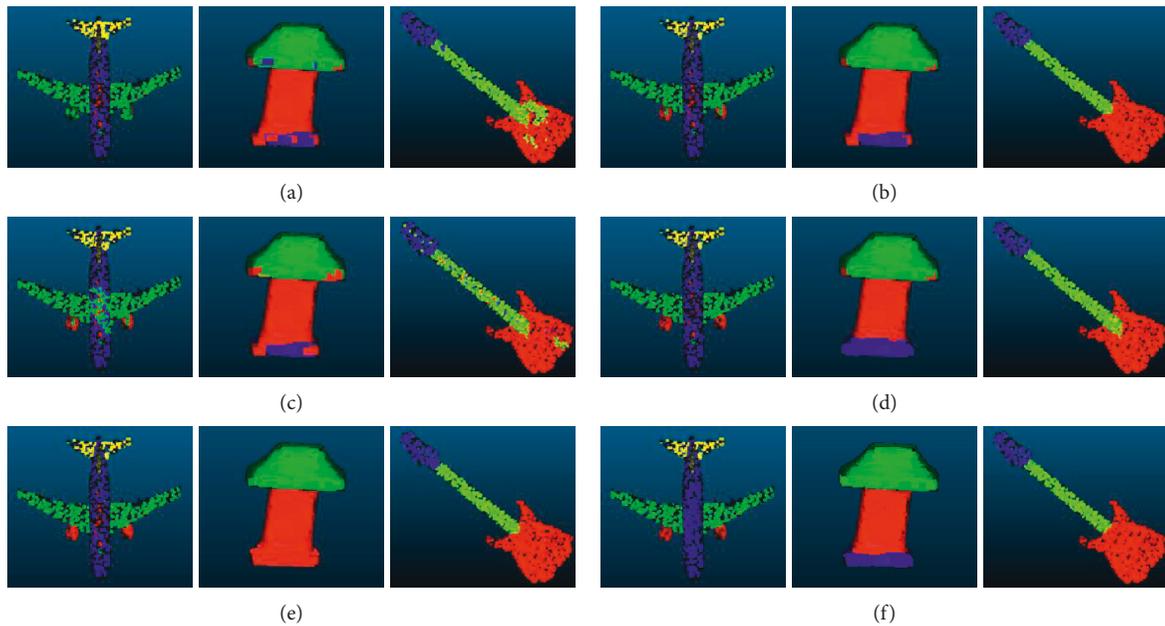

FIGURE 9: Point cloud parts segmentation example diagram. The point cloud model is divided according to the internal category (left: airplane, middle: lamp, and right: guitar). (a) random selection, (b) farthest selection, (c) DBSCAN, (d) k-means, (e) agglomerative clustering, and (f) ours.

divided into several parts. Random selection leads to a large number of point cloud classification errors, and it loses an array of model details. The engine of an airplane is almost confused with the wing. The parts of the guitar are not well differentiated.

The same problem exists in the DBSCAN sample method. In the airplane model, part of the fuselage point cloud is mistaken for the wing. And, of the lamp model, the base is confused with a lampshade. There are some classification errors on the guitar. In agglomerative clustering models, the lamp is only divided into two parts, and there are a few classification errors on the aircraft fuselage.

Although k-means and farthest selection has better segmentation effect, there are still a few mistakes. Compared with the above method, our method performs well in these point cloud models. The base, middle part, and shade of the lamp are clearly divided into three parts, and there is no error on the fuselage of an airplane. We can find that the point cloud deep learning network enables to capture better semantic information by adaptive clustering with parts

segmentation task. This strategy suppresses the noises of redundant local details and brings significant improvement to the edge performance.

4.4.3. Accuracy Analysis. Feature extraction plays an important role in the optimization process of a deep learning network. Among them, it has a great influence on the accuracy of network classification. We calculate the classification accuracy of each point cloud model and then analyze the influence of feature extraction on network accuracy by average value.

It can be seen from Table 4 that the point cloud feature extraction method based on adaptive clustering has achieved good results in some point cloud models. The average mAP is 89.09%, which is the best performance among these feature extraction methods. Similar to the performance on parts segmentation, the AOMC clustering method has a 0.84% benefit over the second-best clustering algorithm.

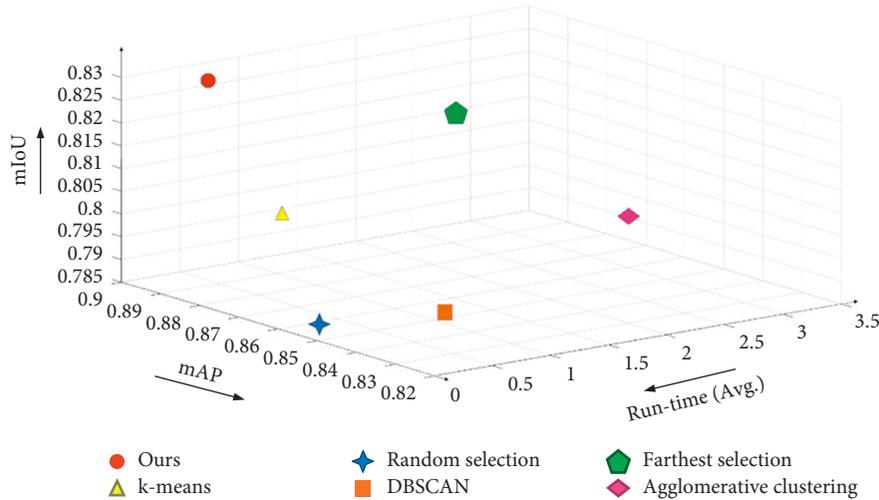

FIGURE 10: Comprehensive comparison of our method with other cluster feature extraction methods.

What’s more, DBSCAN still performs not well in classification; the proposed method has a 6.67% advantage over that. Because of the inaccurate extraction of detailed information, the random selection method cannot accomplish the tasks of a deep learning network well.

Figure 10 shows the visual comprehensive comparison of different cluster feature extraction methods. From the comparison results, it can be seen that our method has high real-time performance. In the task of point cloud segmentation, the performance of this algorithm is the best. However, in the classification task, the comprehensive performance of this algorithm is not good, and it only performs well in several point cloud models. The comprehensive performance of the AOMC algorithm is better than that of other models. We can choose different scale point cloud densities according to different task requirements, which makes the algorithm more flexible.

As can be seen from Figure 11, the point cloud feature extraction method based on adaptive unsupervised learning makes the loss function optimization speed of the deep learning network faster and the loss value smaller. The main reason is that the adaptive clustering method can extract more detailed information, thus increasing the classification gap between hierarchical learning features of point cloud categories. At the same time, due to the high complexity of the farthest selection point sampling algorithm, the network convergence rate is slow. Because of the neglect of more detailed information in point cloud models, the random selection method has the lowest overall accuracy and the biggest loss value among all experimental methods.

It can be seen from Figure 12 that when the number of training times reaches a certain number, the accuracy of the deep learning network using the adaptive clustering method is higher than that of the other point cloud feature extraction methods. It is proved that the deep learning network using an adaptive clustering algorithm has a relatively high optimization speed. At the same time, the deep learning network used for feature extraction has higher accuracy. Compared with some point cloud feature extraction methods, the adaptive point cloud feature extraction method obtains more detailed targets, to improve the hierarchical feature learning effect.

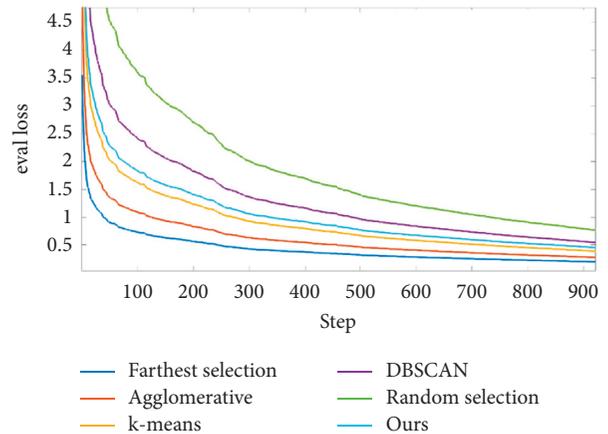

FIGURE 11: Training loss curve of the classified network.

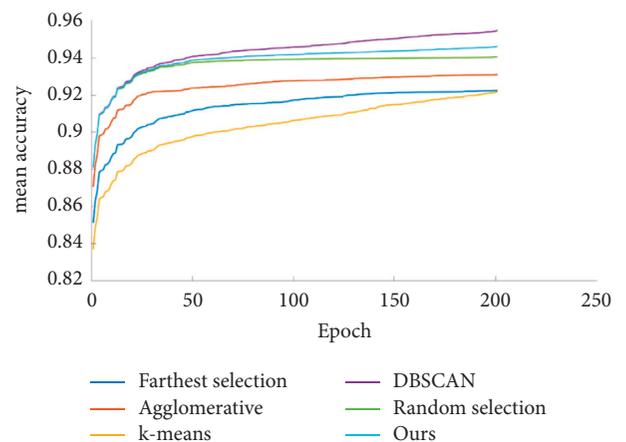

FIGURE 12: Training accuracy curve of classification network.

The experiments provide strong evidence for the advantages of adaptive unsupervised clustering for point cloud feature extraction. Adaptive point cloud clustering feature extraction method obtains better performance in time complexity. The reason is that the algorithm we proposed

avoids the overall traversal of the point cloud model and reduces the amount of calculation. In the point cloud deep learning task, the adaptive point cloud feature extraction method obtains higher accuracy of point cloud classification and parts segmentation. In the training process of the point cloud deep learning network, an adaptive feature extraction algorithm can improve the convergence rate of the network. Compared with the random selection method, the point cloud deep learning network achieves higher mean accuracy.

5. Conclusion

In this paper, we propose a novel point cloud feature extraction method based on unsupervised learning and adaptive optimization. AOMC point cloud feature extraction method consists of the cluster centers' number generation, adaptive clustering, and the applying tasks of the deep learning network. The accuracy and speed of the deep learning network are improved effectively. The performance of classification and parts segmentation is better.

Comparison results demonstrate the efficacy of the proposed methods. As can be seen from the experimental results, the method we proposed improves the effect of point cloud feature extraction and achieves the purpose of point cloud hierarchical feature learning. The accuracy of the point cloud deep learning network is improved. AOMC clustering algorithm improves the accuracy of the initial point of the clustering center, so as to improve the convergence rate and accuracy of the clustering processing. In the meantime, the method of selecting the best clustering center number by quantization SSE is put forward so that the point cloud clustering number and the point cloud category can be adapted to each other, and the fixed value method is no longer used to determine the amount of clustering center. As a result, it improves the rationality and accuracy of the point cloud deep learning. What is also worth noticing is that our clustering method realizes the purpose of improving the classification accuracy, parts segmentation accuracy, and convergence rate of the deep learning network.

The proposed method still has some drawbacks. It does not achieve the best performance in all point cloud models. And the steps of the algorithm are complicated. In the future, we plan to simplify the algorithm steps of AOMC. And improve accuracy for all models.

The traditional template scheduling method provides designers with design materials that do not reflect the real intention of designers, and a plane method based on three-dimensional virtual vision technology is proposed. In the given development environment, the mouse uses hand drawing, and the handwriting is formed by the obtained point sequence. The hand drawing adopts the method of smoothing noise to eliminate the noise, and the hand drawing stroke adopts two loops. The virtual model is drawn into 3D manually to realize the graphic design. After establishing the three-dimensional graphic design model, the visual effect is improved by using color mapping. The experiments show that this method can effectively realize the three-dimensional virtual model based on manual drawing, make the three-dimensional effect more real, meet the requirements of designers, and help designers show the real intention of design.

1. Introduction

As the market of practical design becomes bigger and bigger, the requirements for graphic design become higher and higher. For designers, the most important thing is “creativity,” which is the key to differentiate designers from craftsmen [1]. Designers must form their own style of creation. Graphic design cannot be separated from the development of productivity and material civilization and even more so from the promotion of economic development [2]. Design works should put practicality in the first place and then take into account its artistry.

Grobius believed that the creation of beauty and industrialized production could be perfectly unified. He pointed out the following. “History shows that the idea of beauty changes with the progress of ideas and technology. Whoever thinks he has discovered eternal beauty is bound to fall into imitation and stagnation.” Clothing design works such as those inspired by the traditional Chinese art of paper-cutting are loved by international and domestic fashion darlings, and many international high-end private custom clothing brands have absorbed a large number of traditional Chinese crafts such as embroidery [3], tassels,

batik, blue and white ceramics, and so on to design a large number of classic works, as can be seen from the traditional Chinese elements absorbed in large quantities in the 2016 Veep lingerie; when tradition and innovation collide, the graphic design charm is remembered and recognized by the public, which improves the practicality of design works [4]. As the market for practical design becomes larger and larger, the requirements for graphic design become higher and higher, and for designers, the most important thing is “creativity,” which is the key to differentiate designers from craftsmen. In the traditional logo design, the logo is just a simple trademark or logo, but now the logo design, in addition to the role of trademark or logo, carries more modeling, decoration, composition, and other roles, such as the trademark of CHANEL (Chanel) [5]. For example, our design works can be used in different positions of different products to meet people’s aesthetics and achieve the dual effect of aesthetics and practicality [6].

In the process of graphic design, textual elements are mainly divided into various forms, such as advertising slogans, theme words, and supplementary descriptions. As an extension of graphic design and the main carrier of information dissemination, the text elements in graphic

design should not only focus on the functionality of text information but also need to take into account its cultural expression [7]. In addition, designers need to combine the artistic form of graphic image to design the text elements in graphic design, so as to bring people a refreshing feeling [8].

In graphic design, picture elements can be divided into painting elements, photography elements, and graphic elements, which not only contain the expression of image language and graphic language but also have the characteristics of enhancing the visual recognition and memory of the visual language of graphic design [9]. Among them, painting elements can express different visual languages by using various painting tools and styles selected by designers. Photography elements can greatly enhance the persuasion of graphic images, and graphic elements have the intuitive effect of simplifying abstraction [10]. The rational use of graphic elements enables graphic works to better express visual language. Therefore, based on the three-dimensional virtual vision technology, this paper realizes the high autonomy of planners through the 3D modeling of manual operation.

In this paper, the hand drawing adopts the method of smoothing noise to eliminate the noise, and the hand drawing stroke adopts two loops. The virtual model is drawn into 3D manually to realize the graphic design. After establishing the three-dimensional graphic design model, the visual effect is improved by using color mapping.

2. Related Work

Graphic design cannot be separated from the development of productivity and material civilization, and even more so from the promotion of economic development, design works should put practicality in the first place and then take into account its artistry [12]. Many of the world's high-end brands are fine-tuning their trademarks and advertising slogans with the development of the times, including car brands, food brands, clothing brands, daily-use brands, and so on. This highlights the fact that the market positioning of graphic design is not static, and its practicality is the first and artistry is the second in the role of marketing [13].

In the visual language of graphic design, visual recognition refers to the image that has certain color, size, shape, or structure and can attract people's attention from the visual aspect. The amount of information that people can obtain is greatly increased, which not only makes people's awareness of information greatly enhanced but also makes it difficult for people to focus on the visual aspect. Therefore, in order to attract people's attention to graphic design from the visual aspect, it is necessary for graphic design to start with image design and effectively attract the public's attention through special and distinctive design images, which is the centralized embodiment of the visual language of graphic design [14, 15]. The visual language of graphic design is further enhanced. It is believed that with the continuous development of visual art, more and more novel visual expressions will appear in graphic design, and the visual language of visual recognition will be further enhanced.

In the process of graphic design, in addition to using bright colors and creative shapes to attract people's

attention, designers also need to integrate some information into the visual language of graphic design, so that people can read the information in the process of watching the graphic design content, so as to achieve the communication and dissemination of information, and this is the readability of the visual language of graphic design. In order to make the visual language of graphic design have certain readability, designers usually need to give certain spiritual and cultural connotation to the graphic design image in the process of graphic design, so that the visual language of graphic design image can be understood by people [16, 17]. Therefore, designers need to strengthen the coherence of the visual language in the graphic design image when designing, so that the graphic design can successfully realize the communication and dissemination of information.

In addition to the need to communicate and express information through the visual language of graphic design, graphic design designers also need to make people leave a long-term impression of the graphic design image, and when they think of the impression of the graphic design, they can recall the information that the graphic design works want to convey, and this is the memorability of the visual language. In the visual language expression of graphic design, the memorability of visual language is dependent on the visual recognition characteristics of visual language because graphic design with strong visual recognition characteristics has more innovative and unique graphic design image, which can cause strong stimulation to people's visual senses and trigger the resonance in people's heart, so that people can maintain a deep memory of the image of graphic design [18]. In the visual language of graphic design, the harmony and proportion of graphic images can make people find a unique attraction and charm in the process of viewing graphic design, which in turn forms a conditioned reflex in people's mind and stores their visual impression of graphic design for a long time [19]. If we can control the memorability of visual language in the process of graphic design, we can make graphic design further develop into an innovative and unique art form.

3. Methodology

The overall structure of the 3D simulation system for floor plan design was designed using virtual vision technology to provide services to each application system so that each heterogeneous system can easily access data-level services. The 3D simulation technology was used for distributed 3D floor plan design, and the interior space hierarchical layout was realized on the basis of modeling software. The operating system is Win7, and 3D simulation is used as a 3D program development tool, and the OpenGL graphics library is used to provide more point, line, and surface drawing functions in the modeling process. The configuration is shown in Figure 1.

Based on the overall design architecture, the system is modularized and functionalized to provide executable real-time 3D application files for 3D graphic design through virtual vision technology. The application loading mode of the 3D graphic design process is dynamically changed using virtual vision technology. To make the designed software

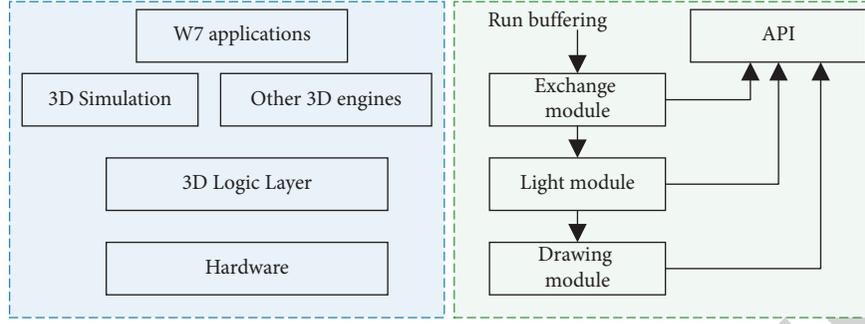

FIGURE 1: Overall structure of the 3D simulation system for graphic design.

functions more reasonable, 3DMAX 7.0 software is adopted as the 3D model making tool [20].

The 3D image virtual reconstruction system is mainly composed of three parts: sensor module, upper computer 3D imaging module, and circuit module, and its specific structure is shown in Figure 2.

It can be seen from Figure 2 that the system architecture consists of hardware structure, interaction of data and instructions, and management of system coordination. The main control chip is the core of the system, which can realize three-dimensional image reconstruction by combining microcontroller, Gigabit Ethernet, and other devices.

Based on the stereo sensors and display technology in 3D virtual reality technology to design the vision module, the module is mainly composed of multiple stereo vision sensors, mainly through the deployment of stereo vision sensors to the design of the indoor environment for three-dimensional imaging display. The specific model of the stereo vision sensor is Xtion ASUS, and its specific technical parameters are given in Table 1.

The data processing module consists of a PC and a GPU. The PC is mainly used for core data processing, and its specific parameters are given in Table 2.

The GPU is mainly used for image data processing, and the model chosen is Quadro Nvidia 3000M GPU, whose specific parameters are given in Table 3.

Establishing a good 3D virtual model requires corresponding technologies and tools. Firstly, the acquisition process of hand drawing is introduced: hand drawing with the mouse and forming a pattern with a given sequence of points R describes a sequence of ordered points

$$H(\alpha_i, \beta_i, \chi_i, U_m), \quad (1)$$

where q_i indicates the points in the display. The speed of each point is set, i.e., $v_i = |\vec{q}_i \vec{q}_{i+1}|$; the faster the plotting speed is, the more dispersed the points are and the faster the points are collected.

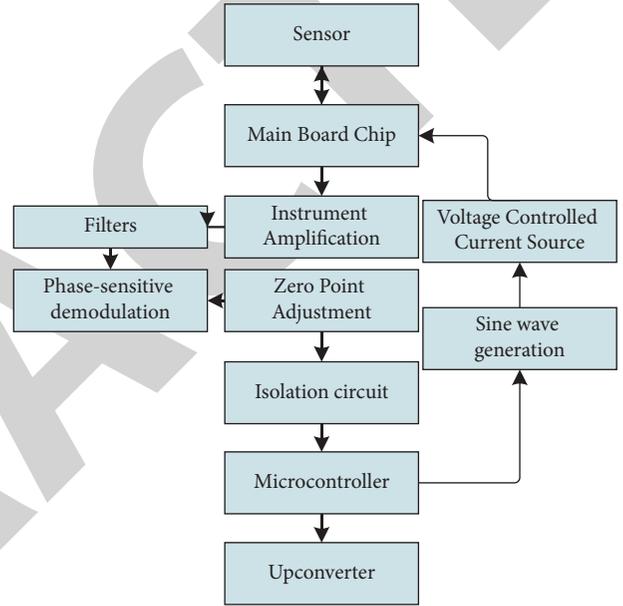

FIGURE 2: Diagram of the overall system structure.

When drawing with the mouse, the handshake will make a noise. In addition, there will be some errors when converting the input data into coordinate points on the display. The lower the resolution of the display, the greater the error. This section uses noise smoothing. The basic idea of smoothing noise is to adjust the value of the current point according to the value of adjacent points. Thus, we have

$$R^* = \{q_i^* \mid 0 \leq i \leq M - 1\},$$

$$q_i^* = \sum_{j=i-N}^{i+N} \omega_j q_j. \quad (2)$$

TABLE 1: Specific technical parameters of stereo vision sensor.

Serial number	Technical index	Specific parameters
1	Model	Xtion ASUS PRO
2	Size	$5 \times 3.5 \times 18$ cm
6	Viewable angle	Vertical angle: 57.5° , horizontal angle: 45°
7	Detection distance	0.9~4.6 m
8	Supported operating system	Win10, Vista

TABLE 2: Specific parameters of PC.

Serial number	Technical index	Specific parameters
1	CPU	Intel Core i5-0773M
2	Main frequency	4.0 GHz
3	Memory	16 GB
4	Graphics card model	Radeon AMD HD 0574

TABLE 3: Specific parameters of GPU.

Serial number	Technical index	Specific parameters
1	Base model	3000 MB
2	Number of CUDA cores	1772
3	Specific type of memory	GDDR4
4	Maximum memory capacity	9182 MB
5	Memory bit width	334 bit
6	Power consumption	240W
7	Resolution	2260×4186

In this section, manually draw the second-order curve corresponding to B, which is controlled by the shape of the multi-control point curve described in the following equation:

$$G(w) = \sum_{n=0}^m g_n f_{n,l}(w), \quad (3)$$

where $f_{n,l}(w)$ is used to describe the B-sample mixed basis function.

From (3), the points $G(w)$ on the fitted curve are mainly determined by the control points g_n . The inverse subdivision method is used to reduce the noise to ensure that it has equally spaced control points, where

$$A = [a_0, a_1, a_2, \dots, a_m]^T; B = [b_0, b_1, b_2, \dots, b_n]^T; S = \begin{bmatrix} X \\ Y \\ Z \end{bmatrix},$$

$$X = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & \dots \\ \frac{1}{2} & \frac{3}{4} & 1 & \frac{1}{2} & 0 & 0 & 0 & \dots \end{bmatrix},$$

$$Y = \begin{bmatrix} 0 & 0 & \frac{1}{2} & -\frac{1}{4} & \frac{3}{4} & 0 & 0 & \dots \\ 0 & 0 & 1 & \frac{1}{2} & -\frac{1}{2} & \frac{1}{4} & \frac{3}{4} & \dots \\ \vdots & \ddots \end{bmatrix},$$

$$Z = \begin{bmatrix} \dots & 0 & 0 & 0 & \frac{3}{4} & \frac{1}{2} & 1 & \frac{1}{4} \\ \dots & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}. \quad (4)$$

Because the translation is carried out in the way of analysis and smoothing, the control points can be obtained only by the inverse division of a point sequence, so the adjusted curve corresponds to the initial input.

Through the combination of curves, the uniform distribution of points and the adaptive correction of points are realized, which is convenient for the control and operation of 3D model mesh obtained in graphic design.

After acquiring and preprocessing hand-drawn strokes, 3D virtual modeling is performed to realize the graphic design. For multi-stroke input, the input stroke information is saved by quaternions $H(\alpha_i, \beta_i, \chi_i, \delta_i) \rightarrow U_i(D_i)$, and all elements are saved by means of a class library. Among them, α is used to describe the recognized stroke information, β is used to describe the spatial location, χ is used to describe the topological information of the input strokes, and δ is used to describe the stroke characteristics. The stroke information obtained after processing is described by U_i , and the constraints that meet the design conditions are described by D_i . Stroke spatial location and topological information are mainly obtained through the stroke recognition process. The information of strokes designed by the designer is saved, and the angles of the planes in which different strokes are located are derived to obtain the spatial positions among the strokes. The three-dimensional modeling process of the designer's hand-drawn work is as follows.

After obtaining and preprocessing handwritten patterns, 3D virtual simulation is carried out to realize graphic design. To input multiple strokes, input and save stroke information through four elements, all of which are stored in the class library. In particular, the identification data used to describe the spatial position and the topological data used to describe the input stroke and the stroke features are described. After processing, the stroke information obtained is described in the description that meets the project conditions. The spatial position and topological information of handwriting are mainly obtained through the process of handwriting recognition. Save the designer's design information and export different angles to the plane, so as to obtain the spatial position between strokes. The constructor draws the hand-drawn work as follows.

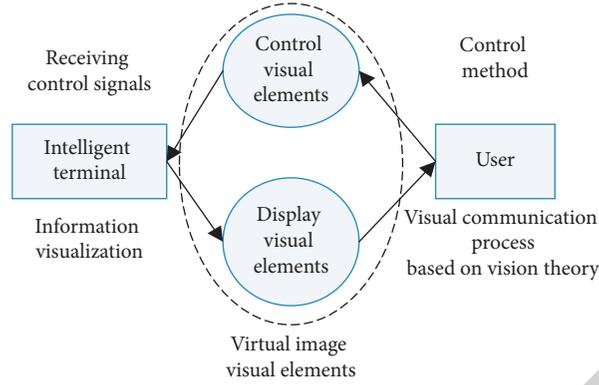

FIGURE 3: Virtual image visual interaction process.

- (1) Initialize the input information $H(\alpha_i, \beta_i, \chi_i, \delta_i)$.
- (2) Identify the strokes drawn by the designer: $H(\alpha_i, \beta_i, \chi_i, \delta_i) \rightarrow U_i(D_i)$, and output the result if it is a single stroke; if not, proceed to the next step.
- (3) Reasoning about the combined condition constraints of the design work.

$$D_m(U_i \wedge U_{i-1} \wedge \dots \wedge U_1) \rightarrow U_m(U_j(D_k), \dots, U_n(D_i), D_m). \quad (5)$$

- (4) Judge whether U_m belongs to the known model; if it does, insert it into the model and realize the 3D model construction; otherwise, repeat step (1).

In the process described above, step (2) aims to identify the input manual drawing, form the basic information of the image, and determine whether the modeling process is single or multiple. Otherwise, the next step will be to achieve matching by forcing the solution to obtain the 3D model.

After establishing the 3D planning work model, this section needs to show their real perception ability to improve the visual effect. The color effect can be obtained by three-dimensional simulation. To perform color mapping, you must set a set of colors and vertex colors for all vertices:

$$k[i][j] = \frac{b_{oc} + (t_{oc} - b_{oc})}{j \times i}. \quad (6)$$

After the information data are collected through the above steps, the virtual reconstruction of the 3D image is completed by using the visual interaction technology in visual communication, whose visual elements are mainly composed of display visual elements as well as control visual elements, as shown in Figure 3.

In Figure 3, the visual communication technology is applied to the virtual reconstruction, and the user sends the operation signal through the intelligent terminal, and after the internal processing and storage of the system, the display visual elements are fed back to the 3D image. The user completes the virtual graphic design of the 3D image through the feedback information data.

4. Experiments

In the range of 20–30 elements, the indoor environment is simulated by environmental interior design, interior design technology based on 3D virtual reality, system design based on environmental factors, and optimal indoor configuration system design, as shown in Table 4. It can be seen that within the range of 20–30 elements, the indoor design time simulation of the indoor design scene of the environmental interior design system based on 3D virtual reality is less than that of the indoor environment optimization based on environmental factors and layout optimization.

The comparison results of the time spent on indoor environment modeling are shown in Table 5.

It can be seen that within the range of 30–40 indoor environment design elements, the indoor environment design technology of scene simulation system based on 3D virtual reality takes less time than the simulation based on environmental factors and the optimization of indoor environment system [21, 22].

First, the designer who draws the objects manually starts and then carries out three-dimensional virtual simulation. The three-dimensional virtual simulation results shown in Figure 4(a) are shown in Figure 4(b). The diagram manually displays the three-dimensional virtual simulation results as shown in Figures 5(a) and 5(b).

The analysis of Figures 4 and 5 shows that this method can effectively realize the three-dimensional virtual simulation based on manual drawing, make the three-dimensional effect more realistic, and help the designer to show the

Number of unsatisfied cases	3	5	5
Number of generally satisfied cases	3	11	15
More satisfied cases	13	18	19
Very satisfied cases	35	11	4
Average score	4.57	3.55	3.41

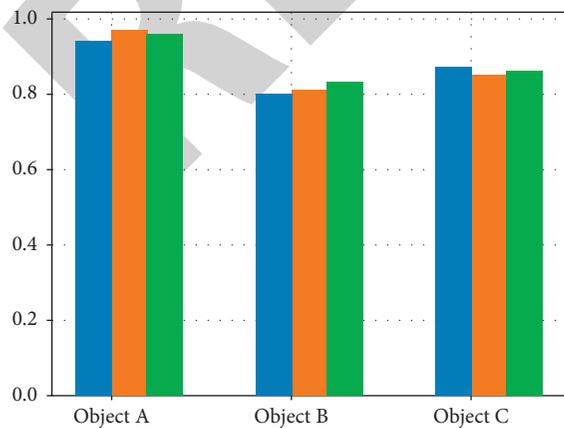

FIGURE 6: Design accuracy comparison results.

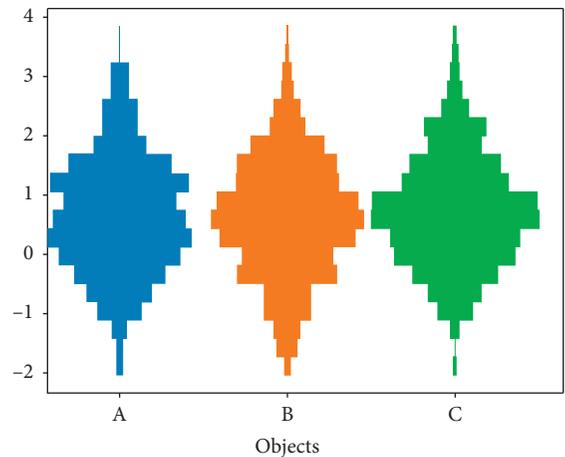

FIGURE 7: Comparison results on different design objects.

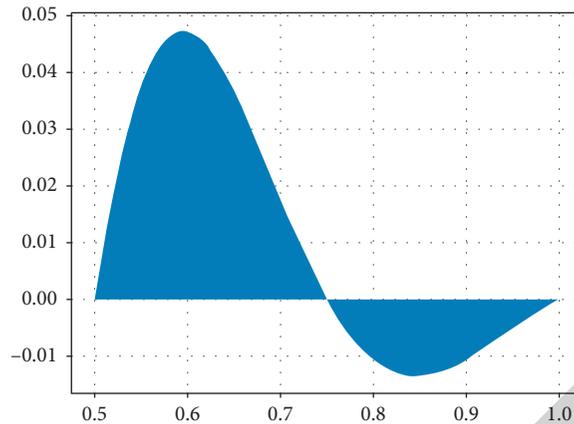

FIGURE 8: Changes in design fit.

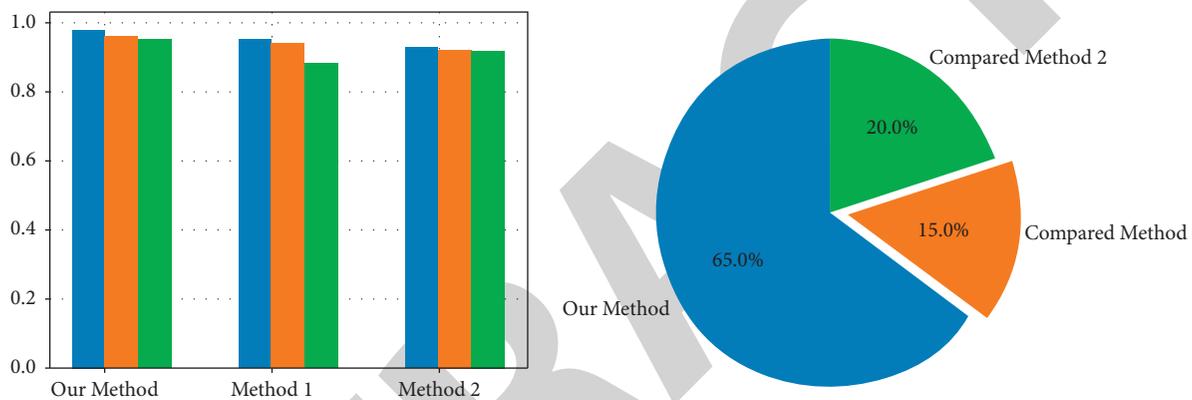

FIGURE 9: Comparison results of user satisfaction.

real intention. Planning and design is an uncertain process, so this section adopts the fuzzy planning evaluation method. The fuzzy evaluation method has been applied to psychology to quantify fuzzy problems [23].

When evaluating planning and design methods, it is not determined which type they belong to. Generally speaking, appraisers prefer one evaluation level, but there are other evaluation levels that cannot accurately evaluate their results.

The evaluation levels on both sides of the most satisfying level are compared in terms of their degree of conformity. The confidence level is assigned, and then the remaining levels are evaluated. If the participant thinks that the actual feeling matches the leftmost rank, the evaluation is performed in the order from left to right; otherwise, the evaluation is performed in the order from right to left.

The analysis of Tables 6 and 7 shows that no users are satisfied with the method, only two users are dissatisfied with the method, and all other users are satisfied with the method, of which 34 users are satisfied with the method. In contrast, 9 users were dissatisfied with the compressed sensing method and machine vision, only 10 users were satisfied with the compressed sensing method, and 6 users were satisfied with machine vision.

This paper systematically compares various planning methods based on 3D virtual technology and establishes

three image types to be designed. In order to verify the design effect of three systems in three images, the results are shown in Figure 6.

For different design objects, we have compared the design effects of our model in detail. The specific results are shown in Figure 7. Further, we show the changes of our model in the design fit in Figure 8, and we can see that it has a good design fit.

From Figure 9, the user's evaluation of this method is 0.65 on average, which is significantly higher than that of the compressed sensing method and machine vision method with 0.2 and 0.15, which shows that this method meets the design requirements and verifies its effectiveness.

5. Conclusion

In graphic design, the main thinking and creativity of planners can be enhanced through visual expression so as to promote graphic design works to be more beautiful. A scheduling method based on 3D virtual vision technology is proposed. In order to create conditions, the acquisition and preprocessing of handwritten patterns are introduced. On this basis, a 3D virtual template with brush image and color is established. Experiments show that this method meets the requirements of designers and helps them show their real intention.

AI technology is rapidly changing traditional industries by using the technologies of big data, machine learning, and deep learning in AI technology. This study transforms and constructs the links of market research, market strategy, marketing strategy, and marketing activities in the marketing system. The use of AI can help companies to understand customer needs more comprehensively, find market opportunities more quickly, establish business goals more accurately, and achieve smart marketing and precision marketing in the true sense. AI technology also brings new challenges to the development of enterprises. This study analyzes the data risk, payment risk, ethical risk, and decision-making risk in the marketing system and puts forward the solutions.

1. Introduction

With the rapid development of science and technology, the knowledge economy system has gradually taken shape. The emerging high-tech industry represented by AI (Artificial Intelligence), as a powerful engine to stimulate social development, is imperceptibly affecting people's production and lifestyle [1, 2]. AI, a part of computer science, actually attempts to create a new type of intelligent machine. Such machines can respond to external stimuli like real humans. Large domestic and foreign Internet companies and venture capital institutions have set their sights on this industry [3].

In recent years, AI technology has developed rapidly with the strong support of national policies. AI is a technology that studies and develops to simulate, extend, and expand human intelligence, including big data, machine learning, deep learning, natural language understanding, image recognition [4, 5]. In case many traditional industries still do not use AI technology to improve the level of intelligence and complete the upgrading of the traditional system, they might be replaced by AI in the future.

Marketing is a very important link in traditional economic life, mainly around customers. At present, the global economy is in a period of decline, and business operations are facing great difficulties. How to expand the scale of operations and reduce operating costs have become important issues for enterprises to consider [6]. The use of AI

can help enterprises to more comprehensively understand customer needs and find market opportunities more quickly. To establish business objectives more accurately, it is very necessary to study the application prospects of AI technology in marketing. This study uses AI technology to discuss the methods of transforming and constructing the traditional marketing system, analyzes and studies the possible risks of AI, and puts forward the solutions at the end.

2. Relevant Overview and Application of AI in Marketing

2.1. AI. AI is one of the most emerging fields of science and engineering. It was proposed by scientists such as McCarthy, Minsky, Rochester, and Shennong at the Dartmouth conference in 1956 [7]. In the subsequent development, different scholars have given different definitions of four different dimensions: human-like thinking, human-like action, rational thinking, and rational action. The relevant definitions are shown in Table 1.

Combining the viewpoints of different scholars, AI belongs to a branch of computer science. It is a technology to study and develop theories, methods, technologies, and application systems for simulating, extending, and expanding human intelligence. It tries to understand the

TABLE 1: Definitions of AI in four dimensions.

Dimension	Definitions	Representative scholar
Human-like thinking	AI has spontaneous behaviors related to human thinking and activities, such as decision-making, problem-solving, and learning.	Richard Bellman
Humanoid action	AI is the art of creating machines that enable them to exhibit human-like intelligence.	Ray Kurzweil
Rational thinking	AI is a subject that studies how to make computers perceive, reason, and act.	Patrick Winston
Rational action	AI is concerned with the intelligent behavior in artificial products.	Nils Nilsson

nature of intelligence, imitates human intelligence, and produces machines that are similar to human intelligence.

In other words, AI is a technical science that studies human thinking patterns and applies human thinking to machines, so that machines have human thoughts and behaviors, thereby replacing humans to complete certain tasks. As a new technical science, AI is different from general computer code programming. Its core idea is to use specific algorithms to judge and summarize events, so as to quickly complete the predetermined settings and operations [8]. This is inseparable from a large amount of data analysis, deductive inference, and calculation. After more than 60 years of development, AI has become an interdisciplinary frontier science covering multiple fields and multiple disciplines.

2.2. Marketing. Marketing is an activity or action. As for the concept of marketing, Philip Kotler believes that marketing is the management process of exchanging the products produced by individuals or organizations with others, so as to meet people's practical needs [9].

The American Marketing Association proposed that marketing is an activity process of disseminating valuable market supply. In fact, it is the process of realizing a function and a series of creation and communication, and then influencing this value on customers and realizing profits in this process. Many experts and scholars have defined marketing and have their own views.

In short, the market is a starting point and a destination in commodity marketing activities. In fact, marketing is not only a function but also a way to create, communicate, and deliver customer value to realize self-interest. Products can be delivered to consumers and partners through marketing. Marketing is not only an activity but also a process of sales behavior and art of creating and meeting customers.

2.3. Intelligent Marketing

2.3.1. Connotation of Intelligent Marketing. The traditional marketing model is crafted mainly through apps and offline and online advertising, or local promotion through bank outlets. These methods have the characteristics of high cost and low efficiency. Intelligent marketing uses AI technology to obtain customers through multi-dimensional online and offline intelligence and makes intelligent analyses based on big data information processing technology [10].

You can see the product needs of customers through user portraits, so as to achieve an accurate match between

products and customer needs. This method greatly improves the efficiency and reduces the cost. It can not only improve customer satisfaction with products but also indirectly enhance the market competitiveness of banks, as shown in Table 2.

Intelligent marketing is mainly divided into two steps. The first step is personalized recommendation and intelligent customer acquisition. In order to attract customers, customer groups are divided according to customers' differentiated consumption preferences. The second step is differentiated classification and precision marketing to develop differentiated marketing strategies for different products and different customers to achieve personalized precision marketing.

Personalized recommendations and intelligent customer acquisition are based on multi-channel data. Using big data, AI, and other technologies to deeply mine the relevant information of customers in multiple dimensions, analyze the daily behavior characteristics of customers, accurately identify customer needs, and achieve accurate portraits of customers. Differentiated classification and precision marketing are precision marketing after mining customers and screening customer needs through AI [11]. Formulate differentiated marketing strategies for different customer groups, personalize products to meet their needs, save marketing costs, improve marketing efficiency, and improve customer experience.

2.3.2. Technical Foundation of Intelligent Marketing. The rise of AI marketing is inseparable from the support of technology. According to the research of previous literature, the technical basis of the development of AI marketing can be roughly divided into three aspects:

- (1) Mobile Internet and 5g technology provide the guarantee of massive data sources for the development of intelligent marketing. The important foundation of intelligent marketing development is data. Continuous and reliable data acquisition is one of the core technologies required by intelligent marketing. With the development of mobile Internet and 5G technology, marketing activities have widely penetrated consumers' daily behaviors such as work, entertainment, life, and consumption with the help of virtual reality technology, simulation technology, and artificial bio-intelligence technology, and comprehensively recorded consumers [12, 13]. The behavior data provided by intelligent marketing provides a massive source of data information for the

TABLE 2: Comparison of traditional marketing and intelligent marketing.

	Traditional marketing	Intelligent marketing
Customer acquisition mode	Offline physical outlets, mobile apps, etc.	Offline promotion, online drainage, the introduction of third-party platforms, with the help of partners' traffic channels and scene resources, expand customer contact business scenarios, and acquire customers through multiple channels.
Marketing mode	Lack of customer demand and product matching mechanism, and failure to recommend differentiated products and services based on customer characteristics.	Automatically generate customer portraits and labels based on AI analysis, and intelligently recommend products based on customers' age, risk appetite, income, and other levels to improve marketing efficiency.

follow-up analysis and processing of intelligent marketing.

- (2) Cloud computing helps intelligent marketing complete complex data calculation and processing analysis. In the era of the mobile Internet, the development of big data has caused the exponential growth of network data. How to calculate, process, and analyze these massive data has become an important problem that must be solved in the development of intelligent marketing. With its powerful data computing ability, cloud computing technology solves the problem of massive data processing in the application of AI technology. The interconnection of all things is realized through the connection of multi-dimensional data, which makes the interactive experience between consumers and intelligent devices much better. The marketing scenario is also more intelligent due to timely and accurate data analysis [14].
- (3) The commercial application technology of AI provides a network application environment for the development of intelligent marketing. The development environment of AI commercialization and the support of AI commercialization application technology have created a good external network application environment for the development of intelligent marketing.

2.4. Problems of the Traditional Marketing Model

2.4.1. Marketing Effect Is Not Ideal. In short, each product has a relative consumer group. However, the traditional marketing model only focuses on the promotion of products and providing corresponding services to consumers, and does not carry out personalized marketing for specific consumer groups. With the development of the times, it only chooses the traditional marketing model. That is, it cannot be promoted to the corresponding consumers according to the special properties of the product and the corresponding scope of application. It will lead to the retention of a large number of products and seriously affect the development of the enterprise itself. Therefore, in the current social development process, enterprises should promote products according to their own scope of use and unique attributes of products, and recommend products to corresponding audience groups in a targeted manner.

2.4.2. The Pattern Is Monotonous and Not Rich. Most of the traditional marketing models carry out product promotion and marketing through traditional media such as newspapers, TV, and magazines. However, these traditional marketing methods are relatively single and cannot cover all consumer groups. Information sources of current consumer groups are not limited to newspapers, TV, and magazines, and most consumer groups are doing shopping on the Internet environment. Therefore, if only the traditional marketing model is adopted, the long-term development of the enterprise itself cannot be promoted.

2.4.3. Traditional Marketing Costs Are Too High. Cost consumption is a very important factor in the production and marketing process of enterprises. In the process of using the traditional marketing model to promote product brands, there are many promotion processes and links, which further increases the cost of consumption. In the traditional marketing model, the communication between enterprise sales staff and consumers is prone to problems [15]. If the enterprise does not take corresponding adjustment measures, it will greatly increase the marketing cost of the enterprise, and even seriously affect the actual marketing effect of the enterprise's own brand products. In a word, in the marketing process of enterprise products, the relationship between cost and output is the biggest influencing factor.

2.5. Application of AI in Marketing

2.5.1. Marketing Characteristics of AI

(1) *Cross Time and Space Marketing.* Using the marketing method of AI, we can quickly obtain all the information of network users, who come from all over the country and even the world. AI can accurately screen their daily browsing records and push them with marketing information in line with users' preferences. This was something that could not be done in the past. The previous marketing was only manual marketing for the local area and a small area. Now, the use of AI can expand the scope of marketing to the whole country and even the world, so that more people can see the marketing copy and advertisements of enterprises.

(2) *Multimedia Marketing.* Now is an era of rapid technological development, and people can obtain information in various forms on the Internet. The use of AI for marketing is

in line with this characteristic. AI can convert the marketing scheme into various forms and appear on the user's push page. Users can use the network to further understand the products in various forms such as video, pictures, and text [16]. The characteristics of multimedia can enable AI to accurately understand the effect of marketing and collect the reactions of various users when they see advertisements and the reading volume of advertisements. It makes it easier to determine the customer group, and it can also better accumulate the experience for the future marketing of the enterprise.

(3) *Growth*. A very big benefit of using AI is that marketing can be kept growing. Most of the people who use smart products and the Internet are teenagers and middle-aged people. Middle-aged people now have enough economic strength, so their purchasing power is also very strong. Although teenagers have insufficient purchasing power now, marketing to their group can effectively cultivate potential customers for the future market. Therefore, using AI for marketing is a growing marketing method.

(4) *Interactive Quality*. The progress of traditional offline marketing is very slow, and the interaction is also very poor. Most users are office workers and they do not have time to specifically evaluate the marketing effect. With the use of AI marketing methods, it is possible to conduct surveys on marketing objects through the release of questionnaires on online platforms. Or you can put forward some suggestions for improvement, and constantly enrich the content of AI marketing so that they can better meet the needs of users and achieve the purpose of marketing.

(5) *Hommmization*. Nowadays, many young people are reluctant to communicate with people directly, they like an independent life, and AI marketing is very suitable for users' needs. Users can learn the detailed introduction of the product through online marketing, and they can also communicate with the product and customer service through the online platform, and make purchases according to their own wishes. The offline marketing methods are somewhat forced marketing. It is possible that users do not need this product. Forced marketing will make them feel oppressed and have a bad impression of the product.

2.5.2. *Application Status*. With the popularity of the Internet, using computers and mobile phones to browse websites or application software is also known as a basic activity in people's daily life. During browsing the web, people often find that advertisements pop up, which is actually the "precision positioning marketing" of intelligent marketing. Based on the big data system and combined with the consumer behavior data provided by the demand-side platform, merchants can accurately grasp consumer preferences and demand information, so as to place advertisements in a targeted manner.

The application of AI in marketing can be summarized from the development history, logic principles, and practical effects of platforms such as demand-side platforms (DSP), data management platforms (DMP), real-time bidding (RTB), supply-side platforms (SSP), and other platforms [17].

In the first stage, thanks to the acquisition of consumer behavior data, precision marketing has achieved good marketing results in a short period of time. In addition to the lack of consumer information protection in China, intelligent precision marketing can obtain a large amount of consumer behavior data and preference data—and DSP, DMP, RTB, and other platforms have developed rapidly.

In the second stage, with the cooperation of major e-commerce platforms, major commercial databases have realized technology connection, resource sharing and data exchange, and the breadth and depth of intelligent precision marketing have been better developed.

In the third stage, intelligent precision marketing is widely used by major e-commerce platforms, search engines, and various web pages. Various industries imitate this marketing model, resulting in consumers' misunderstanding of precision marketing. For example, consumers constantly pop up marketing advertising pages when browsing the web, which affects consumers' normal life and work and hinders the development of intelligent marketing.

2.5.3. Existing Problems

(1) *Lack of AI Talents*. If enterprises want to improve their marketing competitiveness, they must keep up with the pace of social development, pay attention to the application of AI and use the network for more extensive marketing. In the process of application, there may be some problems. The use of AI in marketing is rising in recent years, so the gap between AI talents is very large. Many enterprises lack AI talents and can not effectively use AI for marketing.

(2) *Improper Management Methods*. Some enterprises use AI to establish platform-related websites, but there is no special management department to manage them, so the role of AI can not be brought into play. Enterprises do not know much about AI, so they should hire professionals to operate and help enterprises carry out effective marketing. Some enterprises will invite professional technicians to operate, but some of them cannot manage well because of a lack of experience and lack of experience in online marketing.

(3) *Lack of Innovation Consciousness*. The use of AI can speed up work efficiency to a great extent. However, due to the low innovation consciousness of enterprises, they do not pay attention to the combination of AI and market demand, and only use AI to put targeted advertising, which will lead to the lack of competitiveness in enterprises and the failure of marketing. Therefore, enterprises should cultivate their

awareness of innovation, use AI to collect information and data, and come up with some novel marketing means.

3. Construction of the Marketing System Based on AI

According to the traditional marketing system, based on the characteristics of market research, market strategy, marketing strategy, marketing activities, and other links, combined with various technical means of AI, a new system diagram based on AI has been established.

3.1. Market Research

3.1.1. Market Environment. Through data mining, data sharing, web crawler, and other technical means, we can more accurately understand and perceive the changes in the market environment. Seize the huge opportunities brought by market demand to enterprises in time to avoid the negative impact on enterprises due to changes in market conditions.

In terms of macro environment, AI can comprehensively analyze the impact of multiple indicators on industrial development, so as to realize the visualization of analysis results [18]. In terms of the perception of the microenvironment, the microenvironment model is established by using the micro marketing channels, enterprises, customers, competitors and other indicators, and through the deep learning algorithm, which can be dynamically observed at any time.

3.1.2. Consumer Behavior. Part of consumer behavioral data can be collected by conducting extensive market research and industry research. More importantly, through cooperation with Taobao, Pinduoduo, and other large e-commerce and offline stores, we can obtain massive consumer consumption data. On this basis, machine learning algorithms and natural language understanding technologies are used to conduct an in-depth analysis of data, accurately understand consumers' consumption needs, and predict consumers' future consumption behavior.

3.2. Market Strategy

3.2.1. Market Segmentation. The data mining algorithm is used to comprehensively analyze the consumers in the market, design the prediction algorithm, determine the market segmentation standard, and divide the consumers into several potential customer groups. It overcomes the biggest "expensive" problem of market segmentation without manual intervention. It has the characteristics of low cost and good effect.

The use of AI technology can even achieve complete market segmentation, and each consumer in the market constitutes an independent sub-market. Enterprises produce

different products for each consumer according to their different needs, as well as comprehensive standard segmentation, and subdivide the whole market from multiple angles.

If we consider technologies in China, Baidu is one of the most powerful AI companies in China, and it has achieved leaps in many market segments. For example, opening Baidu Maps can realize automatic navigation only through manual dialogue; opening Xiaodu smart speakers can realize intelligent and visual control of all home appliances; and through AI fundus screening all-in-one machine, the diagnosis of ophthalmic diseases can be realized; using EasyDL customization Image recognition tools can be used to identify genuine and fake jadeite, fake and inferior traditional Chinese medicine, etc.

3.2.2. Target Market. On the basis of market segmentation, the deep learning algorithm is used to learn the laws from a large number of market data, identify and judge, determine the target market, and meet the needs of some sub-markets with corresponding products and services. Using the powerful data analysis means of AI, while refining and specializing the products, it can even achieve complete market coverage in theory and maximize the profits of enterprises [19]. Data mining technology has great potential for finding the target market. For example, someone once used the association algorithm in data mining technology to find the accurate relationship between power consumption and consumer products.

3.2.3. Market Positioning. Master the market status of similar products by means of big data analysis, integrate their own product attributes, and determine their unique market positioning. Create a distinctive and distinctive image for enterprise products. Leave a deep impression on customers, occupy their own position in the market, and enhance the vitality and pertinence of products. For example, in the Taobao interface, due to the different historical data consumed by each user and the different interfaces presented, the products sold on Taobao are more targeted and more attractive to consumers. In fact, relying on its technical service advantages in Taobao, Alipay, and Alibaba cloud, Alibaba has deeply integrated AI technology, and has formed an industrial layout in retail, automobile, finance, and other aspects.

3.3. Marketing Strategy

3.3.1. Marketing Mix. Deepen the analysis of marketing data and accurately grasp the market demand through big data algorithms. Through the deep learning algorithm, determine the marketing strategy, realize the marketing strategy combination model, optimize the marketing effect, and realize real precision marketing. For example, Xiaomi company has launched a marketing 1.0 solution based on AI,

including data linkage and media linkage. Through intelligent algorithms, we can have a deeper insight into the needs of users and deliver the right advertisements to accurate users more accurately.

3.3.2. Marketing Budget. The marketing budget is closely related to the company's production, supply, finance, R&D, etc. Using the data mining technology of AI, it can accurately determine the various resources required by each department to achieve the marketing objectives, and reasonably adjust the marketing budget. This will greatly improve the efficiency of the budget, improve the management level of enterprises, and optimize the input-output ratio of enterprises.

3.3.3. Precise Screening Push. There are many ways of marketing communication, but the push of selected content in the mobile client. The banner advertisements at the end of the tweets on the official account are unique products in this information age, and this is due to the addition of AI.

AI can intelligently analyze big data and mine the potential behavior activities behind these behavior data by recording the behavior of each user. The operation mode of Taobao we commonly use is a typical example. It will make a targeted push for your Taobao home page products according to your search keywords and historical consumption records. This is why when we enter the Taobao interface, we will find that each user's interface is different.

3.3.4. Online Service. Today, online shopping has become an indispensable part of people's life, and AI customer service is gradually replacing traditional artificial customer service. AI customer service can collect past customer service consultation records, analyze and summarize the problems mentioned more frequently, and answer most of the doubts for customers in a timely and accurate manner.

On this basis, the intelligent chat system will also extract effective keywords from the messages you launch, analyze the click-through rate and click times of users on relevant products, predict consumers' preferences, better guess consumers' real ideas, quickly respond intelligently through natural interaction, and recommend more suitable products faster and more standardized. This approach not only greatly reduces the waiting time of customers, but also greatly improves the sales efficiency and establishes stronger contact with customers.

3.3.5. Customer Follow-Up Management. Customers are the most important resources of enterprises. Making good use of customer autonomy can help enterprises improve their core competitiveness and ultimately greatly improve the company's profit margin. In the past, in order to improve customer loyalty, enterprises would set up special departments to carry out follow-up management of customers.

In 1999, Inc proposed the concept of Customer Relationship Management (CRM). The goal of CRM is to reduce the cost of the enterprise by improving the business process management of the enterprise in all aspects [20]. If the

element of AI is introduced, it will surely attract more new customers while retaining old customers with the advantage of providing faster and more professional services. Such a new type of customer follow-up management mechanism has greatly improved the relationship between customers and enterprises, achieved continuous contribution to customer value, and comprehensively improved the profitability of enterprises.

3.3.6. Marketing After-Sales. After-sales service is an important part of marketing. It is also a means of promotion. Good after-sales service will bring a better reputation to enterprises and brands. Conversely, if major brands want to occupy an advantage in the market for a long time and improve customer stickiness and satisfaction, high-quality after-sales service is an indispensable part, which is mainly divided into after-sales service and after-sales follow-up. Good after-sales service can make customers think they have made the right decision, while high-quality after-sales follow-up can prevent returns and transfer them to other customers.

For example, in the past, small and micro enterprises had insufficient human resources and it was difficult to ensure good after-sales. Large brands continued to occupy the market with resource advantages, resulting in a vicious circle of growing large enterprises and declining small and medium-sized enterprises, and serious market polarization. But now, through the use of AI, this situation will be reversed to a great extent. By mining and optimizing relevant data, it can better meet the different needs of consumers and save material and human resources.

3.4. Marketing Activities

3.4.1. Marketing Plan. When determining a specific marketing plan, through in-depth mining and understanding of market data, the use of AI technology can better and accurately analyze the situation, and clarify the product status, market status, competition status, and macro environment. It can also better predict opportunity risks, assist marketing planners, determine marketing goals, understand financial risks, achieve closed-loop and complete control of the entire marketing plan, and adjust plan deficiencies in a timely manner according to external changes.

3.4.2. Marketing Organization. AI reduces the size of the marketing organization and also enhances the management capabilities of the marketing organization. It can make full use of the wireless, network, and mobile tools, such as mobile apps, WeChat applets, to improve the efficiency of the marketing organization, and realize intelligent management and intelligent presentation in the true sense. At present, the more common software in mobile phones includes Taobao, Pinduoduo, and JD.com. AI algorithms are used without exception. Every consumer's consumption behavior and consumption records affect the marketing organization behavior of the enterprise and ensure the realization of the marketing effect.

3.4.3. Marketing Control and Execution. Even if companies in the same industry adopt the same marketing strategy, the effects are sometimes quite different. The main reason is that there are differences in the control and execution capabilities of marketing organizations. Through AI technology, every link of marketing activities can be tracked and evaluated to ensure marketing effectiveness. Using big data, algorithms can also clean and standardize data such as annual plans, profitability, and work efficiency, and then mine and present them. Assist managers to improve the efficiency of marketing control and execution.

4. Risk Analysis and Solutions

4.1. Risk Analysis

4.1.1. Data Risk. The integrity and quality of source data will have a great impact on AI algorithms and applications, but objectively speaking, the data standards of marketing are different and the circulation efficiency is very low, which greatly reduces the value of analysis. Data leakage accidents occur frequently and lack effective data supervision, resulting in a grey industrial chain and undermining the fair market environment [3, 21]. Failure to monitor data quality may lead to the decline of enterprise operation efficiency, especially the lack of core data may lead to wrong judgment. Hackers' attacks and modification of data may bring unpredictable risks to the whole system, and in serious cases, it can lead to the collapse of the whole marketing system.

4.1.2. Payment Risk. In marketing activities, online payment is often required. As one of the most popular technologies, biometrics, such as face recognition, has inherent loopholes, which may lead to security failure. At this time, the face is biological information that can be obtained without personnel cooperation. Attackers can obtain photos through social networks, copy facial features, generate dynamic portraits using 3D technology, and train "blink/speak/shake your head" and other contents, which may successfully pass the security system. Intelligent speech technology also has the problems of weak recognition ability and low recognition rate. Hackers can hide malicious instructions in white noise or "dolphin attack" through ultrasound.

4.1.3. Ethical Risk. In the process of marketing, with the continuous progress of AI algorithms, humanoid performance will be more obvious, which brings new challenges to social governance and supervision. Do humans recognize the subject rights and prediction functions of AI in marketing systems?

In the market environment, fairness is one of the most important criteria. But the sources of AI algorithms are algorithm designers and software developers. In their work, they have their own subjective attitude and even bias and will write this bias into intelligent algorithms consciously or unconsciously. At the same time, the market research data to be processed may also have problems such as different data

standards, which will lead to discriminatory follow-up operations.

4.1.4. Decision Risk. The basic process of AI deep learning can be divided into training and inference, that is, training the deep neural network model on the basis of big data, and then inferring the data and drawing a conclusion on the basis of training. Obviously, if there is a problem with the market-oriented data, it may not only lead to the problem of the trained network model but also get the wrong decision-making results. This will produce destructive results for the whole marketing system.

4.2. Corresponding Solutions. The marketing system involves all aspects of society and plays an important role in economic construction. To avoid the above problems, first of all, we should pay attention to the cultivation of senior talents of AI [22]. In particular, we should pay attention to cultivating their ideology to ensure that they can correctly recognize their subconscious attitudes toward inequality and even discrimination. Ensure the fairness of AI algorithm, protect the fairness and justice of the economic market, and ensure the long-term stability of economic construction.

Second, accelerate the development of AI algorithm frameworks with my country's independent intellectual property rights, eliminate the potential negative impact of foreign AI algorithm frameworks on economic development under the background of trade wars, and ensure that AI technology can finally be truly applied in my country's economic construction, establish a good platform, and lay a solid technical foundation.

Finally, it is necessary to support the development of AI chips with China's independent intellectual property rights. In the field of marketing, the core role is the intelligent processing of marketing data. Only by grasping the initiative in the development of AI chips and improving the technical level of chips, we can avoid the entire marketing system and even the national economy being controlled by others. At present, Baidu has developed the AI chip "Kunlun" in China, and large companies such as Huawei and Alibaba have followed suit and developed the latest AI chip products. This has greatly promoted the development of the smart chip industry.

4.3. Challenges Faced. The application of AI technology in the field of marketing has brought great convenience to enterprises and consumers, but technology has two sides. We must treat AI technology rationally and face up to the problems in the application of AI. According to the research of previous literature, we can understand the challenges faced by marketing in the era of AI from the following aspects.

One is the lack of compound marketing talents under the background of AI, which brings about the further connection between technology and marketing. At present, a

significant problem in the field of intelligent marketing is the further in-depth connection between technology and marketing. The lack of compound talents who understand the technology and the market makes enterprises face great obstacles in the process of applying AI.

The second is the data privacy protection and traffic fraud exposed in the process of AI marketing. The exposure of various data privacy news cases has made more and more users highly sensitive to the use of new technologies. A large number of illegal monitoring and interpretation of data without the consent of users seriously interfere with consumers' daily life. Some enterprises even use intelligent technology to predict and analyze users' personal information to obtain users' privacy.

The third is the psychological burnout of consumers in the all-around AI marketing environment. AI technology can recommend various personalized information to consumers, but this kind of continuous and accurate recommendation based on consumers' use traces is difficult to prevent consumers from getting bored [13, 19]. Ad recommendation anytime and anywhere, no ad interception across screens, and tracking recommendation of user browsing records have become more automatic and frequent driven by intelligent technology. Although AI technology can help enterprises accurately analyze user data, the data cannot fully reflect the hearts of consumers. Enterprises should avoid blindly following intelligent technology to prevent consumers from getting bored.

5. Conclusion

In the era of AI, marketing practitioners should make full use of the technical means of AI. Change the current situation of the marketing industry, improve the efficiency and pertinence of traditional marketing activities, realize the customized and intelligent design of products, and realize personalized and accurate marketing to customers. Fundamentally improve the economic benefits of enterprises and improve the vitality of products. The application of AI in the field of marketing is still in the initial stage of development. Enterprises must treat AI technology rationally when applying AI technology. We should not only see the convenience of data analysis and accurate identification brought by AI to enterprise marketing but also see the technical traps, user privacy, and other problems brought by AI applications. Of course, the application of AI technology in the field of marketing will have further development in the future, and enterprises should also carry out exploration and research in time.

As one of the public service resources, medical and health care has a great guarantee for people's healthy life and life safety and is an important part of ensuring the normal and orderly operation of urban functions. This paper takes the spatial pattern of urban medical resources in Hohhot as the research object and collects three types of urban medical resources, including clinics (health centers), specialized hospitals, and general hospitals, a total of 1300 sample points, based on GIS spatial analysis methods, using the average nearest neighbor, kernel density estimation method, standard deviation ellipse method, and accessibility measure to analyze the spatial distribution of medical resources. The results show that the medical resources in the urban area of Hohhot are all in a state of agglomeration, but due to the different functions of different types of medical resources, their distribution ranges and distribution directions also show different characteristics. Saihan District, Yuquan District in the southwest, has fewer medical facilities resources, and the distribution of the accessibility of the three types of medical facilities is quite different. Therefore, the spatial balance of comprehensive medical resources in the urban area of Hohhot needs to be further improved. The results of this paper have implications for the layout of medical facilities and planning has important reference significance.

1. Introduction

As the largest developing country, China is in a stage of rapid development. With the continuous development of the social economy, people's income level is continuously improved, living conditions are continuously improved, the demand for a better life is increasing day by day, and material life has been greatly satisfied at the same time [1–4]. The demand for various public service resources has also increased. During the “Twelfth Five-Year Plan” period, the state proposed to accelerate the establishment of a sound basic public service system, adhere to the people-oriented approach, improve the level of basic public services in cities, and strive to promote the balance of basic public services [5, 6]. Therefore, the spatial layout of public service facilities is related to people's quality of life and social justice [7–10]. The rational and scientific allocation of medical resources is related to whether residents can enjoy the various functions and services of urban medical resources conveniently and equally and is an important foundation for realizing the harmony and unity of the three pillars of economic

development, social equity, and environmental friendliness [11–13]. In the past, the evaluation methods of medical resource allocation were mostly based on traditional databases to establish information systems and quantitatively evaluate medical resource allocation capabilities by using indicators such as the balance of medical resource supply and demand, the professional skills of medical staff, and medical technicians with a population of 1,000 [14–16]. However, the traditional database lacks spatial expression ability, which limits its ability to provide decision-makers with information on the spatial distribution of medical resources and decision support [17–20].

Basic public services include basic education, social employment, social security, and medical and health care. As one of the public service resources, medical and health care has a great guarantee for people's healthy life and life safety and is an important part of ensuring the normal and orderly operation of urban functions [21–23]. The research focus of foreign scholars on medical resources has shifted from the selection and layout of locations to the research on the fairness and accessibility of medical resources and then

gradually shifted to the spatial distribution and formation mechanism of medical resources. However, Chinese scholars have used the quantitative measurement method to study the fairness of hospital medical resource allocation from the number of hospitals and the number of doctors and have also conducted research on site selection, accessibility, and layout evaluation. At the end of 2019, a sudden outbreak of COVID-19 plunged the whole of China into a disaster. All cities responded quickly and set up designated isolation hospitals to fully guarantee the people's medical problems. However, in areas with severe epidemics, it is still difficult to find a bed, so the spatial distribution of medical resources will directly affect the time efficiency of patient treatment when the disease occurs [24–30].

As a part of urban public service facilities, medical service facilities also occupy an important position in the city's resource allocation. In the "Planning and Design Standards for Urban Residential Areas" (GB50180-2018), it is also mentioned that health centers and outpatient departments should be configured within the 15-minute living circle, which reflects the state's emphasis on the layout and distribution of medical service facilities. Studying the accessibility of medical service facilities and analyzing and evaluating the distribution of urban residents, it can not only improve the convenience and fairness of residents' access to medical service resources but also help optimize the layout of urban medical service facilities and improve medical services.

In China, many scholars have studied the accessibility and spatial distribution characteristics of medical facilities. Scholars in the field of geography mainly focus on the spatial distribution characteristics of facilities. Zeng Wen et al. took Nanjing City as an example to analyze the spatial pattern and causes of its medical service facilities. Mingji Quan took the Yanbian area as a sample, compared the spatial layout of medical facilities in the Yanbian area from 2007 to 2019, and summarized the evolution characteristics of medical facilities. Such studies are mostly theoretical explorations and lack planning advice to guide practical operations. Scholars in the field of planning focus more on evaluating the service level of facilities and exploring the spatial distribution mechanism. Taking the Hong Kong Special Administrative Region as an example, Ma Qiwei et al. analyzed the spatial layout and functional differences of medical service facilities, analyzed their influencing factors, and put forward suggestions for the path transformation suitable for the mainland on this basis. Taking Nanjing as an example, Cao Yang et al. comprehensively evaluated the service level of medical facilities from the perspective of residents' activities and put forward suggestions for improving the function of medical resources and optimizing the layout. Taking Hefei City as an example, Li Zao et al. analyzed the distribution pattern of its medical facilities and made a suitable aging analysis. However, from the perspective of the research scope, such research mostly focuses on a single urban or rural area and lacks thinking from the perspective of urban-rural integrated development.

Therefore, based on GIS spatial analysis methods, this paper uses the average nearest neighbor, kernel density

estimation method, standard deviation ellipse method, and accessibility measure to analyze the spatial distribution of medical resources in the urban area of Hohhot. On this basis, its spatial pattern is evaluated and the deficiencies in the current model are found out.

2. Overview of the Study Area

Located in the Inner Mongolia Autonomous Region, Hohhot is the political, economic, and cultural center of the Inner Mongolia Autonomous Region approved by the State Council and an important central city in the northern border areas of my country. The city has a total of 4 municipal districts, 4 counties, and 1 flag. The city has a total area of 17,200 square kilometers, of which the built-up area is 260 square kilometers. The total population of Hohhot by the end of 2020 was 2.52 million. Among them, 439,575 people were in Xincheng District, 238,970 people were in Huimin District, 208,694 people were in Yuquan District, 563,712 people were in Saihan District, 359,107 people were in Tumutuo Banner, 199,763 people were in Tuoketuo County, 203,893 people were in Helinger County, and 139,297 people were in Qingshuihe County. There are 167,023 people in Wuchuan County. A schematic diagram of the administrative divisions and population distribution of the study area is shown in Figure 1.

The acquisition method of medical resource data involved in this study is network survey, mainly from AutoNavi electronic map, and the data vector files of each region are from the resource and environment data cloud platform. The number of medical resources collected in the urban area of Hohhot includes a total of 1,176 clinics (health centers), a total of 23 specialized hospitals, and a total of 136 general hospitals. There are 13,760 beds in health institutions, including 3,505 in Xincheng District, 4,461 in Huimin District, and 2,696 in Yuquan District. There are 33,805 technicians in medical institutions, including 6,688 in Xincheng District, 5,768 in Huimin District, and 5,489 in Yuquan District. A more intuitive distribution of medical resources is shown in Figure 2.

3. Research Method

3.1. Average Nearest Neighbor. Average Nearest Neighbor refers to the average of the closest distances between points. The spatial pattern is judged by comparing the calculated average distance of the nearest neighbor point pair with the average distance of the nearest neighbor point pair in the random distribution pattern. It can be expressed as follows:

$$D_{ANN} = \frac{\bar{r}_i}{r_E} = 2\sqrt{d}, \quad (1)$$

$$\bar{r}_E = \frac{1}{2\sqrt{n/A}} = \frac{1}{2\sqrt{D}}. \quad (2)$$

Formulas (1) and (2) refer to the actual nearest neighbor distance, in m, that is, the average distance between each hospital in the main urban area of Hohhot and its nearest hospital; \bar{r}_E is the theoretical nearest

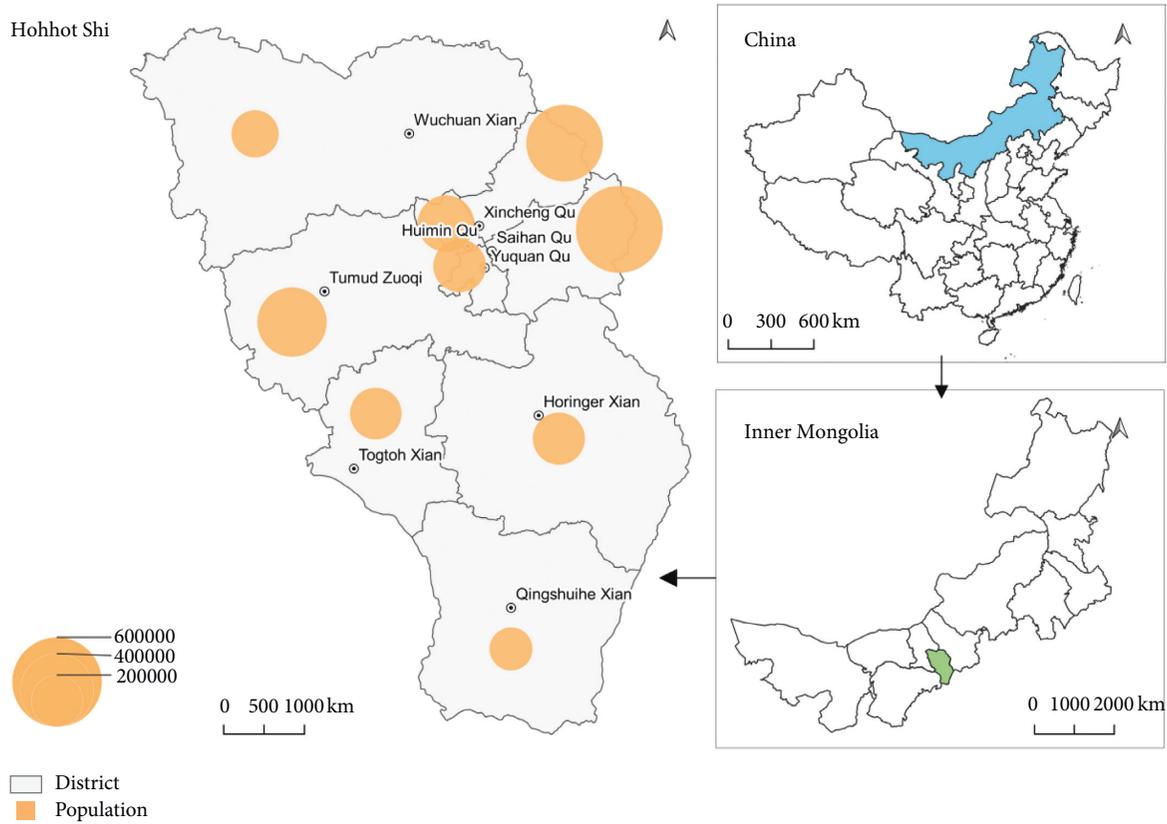

FIGURE 1: Schematic diagram of the administrative division and population distribution of the study area.

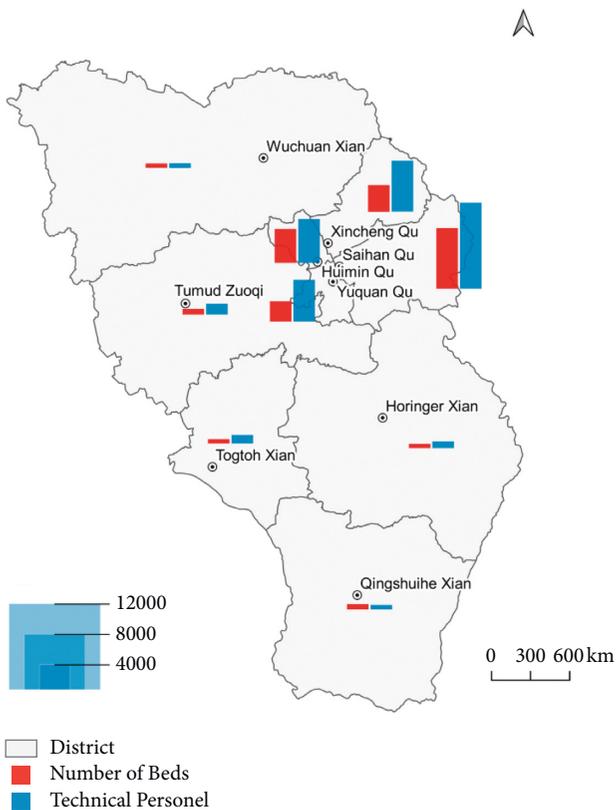

FIGURE 2: Distribution map of medical resources in Hohhot.

neighbor distance, in m, that is, the expected average distance between hospitals under random distribution mode, in m; n is the total number of hospitals; A is the total area of the main urban area of Hohhot City, in m^2 ; D is the main urban area intrahospital point density; and D_{ANN} is the nearest neighbor index. When $D_{ANN} = 1$, the hospital distribution state is random distribution; when $D_{ANN} < 1$, the hospital distribution state is an agglomerative state; and when $D_{ANN} > 1$, the hospital distribution state is discrete.

3.2. Kernel Density Method. The kernel density method is a density function used to estimate unknowns in probability theory. According to the estimation of known medical resource data points, the spatial aggregation degree of elements is analyzed. Information is effectively visualized. Its formula is as follows:

$$K(x) = \frac{1}{nd} \sum_{i=1}^n a\left(\frac{x - X_i}{d}\right). \quad (3)$$

In the formula, $a(x - X_i/d)$ is the kernel density function; $d(d > 0)$ is the distance from the hospital point to the time point X_i ; and $K(x)$ is the estimated value of the kernel density. Using the kernel density method, the spatial distribution information of clinics (health centers), specialized hospitals, and general hospitals is visually expressed by the

graphical method, and its spatial distribution characteristics are explored.

3.3. Standard Deviation Ellipse. The standard deviation ellipse method refers to analyzing the spatial distribution characteristics of medical resources from the center, distribution range, shape, and direction of the ellipse by constructing a standard deviation ellipse. It is an important method to study the distribution direction and characteristics of spatial points, and it is also one of the most commonly used methods in spatial pattern analysis. Its formula is as follows:

$$\begin{aligned} \text{SDE}_x &= \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n}}, \\ \text{SDE}_y &= \sqrt{\frac{\sum_{i=1}^n (y_i - \bar{Y})^2}{n}}. \end{aligned} \quad (4)$$

In the formula, x_i and y_i represent the coordinates of medical resource data points i ; $\{\bar{X}, \bar{Y}\}$ represents the average center of medical resource data points; and n represents the total number of study areas.

3.4. Accessibility Measure. At present, the measurement methods of the accessibility of medical service facilities are mainly divided into two categories in the macroscopic view as follows: one is the potential model and the other is the two-step mobile search method. The two models can effectively measure the accessibility of service facilities by combining relevant evaluation factors such as medical population and hospital level with different calculation methods. This paper mainly uses the GIS-based network analysis method combined with the improved potential model to measure and evaluate the accessibility of medical service facilities in the main urban area of Hohhot City.

- (1) *Potential Model.* Mainly derived from the law of universal gravitation in physics, it was first proposed by the French scholar Lagrange and later cited by geography, adding various influencing factors such as region, grade, and economy, and deformed and developed into a potential model. Today, the potential model has developed into a classic model for studying the interaction of social and economic spaces.

$$A_i = \sum_{j=1}^n \frac{S_j}{D_{ij}}. \quad (5)$$

Potential is the gravitational force that one object exerts on another object. In the formula, A_i is the potential of facility i to facility type j ; it is the facility scale of facility j .

- (2) *Improved Potential Model.* At present, for the research and development of the accessibility of urban medical facilities, factors such as the population of residential areas, the service capacity of public

facilities, and the attenuation of the spatial distance between residential areas and medical service facilities are integrated into the basis of the potential model. It is also possible to set different influencing factors and other factors for different types of medical service facilities, such as service capacity, residents, city types, and resident types reachability for a more scientific explanation.

$$A_i = \sum_{j=1}^n \frac{S_j}{V_j D_{ij}^\beta}, \quad (6)$$

$$V_j = \sum_{i=1}^n \frac{P_i}{D_{ij}^\beta}. \quad (7)$$

In formula(7), A_i is the accessibility index of a certain settlement i to all medical service facilities j in the area; S_j is the facility scale of a medical service facility j . In this paper, the hospital or health center mainly includes the following: the beds represents the number of patients that can be carried D_{ij} represents the distance from settlement i to the medical service facility j . The data in this part are mainly calculated by the OD travel table obtained from the analysis of the GIS network data. In formula (8), V_j is the service capacity of facility j ; P_i is the population of a settlement i ; and β is represented as the travel friction coefficient. After scholars' research on it, the value range of β is mainly between $[0.9-2.29]$; β , as an influencing factor that can reflect residents' willingness to travel, should have different values in different types of medical facilities. After comparative research, the friction coefficient β in this paper is 1 in general hospitals. Since the single statistical accessibility is not obvious to the data, we used the dispersion standardization method to process the data on the accessibility data from residential areas to various medical service facilities in Hohhot City. Rationality analysis is carried out using the interpolation analysis diagram of the property. The standardization of dispersion is a linear transformation of the original data so that the result falls into the $[0, 1]$ interval. The conversion function is shown in the formula, where \max is the maximum value of the sample data and \min is the minimum value of the sample data.

$$X_j = \frac{A_i - \min_{1 \leq j \leq n}(A_j)}{\max_{1 \leq j \leq n} A_j - \min_{1 \leq j \leq n}(A_j)}. \quad (8)$$

In the formula, X_j is the normalized value and A_i is the original value.

4. Results and Analysis

4.1. Spatial Aggregation Analysis of Medical Resources. To study the spatial pattern of medical resources in the main urban area of Hohhot City, it is first necessary to determine the relationship between these medical resources and whether the spatial distribution of these medical resources is random, agglomerated, or divergent. Therefore, based on the GIS spatial analysis method and ArcGIS software, the

average nearest neighbor analysis was performed on the three types of medical resources in the main urban area of Hohhot: clinics (health centers), specialized hospitals, and general hospitals, and the nearest neighbor ratio, Z score, and P were calculated. The nearest neighbor ratio was used as the basis for the spatial distribution and agglomeration degree of medical resources in the main urban area of Hohhot City, and the Z score and P value were used to test the significance of the results. The calculation results are shown in Table 1.

4.2. Spatial Structure Analysis of Medical Resources. Through the calculation of the nearest neighbor ratio D_{ANN} for the medical resources in the urban area of Hohhot, it can be seen that within this range, the spatial distribution of the three types of medical resources is in a state of aggregation. In order to observe the scope and size of each type of medical resource agglomeration more intuitively and understand its spatial structure, the nuclear density method is used to detect the state of medical resource agglomeration. The density of medical resources gradually decreases from the southwest high-density area to the Yuquan area, and its spatial pattern is mainly concentrated in the central and northeastern regions. The distribution of residents' medical resource needs is shown in Figure 3.

4.3. Spatial Analysis of Accessibility of Medical Resources

4.3.1. Accessibility from Residential Areas to General Hospitals. The layout of general hospitals in the central urban area of Hohhot is relatively concentrated. Large general hospitals with more than 500 beds are roughly distributed at the junction of the three urban areas, and the junction is also the center of the city's first development. There are a large number of residential areas and groups. The main road has a superior geographical location, so the accessibility from the residential area in the center to the general hospital is at the most advantageous level. In response to the trend of urban development, for Saihan District in the east, there are corresponding large-scale general hospitals, and the economic and technological development situation is relatively good. Most of the new urban areas are located in the central and northern parts of the city, so its residents have access to general hospitals in a relatively favorable position. In the southwestern region, due to development problems, the population agglomeration is relatively low, and most of the general hospitals allocated have low service capacity, resulting in the low accessibility of residents in the western and southern urban areas to general hospitals.

The accessibility standardized statistics are shown in Figure 4. The serial number on the horizontal axis in the figure represents the range of the standardization value of accessibility, and the corresponding relationship is shown in Table 2. According to the standardized statistics of accessibility, most of the values are between 0.1 and 0.6, accounting for more than 85% of the total number of residential areas, and the distribution in each value segment

is relatively uniform, indicating that the number of residents from residential areas to general hospitals is relatively uniform. The accessibility is distributed in each numerical segment, and there is no obvious area where the numerical values are agglomerated.

4.3.2. Accessibility from Residential Areas to Specialist Hospitals. As the distribution of specialized hospitals is relatively scattered, the scale is small, and most of the geographical locations are at the boundary of the coverage of general hospitals, and the relatively advantageous location is at the junction of general hospital and specialist hospital services. Most of these types of areas have moderate-sized residential areas, dense populations, and relatively convenient transportation. In addition to the farmer's area in the west and the recreational area in the south, the main areas where residents have insufficient accessibility to specialized hospitals also added more peripheral areas in the northeast and east. There are fewer specialized hospitals in these areas, which are affected by distance factors, resulting in reduced accessibility.

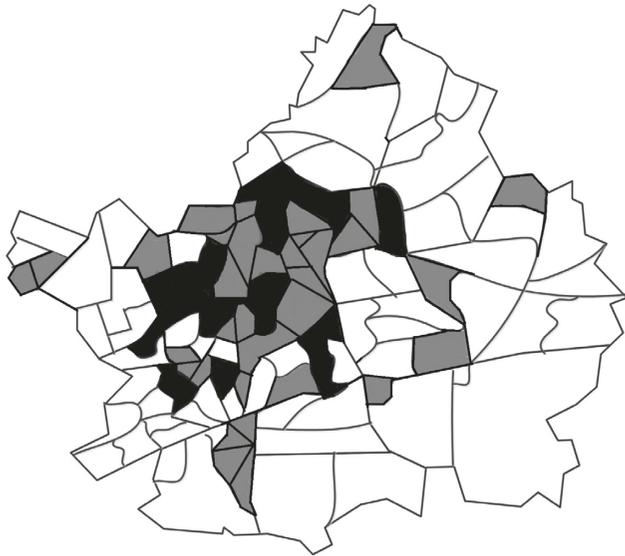

The standardized statistics of the accessibility data are shown in Figure 5. The serial number of the horizontal axis in the figure represents the range of standardized accessibility values, and the corresponding relationship is shown in Table 3. A large number of standardized data are concentrated between 0 and 0.1, accounting for more than 80% of the overall data. Most of the numerical areas in this concentration are clusters with low accessibility, indicating that the accessibility from residential areas to specialized hospitals is local.

4.3.3. Accessibility from Residential Areas to Health Centers. Since most of the health centers use their surrounding communities or residential communities as their service units, the accessibility coverage of residents in Hohhot to the health centers is relatively balanced, and the more advantageous locations are mostly around large-scale community health centers, or adjacent to. There are many areas where small clinics are concentrated. However, most of the central urban areas are within the relatively good accessibility range, and even residents in the relative leisure and underdeveloped areas in the southwest of the city can have relatively average accessibility to health centers.

The standardized statistics of accessibility data are shown in Figure 6. The serial number on the horizontal axis in the figure represents the range of standardized accessibility values, and the corresponding relationship is shown in Table 4. The standardized numerical distribution of the accessibility of residential areas to health centers is concentrated between 0 and 0.2, and there is also a relatively scattered data distribution between the values of 0 and 1. Based on the analysis in Figure 5, most of the residential areas in the data concentration area are located within the service scope of the health center, so the entire data analysis shows that the level of accessibility from the residential area to the health center is relatively balanced.

5. Conclusion

This research quantitatively studies the spatial distribution characteristics and accessibility of medical service facilities through quantitative models such as GIS spatial autocorrelation and network analysis. The three types of medical resources in the urban area of Hohhot all showed a state of

agglomeration and distribution, showing a high degree of agglomeration. As the settlement of urban population, the main urban area has a large demand for medical resources. Therefore, the agglomeration of medical resources provides great convenience for residents to live healthy life.

The accessibility of residents in general hospitals, specialized hospitals, and health centers in the central urban area of Hohhot was analyzed using the improved potential model and variance-normalized data. From the analysis results, it can be concluded that even in the urban area of Hohhot under the measurement of the accessibility of three different types of medical facilities, the accessibility of medical service facilities in the urban center and the more developed central and northeastern urban areas is better. However, the accessibility of medical resources in less developed areas such as southwestern urban areas is relatively weak. After comprehensively comparing the accessibility of different types of medical facilities, it can be seen that the medical resources of general hospitals and specialized hospitals are complementary in some locations in the urban area. Residents in the outer circle have limited medical resources. As a community-based medical service facility, although the accessibility performance of the western and southern urban areas is slightly weaker, the health center can still provide urban residents with a relatively balanced index of medical resource accessibility. Combined with the urban

development planning of Hohhot, the following optimizations can be provided:

- (1) Integrate medical resources in central urban areas with relatively abundant medical resources to avoid resource waste caused by high aggregation.
- (2) In the southwest of the city, the existing specialized hospitals can be used to appropriately increase their scale, improve their service capabilities, and enhance the willingness of surrounding residents to seek medical treatment.
- (3) Leisure and farmer areas in the east and north of the city can improve the scale and medical level of small general hospitals in their areas, and large-scale health centers can be established in their areas to provide basic medical services to residents.
- (4) The scale of the research in this paper is relatively small, and the scope is mostly the central area of the city. The research method is relatively simple. In future work, the Gini coefficient and spatial correlation analysis can also be used to make reasonable analyses, improve the analysis system, and provide more reasonable advice.

With the rapid development of science and technology, information has become the theme of the 21st century. The development of network-based e-commerce has changed the global economic model, business management model, and people's work, life, and consumption patterns, forming a global information economy. As the core part of enterprise management, financial management has been strongly impacted by the management environment, application of technical methods to function execution, and management concepts. Under the background of big data, how to manage financial affairs of enterprises has become a problem worth exploring. This paper mainly discusses the financial operation revenue management from the perspective of big data, briefly discusses the big data and financial operation revenue management, and analyzes the relevant strategies for the effective development of financial operation revenue management combined with case studies.

1. Introduction

In the perspective of my country's rapid economic development, the cost control of enterprises is becoming more and more important. Only by doing well in cost control can enterprises benefit and consolidate their market position, which is conducive to the long-term development of enterprises. At present, there are many problems in the financial operation [1, 2] and cost control of enterprises, which need to be intervened and solved in time, so that the financial operation [3, 4] and cost control of enterprises will develop in a scientific and rational direction [5–8].

The object of enterprise financial operation [9–12] is the total funds flowing in the enterprise, and the efficiency of enterprise financial operation refers to the efficiency of the enterprise's working capital. The profit of a company often refers to the profit in operation, which shows the importance of the financial operation of a company. A good corporate financial operation not only invests effort in reaping profits [13], but also improves the layout of the company's debt repayment and analyzes market conditions and capital use

risks, which can provide a reliable reference for corporate investors and creditors.

Cost control refers to the measures taken by enterprises to prevent and control production-consumption in order to achieve profitability. This can not only allow enterprises to successfully complete the set goals, but also retain costs as much as possible to maximize profits. Language is an effective help to achieve long-term development. Cost control involves many aspects, such as the cost control of raw material purchase in the early stage of production, and also includes the cost control of manpower and material resources in the production process. The expenses incurred by the enterprise department in the management process should also be included in the scope of cost control. What is more, the transportation and sales expenses incurred after the production is completed also need to be included in the content of cost control. It can be said that cost control covers all aspects of enterprise operation and management and is the key to enhancing enterprise profitability.

Although there are not a lot of financial management personnel in many enterprises [14–16], the quality of

financial management personnel is uneven [17], resulting in a low overall level of financial management [18]. Here, it is particularly important to pay attention to the financial personnel who are in line with international affairs [19], communicate, and contact. Since many enterprises are currently paying great attention to economic development, there is a situation in which scientific and technological personnel despise financial management personnel. Although financial management personnel have higher authority and rank in some enterprises [20], their work still revolves around transactional work, a huge amount of work. Pressure and complicated management matters have caused many financial managers to fail to take the time to learn management knowledge and improve management skills [21]. This is also the root cause of the generally low quality of financial managers in many enterprises [22]. In order to make the financial operation and management cost control of the enterprise return to the right path and play an active role, it is necessary for the enterprise to strengthen its attention. It is necessary not only to conduct regular reviews and inquiries on financial management [23], but also to go deep into the financial interior to explore the progress of financial management [24] and actively assist the financial management department to solve the problems encountered. In addition, it can also increase the investment and support for the financial department, which can be manpower support or capital investment, so as to effectively strengthen the position of financial management in enterprise operation management.

In addition, we must pay close attention to the control of cost stages, including preproduction control, in-production control, and circulation control, and set up a “one-to-one” supervision team for these three stages of cost control to effectively implement raw material purchase, product packaging, publicity, and planning, as shown in Figure 1. Infiltrate the supervision function in multiple links such as long-distance transportation, effectively control the cost expenditure, do a good job in the cost budget of each stage, reasonably divide the cost consumption ratio, and effectively control the overall operating cost of the enterprise within the planning scope.

2. Current Status of Corporate Financial Management

2.1. The Traditional Concept Has Not Changed. In the context of the rapid development of the Internet, big data is the main development direction at present, and the application of big data in work and life will become more and more common. The most significant feature of big data is the integration of resources to facilitate financial management. At the same time, big data also has strong data analysis and computing capabilities. Since there are still some problems in the process of financial enterprise management informatization construction in my country, it has caused certain obstacles to the construction of accounting informatization, thus limiting the value of big data services to play their due value. The method of financial management generally includes five basic links: financial analysis,

FIGURE 1: Planned scenario.

financial forecasting, financial decision-making, financial budgeting, and financial control. Each link has professional business methods and mathematical models; for example, the capital asset pricing model, accounts receivable turnover rate, capital structure, leverage principle, etc. are all important methods in financial management. At present, many enterprises still focus their financial management on fund management, and their work is limited to the settlement of accounts [25]. Enterprise financial management in the information age should first change the thinking of financial personnel, letting them clarify their responsibilities, not only limited to the statistics and comparison of accounts, but they should also focus on asset management, investment management, and financing management throughout the economic activities of enterprises.

In the case of technical limitations, the overall development level of big data services in my country is relatively low, the service methods provided by big data service providers are relatively simple, and the software service functions are relatively small. For the construction of enterprise financial management informatization, the services provided by big data are still difficult to meet the diversified needs of their own construction. At this stage, there are relatively few service providers providing big data in the Chinese market, and the main target groups of these providers are e-commerce companies, and they mainly provide financial management services for e-commerce companies. From this perspective, the research and development of big data in my country are simply optimized and upgraded according to the relevant needs of financial management, so as to meet the daily financial management needs of e-commerce companies. Since the content of big data services cannot fully meet the needs of e-commerce companies' financial management informatization construction, e-commerce companies should not rely too much on big data in the construction process; otherwise, it will limit the integration of e-commerce companies and hinder e-commerce companies. The development of financial management reduces the efficiency of financial management of e-commerce enterprises.

2.2. Provide Good Service for Enterprise Decision-Making. Although computers have been used in the financial management of enterprises, they have not played an important

role. In the past, financial work focused on statistical billing, bookkeeping, and bookkeeping and did not pay attention to the decision-making of the enterprise. The relevant staff of the enterprise did not pay much attention to the impact of the accounting statements on the future development of the enterprise and could not provide good services for the enterprise's decision-making.

2.3. Lack of Support for Management Information. When many enterprises carry out information-based financial management activities, they do not carry out overall planning and do not have a complete management system. In the past, financial management used specific financial software, and there was almost no communication with other departments. The accounting department had no business dealings with other departments. The only beneficiary of informatization in financial management was the accounting department, which could not effectively improve the efficiency of the entire enterprise.

Big data financial accounting information security can be divided into physical equipment security, network security, and business data security. Among them, physical equipment security refers to whether online accounting services are unblocked; network security refers to the protection of hardware, software, and data in the network system; commercial data security refers to whether it can provide timely and accurate services to customers, whether e-commerce enterprises and commercial information resources will be tampered with and leaked, etc. Therefore, in the field of information technology, the mentioned security is a relative concept, and absolute information technology security does not exist yet. In addition, big data platforms, data, etc. are managed by big data service providers, and these data are transmitted between users and the cloud, which is very likely to face risks such as interception or destruction by third parties. At the same time, due to the complex configuration of big data equipment and systems, and a large amount of data storage, once a risk occurs, it will cause irreparable losses. Therefore, in the construction of financial enterprise management informatization, the most important point is to ensure the security of financial information, which is of great significance to the long-term development of the enterprise. Under the background of big data, the scope of financial calculation is extremely wide, and if financial calculation cannot be combined with management, it will affect the transformation from accounting to enterprise management.

Accountants are the main participants in the construction of enterprise financial management informatization, and to a certain extent, the security awareness of accountants will have an impact on the security of accounting information. Because some accountants associate the effect of accounting work with managers and believe that the security of information depends on managers, accounting practitioners are not fully aware of accounting informatization. When the security awareness of accounting practitioners is weak, or the cognition of accounting informatization is lacking, accounting information loss

events will occur frequently. Although big data services can provide convenience for e-commerce enterprises' financial management informatization construction, it is also difficult to avoid security problems.

In addition, in the construction of enterprise management informatization, there is a lack of effective application of new technologies, which leads to problems in the enterprise's informatization risk early warning mechanism. Due to the lack of an information-based risk early warning mechanism, the security of corporate financial data has been adversely affected. Restricted by factors such as low technical level and insufficient professional quality of staff, various technical problems are faced in the process of big data application. Therefore, it is of great significance to build an information-based risk early warning mechanism.

3. The Impact of Big Data on Financial Management

3.1. Informatization Promotes Business Process Reorganization in Financial Management. Although traditional financial management also uses computers, it only records the accounts and simply applies the computer. The financial work is separated from other work, the financial work efficiency is not high, and the waste of funds is serious. The informatization of financial management is to eliminate the information isolation of various departments and realize the integrated management of finance. Therefore, financial management must undergo a thorough change. The new financial management is different from the traditional financial management [25]. It conducts a comprehensive and in-depth analysis of financial work, improves the key links of financial management, and realizes the reorganization of business processes. Financial management in the traditional sense cannot adapt to today's economic development situation, so we are urgently required to improve the business process of financial management. We need to analyze every link in the business process. Accounting after the fact is a major feature of traditional financial management. This method is not conducive to taking advantage of computers and cannot preprocess finances. Therefore, it is necessary to change this model of traditional financial management and strengthen the connection between the financial department and other departments. Financial personnel have changed from former information processors to administrators of business work. Relying on information technology, they focus on business process processing and finally achieve the goal of enterprise management. In addition, the big data platform has certain limitations in network transmission. Frequent data access and massive data exchange will lead to network congestion and data delay, and the weak network transmission capacity limits the development of financial enterprise management informatization. Figure 2 shows the trend chart of financial management informatization.

Judging from the financial management work of Chinese enterprises, although many enterprises have recognized the importance of big data application and have also

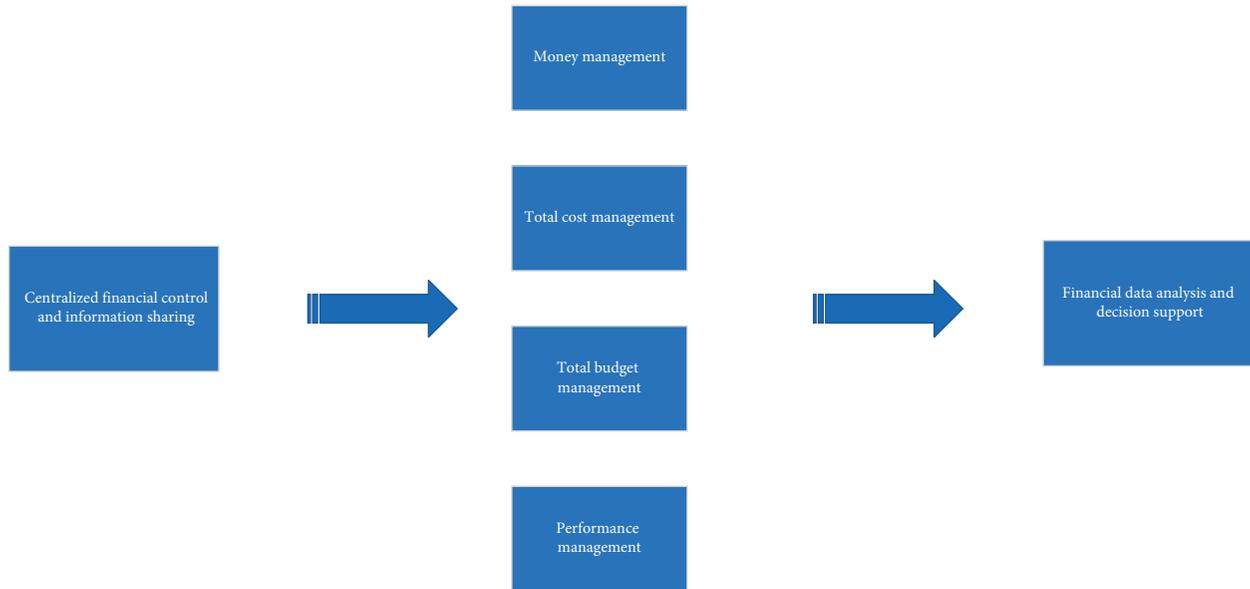

FIGURE 2: Trend chart of financial management informatization.

begun to actively explore specific countermeasures for the application of big data in the construction of financial enterprise management informatization, due to the lack of various mature technologies, the overall level of financial enterprise management informatization construction is relatively low. At the same time, due to the limitations of capital and technology, the service scope of big data is relatively small. In recent years, my country's scientific information technology has developed rapidly. As a new type of network technology, big data technology has entered the public's field of vision. Most e-commerce enterprise managers have limited awareness of big data, so they choose big data. There is certain blindness in data service providers, and it is difficult to correctly view big data service providers. Many business managers believe that the big data service provider with the largest number of users is the best. In addition, big data is still in the processing and development stage; further, development is still required, and a lot of costs must be invested in this process, which will limit the development of big data to a certain extent, but also increase the development of big data. risks faced. Compared with Western countries, my country's scientific research capabilities and financial support are relatively weak, resulting in the relatively weak competitiveness of my country's big data.

3.2. Informatization Promotes Internal Control of Financial Management. The internal control of financial management is to strengthen the protection of the funds of the enterprise, ensure the integrity of financial-related information, ensure the smooth implementation of relevant policies, improve the efficiency of financial management, effectively reduce the risk of financial management, and promote the realization of financial goals. The informatization of financial management has changed the traditional concept of financial

management and expanded the scope of financial management. The use of informatization has led to internal changes in financial management, providing opportunities for further improvement of financial management, but also bringing risks. Information-based financial management is the comprehensive control and overall control of the enterprise. With the large-scale use of the network in life, people are paying more and more attention to the application of the network in financial management. Practice shows that the use of information technology solves the problems that cannot be solved by the traditional management model but increases the data risk of financial management. Therefore, it is necessary to strengthen the training of financial-related staff, accelerate the integration of financial management and information technology, focus on solving problems that arise, establish a financial management model that is compatible with social development, meet the development needs of enterprises, and bring more benefits to enterprises.

3.3. Informatization Increases the Risk of Investment. Information is the most important factor of production in today's era and an indispensable part of the operation of an enterprise. Information occupies a dominant position in enterprises, and investment in intangible assets is favored by business leaders. The proportion of an enterprise's intangible assets determines its position in the market. The development cost of information products is extremely high, which increases the business risk of enterprises. Market instability and changes in financial structure result in the variability and diversity of financial risks. There is a certain amount of uncertainty when developing information resources. Therefore, enterprises should strengthen the identification of risks and adopt reasonable control strategies. Figure 3 shows risks of Informatization Investment.

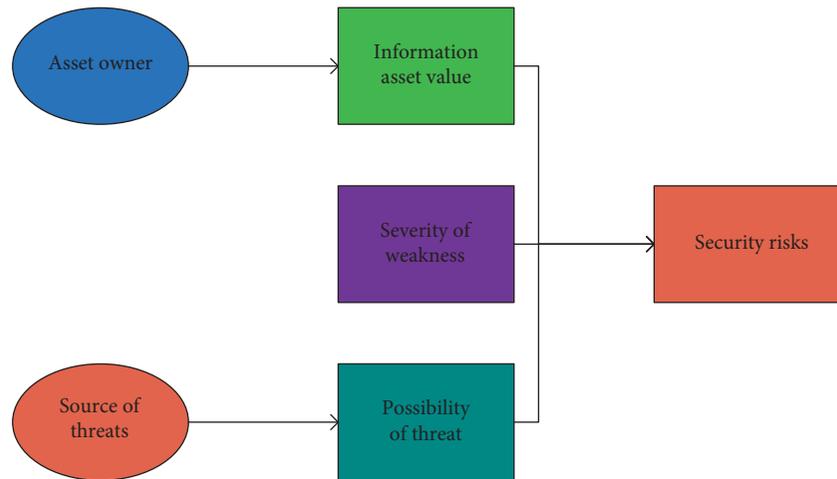

FIGURE 3: Risks of informatization investment.

4. Management Strategies of Enterprise Financial Operation Revenue from the Perspective of Big Data

4.1. Increase Capital Investment and Build a Big Data Platform. Adequate funds are an important guarantee for the research and development of big data technology, which can promote the development of big data technology. Therefore, from the national level, further improving the development level of big data technology can improve the comprehensive strength of the country. In this context, government departments need to give full play to their guiding role, actively deal with the problems of capital and technology of national big data technology research enterprises, comprehensively integrate the country’s human, technical and financial resources, and promote complementary advantages between enterprises, achieve common development, and solve the problems of the insufficient national technology and insufficient funds. In addition, government departments can also consider establishing domestic demonstration projects for building big data platforms independently, guiding and regulating the research and development of big data platforms, and strengthening network construction to improve network transmission speed and efficiency. Figure 4 shows financial operation model from the perspective of big data.

4.2. Increase Service Content and Provide Rich Big Data Services. Providing rich big data services is the main direction of big data development in the future. Especially with the rapid development of science and technology, the healthy and sustainable development of various fields requires the technical support of big data. First of all, big data service providers need to fully understand the various needs of enterprises to ensure that each field can realize the construction of enterprise management informatization. In the process of developing and researching big data, big data suppliers need to maintain close contact with various industries, take

meeting the actual needs of users as the guide, and improve the existing service content, so as to ensure that the big data service content can be more complete and more diversified service functions and fully meet the diversified needs of enterprise financial management informatization construction. For example, the analysis of financial statements and information decision-making can more comprehensively integrate all the management work of the enterprise, thereby helping the enterprise achieve the goal of informatization construction. Secondly, big data suppliers also need to provide customized services for enterprises, so as to meet the individual needs of enterprise financial management informatization construction and promote the sustainable and healthy development of enterprises.

4.3. Improve the Security of Big Data Services. The security of financial information has a direct impact on the development of enterprises. In this regard, enterprises must attach great importance to the processing and storage of financial information, and this is also an important factor affecting enterprise data security. In the process of enterprise financial management informatization construction, it is particularly necessary to pay attention to the security of big data services. Specifically, we can start from the following aspects. First, improve the technical level and strengthen the flexible application of various security technologies, so as to ensure the reliability and security of big data at the technical level, especially to solve the problem of data storage. For example, enterprises can develop various protection software to ensure the security of accounting data and information, and design-related usage protocols to ensure that various accounting information and data are more comprehensively protected to avoid threats to data security caused by hackers or viruses. Second, in the process of selecting a big data service provider, we must fully consider our own needs and try to choose a supplier with high quality in terms of reputation, so as to provide a stronger security guarantee for the construction of enterprise financial management

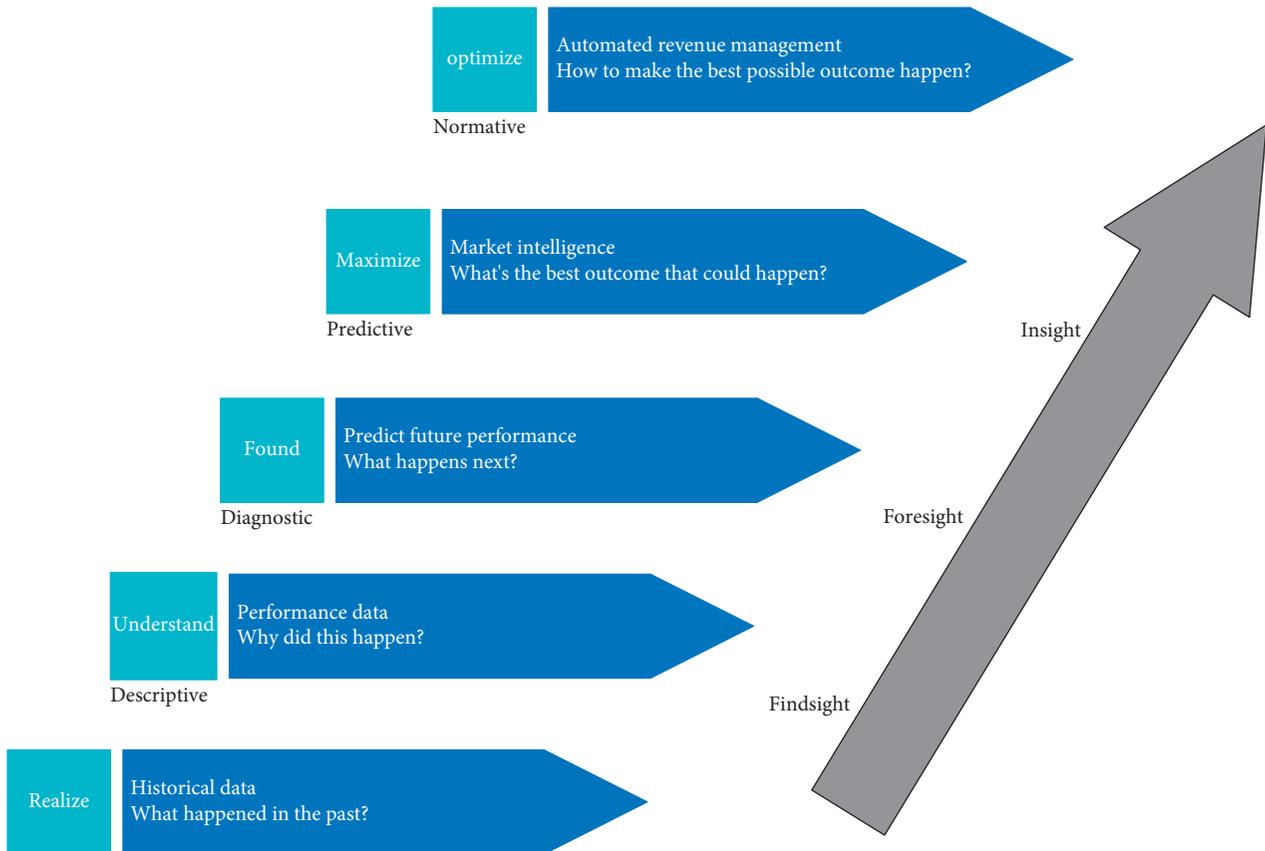

FIGURE 4: Financial operation model from the perspective of big data.

informatization. Third, from a legal perspective, protect big data services. The state needs to introduce corresponding policies and measures to further standardize the big data service market and create a good environment to ensure the security of corporate financial information.

4.4. Strengthen Safety Awareness and Improve Safety Management. In the process of informatization construction of financial enterprise management, it is necessary to strengthen the safety awareness of relevant staff, which is an important prerequisite for informatization construction. First of all, enterprises can establish an information security publicity and education platform to ensure that every accounting practitioner can recognize the importance of information security and apply this awareness to future work to avoid accounting information leakage. Secondly, government departments need to attach great importance to and strengthen the interaction with relevant technical departments, increase the introduction of big data technology-related guarantee resources, actively learn advanced cloud technology experience, and provide strong support for the application of big data in the construction of accounting informatization. Finally, big data service providers need to increase the construction of industrial parks, demonstration projects, and other projects under the guidance of advanced technical means, so as to improve the security level of big data services.

4.5. Optimize the Current Management System of E-Commerce Enterprises. In the context of the era of big data, in order to effectively exert the advantages of big data, we should pay attention to the rational use of management software systems and optimize and improve the actual needs of enterprise development. In addition, enterprises should pay attention to the introduction of advanced technology, which can ensure that the management system is further improved and can also ensure the work effect, thereby minimizing the operating cost of e-commerce enterprises.

5. Innovations in Financial Management Technology Methods from the Perspective of Big Data

In the network economy society, traditional financial management methods and methods are facing new challenges, and some new financial management technical methods have emerged as the times require.

- (1) Network financial management. It is the enterprise that uses the network to realize the financial management function. Enterprises apply network technology to financial management, so as to solve a series of problems that cannot be solved by the current financial activities, such as cross-regional financial data transmission, accounting statement consolidation, and dynamic analysis of financial and

resource status, forming a brand-new financial management system. Network financial management relies on network financial software to complete the implementation, and network financial software will complete the collaborative management of finance and business, online management, and management of e-commerce. Through the network financial software, dynamic accounting and online economic resource management can be realized, and remote financial management, material management, and remote control behaviors such as remote reporting, accounting, auditing, and auditing of branches can be realized.

- (2) Flexible financial management (as shown in Figure 5). In order to enhance survivability in the unpredictable and changeable environment in the network age, enterprises must implement flexible management and launch new products and personalized products to meet the dynamic and continuous innovation of the network economy. The flexible management of enterprises includes the management of production, personnel, information, and other aspects. The flexible management of finance is to realize the optimization of financial information resources through network technology from the perspective of financial accounting, planning, control, and analysis. Flexibility, in order to promote enterprises to improve the degree to which various financial information resources are used in a variety of ways, thereby promotes the comprehensive management of enterprises.
- (3) Financial regeneration management. Business process regeneration is a new idea put forward by the American management scholars Michael and Hamer in the early 1990s. The goal of enterprise process regeneration management is to revive the vitality of the enterprise, rebuild the organizational structure and strategic planning, and restart the new life. Financial regeneration management is the revolutionary adjustment of financial activities and financial relations and the reallocation of financial resources; the purpose is to adapt to the needs of enterprises inside and outside and to adapt to the goals of enterprise management. Financial regeneration management is an important financial strategy to assist enterprises in their efforts to reduce product costs and improve economic efficiency. The development of electronic commerce and the development of network financial software make it necessary and possible for enterprise financial regeneration management. Enterprise financial regeneration management not only reduces labor costs and improves work efficiency, but also brings a series of new changes to enterprise management, such as customer orientation of values, employees implementing self-management, and the measurement of performance being transformed into the measurement of group results. Financial regeneration

FIGURE 5: Smart factory.

management brings new opportunities and challenges to enterprise management and also highlights the status of financial management.

- (4) Financial virtual management. Virtual financial management must be implemented for virtual enterprises based on e-commerce. A virtual enterprise is a dynamic short-term strategic alliance consisting of several companies with common goals and cooperation agreements. Relying on the network, virtual enterprises break through the physical boundaries of enterprises. Although there are functions such as production, marketing, design, and finance on the surface, there is no organization within the enterprise to perform these functions. In the case of limited resources, in order to gain an advantageous position in the competition, the enterprise only masters the core functions; that is, the high value-added part that is highly dependent on enterprise knowledge and technology is in its own hands, and other low value-added departments are virtualized. Financial virtual management is to take the core functions of the enterprise as the center of financial management and to carry out centralized and coordinated financial management for each virtualized functional department. The supervising and coordinating functions of the middle managers of virtual enterprises are replaced by computer networks, and the organizational structure of enterprises tends to be flat. Financial virtual management is horizontal management that adapts to it, which can remove many intermediate links and enable the generation and confirmation of value. Financial virtual management also includes the management of virtual operations through the network, financial information, and other information generated by virtual transactions. Financial virtual management is a comprehensive and innovative financial management strategy based on a network technology to realize the optimization of financial information resources.

6. Conclusion

To sum up, as the process of economic globalization is gradually accelerating, under such an economic background, the competition of enterprises is becoming more and more

ferce, and the financial operation and cost control of enterprises will play a crucial role in helping enterprises to improve their competitiveness to enable enterprises to emerge suddenly and gain an advantage in the market. In view of this, enterprises should pay attention to cost control and control costs from all aspects, so as to improve the economic benefits of enterprises. This paper focuses on financial operation revenue management from the perspective of big data, hoping to make some achievements in financial operation management.

Since the “Belt and Road” Initiative was put forward in 2013, it has attracted more and more attention. Many countries along the Belt and Road have participated in it, which has further deepened regional economic integration. Complex network analysis is an interdisciplinary method, which has a perfect overall perspective and data indicators that can quantify the relationship. More and more scholars have begun to pay attention to it and use it to carry out research. Based on the perspective of complex networks, this paper constructs the “Belt and Road” directed weighted network, respectively, according to the import and export trade data of countries and international organizations that have signed cooperation documents, and then studies the characteristics of the “Belt and Road” trade network by using a variety of network topology attribute analysis methods and node centric indicators.

1. Introduction

At the end of the 20th century, the establishment of WTO, G20, APEC, and other international trade organizations promoted the flow of production factors in various countries, adjusted the distribution of means of production in various countries, promoted the optimization of global industrial structure, and had a far-reaching impact on the development of the world economy [1, 2]. Since the beginning of the 21st century, similar regional cooperation cases have sprung up.

The “Belt and Road” Initiative takes peace and cooperation, openness and inclusiveness, mutual learning, and mutual benefit as the core spirit, adheres to the principles of joint consultation, joint construction, and sharing, and sends invitations to all countries and international organizations around the world to jointly address global economic issues, seek new development opportunities, and achieve mutual complementarity of strengths among countries, mutual benefit, and win-win results [3–8]. Since the Belt and Road Initiative was put forward, it has attracted wide attention, and more and more countries have participated in

it. By the end of January 2020, 138 countries and regions have signed cooperation documents with China to jointly build the Belt and Road. At present, domestic economic development has entered the new normal, and the downward pressure on the economy is great. Expanding foreign cooperation has become an important way to promote the rapid transformation and development of the domestic economy. China has problems such as irrational industrial structure and large regional economic development gap [9–12]. The proposal of the “Belt and Road” Initiative will help to transfer the excess capacity in the eastern coastal areas to the central and Western regions and overseas so as to optimize the industrial structure and narrow the gap between the rich and the poor.

At present, domestic and foreign scholars' research on the trade of “the Belt and Road” is mostly from the perspective of the two countries participating in the cooperation and carries out empirical analysis on the economic and trade reciprocity brought about by the “Belt and Road” Initiative. However, this kind of analysis lacks a discussion on the overall pattern of trade among the Belt and Road cooperative countries, and there are few studies on quantitative analysis

of the interaction of trade among the Belt and Road countries through complex network analysis (CNA). Considering the interaction among multilateral countries, this paper constructs a trade network based on the bilateral import and export trade data of the “Belt and Road,” explores the attribute characteristics of the “Belt and Road” trade from the perspective of a complex network, as well as the changes in the topology of the trade network since the “Belt and Road” Initiative, and puts forward and analyzed the deep-seated reasons affecting the changes in the pattern of the “Belt and Road” trade network, which has strong theoretical significance. The Belt and Road Initiative takes into account the needs of countries along the Belt and Road in economic development and trade cooperation and is conducive to promoting economic and trade exchanges between regions and countries.

Based on the import and export trade data of countries along the Belt and Road from 2009 to 2017, this paper uses the complex network analysis method to build the “Belt and Road” trade network, discuss the overall topology of the network and important trading countries, explore the changing trend of the trade network and the division of communities, discuss the main factors affecting the trade cooperation of countries along the Belt and Road, and then put forward some suggestions on the development of China’s “the Belt and Road” cooperation, which has strong practical significance.

2. Construction of Trade Network

Nodes and edges between nodes are two essential elements for building complex networks [13]. In “the Belt and Road,” trade, countries, and economies act as nodes, and trade relations act as links, forming a network structure. However, such a simple undirected, weightless network is challenging to describe the direction and scale of trade flow, and the network’s topology is abstracted too simply, which will cause much information to be ignored and be quite different from the real trade network. Generally speaking, trade activities are bidirectional, including import and export. Scholars often combine import and export data into a network to conduct research. Import and export trade have significantly different meanings for a country: import reflects the inflow of goods and the country’s demand for consumer goods, while export shows more of the country’s resource output capability and manufacturing level. This paper constructs “the Belt and Road” import and export trade network and compares and analyzes the differences between national nodes in the two networks.

As of the end of January 2020, our country has signed 200 cooperation documents on the joint construction of the “Belt and Road” with 138 governments and 30 international organizations. The trade data of various countries in this paper are selected from the United Nations Trade Database (UNComtrade Database), and the bilateral trade data of the countries cooperating with the “Belt and Road” Initiative from 2009 to 2017 are extracted [14–16]. Specifically, this paper only studies commodity trade but does not include service industries. The customs HS code (Harmonized

System) of trade data selects the latest version according to the data year, and trade data consists of all commodity codes (Commodity Codes), namely, AG1–AG6. The scale of the “Belt and Road” trade data is vast, the trade volume between countries is very different, and some countries have the phenomenon of missing trade data. Taking into account these factors may have an impact on the analysis of the network topology, setting a threshold of \$1 billion for trade volume. Mainly analyze the trade network composed of significant import and export member countries. These countries’ import and export trade volume accounts for 84.9% and 83.5% of the total import and export trade volume of the “Belt and Road,” which is sufficiently illustrative and representative. After data preprocessing, the “Belt and Road” import trade network in 2017 included 93 nodes and 507 edges, and the export trade network had 101 nodes and 484 edges, excluding self-loops. Table 1 shows the number of nodes in the network.

We build “the Belt and Road” trade network through the adjacency matrix. In the import trade network, the trade volume of country i imported from country j is m , and we write as

$$w_{ji}^{\text{in}} = m. \quad (1)$$

The export volume of country i to country j is n , denoted as

$$w_{ij}^{\text{out}} = n. \quad (2)$$

Through the visualization processing of Gephi software, the “Belt and Road” import and export trade network in 2017 can be obtained.

3. Topological Structure Analysis of the Trade Network

3.1. Basic Characteristic Indicators of the Network. In complex network analysis, the degree is the most direct and important concept to describe the characteristics of nodes [17]. In an undirected network, the degree k_i of node i equals the number of edges directly connected to this node. For directed networks such as the “Belt and Road” trade network, we can introduce the concepts of in-degree and out-degree to expand: in-degree refers to the number of edges pointing from other nodes to this node, and out-degree refers to the number of edges from this node to other nodes. The average degree of all nodes in the network is the average degree of the network (AverageDegree) [18–20]. On average, each country in the “Belt and Road” trade network has import trade with 5 other countries and export trade with 5 other countries. In contrast, import trade is more extensive than export trade. Table 2 shows the average degree of import and export network.

From a statistical point of view, the number of all nodes with a degree of a certain value can be compared to the total number of nodes in the network as the probability of the degree value appearing. Thereby, the degree distribution of network nodes is obtained. The most common data distribution in daily life and study research is the normal

TABLE 1: Number of nodes in the network.

	Import trade network	Export trade network
Number of nodes before processing	145	145
Number of connected edges before processing	12133	10542
Number of nodes after processing	92	103
Number of corresponding edges after processing	509	488

TABLE 2: Average degree of import and export network.

	Import trade network	Export trade network
Average in-degree	5.48	4.81
Average out-degree	5.48	4.81

TABLE 3: Import and export network assortativity coefficient.

	Import trade network	Export trade network
Assortativity coefficient	-0.39	-0.40

distribution (Gaussian distribution). In economics research, many data distributions are often very different from normal distributions. Such distributions do not have a single characteristic scale and are also called “scale-free” distributions.

In 2017, the “Belt and Road” import and export trade network all obeyed such high-degree nodes, which accounted for a minority. And nodes with small-degrees account for the vast majority of “long-tailed distributions” (a type of “scale-free” distribution). In the import and export networks, 57% and 60% of the nodes have degrees less than or equal to 5, respectively. This shows that, in “the Belt and Road” trade cooperation, the trade connections of most countries are still relatively limited, and the network structure is not balanced.

Another dimension to studying the total nature of the BRI trade network is the degree of correlation. The correlation of degree considers the correlation of degree attributes between each node in the network. If the correlation is positive, it means that a node with a large degree is more inclined to connect to other nodes with a large degree. Such a network is called a “homologous network”; otherwise, it is called a “heterogeneous network.” The “assortativity coefficient” is an important indicator to quantify the network’s assortativity. It is defined as follows:

$$r = \frac{1}{\sigma_q^2} \sum_{j,k} jk(e_{jk} - q_j q_k), \quad (3)$$

where σ_q^2 is the variance of the redundancy distribution q_k .

After calculation, $r_{2017\text{import trade}} = -0.39$, and $r_{2017\text{export trade}} = -0.40$. Table 3 shows the import and export network assortativity coefficient. It shows that the import and export trade networks of “the Belt and Road” are all heterogeneous networks. Those countries with many trading partners are more willing to establish economic and trade connections with countries with few trading partners. There are trade connections between various countries, and the right to speak in trade not only is in the hands of big countries but also shows the pursuit of equality and win-win cooperation among countries along the “Belt and Road.”

3.2. Centrality of Network Nodes. In complex networks, the location of a node determines its importance. Various centrality indicators can analyze the location of nodes in the network from different sides and then measure the importance of nodes placed in the network. The nodal centrality indicators studied in this paper mainly include degree centrality, betweenness centrality, closeness centrality, and eigenvector centrality.

3.2.1. Degree Centrality. Degree centrality is to use the degree of a node as a criterion for measuring the importance of its location. The larger the degree, the more important the node in the network:

$$DC_i = \frac{k_i}{N-1}. \quad (4)$$

Among them, N is the number of nodes in the network, and k_i is the degree of node i . Considering the influence of trade scale, the trade volume between the two countries is used as the weight of the connected edges, and for the directed weighted network, there are

$$DC_i^{\text{in}} = \sum_{j=1}^N w_{ji},$$

$$DC_i^{\text{out}} = \sum_{j=1}^N w_{ij}. \quad (5)$$

Table 4 shows the weighted in/out-degree of import and export network. By comparing the top ten countries with weighted in-degree and weighted out-degree in 2017, it is found that our country has the most extensive connections and the most significant trade volume in the import and export trade network. South Korea and Russia ranked second and third, respectively, and other countries with large trade volumes were mainly concentrated in Southeast Asia and the Middle East.

3.2.2. Betweenness Centrality. Bridges are often the only way to connect two places. In the trade network, if the connection between node A and node B must pass through node C, then C is such a node that acts as a bridge intermediary.

TABLE 4: Weighted in/out-degree of import and export network.

ID	Import trade network countries	Import trade network weighted in-degree	Export trade network countries	Export trade network weighted out-degree
1	China	$8.74E+11$	China	$8.26E+11$
2	South Korea	$3.32E+11$	South Korea	$2.99E+11$
3	Russia	$1.97E+11$	Russia	$2.09E+11$
4	Italy	$1.66E+11$	Singapore	$1.98E+11$
5	Malaysia	$1.34E+11$	Italy	$1.62E+11$
6	Thailand	$1.13E+11$	Malaysia	$1.07E+11$
7	Vietnam	$1.09E+11$	Vietnam	$8.62E+10$
8	Singapore	$1.08E+11$	United Arab Emirates	$8.58E+10$
9	Saudi Arabia	$1.08E+11$	Indonesia	$8.18E+10$
10	United Arab Emirates	$8.81E+10$	Poland	$7.01E+10$

The topological index that measures this characteristic of a node is called betweenness centrality, which is specifically defined as

$$BC_m = \sum_{s \neq m \neq t} \frac{n_{st}^m}{g_{st}}, \quad (6)$$

where g_{st} is the number of shortest paths from node s to node t and n_{st}^m is the number of shortest paths from node s to node t through node m .

From the perspective of the ability to control trade cooperation, countries with higher betweenness centrality have a more vital ability to influence trade activities, and excluding these countries will also have a more significant impact on the trade network.

Table 5 shows the betweenness centrality of countries in the “Belt and Road” trade in 2017. It can be seen from the above table that our country has played a very important role in connecting the “Belt and Road” import and export trade network. Betweenness centrality is nearly twice as high as the second. In addition to China, countries such as Italy, Russia, South Korea, the United Arab Emirates, South Africa, and Turkey also play a key “trade bridge” role. In fact, Italy, Russia, South Korea, the United Arab Emirates, and South Africa are the core trade countries in Western Europe, Eastern Europe, East Asia, the Middle East, and Africa, respectively. Each intraregional node realizes cross-regional trade by connecting with these countries.

3.2.3. Closeness Centrality. Another metric based on the shortest path between nodes is closeness centrality. If betweenness measures a country’s ability to control a trade network, closeness quantifies the centrality of the country’s topological position in the network. Closeness centrality is the average length of the shortest path from each node to other nodes. For a node, the closer it is to other nodes in the network, the higher the closeness centrality is:

$$CC_i = \frac{1}{d_i} = \frac{N}{\sum_{j=1}^N d_{ij}}. \quad (7)$$

Table 6 shows the closeness centrality of countries in the “Belt and Road” trade in 2017. Similar to betweenness centrality, the closeness centrality of China, Italy, Russia,

South Korea, the United Arab Emirates, and Turkey is also at a high level in the network. It shows that these countries are not only trade bridges but also trade centers of various regions. The comparison of import and export networks shows that the imported network is closer, the connectivity between nodes is more robust, and its closeness centrality is generally higher than that of the export trade network.

3.2.4. Eigenvector Centrality. The importance of a node in the network is not only determined by the number of other nodes it is connected to but also closely related to the significance of these connected neighbor nodes. Imagine that node A is connected to several “network edge” nodes, and node B is connected to a small number of nodes with large betweenness. Although the degree of node B may be equal to or even smaller than that of A, the position of B in the network is much more important than that of A because it is also very likely to be an important “bridge” in the network. Based on this idea, the eigenvector centrality is defined as

$$x_i = c \sum_{j=1}^N a_{ij} x_j, \quad (8)$$

where C is a proportional constant, x_i is the important measure of node i , and a_{ij} is the network’s adjacency matrix.

It can be obtained by iterative calculation:

$$x = \lambda_1^{-1} Ax, \quad (9)$$

where λ_1 is the characteristic single root with the largest modulus of matrix A and x is the main eigenvector corresponding to λ_1 .

Table 7 shows that the countries with high eigenvector centrality are mainly concentrated in East Asia and Southeast Asia. These countries are often the origin of raw materials for industrial production and are located on the “Belt and Road” shipping routes with convenient transportation. Most of the countries that trade with them are countries with a high degree of weight or betweenness.

Combining the above four different network centrality indicators, it can be found that our country has a pivotal position in the “Belt and Road” trade network. Specifically, our country’s weighted in-degree and weighted out-degree are ranked first, and it is the largest import and export trade

TABLE 5: The betweenness centrality of countries in the “Belt and Road” trade in 2017.

ID	Import trade network countries	Import trade network betweenness centrality	Export trade network countries	Export trade network betweenness centrality
1	China	0.27	China	0.23

9	Vietnam	0.45	Egypt	0.29
10	Malaysia	0.43	Austria	0.29

country. Our country’s closeness centrality is the highest, which means that our country is at the center of the trade network. At the same time, our country also plays a powerful bridge intermediary role, strengthening economic and trade exchanges between regions.

3.3. *Small-World Network Features.* “Small-world network” is a representative class of complex networks. In such a network, many nodes are not directly connected but can be reached from any other node in the network via a small number of countable paths. The topological metrics that best describe this property are “average path length” and “clustering coefficient.” The path in the network that connects the fewest edges between two nodes is the shortest between two points. The average path length is defined as the average of the geodesic distance between any two points in the network:

$$L = \frac{\sum_{s,t \in V} d(s, t)}{n(n-1)}, \tag{10}$$

where V is the set of nodes in the network, $d(s, t)$ is the shortest distance from s to t , and n is the number of nodes in the network.

The average path length reflects the closeness between nodes in the network, while the clustering coefficient reflects the “structure” of the network. It depicts the probability that nodes B and C connected to node A are also connected. E_i is the number of edges between all adjacent nodes of node i .

$$C_i = \frac{E_i}{(k_i(k_i - 1))/2} = \frac{2E_i}{k_i(k_i - 1)}. \tag{11}$$

The small-world network is a “transition type” between the fully regular nearest neighbor network and the random ER random network. The nodes in the former network have high clustering and long average distance, while the latter is the opposite. Small-world networks can be generated by adding randomness to the regular network. The small-world characteristics of the network can be measured using the Sigma parameter and the Omega parameter, which are defined as follows:

$$\text{Sigma} = \frac{C/C_r}{L/L_r}, \tag{12}$$

where C and L are the average clustering coefficient and average shortest path length of the network, respectively. C_r and L_r are the average clustering coefficient and shortest path length of the equivalent random graph. If $\text{Sigma} > 1$, the network is generally considered to have small-world properties.

The small-world coefficient (Omega) is between -1 and 1 . The value close to 0 represents that the network has small-world features. The value close to -1 represents that the network is a lattice shape, and the value close to 1 represents that the network is a random graph by calculating the Sigma, Omega coefficients, and related indicators of the “Belt and Road” trade network in 2017 as shown in Table 8.

The Sigma coefficients of the “Belt and Road” import and export trade network are all greater than 1, and the Omega

TABLE 7: The eigenvector centrality of countries in the “Belt and Road” trade in 2017.

ID	Import trade network countries	Import trade network betweenness centrality	Export trade network countries	Export trade network betweenness centrality
1	China	0.73	China	0.61
2	South Korea	0.53	South Korea	0.43
3	Malaysia	0.19	Vietnam	0.36
4	Vietnam	0.18	Singapore	0.24
5	Thailand	0.15	Malaysia	0.23
6	Russia	0.14	Vietnam	0.19
7	Singapore	0.12	Indonesia	0.18
8	United Arab Emirates	0.12	Russia	0.17
9	Indonesia	0.11	Philippine	0.14
10	Italy	0.09	Italy	0.14

TABLE 8: “Small-world” indicators of the “Belt and Road” trade network in 2017.

	Import trade network	Export trade network
Sigma	1.13	1.15
Omega	-0.04	-0.02
Average path length	1.38	1.27
Average path length (weighted)	3.42E+9	3.08E+9
Average clustering coefficient	0.52	0.53

coefficient is close to 0. It shows that these two trade networks align with the characteristics of the small-world network. The Omega coefficients of the import and export trade network are all less than zero, and they tend to be random networks. The average path length of the export trade network is shorter. It shows that the export trade between countries along the “Belt and Road” is closer.

According to the phenomenon of “small-world” and trade networks, a trade network with the characteristics of “small-world” has unique advantages in terms of transaction efficiency. Because of its robust network connectivity, it can realize the overall situation Pareto Improvement of Networks.

4. Evolution of Node Importance

The previous section discussed the importance of nodes in the “Belt and Road” trade network in 2017 from different dimensions by analyzing various node centrality indicators. To study the changes in node attributes in the import and export trade network in the past nine years, the author first uses the PageRank algorithm to extract the top ten important nodes in the trade network in 2017 and then discusses the degree centrality, betweenness centrality, and closeness centrality of these core countries.

4.1. Network Core Node Selection. The PageRank algorithm [21–23] is a well-known key technology for web page ranking. It gave birth to the emergence and development of the Google search engine. The algorithm’s starting point is that a node’s importance depends on the number and quality of nodes pointing to it.

From this point of view, the PageRank algorithm can be regarded as a generalization of eigenvector centrality on

directed graphs. The PageRank algorithm is divided into three steps. The initial step will equally divide the total PR value among all nodes, and then

$$\sum_{i=1}^N PR_i(0) = 1. \quad (14)$$

In the second step, the PR value of each node in step $K - 1$ is equally divided by the nodes it points to, and the new PR value of each node is the sum of the PR values it has obtained. The third step is to reduce the scale factor s to keep the total PR value of the network at 1, and then

$$PR_i(k) = s \sum_{j=1}^N \bar{a}_{ji} PR_j(k-1) + (1-s) \frac{1}{N}. \quad (15)$$

Through calculation, the top ten core node countries with the average PageRank score of the “Belt and Road” import and export trade network in the past nine years are extracted, as shown in Tables 9 and 10.

The top ten countries in the PageRank score of the “Belt and Road” import trade network include China, South Korea, Russia, Italy, Saudi Arabia, Malaysia, the United Arab Emirates, Singapore, Thailand, and Indonesia. Among them, our country has always maintained first place in PR worth and is much higher than second South Korea. In the past 9 years, the fluctuation of our country’s PR value has been slight, and the overall trend has maintained an upward trend, indicating that our country’s position in the “Belt and Road” import trade network is improving. Except for Saudi Arabia and the United Arab Emirates, two Middle Eastern countries, two European countries, Italy and Russia, and other core countries are mainly located in Southeast Asia, which shows that the import trade of the “Maritime Silk Road” is more active.

TABLE 9: Top 10 countries in the “Belt and Road” import trade network PageRank value.

The top ten countries in the PageRank score of the “Belt and Road” export trade network include China, Italy, Russia, South Korea, Singapore, the United Arab Emirates, Turkey, Malaysia, Poland, and Saudi Arabia. Comparing the two networks, our country’s advantages in export trade are not as obvious as those in import networks. It shows that our country still has development potential in export trade, and the other node members in the two networks have not changed much.

Through screening the core nodes of PageRank, the countries in the “Belt and Road” trade network can be divided into import, export, and two-way trade, as shown in Table 11. Among them, import-oriented countries are represented by Thailand and Indonesia, and Poland and Turkey represent export-oriented countries. China, Italy, Russia, South Korea, Singapore, and the United Arab Emirates are all at the core of the import and export network and are two-way trade countries.

4.2. Changes in the Degree Centrality of Core Nodes. For the above representative important nodes, combined with the analysis methods of nodal degree centrality, betweenness centrality, and closeness centrality in the previous chapter, we further study the changes in the topological structure of the import and export trade network in 9 years.

According to the degree centrality, both networks can be divided into three echelons. Our country is in the first echelon, Italy, Russia, and South Korea are in the second echelon, and other core node countries form the third echelon. Overall, the degree centrality of the two network core nodes fluctuated relatively minor, and there was no obvious improvement

around 2014. Except for China, the in-degree value of the imported network and the out-degree value of the export network are concentrated between 0.1 and 0.4. Our country’s inbound and outbound centrality is ahead of other countries and maintains a steady growth trend. Compared with import trade, more countries have trade connections with our country in the export network, reaching 80. It accounts for 79% of the total number of exporting countries in the “Belt and Road.”

In the import trade network, Italy, Russia, and South Korea are ranked after our country. Italy and South Korea have very similar in-degree curves, with fewer import partners in 2011 and 2012. In addition, affected by the sharp drop in international crude oil futures prices and Western economic sanctions, the financial crisis in Russia in 2014 and 2015 caused its import and export trade to enter an “ice period.” The remaining core nodes are Southeast Asian countries, and their trade connections are mainly distributed along the “Maritime Silk Road.” The Italian economy was affected by the European debt crisis in the export trade network. Before 2013, the export trade volume was less than 1 billion US dollars. It then increased in 2014 and remained around 0.4. South Korea, which ranks second in the centrality of out-degree, has been very active in export trade in recent years, and the average out-degree has increased by 25% compared with the average in-degree. In 2017, 33 countries became their export trading partners. In contrast, Russia’s import and export trade is more balanced, including 25 partner countries.

4.3. Changes in Betweenness Centrality of Core Nodes. Compared with degree centrality, the betweenness variation of the two networks fluctuates greatly, and there is no

TABLE 11: Types of “the Belt and Road” trade countries.

Import trade country	Export trade country	Two-way trade country
Thailand and Indonesia	Poland and Turkey	China, Italy, and Russia South Korea and Singapore United Arab Emirates

obvious echelon division. Same as the degree centrality, in the two networks, our country’s betweenness also ranks first, and the import betweenness is generally higher than the export betweenness, indicating that our country’s role as a bridge in import trade is more prominent. In 2012 and 2015, due to the strengthening of import trade with Belarus, Sudan, Romania, Nigeria, and other countries, our country’s betweenness showed a stepwise increase. Affected by the financial crisis, our country’s export betweenness dropped from 0.31 in 2009 to 0.17 in 2011 and then remained relatively stable at around 0.2.

In the import trade network, in addition to China, the betweenness of Russia, the United Arab Emirates, and Indonesia also increased significantly in 2012. Among them, Russia and Indonesia have strengthened their import cooperation with the United Arab Emirates, Ecuador, and other Middle East and South American countries. But the increase in the betweenness of the UAE is due to the significant reduction in the import trade between Turkey, which has a strong trade connection, and the large betweenness countries such as Singapore and South Africa. On the other hand, it is due to the increase in the import trade volume between the UAE and regional representative node countries such as South Africa and Indonesia. In the export trade network, the value of Italian exports to Ukraine and South Africa nearly tripled. So, from 2014 to 2016, its export betweenness increased rapidly. However, Austria, Latvia, Slovenia, and other European countries reduced their export trade to South Korea, Russia, and the United Arab Emirates; the three countries’ exports declined between 2013 and 2015.

4.4. Discussions. Through the above two centrality analyses on the core nodes of the “Belt and Road” import and export network, it was found that the proposal of the “Belt and Road” Initiative has a more significant impact on the export network than the imported network. The specific performance is that, after 2013, the export trade links between regions along the “Belt and Road” have become very close, and the overall export network has shown a trend of “decentralized” coordinated development. Affected by the external macroeconomic environment, the betweenness centrality of countries in the past nine years has been relatively sensitive and fluctuated wildly. As the only country in the EU that has signed a memorandum of understanding, Italy’s influence on the trade network is gradually increasing. The UAE does not have the most significant number of trade connections in the import and export network. Still, its betweenness centrality is prominent, which shows that the UAE has a powerful ability to control trade in the Middle East. On the one hand, the top-level strategy of “the Belt and Road” has extensively promoted our country’s foreign

export trade. On the other hand, as a bridge of the trade network center, our country has strengthened the trade links between regions and countries along the “Belt and Road.”

5. Conclusions

The “Belt and Road” trade network is a typical complex network. There are few pieces of authoritative literature at home and abroad that apply the complex network analysis method to the “Belt and Road” trade. This study has some innovations in terms of angle and method. This paper studies the trade networks of countries along the “Belt and Road” from the perspective of complex networks. This perspective is different from the model of taking a single country as the research object in most “the Belt and Road” trade studies but comprehensively analyzes the multilateral trade relations of countries along the “Belt and Road” and desalinates the impact of countries’ own attribute differences on trade characteristics.

This research has certain characteristics of theoretical research and practical guidance. The theoretical characteristics are as follows. Although the practice of applying complex network technology to the research of international trade networks has been adopted by some scholars, most of the current research and analysis dimensions related to trade networks are one-sided. For example, only the topological structure of the network is analyzed and elaborated, and the influence factors of time and trade networks are not considered. In addition, through the application of analysis software, the network can be visually presented, which is more intuitive and convenient for further understanding and analysis. On the other hand, the research ideas and methods of this paper can also be extended to the trade network research of other regional or economic organizations, such as APEC, WTO, and G20, which provides a certain theoretical and methodological reference for subsequent related research. The characteristics of practice guidance are as follows: the research scope of this paper is the “Belt and Road” trade network. The node is composed of 138 cooperative countries. Compared with other global trade networks, it is more specific and focuses on the regional economy. The research results provide a theoretical basis and policy suggestions for guiding China to cope with the changes in the “Belt and Road” trade network.

In recent years, there are many cases of college students who have psychological problems affecting their studies, dropping out of school, and even committing suicide. College students, as a part of high-level talents, have always been regarded as outstanding members of society. They default to have strong psychological qualities, but the reality is disappointing. Various pressures such as academics, social relations, and employment make college students the mental exhaustion has led to many bloody tragedies. The timely detection of psychologically abnormal students has become one of the most concerned and thorny issues in major universities. By constructing a mental health state perception model for college students and optimizing the model parameters, it can be seen that the f score of the internal and external tendency model has increased by 3.3%, the f score of the depression binary model has increased by 2.5%, and the anxiety binary model of the f score has increased by 2.5%. The score increased by 8%. The established model has an obvious effect and can quickly analyze the difference between the behaviors of psychologically abnormal students and normal students in school and also provide a management decision-making basis for college student managers and psychological counselors.

1. Introduction

The frequent dropout and suicide incidents in recent years have proved that many students have more or less psychological problems, and these psychological problems have aroused widespread concern in society. At the same time, at all stages of life, people may have psychological problems due to various complex reasons. Early detection of these psychological problems can play a huge role in protecting personal safety. Because of the rapid development of disciplines such as computer science and mathematics, technologies such as deep learning, data mining, and big data are also making rapid progress and are increasingly integrated into people's daily lives. More and more algorithms are emerging in the field of computer science to solve certain problems and in many ways outperform traditional methods. For example, traditionally, people use indicators such as degree centrality and edge betweenness to analyze social networks, which can better describe some characteristics of social networks but usually only express part of

the information in social networks and may contain more noise, and network representation learning based on deep learning solves this problem very well, which usually captures more information in the network for more detailed analysis and identification. This research uses network science, deep learning, network representation learning, other technologies, and students' social network data to identify students who are more likely to have psychological problems. Accurate identification can give families and schools the opportunity to intervene in students as early as possible and prescribe the right medicine to solve students' problems. Helping psychologists provide psychological counseling can largely avoid the deterioration of students' psychological problems; reduce school dropout, suicide, and other incidents; and reduce social tragedies. At the same time, a new way to efficiently utilize multiview network data is proposed; more potential social information between views is preserved; and the problem of label imbalance that is common in such data is proposed. It is proposed to identify students' psychological problems through deep learning technology,

which also provides a direction for the identification and research of students' psychological problems in the future [1–7].

2. Related Work

In recent years, many experts and scholars have realized the importance of educational big data. They have used data mining technology to analyze and mine the data generated by students in school and have achieved remarkable results. They have put the data mining results into education and teaching. A person's psychological characteristics are often expressed through daily life behaviors and routines. Therefore, recently, researchers have begun to try to dig out information that can reflect their mental health status from the daily behavior data of college students. Several studies have shown a strong relationship between mental health status and online behavior. DongNie et al. explored the relationship between search behavior and personality traits and further attempted to determine how search behavior can be used to identify personality. They collected two data sets: one from a questionnaire on 16 personality factors and the other from web access logs from Internet gateways. By calculating the correlation coefficient between individuals' search behavior and personality, some interesting patterns were found; there are several specific behaviors that have a strong correlation with personality, such as directory index search, knowledge search, dwell time, keyword usage, click habits, and so on. Through regression analysis, most personality dimensions can be predicted by search engine behavior. AngLi et al. propose an algorithm for predicting mental health problems through network usage behavior. They recruited 102 college students and used the SCL-90 questionnaire to conduct a psychological survey. Through the results of the questionnaire, they obtained the mental health level of college students (10 dimensions) and conducted statistical analysis on the online behavior of college students. Based on web usage behavior, a computational model for predicting the scores of each dimension of SCL-90 is established. The results show that the fluctuation range of the Pearson correlation coefficient between the predicted score and the actual score of each dimension is between 0.49 and 0.65, and the fluctuation range of the relative absolute error is between 75% and 89%. Zangane and Hariri et al. explore the role of emotional factors in doctoral students' online information retrieval. Their study sample, 50 PhD students, aggregated information by observing user facial expression records, Morae software log files, and pre- and postsearch questionnaires. The findings suggest that there is a significant relationship between emotional expression and the individual characteristics of searchers. Searcher satisfaction with search results, Internet search frequency, search experience, interest in search tasks, and familiarity with similar searches were associated with increased happiness. An examination of user emotions during search shows that users with happy emotions spend a lot of time searching for and viewing search solutions. ChangyeZhu and BaobinLi et al. proposed a new method to detect depression through time-frequency analysis of network behavior. They recruited

728 graduate students, obtained their depression scores through the Zung self-rating depression scale (SDS), and then collected digital records of their online behavior. Through time-frequency analysis, they built a classification model to distinguish between high and low SDS groups, and a predictive model that more accurately identified the mental state of the depressed group. The experimental results show that both the classification model and the prediction model can better reflect the change in mental health, and the time-frequency feature can better reflect the change in mental health. The research at this stage is mainly limited to the behavior analysis of a certain type of specific group and the psychological analysis and interpretation of the influencing factors. However, the continuous update and iteration of data mining technology have provided a great boost to the research work in psychology. Driven by data mining technology, the construction of university informatization platforms has become more perfect. The use of mathematical models in machine learning makes it possible to predict the psychological state of students. Based on the main research contents of the above research scholars, the analysis of college education data has always been a research hotspot in the field of data mining. Through the data mining of students' in-school education, the researchers use data mining technology and analysis theory to draw conclusions about students' academic performance, social relations, and poor students and provide data support and data support for the construction of college informatization and smart campuses. The theoretical basis also provides valuable guidance and suggestions for college administrators [8–14].

3. Related Technical Methods

3.1. Data Processing Technology

3.1.1. Data Filtering. Although data mining is a method for massive data analysis, it does not mean that we need to use all the collected data because, when collecting data in the early stage, we did not specifically consider the use of these data in the future. However, the value density of these data is very low, which is not conducive to later data analysis. Therefore, when there are specific research goals, only the data that are useful for target analysis need to be selected. For the research purpose of this study, the original data are the records of students' online behavior in school collected through the network system. The key information in the records are the student ID, the website visited, the type of website visited, the time of visiting the website, and so on. The rest of the information cannot be used, such as some parameters and codes designed by the log system to ensure security, which are useless for our analysis.

3.1.2. Data Cleaning. Data cleaning is mainly to solve the problem of poor data quality caused by some accidental factors for some useful data after data screening. The main means are as follows:

Missing value processing: when the data set with missing data accounts for a relatively low proportion of the whole

data set and the data volume of the sample is relatively large, in this case, it can be processed through the deletion method, that is, the data items with missing values can be directly discarded. Another common processing method is the filling method. This method is used to fill in the data according to the average value of the data near the dimension where the missing value is located when the data volume itself is not particularly large and there are many missing samples.

Outlier processing: it is also called outlier processing or error value processing. If the value of one dimension in a data item is far greater than or less than the value of other data items in the sample, the data item with the outlier is called an outlier. In the case of outlier data, it cannot be discarded directly. It is necessary to analyze it to judge whether it is reasonable and then decide on the processing strategy. For example, in real life, the age range of people is greater than 0 and less than 150. When the value in the data item exceeds this range, it can be regarded as an abnormal value. This method is a simple analysis method.

When the data is considered to have the same meaning as the addition and subtraction of several dimensions, they can represent the same meaning. Eliminating duplicate data dimensions plays a certain role in data downsizing and model burden reduction. It ensures the uniqueness and representativeness of data dimensions.

Noise data processing: the random error or variance of the measured data caused by some reasons is the so-called noise, which is the interference to the data. The commonly used methods are the box division method and regression method. The box division method forms a small group of nearby ordered values, namely "box," and then smoothes these ordered data values with the mean, median, or boundary of the data in the box to make these data locally smooth. The regression rule is to use a regression function to fit these noisy data and play the role of smoothing data denoising [15].

3.1.3. Data Conversion. Data conversion processing can also be called data mapping processing, which generally has three cases. One is the encoding conversion of text data. Since the computer cannot directly process text data, such as calculating the distance between two data, it is necessary to numerically encode the text. For example, in the gender type, the male is coded as 1, and the female is coded as 0; common encoding methods include one-hot encoding and so on. The second is format conversion. For example, date data need to be converted into a unified format type to facilitate subsequent analysis and processing. The third is the mathematical processing of numerical data. For example, when it is found that the numerical value of a certain dimension encountered changes in the form of an exponential, the exponentially changing data can be quickly converted into decimal numerical data, which is convenient for observation and analysis through the following formula [16]:

$$y = \log_m(x + k). \quad (1)$$

In the same way, when the data changes in the form of a power function, it can be processed by the method of

opening the n^{th} power, and it can be converted into small numerical data that is easier to observe by formula (2), where y is the converted value and x is the value obtained before conversion.

$$y = \sqrt[n]{x}. \quad (2)$$

3.1.4. Data Integration. The student's on-campus network behavior data are recorded in the log system and saved in log format, while some basic information data of the student are saved in the student management system. During data analysis and model training, it is cumbersome and error-prone to operate the data in each system, so a data integration method is needed to extract these data and save them in the same environment for processing.

3.2. Data Analysis Technology. The biggest difference between logistic regression analysis and linear regression analysis is that the data types of the variables Y analyzed are different. Logistic regression analysis can analyze discrete categorical data, while linear regression analysis can only analyze continuous data types [17].

3.2.1. Logistic Regression Distribution

Definition 1 (Logistics). Let x be a continuous random variable, when x has the following distribution function and density function; then x is said to obey the logistic regression distribution.

$$F(x) = P(X \leq x) = \frac{1}{1 + e^{-(x-\mu/\gamma)}}, \quad (3)$$

$$f(x) = F'(X \leq x) = \frac{e^{-(x-\mu/\gamma)}}{\gamma(1 + e^{-(x-\mu/\gamma)})^2}.$$

The distribution function and density function plots are shown in Figure 1.

3.2.2. Binary Logistic Regression Analysis. Binomial logistic regression is suitable for dealing with the situation when the value of the dependent variable y has only two categories, which is essentially a prediction model of classification probability. The value of the variable x is a real number. When the value of the dependent variable y is 1, the probability model is shown in equations 4 and 5, and when it is 0, it is shown in the following equations:

$$P(Y = 1|x) = \frac{\exp(\omega \cdot x + b)}{1 + \exp(\omega \cdot x + b)}, \quad (4)$$

$$P(Y = 0|x) = \frac{1}{1 + \exp(\omega \cdot x + b)}, \quad (5)$$

where $x \in R^n$ is the input value of the model, $y \in 0,1$ is the output value of the model, $\omega \in R^n$ is the parameter, ω is called the weight vector, b is called the bias, and $\cdot x$ is the inner

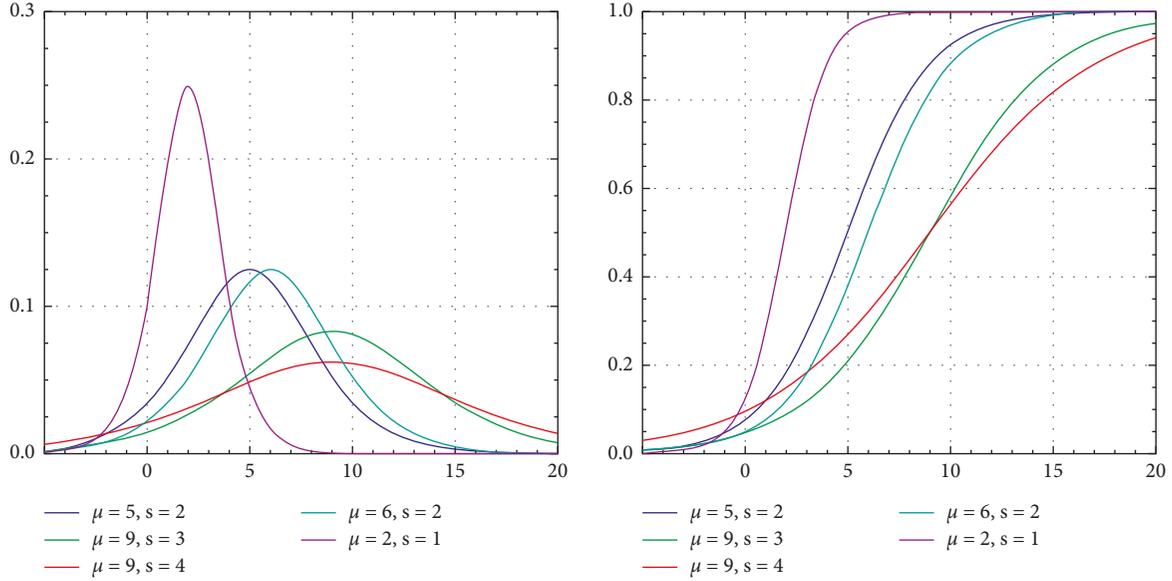

FIGURE 1: Distribution function and density function.

product of ω and x . Assuming a given input vector $x = (x_1, x_2, x_3, \dots, x_n)$, the logistic regression analysis model can separately calculate $p(y=0|x_n)$ and $p(y=1|x_n)$ for each dimension x of the input vector value. The concept of event probability and logarithm is introduced here. Let P be the probability of occurrence of an event, and $1 - P$ corresponds to the probability that it does not occur. The probability of an event can be expressed by the ratio between the two, that is, $P/(1 - P)$; on this basis, the logarithmic probability of the event can be obtained by taking the logarithm. The formula is shown in (7). The odds can be given by the following equation [18]:

$$\text{logit}(p) = \log \frac{p}{1 - p}, \quad (6)$$

$$\text{logit}(p) = \log \frac{p(Y = 1|x)}{1 - p(Y = 1|x)} = \omega \cdot x + b. \quad (7)$$

It can be seen from formula (7) that when the value of the dependent variable y is 1, the calculation formula of the logarithmic probability of logistic regression analysis is actually a linear function. The logistic regression analysis is essentially fitting this linear function so that this linear function can distinguish the two categories of the original data as much as possible. The larger the value of the linear function, the greater the log probability of the logistic regression, the closer the classification type is to class 1, and vice versa; it is closer to class 0.

3.3. Data Mining Technology

3.3.1. Classification Algorithm. The essence of a classification algorithm is to train a classifier on a labeled data set so that it can divide a new data set. The process of evaluating the results of the classification algorithm is inseparable from the existence of a confusion matrix, which is a computing tool often used in classification algorithms. Figure 2 shows the

composition of the confusion matrix [19]. Then the basic elements of classification problems are as follows: training data, that is, the sample data set used to learn the model; feature, that is, the attribute used to describe data and the basis of classification; model, that is, the external framework of classifier; algorithm, that is, the method of constructing classification rules; and evaluation, that is, the final evaluation of the effect of the model. The purpose of the classification algorithm is to mine the hidden rules in label data, so as to divide the data set in feature dimension space.

There are four parameters in the confusion matrix, which are as follows:

TP (true positive): true examples, which refer to the positive tuples correctly classified by the classifier

TN (true negative): true negative, which refers to the negative tuples correctly classified by the classifier

FP (false positive): false positive, which refers to negative tuples that are misclassified as positive tuples by the classifier

FN (false negative): false negative, which refers to the evaluation index of the positive tuple classification model that is misclassified as a negative tuple by the classifier can be calculated by the four parameters of the above confusion matrix:

Accuracy rate: also known as overall recognition rate, it generally measures how well the classification model can correctly identify various data sets:

$$\text{accuracy} = \frac{(TP + TN)}{(P + N)}. \quad (8)$$

Precision: it reflects the proportion of correct classification in the classification results of the classification model for each category, that is, the accuracy of the model when judging each category.

$$\text{precision} = \frac{TP}{(TP + FP)}. \quad (9)$$

		Predictive classification		
		+	-	Total
Actual classification	+	TP (true positives)	FN (false negatives) Type II error	TP+FN (Actual positive)
	-	FP (false positives) Type I error	TN (true negatives)	TP+FN (Actual negative)
total		TP+FP (Predicted positive)	FN+TN (Predicted positive)	TP+FP+FN+TN

FIGURE 2: Confusion matrix.

Recall rate: also known as sensitivity, it can reflect the sensitivity of the classification model to each category of data set, that is, the proportion of a certain type of data that can be correctly identified by the model.

$$\text{recall} = \frac{TP}{(TP + FN)} = \text{sensitivity}. \quad (10)$$

F score: since the above two indicators are negatively correlated, in order to measure the comprehensive performance of the model on the two indicators, their harmonic mean is used as a new indicator, and the value of this indicator ranges from 0 to 1. The larger the value, the better the effect of the model.

$$F_1 = \frac{2 \times \text{precision} \times \text{recall}}{\text{precision} + \text{recall}}. \quad (11)$$

3.3.2. *Integration Algorithm.* There is no perfect algorithm model in the field of data mining. The idea of an integrated algorithm is to combine different types of algorithm models through a certain strategy, so as to improve the overall model's ability to classify data sets. There are two main strategies for ensemble learning algorithms: bagging and boosting. The main idea of the bagging strategy is to combine the results of each base classifier and then determine the final classification result of the overall model by voting, which can effectively increase the stability of the classification. When training the base classifier, a part of the data of the sample is extracted by the method of bootstrap to construct the training data set of the base classifier. This kind of "incomplete learning" is to reduce the difference between each base classifier.

4. Feature Construction of a Mental Health State Perception Model Based on Deep Learning

4.1. *Data Preprocessing.* The network log data mainly comes from a dedicated network log collection server. Through the user's application to access the network, the link data accessed by the user is collected, so as to obtain the user's network log information. The main content of the log information is: "A record of a user accessing a certain network type at a certain point in time." A sample of log information is shown in Table 1 [20].

TABLE 1: Sample table of log information.

Property name	Numerical value
Student ID	2021*****
Gender	Male
Age	Twenty-one
Point in time	2021-11-15, 00:00:00
Website name	Taobao
Site type	Shopping

Compared with the website type, the attribute of the website name is too careful and narrow, and it obviously belongs to the category of shopping. There is no need to distinguish the two. Therefore, when extracting feature dimensions from log information, the website name is not a required item. For the point-in-time information, in order to facilitate the processing of data at a point in time, it is divided into two parts: the part of year-month-day is used as "date," and the part of hour:minute:second is used as "time." The finally extracted feature dimensions are student ID, gender, age, date, time, and website type; the format is shown in Table 2 [21].

4.2. *Static Variable Analysis Based on Binary Logistic Regression.* As shown in Table 2, there are two static variables in this research, gender variable and age variable. Static variables are property variables that are basically unchanged or unchanged for a long time. Firstly, the univariate binary logistic regression analysis was performed on the gender variable and the age variable. The dependent variable was divided into three groups. The extroverted "1" and the introverted "0" were the one group, and the depression "1" and the asymptomatic "0" were the one group.

Next, a multivariate binary logistic regression analysis was performed with the combination of gender and age as the dependent variable, and the results are shown in Table 3.

It can be seen from the results in Table 3 that the results of logistic regression are the same as those of univariate analysis. Combining the results of the two analyses, it can be concluded that the gender and age factors are not statistically significant for the psychological state indicators and can be ignored.

4.3. *Feature Construction Based on Information Entropy.* This study proposes two concepts for the design and construction of features. These two concepts are regularity

TABLE 2: Network log feature dimension table.

Student ID	Gender	Age	Date	Time	Site type
2018*****	Male	Twenty-one	2018-11-15	00:00:00	Shopping

TABLE 3: Logistic regression results of gender and age variables.

	Regression coefficients	Standard error	$P > z $
Dependent variable: extroversion			
Sex	-0.0628	0.063	0.316
Age	-0.0497	0.101	0.626
Dependent variable: depression			
Sex	-0.0007	0.001	0.502
Age	0.4027	0.405	0.322
Dependent variable: anxiety			
Sex	-0.1113	0.257	0.665
Age	-0.1583	0.090	0.078

of surfing behavior and degree of dependence of surfing behavior. The regularity of surfing behavior is a measure of the regularity of students' surfing behavior of visiting different types of web pages within a period of time. The design of this regularity is based on the concept of Shannon's information entropy. According to the information entropy, the order and purity of a data set can be measured. Therefore, combined with the theory of information entropy, a method for calculating the regularity of students' online behavior is designed. Method. For example, for online shopping behavior, let Shopping Regularity be SR, set shopping times to different intervals, and the shopping frequency interval is $[0, 5]$, $[6, 11]$, $[12, 25]$, $[26, \dots]$, according to the number of times of shopping per day to determine which interval it belongs to, and finally we will get the frequency distribution corresponding to these n intervals as $C = \{C1, C2, \dots, Cn\}$, and the probability corresponding to each interval is p , and the calculation formula is as follows:

$$p_i = \frac{c_i}{s},$$

$$i = 1, 2, \dots, n, \quad (12)$$

$$S = \sum_{i=1}^n c_i.$$

Then the calculation formula of shopping regularity SR is

$$SR = - \sum_{i=1}^n p_i \log p_i. \quad (13)$$

The method of interval probability is also used to calculate the degree of dependence on online behavior. As shown above, the number of visits of a certain type of Internet access in the day is divided into intervals, and then the frequency of occurrence of this type in which interval is calculated in the statistical period. If the interval is the highest, then it is determined that the interval is dependent

on this type of network behavior. If the interval is a low-order partition, the degree of dependence is light, and if it is a high-order partition, the degree of dependence is higher. This research transforms mild dependence into number "1," moderate dependence into number "2," and high dependence as "3." When defining the interval division of the degree of dependence, two cases are considered. When accessing data of social platform type, such as when processing microblog data, it is divided into two types: browsing microblogs and publishing microblogs. The interval can be divided into $[0, 30]$ times as a low degree of dependence interval, $[31, 60]$ times as a medium degree of dependence interval, and more than 60 times as a high degree of dependence interval. The dependence degree interval for publishing microblogs can be divided into $[0, 10]$ times as a low dependence degree interval, $[10, 19]$ times as a medium dependence degree interval, and more than 20 times as a high dependence degree interval. The feature dimensions of the final constructed sample data set are shown in Table 4.

4.4. Feature Selection Based on Genetic Algorithm. After removing the uncorrelated static variables, the regularity and degree of dependence of various network types and the existence of the student ID are left in the sample data set. For each pair of labels, not all types of network behavior data are helpful for model training, and redundant data participating in the training will reduce the accuracy of the model. Therefore, this study uses the adaptive iterative ability of the genetic algorithm to perform feature selection and uses it to perform feature selection according to different label states. The iterative graph of the feature dimension obtained by the genetic algorithm is as follows: the horizontal axis is the number of feature combinations, and the vertical axis is the fitness function score, as shown in Figure 3.

When based on the internal and external trend tags, the extracted feature dimensions are 8, and the effect is the best.

TABLE 4: Sample data set example table.

Student ID	Gender	Age	Shopping regularity	Shopping dependence	Browsing Weibo regularity
*****	1	Twenty-one	2.35	2	3.25

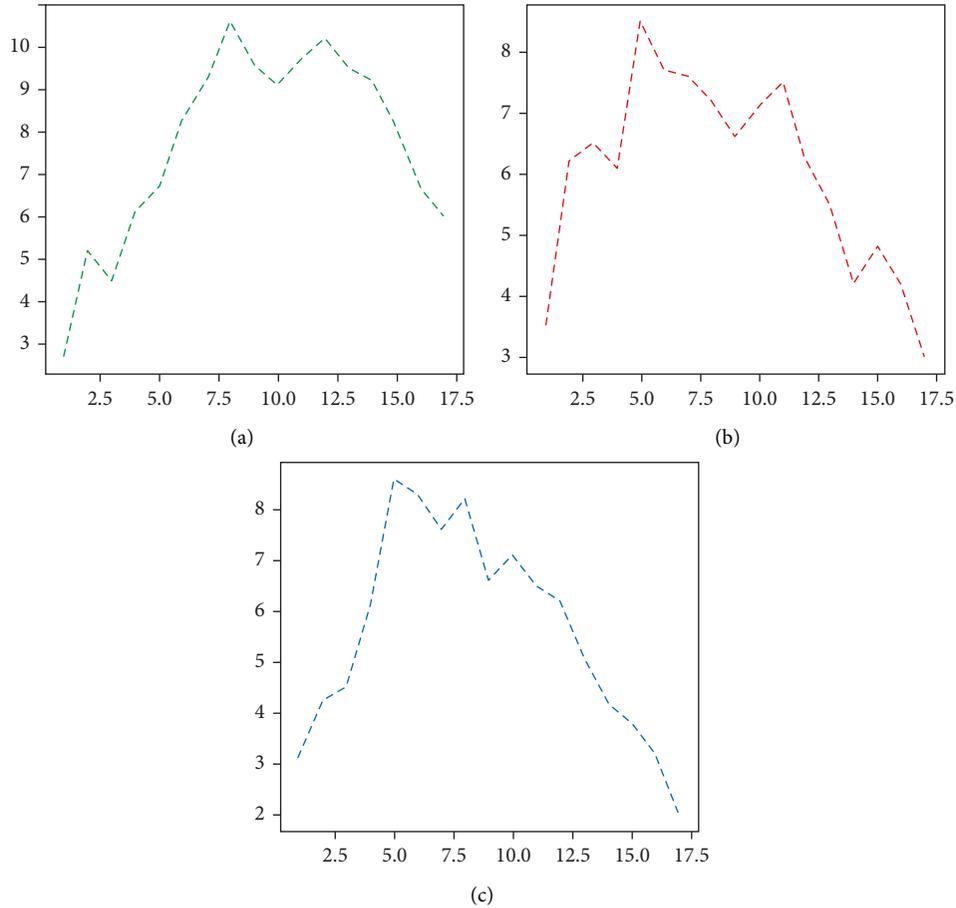

FIGURE 3: Iterative diagram of genetic algorithm.

These feature dimensions are WeChat regularity, WeChat dependence, WeChat posting regularity, Weibo regularity, video Watching regularity, video viewing regulation dependence degree, reading regularity, and reading dependence degree.

Based on the label of depression or not, the effect is best when the extracted feature dimensions are 5. These feature dimensions are shopping dependence, listening to music, WeChat dependence, map website regularity, and game dependence. Based on the anxiety label, the extracted feature dimension is 5, and the effect is the best. These feature dimensions are short video website dependence degree, information website dependence degree, music listening regularity, game regularity, and shopping regularity.

5. Experiment and Result Analysis

5.1. *Experimental Environment.* The experimental environment and related parameters are shown in Table 5.

TABLE 5: Experimental environment and configuration.

Lab environment	Environment configuration
Operating system	Windows 10
CPU	Intel(R) Core(TM) i5-6500 3.2 GHz
RAM	32G
Programming language	Python
Programming tools	Jupyter notebook

5.2. *Data Preparation.* The data used in this experiment comes from two parts, which are divided into two parts: label data and feature dimension data. The processing of these two parts of data is as follows: label data processing: when labeling the psychological state information of internal and external tendency, the data with external tendency score are classified as label “1,” and the data with internal tendency score are classified as label “0.” For the pair of labels with or without depressive symptoms, the score 4 is taken as the threshold. The data less than the threshold are classified as the label with no depressive symptoms “0,” and the data

TABLE 6: Sample data set example table.

Student ID	Shopping regularity	Shopping dependence	Weibo regularity	...	Label 1	Label 2	Label 3
*****	3.25	2	2.35	...	0	1	1

greater than the threshold are classified as the label with depressive symptoms “1.” Similarly, for the treatment of the pair of labels with or without anxiety symptoms, the score 4 is also used as the threshold. The data less than the threshold are classified as the label without anxiety symptoms “0,” and the data greater than the threshold are classified as the label with anxiety symptoms “1.” Examples of specific sample data sets are shown in Table 6.

5.3. Comparison and Analysis of Model Experiment Results.

The optimal model of the three mental state models is the random forest model, which does have a strong role in the field of classification. The parameter adjustment and optimization of the random forest model is mainly carried out through the grid search method. The parameter adjustment of the random forest mainly involves the following parameters: (1) `n_estimators`: the maximum number of iterations or the number of weak learners. If `n_estimators` is too small, it is easy to underfit, and if `n_estimators` is too large, overfitting will occur, so a suitable value for `n_estimators` is very important. (2) `min_samples_split`: the minimum number of samples required for internal node subdivision 3, `min_samples_leaf`: the minimum number of samples for leaf nodes 4, and `max_depth`: the maximum depth of the decision tree. Taking the GA-RF model of the two-category depression as an example, the process of parameter adjustment is as follows: in the first step, take `n_estimators` as the variable; the initial value is 10, and the interval is 10; and the output result is shown in Figure 4.

In the second step, (`min_samples_split`, `max_depth`) is used as the parameter combination; the starting value of `min_samples_split` is set to 100, and each change is 200; and the starting value of `max_depth` is set to 3, and each change is 2, and the output result is shown in Figure 5.

In the third step, take (`min_samples_split`, `min_samples_leaf`) as the parameter combination; the starting value of `min_samples_split` is set to 20, and each change is 10; and the starting value of `min_samples_leaf` is set to 60, and the output results are shown in Figure 6.

After comprehensively considering the above three steps, the optimal parameter combination of the depression model is obtained: `n_estimators` = 50, `min_samples_split` = 150, `max_depth` = 7, and `min_samples_leaf` = 25. Follow this step for the optimal parameters of the other two models and bring these parameters into the model. The f value of the model is shown in Table 7.

It can be seen from Table 7 that after the optimization of the model parameters, the f score of the model has been improved. For the internal and external tendency model, the f score increased from 0.765 to 0.79, an increase of 3.3%. For the depression binary model, the score of F increased from the original 0.81 to 0.83, an increase of 2.5%. For the anxiety

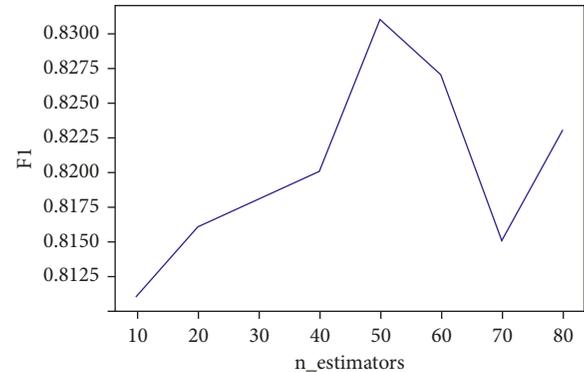

FIGURE 4: F1 values of GA-RF under different iterations.

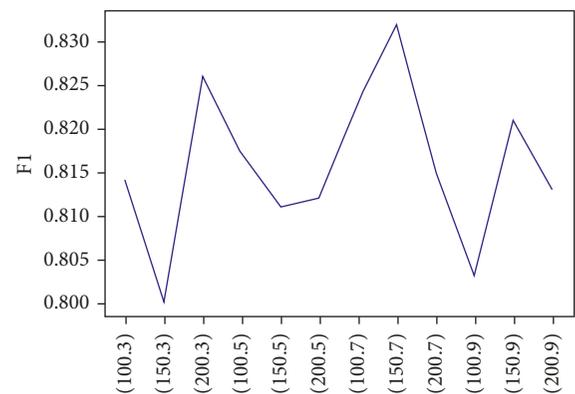

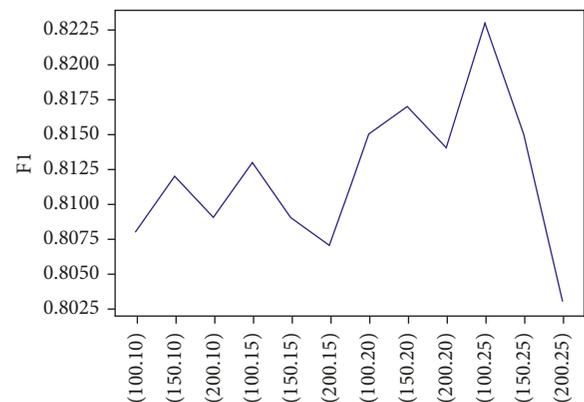

FIGURE 5: F1 values of GA-RF under different parameter combinations (`min_samples_split` and `max_depth`).FIGURE 6: F1 values of GA-RF under different parameter combinations (`min_samples_split` and `min_samples_leaf`).

TABLE 7: Model output values under optimal parameters.

Model	n_estimators	min_samples_split	max_depth	min_samples_leaf	F1 value
Internal and external tendencies	70	300	13	50	0.79
Depression	50	150	7	25	0.83
Anxiety	55	100	7	30	0.81

binary classification model, the score of f increased from the original 0.75 to 0.81, an increase of 8%.

6. Conclusion

Nowadays, the topic of students' mental health has attracted more and more attention from society. For example, the incidents of college students committing crimes and committing suicide caused by the abnormal psychology of college students have also often caused heated discussions in public opinion. At present, most of the students have insufficient understanding of mental illness or even have an attitude of neglecting and not paying attention, so these students with mental abnormalities cannot be found and treated effectively in time. These students and conducting interventions are a top priority in student management efforts. With the development of data mining technology, the construction of the data analysis model has been solved for us in terms of model analysis. This paper is based on the research on the psychological state prediction model that is used to capture students' psychological state information based on the students' online data collected on the university campus and the psychological assessment scale indicators. This research is based on the deep learning theory. The model is constructed, analyzed, and adjusted, aiming to grasp the psychological state information of students more comprehensively and accurately through the network behavior data of students in school. The results of the model experiments show that the f scores of the three models have improved. The models used in this study are only classification models in the field of machine learning, and the more popular deep learning models are not used. The next step will use deep learning. The network structure model of the aspect is used for model experiments to compare the operation of the two models.

As an important linguistic phenomenon in verbal communication, relayed speech exists in a large number of news texts and is also one of the most prominent features of the Chinese language. However, at present, there are few systematic comparative studies on the recognition of the relayed problems in Chinese language crossover, and the existing methods are highly subjective. This paper makes a qualitative comparative analysis of the reported speech in the Chinese language by the DE-BP model, which combines differential evolution (DE) algorithm and BP (backpropagation) neural network to recognize the Chinese cross-language paraphrase. After that, we obtained some meaningful findings as follows. In the Chinese language, the frequency of indirect paraphrase is the highest, followed by direct paraphrase, while other categories, namely, free indirect paraphrase, free direct paraphrase, and narrative paraphrase of speech acts, are relatively rare. Through the identification and manual labeling of reported verbs and then the word frequency statistics, it is found that the number of reported verbs in English newspapers is dominant in general, and there is a significant difference between them.

1. Introduction

Relaying speech is a basic form of human language. When people want to convey what has happened in the past, what is happening now, or what may happen in the future, either in their own words or in the mouths of others, they need to communicate through relaying speech [1]. Only in this way has human civilization survived; without speech, language has been reduced to mere communication tools. The most basic feature of reported speech is reflexivity (i.e., people use language to refer to language itself). People report not only what others say but also what others comment, criticize, and so on. Accordingly, the definition of relayed speech generally involves two features, namely, reflexive feature and two-layer structure [2]. The reported speech is defined as the speech of the words, words of words, and also the words of the words and words about words. The uniqueness is embodied in paraphrased words. Two different contexts or styles can also appear in a single syntactic structure and in the process of interaction between speakers and hearers [3].

Paraphrased words have common features in all human languages. Now, we know that all languages have been paraphrased in one way or another; even those innate configurations of bad language also have their own paraphrased way and sometimes may have to rely on contextual characteristics; paraphrased words have a certain universality in human behavior. Most languages have their own paraphrased way; as said, paraphrased words as a kind of double-layer structure in the process of the formation and development of human language are indispensable and play an important role. Every conversation is filled with numerous paraphrases and interpretations of what others have said. According to this line of thinking, every speech is actually a free translation because every speech is a patchwork of quotes, assimilation, and conversion of others' words [4, 5].

As for the terms of paraphrased speech, the usage is more complicated. For the paraphrased speech (perhaps the most well-known term so far), there is no unified opinion, and there is no consistent view among the various expressions of the verbal paraphrase phenomenon. By telling a story,

considering the ability of human memory and expression, most of the words may not be original but transferred from other people or other media [6].

The research on the recognition of Chinese language paraphrase will further enrich the research on paraphrase, which is a common phenomenon in communication, no matter in daily conversation or written discourse, which is full of a large number of other speeches. On the one hand, it can explain the ideographic meaning of public discourse, and on the other hand, it can deepen the understanding of the discourse reported by people in the news. As a language form, reported speech not only contains two speech forms and contexts but also reflects the system and essence of social communication and cognition. Analysis of relayed speech helps to show the conversational nature of language: constructive studies of dialogue, especially of relayed forms, because they reveal the basic and constant active acceptance of other speakers that constitutes the essential feature of dialogue. Human personality is only a part of the society as a whole, which is realistic from the perspective of history but productive from the perspective of culture [7, 8]. The study of reported speech is helpful to further understand the sociological essence behind these phenomena. In addition, the study of reported speech also helps to reveal the complex cognitive mechanism of human beings, including perception, storage, memory, and verbal expression, and can further enrich the different perspectives on paraphrased speech [9].

It can further verify the feasibility of the critical linguistics and corpus-combined technology. Critical discourse analysis has made great achievements in revealing the relationship between language and ideology, but criticism and doubts about it have been constantly heard. Although many scholars put forward criticisms, they also put forward many constructive suggestions, such as proposing that only reliable conclusions can be drawn based on a large corpus to strengthen critical discourse analysis. Contrastive analysis is an important means of language research [10]. It is of great academic and practical value to reveal the common and special laws between one's own language and other's language by studying other languages or by contrastive analysis of different languages. This research is faced with two main difficulties: First, the research on free translation of Chinese is not enough, and there is still a big gap in theory and category. Second, there are few direct references. Because of the above difficulties, it is of great significance to strengthen the research on the recognition methods of Chinese free translation [11].

From the perspective of application, it will help improve the level of Chinese journalists' news reporting, distinguish foreign news pitfalls, maintain the national image, improve the ability of critical thinking and reading, and enlighten the field of foreign language teaching and translation to a certain extent. From the point of communication, the success of external publicity is largely determined by the effect of information dissemination. In fact, China's current external communication capacity is far from satisfying the image of a rapidly rising power. This study is helpful in enhancing the mutual understanding between China and foreign countries,

improving the effectiveness of communication, and avoiding misunderstanding and has a strong realistic and contemporary significance [12, 13]. It gives a qualitative comparative analysis of the reported speech in the Chinese language from the types of reported speech by the DE-BP model and obtains some meaningful findings.

This section mainly introduces the research topics of discourse paraphrase in existing literature, the related research on Chinese language paraphrase recognition, and the specific application of recognition methods in news discourse, summarizes the achievements and shortcomings of previous studies, and determines the direction of this research. Discourse paraphrase is a universal phenomenon in human speech communication, which has been widely concerned by linguists, philosophers, and literary critics. Various terms have appeared successively, including quotation and paraphrase [14]. The study of language expression has always been troubled by the confusion of terms and concepts. Different terms represent different aspects of the process of language translation, and different theoretical perspectives reflect the complexity and diversity of discourse translation itself [15].

Quotation is widely used in literature, reflecting scholars' discussions on the reflexivity of language and the nature of paraphrase. In semantic and philosophical studies, quotation is a general term, and its classification is mainly based on the use and mention of language [16, 17]. From the perspective of projection structure, the juxtaposition is a quotation, while the subject-subordinate is a report. Thus, it can be seen that quotation is not very clear in terms of conceptual significance. Sometimes it refers to the quotation of abstract language expression, and sometimes it only refers to the direct quotation of concrete discourse. Quoted speech is a term widely used in linguistic research of speech paraphrase, mainly used to refer to different ways of paraphrasing another speech. It mainly focuses on the grammatical characteristics of different types of relayed speech and the rules of phase five conversion [18]. Most of the researches on discourse relayed use direct speech and indirect speech to refer to relayed speech. A relatively general term is used when discussing paraphrasing in various styles. According to the stylistic attributes of the original discourse, three direct forms of discourse are distinguished: direct speech, direct thinking, and direct writing. Thus, relayed speech is a term mainly used in linguistic research of discourse relaying [19].

As far as English is concerned, the differences between direct and indirect discourse lie in tenses, person, and the form of expression of the original discourse. In terms of morphology, direct discourse retains the original tense of the verb, while indirect discourse needs to refer to the time in the clause to move the time of the relayed discourse. Textual free translation mainly focuses on various free translations in literary works, especially the analysis of the relationship between direct speech and indirect speech. In addition to direct speech and indirect speech, there are also free direct speech, free indirect speech, and narrative paraphrase of speech act in the Chinese language [20, 21]. Direct speech has two features that can show the presence of the narrator:

quotes and paraphrases clauses; free direct speech is to remove one or two of these characteristics; The narration of speech act only conveys the occurrence of the act, but does not convey the content and form of speech, so the content of speech is not so important in this form [22].

The pragmatic study of discourse retransmission tends to explore the mode and function of discourse retransmission in context. Speech connects two discourse events. The main term used is relayed speech, and direct speech and indirect speech are used when referring to various types of relayed speech. From the perspective of linguistic function, the paraphrase is referred to as the signal sound in the text: if the speaker or writer in some way signals the presence of another voice in the text, then any paragraph derived from that voice [23, 24]. Free translation is a misleading term that means that one can freely translate the words of another while retaining the nature of the original speech. The term used is constructed dialogue: framing discourse as dialogue is not paraphrasing but a recontextualization of words within the current discourse [25]. In the study of discourse free translation, free translation is a topic that scholars pay most attention to. The early studies mainly describe the grammatical characteristics of various types of reporting and the rules of conversion from direct speech to indirect speech under the influence of structuralism. When people want to paraphrase what they have said before or what someone else has said, there are two ways: give the exact expression of direct speech used by the original speaker; modify indirect discourse according to the relayed context [26].

The function of discourse retransmission is closely related to various ways of discourse retransmission [27]. This section mainly introduces the attitude of the narrator and the pragmatic functions of discourse retransmission in the specific discourse. In the sequence of relayed speech, direct speech is the conventional pattern, and from direct speech to the right, the sense of freedom gradually strengthened. Free indirect speech is on the more indirect side of the speech expression gradient, allowing the narrator to take two perspectives, creating a distance between the reader and the character's words and inserting the author's voice, resulting in a satirical effect. The sound effect of direct speech is a kind of guidance and quotation, not indirect speech with direct speech mixed with narrative language. It provides the narrator with a summary of the character's language, and can speed up the contrast between the narrator's direct speech and the interrogative speech and control the dialogue [28].

The narrative of speech act has the function of highly checking and concealing and turning the human and object discourse into speech act to narrate, and the author exercises the biggest intervention right. The recognition of discourse paraphrase focuses on the stylistic effects of various paraphrase types in literary works, and its advantage lies in that these categories are regarded as a conscious paraphrase of any words or thoughts by the author through the choice of structure. Attitude refers to the current relayed on the original information or speaker evaluation, including neutral, positive, and negative [29]. Therefore, no matter how precise the paraphrased words may be and no matter how pure the motives of the paraphrase may be, removing a

passage from its original context and recontextualizing it in a new network of relationships are bound to interfere with its original effect [30]. Functional research of discourse paraphrase is reflected in two aspects: the intervention and paraphrase of the relayed discourse and the pragmatic functions of discourse in the whole discourse. Stylistics studies have shown that different ways of paraphrases and narrator paraphrases are related to the degree of involvement as reported speech. Recent empirical studies have fully demonstrated that discourse paraphrasing appears in different types of discourse and has multiple functions. On the one hand, citing the discourse of others can provide an objective basis for the current discourse. And different free translation methods reflect the differences between subjects. From the perspective of the existing research on speech paraphrase, the research on speech paraphrase recognition has gradually moved from static grammatical description to dynamic pragmatic study, and significant findings have been obtained [31].

This paper mainly uses the DE-BP method to study the recognition problem of Chinese cross-language paraphrase, which is beneficial to verbal communication. This research mainly consists of four parts. The first part introduces the research background and significance of comments on the framework of this paper. The second part mainly introduces the DE-BP-based Chinese cross-language paraphrase recognition. The third part introduces the experimental results and analysis. The fourth part is the summary part of this research.

Based on the above analysis, the main contributions of the paper are shown as follows:

- (1) It makes a qualitative comparative analysis of the reported speech in the Chinese language by the DE-BP model
- (2) It is found that other categories, namely, free indirect paraphrase, free direct paraphrase, and narrative paraphrase of speech acts, are relatively rare
- (3) It is found that the number of reported verbs in English newspapers is absolutely dominant in general, and there is a significant difference between them

2. DE-BP-Based Chinese Cross-Language Paraphrase Recognition

2.1. Chinese Cross-Language Paraphrase Recognition. Chinese cross-language paraphrase recognition is the restriction of the various contextual factors, making it impossible to accurately reproduce the original discourse, and this research fully reveals that the speech paraphrased the complex characteristics of a speech act; however, the research on fidelity of speech transmission is also lacking of detailed description, because the specific forms of speech reporting are closely related to fidelity. In a specific context (e.g., news context), what is the similarity or arbitrariness between the paraphrase and the original discourse? In addition, the relationship between various forms of retransmission and the authenticity of the content of retransmission needs further investigation. The typical Chinese cross-

language paraphrase recognition process is given in Figure 1, in which the meaning A is interpreted from the end of the original sentence and assigned the corresponding importance weight, finally obtaining the cross-language interpretive awareness.

As can be seen from the figure, the research trend of discourse paraphrase has shifted from static description to pragmatic function of discourse paraphrase in a specific context, revealing the essential characteristics of discourse paraphrase and the contextual factors that influence the choice of discourse paraphrase. Words can be seen from a sentence input, paraphrasing words is essentially a process of the project, and another word is a token of the characterization and again is weaker than the restatement of the literal type, factors influencing the discourse context of conveying including before the words and the words of the various factors, especially the restriction role of conveying paraphrased context of discourse.

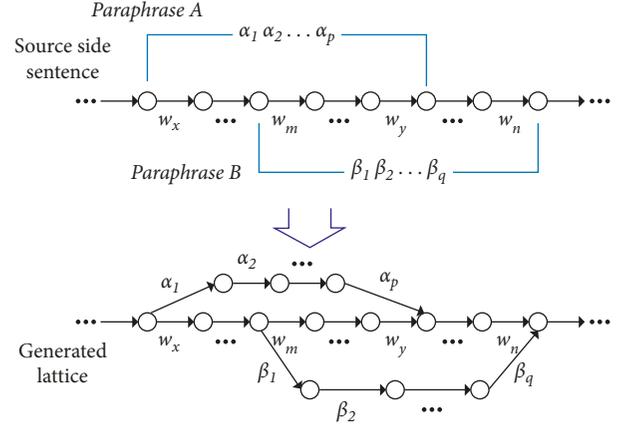

FIGURE 1: The typical Chinese cross-language paraphrase recognition process for an input sentence.

2.2. DE-BP Model. Based on the above discussion, the BP (backpropagation) neural network is used here to solve the problem. By simulating the neural function of the human brain, the data samples are learned, and the link weights and thresholds between units are established to deal with complex nonlinear problems without specific functional forms. According to the error between the actual value and the expected value, from the output layer through the hidden layer to the input layer, the link weight between each layer is revised layer by layer. By iteratively correcting the weights, the gap between the observer and the predicted value becomes smaller and smaller, and the model performance becomes better and better. When the error is less than a certain value, it indicates that the network training is completed.

$$E = \sum_{i=1}^m (x_i - c_i)^2. \quad (1)$$

Then, we expand the above error definition to the hidden layer:

$$E = \frac{1}{2} \sum_{k=1}^l [d_k - f(\text{net}_k)]^2 = \frac{1}{2} \sum_{k=1}^l d_k - f\left(\sum_{j=0}^m \omega_{jk} y_{jk}\right)^2. \quad (2)$$

We expand further to the input layer; there is

$$\begin{aligned} E &= \frac{1}{2} \sum_{k=1}^l d_k - f\left[\sum_{j=0}^m \omega_{jk} f(\text{net}_j)\right] \\ &= \frac{1}{2} \sum_{k=1}^l d_k - f\left[\sum_{j=0}^m \omega_{jk} f\left(\sum_{i=0}^n v_{ij} \chi_i\right)\right]^2. \end{aligned} \quad (3)$$

It can be seen from the above formula that the network input error is a function of the weights of each layer, so the error can be changed by adjusting the weights. Obviously, the principle of adjusting weights is to reduce errors continuously, so the weights should be proportional to the gradient descent of errors:

$$\Delta \omega_{jk} = -\eta \frac{\partial E}{\partial \omega_{jk}}, \quad j = 0, 1, 2, \dots, m; k = 1, 2, \dots, \ell, \quad (4)$$

$$\Delta v_{ij} = -\eta \frac{\partial E}{\partial v_{ij}}, \quad i = 0, 1, 2, \dots, n; j = 1, 2, \dots, m.$$

Then, the weight adjustment formula of each layer is

$$\Delta \omega_{jk}^{h+1} = \eta \delta_{h+1}^k y_j^h = n(d_k - o_k) o_k. \quad (5)$$

According to the above rule layer-by-layer analogy, the weight adjustment formula of the first hidden layer is as follows:

$$\Delta \omega_{pq}^1 = \eta \delta_q^1 \chi_p = \eta \left(\sum_{r=1}^{m_2} \delta_r^2 \omega_{qr}^2 \right) y_p^1. \quad (6)$$

There are some problems such as slow convergence speed, poor performance, uncertain learning rate, and easy to fall into local minimum. A proposed optimization algorithm for the traditional BP neural network, in the whole calculation process, generally exists in the local extremely small convergence speed and sometimes even oscillation and divergence problems to overcome its limitations in the traditional BP neural network. The differential evolution (DE) algorithm is introduced into the neural network to optimize the initial weights and thresholds of the network, which shows better nonlinear mapping ability and improves its prediction accuracy. Population initialization is as follows:

$$x_{i,1} = x_i^L + \text{rand}(x_i^U - x_i^L), \quad i = 1, 2, \dots, NP. \quad (7)$$

The mutation operation formula is as follows:

$$v_{i,G+1} = x_{r1,G} + F(x_{r2,G} - x_{r3,G}). \quad (8)$$

Then the interlace operation is as follows:

$$u_{ji,G+1} = \begin{cases} v_{ji,G+1}, & r_j \leq CR \text{ or } j = \text{rand}(i), \\ x_{ji,G}, & r_j \geq CR \text{ or } j \neq \text{rand}(i). \end{cases} \quad (9)$$

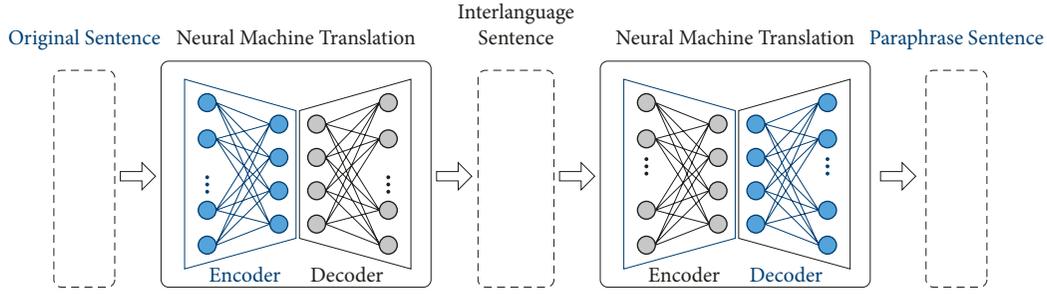

FIGURE 2: DE-BP-based Chinese cross-language paraphrase recognition frame.

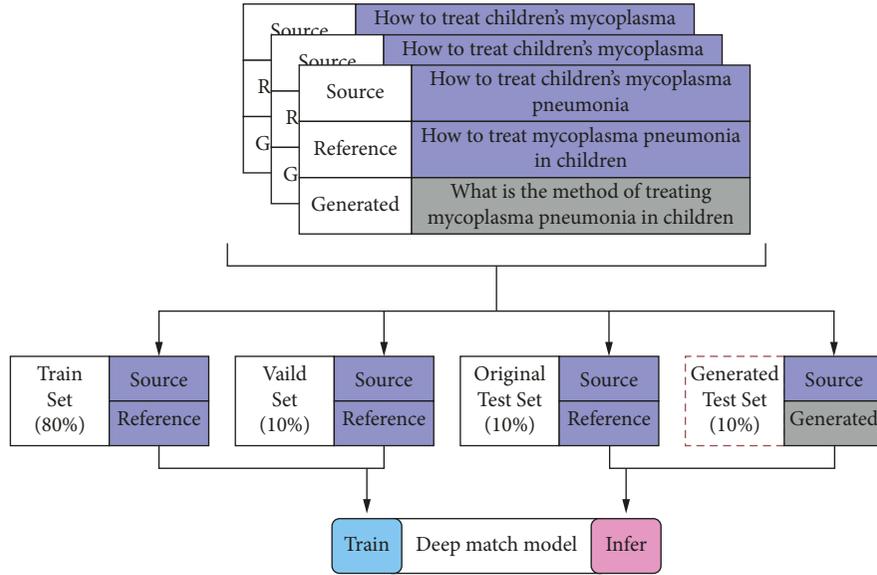

FIGURE 3: The process of similarity calculation.

Formulas (7)–(9) mainly study the mutation operation formula and interlace operation.

Accordingly, the selection operations are as follows:

$$x_{i,G+1} = \begin{cases} u_{i,G+1}, & f(u_{i,G+1}) \leq f(x_{i,G}), \\ x_{i,G}, & f(u_{i,G+1}) > f(x_{i,G}). \end{cases} \quad (10)$$

The fitness function is

$$f(X) = \sqrt{\frac{1}{N} \sum_{i=1}^N (Y_i^0 - Y_i)^2}. \quad (11)$$

Based on (1)–(11), Figure 2 gives DE-BP-based Chinese cross-language paraphrase recognition proposed in this paper, which mainly includes the original sentence, the neural machine translation, the interlanguage sentence, the neural translation, and the paraphrase sentence.

3. Experimental Results and Analysis

3.1. Introduction to Experimental Dataset. This study mainly adopts the method of corpus research and combines

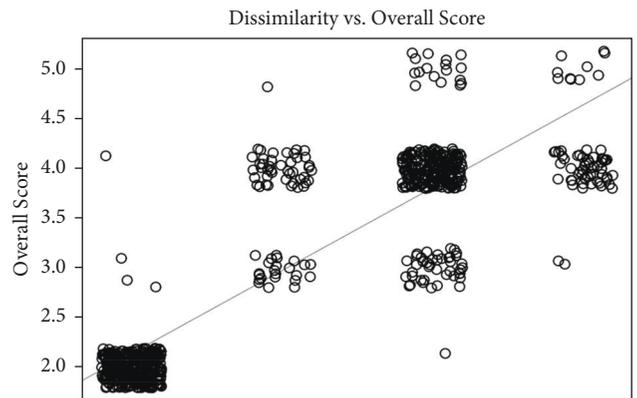

FIGURE 4: The relationship between Chinese paraphrase accuracy and corpus similarity.

quantitative statistics with qualitative analysis. First of all, we collected news texts from People’s Daily for consecutive months and established a large database. Then, according to the research purposes of different chapters, we extracted samples from the main corpus and built a secondary corpus. For some chapters, we also classified and collected them according to the subject needs. Then, we sorted all the

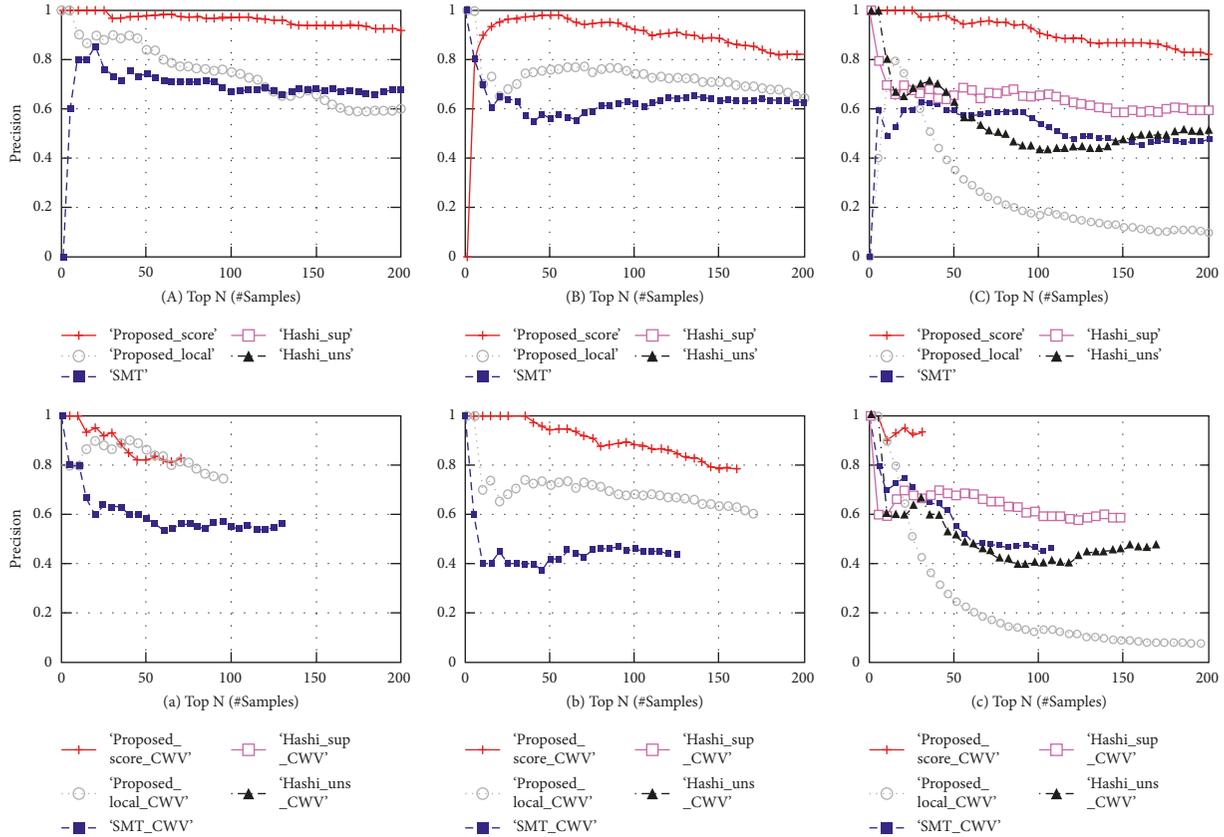

FIGURE 5: The recognition accuracy: English (a), Chinese (b), and Japanese (c).

subcorpora in each chapter of the newspaper into text documents to establish a pair of subcorpora.

In corpus collection, we mainly consider the following issues: the collected newspaper texts are all issued in years to reflect the recent situation. The establishment of the Chinese newspaper corpus should not only pursue the size but also consider whether it can fully explain and fit the research objectives of this paper.

3.2. Experimental Result Analysis. After establishing the cross-language recognition method based on the DE-BP algorithm, the established method is verified based on the data of 3.1. The specific simulation results are described as follows: after the corpus is established, we will mark the corpus of each section. Indirect reporting is judged by the absence of quotation marks and the use of the third person; free direct paraphrase is mainly in quotes without leading sentences. Among them, the indirect paraphrase is the residual form of indirect speech, which needs to be judged according to the specific context.

The main characteristic of narrative paraphrase of speech act is that it usually centers on a paraphrase verb or is used alone or forms a verb-object structure to indicate who performs a speech act. The specific results of similarity calculation between corpus are shown in Figure 3. The main purpose of the results of the graph is for the subsequent Chinese language paraphrase recognition service.

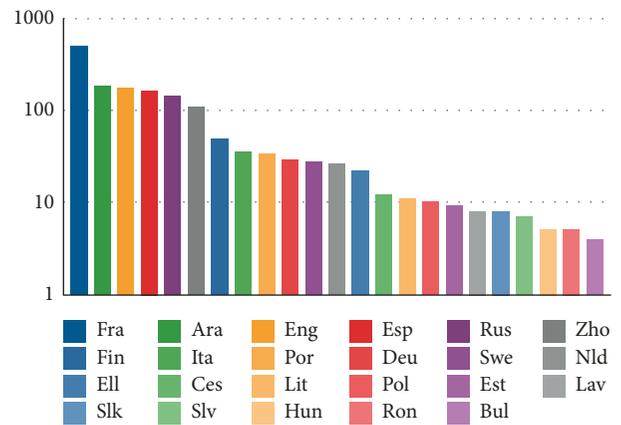

FIGURE 6: A graphical representation of the size of the set of definitions for each language.

Finally, we use two sets of classification models to analyze the sources of information: the former takes the proper nouns and pronouns that appear in the discourse to represent people or organizations as the judging criteria. According to the categorization of definite degree, the definite source of information generally has a surname or a given name, uses a definite noun phrase, or uses a definite anaphora or anaphora pronoun. Ambiguous sources are represented by indefinite noun phrases or by coreferential pronouns with no definite identity in the context. Sources

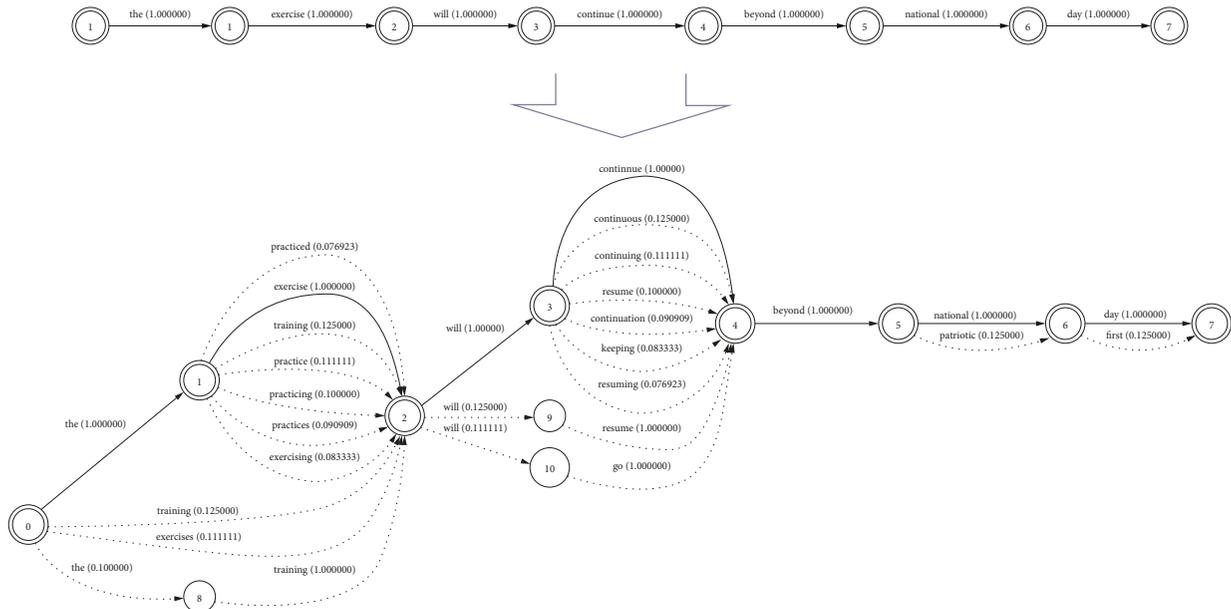

FIGURE 7: The example of a paraphrase process for an input Chinese sentence.

that cannot be identified are more complex, use the passive voice of the hidden actor, or use an unidentifiable noun structure, prepositional phrase construction that conceals the source, or some other vague expressions. Since the similarity is calculated in Figure 1, based on the obtained similarity, the relationship between Chinese paraphrase accuracy and corpus similarity is shown in Figure 4, as can be seen from the figure above. The higher the similarity is, the higher the recognition accuracy will be, and vice versa.

The recognition accuracy of Chinese cross-language paraphrase by different algorithms is shown in Figure 5. The curves are drawn from 2,000 samples, with each dot representing 50 samples. Then, we analyze the extent to which all methods of free translation are related to content word variation extraction. The bottom half of Figure 5 shows the results of the evaluation (curves labeled with CWV). PosedScore’s sample size was significantly reduced compared to English and Japanese, but accuracy remained high. This is mainly due to the linguistic crossover caused by globalization.

In addition, the graphical representation of the size of the set of definitions for each language is shown in Figure 6. It can be seen from the figure that we extracted a significantly different number of identifying definitions for each language. The number of free translations generally varies greatly in size from the collection of French, Arabic, and Chinese free translations and other free translations used to extract free translations for that language. This is because we used a relatively large bilingual corpus for these three languages and a smaller recognition scale for the other languages, resulting in similar recognition results.

In the traditional sense, indirect speech is characterized by the use of the third person as the subject of the introductory sentence, and then the related sentence usually uses an object clause, as well as the moving of the verb tense, such as the present tense to the past tense. In addition, the words and phrases about time and place should be changed

accordingly, such as today to yesterday. In addition, it should be pointed out that those paralinguistic features originally directly reported are also lost; for example, pronunciation and intonation, omission of address forms, and gestures and expressions are simplified or lost. Because individual words are separated from the original discourse, they have been broken away from the original grammatical structure and lost the original context, and the semantics have changed, or even the opposite.

Figure 7 gives the example of a paraphrase process for an input Chinese sentence. Figure 2 shows nodes (double circles) and edges (solid lines) from the input sentence by the original word, and at the bottom, Figure 2 shows the last lattice of new nodes (single-line circles) and new edges (dashed lines) from the paraphrase. It can be seen that the proposed method increases the diversity of source phrases and thus provides more flexible translation options in the decoding process.

4. Conclusions

The use of various paraphrasing strategies shows that the news paraphrase controls and manipulates the paraphrase; even if the paraphrase is highly similar to the original language, it will deviate from the original speaker’s intention in a specific context.

On the whole, it is the way in which the Chinese language paraphrases behavior. The diversity of choice of diction and its influence on similarity reflects the conventional choice of paraphrase under the constraints of institutional context. However, the strategic regulation of news relaying behavior in the process of original discourse event itself (such as the adjustment of information type, information state, and amount of information) and relaying expression fully reflects the active choice of the relaying behavior under the influence of various institutional context factors. On the one

hand, it reflects the adaptability of news discourse reporting behavior, and on the other hand, it also reflects the subjectivity of news discourse reporting behavior. However, the research in this paper is only limited to small Chinese language paraphrases data. Big data and multiple kinds of data will be the focus of future research [32].

3D animation stereo space design is to process and analyze the collected target image information on the computer and finally obtain a 3D model that can represent the corresponding structure. As a branch of computer vision, 3D animation stereo space design is an important part of realizing the key technology of environment perception. What humans see in the three-dimensional world is a two-dimensional picture. Combined with the visual mechanism and the prior information of the object, it can realize the perception of the environment and promote the convenience of life and production. Games, movies, virtual humans, and any product that uses 3D technology require 3D engine support. The 3D engine encapsulates hardware operations and graphics algorithms and can manage a large number of texture and model resources to construct complex 3D scenes. In order to facilitate the research related to virtual human, in this paper, through the research and study of graphics-related mathematical knowledge and related technologies of engine architecture, an intelligent virtual animation generation engine based on DirectX12 is realized, and three-dimensional characters are controlled through related components, and the function of each module is tested and guaranteed. Test cases were designed to test the various functions of the engine and finally showed that the design goals in the demand analysis have been completed, and a lightweight three-dimensional animation three-dimensional space model has been realized.

1. Introduction

The emergence of digital technology has widened the expression space of animation art with its own advantages. It has brought new opportunities to animation art and scene design. According to the current research situation of scene design, in the conception method of animation scene design, people have formed thinking methods such as establishing the overall modeling consciousness, grasping the theme, determining the tone, and exploring unique and appropriate modeling forms. In terms of the expression of space in the scene, there are some specific methods for the elements and classification of animation scene and the methods of shaping the scene, such as using the sense of gravity, strengthening the depth of field, and using character scheduling. In the traditional scene design, there is also a certain theoretical basis for the light and shadow modeling and color creation in the scene. Light and shadow play an important role in

animation film scene design, such as shaping space, creating atmosphere, and creating suspense. Nowadays, in the animation scene design, the design and research of furnishings and props are also an important aspect. In the film, they play an important role in explaining the character's identity, shaping the psychological space, depicting the task character, and setting off the task emotion. With the rapid development of the animation industry, the term "scene design" is gradually known to people, but from the previous development, film and television animation scene design is often ignored in the animation industry and animation theory circle. From the perspective of professional training and theoretical research, it is basically in its infancy. For digital scene design, in terms of the research on the characteristics and performance methods of scene design, there is still room for further research. There are only a few books on scene design in the market, which often elaborate scene design from the perspective of two-dimensional animation

or basic theory, without involving some characteristics of digital level. This paper attempts to build a lightweight 3D rendering platform that can quickly combine some intelligent algorithms with character control through the intelligent control framework to realize the interactive 3D animation space based on the natural user interaction interface [1–9].

2. Related Works

Since the 1970s, foreign countries have carried out a lot of research on graphics and engines. After half a century of development, a number of very excellent 3D software companies have been born. They include Discreet (later merged by Autodesk), Epic Games, Unity Technologies, Id Software, etc. These companies have played a great role in the development of computer graphics and the promotion of 3D engines and have produced rendering engines such as 3ds Max, Maya, Unreal, Unity, and Blender. These engines are widely used to this day. Later, more special 3D engines were born. Zbrush developed by Pixologic is a 3D engine for sculpting modeling, Houdini developed by Side Effects Software focuses on special effects design and terrain editing, Substance Painter and Substance Designer developed by Allegorithmic are mainly used for texture material design, Marvelous Designer developed by Foundry Video Effects Company realizes clothing tailoring and cloth simulation, and Daz 3D produced by Daz Production Company can edit high-quality character models. The current hot direction in the generation of 3D human animation is to reduce the cost and increase the restoration degree of animation. Abroad, Ryo et al. proposed a method to create a spatial 3D model using the Kinect sensor. The 3D information of the space is obtained from the Kinect sensor, and the 3D model is created by synthesizing the images and the obtained 3D information. Kunlin et al. parameterized the standard model according to anthropometric parameters. Then, the Kinect depth map of the human body model was optimized by processing and matching the point cloud data by using the PCL library. Quick integration with the PCL library yields a realistic human model. A new method for 3D human modeling based on a single Kinect was obtained by using an iterative closest point algorithm to register the captured upper human 3D point cloud data with standard reference human data. Zhang et al. proposed a highly personalized human modeling analysis method based on a single Kinect. First, a high-precision human positioning point cloud based on a single Kinect is obtained, and then, on the basis of ensuring the accuracy of the head of the point cloud, the point cloud information is preprocessed. Finally, by using hierarchical compactness to support radial basis functions (CS-RBFs), a 3D human body model is obtained by fitting the sampled point cloud to the existing human body. At present, there are few related papers on directx12 and Vulkan. Some articles have a clear description of the modules of the 3D engine. Compared with the above research, this research is more inclined to extend from the 3D animation design, from the basic data structure design to the implementation of related technologies [10–19].

3. Key Technologies of 3D Animation Stereo Space

3.1. Scenario Management Technology. 3D characters and their environments can be collectively referred to as 3D scenes. The 3D engine needs to fully describe the scene and each object in it in order to integrate various model data and present them on the computer screen. According to different application requirements, the scene management technology in the engine can be divided into two categories:

- (1) Scene management based on space division: this technology includes a variety of space conversion and division algorithms, including quadtree, octree, and Bsp tree. The core is to establish a hierarchical structure according to the spatial distribution relationship of objects, and the nodes in the tree represent an area of space where objects are stored on leaf nodes. This type of scene management mainly uses the tree structure to quickly locate scene objects, optimize collision detection, and view frustum culling [20].
- (2) Scene management based on parent-child relationship: this management technology is also called “scene graph.” The core is to establish a hierarchical tree structure based on the parent-child affiliation of objects. The nodes in the tree are objects with local transformation attributes, and the world transformation is obtained by passing the local transformation between the parent and the child. This type of scene management mainly records the transformation transfer direction through a tree structure, so as to perform the overall transformation of multi-component objects. In the space partitioning technology, nonleaf nodes represent a space region and are mainly used for the efficiency optimization of internal computing.

In the scene graph, nodes represent objects with local transformation properties, which is convenient for batch manipulation of scene objects. After many 3D software tests, scene graph technology is very suitable for developers to create and design 3D scenes. Since this article focuses on the display of 3D characters and their environments, this article will focus on the technical details of the latter.

3.2. Character Animation Technology. 3D animation is one of the core technologies of virtual characters. Excellent animation performance can not only increase the authenticity of the characters but also enrich the interactivity of the characters. Animation technology has undergone a long history of evolution, but currently the most widely used animation technologies are mainly in the following two categories:

- (1) Vertex animation and vertex animation texture technology (VAT): vertex animation directly records the spatial position of each vertex of the model mesh, which can simulate very complex animation

scenarios. This animation technology is often used to simulate some very real object systems such as cloth and fluid. However, in the early stage, due to the large storage space required for vertex animation and the difficulty of mixing and reusing, it was rarely used in real-time systems. With the development of GPU hardware, the vertex animation texture (VAT) technology was born. For an animation with n vertices and a time length of f , the coordinates of the vertices at each moment are stored in a texture of size $n * f$: animation texture sampling is performed in the vertex shader, and the pose transformation of the vertices is performed. The animation texture technology is often used for thousands of identical animated objects in the picture. It can greatly improve the efficiency of animation operation [21].

- (2) Skeletal animation consists of two parts of data: the skinned mesh and the skeleton. The skinned mesh records the index of the bones affecting the vertices, and the skeleton records the parent-child relationship between the bones, as well as the local coordinate transformation curve of each bone. Through the local coordinate system transfer technology in the scene graph, the bone pose at a specific moment is calculated, and then the bone animation is mixed according to the bone index recorded by the vertices of the skinned mesh to obtain the final vertex coordinates, specifically as shown in Figure 1.

In the binding pose, set the palm bone world transformation matrix to $\text{WorldMat}_{\text{Bind_Bone}}$ and the thumb mesh world transformation to $\text{WorldMat}_{\text{Bind_Finger}}$; the offset matrix formula is as follows:

$$\text{WorldMat}_{\text{Bind_Bon}} = \text{Worldmat}_{\text{Bind_Finger}} \text{WorldMat}_{\text{Bind_Bone}}^{-1} \quad (1)$$

The original coordinates of the mesh vertices are multiplied by the offset matrix to obtain the mesh vertex coordinates under the bone coordinate system and then multiplied by the skeletal animation matrix at a certain time to obtain the mesh vertex coordinates under the world coordinate system. The formula is as follows:

$$\text{WorldMat}_{\text{Anim_Finger}} = \text{OffsetMat}_{\text{Finger2Bone}} \text{WorldMat}_{\text{Anim_Bone}} \quad (2)$$

3.3. Rendering Technology. The quality and efficiency of 3D rendering are closely related to the effect and fluency of character display. For the choice of rendering technology, it is necessary to consider satisfying complex materials and enriching the content of the picture and also consider maintaining the frame rate as much as possible in some extreme cases. Today's rendering technologies are mainly divided into two categories:

- (1) Ray tracing/path tracing rendering technology: the core idea of ray tracing rendering technology is to shoot multiple rays from the camera toward the

screen pixels, use the scene management based on space division, accelerate the intersection and reflection of scene objects, and calculate the direct light source, the contribution of the indirect light source to the pixel, and finally the actual brightness.

- (2) Rasterization rendering technology: rasterization technology mainly maps the triangle surface transformation in all mesh models to the screen space through perspective projection and then disassembles them into pixels and obtains the actual brightness of pixel coloring according to the scene lighting information. Ray tracing technology is a rendering framework that can solve global illumination and can bring quite realistic lighting effects, but due to the need for a large number of ray calculations, it is often only suitable for offline rendering areas. For real-time rendering, most engines still use rasterization rendering architecture. In order to improve the real-time performance of interactive characters, this article will also use rasterization rendering technology as the rendering core. According to the different processes of rasterization rendering, it can be divided into the following two categories: forward rendering and deferred rendering.

3.4. Interactive Technology. Interactive intelligent characters are often able to respond to external input, as shown in Figure 2.

The technology in which machines process external input and feedback response is called human-computer interaction. Human-computer interaction technology can be divided into the following three categories according to the development period:

- (1) Input interaction based on command line interface (CLI): command line input interaction is the earliest human-computer interaction technology. The user inputs instructions through the keyboard, and the computer processes and feeds the results back.
- (2) Input interaction based on graphical interface (GUI): GUI is the most common interaction mode today, and most 3D games and interactive videos use graphic interaction technology.
- (3) The input interaction based on natural user (NUI) is more natural and humanized than the previous two interaction methods. The user can control or interact with the virtual character through body movements and voice information. Restricted by hardware devices, in this way, the interaction between virtual characters and real users is more natural and harmonious. as shown in Figure 2.

4. Design of 3D Animation Three-Dimensional Space Model Based on Virtual Reality

4.1. Component System Design. The core of the traditional component system is as follows:

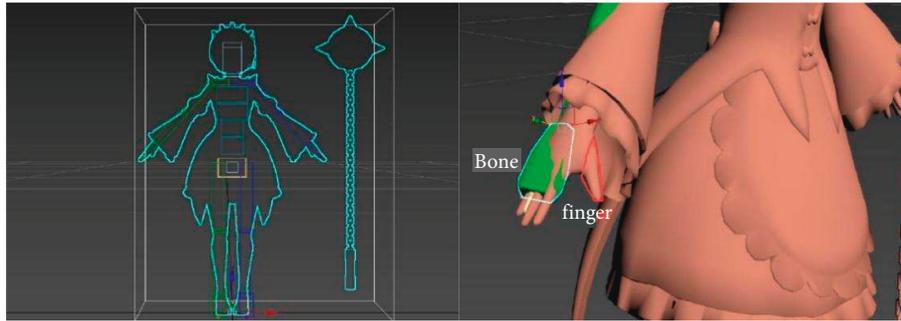

FIGURE 1: Bounding box view of the rig in 3 ds max.

FIGURE 2: The virtual human receives external input.

- (1) Each component inherits from a component base class and implements the Update function in the base class.
- (2) There is a component list inside the entity class, which directly stores the base class component pointer. If the entity of the traditional component system is accessed through the System, the System will traverse the component list in the entity to determine whether it has all the required components, as shown in Figure 3.

In this working mode, the component data pointed to by the pointer is discrete. When the System operates a large number of entities, the Cache hit rate is not high, causing frequent page replacement and even page “jitter.” In order to store component data in contiguous space as much as possible, all components of all entities are placed in a contiguous memory block. In this version, the data between entities is discrete, which will reduce the Cache hit efficiency when operating a large number of entities. Since the separation of data and operation functions is achieved, the data should be stored continuously, as shown in Figure 4.

As shown in Figure 4, the same components of all entities are stored together, but, for example, Entity2 does not contain the HealthCmpt component, while Entity1 and Entity3 do not contain the AttackCmpt component. When all the entity components are stored together, there will be gaps, making the entity and the corresponding component data. Location relationships are not easy to manage. Therefore, a better method is to put the component data of

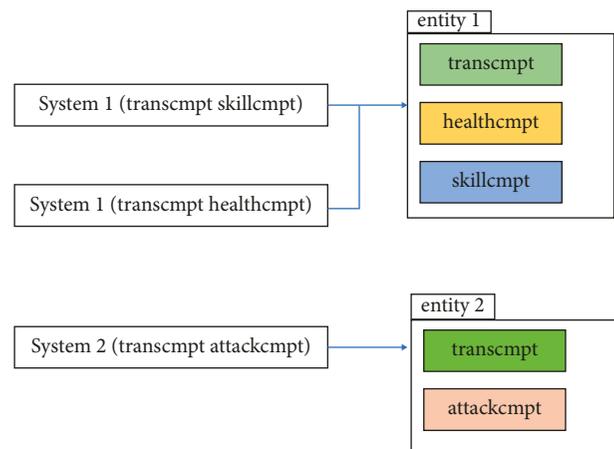

FIGURE 3: List of components in the system access entity.

entities with “similar components” in an Archetype, as shown in Figure 4. Entity is only used as an index pointing to the Archetype to indicate the location of the data contained in the entity in memory. There is a memory pool implementation in Archetype, and each block of memory is divided into a fixed size, which is convenient for memory alignment and improves the efficiency of continuous data reading, specifically as shown in Figure 5.

Component addition or deletion is an important function of ECS. The operation process design is shown in Figure 6.

4.2. Local Coordinate System Transfer Design. Many 3D animation engines, including 3 ds Max, Unity, and Unreal, build scenes through SceneGraph. SceneGraph is a multifork tree that records the parent-child relationship between scene nodes. In the engine, the transform of the parent node property changes that affect child nodes is called parent-child pose transfer. The effect of the translation operation on subsequent nodes is very intuitive. Only the translation transformation of the parent node is directly applied to the child nodes, as shown in Figure 7.

But when it comes to the rotation and scaling of the parent and child classes, the child class will appear in an unbelievable shape, as shown in Figure 8.

It can be seen that the scaling of the parent class is not directly used for the subclass objects but produces “nonequal

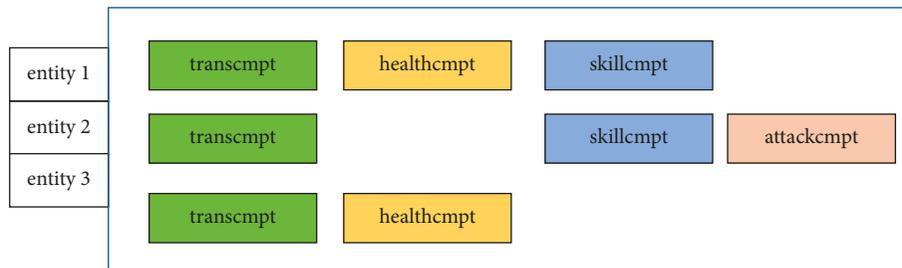

FIGURE 4: Contiguous storage of components.

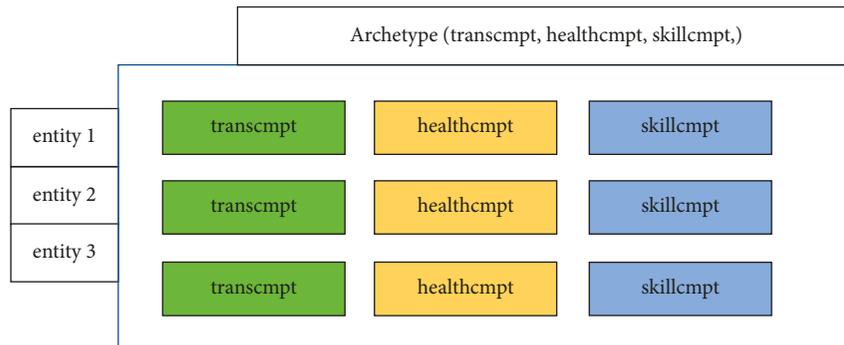

FIGURE 5: Centralized storage of entity with the same components.

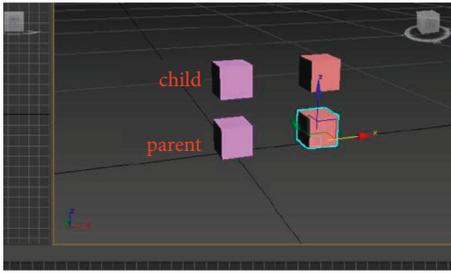

FIGURE 7: The effect of translation operation on parent and child nodes.

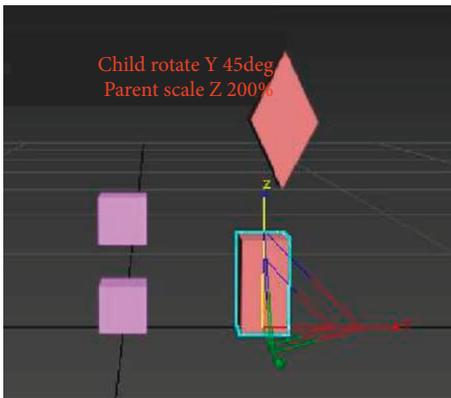

FIGURE 8: The effect of rotation and scaling on parent and child nodes.

scaling with angles” according to the rotation of the subclass. Nonequal scaling with an angle can be used as an example with a cube, as shown in the figure below. Double scaling with an angle of 45 degrees will result in what is shown in Figure 9.

Unequal scaling with angles can be split into two rotations and one scaling. For example, double scaling with a 45-degree angle is equivalent to the following: first rotate the coordinate system counterclockwise by 45 degrees to get the blue color shown in Figures 5–13, extend the new coordinate system to double the Y-axis direction, and then rotate the coordinate system 45 degrees clockwise to return to the original black coordinate system.

In order to store and load the scene, the basic data needs to be serialized and deserialized. Serialization and deserialization mean that all types of data are uniformly converted into binary and then stored in binary form or transmitted over the network. Relatively, when the file is read and the network is received, it is written according to the binary. The order of input is restored to the corresponding data structure.

A large amount of continuous data of the same type such as grids and animations can be read and written in binary using traditional data structures such as Vector. But sometimes it is necessary to record not only the value of the data, but also the dependencies between the data. The SceneGraph that represents the scene structure is this kind of

data with dependencies, including the parent-child relationship between scene nodes and the mount relationship between entity and component. This kind of dependency obviously cannot be recorded with traditional data structures.

The data structure relationship designed in this paper is shown in Figure 10. This kind of inclusion relationship is very suitable for storing with JSON. JSON is a typical data structure that can be nested. It is very suitable for recording complex hierarchical data relationships. Many games in the market use JSON to store complex character attributes and level progress. Similarly, JSON can also be used to store the hierarchical relationship of SceneGraph. Another advantage of the JSON data structure is that it is convenient to add properties to JsonNode in the form of Key-Value, which is just suitable for storing resource indexes in material components and mesh components. There are many C++ JSON open-source libraries on GitHub. This article will use the cJSON open-source library to JSONize the scene structure. JSON data will change size according to the depth of SceneGraph, and it is also dynamic data, similar to Vector and String formats. When serializing JSON data, size is also required for reading and writing.

Through the serialization of static data and dynamic data, this study designs the following binary file structure. By storing and reading the binary file of this structure, the storage and restoration of 3D rendering scenes are basically realized, as shown in Figure 11.

4.3. Graphic Rendering Design

4.3.1. GBuffer Design. The first texture of the GBuffer can be used to record the normal information of the object. The normal may be the built-in normal of the object vertex, or the sampled normal calculated by the normal map and the surface tangent. The three-dimensional normal vector can be obtained through the text. The mentioned “normal compression formula” compresses the normal information into two dimensions. The second texture of the GBuffer can be used for the diffuse reflection color of the object. The diffuse reflection color will be obtained by sampling the diffuse reflection texture of the object material in the shader of the GBuffer. The first three channels of the four channels of RGBA are occupied, and the remaining one channel can be used to store other data. The third texture of GBuffer can be used to store special rendering information, such as Roughness (Roughness), Metalness (Metal), and masking (Ao) that may be statically baked for PBR material rendering. The last channel is used to store the RenderType, and the subsequent lighting processing stage will decide which lighting model to call for rendering based on the RenderType of the vertex. Since an object is basically not rendered by two different lighting models at the same time, the meaning of each channel will change with the RenderType. For example, when performing NPR rendering, it may be written into the MetalRoughAo texture, Emmissive, Shadow, equal coefficient. The sizes of the Gbuffer parts are as follows, totaling 80 bytes, as shown in Table 1.

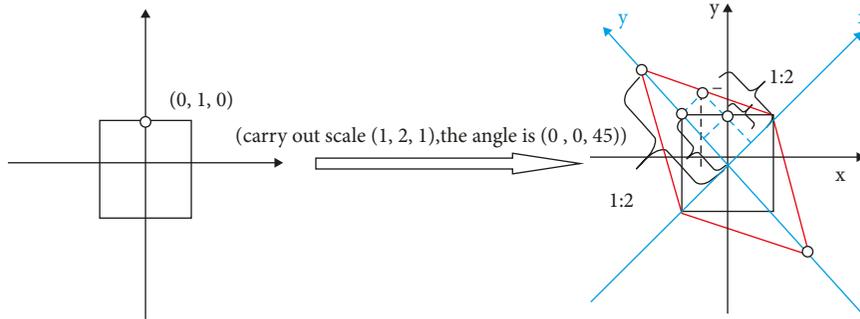

FIGURE 9: Unequal scaling with angles.

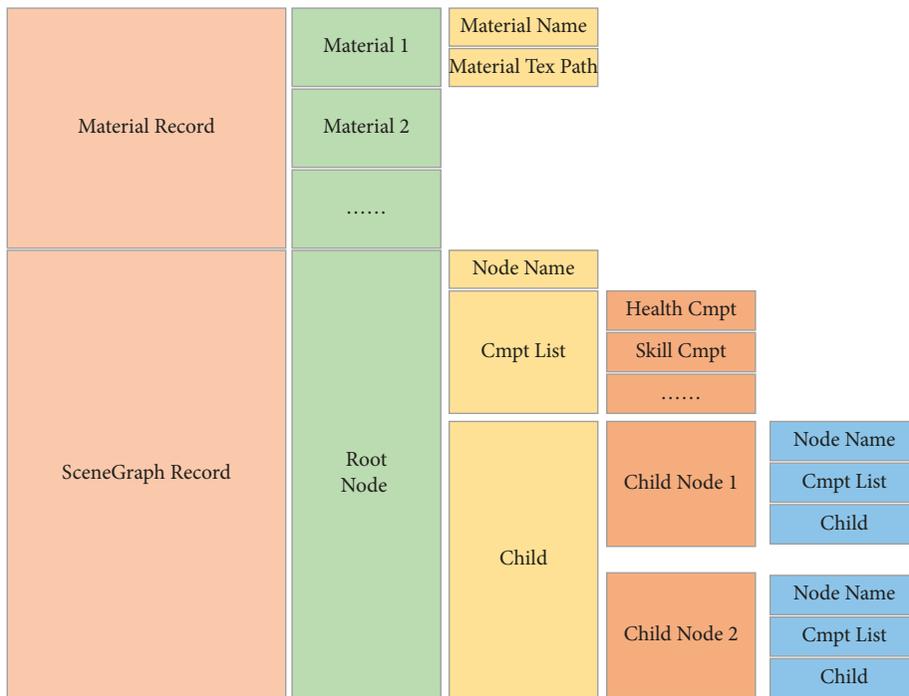

FIGURE 10: Inclusion relationship of scene data.

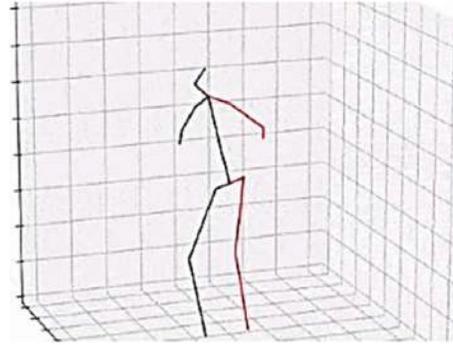

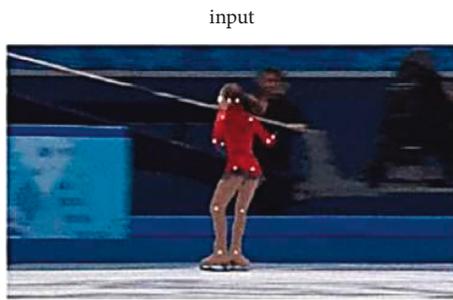

FIGURE 12: VideoPose3d recognition renderings (officially provided).

FIGURE 13: Test sample FBX file.

TABLE 1: GBuffer structure diagram.

4Byte	4Byte	4Byte	4Byte
Normal.X	Normal.Y	—	—
Albedo.R	Albedo.G	Albedo.B	Padding
Metal	Roughness	Occlusion	RenderType

4.3.2. Construction of Deferred Rendering Pipeline. First, we set the rendering target as a screen-sized texture, judge the lighting rendering model to be called according to the A channel data RenderType stored in the GBuffer, read other required parameters from the GBuffer, and perform lighting calculations. Subsequent forward rendering image post-processing can be performed to process some objects with transparency, but obviously, transparent objects cannot be rendered between front objects, which is even the disadvantage of delayed rendering [22].

4.4. Animation System Design. VideoPose3d is an open-source video input 3D pose estimation library, which is different from using the depth camera Kinect for 3D pose estimation. The library only needs the video data provided by the nondepth camera and processes the input video through a neural network to obtain coordinate estimation of

3D joint points. This chapter attempts to combine this neural network with 3D character animation, so that 3D characters have the interactive ability of action simulation.

The VideoPose3d model was presented as a paper at Facebook's 2019 Conference on Computer Vision in Pattern Recognition (CVPR). It has been open sourced on GitHub. Different from the traditional learning model based on joint point detection, this model uses the two-dimensional key points of the video frame as the input stream to perform time series convolution, so as to train to recognize the three-dimensional pose in the video, validated on the Human36 m dataset with good results. Another reason for choosing VideoPose3d is because the model provides a semi-supervised learning method for unlabeled video, by predicting the 2D key points of the unlabeled video, then estimating the 3D pose, and projecting the 3D pose to the 2D pose in reverse by passing in the camera parameters.

5. Analysis of Experimental Results

5.1. Test Environment and Tools. This article uses Windows 10 as the test operating system and uses Microsoft's C++ development environment Visual Studio 2019 for engine development. Vs 2019 provides a wealth of extension plug-ins, and you can download the HLSL syntax highlighting tool to improve the efficiency of Shader programming. In order to use the DirectX12 graphics development interface, the DirectX12 SDK needs to be installed, but most of the current Windows 10 SDK integrates the DirectX12 development environment. If the operating system includes it, you can write code directly without additional configuration. Part of the interface is written by Qt5.12.2. Qt's.ui file needs to be precompiled by Qt's built-in compiler, so the computer must install the corresponding version of Qt. The entire project is compiled and built through CMake, which is convenient to adapt to different versions of the Vs development environment.

5.2. 3D Animation Stereo Space Test. Take the FBX file below as a test example and refer to the running action around frame 180. Next, we will import the FBX into the engine for testing.

FIGURE 14: The test sample FBX file is imported into the engine of this subject and assigned to the material.

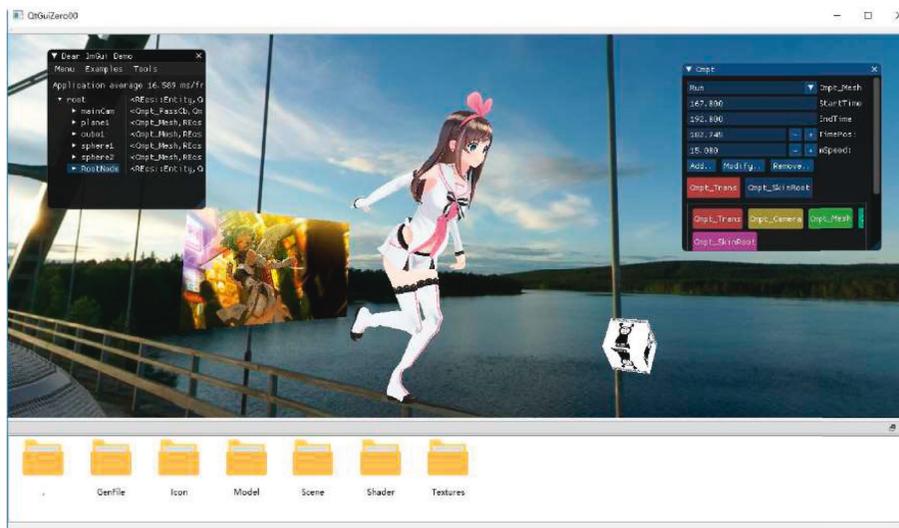

FIGURE 15: Comparison of running actions of the same keyframes in the engine.

The running action of about 180 frames imports the FBX into the engine and sets the material to paste the texture FBX on the model. The effect is as shown in Figure 13.

Comparing Figures 13 and 14, it is shown that the engine basically uses the material function to restore the character image. Next, adjust the time axis of the CmpT_SkinRoot component of the color correction root node to around 180 frames, and the following effects can be obtained.

It can be seen from Figure 15 that the FBX animation data analysis of the animation system in this study shows that the transformation of the local coordinate system of the bones is normal, and the simultaneous animation effect in 3ds Max is restored. The end result is a demonstration of skeletal skinning techniques and a reproduction of the same animation system as 3ds Max's internal poses.

6. Conclusion

The advent of the digital age has had varying degrees of impact on all aspects of our lives. It has also had a great impact on art and even animation scene design. From the

many breathtaking special effects in TV films and digital 3D animations that rely entirely on digital media, the powerful influence of digital technology is vividly displayed. The core purpose of this paper is to build a 3D character display platform based on DirectX12. In order to realize the display of 3D characters, the basic data required for 3D character display is firstly displayed, and then the related programming of DirectX12 is carried out around the acquisition and conversion of these data. In the development of the engine, the functions and architectures of many existing engines and open-source engines were referenced to design the various modules of the engine.

Data Availability

The dataset can be accessed upon request.

In view of the problems of low measurement accuracy and repeated calibration during the use of coal mine water quality analysis, the hyperspectral reflection noncontact measurement technology was proposed to solve the existing problems. KCl, NaCl, pH, NaHCO₃, and CaCl₂ were used to indicate the characteristic ion information of Na⁺, K⁺, Ca²⁺, Cl⁻, HCO₃⁻, and pH mine water in the laboratory, and 2220 spectral data were obtained by spectral determination. Savitzky–Golay convolution smoothing was used to smooth and denoise the original spectral data of each ion, and the relationship between the spectrum and the concentration of each reagent was obvious after smoothing and denoising pretreatment. The principal component regression method was used to build the inversion model of each ion content, and through the modeling study, the prediction set of KCl was found: the coefficient R² reaches 0.907, RPD is up to 2.7; the prediction set of NaCl was found: the coefficient R² reaches 0.957, RPD is up to 3.1; the PH prediction set was found: the coefficient R² reaches 0.785, RPD is up to 2.1; the prediction set of NaHCO₃ was found: the coefficient R² reaches 0.137, RPD is up to 1.2; the prediction set of CaCl₂ was found: the coefficient R² reaches 0.622, and RPD is up to 1.7. The results show that the hyperspectral method can play a better role in the extraction of K⁺, Cl⁻, Na⁺, Ca²⁺, and pH. It is difficult to extract HCO₃⁻ ions.

1. Introduction

Water hazard is one of the main threats to the safety of coal mine production, which causes serious loss of life and property. The prevention and control of water disaster in coal mines take water filling channel, water filling source, and water filling intensity as the main objects and take exploration, prevention, blocking, dredging, drainage, interception, and monitoring as the main means. Water samples are collected after water inrush or water gushing occurs in a mine, and the source of the water inrush or water gushing is judged by using the chemical composition of the water. It is a method widely used by technicians of geological survey and water control engineering in coal mines.

In foreign countries, the rock mass structure of coal seam floor and the prevention and drainage technology have been studied in depth, and a lot of experience has been accumulated in the mechanism of water inrush and the identification of water hazards. In the book Hydrogeochemistry

written by Clevers et al., the application of groundwater pollution and chemical evaluation in hydrochemical analysis is systematically discussed from the perspective of hydro-geochemistry [1–4]. Clevers et al. obtained it by using the 3D edge detection seismic attribute method [1–4]. Clevers et al. used hydrological observation and a tracer test to test the effect of the tunnel drainage system [1–4]. However, there is little research work on the application of mine water chemistry and the identification of mine water inrush sources.

The main method of discriminating the source of water inrush in coal mines in China is the conventional hydrochemical discrimination method. By measuring the eight most widely distributed ions in groundwater, such as Ca²⁺, Mg²⁺, K⁺, Na⁺, CO₃²⁻, HCO₃⁻, SO₄²⁻, and Cl⁻. Its concentration accounts for more than 90% of the total ion concentration in groundwater, as well as the characteristic ion ratio, hardness, temperature, TDS index, and pH value [5–10]. The mine water chemical data of Taoyuan Coal Mine

was processed by using Piper's three-line diagram [5–7]. The hydrochemical characteristics of each aquifer in the Xuzhou mining area were introduced [8, 9]. Conventional hydrochemical methods were used to carry out hydrogeochemical analysis of underground aquifers in a mine in Xuzhou [10–12]. The conventional hydrochemistry of four water-bearing subsystems in Yaoqiao Mine, Xuzhou, was studied [13–16]. A systematic study on the hydrochemical characteristics of groundwater in the Ordovician karst aquifer in the middle part of the Taihang Mountains was made [17–20]. The Chongqing Research Institute of China Coal Science and Technology Group, Beijing Huanan Auto, and Wuhan Dida Huarui have carried out relevant research on water quality analysis technology and equipment and have applied it in various coal mine groups [21–29].

However, there are still some problems in the current underground ion electrode monitoring, such as inaccurate measurement and repeated calibration during use, which cannot meet the needs of online identification of water sources. It is urgent to develop a new type of online water quality analysis sensors.

2. Hyperspectral Experimental Determination of Common Ions in Mine Water

The purpose of the experimental test is to find the hyperspectral characteristic band of the liquid related to the coal mine. The experimental spectral acquisition equipment is a self-made spectral probe, and the experimental measurement process is composed of three parts of spectrometer calibration, standard solution production, spectral measurement, and accuracy evaluation [30].

Five reagents, NaCl, KCl, CaCl₂, NaHCO₃, and pH buffer, were measured to indicate Na⁺, K⁺, Ca²⁺, Cl⁻, HCO₃⁻, and pH ion information, wherein the potassium ion and the chloride ion are indicated by KCl standard solution for a set of data (see Table 1 for details) [31–33]. Before measurement, the mother liquor is diluted with deionized water, and according to the test requirements, the sodium ion, potassium ion, chloride ion, and calcium ion dilution levels are 10, 50, 100, 500, 1000, and 10000 mg/L, the carbonate dilution levels are 0.44, 2.2, 4.4, 22, 44, and 440 mg/L, and the pH dilution levels are 4, 6.86, and 9.18. According to the order of KCl, NaCl, pH, NaHCO₃, CaCl₂, pure water, empty barrel, and green plants, 8 kinds of targets were measured, totaling 2220 hyperspectral data. Figure 1 shows the number of spectra of various standard solutions.

3. Ion Hyperspectral Data Preprocessing and Sensitive Band Selection

We carry out spectral quality evaluation on all obtained spectral data and select qualified spectral data [34–37]. At the same time, due to the influence of the external environment, there are many “burr” noises on the spectral curve, so it is necessary to reduce the noise on the spectral curve after smoothing and filtering. In this study, Savitzky–Golay

convolution smoothing was used to smooth and denoise the original spectral data of each ion. The value of the spectrum after Savitzky–Golay smoothing at wavelength I is

$$x_{i,\text{Savitzky-Golay}} = \frac{\sum_{j=-m}^m c_j x_{i+j}}{N} \quad (1)$$

In the formula, $x_{i,\text{Savitzky-Golay}}$ is the smoothed value at the wavelength I , x is the value before smoothing, m is the number of smoothing windows on the wavelength side, N is the normalization index, and $\sum_{j=-m}^m c_j$ is the smoothing coefficient, which can be obtained by polynomial fitting.

After smooth denoising pretreatment, the relationship between the spectrum and the concentration of each reagent is evident. Compared with the spectral data of “pure water + gradient” concentration, KCl, NaCl, pH, NaHCO₃, and CaCl₂ have obvious sensitive bands and rules. The higher the concentration of KCl, NaCl, and CaCl₂, the lower the overall reflectivity, which should be the mechanism under the action of Cl⁻. The pH data show that the reflectivity of pure water and acidic liquid is in the middle. The reflectivity of neutral liquid is low and that of alkaline liquid is the highest. As a whole, the higher the concentration of NaHCO₃, the higher the reflectivity. Figure 2 shows the comparison of the KCl, NaCl, and pH spectral data before and after denoising, while Figure 3 shows the comparison of the spectral data of NaHCO₃, CaCl₂, and pure water before and after denoising.

4. Establishment of the Quantitative Inversion Prediction Model for Ion Hyperspectral Data

The mine water is a complex system composed of various chemical ions in the water. In this study, the principal component regression (PCR) method is used to establish the quantitative inversion model, which is based on principal component analysis (PCA) [38–46]. PCA is a multiple collinearity regression analysis method. The principle is that after the multicollinearity in the regression model is eliminated by the principal component analysis method, the principal component variables are used as independent variables for regression analysis, and then, the original variables are substituted back into the new model according to the score coefficient matrix.

The basic steps of PCA are as follows:

- (1) The aim is to acquire a principal component of independent variable data through principal component analysis and select a principal component subset through standardized classification.
- (2) The principal component obtained in step (1) is used as a new independent variable, and an estimated regression coefficient vector is obtained through linear regression analysis (the dimension is equal to the number of the selected principal components).
- (3) We transform the regression coefficient vector into the proportion of the actual independent variables and use the selected PCA load (corresponding to the eigenvector of the selected principal component) to

TABLE 1: Standard solutions of five ions.

obtain the final PCR estimator (dimension equal to the total number of independent variables) for estimating the regression coefficients.

For model evaluation, cross-validation was used to evaluate the model, and determination coefficients (R^2 and root mean of squared error (RMSE) were selected. The RMSE and relative percent deviation (RPD) were used as evaluation indexes. When the R^2 value of the calculated validation set is closer to 1, the RMSE value is lower, and when the RPD value

is closer to 2, the model is more stable, the accuracy is higher, and the model is better. When R^2 is less than 0.50 and RPD is less than 1.40, the estimation ability of the model to the sample is poor, and the model is not available; $0.50 < R^2 < 0.75$ and $1.40 < RPD < 2.00$, the estimation ability of the model to the sample is improved, but only rough estimation can be made, and the model is available. When $R^2 > 0.75$ and $RPD > 2.00$, the model accuracy is high, the model is good, and the calculation formula is

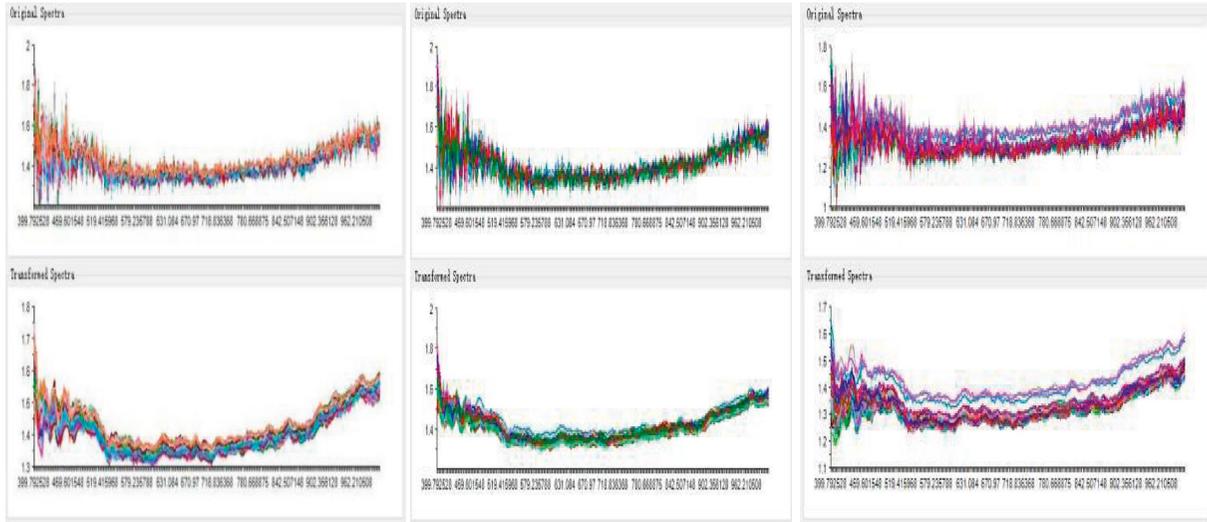

FIGURE 2: Comparison of the KCl, NaCl, and pH spectral data before and after denoising.

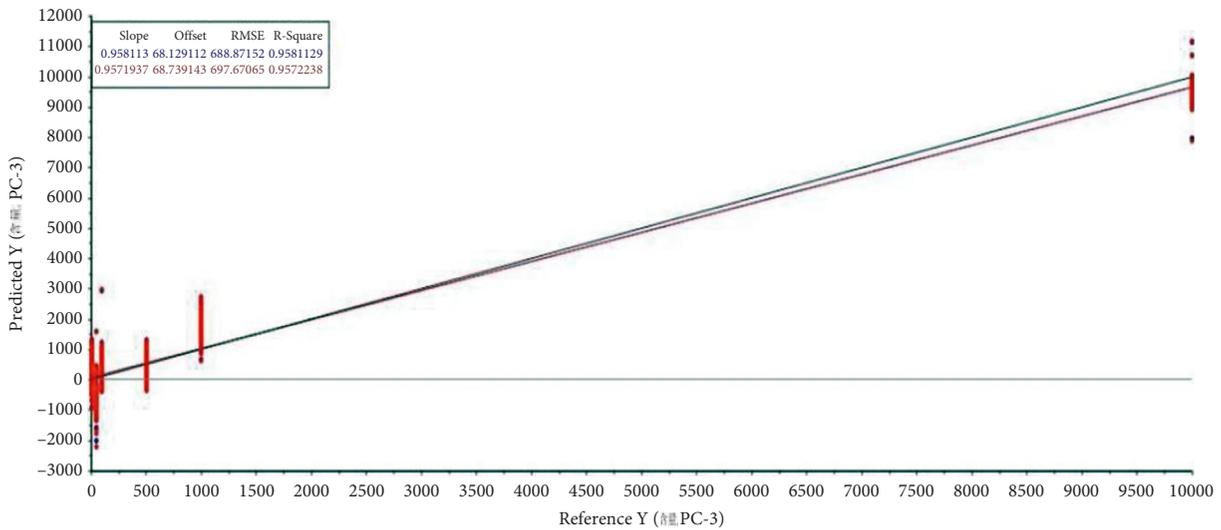

FIGURE 8: Comparison between measured and predicted NaCl sets.

4.1. *KCl Content Spectral Prediction Modeling.* 382 standard solution spectral data were selected, the largest 7 principal components were selected, and the weights were set equally [47–51]. CV prediction detection, cross-validation, and the principal component analysis model were established when the proportion of the validation set and modeling set was 0.70. The first three principal components can represent more than 80% of the content information. In the modeling set, the coefficient reaches R2 which reaches 0.908, and in the prediction set, the coefficient reaches R2 which reaches 0.907, and RPD is up to 2.7. In the process of computational modeling, the importance of all sample points and the samples collected in the middle section play a greater role. Figure 4 shows the KCl principal component results, Figure 5 shows the comparison between the KCl actual measurement set and prediction sets, and Figure 6 shows the role of sample points in the calculation of KCl content.

4.2. *NaCl Content Spectral Prediction Modeling.* Three hundred and ninety-nine standard solution spectral data were selected, the largest seven principal components were selected, and the weights were set equally [47–51]. CV prediction detection, cross-validation, and the principal component analysis model were established when the proportion of the validation set and the modeling set was 0.70. The first three principal components can represent more than 90% of the content information. In the modeling set, the coefficient reaches R2 which reaches 0.958, and in the prediction set, the coefficient reaches R2 which reaches 0.957, and RPD is up to 3.1. In the process of computational modeling, the importance of all sample points and the samples collected in the middle section play a greater role. Figure 7 shows the NaCl principal component results, Figure 8 shows the comparison between measured and predicted NaCl sets, and Figure 9 shows the role of sample points in the calculation of NaCl content.

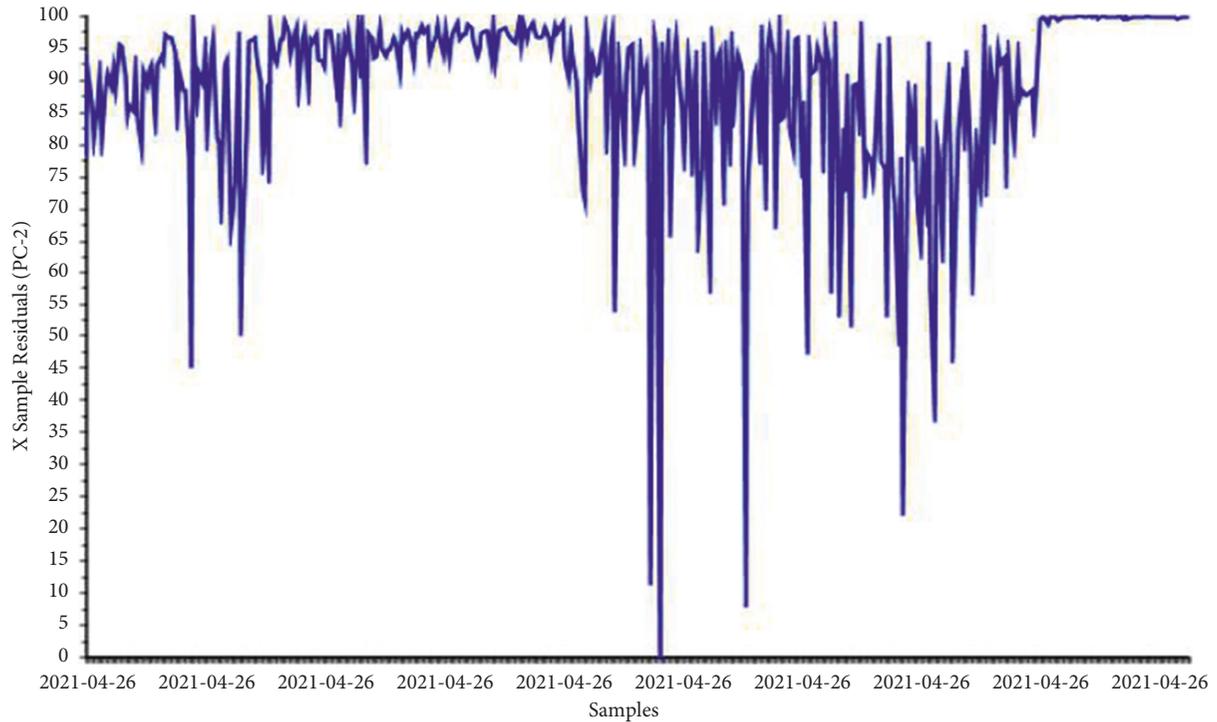

FIGURE 9: The role of sample points in the calculation of NaCl content.

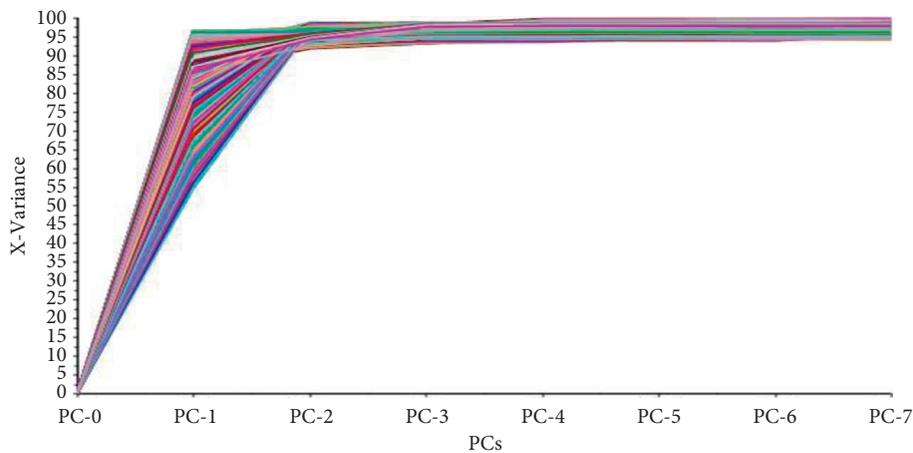

FIGURE 10: pH principal component results.

4.3. *pH Content Spectral Prediction Modeling.* 240 spectral data of standard solution were selected, the largest 7 principal components were selected, and the weights were set equally [47–51]. CV prediction detection, cross-validation, and the principal component analysis model were established when the proportion of the validation set and the modeling set was 0.70. The first three principal components can represent more than 85% of the content information. In the modeling set, the coefficient reaches R^2 which reaches 0.791, and in the prediction set, the coefficient reaches R^2 which reaches 0.785, and RPD is up to 2.1. In the process of calculation and modeling, the importance of all sample points and the samples collected in the

previous section play a greater role. Figure 10 shows the pH principal component results, Figure 11 shows the comparison between measured and predicted pH sets, and Figure 12 shows the role of sample points in the calculation of pH content.

4.4. *NaHCO₃ Content Spectral Prediction Modeling.* 404 standard solution spectral data were selected, the largest 7 principal components were selected, and the weights were set equally [47–51]. CV prediction detection, cross-validation, and the principal component analysis model were established when the proportion of the validation set and the modeling set was 0.70. The first three principal

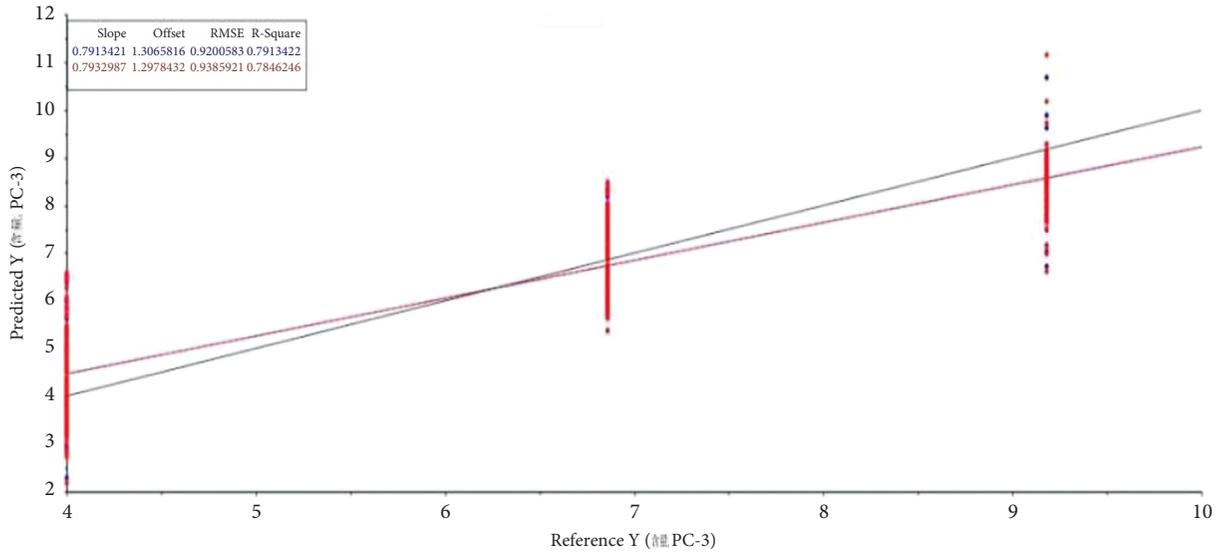

FIGURE 11: Comparison between measured and predicted pH sets.

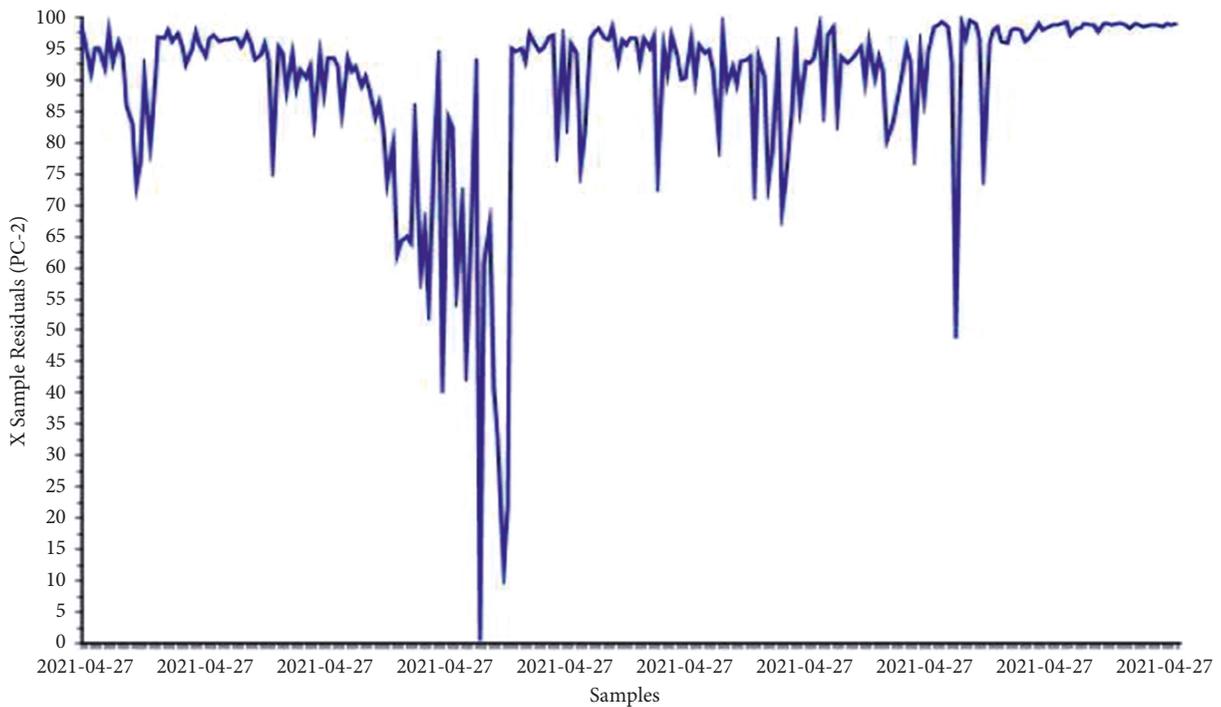

FIGURE 12: The role of sample points in the calculation of pH content.

components can represent more than 75% of the content information. In the modeling set, the coefficient reaches R2 which reaches 0.162, and in the prediction set, the coefficient reaches R2 which reaches 0.137, and RPD is up to 1.2. In the process of computational modeling, the importance of all sample points and the samples collected in the middle and back end play a greater role. Figure 13 shows the NaHCO₃ principal component results, Figure 14 shows the comparison between measured and predicted NaHCO₃ sets, and Figure 15 shows the role of sample points in the calculation of NaHCO₃ content.

4.5. CaCl₂ Content Spectrum Prediction Modeling. Four hundred and seventeen standard solution spectral data were selected, the largest seven principal components were selected, and the weights were set equally [47–51]. CV prediction detection, cross-validation, and the principal component analysis model were established when the proportion of the validation set and the modeling set was 0.70. The first three principal components can represent more than 55% of the content information. In the modeling set, the coefficient reaches R2 which reaches 0.630, and in the prediction set, the coefficient reaches R2 which reaches

0.622, and RPD is up to 1.7. In the process of computational modeling, the importance of all sample points and the samples collected in the middle section play a greater role. Figure 16 shows the CaCl₂ principal component results, Figure 17 shows the comparison between measured and predicted sets of CaCl₂, Figure 18 shows the role of sample points in the calculation of CaCl₂ content, and Figure 19 shows the comparison of extraction accuracy of various ions.

5. Conclusion

Through the spectrum analysis of the characteristic ions of the mine water, the principal component regression method is used to carry out the quantitative inversion modeling of various ions, and the five standard solutions of KCl, NaCl, pH, NaHCO₃, and CaCl₂ indicate six ions (KCl includes K ions and Cl ions). The extraction precision of KCl and NaCl is higher than 0.9, followed by pH and CaCl₂, the precision is more than 0.6. The extraction precision of HCO₃⁻ is the lowest, only 0.162. The results show that the hyperspectral method can play a better role in the extraction of K⁺, Cl⁻, Na⁺, Ca²⁺, and pH. It is difficult to extract HCO₃⁻ ions.

One of the sources of “invariance principle” is that the limit properties of the uniform empirical process coincide with that of a Brownian bridge. The deep discussion of limit theorem of the uniform empirical process gathered wild interest of the researchers. In this paper, the precise convergence rate of the uniform empirical process is considered. As is well-known, when ε tends to 0, the precise asymptotic theorems can be demonstrated by referring to the classical method of Gut and Spătaru, by using some nice probability inequalities and so on. However, if ε tends to a positive constant, other powerful methods and tools are needed. The method of strong approximation is used in this paper. The main theorems are proved by using the Brownian bridge $B(t)$ to approximate the uniform empirical process $\alpha_n(t)$. The relevant results for the uniform sample quantile process are also presented.

1. Introduction and Main Results

Random phenomena exist in almost every branch of science and engineering and permeate every aspect of ordinary people’s modern life [1, 2]. Probability theory is a subject that studies the quantitative regularity of random phenomena everywhere. Probability is a method of thinking about the world [3].

Probability limit theory is one of the main branches of probability theory [4, 5]. The famous probability scientists Kolmogorov and Gnedenko once said, “the epistemological value of probability theory can be revealed only through the limit theorem. Without the limit theorem, it is impossible to understand the real meaning of the basic concepts of probability theory.” Probability limit theory is also an important basis of statistical large sample theory [4]. People are very concerned about whether the estimator approximates the real parameter when the sample size tends to infinity, that is, the so-called consistency in statistical large sample theory. Furthermore, we need to consider the speed at which the estimator approximates the real parameters and how to solve these statistical large sample problems. The solution of these problems must rely on the probability limit theorem.

Let $\{X, X_n; n \geq 1\}$ be a sequence of independent and identically distributed (i.i.d.) random variables with the common distribution function F , and set $S_n = \sum_{i=1}^n X_i$ for $n \geq 1$. Hsu and Robbins [6] introduced the following complete convergence.

$$\sum_{n=1}^{\infty} P\{|S_n| \geq \varepsilon n\} < \infty, \quad \varepsilon > 0, \quad (1)$$

This holds if $EX = 0$, and $EX^2 < \infty$. The converse part was proved by Erdős [7]. The complete convergence is stronger than the almost sure convergence. Obviously, the sum in (1) tends to infinity as $\varepsilon \searrow 0$.

The first result on the convergence rate of this kind was given by Heyde [8]. It is proved that

$$\lim_{\varepsilon \searrow 0} \varepsilon^2 \sum_{n=1}^{\infty} P\{|S_n| \geq \varepsilon n\} = EX^2, \quad (2)$$

if $EX = 0$, and $EX^2 < \infty$. Heyde [8], Alam [4] got general conclusions and termed them “precise asymptotics.”

The precise asymptotics for “ S_n ” have been extensively studied. One can refer to Zhang [9], Huang [10], and so on. Now, we consider the relevant results for the uniform empirical process. Let $\{U_1, U_2, \dots, U_n\}$ be a sequence of i.i.d. $U[0, 1]$ -distributed random variables. Define the uniform empirical process as $\alpha_n(t) = n^{-1/2} \sum_{i=1}^n (I\{U_i \leq t\} - t)$, $0 \leq t \leq 1$. Denote the norm of a function $f(t)$ on $[0, 1]$ by $\|f\| = \sup_{0 \leq t \leq 1} |f(t)|$, and $\log x = \ln(xve)$. The following is one conclusion provided by Zhang and Yang [11].

Theorem 1. Let $\{B(t); 0 \leq t \leq 1\}$ be a Brownian bridge, and for any $\delta > -1$, we have $\lim_{\varepsilon \searrow 0} \varepsilon^{2\delta+2} \sum_{n=1}^{\infty} (\log n)^\delta / n P\{\|\alpha_n\| \geq \varepsilon \sqrt{\log n}\} = E\|B\|^{2\delta+2} / \delta + 1$.

The proof of Theorem 1 is based on the classical method introduced by Gut and Spătaru [12]. In this paper, we consider the situation “ $\varepsilon \searrow c_0$ ” where c_0 is a positive constant,

and the classical argument for the case of “ $\varepsilon \searrow 0$ ” does not work anymore. We will use more powerful tools, such as strong approximation. Besides the uniform empirical process, we also consider the uniform sample quantile process. Let $0 = U_0^{(n)} \leq U_1^{(n)} \leq \dots \leq U_n^{(n)} \leq U_{n+1}^{(n)} = 1$ denote the order statistics of the random sample U_1, U_2, \dots, U_n , for each $n \geq 1$. Define the uniform quantile function as $U_n(y) = \begin{cases} U_k^{(n)} & \text{if } (k-1)/n < y \leq k/n, k = 1, 2, \dots, n \\ 0 & \text{if } y = 0 \end{cases}$. The uniform sample quantile process should be defined as $u_n(y) = n^{1/2}(U_n(y) - y)$, $0 \leq y \leq 1$. The following are our main results.

Theorem 2. Let $a > -1$, $b > -1$, and $d_n(\varepsilon)$ be a function of ε such that $d_n(\varepsilon) \log n \rightarrow \tau$ as $n \rightarrow \infty, \varepsilon \searrow \sqrt{a+1}/2$. Then,

$$\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} n^a (\log n)^b P\{\|\alpha_n\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\} = 2 \exp\{-4\tau \sqrt{a+1}\} \Gamma(b+1), \quad (3)$$

and

$$\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} n^a (\log n)^b P\{\|u_n\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\} = 2 \exp\{-4\tau \sqrt{a+1}\} \Gamma(b+1), \quad (4)$$

Theorem 3. Let $a > -1$, $b > -1$, and $d_n(\varepsilon)$ be a function of ε such that $d_n(\varepsilon) \log \log n \rightarrow \tau$ as $n \rightarrow \infty, \varepsilon \searrow \sqrt{a+1}/2$. Then,

$$\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} \frac{(\log n)^a (\log \log n)^b}{n} P\{\|\alpha_n\| \geq \sqrt{2 \log \log n} (\varepsilon + d_n(\varepsilon))\} = 2 \exp\{-4\tau \sqrt{a+1}\} \Gamma(b+1), \quad (5)$$

and

$$\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} \frac{(\log n)^a (\log \log n)^b}{n} P\{\|u_n\| \geq \sqrt{2 \log \log n} (\varepsilon + d_n(\varepsilon))\} = 2 \exp\{-4\tau \sqrt{a+1}\} \Gamma(b+1). \quad (6)$$

Remark 1. We define the general empirical process as $\beta_n(x) = \sqrt{n}(F_n(x) - F(x))$, $-\infty < x < \infty$, where $F_n(x) = 1/n \sum_{i=1}^n I_{(-\infty, x]}(X_i)$. If $F(\cdot)$ is a continuous distribution function since $\alpha_n(F(x)) = \beta_n(x)$, the results for $\beta_n(x)$ can be obtained immediately from the uniform case. But we cannot handle the quantile process in the same way.

2. Proofs

The starting point of this paper is the empirical distribution function. The empirical distribution function plays a very important role in statistics [13–18]. Although it is not a beautiful piecewise function, as a nonparametric estimation

of the distribution function, it is unbiased, consistent, and asymptotically obeys the normal distribution. The empirical process is constructed on the basis of the empirical distribution function. The uniform empirical process is a special and important one [19–21].

We lay out some lemmas which will be used in the proofs later. Lemma 1 is well known (cf. [22]). Lemma 2 and 3 are from Csörgő and Révész [23, 24].

Lemma 1. *Let $\{B(t); 0 \leq t \leq 1\}$ be a Brownian bridge. Then, for all $x > 0$,*

$$P\{\|B(t)\| \geq x\} = 2 \sum_{k=1}^{\infty} (-1)^{k+1} e^{-2k^2 x^2}. \quad (7)$$

In particular,

$$P\{\|B(t)\| \geq x\} \sim 2e^{-2x^2} \text{ as } x \rightarrow +\infty. \quad (8)$$

Lemma 2. *There exists a sequence of Brownian bridges $\{B_n(t); 0 \leq t \leq 1\}$ such that for all n and x we have*

$$P\left\{\sup_{0 \leq t \leq 1} |\alpha_n(t) - B_n(t)| > n^{-1/2} (K \log n + x)\right\} \leq Le^{-\lambda x}, \quad (9)$$

where K, L, λ are positive absolute constants.

Lemma 3. *There exists a sequence of Brownian bridges $\{B_n(t); 0 \leq t \leq 1\}$ such that for each $n = 1, 2, \dots$, and for all $|z| < c\sqrt{n}$ and $c > 0$, we have*

$$P\left\{\sup_{0 \leq t \leq 1} |u_n(t) - B_n(t)| > n^{-1/2} (A \log n + z)\right\} \leq Be^{-Cz}, \quad (10)$$

where A, B, C, c are positive absolute constants.

First, we obtain the conclusion for the Brownian bridge $\{B(t); 0 \leq t \leq 1\}$.

Proposition 1. *Let $a > -1, b > -1$, and $b_n(\varepsilon)$ be a function of ε such that*

$$b_n(\varepsilon) \log n \rightarrow \tau \text{ as } \varepsilon \searrow \frac{\sqrt{a+1}}{2}. \quad (11)$$

Then, $\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} n^a (\log n)^b P\{\|B\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\} = 2 \exp\{-4\tau \sqrt{a+1}\} \Gamma(b+1)$.

Proof. By Lemma 1 and (11), we have $P\{\|B\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\} \sim 2 \exp\{-4 \log n (\varepsilon + b_n(\varepsilon))^2\} \sim 2 \exp\{-4\varepsilon^2 \log n\} \exp\{-8\varepsilon b_n(\varepsilon) \log n\}$ as $n \rightarrow \infty$, uniformly in $\varepsilon \in (\sqrt{a+1}/2, \sqrt{a+1}/2 + \delta)$ for some $\delta > 0$. Therefore, for any $0 < \theta < 1$, there exist $\delta > 0$ and n_0 such that for all $n \geq n_0$ and $\varepsilon \in (\sqrt{a+1}/2, \sqrt{a+1}/2 + \delta)$,

$$\begin{aligned} & 2 \exp\{-4\varepsilon^2 \log n\} \exp\{-4\sqrt{a+1} \tau - \theta\} \\ & \leq P\{\|B\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\} \\ & \leq 2 \exp\{-4\varepsilon^2 \log n\} \exp\{-4\sqrt{a+1} \tau + \theta\}. \end{aligned} \quad (12)$$

We calculate that $\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} n^a (\log n)^b \cdot \exp\{-4\varepsilon^2 \log n\} = \lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \int_e^{\infty} x^a (\log x)^b \exp\{-4\varepsilon^2 \log x\} dx = \lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \int_1^{\infty} y^b \exp\{-[4\varepsilon^2 - (a+1)]y\} dy = \lim_{\varepsilon \searrow \sqrt{a+1}/2} \int_{4\varepsilon^2 - (a+1)}^{\infty} z^b e^{-z} dz = \Gamma(b+1)$.

From (12), and noting that θ is arbitrary, we get the proposition immediately. \square

Proof of Theorem 2. Here, we only present the proof for (3) since the argument for (4) is similar. It is obvious, for $p < -1/2$,

$$\begin{aligned} & P\left\{\sup_{0 \leq t \leq 1} |B(t)| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon)) + (\log n)^p\right\} \\ & - P\left\{\sup_{0 \leq t \leq 1} |\alpha_n(t) - B(t)| \geq (\log n)^p\right\} \\ & \leq P\left\{\sup_{0 \leq t \leq 1} |\alpha_n(t)| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\right\} \\ & \leq P\left\{\sup_{0 \leq t \leq 1} |B(t)| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon)) - (\log n)^p\right\} \\ & + P\left\{\sup_{0 \leq t \leq 1} |\alpha_n(t) - B(t)| \geq (\log n)^p\right\}. \end{aligned} \quad (13)$$

From Lemma 2, we have $P\{\sup_{0 \leq t \leq 1} |\alpha_n(t) - B(t)| \geq (\log n)^p\} \leq P\{\sup_{0 \leq t \leq 1} |\alpha_n(t) - B(t)| \geq K \log n + (a+2) \log n / \lambda / \sqrt{n}\} \leq Le^{-(a+2) \log n} = Ln^{-(a+2)}$, and then $\sum_{n=1}^{\infty} n^a (\log n)^b P\{\sup_{0 \leq t \leq 1} |\alpha_n(t) - B(t)| \geq (\log n)^p\} \leq L \sum_{n=1}^{\infty} n^a n^{-2} (\log n)^b < \infty$. Furthermore, it follows

$$\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} n^a (\log n)^b P\left\{\sup_{0 \leq t \leq 1} |\alpha_n(t) - B(t)| \geq (\log n)^p\right\} = 0. \quad (14)$$

On the other hand, since $p < -1/2$, we have $P\{\|B\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon)) \pm (\log n)^p\} = P\{\|B\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon)) \pm 1 / \sqrt{2} (\log n)^{p-1/2}\} \sim 2 \exp\{-4 \log n (\varepsilon + b_n(\varepsilon))^2\} \sim 2 \exp\{-4\varepsilon^2 \log n\} \exp\{-8\varepsilon b_n(\varepsilon) \log n\} \sim P\{\|B\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\}$, as $n \rightarrow \infty$

$(\varepsilon + b_n(\varepsilon) \pm 1 / \sqrt{2} (\log n)^{p-1/2})^2 \sim 2 \exp\{-4\varepsilon^2 \log n\} \exp\{-8\varepsilon b_n(\varepsilon) \log n\} \sim P\{\|B\| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon))\}$, as $n \rightarrow \infty$

With Proposition 1, it follows

$$\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} n^a (\log n)^b P \left\{ \sup_{0 \leq t \leq 1} |B(t)| \geq \sqrt{2 \log n} (\varepsilon + b_n(\varepsilon)) \pm (\log n)^p \right\} = 2 \exp\{-4\tau\sqrt{a+1}\} \Gamma(b+1). \quad (15)$$

From (13) to (15), we get the result of Theorem 2. \square

Proof of Theorem 3. In this part, we only present the outline of the proof for the uniform sample quantile process, so the arguments for Theorem 2 and 3 are mutually complementary.

Follow the proof of Proposition 1 closely, we can get the following conclusion. For any $0 < \theta < 1$, there exist $\delta > 0$

and n_0 such that for all $n \geq n_0$ and $\varepsilon \in (\sqrt{a+1}/2, \sqrt{a+1}/2 + \delta)$, $2 \exp\{-4\varepsilon^2 \log \log n\} \exp\{-4\tau\sqrt{a+1} - \theta\} \leq P\{\|B\| \geq \sqrt{2 \log \log n} (\varepsilon + d_n(\varepsilon))\} \leq 2 \exp\{-4\varepsilon^2 \log \log n\} \exp\{-4\tau\sqrt{a+1} + \theta\}$

On the other hand, $\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} (\log \log n)^a (\log \log n)^b / n \cdot \exp\{-4\varepsilon^2 \log \log n\} = \Gamma(b+1)$.
Therefore, we have

$$\lim_{\varepsilon \searrow \sqrt{a+1}/2} [4\varepsilon^2 - (a+1)]^{b+1} \sum_{n=1}^{\infty} \frac{(\log n)^a (\log \log n)^b}{n} P\{\|B\| \geq \sqrt{2 \log \log n} (\varepsilon + d_n(\varepsilon))\} = 2 \exp\{-4\tau\sqrt{a+1}\} \Gamma(b+1). \quad (16)$$

Like (13), we have. $P\left\{ \sup_{0 \leq t \leq 1} |B_n(t)| \geq \sqrt{2 \log \log n} (\varepsilon + d_n(\varepsilon)) + (\log \log n)^p \right\} - P\left\{ \sup_{0 \leq t \leq 1} |u_n(t) - B_n(t)| \geq (\log \log n)^p \right\} \leq P\left\{ \sup_{0 \leq t \leq 1} |u_n(t)| \geq \sqrt{2 \log \log n} (\varepsilon + d_n(\varepsilon)) \right\} \leq P\left\{ \sup_{0 \leq t \leq 1} |B_n(t)| \geq \sqrt{2 \log \log n} (\varepsilon + d_n(\varepsilon)) - (\log \log n)^p \right\} + P\left\{ \sup_{0 \leq t \leq 1} |u_n(t) - B_n(t)| \geq (\log \log n)^p \right\}$

By lemma 3, let $z = \log n/\lambda$, we can get. $\sum_{n=1}^{\infty} (\log n)^a (\log \log n)^b / n P\left\{ \sup_{0 \leq t \leq 1} |u_n(t) - B_n(t)| \geq (\log \log n)^p \right\} \leq \sum_{n=1}^{\infty} (\log n)^a (\log \log n)^b / n P\left\{ \sup_{0 \leq t \leq 1} |u_n(t) - B_n(t)| \geq C \log n + \log n/\lambda/\sqrt{n} \right\} \leq \sum_{n=1}^{\infty} (\log n)^a (\log \log n)^b / n \cdot Le^{-\log n} < \infty$

The rest of the proof is similar to Theorem 2 and is omitted here. \square

3. Conclusion

The empirical process theory plays an important role in large sample theory in statistics. The researchers are very much interested in the large sample properties of the statistical estimator. As long as the sample size tends to infinity, the estimator converges to the true value of the parameter. In the procedure of demonstration of large sample properties, especially for the estimators in the semiparameter models, this study on convergence rates for the uniform empirical process and the uniform sample quantile process can provide a series of effective methods and tools.

The limitation of this study may lie in the lack of consideration of the exact asymptotic properties of uniform empirical processes; in addition, in the study of the convergence rate of the uniform empirical process and uniform

sample quantile process, the influence of the exact asymptotic behavior of self-regularity and logarithmic law on the convergence rate should also be taken into account.

Due to the needs of practical applications, dependent random samples are often of more interest to statisticians. Positive and negative concomitants also widely exist in real life and engineering, such as reliability testing, statistical mechanics, and so on. The limit properties of the sequences of associated random variables, such as the law of iterated logarithm and the law of large numbers of the sequences of associated random variables, will be a hot topic in the future. In the future, the asymptotic properties of the test statistics of the model and parameters will be studied by parameter estimators.

The combination of visual communication design of food packaging and digital media art is the new trend. In this study, the visual communication design of interactive packaging of Internet-famous food is analyzed, and an innovative identification method of the interactive packaging visual communication design based on artificial intelligence is put forward. The weighted fusion rule of conjunction disjunction double operators is used to fuse the innovative evaluation information of multiple expert groups on interactive packaging, and finally, the innovative multigroup discrimination results of interactive packaging are obtained. Considering both the consistency of evaluation information and the contradiction of evaluation information, the weight factor is introduced to achieve the balance between conjunction operator and disjunction operator. The designed conjunctive disjunctive double operator weighted fusion rule can support the contradiction handling in the innovative discrimination of interactive packaging and has the advantages of convenient application and easy programming.

1. Introduction

Internet-famous food is a novel, popular snack food with distinctive cultural transmission characteristics with the emergence of new trends such as multimedia technology and webcast. It has the properties of both food and network information carrier. But food attribute is its essential attribute. Therefore, when carrying out the innovation of its interactive packaging visual communication design [1–9], we must first consider its food attributes.

Under the severe situation of increasingly fierce market demand, the food industry should not only work hard at the level of market demand and strict control of food quality and safety but also should further grasp the aesthetic characteristics of the public, use artistic advertising creative design to attract customers' attention, expand publicity and planning, and establish brand awareness, so as to promote the overall growth of food sales [10, 11]. Digital media art [12–16] has the comprehensive characteristics of “sound, image, form, and sound”, which has a key practical

significance for accelerating the dissemination of information content in the food industry and getting rid of the restrictions of food advertising on time and indoor space. Customers can use diversified digital media technology and Internet platforms to independently search for advertisements related to food enterprises, strengthen the promotion scope and resource sharing level of food advertising, and indirectly expand the scope of food advertising.

With the strong support of a series of digital media technologies, packaging designers show diversified performance effects according to the reasonable arrangement of the visual effect elements such as color, graphics, and text, and it also improves the intimate interaction with the public, mobilize enthusiasm, and creative thinking and meets the artistic needs of these people, and it further promotes the development trend of creative design of food packaging in the period of digital media technology [16]. Digital media art combines electronic information technology with media art to become a scientific and reasonable art with strong expressiveness and high scientific and technological content.

Taking this as an opportunity, this paper carries out the research on the visual communication design innovation of Internet-famous food interactive packaging based on artificial intelligence. Firstly, the visual communication design of interactive packaging of Internet-famous food is analyzed. Then, taking the interactive packaging design of an Internet-famous food as the object, using artificial intelligence algorithm, an innovativeness identification method of interactive packaging visual communication design is proposed.

2. Analysis of the Visual Communication Design of Interactive Packaging of Internet-Famous Food

The application of new media technology in food packaging design can not only improve and update the visual elements of the plan of food packaging materials but also introduces more practical sensory stimuli, so as to improve the competitiveness of products.

2.1. Communicating More Product Information to Consumers. The more basic function of food packaging is not only to store food commodities but also to display the basic information of food, including the name, production date, shelf life, origin, specification, and other basic information of the food. The digital media art plays a key role here, and Figure 1 shows several examples of the Internet-famous food packaging design enabled by digital media technology [17–20]. Many contemporary food packages are printed with two-dimensional codes and the application of the two-dimensional code technology is to make full use of the information content storage and expansion functions of digital media art. By scanning the QR code, customers can obtain more and more product-related information, so as to have a deeper understanding of the food categories. In fact, for example, the two-dimensional code displayed on the package of a well-known brand of milk containing beverage, and after scanning, consumers can immediately log in to the manufacturer's official website. The website presents the product variety, the surrounding environment of the production site, the natural environment of the production line, the natural environment of milk raw materials, etc., so that customers can have a deeper understanding of the manufacturer of milk containing beverage and cannot help thinking that the product will appear in similar transactions in the future.

At the same time, the two-dimensional code on the food packaging generally has various decorations such as animation elements, so the visual impact is more prominent, completing the unity of artistic beauty and practicality.

2.2. Building an Interactive Bridge between Products and Consumers. AR technology is a digital media technology commonly used in food packaging, especially in dairy packaging. It plays a key role in combining food visual effect elements to enhance the charm of food packaging. By using AR technology, customers can use mobile phones and other devices to scan the AR identification control module on food packaging to obtain the content of interaction and

FIGURE 1: Food packaging design enabled by digital media technology.

communication with AR, such as 3D display of the food origin [18]. Customers can visit the origin of food in a 720° panoramic view to obtain different visual effects of tourism experience.

It is not difficult to see that AR technology has built a bridge for the interaction between customers and virtual scenes, thus improving the interest and interactivity of food packaging materials and bringing more in-depth shopping experience to customers.

2.3. Realizing the Publicity and Marketing of Internet-Famous Food Products. No matter what kind of digital media art it may be, its application in food packaging is not rigid but expressive and harmonious [19]. For example, the food industry uses digital media art to apply various artistic creative patterns, such as various animation element pattern design, data element pattern design, and digital media technology content, such as H5 web page, WeChat public platform, and Sina Weibo post.

On the one hand, it conforms to the visual effect art aesthetics of the product packaging design, increases the visual effect art aesthetics of the food packaging, and attracts more customers' visual actual effect. On the other hand, it also makes use of food packaging materials more extensive. When customers appreciate this artistic creative pattern, it is easier for them to take the initiative to master the technical content of digital media in the pattern design, so as to achieve the expected publicity planning and promotion effect. In this way, food packaging reasonably connects the gap between the data world and the physical world and completes data marketing. The application of digital media art in food packaging materials has a certain inevitable trend, which is also the main countermeasure to improve the competitiveness of the food industry.

3. Innovativeness Identification Method of Interactive Packaging Visual Communication Design Based on Artificial Intelligence

For the Internet-famous food product, there are many feasible packaging design schemes in the process of

interactive packaging design. With the deepening and popularization of the innovative design in the food packaging industry, the key technical problem to be solved is how to distinguish the innovation of interactive packaging design, so as to provide basis for subsequent product promotion and marketing.

3.1. Evidence Theory. It is a feasible way to identify the innovation of interactive packaging design that experts belonging to multiple groups evaluate the innovation of interactive packaging design according to their own experience and wisdom and then integrate the evaluation information of the multiple groups [21–25]. However, they are affected by many complex factors, such as experts' knowledge background, practical experience, and the group interest they represent, and the evaluation information given by the experts from the multiple groups in the innovative evaluation of the interactive packaging design is also highly uncertain. The fusion of multigroup evaluation information is essentially an uncertain reasoning and decision-making process.

As an uncertain reasoning method, evidence theory has unique advantages in information fusion and has been widely used [26–34]. When the evaluation information of the multiple groups supports the proposition that “the innovation of interactive packaging design is the best,” when these evidences are fused together, the fusion results should support this proposition to a greater extent. In other words, the fusion rules should be able to achieve “downward focus,” that is, the focus from a subset with a larger cardinality to a subset with a smaller cardinality, so as to facilitate the decision-making and judgment. Sometimes, the evaluation information of some groups may be contradictory. For example, for a certain two groups, one may think that “the innovation of interactive packaging design is excellent” and the other may think that “the innovation of interactive packaging design is poor.” At this time, the two groups have contradictory evaluation information on the innovation of interactive packaging design.

In this case, the conclusion is that “the innovation of interactive packaging design is excellent (the second group is not trusted)” or “the innovation of interactive packaging design is inferior (the first group is not trusted)” or “the innovation of interactive packaging design is excellent or inferior (it is impossible to judge which group is not trusted)” will be drawn. Therefore, when there are contradictions in the evaluation information, the fusion rules should be able to achieve “upward” processing, so as to delay the decision-making and avoid unreasonable conclusions in case of evidence contradictions. It can be seen that when there are contradictions in the evaluation information of multiple groups, using the traditional evidence fusion rules will produce a conclusion contrary to common sense. Therefore, there is an urgent need for an innovative identification method of interactive packaging design that can deal with this contradiction.

3.2. Technology Roadmap. An innovative identification method of interactive packaging visual communication design is proposed as shown in Figure 2.

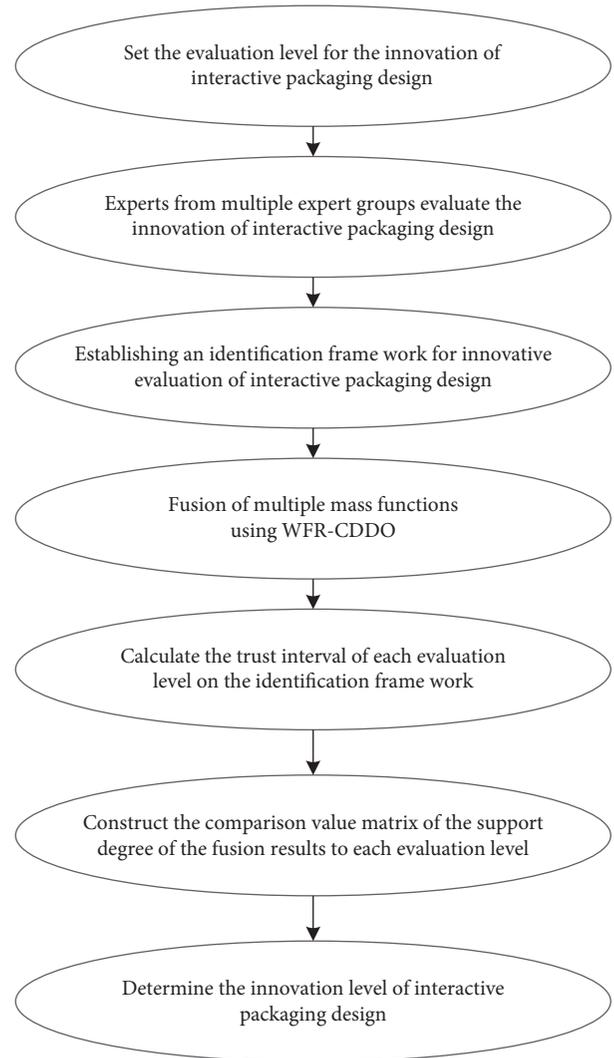

FIGURE 2: Innovativeness identification method of interactive packaging visual communication design.

Its steps are as follows.

Step 1. Set the innovativeness evaluation level of interactive packaging design as m levels: S_1, S_2, \dots, S_m . From S_1 to S_m , the innovativeness decreases.

Step 2. Experts from n expert groups evaluate the innovativeness of interactive packaging design.

Here, there are ε_i experts in the i -th expert group, $i = 1, 2, \dots, n$.

In the i -th expert group, the evaluation results of λ_i experts is that “the innovation of interactive packaging design definitely belongs to a certain level,” where the number of experts who think the innovation of interactive packaging design belongs to S_1, S_2, \dots, S_m is $\varepsilon_{i1}, \varepsilon_{i2}, \dots, \varepsilon_{im}$, where $\varepsilon_{i1} + \varepsilon_{i2} + \dots + \varepsilon_{im} = \lambda_i$; the evaluation results of μ_i experts is “the innovation of interactive packaging design is vague and belongs to one of several levels,” where the number of experts who think the innovation of interactive packaging design belongs to one level in $\{S_x, \dots, S_y\}$ is

$\varepsilon_{i,(x,\dots,y)}$, where $x = 1, 2, \dots, m$, $y = 1, 2, \dots, m$, $x \neq y$, and $\dots + \varepsilon_{i,(x,\dots,y)} + \dots = \mu_i$, $\lambda_i + \mu_i = \varepsilon_i$.

Step 3. An identification framework for interactive packaging innovation evaluation is established as

$$\Theta = \{S_1, S_2, \dots, S_m\}. \quad (1)$$

The evaluation information of n expert groups is regarded as evidence and further expressed as the basic probability assignment function under the identification framework $\Theta = \{S_1, S_2, \dots, S_m\}$, which is expressed by mass. There are n mass functions $mass_1, mass_2, \dots, mass_n$. For $mass_i$:

$$\begin{aligned} mass_i(S_1) &= \frac{\varepsilon_{i1}}{\varepsilon_i}, \\ mass_i(S_2) &= \frac{\varepsilon_{i2}}{\varepsilon_i}, \dots, \\ mass_i(S_m) &= \frac{\varepsilon_{im}}{\varepsilon_i}, \dots, \end{aligned} \quad (2)$$

$$mass_i(\{S_x, \dots, S_y\}) = \frac{\varepsilon_{i,(x,\dots,y)}}{\varepsilon_i}, \dots$$

Step 4. Weighted fusion rules of conjunction disjunction double operators (WFR-CDDO) is adopted to realize the fusion of n mass functions $mass_1, mass_2, \dots, mass_n$.

The expression of conjunction operator (CO) is

$$mass'(S) = \frac{1}{1-k} \sum_{S^p \cap S^q \cap \dots \cap S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_n(S^r), \quad (3)$$

where $mass'$ represents the mass function obtained by fusing n mass functions $mass_1, mass_2, \dots, mass_n$ with conjunction operator, $S^p, S^q, \dots, S^r \subset \Theta$, $S = S_1, S_2, \dots, S_m, \dots, \{S_x, \dots, S_y\}, \dots$; $k = \sum_{S^p \cap S^q \cap \dots \cap S^r = \emptyset} mass_1(S^p) mass_2(S^q) \dots mass_n(S^r)$ is a contradiction coefficient, reflecting the contradiction degree between n mass functions. If k is bigger, it means that the degree of contradiction among n mass functions $mass_1, mass_2, \dots, mass_n$ is higher.

The expression of the disjunction operator (DO) is

$$mass''(S) = \sum_{S^p \cup S^q \cup \dots \cup S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_n(S^r), \quad (4)$$

where $mass''$ represents the mass function obtained by fusing n mass functions $mass_1, mass_2, \dots, mass_n$ with disjunction operator.

The expression of WFR-CDDO is

$$\begin{aligned} mass'''(S) &= \alpha \cdot mass'(S) + \beta \cdot mass''(S) \\ &= \alpha \frac{1}{1-k} \sum_{S^p \cap S^q \cap \dots \cap S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_n(S^r) \\ &\quad + \beta \sum_{S^p \cup S^q \cup \dots \cup S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_n(S^r), \end{aligned} \quad (5)$$

where α and β are the weighting factors of CO and DO, $\alpha \geq 0, \beta \geq 0$ and $\alpha + \beta = 1$. If we use k as the weighting factor of DO, that is, $\beta = k$, so $\alpha = 1 - k$.

WFR-CDDO is further expressed as

$$\begin{aligned} mass'''(S) &= \sum_{S^p \cap S^q \cap \dots \cap S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_n(S^r) \\ &\quad + k \sum_{S^p \cup S^q \cup \dots \cup S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_n(S^r). \end{aligned} \quad (6)$$

Then, n mass functions are fused through WFR-CDDO, and the fusion results are calculated in turn as $mass'''(S_1)$, $mass'''(S_2)$, \dots , $mass'''(S_m)$, \dots , $mass'''(\{S_x, \dots, S_y\})$, \dots

Step 5. Under the identification framework $\Theta = \{S_1, S_2, \dots, S_m\}$, the belief function and plausibility function of level S_j are calculated as

$$Bel(S_j) = \sum_{S^p \subseteq S_j} mass'''(S^p), \quad (7)$$

$$Pl(S_j) = \sum_{S^p \cap S_j \neq \emptyset} mass'''(S^p). \quad (8)$$

They form the trust interval $[Bel(S_j), Pl(S_j)]$ of level S_j , where $j = 1, 2, \dots, m$.

Step 6. Based on the trust intervals $[Bel(S_1), Pl(S_1)]$, $[Bel(S_2), Pl(S_2)]$, \dots , $[Bel(S_m), Pl(S_m)]$ of S_1, S_2, \dots, S_m , we calculate the matrix:

$$\Delta = (\Delta_{j,l})_{m \times m}, \quad (9)$$

where

$$\Delta_{j,l} = \frac{\max\{0, Pl(S_j) - Bel(S_l)\} - \max\{0, Bel(S_j) - Pl(S_l)\}}{Pl(S_j) - Bel(S_j) + Pl(S_l) - Bel(S_l)}. \quad (10)$$

It represents the comparison between the degree of support of the fusion result for “the innovation of interactive packaging belongs to S_j ” and the degree of support of the fusion result for “the innovation of interactive packaging belongs to S_l ,” where $Bel(S_j)$ and $Pl(S_l)$ are the lower limit and upper limit of trust interval $[Bel(S_l), Pl(S_l)]$ of level S_l , respectively, and $l = 1, 2, \dots, m$.

Step 7. According to $\Delta = (\Delta_{j,l})_{m \times m}$, if $\Delta_{j,l} > 0.5$, the degree of support of the fusion result for “the innovation of interactive packaging belongs to S_j ” is higher than that of the fusion result for “the innovation of interactive packaging belongs to S_l ,” which is recorded as $S_j > S_l$. If $\Delta_{j,l} < 0.5$, the degree of support of the fusion result for “the innovation of interactive packaging belongs to S_j ” is lower than that of the fusion result for “the innovation of interactive packaging belongs to S_l ,” which is recorded as $S_j < S_l$. If $\Delta_{j,l} = 0.5$, the degree of support of the fusion result for “the innovation of interactive packaging belongs to S_j ” is equal to that of the fusion result

for “the innovation of interactive packaging belongs to S_j ,” which is recorded as $S_j \approx S_l$. After judgment in turn, the evaluation level with the highest degree of support is the innovation level of interactive packaging design.

4. Case Study

The shape, color, pattern, and material of packaging should be able to arouse people’s favorite emotions because people’s likes and dislikes play a very important role in buying impulse. Favors come from two aspects. The first is practical, that is, whether the packaging can meet the needs of consumers in all aspects and provide convenience, which involves the size, size, beauty, and other aspects of the packaging. The same skin care cream can be packaged in large bottles or small boxes. Consumers can choose it according to their habits; the same products with exquisite packaging are easy to be selected as gifts and those with poor packaging can only be used by themselves. When the packaging of the product provides convenience, it will naturally arouse consumers’ favor. The interactive packaging design of a certain nut food is shown in Figure 3.

It is now necessary to identify the innovation of the interactive packaging visual Chuangda design. The implementation steps are as follows:

We set the innovative evaluation level of interactive packaging as level 3: S_1, S_2, S_3 , which are superior, medium, and inferior in sequence. Experts from four expert groups evaluates the innovation of interactive packaging visual communication design. Here, the number of experts included in the four expert groups are as follows: $\varepsilon_1 = 25$, $\varepsilon_2 = 28$, $\varepsilon_3 = 30$, and $\varepsilon_4 = 27$. The evaluation results of the four expert groups on the innovation of interactive packaging visual creative design are shown in Table 1–4, respectively.

Then, we construct the identification framework for the innovative evaluation of the interactive packaging visual creative design $\Theta = \{S_1, S_2, S_3\}$.

The evaluation information of the four expert groups is regarded as evidence and further expressed as the basic probability assignment function under the identification framework, which is expressed by $mass_1, mass_2, \dots, mass_4$.

For $mass_1$, $mass_1(S_1) = 0.8000$, $mass_1(S_2) = 0.0400$, $mass_1(S_3) = 0.0400$, $mass_1(S_1, S_2) = 0.0400$, $mass_1(S_2, S_3) = 0.0400$, and $mass_1(S_1, S_3) = 0.0400$.

For $mass_2$, $mass_2(S_1) = 0.0357$, $mass_2(S_2) = 0.0714$, $mass_2(S_3) = 0.7500$, $mass_2(S_1, S_2) = 0.0357$, $mass_2(S_2, S_3) = 0.0357$, and $mass_2(S_1, S_3) = 0.0714$.

For $mass_3$, $mass_3(S_1) = 0.8333$, $mass_3(S_2) = 0.0333$, $mass_3(S_3) = 0.0333$, $mass_3(S_1, S_2) = 0.0333$, $mass_3(S_2, S_3) = 0.0333$, and $mass_3(S_1, S_3) = 0.0333$.

For $mass_4$, $mass_4(S_1) = 0.7778$, $mass_4(S_2) = 0.0370$, $mass_4(S_3) = 0.0370$, $mass_4(S_1, S_2) = 0.0741$, $mass_4(S_2, S_3) = 0.0370$, and $mass_4(S_1, S_3) = 0.0370$.

Based on WFR-CDDO, $mass_1, mass_2, \dots, mass_4$ are fused.

CO is $mass'(S) = 1/1 - k \sum_{S^p \cap S^q \cap \dots \cap S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_4(S^r)$, where $mass'$ represents the mass function obtained by fusing four mass functions with CO,

FIGURE 3: The interactive packaging design of a certain nut food.

TABLE 1: Evaluation results of the first expert group on the innovation of interactive packaging visual creative design.

	S_1	S_2	S_3	S_1, S_2	S_2, S_3	S_1, S_3
Number of experts	20	1	1	1	1	1

TABLE 2: Evaluation results of the second expert group on the innovation of interactive packaging visual creative design.

	S_1	S_2	S_3	S_1, S_2	S_2, S_3	S_1, S_3
Number of experts	1	2	21	1	1	2

TABLE 3: Evaluation results of the third expert group on the innovation of interactive packaging visual creative design.

	S_1	S_2	S_3	S_1, S_2	S_2, S_3	S_1, S_3
Number of experts	25	1	1	1	1	1

TABLE 4: Evaluation results of the fourth expert group on the innovation of interactive packaging visual creative design.

	S_1	S_2	S_3	S_1, S_2	S_2, S_3	S_1, S_3
Number of experts	21	1	1	2	1	1

$S^p, S^q, \dots, S^r \subset \Theta$, $S = S_1, S_2, S_3, \dots, \{S_x, \dots, S_y\}, \dots$; $k = \sum_{S^p \cap S^q \cap \dots \cap S^r = \emptyset} mass_1(S^p) mass_2(S^q) \dots mass_4(S^r)$.

DO is $mass''(S) = \sum_{S^p \cup S^q \cup \dots \cup S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_4(S^r)$, where $mass''$ represents the mass function obtained by fusing four mass functions with DO.

The expression of WFR-CDDO is

$$\begin{aligned}
 mass'''(S) &= \alpha \cdot mass'(S) + \beta \cdot mass''(S) \\
 &= \alpha \frac{1}{1-k} \sum_{S^p \cap S^q \cap \dots \cap S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_4(S^r) \\
 &\quad + \beta \sum_{S^p \cup S^q \cup \dots \cup S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_4(S^r).
 \end{aligned} \tag{11}$$

It is further expressed as

$$\begin{aligned}
mass'''(S) = & \sum_{S^p \cap S^q \cap \dots \cap S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_4(S^r) \\
& + k \sum_{S^p \cup S^q \cup \dots \cup S^r = S} mass_1(S^p) mass_2(S^q) \dots mass_4(S^r).
\end{aligned} \quad (12)$$

According to WFR-CDDO, four $mass$ functions $mass_1, mass_2, \dots, mass_4$ are fused. We calculate the fusion results in turn: $mass'''(S_1)$, $mass'''(S_2)$, $mass'''(S_3)$, \dots , $mass'''(\{S_x, \dots, S_y\})$, \dots :

- (i) $mass'''(S_1) = 0.7638$
- (ii) $mass'''(S_2) = 0.0141$
- (iii) $mass'''(S_3) = 0.1011$
- (iv) $mass'''(S_1, S_2) = 0.0422$
- (v) $mass'''(S_2, S_3) = 0.0309$
- (vi) $mass'''(S_1, S_3) = 0.0479$

Then, we calculate on identification framework $\Theta = \{S_1, S_2, S_3\}$.

The reliability function and plausibility function of S_1 are $Bel(S_1) = 0.7638$ and $Pl(S_1) = 0.8539$, which constitute the trust interval of S_1 : $[Bel(S_1), Pl(S_1)] = [0.7638, 0.8539]$.

The reliability function and plausibility function of S_2 are $Bel(S_2) = 0.0141$ and $Pl(S_2) = 0.0872$, which constitute the trust interval of S_2 : $[Bel(S_2), Pl(S_2)] = [0.0141, 0.0872]$.

The reliability function and plausibility function of S_3 are: $Bel(S_3) = 0.1011$ and $Pl(S_3) = 0.1799$, which constitute the trust interval of S_3 : $[Bel(S_3), Pl(S_3)] = [0.1011, 0.1799]$.

Based on the trust intervals of S_1, S_2, S_3 , we calculate

$$\Delta = (\Delta_{j,l})_{3 \times 3} = \begin{bmatrix} 0.5 & 1 & 1 \\ 0 & 0.5 & 0 \\ 0 & 1 & 0.5 \end{bmatrix}. \quad (13)$$

According to $\Delta = (\Delta_{j,l})_{3 \times 3}$, $\Delta_{1,2} = 1 > 0.5$, so the degree of support of fusion results for “the innovation of interactive packaging visual communication design belongs to S_1 ” is higher than that of fusion results for “the innovation of interactive packaging visual communication design belongs to S_2 ,” that is, $S_1 > S_2$.

$\Delta_{1,3} = 1 > 0.5$, so the degree of support of fusion results for “the innovation of interactive packaging visual communication design belongs to S_1 ” is higher than that of fusion results for “the innovation of interactive packaging visual communication design belongs to S_3 ,” that is, $S_1 > S_3$.

$\Delta_{2,3} = 0 < 0.5$, so the degree of support of fusion results for “the innovation of interactive packaging visual communication design belongs to S_2 ” is lower than that of fusion results for “the innovation of interactive packaging visual communication design belongs to S_3 ,” that is, $S_2 < S_3$.

Therefore, the evaluation grade with the highest degree of support for fusion results is S_1 , and the innovation of interactive packaging visual communication design belongs to S_1 .

5. Conclusions

As a comprehensive course across social sciences and humanities and social sciences, digital media art can be applied

to the Internet-famous food packaging design, promote the reform and improvement of visual communication design of Internet-famous food packaging, make electronic information technology and news media technology organically combine with Internet-famous food packaging technology, and give new meaning to Internet-famous food packaging. When the evidence fusion rules in the classical evidence theory deal with the evidence contradiction in the innovative identification of interactive packaging visual communication design, they will get wrong results that are contrary to the common sense. Compared with the evidence fusion rules in the classical evidence theory, the conjunction disjunction double arithmetic weighted fusion rules provided in this study can support the contradiction processing in the innovative identification of interactive packaging visual communication design.

Urban green space designed based on the concept of sponge city is an important sponge carrier. Guided by the theory of landscape ecology, this article introduces the artificial neural network (ANN) model and uses the research method of landscape pattern index to establish a model for the proportion of urban green space types and the characteristics and dynamic changes of landscape spatial pattern. Based on the optimal landscape pattern index, the theoretical value of the optimal proportion of ecological green space, community park, comprehensive park, roadside green space, protective green space, and strip green space is obtained through the model. Based on this proportion value, combined with the ANN model, the reasonable evaluation results of patch density and average perimeter area ratio, spread degree, and diversity index of planned green space are obtained. Then, according to the influence of various green spaces on each landscape index, the development trend of urban green space construction in the future is predicted.

1. Introduction

Due to global warming and the acceleration of urbanization, coupled with the increasingly prominent problem of natural resources, the environmental quality of urban development is also increasingly worrying. After meeting the needs of material and cultural life, modern people begin to put forward higher requirements for the living environment. People's longing for a better life includes people's hope to see blue sky, green grassland, and breathe fresh air. Therefore, it has become an urgent hope for modern people to change the current situation of the city and build a new ecological city more suitable for people's living. In this context, the concept of "building a sponge city with natural accumulation, natural infiltration, and natural purification" came into being [1–5].

The essence of sponge city is to establish an ecosystem in the city; use the power of nature for drainage; build a sponge city, make the rainwater of the city reach the natural accumulation, natural infiltration, and natural purification; make the city closer to nature; plan all kinds of resources as a whole; reduce the damage of development and construction to the original ecosystem; and realize the harmonious co-existence between mankind and nature.

As a recreational place for residents, urban green space has important value in the fields of ecological environment, society, and culture. In the construction of sponge city, urban green space, as an important carrier, can effectively play the "sponge" role of "infiltration, stagnation, storage, purification, utilization, and drainage" through the application of low-impact development engineering technology in the construction process [6–9]. However, the green space designed based on the concept of sponge city not only bears the inherent role of recreation, greening, and beautifying the environment, but also should play the role of sponge carrier in the face of water environment problems. If we can form an effective feedback mechanism for such green space from the perspective of users, it will promote the improvement of such sponge facilities and the effective play of sponge function.

From the perspective of land planning, environment, and ecology, urban green space refers to urban nonconstruction land dominated by natural and artificial vegetation. The main contents include two levels: one is the land used for greening within the scope of urban construction land, and the other is the area outside the scope of urban construction land, which plays a role in urban ecology, landscape, and

residents' leisure life and has a good greening environment. From the perspective of architecture, urban planning, and landscape architecture, urban green space refers to the area where green plants are planted within the scope of urban planning land, which can improve and maintain the ecological environment; beautify the city appearance; provide leisure and recreation sites; or have the functions of sanitation, safety, and protection. According to this definition, the production land of agriculture, forestry, and animal husbandry outside the urban regional planning and nature reserves do not belong to the category of green space. The definitions of urban green space obtained from different angles are different. Generally speaking, urban green space can be divided into broad and narrow concepts. In the narrow sense, it refers to the green land within the scope of urban land construction. In the broad sense, it generally refers to all areas covered by green plants. At present, the urban green space system we plan should be the combination of broad and narrow green space, so as to make a more reasonable analysis and discussion.
